CONCLUSION.—I have now gentlemen, to thank you for your support and attendance to me as Chairman of the Association. We are only a small number in this district, so that everybody should make an effort to attend the meetings and make them as representative as possible. I now vacate the chair.

INDIAN TEA ASSOCIATION.

(From the Report of the General Committee for the year ended 31st December, 1902.)

The General Committee have now the honour to submit to members their Report for the past year. Mr Lockhart Smith was elected Chairman in place of Mr Ashton; and Mr W Warrington (who had succeeded Mr Brown in March) was elected Vice-Chairman.

AMERICAN AND FOREIGN MARKET FUND.—The subscriptions received during the year for this Fund amounted to R55,564-11-6.—A sum of R52,500 has been devoted to the export Lounty on green teas.—The tea rooms at 48, Faubourg St Honoré, Paris, have been also maintained; and work in Italy, Turkey and other European countries has been pushed on as vigorously as the limited funds at the disposal of the Association would permit.—In the early part of the year advertising in America had to be discontinued owing to the uncertainty about funds. The result was that Indian teas lost ground to a certain extent; while Ceylon teas—which have been and are still being actively pushed—made greater progress even than before. Later in the year it was found possible to renew the advertisements which are at present appearing as formerly. Now that the Cess is practically an accomplished fact, it may be confidently said that much more strenuous and sustained efforts will be made in America than have been made in the past. At the present moment it is not possible to indicate the extent to which Indian tea will be able to take advantage of the St Louis Exhibition. But to the General Committee there would seem to be no reason why a portion of the Cess Funds should not be expended on an exhibit; although this is, of course, a matter

which the Cess Committee will be called upon to decide. At the same time the existence of the Cess affords no reason why Government should not be asked for financial assistance.—Another opportunity of pushing Indian tea in what is believed to be a promising market, will be afforded by an Exhibition which is to be held at Capetown in November, December, January and February 1903 and 1904. So far but little has been done in South Africa by Indian tea producers. But during the past year an arrangement was made by the London Association with an agent in Johannesburg to sell a minimum quantity of 1,200 half chests of suitable tea in consideration of a bonus of 1½d per lb. The tea was to be bought in Calcutta by Messrs McLeod & Co., who, up to date, have shipped 490 half chests. No information is of course available at present as to the reception the teas have met with in South Africa. But it is stated that the quality of the tea usually sold in the Transvaal is very inferior; and that the price is about four shillings a pound. If this is so, there would seem to be no reason why Indian teas at moderate prices should not find a ready market.

CONSUMPTION OF TEA IN INDIA.—Throughout the year the Indian Tea Markets' Expansion Commission—which was mentioned in the last Report—has vigorously pushed the sale of tea in India. It has been thought that the work of the Commission has been hampered by the sale in the Calcutta bazaars and elsewhere of tea refuse. Large quantities of this commodity are sent to Calcutta; and although a fair proportion is sold to reputable European firms for the manufacture of caffeine, there is no doubt that much is disposed of for local consumption. At the instance of the Committee, Messrs Andrew Yule & Co. have made enquiries into this trade; but without the co-operation of all producers, there does not appear to be any prospect of its being suppressed.

INDIAN TEA IN RUSSIA.—It was stated in the last Annual Report that the Committee were giving attention to the possibility of developing the Russian market. In the absence of funds for advertising purposes, they have since been making enquiries as to the different routes by which Indian tea is carried to Russia. In March they invited the attention of the Bengal Chamber of Commerce to the question. They asked if the Chamber could take any action which might be calculated to promote the establishment of a direct line of steamers between Calcutta and Russian ports. The Committee of the Chamber expressed the opinion that the direct trade between Calcutta and Russia was too insignificant to warrant the establishment of a direct line. Sir Charles Scott, the British Ambassador at St Petersburg had intimated, in an official despatch to the Foreign Office, that if British Navigation Companies were to enter into arrangements with Russian Railway Companies, they could obtain the same reduced rates as the Volunteer Fleet. The Liners' Conference submitted the question to the various steamship-owners, who would, they hoped, make arrangements for assisting the development of the tea trade in Russia. More recently the Committee suggested to the Bengal Chamber of Commerce that an attempt should be made to persuade the Russian Government to reduce the import duties on tea. No action will however be taken, as His Majesty's Ministers think there is no substantial case so long as the duties do not differentiate against Indian tea.

INDIAN TEA IN AFGHANISTAN.—The Afghan officials to whom reference has been made expressed themselves as being well satisfied with the samples sent to them. But so far it has not been found to be possible to work up the trade to any extent.

INDIAN TEA IN PERSIA.—In their last Annual Report the Committee referred at length to the mission to Persia which had been undertaken by Mr. E. G. Foley. As a result of that mission two or three caravans with fairly large quantities of tea from the Kangra Valley, Debra Dun, and Calcutta, were despatched by the Nushki Seistan route to Meshed. The reception which was accorded to these experimental ventures did not however justify further efforts. It was only with the greatest difficulty that the tea was disposed of even at the lowest prices. In the case of the caravan from the Kangra Valley no tea was sold for some months, the prices offered being barely sufficient to pay the cost of carriage. Business in Persia is not conducted on cash basis, credits frequently extending for two or three years; and sales of tea at twelve months credit were effected by the Kangra Valley agent with difficulty.

INDIAN TEA IN CHINESE TURKESTAN AND TIBET.—An expression of opinion was invited by Government as to what would be a reasonable rate of duty in Tibet having regard to (a) the cost of transit from India to Tibet, and (b) the price at which China tea is sold at Lhasa. The General Committee, to whom the point was referred, expressed the opinion that the duty should not exceed that levied on China tea imported into India. At this point the question stands at present, at least so far as Tibet is concerned. The Government of India have not yet given any indication as to whether they can take action in regard to Chinese Turkestan.

CEYLON IMPORT DUTY ON TEA.—The Committee referred in their last report to a representation which they had made to the Government of India upon certain matters relating to this duty. Their main suggestion was of a two-fold nature. Firstly, that the Ceylon Government should be asked to exempt Indian tea from the payment of the import duty of four annas per lb; and secondly that, if necessary, the Indian Government should similarly exempt Ceylon tea from the payment of the five per cent *ad valorem* duty levied in this country. Further, the Committee proposed that, if the Ceylon Government declined to make this exemption, the Indian duty should be enhanced to a protective rate. In June the Government of India intimated that they were not prepared to adopt any of these proposed courses of action. They submitted, at the same time, a statement of the views expressed by the Ceylon Government on the question. From this it appeared that the Lieutenant-Governor of Ceylon was unwilling to exempt Indian tea from the payment of import duty. In their representation the Committee had complained of the heavy transshipment charges at Colombo; and had asserted that it was cheaper in the case of teas destined to Russia for example, to tranship at Singapore. The Ceylon Government denied that the charges were high, but they did not controvert the assertion that transshipment at Singapore was cheaper. They further contended that Indian teas competed on actually level terms with all Ceylon teas which are sold, and exported without being blended, or made into packets. It was recognised in Ceylon that the object of Indian

growers was to obtain facilities for blending in Colombo. This was considered both by Ceylon planters and merchants to be undesirable; their object being that pure Ceylon tea only should be exported from the island. Looking at the question purely from the Ceylon point of view, but little fault can be found with this decision. But the Committee still think it is unfair to Indian growers that Ceylon tea should be freely admitted into India for blending or any other purposes. For if Ceylon will only admit Indian teas under certain restrictions, it is but right that similar restrictions should be enforced in India against the produce of the island. As matters at present stand, however, there is nothing to prevent the sale in India of blended Indian and Ceylon teas; while the sale of such in Ceylon, or their export from Colombo, is debarred. So far the Committee have not reopened the question with Government, but possibly their successors will consider the advisability of making a further representation.

EXPORT BOUNTY TO ENCOURAGE THE MANUFACTURE OF GREEN TEA.—It is with much satisfaction that the Committee record a considerable advance in the manufacture of Indian green tea during the past year.

Before the end of the season the bounty will have been paid upon 720,000 lb. of Indian green tea. When it is remembered that last season the quantity upon which the bounty was paid did not exceed 30,000 lb. the nature of the advance which has been made will be readily perceived. With the advent of the Cess and the consequent possibility of a bounty on a more extended scale, the prospects of Indian green tea would appear to be distinctly good.

ULLAGE AND DEPRECIATION OF TEA.—The following amended rules for dealing with claims for ullage and depreciation of tea were adopted in May by the Indian Tea Association (London) after consultation with representatives of the Conference Liners, *viz.*—

(1) Metal packages.—No ullage to be recognised unless the fastenings are intact, and unless the metal is perforated. (2) Packages country coopered but not Dock coopered.—No ullage to be recognised. (3) Packages country coopered and Dock coopered. Allowance to be one-half of amount of agreed loss. (4) No claims to be recognised for ullage in respect of packages of Fannings, or Dust Tea, which exceed 110 lb. in weight nett of Dust or 120 lb. nett of Fannings. (5) No claims for depreciation in value to be recognised unless ullage amounts to 10 lb. or over. (6) That any such allowance shall not exceed 1d per lb. (7) All claims for depreciation to be accompanied by satisfactory evidence of such depreciation. (8) Minimum ullage to be recognised for any package—4lb.

MAP OF THE TEA DISTRICTS.—In their last Annual Report the Committee mentioned that they were arranging for the compilation of a map of the tea districts. The map was published in September last, and shows the position of all tea estates in Assam and Bengal.

ESTIMATES OF THE CROP.—At the last Annual Meeting of the Association the following resolution was unanimously adopted:—"That in view of it having been found to be impracticable to obtain complete returns from producers, the General Committee be instructed to discontinue the publication of figures relating to the output of the crop." The practical effect of this resolution

is that the statistics published by the Association are restricted to those of exports. These are issued in a monthly statement, and include the shipments from Calcutta, Chittagong, and Southern Indian ports.

FINANCE.—The total planted area represented by the Association during the year was 359,206½ acres, or an increase of 13,439½ acres on that of the previous year. The year's subscription at the rate of one anna per acre amounted to R22,398-14-3. The revenue account shows a surplus of R2,808-6-9, which has been transferred to capital account. The balance in hand on the 31st December 1902 amounted to R38,177-10-3, less sundry liabilities amounting to R850-15-2.—**LOCKHART SMITH**, Chairman, Calcutta, 31st January, 1903.

KANDY DISTRICTS PLANTERS' ASSOCIATION.

ANNUAL REPORT, 1902.

MEMBERSHIP.—There are 45 votes enrolled on the Register against 51 last year, the decrease being mainly due to the formation of the Kurunegala Association.

FINANCE.—The financial position is satisfactory showing a credit balance R209-74.

TEA.—The past season has been generally unfavourable both in yield and prices, though the returns during the last few months have improved matters somewhat on low-lying estates. The shot-hole borer appears to be on the increase.

The estimates for 1903 are as follows:—Including 1,626 acres at 400 lb. per acre=650,400 lb. Estimated for ten estates which have not sent their returns.

Total acreage of Tea ..	12,780	
„ Bearing ..	12,391	
„ Crop ..	5,004,050 lb.	} 450 lb. per acre.
„ Green Tea ..	684,800 „	
„ Native Leaf ..	555,000 „	
Total acreage abandoned this year ..	203 „	

The figures of Green Tea are not, however, considered very reliable.

COCOA.—Crops have been very good, but the continued wet weather prevented estates unprovided with artificial drying apparatus from curing satisfactorily.

Canker continues to do much damage and no really effectual remedy has so far been found. Estimates:—

Total acreage ...	7,592
Do ...	7,166

Estimated crop 17,490 cwt. (2.44 cwt. per acre.) There are about 412 acres for which no estimates have been sent in.

CARDAMOMS.—This industry has increased considerably of late, with the result that prices have fallen very materially, and it is now proposed to raise a cess of 50 cents per acre with the object of obtaining funds to advertise and push the sale of the product.

LABOUR.—Labour has been scarcer this year than it has been for some time past, and advances are steadily moving upwards instead of being reduced, so that the Labour Federation has not been successful in accomplishing what was hoped from it. This Association considers that Mr. Westland's scheme for recruiting labour from the coast should be given a trial.

Mr. HARRY CREASY'S proposed amendment of the Cooly Labour Ordinance has the same end in view of reducing advances, but as the Sub-Committee of the Labour Federation of the Parent Association deprecated further cooly legislation no further action is considered advisable.

CEYLON PLANTERS' RIFLE CORPS.—The numbers of this Corps have increased during the past year, and the total is now 790 against 536 previously.

COCOA-STEALING LEGISLATION.—His Excellency the Governor has stated that he is unwilling to take any action until another Commission is appointed to re-investigate the matter. This Association would respectfully express its opinion that the cocoa planters have already made out a good case, and that their demand is a perfectly just and equitable one, and hope that Government will see its way to yield on the point.

TEA CESS.—The present statistical position of the tea industry is more favourable than it has been for some time past, and the estimates of this season show a probably considerable decrease in the amount of tea to be put on the London market, due largely to the growth of the green tea industry, and this Association is therefore of opinion that it would be inadvisable to do anything at this juncture to check the expansion of the green tea industry, and therefore recommend the increase of the Cess as suggested by the Thirty Committee, on the understanding, however, that the Cess shall not be continued longer than really necessary to put the new industry on a sound footing. This Association does not approve of the proposal that a petition be made for a Government grant.

THIRTY COMMITTEE.—This Association consider it is impossible for those outside the Committee and not thoroughly cognisant with all the details that have been discussed to pass reliable or accurate criticism on its working and decisions, and they therefore recommend that the best course is to elect the best men available and leave them a free hand.

KANDY HOSPITAL.—The Association considers that the medical staff of the Kandy Hospital does not meet the requirements of the district, and that a large staff should be maintained for so important a centre as Kandy.

A vote of thanks is due to the Parent Association for allowing them the use of the rooms in the Victoria Commemoration Buildings during the past year.

ARE MELONS FRUIT?—The other day a man was asked whether a melon is a fruit or a vegetable. This enquiry led to the further question as to what is the difference between fruits and vegetables, any way? For the benefit of those who do not know, the statement is made that fruit is the part of a plant which contains the seed; but the plant itself is a vegetable. Apples, berries, melons, pumpkins, tomatoes, and the like are fruits; cabbages, radishes, beets, greens, turnips, and the like are vegetables, because it is the plant that is eaten, and not merely the part which contains the seed.—*Journal of the Department of Agriculture of Western Australia* for January.

THE NEW PHOSPHATE MANURE,

(From Mr. John Hughes.)

Dundee, Jan. 20.—I am up here to explain at the annual meeting of the Dundee Farmers' Club the properties and advantages of the New Manure Basic Superphosphates which has attracted a good deal of attention and has been specially successful in Scotland where the soil is generally deficient in lime and the period of active growth limited to a few months in the year. Already the manufacture has mounted up to over 1,500 tons during the last year alone and during the coming year the demand is likely to be quite double the above figures. Some has already gone out to Ceylon in compound manures for tea, also 100 tons to Jamaica, 50 tons to Adelaide, 20 to Demarara and some to the Cape.

(Editorial Remarks.)

Less than a generation ago the farming ranks provided some of the most unresponsive audiences for the man of science, especially when the subject down for exposition was only feebly in touch with the affair of rent paying. If Mr Hughes, who lectured so clearly and with such hearty acceptance yesterday evening to the members of the Carse of Gowrie Farmers' Club, had made his discovery of basic superphosphate in the eighties, instead of some two years ago, he would have run the risk of being for a time at least a voice crying in the agricultural wilderness. Without a doubt the world is making advances. The constant small rain of educational agencies and the ever-widening stream of knowledge founded upon experimental science must needs liberalise the world and give increasing clearness of outlook to all those who would as much as possible translate thought into action. When Liebig dissolved bones with vitriol in order to make the resulting compound useful for plant life he was probably classed by some as a visionary, but when he was rapidly followed by Sir John Bennet Lawes the world 'caught on,' to use the popular phrase. The super-phosphate by whose means Sir John worked into a handsome fortune is now, however, in some small danger from the 'basic super,' which is nothing more than the old 'super' with enough of added lime to render it alkaline. Already the prospects for the new phosphatic compound are highly favourable. It is making bold headway in the early stages of 'life' without undue puffing and log-rolling aids.—*Dundee Advertiser*, Jan. 21.

ADDRESS ON THE NEW PHOSPHATE.

Mr Hughes, who was most cordially received, began his remarks by referring to the early experiments conducted by the late Sir John Bennet Lawes in treating mineral phosphate of lime with acid in order to make the resulting compound more or less available for plant food. The acid-treated phosphate, or superphosphate as it came to be named, came to be most extensively used, especially for root-growing. Over two years ago Mr Hughes began to experiment with high class superphosphate by treating it with certain proportions of lime, his object being to produce a phosphate high in solubility and with an alkaline instead of an acid reaction. The result was the substance now known as basic superphosphate—a very light, dry powdery substance, occupying fully $2\frac{1}{2}$ times the bulk of ordinary basic slag. In chemical composition the new phosphate contains 25 to 27 per cent phosphate of lime,

which, though not soluble in water, is readily soluble in the acid juices of the plant roots. Mr Hughes explained that the new manure contained from 33 to 35 per cent of lime in combination with phosphoric and sulphuric acid. The great advantage of the basic superphosphate, Mr Hughes claimed, is that it is ten times more soluble than slag, the figures being 66.8 against 6.6 per cent. Treating the basic super and the slag with a very weak solution of citric acid, Mr Hughes found that 94 per cent of the former had dissolved against fully 38 per cent of the latter. The soils most suitable for the new manure were those naturally deficient in lime. It was specially useful on peaty and cold stiff soils, and had already proved of great advantage to soils subject to finger-and-toe. As for times of sowing, November till February were suitable, but it could be drilled in along with the crop in spring, a fair dressing being 3 cwt. per acre. Mr Hughes claimed that the new phosphate was a great improvement upon slag in rapidity of action, while its alkaline nature gave it an advantage over superphosphate, especially where land was deficient in lime or given to souring. The lecture, which was of a most practical and interesting nature, was followed with great closeness, and at the end Mr Hughes was heartily applauded.—*Ibid.*

A POT OF BASIL.

AND MOSQUITO PREVENTIVES.

Mr. A. E. Shipley's interesting article (p. 205) on *Ocimum viride* and its influence on mosquitoes recalled some observations that I made upon the papaw tree (*Carica papaya*) in China. My house, on the bank of the river at Whampoa, near Canton, was singularly free from mosquitoes, though the other houses on the same island were more or less infested with them. A line of papaw-trees, stretched between my house and the river, I frequently watched these trees, yet I never saw a single insect alight on them, though flies and other insects settled in numbers upon the bamboos and banana-plants not far away. In fact, the papaw-trees seemed to keep insects at a distance and to act as a rampart guarding the house from mosquitoes. The probability of this suggestion was considerably strengthened by the increase in the number of mosquitoes entering the house after a typhoon had blown down two papaw-trees and thus made a gap in the row, and by the still further increase when a second typhoon felled another of the trees. I have questioned a number of persons living in the tropics, and one of them stated that he was familiar with the fact that papaw-trees repelled mosquitoes.

That the papaw-tree possesses some curious property—in addition to the notorious proteolytic action of its juice—is suggested by the widespread practice of hanging meat in its shade to render the meat tender. The custom is frequently regarded as a senseless one, but its wide distribution causes one to ask: is it not possible that the papaw-tree should exhale a gaseous product which either repels meat-destroying insects or exerts an antiseptic action on putrefactive bacteria, or, finally, is a volatile ferment? The peculiar relation in regard to temperature displayed by the proteolytic ferment of the papaw juice renders the last possibility less improbable than at first impression.

—*Nature*, Jan. 22.

PERCY GROOM.

COCOA IN TRINIDAD.

(By W J S Tucker.)

WEATHER.—The weather during the greater part of the past fortnight has been rather too wet for this period of the season but for the past two or three days there has been a change for the better, and, with a continuance of dry weather, it is expected that Sugar making will begin about the middle of present month.

COCOA.—The wet weather mentioned above has interfered somewhat with drying operations, and this will probably affect receipts for the early part of present month, but we look for large receipts from that date onwards. We quote prices today at \$12.50 for Ordinary and \$12.75 to \$13.10 for Estates.

My artificial Cocoa Dryer is used on several estates in the island and thoroughly removed all trouble in drying the cocoa during heavy rainy weather.

PRODUCE SHIPPED TO 30TH DECEMBER 1902.

Years.	Cocoa. lb.	Coffee. lb.	Coconuts. Number.
1899 ...	24,743,860	10,880	11,545,830
1900 ...	29,465,752	7,220	8,316,256
1901 ...	21,137,304	20,880	11,265,876
1902 ...	32,123,540	39,900	11,902,156

PROGRESS IN BRITISH GUIANA IN 1902.

The Report on British Guiana in 1901-1902 was issued on Wednesday in the annual series of colonial reports as a Parliamentary paper [C. 1,338-2]. In the general review of the condition of the colony, perhaps the most interesting observations are those on the position of its sugar industry. Towards the end of 1901 the price of sugar reached the lowest point ever recorded, but the conclusion of the Brussels Convention has done much to relieve the feeling well nigh of despair that had come to those interested directly or indirectly in the industry. The crisis is by no means over and a period of struggle must still be looked forward to, but it is confidently hoped that the Sugar Convention will in time restore public confidence in the industry and secure for it the capital which it so much needs. Meanwhile, a scheme of experimental cane cultivation is being worked out and is in process of extension over the sugar estates, where over 6,000 acres are now being utilised for cultivating new varieties. The general area under cane increased from 67,884 acres in 1900-1901 to 72,148 in 1901-1902. The Government of the colony recognizes fully the need of encouraging agriculture of every kind, and a Board of Agriculture has been constituted with the object of promoting the cultivation of the many tropical, agricultural, and horti-agricultural products which can be grown in British Guiana, the spread of agricultural knowledge, and the improvement of the breeds of live stock in the colony. There has been a steady development of the rice industry since it was first seriously taken up about seven years ago. While the local consumption of rice remains the same, the quantity of imported rice has decreased notably, and the colonial industry seems to have established its position. The cultivation of products other than sugar cane has been greatly furthered by the more liberal land legislation begun in 1890, which has enabled the people to settle on the Crown lands of the colony and take up largely increased areas for development. This desirable movement is still going on. The output of gold during the

year—all of which was produced by alluvial working—fell to 101,332oz. from 114,102oz., the figure for 1900-1901. The decrease is attributed partly to the diversion of activity towards diamond seeking and partly to the more or less continued heavy weather. Diamonds to the total weight of 8,227 carats were found during the year, 91,206 stones being registered. In the previous year 4,981 stones only, weighing 740 carats, were registered as found. Maps, accompanied by short explanatory pamphlets prepared by the Government geologist, have been published, and illustrate the general structure of the chief gold and diamond fields of British Guiana. The work of demarcating the boundary with Venezuela was continued during the year. Some 300 miles remain before Mount Rotaina, the terminal point, is reached, but as the country now to be traversed is less difficult future progress should be more rapid. The most friendly relations were maintained between the Commissioners of the colony and those of the republic.—*London Times*, Jan. 16.

PLANTING NOTES.

THE SUPPLY OF BALATA—in sight is said to be so great that no fears of a shortage need be entertained for years to come, if the business is properly and intelligently handled. Experts report that there is not a tributary to the Amazon which does not show forests of this tree upon its banks. The importance of this new industry in Brazil may be realised when it is known that the market price of balata is equal to that of the best rubber and the cost of production is less than one-tenth that of rubber. Balata has another advantage in that it does not necessitate the risk of life attendant upon the gathering of rubber. The balata grows upon high ground, as well as on the margins of the swampy streams, where the fevers lurk. It is a common saying in Para that every ton of rubber from the upper river costs two lives. This can never be said of balata, for men work at this industry with no greater risk than usually attends any labour in the Tropics; and four men will gather as many kilograms of balata per day as thirty men can obtain of boracha.—*India Rubber Journal*, Jan. 5.

FRUIT AND ALCOHOL.—The more fruit you eat the less alcohol you will need. In the first place, the amount of water in fruit is considerable. In water melons it is no less than 95 per cent; in grapes, 80 per cent; in oranges, 86 per cent; in lemons, 90 per cent; in peaches, 88 per cent; in apples, 82 per cent; in pears, 84 per cent; in plums, 80 per cent; and in strawberries, 80 per cent; not a fruit in the whole category containing less than 80 per cent. The irresistible conclusion, considering these facts, is that fruit plays an important part in diet as a thirst quencher. Certainly when fruits are freely represented in the diet less fluid requires to be consumed; and fruits would appear to be endowed with a subtle inimitable flavour which is ample inducement to imbibe fluid in this most wholesome form. The question so prominent in most people's thoughts as to what to drink might therefore, on sound physiological reasoning, be answered: eat sound, ripe, juicy fruit. It is noticeable that as fruit enters into the diet the indulgence in alcoholic drinks is undoubtedly very much diminished.—*Exchange*.

Correspondence.

To the Editor.

TRAWLING IN CEYLON.

Jan. 27, 1903.

DEAR SIR,—I see Dr. Gandevia has been writing rather strongly on the trawling question in Ceylon. His first contention that trawlers do not place on the world's market an abundant and constant supply of fresh wholesome fish at a cheap price, is, however, open to doubt. At Grimsby, Hull, and Aberdeen, three, if not the greatest, at least among the greatest trawling centres in the world, the past year has not been attended with the same prosperity as in past years. This is not accounted for by competent writers and experts on the subject as due to a scarcity of fish. Fish were plentiful, but trawlers were too numerous, the supply was too abundant and the prices consequently unremunerative. The picture of thousands of "devastated" villages is, from my little experience, considerably overdrawn; in fact the seven-mile limit to British Trawlers has proved quite sufficient to protect the coast line fishermen at home, and were the Danish and Norwegian Trawlers not permitted (by the North Sea Convention, I think) to lower their beams as close as three miles off the coast there would be little cause to complain. By all means protect the foreshore fisheries in Ceylon, but let the protection be reasonable. Five or seven miles would be ample in my opinion as a reserve for the line fishermen. If the trawlers do not go raking along the spawning beds, I do not think the churning of steamer screws will frighten the fish away. Dr. Gandevia's object is praiseworthy enough, but I do not think Government should, without expert advice on the matter, do anything to crush the life out of a new industry by making the conditions of its prosecution impossible without being thoroughly satisfied that the industry is injuriously affecting the coast fishermen's interest.—Yours, &c. SEER.

SIR,—Dr. Gandevia's letter in one of your numbers, regarding Trawling in Ceylon is deserving of attention. Facts are what is wanted and sayings and assertions are to be taken for what they are worth. Not long ago dead fish was washed ashore, and it was found that the fish caught by trawling was more than could be cured or preserved, and the rest was thrown overboard. Surely this is not a desirable proceeding to destroy fish which could be fished by villagers on the coast. To destroy the food of man for the benefit of a few speculators is not a matter to be encouraged.

In the North-East monsoon there is an abundance of fish near the coast, and most likely it is due to the smooth sea at that time of the year and the abundance of food for fish washed down from land by the burst of the North-East monsoon. If such is the case, it is a pity that fish should be prevented from coming near land by trawling a few miles from the coast.

As we have laws for the protection of land animals by game laws, why should not there be the same protection for fish on the coast, to prevent

fish being caught and destroyed because the catch is in such abundance that it could not be preserved. To my mind, trawling should be allowed during the South-West monsoon from April to November, and for the four months from December to March it should be disallowed. This will give the fishermen on the sea coast the benefit they need and the trawler, his share as well.

To allow trawling all the year round, would impoverish the inhabitants along the sea coast, whose trade is in fishing, and also affect the spawning. These are matters which deserve careful attention as it may lead to crime, poverty and to the restriction of a fresh fish diet, and to encourage a badly-cured fish one. The appended extract will show the distress caused in fishing villages when deprived of their living.—Yours truly,

TRUTH.

TROUBLED FISHERFOLK.

London, Jan. 13.—Forty thousand fishermen on the coast of Brittany have been deprived of their means of livelihood, owing to the disappearance of sardines from the adjacent waters of the English Channel and the Atlantic Ocean. Great distress consequently prevails among the residents of the coastal districts.—*Australian paper.*

TOBACCO IN INDIA AND IN CEYLON.

Feb. 4.

DEAR SIR,—I rather like a weed—I mean between the lips, and not on the plantation; but I don't see why I should pay more for a cigar than my brother in India. I found the other day in the *Indian Planting and Gardening*, a protest against the prices put on Indian cigars by the three leading manufacturers there, while their quality has been deteriorating. On that point I do not wish to say anything; but the writer speaks of a box of a hundred Manila or Havana cigars being available for R4.50 to R5, and of Londres at R6. How is it we cannot get these brands in Colombo at these prices? Is it that the duty here is heavier than in India? Or is it that our shopkeepers have forgotten to alter the prices which they had arranged in combination, when the rupee was worth only thirteen pence? This forgetfulness extended to other articles as well, until some Cash-stores were started. Can no one start cigars at reasonable prices?

SIXTEEN-PENCE.

[Imported cigars pay R1½ per lb. here. In India 5 p.c. *ad valorem.*—ED. T.A.]

OVER-PRODUCTION : NOVEL PROPOSAL IN BRAZIL.

Feb. 5.

DEAR SIR.—Enclosed is a cutting from the *Financial Times* of 10th January. What about the over-supply of Cardamoms being treated in some such manner?—Yours truly,

VISITOR.

(Extract referred to.)

TWO BIRDS WITH ONE STONE.—A Committee recently appointed by the Agricultural, Commercial and Industrial Society of San Paulo, in Brazil,

to inquire into the causes of the fall in the price of coffee has just issued its report, in which a number of measures for reducing the output so as to establish an even balance between production and consumption are proposed. In consequence of this report the Brazilian Government now contemplates placing a duty of 20 per cent on all exports of coffee, which is to be exacted in kind. The berries thus taken in taxation will be "denaturalised" and sold to the planters as manure. By this means exports will, it is estimated, be reduced by one-fifth, and values will rise accordingly. That the theory will work out so smoothly in practice is another matter. But certainly as a fiscal expedient the proposal is ingenious.

LONDON SALES OF CEYLON RUBBER

London, E.C., Jan. 23.

DEAR SIR,—At our auctions today the following lots of Ceylon-grown Para rubber were offered and sold:—

<i>Mark.</i>	<i>per lb.</i>
Eadengola ... 3 cases Fine thin biscuits at...	4/2½
Hatherley ... 1 case Very pale yellow do. at...	4/2½
Culloden ... 6 cases Fine thin biscuits at...	4/3
Do. ... 5 cases Negroheads at 3/3 & 3/4½	
Clyde Estate 2 small lots Fine biscuits at...	4/2½
Do. ... 2 small lots Negroheads at...	3/2
Nikakotua ... 2 cases Fine biscuits at...	4/2½
Do. ... 1 case Negroheads at...	3/2½

As we think these particulars and prices of Ceylon-grown rubber will be of great interest to many Ceylon planters, we suggest your printing same in your next issue.—We are, dear Sir, your obedient servants,

LEWIS & PEAT, Brokers,

HUNTING IN THE HILL DISTRICTS.

(To the Editor, Local "Times.")

SIR,—You called upon me for an exhaustive reply to Mr. North C Davidson's letter published in your columns some two weeks ago, on the subject of Game Protection and the "Hill Districts." I am afraid I have no time for that, but as Honorary Secretary of this Society, I suppose, I ought to take some notice of his remarks upon the rule prohibiting the shooting of sambur above 4,000 feet elevation, and of the blood-and-thunder paragraph about registered packs. The history of this rule which has been exercising the minds and pens of a few people lately, is as follows:—

About four years ago licenses to shoot sambur in the hill country around Nuwara Eliya were issued on such a lavish scale that any common cooly or kangany who applied for one could have it for R3-50. The number of licenses then issued from the Kandy and Nuwara Eliya Kachcheries was very large, and as one license serves for at least 20 persons where coolies are concerned, gang hunting was carried on openly, two, three, and four-days a week! On the Bopatalawa and the Digame Patanas—on the Elk Plains from Black Pool to Ambawella and from Ambawella to the Agra Patanas, on the Rajah Patanas, and in all the open patana and forest within a few miles of Nuwara Eliya, in the Ohiya forests and patana—in Gallagamuwa and all the intervening forest right to the Bagawantalawa estates in Boltumbe and Bambarakotawa well into the Peak range and the Maskeliya estates, sambur were killed wholesale by estate coolies.

It was at that time no uncommon occurrence to see gangs of coolies, aggregating 50 to 60 persons, with dogs and guns, hunting in the Bopats and Digames and other well-known hunting grounds. The results of all this was almost extermination in the tracts of land I have named, and two years ago all the old well-beaten game paths there were grown up and indistinguishable, and hardly a sambur was to be found for miles around. The rule, however, prohibiting shooting, which instructed the different Government Agents not to issue licenses to shoot sambur, eventually made itself felt, and the old haunts are gradually being reoccupied by game. On the Horton Plains and Aldie Patanas, where shooting has never been allowed at any rate for the last 15 or 20 years, and sambur are hunted only by hounds to the knife, a large stock of these animals has always existed and still exists to this present day, in spite of so-called slaughter, and no country has been hunted harder by packs of hounds.

As to the killing of hinds, this has always been found necessary in Scotland's on deer forests; and in England, wherever the wild stag breeds; and a little judicious thinning out in Ceylon is equally advisable. Now, if Government can be persuaded to issue licenses to shoot in the Hill Districts to Europeans only, and absolutely refuse them to all others on any pretext whatever, no harm will be done, and this outcry against the existing rule would cease at once. Fair stalking with the rifle on all the patanas I have named would be quite a legitimate form of sport and would afford much healthy exercise to sportsmen; but it would, I fear, puzzle our game-watchers to determine whether a dead sambur had been fairly stalked or shot over dogs like a hare. —Yours, &c., THOS. FARR.

Ceylon Game Protection Society, Feb. 7th, 1903.

REVIEW OF THE CRUDE RUBBER MARKET.—Rubber production, says the *India Rubber World*, for January 1, not only is not showing the rate of increase maintained for several years up to 1901, but this year will show a material decline. Meanwhile the rubber manufacture in every country in which it has been established has been active, there having been in no country such business conditions as have lessened the demand for rubber goods except, perhaps, in Germany, where the manufacturers have been able through their growing export trade to off-set any check in the trade at home. There is nothing in the conditions outlined above to point to the limit of rubber production having been reached. On the other hand, facilities for reaching the remoter South American fields are being improved all the while, even if slowly, and the tendency is toward the better conservation of native supplies there. The decreased output from the Congo districts has been due in part to a deliberate policy of the rubber trading companies which, for some time, have seen their earnings suffer through the careless handling of their rubber products, of devoting their energies to the better preparation and more careful shipment of rubber, rather than to getting out the greatest possible quantity. It appears now as if manufacturers would have to adapt themselves to a condition of rubber practically as high priced as at any time of considerable duration in the past, in connection with which no promise exists of an early decline in the cost of the other raw materials which enter into their products.

PLANTING ON THE ANAMALAIS.

We were pleased to learn today from Messrs. Martin and Bannatine, how well the new planting district—fostered by Sir Arthur Havelock when Governor of Madras—is developing. Out of 15,000 acres taken up, about 3,000 have been opened in tea and coffee with cardamoms, cinchona and some rubber. The plantations run from 3,000 feet upwards. A cart road is already right into the district. Calicut is the port; but Madras will have to be utilised for the S.-W. monsoon part of the year. The railway is coming nearer. Mr. Martin's tea of good jāt has made splendid growth and a factory is now being built. Not a few still believe in coffee, if only prices would keep up. Cardamoms do well, but get a wintering; and produces expected to be all sold locally. Cinchona trees (from 15 p.c. Java seed) are growing well; and Para rubber in the flats has made growth equal to 6 feet in six months. Altogether therefore, Mr. Martin has reason to be satisfied with the inspection from which he has returned;—nor are the eight Anamalai planters now at work afraid about a labour supply.

GREEN TEA.

We hear of a sample of St. Leonard's green tea, spoken of very highly by an expert, as equal to the very best China of the same class. This is good testimony to the patent process of Messrs. Heath and Wiggin.

COCOS ISLANDS.

WHERE IT IS FASHIONABLE TO DANCE IN BOOTS!

The annual visit to Cocos Islands, which are under the paternal rule of Mr George Clunies-Ross, was paid this year by Mr L H Clayton, district officer at Christmas Island.

Mr. Clayton found nothing of importance to report, but there are one or two very suggestive passages in his remarks. For instance, he tells us of a severe cyclone that visited the islands when all the inhabitants ran into the lagoon up to their necks to escape the falling trees. There seems to be a novel view held concerning the value of boots. The winners of a race were offered as prizes their choice of a piece of serge or a pair of boots. They chose the serge as the men explained that boots were of no use except to dance in!

Mr Clayton visited North Keeling Island where every tree and bush is covered with the nests of frigate-birds, boobys, gannets, terns, &c. The birds are quite tame and have no fear of man. The white tern, Clayton thinks, is the prettiest of all. Mr Ross showed him one of this bird's eggs *in situ*. It had been laid so as to rest between two ribs of a coconut leaf, and was so placed that the swaying of the leaf in the wind did not shake it off. There was no nest of any kind.—*Commercial Intelligence*, Jan. 22.

MOSQUITO BLIGHT ON INDIAN TEA.

Mr. Harold Mann, the scientific Officer of the Indian Tea Association, has left Calcutta to spend six weeks in the tea districts making further investigations into the mosquito

blight. Problems in the manufacturing of tea are to be taken in hand on his return to Calcutta. A further monograph on tea soils will be issued shortly.—*M. Mail*, Feb. 13.

PRODUCE AND PLANTING.

It is somewhat curious to notice the way in which fads are ministered to by public caterers. A correspondent informs us that on visiting one of the co-operative stores he noticed on the menu that

TEA COULD BE HAD AT 2D. PER CUP.

This, he presumed, was ordinary Indian and Ceylon tea. China tea could also be had, but this being an article likely to be asked for by faddists, was marked at 3d. Our correspondent asked the distinction between the two, and was told that the China tea was a special scented sort, and very delicate in flavour. This need not frighten producers of Indian tea any more than the advice given by the late Sir Andrew Clark to his lady friends to drink only China tea. For the present day economic reasons prevent the majority of people from indulging in drinks that cost 50 per cent. more than they have been accustomed to pay. It is only right, however, that those who call for special brands should be prepared to pay something extra for the gratification of their tastes.

The *Grocers' Gazette*, commenting on the

A NEW USE HAS BEEN FOUND FOR TEA

according to the British Consul at Bordeaux who reports that he is informed that tea is largely used to colour brandy, the tannin giving the brown appearance like that produced by long storage in oak casks.—With regard to

DISPUTED BIDDING AT TEA SALES,

the "Grocer" says: "Friction has been experienced for some time past at the tea sales owing to certainty as to whether bids of $\frac{1}{2}$ d per lb are to be allowed. The present rule is to advance by farthings. Competition, however, for the lower grades of leaf tea is generally very keen, it being the desire of every buyer to get his bid accepted by the auctioneer, and in the shouting that always occurs with active markets, everyone yelling out at the same time, it is difficult for auctioneers to do justice to all bidders, which naturally causes great dissatisfaction. On these occasions a buyer is often prompted to offer $\frac{1}{2}$ d per lb. more. Many breaks are divided into two lines, and the buyer then offers a $\frac{1}{2}$ d more and 'drop'; or if the break is in only one line suggests that it should be divided, and he will give a farthing advance and drop which works out the increased equivalent of $\frac{3}{4}$ d per lb. This innovation is resisted by some brokers for reasons of their own, and objected to by others on the ground that it is irregular, whilst there are auctioneers who refuse these $\frac{1}{2}$ d's at the public sales, but accept them privately. At the Indian auctions last Wednesday a definite ruling was asked upon the subject by more than one buyer, but only the usual stereotyped answer was forthcoming, which means that the matter remains as it did before. It is a great pity that brokers cannot come to a decision among themselves, as the uncertainty engenders a good deal of vexation and irritation between buyers, besides often rendering the sale-room the scene of most disorderly proceedings. But those auctioneers who present a firm front and back their own decisions invariably command attention; it is the vacillators who fail to keep order."—*H. & C. Mail*, Jan. 23.

CEYLON TEA IN RUSSIA.

Our Odessa Correspondent writes:—The Colombo representative of a group of Moscow tea merchants states that the export of Ceylon tea last year exceeded by 2,000,000lb, that of the previous twelve months, and the trade is increas-

ing with marvellous rapidity. In this country Ceylon tea finds a constantly enlarging market, and there is, in consequence, a steady decline in the import of the Chinese product. Several of the leading Moscow merchants, I am credibly informed, have expressed the intention of shortly severing their connections with the Chinese planters in favour of the Cingalese growers.—*London Standard*, Jan. 30.

A NEW METHOD!

We have before commented on the extraordinary statements which appear from time to time in the public Press with regard to rubber. The following paragraph is the richest in humour which we have yet seen. It has started its rounds, and sooner or later will appear in different parts of the world:—“American ingenuity has devised several new methods for getting rubber ready for the market. The milk is drawn from the bark by suction, so that the pure sap is obtained free from the grit, bark, and foreign substances which were always present in such large quantities in the rubber sold by natives. After the rubber milk is obtained the pure rubber is separated from the other ingredients of the sap in much the same way that cream is separated from milk, by a patent process. In the new method introduced and practised by the Americans there is no waste of sap. By the natives half of it is wasted. When the rubber is coagulated it is tied up in bales and shipped to New York, where it sells at from 75 cents to 1 dollar (gold) a lb, and the total expense of extracting it, separating and coagulating it, and shipping it to the Eastern market is not more than 5 cents a lb. This shows enormous profit.”—*India-Rubber Trades' Journal*, Jan. 19.

MR. H. H. MANN'S TEA INVESTIGATIONS.

A letter, dated 21st January, from Mr H H Mann, the Agricultural Chemist employed by the Association, stated that he proposed to go on tour on the 9th February, in connection with his experiments against Mosquito blight. Mr Mann also asked the Committee to decide whether, on the completion of this tour, he should work up the soils of the Dooars and Darjeeling Districts, or whether he should continue his work on manufacture. The point was carefully discussed by the Committee, who were of opinion that the investigations into manufacture were the more urgent, and should take precedence over the soils of the two Districts named.—*I. T. A. Minutes*, Feb. 6th.

THE PLANTAIN FIBRE BOOM IN MALABAR.

Calicut, 12th Feb.—A correspondent writes to the *Kerala Sanchari*, the leading vernacular paper in Calicut, to say that a friend of his recently extracted a quantity of plantain fibre and forwarded it to Messrs Eddie and Christy, of London, who valued it at £15 per ton, and also wrote to say that they would give £25 for superior quality of fibre, and were prepared to receive supplies to any extent. Now that a fair start has been made, the opportunity ought to be seized by wealthy Malayalis—and there are several whose

ancestral wealth is rusting in disuse—to launch what promises to be a remunerative industry. The plantain tree is about the most familiar feature in the sub-arborescent vegetation of the Malabar Coast, and the raw material for the fibre is to be had in abundance.—*Madras Mail*, Feb. 14.

POPULAR SCIENTIFIC LECTURES.

“THE PECULIARITIES IN ANIMAL LIFE IN CEYLON.”

(Special.)

The fifth lecture of the series of Popular Scientific Lectures was delivered in the Ceylon Medical College on Saturday, 14th February, by Dr Arthur Willey, the Director of the Colombo Museum. The lecturer first dwelt on that remarkable peculiarity in the fauna of Ceylon first noticed, we believe, by Sir Emerson Tennent viz:—that Ceylon fauna consisted partly of Indian and partly of Malayan and Australian types and—what was more remarkable—were wanting in types which one would certainly expect to meet; as for instance the hamadryad or king-cobra, the tiger, and the antelope. After a brief reference to the Singha or lion in Sinhalese Mythology as being significant of the alien source of the Sinhalese race, the lecturer, with the aid of lantern slides, spoke first of the larger animals such as the leopard, and the various deer found in Ceylon, one species of which, whose headquarters are in Northern India, tradition ascribes as having been introduced by the Dutch, though no record has been found referring to such introduction. He then dwelt on the different lizards including the chameleon, the rare ceratophora or horned lizards found upcountry, and the false snakes or underground lizards. The next branch to be taken up was that of the fishes when the audience were entertained by descriptions of the burying fish like the “Lula” which lies dormant for a long time in dried up tanks waiting for the next rainy season; of the travelling and climbing fish, one species of which may be found in Mount Lavinia climbing on the top of rocks while another may be met with walking along the wayside or even climbing trees; of the king-crab “the last of the Mohicans,” a crustacean of ancient lineage one who can trace an unbroken descent from ancestors living in times long before the advent of that parvenu, Man; and of the erect swimming fish or fish with its dorsal aspect like the back of a razor and its ventral aspect as sharp as the front of a razor—a blunt razor. Dr Willey then turned his attention to those two low marine organisms on the life history and development of which the lecturer may be described as an authority; viz. the Amphioxus and the Balanoglossus. He impressed on his audience the importance of these two organisms lying as they do on the border land between the vertebrates and the lumbricates or earth worms—the highest form of invertebrates; for it is held by most scientists that the evolution of the vertebrates proceeds from the invertebrates through the Amphioxus and Balanoglossus. Dr Willey here showed some splendid slides of the development of the Amphioxus and Balanoglossus, photographs taken evidently from his own excellent set of specimens. The next subject dwelt on was the Molluscs where the audience were shown some beautiful slides of the Pearly and the Paper Nautilus, the shell of the former of which is to be found occasionally in Trincomalee, though

strange to say only three living specimens have so far been found. The last class to be taken up was the Myriopodes, consisting of the centipedes, of which a specimen of the very venomous yellow and black species was shown on the screen; and of the harmless Millepedes, met with so often upcountry. Dr. Willey also mentioned the existence of a third order belonging to this class (Poropidæ?) a few species of which are to be found in Australasia and South Africa. This third order was of interest in that it lay between the earth-worms and the centipedes. It was also of special interest to the Zoologist on account of its methods of reproduction; one species resembling the Mammalia in that respect while another was possessed of an enormous nutritive sac which sufficed for the nutrition of the embryo.—It was evident that Dr. Willey is of opinion that this third order may exist in Ceylon though it has not yet been found.—The lecture terminated shortly after 10 o'clock, Dr. Perry proposing a vote of thanks to the lecturer, for the very interesting lecture he had delivered, in which he had in such a short space of time, been able to give them such a fund of information about the peculiarities in animal life in Ceylon.

COCONUT PLANTING.

SIR,—In one of the most fertile islands of the Godavery I own land on which I planted a coconut tope three years ago. The land is very near the banks of the river, whose water is saltish, owing to its proximity to the sea into which it empties itself. The soil is one of excellent black loam and is, in the opinion of all local planters, eminently adapted for the growth of the coconut palm. So far, the plants, too, are thriving admirably, and if everything goes well with them, will yield fruit in three more years' time. A few days ago I paid one of my occasional visits to the place to see how the plants were progressing. Among others of the village who came to see me was an old experienced planter, who told me the following startling story. It seems he has land in another part of the village, very near mine, where, by the side of a large coconut plantation of his, growing and fruiting since his grandfather's time, he planted another some years ago. The plants grew very vigorously till they were just about to bear fruit, when, from some unknown cause, all of them suddenly drooped down their heads, and died within a short interval of each other. He suspected there was something wrong about the soil (which, by the way, was covered with a deposit of white sand, the result of a recent inundation of the river) and which he replaced about a yard deep with a soil and manure believed to be favourable to the growth of the coconut; and planted another tope, which also shared the same fate, having come out splendidly till the time of the promised fruit and perished equally miraculously. Nothing daunted, the old planter tried various means to eliminate the causes of the evil so far as could be conjectured, and successively altered the manure, the water and other things which might influence the health of the plant one way or the other. But with the same unfortunate result throughout. Now he has given up all thought of remedying the evil, which he attributes to parasitic worms sapping the life out of the plant from behind the root. Against this, too, he wished to provide by pouring in kerosine oil, but

whether this tended to kill the plant instead of the worm I am not sure. Now, in the interests of all local planters, I write this to you in the hope that you or any of your numerous readers will kindly enlighten me as to what conclusion to draw under the circumstances, and what measures to adopt in order to remedy the evil or effectively prevent it before having to attempt a cure.

9th Feb.

COCONUT-PLANTER.

—*Madras Mail*, Feb. 12.

MALARIAL FEVER AND HOW TO PREVENT IT.

A CIRCULAR IN THE NORTH-WESTERN PROVINCE.

Mr. S. M. Burrows, Chairman of the Local Board of Kurunegala, has issued the following circular, at a very opportune time, and it would be well that every recipient do "read, mark, learn and inwardly digest" its invaluable contents, so full is it of wise laws and modern instances. The circular is applicable to all malarial stations, and may, with profit, be adopted by the residents thereof:—

"It is now quite certain that malarial fever is caused by the bite of certain mosquitoes. You cannot catch malarial fever in any other way. How can you avoid being bitten by these mosquitoes?"

1. Use curtains (without holes or tears in them) at night to sleep under. They will save you the expense of doctor's bill, and medicines.

2. Empty and throw away or burn all broken bottles, upright pieces of bamboo, empty coconut shells, tins, old buckets, etc., in which stagnant water collects, and fill up all puddles and stagnant pools near your house, and clean your drains. It is just in these places that the dangerous kind of mosquito breeds. If we would all carry out this plan as far as we possibly can, there would be very few mosquitoes left to give us fever.

3. Keep your houses as clean as possible. The mosquito likes dark, dirty corners and shuns light.

4. Take quinine at regular intervals and in small doses, especially during the malarial season (December, January and February). Quinine prevents the fever germs from spreading. It can do you no harm. It can be had for nothing. Why not take it? Everyone in a malarious place like this should take enough quinine to cover a ten cent piece once in ten days even when quite well: If feverish, more frequently. If we all did this, there would be very little fever.

5. Every person with fever should be sent to hospital, if possible. While he remains in the house, the mosquitoes that bite him will bite you and give you fever. Let us all try and act on these simple rules for a year, and see if we cannot make Kurunegala a healthy place."

MALARIAL FEVER.—The circular issued by Mr. S. M. Burrows and printed in our daily and *T.A.* is well worth the attention of all who reside in feverish districts. Fever has lately been especially trying in and near Anuradhapura, for instance—and this and other places similarly situated will doubtless be glad of good advice.

KURUNEGALA PLANTERS' ASSOCIATION.

ANNUAL REPORT

of the Kurunegala Planters' Association of Ceylon for the year ending February 14th, 1903.

Your Committee have pleasure in submitting the first annual report, and they feel sure that all members of the Association, on perusal of same, perceive that the desirability and necessity for an Association in this district is very obvious, and that the formation of this Association which took place a year ago has already led to beneficial results in the Planting interests.

FINANCES.—Your Committee are glad to be able to report that the finances of the Association are in a satisfactory condition. All liabilities with the exception of cost of recent advertisements have been paid up, there are no subscriptions outstanding, and there is a balance to the credit of the Association of R78 91.

MEMBERS.—There are 28 members on the register—25 estates and three private subscribers—and your committee are in hopes that some more estates in the district, which have not as yet joined, will do so in the coming year.

MEETINGS.—There have been five general meetings and five Committee meetings, and the attendance on the whole has been good.

HOSPITAL.—At an early meeting of the Association it was thought desirable to ask Government to appoint hospital visitors, and Messrs. Scott and Hermon were duly appointed.

LABOUR.—on the whole has been fairly satisfactory. There has been trouble on one or two estates, but otherwise relations between employer and cooly have been harmonious and peaceful, and your Committee see no reason why this satisfactory state of affairs should not continue. The advances all over the district (as far as your Committee are able to ascertain) are considerably lower than they were a year ago.

MAIN ROADS.—suffered considerably during the last wet weather, but are now being put into good order again as before. A toll on the Kandy Road near Mal-lawapitiya was removed by Government at the request of this Association, much to the satisfaction of all residents in the district.

MINOR ROADS.—Your Committee regret that they cannot give a good report in this respect, as some of them are in a state wholly unfit for cart traffic; one or two roads near to the town are in a fair state of repair, but beyond that the rest of the district is in a wretched condition. Plank bridges are rotten, culverts are choked up, and in many places no side drains exist at all, and practically no improvement in the way of necessary new bridges, pavings, drains, &c., have been done at all. Your Committee cannot help feeling that the continual change of Government Agents, which has been going on now for the last five years, has had a disastrous effect in this and many other respects regarding the welfare of the province, and they take this opportunity of pointing out the desirability that may arise of publicly discussing this important question, should further changes again take place.

C.P.R.C.—Your Committee note with much satisfaction that a section of the C.P.R.C has been established at Kurunegala, and under the able guidance and command of Mr H E H Hayes has already attained to a very high standard of efficiency, especially so at the range.

POST OFFICE.—Your Committee would call your attention to the wretched little building that is now used as a Post Office, which is wholly inadequate for the work and should receive your attention.

COCONUTS.—Our Association being largely comprised of representatives of the coconut interest, your Committee have much satisfaction in recording another prosperous year for that industry. With the exception of a decline of 65,069 cwts. in copra; a deficit of 2,262,569 in coconuts in the shell, and 6,826 cwts in coir fibre, all the other products reported—

coconut oil, 512,498 cwts; poonac, 247,696 cwts; desiccated coconuts, 16,227,565 lb; coir rope, 15,631 cwts.—show an appreciable increase over last year and are the highest during the last 10 years, desiccated coconuts being the highest on record. Our best customer for copra and poonac is Germany; France being next with copra. The United Kingdom takes the bulk of coconut oil, desiccated coconuts and coconuts in the shell. America is our next best customer for coconut oil and desiccated coconuts. India, which last year took 141,139 cwts coconut oil, has this year taken only 64,370 cwts. This great falling-off is said to be due to a tax imposed upon the article in India. Singapore takes 15,354 cwts coir rope, out of 15,631 cwts exported. Prices though not so good as during the closing months of 1901 were fairly satisfactory. Copra ranged from R61 to R63 per candy during the first half of the year; at R56 to R58 from July to October, and during November and December touched R37, the lowest price for the year. Coconut oil varied in the varying prices of copra, and at the end of the year was R4 per cwt., below what it was at the commencement. Poonac was R75 per ton from January to March and stood firm at R80 for the rest of the year. Desiccated coconuts varied from 19 cts. to 22 cts. per lb. Though the fall in prices has been considerable for the last few months, your Committee are hopeful that it is only temporary and will soon rise.

There would seem to be a steady increase, both in Britain and the Continent, of the manufacture of coconut butter, and it is good news that we may shortly expect to see this article manufactured locally. We wish the venture all success, as the demand for coconut butter is sure to increase and be in great request by vegetarians of all creeds. There are rumours that the sensitive plant, which has hitherto been considered a nuisance and source of expense on many estates, is likely to prove a blessing. Being a nitrogen-collecting plant it is being cut down twice a year and buried—with results, it is said, far in excess of what might be expected from its nitrogen-producing propensities only.

Your Committee would advise those who have this plant growing on their property to experiment in this direction with a few acres and report results. The year has been an unusually wet one, causing a deal of inconvenience at times, but upon the whole might be considered favourable for the formation of crop, and the probabilities are that 1903 will be a good year in this respect.

COCOA.—Throughout the district cocoa is doing well and cancer (as far as your Committee are able to ascertain) is not at present causing much anxiety. Crops were fairly heavy and realised on the whole good prices.

OTHER PRODUCTS: RUBBER, PEPPER AND VANILLA.—From the results obtained from various estates it would seem that this district is very suitable for the growth of any of these products and a considerable acreage is now planted and being planted with them.

THE RUANWELLA TEA COMPANY, LTD.

ANNUAL REPORT.

DIRECTORS:—Messrs. G H Alston, J P Anderson and H J Scott.

ESTATE INSPECTOR:—Mr J P Anderson. **ESTATE SUPERINTENDENT:**—Mr D I Mackenzie.

ACREAGE:

Tea in full bearing ..	374 acres
Jungle and Wasteland ..	199 do
Total ..	573 acres

The Directors submit herewith to the shareholders the report and accounts of the Company for the past year. The crop amounted to 180,125 lb of tea, which is nearly 20,000 lb. short of the estimate, but shows an excess over 1901 of 13,825 lb. The shortfall in 1902 is wholly attributable to the continual rain and absence of sunshine during the last 3 months of the year. The average net price re-

alised was 27.61 cents per lb., against a cost of production of 23.08 cents per lb. This included the sum of R3,257.16 spent on manuring, or say 1.81 cents per lb. of made tea, and R1,840.16 spent on re-roofing 2 sets of lines with iron, and other repairs to lines, equal to 1.02 cents per lb. of made tea. The Directors regret to state that between 22nd November and 18th December, on which later date the theft was discovered, 5,044 lb. tea were stolen from the Factory. Every effort is being made to trace the thieves, but up to date without success. It is however anticipated that a considerable proportion of the value, R1,421.40, will be recovered, but in the meantime the Directors have decided to set aside this amount to a doubtful debts account. After making this provision the nett profit for the year amounts to R4,205.82, to which has to be added R2,603.31 brought forward from 1901, making a total of R6,809.33 available for distribution. The Directors now recommend the payment of a dividend of 2 per cent for the past year and that the balance of R1,509.33 be carried forward to the present year's accounts. The crop for the current season is estimated at 200,000 lb. Tea costing 23.25 cents per lb. delivered in Colombo. Owing to the demand for Green Teas, the Directors have considered it advisable to undertake their manufacture. The necessary machinery is now on the estate and it is hoped that the manufacture of Green Tea will be commenced in the course of the next few days. The additional expenditure for this work should not amount to more than R50, which is included in the expenditure of 23.25 cents per lb. given above. It is also proposed to continue the planting of para rubber on suitable ground. During the year the Hon. Mr W H Figg resigned his seat on the Board, and the remaining Directors appointed Mr G H Alston to fill the vacancy; in accordance with the articles of Association he now retires, but is eligible for re-election. The appointment of an Auditor for the present year rests with the meeting.—By order of the Directors,

WHITTALL & Co., Agents and Secretaries.
Colombo 5th Feb. 1903.

THE KANDYAN HILLS CO., LTD.

ANNUAL REPORT.

Tea in full bearing ..	410 acres
Not in bearing under two years ..	23 do
Reserve and Forest Lands ..	787 do
Cocoa ..	90 do
Total ..	1,310 do

The Directors beg to present their report for the season ended 31st December, 1902, together with a duly audited statement of accounts for the same period. The Tea Crop including Tea made for others amounted to 206,788 lb., and the Cocoa crop reached cwt 141.1-14, whilst the made Tea gathered from the Estate itself was 182,091 lb as against the estimate of 200,000 lb. The total cost of production, including the expenditure of cents 1.42 on manure, was 25.02 cents per pound of made Tea. After paying interest and all other fees and charges their remains a balance of R2,932.48 at credit of Profit and Loss Account, which the Directors recommend should be carried forward. The new Season's estimate of expenditure amounts to R45,036, or equal to 22.51 cents per pound of made Tea on a crop of 200,000 lb, and includes a sum of R1,960 to be spent on manuring or cts 98 per pound. The Cocoa Crop is estimated at cwt 130 against an expenditure of R3,910. In addition to the above, it has been decided by the Visiting Agent and Directors, that a sum of not more than R2,000 should be spent on Castilloa and Para Rubber to be planted partly in a new clearing, which will be opened for the purpose and partly in ravines and other suitable places on the Estate. At the end of September last the Factory on Pansalatenne was totally destroyed by fire, which necessitated arrangements having to be made for the

manufacture of the Green Leaf from the Estate in the neighboring Factories. Whilst the actual loss to the Company was fully covered by insurance, additional expenditure was incurred for manufacture, and the Superintendent was obliged to resort to finer plucking so as not to exceed the capacity of the Factories, to whom he was indebted for the manufacture of his Teas. The shortage in crop as compared with the estimate is thus partly accounted for, as also the increased cost of production, though the deficiency in crop may be attributed mainly to the abnormally wet season experienced during the latter part of the year. The new Factory has now been completed and is thoroughly up-to-date in its equipment, including Fans and the latest improvements. It will be noticed that in the Profit and Loss Account no special provision has been made for depreciation of buildings and machinery, as the Factory has recently been re-erected, but this has been amply provided for by the surplus remaining over from the amount received as insurance against Loss of Income after covering the cost of rebuilding the Factory. Given a normal season the estimated crop should be realized, and is hoped a better class of Tea manufactured with the ample accommodation and machinery now at the disposal of the Superintendent. In terms of the Memorandum and Articles of Association the Hon. Mr J N Campbell retires from the Board of Directors, but is eligible for re-election. It will also be necessary to appoint a Director in place of Mr W Shakespeare who is shortly leaving the Island. The appointment of an Auditor for the current year rests with the Meeting.

MAHA UVA ESTATE COMPANY, LTD.

ANNUAL REPORT.

DIRECTORS:—Messrs. S Bois, Jas. Polson and G H Alston.

ESTATE INSPECTOR:—Mr. Jas. Polson, ESTATE SUPERINTENDENT:—Mr C W Maclean.

ACREAGE :

Tea in full bearing ..	618 acres
Cardamoms ..	89 do
Fuel ..	20 do
Total Cultivated ..	727 do
Jungle and Waste land, &c. ..	231 do
Total of Estate ..	958 acres

The Directors have now to present to the shareholders the accounts for the past year. The tea crop secured amounted to 242,376 lb. against an estimate of 262,000 lb. the shortfall being due, as in almost all districts, to continued rain and absence of sunshine during the last three months of the year. The cardamom crop however exceeded expectations and yielded about 9,600 lb. against an estimate of 9,000 lb. The prices realised for these products were 34.57 cents per lb. nett for the tea, and 83.33 cents nett per lb. for the cardamoms sold; against 34.78 cents per lb. and 1.25 per lb. respectively in 1901. As shareholders are probably aware, the market for cardamoms has been very low during the last twelve months. After allowing for depreciation on buildings and machinery, and estimating at a low rate for the Cardamoms yet to be sold, the amount at credit of profit and loss account for the year's working was R23,042.31, equal to 7.68 per cent on the paid up capital of the Company, to which has to be added the balance of R3,012.17 brought forward from 1901, and R432.47, being under estimated value of cardamoms appearing as unsold in last year's accounts, making a total of R26,486.95 available for distribution. An Interim dividend of 3 per cent was paid on 5th August last, absorbing R9,000, and the Directors now recommend the payment of a final dividend of 5 per cent, making 8 per cent for the year, and that the balance of R2,486.95

be carried forward to the current year's accounts. The estimates for the present season are 237,000 lb. Tea, including 25,000 lb. tea to be manufactured for others, and 10,000 lb. cardamoms, on an expenditure of R72,906.53, in addition to which a sum of R6,600, has been estimated for new Turbine Piping. In accordance with the articles of Association Mr S Bois now retires from the office of Director but is eligible for re-election. The appointment of an Auditor for the current year rests with the meeting.—By order of the Directors,

WHITTALL & Co., Agents and Secretaries.
Colombo, 4th Feb., 1903.

PASSARA PLANTERS' ASSOCIATION.

THE TENTH ANNUAL REPORT.

CHAIRMAN.—Mr J B Cotton; HON. SECRETARY.—Mr A V Ryall; MEMBER TO D R C AND P R C.—W Stewart Taylor.

COMMITTEES:—*Passara*.—Messrs. Jas. Dunoan, Geo. Kent Deaker, Capt. H Gordon, J J Robinson, W Stewart Taylor, *Madulsima*.—Messrs J M Mason and R Webster, *Lunugala*.—Messrs J D P Maclean, Channing Esdall, F Hall and A L Buyers, *Monaragala*.—J H Betts and E Liesching.

THIRTY COMMITTEE.—Capt H Gordon. KANDY COMMITTEE.—Chairman, Secretary, G K Deaker and J M Mason. HOSPITAL VISITORS, BADULLA.—Messrs G K Deaker and J Duncan, *Lunugala*.—J D P Maclean and F Hall. AUDITOR.—Jas. Duncan.

REGISTER.—The number of estates on the Register is 30 (5 less than in 1901, due to amalgamation of estates).

FINANCE.—The books of the Association are laid on the table for inspection. The amount standing to the credit of the Association (in the Bank of Uva) is R27,343. Last years' accounts were audited by Mr Duncan.

MEETINGS.—There have been four Committee and four general meetings, which have all been well attended, showing the interest members take in the Association.

TEA CROP.—The estimated tea crop for estates on the Register of this Association for 1903 is 4,032,500 lb. off 8,844 acres in bearing; an average of 455 lb. per acre. This speaks well for the suitability of this part of Uva for tea production. There are still 1,357 acres not in bearing; the last three months of 1902 were very unfavourable for the production and manufacture of tea, owing to the continuous wet and cloudy weather. Your Committee are glad to report a marked improvement in the market, and that the immediate futuro is bright, as the stock at the end of 1902 was below 1901, and green tea will (if the bonus is continued) relieve the black tea market of 12 to 4,000,000 lb. Your Committee would recommend you to continue to support the cess and they would also urge you to refrain from returning to coarse plucking, which would only land you in the disastrous position (as regards prices) in which you were a short time ago.

COCOA.—This product has given a fair crop during the year. Your Committee will watch with the deepest interest, the results of the experiments still being made with a hope of checking the pod and other diseases which caused so much loss yearly.

RUBBER.—Some extension of this product has been made during 1902; both Para and castilloa are being planted and on one estate; the oldest Para Rubber tree will be tapped during 1903—the result of which will be watched with the greatest interest by your Committee.

POST AND TELEGRAPH.—Your Committee are glad to announce that your efforts to get a Telegraph Station opened at Madulsima are to be crowned with success.

COACH.—The arrival and departure of the coach at Passara has been most erratic and the coach arrangements still have room for improvement.

WATER SUPPLY AT MUPANE.—The well at Mupane has been built after years of agitation, but whether it will be a success or not remains to be seen.

POLICE MAGISTRATE.—As Government could not see their way (as requested by your Association) to appoint a permanent Police Magistrate for Badulla itself, they consented to have the date published on which the present itinerating Magistrate would be absent from Badulla.

NURSING ASSOCIATION.—Your Committee are sorry to report the proposal to get Agents and Firms in Colombo to allow estates to subscribe towards this worthy institution met with very little success.

RESTHOUSES.—It affords your Committee much satisfaction to report and note the marked improvement in the comfort and cleanliness in the Resthouses generally for which we are indebted to our worthy Government Agent.

LABOUR.—The supply of this has not been quite sufficient for the requirements of the District, and in consequence the advances have increased to a very alarming extent and the labour is generally restless and unsettled and your Committee view this with not a little uneasiness. Your Committee therefore think that any scheme for recruiting labour in new districts should be strongly supported, for the prospects of a good harvest in our present recruiting districts, and the fact that other countries are also competing against Ceylon in those parts convince your Committee that the Ceylon Planters should no longer rely on the old districts for their labour requirements.

TRAMWAY OR LIGHT RAILWAY.—Both the light railways to Kandapola and the Kelani Valley are nearing completion and your Committee hope that His Excellency Sir West Ridgeway will have a survey made (as promised) of a line between Bandarawela, Passara and Badulla before his departure from the Island.

ROADS AND BRIDGES.—The bridge over the (Nukkal) river has been completed after banging fire for two years and it is a great boon during N.E. heavy rains to the Monaragalla Estates. R6,000 has been granted towards widening and protecting the Madulsima Road and Your Committee hope the officer in charge will not take on the labour required for this work locally. Some of the roads are in fair order, but your Committee think the laying and macadamising of metal is much delayed. This should be begun with the first rains in Sept.

HIS EXCELLENCY THE GOVERNOR.—Your Committee are only echoing the voice of this Association when they say how grateful they were at the news of our present Governor Sir West Ridgeway's term of office being extended, but they sincerely regret that that term will expire in October. He has always been a friend to the planters (and to Uva especially).

PASSARA RIFLE CORPS.—This was formed in April, but your Committee regret that some members of your districts have not yet joined. They hope, now the range is completed, they will do so. Of the section there were [?] ex-efficient, six efficient, one non-efficient in class-firing which, they think, was very creditable considering they had no range or practice. The adoption of the report was duly moved, seconded and carried.

HIGHER WAGES FOR INDIAN COOLIES IN THE STRAITS.

The Malay Peninsula Sugar Industry Association have nominated Mr Turner, and Mr Boyd of Gula Estate, to represent them at a conference to be held in Singapore to consider a proposed rate of increase in wages for Indian Immigrants. The feeling of the meeting was that, owing to the greatly increased demand for labour throughout the Colony, and the Federated Malay States, a very material increase on the present rate of wages must be faced.—*Singapore Free Press*, Feb. 10.

TO THE PLANTING WORLD.

Seeds & Plants of Commercial Products.

Hevea Brasiliensis.—Orders being booked for the coming crop August-September delivery 1903, booking necessary before the end of April, quantities of 100,000 and over at special low rates. Plants available all the year round, 100,000 and over at special low rates. A leading Rubber planter in Sumatra, who purchased 50,000 seeds in 1899, and 100,000 in 1900, writes us, under date 15th November, 1900 :—“ I received your letter of 20th October, from which I learn that you added another case of 5,000 seeds to replace the loss, &c. I am satisfied hereby, and even after this adding I am satisfied by the whole delivery of this year.” Special offer, post free on application.

Castilloa Elastica.—True superior variety cultivated in Mexico, seeds from specially reserved old untapped trees. Orders booked for October-November delivery 1903, immediate booking necessary; large quantities on special terms; Plants in Wardian cases.

A foreign firm of Planters writes under date 11th October, 1901 :—“ We beg to enquire whether you would procure us 100,000 Castilloa seeds, in which month we might expect them, and what would be the average price.” Special offer, post free on application.

Manihot Glaziovii.—Seeds and Plants available all the year round, 100,000 and over at special low rates. A Mexican planter in sending an order for this seed wrote on the 22nd August, 1900 :—“ If they arrive fresh and germinate easily I may send you larger orders, as they are for high ground where the Castilloa does not thrive.”

Ficus Elastica.—Seeds available in May-June; booking necessary before the end of March; also plants.

Mimops Globosa (Balata) wood of the tree is much sought for buildings, fruits sweet like a plum and eaten, oil from seeds, said to yield as much as 45 lbs. of dry rubber per tree per annum, the milk is drunk and when diluted with water used as cow's milk, grow from-sea-level up to 2,000 feet, orders being booked for seeds and plants, price on application.

Cinnamomum Zeylanicum (Cinnamon superior variety).—New crop of seed in April to June; booking necessary before the end of February, also plants.

Coffee Arabica-Liberian Hybrid.—A highly recommended leaf-disease resisting hardy new variety of Coffee (cross between Arabian and Liberian). New crop March-April; immediate booking necessary.

A foreign Agricultural Department writes dating 9th September, 1901 :—“ Please accept our order for 175 lbs. of Tea seed and for 2,000 Coffee beans. In regard to Coffee seed I would say that this will be the first importation made by this department, and we will leave the selection of the varieties to be sent to your judgment.”

OUR DESCRIPTIVE PRICE LISTS.

The following six Descriptive Price Lists are now being forwarded with Circulars and special offer of Seeds and Plants of Rubber and other Economic Products :—

1. Tropical Seeds and Plants of Commercial Products, enlarged edition for 1902-1903.
2. Seeds and Plants of Shade, Timber, Wind-Belts, Fuel and Ornamental Trees, Trees for Road-sides, Parks, Open Spaces, Pasture Lands, Avenues, Hedges, and for planting among crops (Tea, Coffee, Cacao, Cardamoms, &c.)
3. Seeds and Plants of Tropical Fruit Trees including Mango grafts.
4. Bulbs, Tubers and Yams.
5. Orchids—Ceylon and Indian.
6. Seeds and Plants of Palms, Calamus, Pandanus, Cycads, Tree and other Ferns, Crotons, Roscs, Dracinas, Shrubs and Creepers.

Special Arrangements made with foreign Governments, Botanical and Agricultural Departments, Planters and others for supplying seeds and plants of Commercial Products in larger quantities.

“ SOUTH AFRICA.”—The great authority on South African affairs of 25th March, 1899, says :—“ An interesting Catalogue reaches us from the East. It is issued by WILLIAM BROTHERS, Tropical Seed Merchants of Henaratgoda, Ceylon, and schedules all the useful and beautiful plants which will thrive in tropical and semi-tropical regions. We fancy Messrs. Williams should do good business, for now that the great Powers have grabbed all the waste places of the earth, they must turn to and prove that they were worth the grabbing. We recommend the great Powers and Concessionaries under them to go to William Brothers.”

Agents in London :—MESSRS. P. W. WOOLLEY & Co., 90, Lower Thames Street.

Agent in Colombo, Ceylon :—E. B. CREAMY, Esq.

Agent in British Central Africa :—T. H. LLOYD, Esq., Blantyre.

To the Editor.

HUNTING IN THE HILLS.

Amherst, Feb. 12.

SIR,—The Hon. Secretary, C.G.P.S., is welcome to call my remarks about Registered Packs and the slaughter committed by them "a blood and thunder paragraph," but why does he not attempt to refute my statements? He goes on to say that since the new law prohibiting shooting at over 4,000 ft. came into force, that is to say in about 3 years, sambur have increased to such an extent that they need "judicious thinning." He admits that he kills hinds on purpose, but defends his action by pointing out that "judicious thinning out" is resorted to on Scotch deer forests. At home there is such a thing as a severe winter and great scarcity of food, and deer forests would soon get overstocked and deer would starve if they were not thinned out; but surely there is no scarcity of food in the hills in Ceylon, so that the Hon. Secretary must consider "judicious thinning out" necessary for some reason not given. Admitting that it were necessary, the merciful plan of thinning out with the rifle, as adopted at home, would surely be better than allowing a large pack of dogs of sorts to kill as many hinds and fawns as they can manage to pull down. I don't think the Hon. Secretary's plan of "judicious thinning out" would commend itself to owners of deer forests at home or to sportsmen in India or elsewhere. From his concluding paragraph, one gathers that the Hon. Secretary prefers to shoot a stag when it is standing to when it is galloping.—Yours, &c.,

NORTH C. DAVIDSON.

DIFFERENT VARIETIES OF PLANTAIN IN THE ISLAND.

Hanwella, Feb. 14.

DEAR SIR,—I shall be glad to know what other useful varieties of plantains are found in the island, beside the following. If any available I should like to have either by purchase or by exchange of plants. I have in possession viz.—1 Kolikuttu, 2 Suwandel, 3 Puwalu, 4 Rata-hondrawalu, 5 Embulhondrawalu, (a) Sudu Embulhondrawalu, (b) Pulli Embulhondrawalu, 6 Watu Palu, 7 Anawalu, (a) Athdath Anawalu alias Supuanawalu, (b) Vanduru Anawalu, 8 Hamban Puwalu, 9 Ratu Kotchi, 10 Sudu Kotchi, 11 Marthawalu, 12 Sudu Kannannoru, 13 Kalu Kannannoru, 14 Sura Mondan, 15 Kalu Mondan, 16 Alu Mondan, 17 Bin-hehel, 18 Puspa Kedeli, 19 Navari, 20 Kitela. The first nine varieties are generally used as fruits and the rest as vegetable.

I learn that the Superintendent of Government School Gardens has a new variety from Queensland called the "Cavendish," but how far it will prove successful in our soil is yet to be seen.—I am, yours faithfully,
G. E. AMARASEKARA.

DR. WILLEY'S LECTURE AND PECULIAR CEYLON FISH.

Havelock Town, Feb. 19.

DEAR SIR,—In reply to the enquiry in your issue of Monday last:—

The fish called *Amphisile* referred to by your correspondent is certainly not the fish referred to by Ælian. It can only move by swimming in the middle stratum of water, feeds on microscopic organisms and has a minute mouth, the gape of which is reduced to zero. On the face of it and relying solely upon Sir E Tennent's quotation I should have said that the fish described by Ælian was *Periophthalmus*, a goggle-eyed fish which crawls and hops about the mangrove flats and also, in some places, on the rocks near the seashore. This fish, which has attained a certain celebrity in books of travel, appears to have been left out of consideration by Sir E Tennent.—Yours faithfully,

ARTHUR WILLEY.

PLANTING NOTES.

DESTRUCTION OF THE OLIVE TREES.—The olive trees which in hundreds of thousands have flourished along the Riviera from times unrecorded, are slowly but surely diminishing in number year by year; and many among the older members of the numerous English colonies sincerely deplore their loss, and the consequent disfigurement of familiar hills and valley. In some places they are being cut down wholesale, and large areas of land on the hillsides have been denuded of all their beautiful trees to make room for the cultivation of more remunerative crops, such as carnations, roses or violets; while, alas, the gnarled and revered old olives, numbers of which have been twisted and torn into the most fantastic shapes by the storms and vicissitudes of actually unknown centuries, are rooted up and hacked to pieces to burn in your hotel bedroom at "two francs fifty" a basket! And why must the inevitable destruction go on? because petroleum is a cheaper lubricant than olive oil; and cotton-seed oil, they say, has falsely assumed the name of olive oil, and taken its place in our salads.—*Travel* for February.

A GOOD YIELD OF RUBBER.—Mr Francis Pears, writing from Muar, gives the following information, which is very welcome:—"In case you have not received previous information, I append particulars of the yield of two cultivated Para trees at Gapis Estate, in Perak, reputed to be 25 years old. The tapping was conducted by Mr Baxendale, and extended over two months, and was done evidently with the intention of procuring a maximum yield.

	Tree No. 1.	Tree No. 2.
Girth at one yard from the ground	89 in.	56 in.
	1b. oz.	1b. oz.
Yield of clean rubber, dry	15 12	11 2
Yield of scrap rubber, dry	2 4	1 8
Total	18 0	12 10

Tree No. 1 had never been previously tapped, and was worked from three channels, whereas tree No. 2 was worked from two channels only, and was tapped during 1901 and yielded 3 lb.—*India-Rubber Journal*, Feb. 2.

"SOIL BACTERIA AND BASIC SLAG."

INTERNATIONAL COMPETITION: CLOSING IN
THREE YEARS.

In order to encourage investigations into the increase of fertility in soils by the action of bacteria and other micro-organisms, under the influence of mineral manures, with special reference to manuring with basic slag, Verein der Thomasphosphatfabriken (Association of Thomas's Phosphate Works) has instituted a competition with prizes amounting to a total of 40,000 marks (£1,950). Scientific essays and experiments conducted by practical farmers will be admissible in the competition. The method of treatment of the subject is left to the discretion of each competitor. The competition is to be open to all, without regard to nationality. The following five gentlemen have consented to act as judges, any of whom will be pleased to give particular information to intending competitors:—Government Adviser Dr L Hiltner, Principal of the Royal Agricultural and Bacteriological Institution, Munich; Professor Dr Alfred Koch, Principal of the Royal Agricultural and Bacteriological Institution, the University, Göttingen; Professor Dr Remy, Principal of the Institute for Researches and Bacteriology, the Royal Agricultural University, Berlin; Professor Dr A Stutzer, Principal of the Royal Agricultural Chemical Institute, the University, Königsberg; and Professor Dr H Wilfarth, Principal of the Ducal Agricultural Experimental Station, Bernburg. Competitors are requested to send in their essays written in German to the association not later than February 1st, 1906, by registered post, the envelope to bear a motto in addition to the address. The name of the competitor in each case must be enclosed with the essay, but in a separate closed envelope bearing the same motto on the outside. The latter will not be opened until the judges have made their awards. The address of the association is Berlin, S W, Hafenplatz 4.—*London Times*, February 6.

RAINBOW TROUT OVA.

BATCH BY THE "HAMBURG" A FAILURE.

The batch of 20,000 Rainbow Ova, received by the Ceylon Fishing Club from the Wyresdale Hatcheries, and which arrived in Nuwara Eliya on the 10th Feb. after a delayed voyage out in the N.L.S.S. "Hamburg," have proved a failure as not 8,000 ova out of the big consignment have hatched out, whether it is due to its remaining packed a longer period than usual, or whether it is due to the arrangement made by the Wyresdale Hatchery to get the ova to hatch out earlier than on previous years, it is difficult to say. Ova was not obtainable till the end of March in other years, but this year the consignment arrived as early as the first week in February. The failure of the consignment is a matter of serious concern, as two shipments went bad last year. In our issue of the 16th instant we gave details of the date of shipment and the number of days the consignment had been on the voyage out, together with the further delay caused by the "Hamburg" arriving in port late on Saturday, the 7th Feb. It is to be hoped that the consignment of Brown Trout Ova, which arrived here this week also from the same Wyresdale Hatchery, will give better results.—*Nuwara Eliya Cor.*

TEA AND COFFEE IN SIERRA LEONE.

In a report on Exotic Plants of Economic Interest in the Botanic Gardens at Entebbe, Uganda, Mr J Mahon states he has a number of seedlings of Sierra Leone highland coffee (*coffee stenophylla*) raised from Singapore seed. Tea grows with but moderate rapidity just here. Our rainfall is not great enough. When we have a period of rains it flushes nicely. If its cultivation were carried on here even on a moderate scale to meet some of the local demands it would be necessary to call in the aid of irrigation. Mr Scott Elliot, the naturalist and traveller, seemed satisfied from his explorations in the Ruwenzori country that large areas there offered a fine field for cultivating tea on a large scale.—*London and China Express*, Jan. 30.

A NEW RUBBER VINE.

The U.S. Consul at Tegucigalpa (Honduras) has received information of the discovery in the Pijo Mountains of a vine growing in an uncultivated state which is said to produce rubber of excellent quality. The vines grow to 100 ft in length, varying in diameter from 4 in. to 2 ft and they are said to belong to the African family of rubber vines. In Honduras no one seems to know the name of the vine or the botanical family to which it belongs. The discoverer (Senor Davadi, Governor of the Department of Comyagua) regards it as superior in quality to the Para rubber of commerce, and asserts that his convictions are borne out by the analyses made by American and European chemists. The vine thrives at great altitudes as well as in the lower valley levels. Such luxuriance of growth has this plant attained that it is quite capable of being cut in commercial quantities. It may be quickly propagated in the rich soil of the department by means of seedlings, and the growth being so much faster than that of rubber trees, Senor Davadi thinks the quantity of gum obtained would be large. The trees require six years' attention before sapping can begin.—*India Rubber Trades' Journal*, Jan. 19.

WHAT DOES THE WORD "PLANTER"
MEAN?(To the Editor, *Indian Planters' Gazette.*)

Sir,—Will you kindly inform me about the following:—The word *planter* is frequently used both in your own paper and in the daily papers, in a very ambiguous way, and I would like to have the matter explained. Does the word *planter* refer to the *manager*, the *shareholder* or the *proprietor* of an estate? In short does it refer to the manager or to the owners of the estate. For instance, in your leader in Saturday's *Gazette*, "The planter's kith and kin at home are full of sympathy for him," this cannot exactly refer to the *manager* of an estate, for he gets his pay whether the concern is paying a profit or not. The same sort of reference occurs in Messrs. Brooke Bond's letter; does "lack of enterprise" refer to the *managers*, or to the *shareholders* of the estates?

MANAGING PROPRIETOR.

Jaipalguri, 3rd Feb. 1903.

[A tea planter is a man actively engaged in the cultivation and manufacture of tea. He may be a

Managing Proprietor, or a Shareholder in one or more concerns: he may be a Manager or an Assistant. It matters not what his exact position is so long as he is actively employed in growing and producing tea. Because a planter draws a salary is no reason why his kith and kin at Home should not be full of sympathy for him. His bread and butter depends on the welfare of tea. If tea goes to the wall so will he. The word, however, is often used in much too wide a sense, leading to the ambiguity complained of. A planter is a producer, but a *producer* may not be a planter, but only an absent proprietor or shareholder. The terms are frequently used very indiscriminately, and planters are often wrongly blamed.—Ed., *I.P.G.*—*Indian Planters' Gazette*, Feb. 21.

MANURING FRUIT TREES.

The season of the year is drawing on when the man with an orchard transfers the manure from his stables to the roots of his trees, or rather the ground above them. His motive is good, but his method often defeats the end he has in view. Who has not, in rambling through country districts in winter and spring seen a pile of manure heaped at the foot of the trees in the orchards? Yes, heaped as though for all the world the trunk was being protected against frost. The veriest tyro should know, and frequently does know, but is too thoughtless to act upon the knowledge that the feeding roots of the tree are far from the trunk. Why, then, manure near the stem? Spread the dung out as far as, or even a trifle farther than, the extent of the branches, and do not put any within 1 yard of the tree trunk.—From *Cassell's "Gardener"* for February.

CULTIVATION OF YAMS AND JERUSALEM ARTICHOKEs.

In a recent issue of your *Journal*, a writer urges the introduction of yams in order to make up for the partial failure of the potato crop in 1902. I feel that it would be folly to attempt such action. In the first place the yam is a tropical species, and would probably only succeed in exceptionally warm seasons, and be then only a fancy dish for the wealthy. It is true there is a hardy variety, which was introduced from China or Japan about fifty years back, *Dioscorea batatas*, and I well remember planting the same. It was shaped like a club, about twenty inches long, and four to five inches in circumference at the thickest part tapering at the top to finger size. This was cut into eight pieces, and planted in April; soon after, a shoot appeared above the ground, like the British *Bryony*, and developed every beautiful marbled heart-shaped foliage, like the *Sarsaparilla* (six feet to seven feet long). When this foliage was killed by frost, I proceeded to sample the crop, very carefully working around the bottle-like neck, and a heavy job it proved, for the tubers ran down about three feet into the rock, and were so brittle that several snapped like a carrot and some yards of soil had to be moved to get out about eight sets. When cooked they proved to be less tasty than a bad waxy potato. It is evident from these facts that *Dioscorea* was useless as a commercial crop, and of doubtful use even after the cook had expended her butter and condiments upon it; either boiled or fried in slices and browned, it was nauseous. I have not tasted other yams than in the tropics, or come across South American sorts cooked in England, but if *Asparagus* is cynically called an excuse for wasting good butter, the *Dioscorea* deserves greater condemnation. No doubt my Indian cook could make any root palatable, but an

reason in writing, is it to say that as we already have a substitute for potatoes available for the poorest, and not by any means despised by the richest, why waste time, labour, land and cooking, on a useless tuber. I refer to the Jerusalem artichoke (*Helianthus tuberosus*). In this neglected vegetable we have a tuber that will grow in any soil, requires no attention when once planted; any odd corner is good enough for it, no frost injures it in the soil, and it is most prolific. The small tubers being set in rows, two feet apart, will give good results; and naturally where well-manured light soil is given (as for early potatoes), the tubers are larger and less rugged in outline. In cooking it, the outer skin should be taken off—if with a silver knife, the tubers do not turn black—and they are cooked till soft; served with white sauce, they possess a nutty sweet flavour, and go well with any roast meat, or preferably, they are worth a course to themselves, while in a white soup they are delicious and very digestible. I find them always appreciated.

GEORGE BUNYARD,

Chairman of the Fruit and Vegetable Committee of the Royal Horticultural Society.

PEARL-FISHERY IN THE RED SEA.

In the latest report issued by the Foreign Office on the trade of Jeddah and Hodeida for the years 1899-1901, Mr. Consul Devey states that there are about 240 sailing vessels registered by the Jeddah harbour department, and only one or two new vessels are built every year. As to those engaged regularly in pearl fishing, there are now only six at Jeddah, 12 at Leeth, nine at Towel, and about 50 of the Jehinah tribe near Yambo. The pearl-shell fishery has ever been one of the chief industries in these waters, and it must be understood that on this coast the most abundant grounds affording the better qualities are to be found from Bab-el-Mandeb to a point north of—the Farsan Islands, and going north the shell occurs less frequently, till some way above Yambo it ceases entirely. Nothing has ever been done to foster, develop, or to replenish this fishery as it becomes exhausted by the total depletion of the shallower or more easily reached beds; fishers must go farther and divers dive deeper. More valuable shells are found at a depth of from 16 to 25 feet than at from 12 to 20 feet. Divers rarely venture in the Red Sea to a greater depth than 30 feet unless for some very special purpose and reward, or it may be for what is known as black coral. Unquestionably the west side of the Red Sea is richer and more productive than the east in shells.—*Egyptian Gazette*, Feb 10.

CEYLON CROWS: TOWN BIRDS!

Some time ago we mentioned the plan inaugurated in Selangor, and commanded by the President of the United Planters' Association, for importing crows from Ceylon and letting them loose among the plantations to there destroy the coffee bugs. Mr. J C Pasqual now writes to the *Malay Mail* protesting against the importation of such crows. He declares that the Ceylon birds, being the inhabitants of towns, are unsuitable for plantation life, and will congregate around the abodes of men until they become a crying nuisance.—*Straits Times*, Feb. 18.

Do Do Do 1901— 8,333,266 lb.

[ESTIMATE for Mar. 1903—8½ to 9 million lb.]

A BIG PINEAPPLE.—Can Ceylon equal what is thus told us by "Modern Mexico":—

The "father of pineapples," and one of the largest ever shipped from Mexico, was received by the Laguna Chica Plantation Company, of St. Louis, last month, from its Mexican plantation. It was 18½ inches in length, 20½ inches in circumference at the larger end, and weighed 18 pounds. It is claimed that the fruit is as delicate and delicious as any of the smaller kinds of pineapples.

The following pages include the Contents of the *Agricultural Magazine* for March :—

Vol. XIV.]

MARCH, 1903.

[No. 9.

INTERESTING PHENOMENA IN PLANT NUTRITION.

WE are told in text-books on Botany that in many cases the root hairs, the ordinary absorptive organs of the plant, are replaced by a fungus whose hyphae absorb nutriment in the same way. Such a fungus

is termed a mycorrhiza which in some cases as in the cone-bearers is ectotropic, *i.e.*, the hyphae do not enter the cells of the root but run between the epidermal cells, while in others as in orchids it is endotropic, *i.e.*, the hyphae enter the cells of the root. There is further the phenomenon, seen in some trees, where the roots are parasitic upon other roots living in the same soil, and are modified in structure to suit this modification of their absorptive functions.

Both these phenomena are very interesting as suggesting the means by which such trees as are dependent to some degree on other organisms for the supply of their food, may have their environments made suitable to their requirements.

Under the conditions in which they grow, it can be imagined that the want of the mycorrhiza in the one case or the absence of the companion tree in the other, would result in growth under great disadvantages. The question is to what extent does Symbiosis exist among plants under cultivation, and to what extent could we control the conditions under which the plants flourish?

In an article on the Sandal-wood tree by Sir Deidrich Brandis, we are told that this tree is so to speak a root-parasite, *i.e.*, it has been ascertained by microscopic examination that its roots

attach themselves to the roots of other plants. Sir Deidrich mentions the trees for which the Sandal-wood has a special affinity, and concludes that in order to thrive it is necessary that the tree requires its roots to be in intimate contact with the roots of other plants of different orders and structure and organisation. Indian Foresters would appear to have long known, as the result of experience, that Sandal-wood thrives particularly well in company with Casuarina and Lantana. Sir Deidrich is reasonably convinced that this tree takes up a large proportion of its mineral food through haustoria, or sucking organs, from the roots of the plants upon which it depends.

The following questions would therefore seem to be very pertinent in regard to any cultivated plant.—Is the tree furnished with root hairs for taking up nutriment directly from the soil? To what extent are the typical root hairs replaced by haustoria or sucking organs? If at all dependent on other trees, what are the best companions for the tree in question?

It is an axiom in agriculture to give each plant plenty of room, but this latest theory would appear to show that it is not at all unlikely that there is something to be gained by association of plants with one another, provided the right plants are grown together. Indeed, the striking luxuriance of virgin forest vegetation appears to suggest some such explanation, and even hint at a system of natural selection of companions by trees that have never been brought under the control of man. Planters will tell us that some forest trees, irrespective of the lightness or density of the shade which they afford, (and possibly also independent of the density or lightness of the wood—as to some extent indicating the demand

for mineral food from the soil) have most beneficial effects on their cultivated crop. Indeed, certain hard-wood non-leguminous trees are fancied in preference to others that might be expected to serve better for shade. In spite of the reputed value of *Albizia Moluccana*, no planter who has any acquaintance with this wonderfully fast-growing tree will advise that it be grown for cocoa-shade, but there are those who stick by such apparently objectionable trees as *Alstonia Scholaris* (Rukattana) relying upon their personal experience of its growth among cocoa. The *Erythrina*s are admitted to be as suitable shade trees for cocoa as could be wished for, but there are old-fashioned growers who still stand by the Jack.

We have heard a deal about the advantages of growing *Grevillea* among tea, and an explanation from a chemical point of view has apparently given satisfaction; but that there may be more than the relation indicated to account for the peculiar beneficial association of different plants, and that a deeper knowledge of biology will probably reveal greater marvels than we have yet known in the vegetable world, is more than likely.

"The science of agriculture," says Sir Deidrich Brandis, in concluding his article, "was many centuries old before the efficacy of the rotation of crops was comprehended. Can it be that we are now to hear of a discovery that will revolutionise the present methods of culture in field and garden?"

It remains to be seen.

OCCASIONAL NOTES.

In the last issue of the *Asiatic Quarterly*, Major Phipson makes a forcible plea for the attention of Government to the problems of rural economy, and enunciates the following principle in support of that plea, namely, "It is not enough for Government to maintain peace and security and suppress crime throughout its jurisdiction, since the very fact of its discharging these functions tends to bring about a more or less rapid increase in population; and such increase, if it is not to become a source of danger and disintegration to the State and misery to the people themselves, demands from it the efficient discharge of its economic functions. He holds that the more efficient a Government becomes in the discharge of any one special function, the more pressing the need for efficiency in others, and that better a falling short in all departments than success in one or two. These views, as the *Indian Agriculturist* puts it, are more academic than practical, but, all the same, Major Phipson's arguments have their application.

Mr. G. E. Amarasekara, Planter, of Hanwela, writes to the *Ceylon Observer* of February 23rd:—"I shall be glad to know what other useful varieties of plantains are found in the island, beside the following. If available I should like to secure them either by purchase or by exchange with the following plants I have in possession, viz.—1 Kolikuttu, 2 Suwandel, 3 Puwalu, 4 Ratahoudrawalu, 5

Embulhondrawalu, (a) Sudu Embulhondrawalu, (b) Pulli Embulhondrawalu, 6 Watu Palu, 7 Anawalu, (a) Athdath Anawalu *alias* Supuanawalu, (b) Vanduru Anawalu, 8 Hamban Puwalu, 9 Ratu Kotchi, 10 Sudu Kotchi, 11 Marthawalu, 12 Sudu Kannannoru, 13 Kalu Kannannoru, 14 Sura Mondan, 15 Kalu Mondan, 16 Alu Mondan, 17 Bin-kehel, 18 Puspa Kedeli, 19 Navari, 20 Kitela. The first nine varieties are generally used as fruits and the rest as vegetable. I learn that the Superintendent of Government School Gardens has a new variety from Queensland called the "Cavendish," but how far it will prove successful in our soil is yet to be seen.—In addition to the "Cavendish," plants of the following varieties have been imported from Queensland for the Government Stock Garden, where they are doing well, but have not fruited yet: Ladies' finger, Sugar, Moka, Borego, Delena, Dacca and Butter.

The first distribution of silkworm eggs to School Gardens has unfortunately not proved successful. A stray egg was hatched here and there, but the worms have not come to anything. The reason for this is that the *ova* did not undergo the necessary refrigeration. Part of the original supply which had been put in cold storage hatched out at Peradeniya and passed through the usual metamorphoses. The supply of eggs secured from these moths will be refrigerated before distribution to schools, so that better results may now be looked forward to. In the meanwhile the mulberry cuttings that have been planted out in School Gardens will have time to develop.

On February 21st the improved box hive kept at the Government Stock Garden was successfully manipulated by the Superintendent of School Gardens, with the help of Mr. H. F. Fernando of the Colombo Museum, a few frames of comb honey were removed, and the hive cleaned out and re-set. The honey, in the opinion of all those who tasted it, was of excellent quality.

We have to thank Prof. Datta, of Sibpur, for a parcel of seeds, consisting of the following varieties:—Soy Bean, Onion, Beta Bengalensis, Buri Cotton (*Gossypium herbaceum*), Jute (*Corchorus capsularis*) and tubers of African yams. We have in return, sent at the request of Mr. Datta, the following seeds—*Ipomoea Muricata*, *Amaranthus Gungeticus* and other varieties Spinach (2 varieties), Luffa (2 varieties), Capsicum (mixed), Ladies' Fingers, Long Runner Bean, Egg Plant, and a few additional varieties in stock.

We have also to thank the Director-General of Agriculture for India for sending us a package of three varieties of American sweet potatoes that have been found suitable for cultivation in India. The potatoes reached us in fair order, considering the long journey by rail and boat from Nagpur, and many of them were found to have sprouted. The three varieties are named "Virginia," "New Jersey," and "Nancimund." We shall have more to say about them in our next issue.

The seeds of *Dendrocalamus strictus* (the male bamboo) widely distributed from the Royal Botanic Gardens were probably not as fresh as they might have been, and many persons failed to grow them. We are glad to say that a fair number of plants have come up in the Government Stock Garden, and that a few can be spared. According to the Botanic Gardens Circular, the bamboos are useful for rafters, battens, spear shafts, fencing, mamoty-handles, &c.

We are obliged to the Hull Oil Manufacturing Co., Ltd., for a sample of Ilomco Castor meal containing 10—12 % ammonia guaranteed. The manure besides contains phosphoric acid equal to about 7 % tribasic phosphate of lime, and potash equal to about 3 % sulphate of potash. It is believed that this meal is the most highly concentrated vegetable source of ammonia at present on the market. The quotation for this excellent fertiliser is 12 shillings 9 pence per unit of ammonia per ton, in double bags, c.i.f. Ceylon, but in order to introduce the meal the manufacturers are inclined to take a little less for a trial parcel. The following is Mr. John Hughes' analysis:—

1. Nitrogenous organic matter	77.64
Water (lost at 212° F.)	10.24
Oil	2.43
2. Mineral matter (ash)	9.69
	<hr/>
	100.00
1. Containing Nitrogen	8.74
Equal to Ammonia	10.61
2. Containing phosphoric acid...	3.20
Equal to phosphate of lime	6.98
Potash	1.59
Equal to sulphate of potash	2.94
Lime	.82
Magnesia	1.24
Soda	.73
Insoluble matters &c.	2.11

We have to acknowledge receipt of the following leaflets and pamphlets from the Department of Agriculture, Cape of Good Hope:—Poultry, Tobacco Culture, Artificial Grasses and Fodder for Stock, Methods of Locust Destruction, Insect Pests, Methods of Preserving Fish by Smoking, the Velvet Bean, Elementary Principles of Silviculture, Treatment of Worms in Domestic Animals, Poultry Raising, Fowl Ticks, South African Poultry Keeping, Trout Breeding and Stocking of Streams, The Ocean and its Resources, Ants, Diseases of Stock and their Treatment, and Fruit Culture.

From India we have received the following numbers of the Agricultural Ledger series: Composition of Indian Cows' and Buffaloes' Milk, *Adhatoda Vasica*, Management of Dairy Cattle in India, *Dendrocalamus Strictus*, *Paspalum Dilatum*, Dairy Farming and Dairy Produce, The Indian Aconites, and a pamphlet on the cultivation of Sweet Potatoes in India by Mr. James Mollison.

The exchanges received during the month are: The Agricultural Gazette of New South Wales;

The Agricultural Journal, Cape of Good Hope; The Journal of the Department of Agriculture, Victoria; The Station, Farm and Dairy; and Australian Products Journal, Sydney; The Queensland Agricultural Gazette; The Veterinary Journal, Edinburgh.

The Sugar Beet and Swiss Chard so highly recommended by the Himalaya Seed Stores are being grown experimentally in the Government Stock Garden.

METEOROLOGICAL OBSERVATIONS TAKEN AT THE COLOMBO STOCK GARDEN DURING THE MONTHS OF JANUARY AND FEBRUARY, 1903.

AGRICULTURAL EDUCATION IN THE EAST.

The appearance of another text-book on Indian Agriculture draws attention to the subject of agricultural education in the East. The author, Prof. N. C. Mukerji, is well qualified to write on the subject, having himself been a distinguished student of Cirencester, where he passed with the highest honours, and spent many years in the study of Indian agricultural problems. After considering all the obstacles that stand in the way of agricultural improvement in the East, and the means of removing such obstacles, the author makes the statement that he looks to education in agriculture for the greatest benefit. But unfortunately, as he puts it, "neither the farm labourer, nor the farmer, nor the landed proprietor cares, as a rule, for agricultural education. Agricultural schools in almost every country are crammed either with place-seekers or town-bred men who fancy they can make their fortune by scientific farming." Mr. Mukerji advocates inducing—by the offer of scholarships or otherwise—sons of *bona fide* culti-

vators, who have passed the middle vernacular and normal school examinations, to come for special agricultural training to a central institution and then go back to their respective villages.

In the case of the late Colombo School of Agriculture the prospect of employment under Government—such as is held out to students of the Technical College—was absent, nor were such scholarships available as Mr. Mukerji suggests and are now given to the students being trained as English teachers for the benefit of private schools.

We are, however, doing the next best thing, now that we have no School of Agriculture, and that is, carrying the agricultural propaganda into the heart of the country and working through the best available medium, namely, the village school boy.

To those who say there is no encouragement for the people to grow fruits and other edible products, on the ground that such cultivation has been tried by planters without success, we would quote Mr. Mukerji to the effect that it will not pay the "gentleman," not only because his standard of living is a bar to such success, but also for another reason—"It is by dint of hard labour and frugality that the Indian (and we may add Ceylon) cultivator makes agriculture pay. If a gentleman were to employ labourers and go in for ordinary farming, he will find these labourers (so industrious when working for themselves) sleeping over *his* work and accomplishing very little when pretending to do work actually in his presence."

This is undoubtedly the true explanation of why Paddy cultivation can not be made to pay the "Gentleman Farmer" at the present market price of grain, and the cultivation of oranges and lemons will only pay the native grower.

SILKWORMS AND SILK.

The following is the text of the Government Entomologist's Nature Study lesson on Silkworms, issued in connection with the attempts that are being made to introduce sericulture as a village industry:—

You probably all know what silk is. You must have seen pieces of silk cloth. But I wonder if you know where the silk comes from, and how it is made? Silk is produced by a particular kind of caterpillar that feeds upon mulberry leaves. I will try to describe to you how the caterpillar lives and makes the silk, and how the silk is afterwards spun to be woven into cloth. Later on I will send you some eggs of the silkworm, so that you can rear them up and watch them at work.

We will suppose that you have some of these eggs. They are small round gray little things, flattened on the top, and about the size of the head of a pin. They look very like the seeds of some plant. You must keep them in a cardboard box and look at them carefully every morning. Some day—sooner or later—you will find a number of tiny dark brown caterpillars wandering about the box; and a corresponding number of

the eggs will be empty, each having a small round hole at one side, through which the little grub has made its escape. They will be hungry; so you must run away at once and bring in some mulberry leaves. Choose the young and tender leaves from the ends of the branches, as the baby caterpillars cannot bite through the older leaves. You should lay the leaves on a paper tray, and with a small feather you can pick up the little caterpillars and place them on their food. They will stay there quite happily as long as the leaves remain fresh, and will gnaw little holes all over them.

You must be careful to keep the tray in some place where the ants cannot get at the silkworms. You might put it on a table the legs of which are standing in pots of water. The worms will wait fresh leaves every morning and every evening, and perhaps in the middle of the day too. If you do not give them enough fresh food, they will become restless and wander away in search of a meal. When you put the fresh leaves in the tray, lay them gently on the top of the old ones. You need not touch the little caterpillars; they will walk on to the new leaves by themselves. Later on, you can take away the old leaves.

You will have noticed that when they first came out of the egg the little caterpillars were of a dark colour and had a rough hairy skin. As they begin to grow, they become paler in colour, and the skin loses most of its wrinkles. But a time comes when the skin, which can stretch only to a certain extent, becomes unpleasantly tight. The silkworm has outgrown its first coat, and must change it for a larger one. How do you think that it manages this? Well, when the skin gets too tight, it suddenly splits along the back, at a point just behind the head, and the caterpillar walks out of its old skin, with a new and larger coat already on its back. Not only has it changed its outside skin, but has at the same time changed the lining of all its internal parts,—its stomach and its breathing tubes. The growing caterpillar provides itself with a new coat, in this manner, four times during its life. For a short time before each change, it becomes sluggish and stops feeding. It should not be disturbed at such times.

When full grown, the caterpillar measures from $2\frac{1}{2}$ to 3 inches in length, and is as thick as a rather stout pencil. It is of a grayish white colour, sometimes with a few blackish markings on the back. You will notice that the part immediately behind the head is considerably thicker and more wrinkled than the rest of the body. This is the part that carries the three pairs of true legs, which are thin, horny and pointed. Further back, you will see five pairs of stouter fleshy legs called the claspers. They use these clasping legs for holding on to the branches of the tree, while the small pointed legs in front are used more like hands. Just above the end of the body is a short fleshy tail or horn. If you look carefully, you will see that the body is divided up into joints. There are thirteen of these, counting the head as the first joint. Look still more closely on the sides of the body, and you will find, on each side,

a row of tiny black rings, one on each joint of the body. You will find it difficult to guess what these are for. They mark a corresponding number of tiny openings into the body, through which the caterpillar breathes. Insects do not breathe through their mouths, but through separate openings, usually on the sides of the body, as in this caterpillar.

As the silkworm grows larger, it will of course require more food, but it will now be able to eat the older and coarser leaves of the mulberry. When they are quite small, a large number of the worms may be kept on a single tray, but as they grow, they will want more room, and must be separated and put on to fresh trays. A convenient way to keep them is to make a framework, with several shelves, on the plan of the above sketch.* Thin bamboos or any straight jungle sticks will do for the posts, and the shelves may be made of split pieces of bamboo laid close together. The paper trays can be placed on these shelves.

The posts of the frame must stand in tins containing water with a little kerosine floating on it. This will prevent the ants from climbing up and eating the caterpillars.

When the silkworms have grown to their full size, which will be in about five weeks' time, they will stop feeding and begin to spin the wonderful silken cases in which they hide themselves for a time before appearing as moths. These cases are called cocoons. You must now hang some bunches of fine twigs above the trays, in such a position that the silkworms can climb up into them and spin their cocoons there. Now, watch one of the caterpillars after it has climbed on to the twigs. You will see it twisting its head about and fastening fine threads of white or pale yellow silk to the twigs all round about it. If you look very closely, you will see the silken thread coming out of a small pointed knob just below the head of the caterpillar. It goes on spinning more and more silk all round itself, until it is quite hidden. And it will go on spinning, inside this covering, long after you have lost sight of it, until it has formed a stout egg-shaped case for itself. The cocoons are quite soft at first, so you must be careful not to touch them for at least a week after they have begun to spin. After that time you may take one of the cocoons and examine it. You will find that the outer part is loose and fluffy. If you pull off the outer part, you will see inside the egg-shaped case that I have told you about. It is very tough. You could not tear it open with your fingers. But it is made of just the same fine silk that you have seen on the outside; only the caterpillar has stuck it together with a kind of gum. Take a pair of finely-pointed scissors and cut open one side of the cocoon. See how soft and smooth the inside of the case is. If only a few days have passed since the cocoon was commenced, you will find the caterpillar still inside it, but very much changed in appearance—quite shrunken and shrivelled. You will hardly recognize it. If you cut open another cocoon later

on, instead of the shrivelled caterpillar, you will find a plump, smooth, dark brown object which is called a chrysalis; and just behind it you will see the empty skin of the caterpillar. The skin has been shed just as on previous occasions, only instead of a caterpillar with a new coat appearing beneath it, this shiny brown chrysalis has taken its place. The chrysalis cannot walk about. It can only wriggle. It has no legs. Nor does it eat anything in this stage. Look at it closely, and notice the marks on it. They faintly show the wings and legs of the coming moth.

Nothing more will happen for about a fortnight. Then, some morning, you may be surprised to see a creamy white moth hanging on to the outside of its cocoon. At the end of the cocoon is a large hole through which the moth has come out. If you can find it immediately after it has come out, you will notice that its wings are quite small. Watch it for about half an hour, and you will see these little pad-like wings steadily growing and spreading out until they have reached their full size. Notice the shape of the moth. It has a small head with two large blackish eyes and a pair of feathered horns or feelers. There are four wings, the front pair with a curved point at the tip, the hind pair rounded. The moth has only six legs, and these legs have been developed from the small horny legs that you saw just behind the head of the caterpillar.

When several moths have appeared, some of them will commence pairing. The pairs should be placed on fresh sheets of paper on the trays. The females will lay their eggs on the paper, and these eggs must be kept to raise new broods of caterpillars. They will not hatch out for several months. When first laid, the eggs are of a pale yellow colour. They gradually darken, until, in two or three days' time, they are slaty gray.

We have now watched the whole life of the silk worm insect from the egg to the moth. But if we want to use the cocoons for making silk, we must not allow the moths to come out. The pierced cocoons are of no use for spinning, though "floss silk" can be made from them. If, then, the cocoons are to be used for spinning, they must be taken, about eight days after they have been formed, and either baked or thoroughly dried in the sun. They may then be packed and sold to the manufactory, where they are converted into spun silk.

Though you will have nothing to do with the further treatment of the cocoons, it may interest you to know what will happen to them.

The first process is known as "reeling." The cocoons are placed in boiling water for a few minutes to soften the gummy matter that binds the fibres together. The loose outer silk is removed, and the ends of the silk fibre are found by brushing the cocoons with a bunch of fine twigs or stiff brush. The fibres of four or five cocoons are then lightly twisted together and attached to what is called the "reeling machine," which gradually winds off the silk from the whole cocoon. As one cocoon is exhausted, the fibre from another one is attached in its place. These four or five fibres from the several cocoons adhere together

* Not reproduced.

and form a single rounded thread which is still, however, much too fine and delicate for use, and several of these threads have to be twisted and spuntogether to form a thicker thread. These are what are used in weaving and from which all the gay-coloured cloths that you know so well are manufactured. The actual weaving is too complicated a process to be described here, but perhaps some of you may have seen native cotton cloths being woven. Silk cloths can be woven in just the same manner.

E. ERNEST GREEN,
Government Entomologist.

September, 1902.

INDIAN PLOUGHS AND WATER LIFTS.

There are many of our readers who will be glad to know what farm implements and machines can be cheaply procured from the neighbouring continent where they have been found useful. The following extract from a review of Prof. Mukerji's work on Indian Agriculture by the *Indian Agriculturist* gives the views of that experienced officer on the subject:—

Among different forms of improved plough preference is given to the Meston, which has recently been invented by the Agricultural Department of the North-Western Provinces, and the price of which is only Rs. 4. It is said, however, to be useless for heavy soils. Of other varieties, we are told: "The Watt's Plough, also N.-W.P. Agricultural Department plough, is stronger and more efficient, but its price is Rs. 7. The Shibpur plough is rather too heavy for ordinary Bengal bullocks, and its price is Rs. 7'8. Both Watt's plough and Sibpur plough can be used for ploughing heavy soils. Jessop & Co.'s 'Hindustani Plough,' 'Seeley's S. S. Plough,' the 'Kai-er Plough,' and the 'Baldeo Plough' of the N.-W. P. Agricultural Department, are other improved ploughs that may be mentioned here. The Baldeo plough, which has also a mould-board like the other improved ploughs, has been actually sold for Rs. 3 each, but it is too light and inefficient, and it is altogether unsuitable for heavy classes of soil. Of the ploughs tried at the Sibpur Farm, the soil of which is very heavy, the Sibpur plough has been found the most effective. It does a little over one-third of an acre a day (8 hours) at the first ploughing, and a little over half an acre a day at the subsequent ploughings. The bullocks should be at least high-class Bengal bullocks. The comparative efficiency of the different forms of water-lift in use is exhaustively discussed, and the following are the conclusions arrived at: "(1) The Don is the best implement for Indian use for small depths (up to 6 ft.), its lifting capacity being 10,000 gallons per hour. (2) Next to it comes the swing basket, which, in the hands of dexterous coolies, will lift about 2,000 gallons of water per hour from a depth of 10 ft. (3) For medium depths, either a double or triple series of Dons, or the

lever and bucket lift *tera*, is the best, 500 gallons of water can be raised per hour with *tera*. (4) For great depths, the single and double *mot* and the Egyptian or Punjab pattern Persian wheel are the best. The *mots* will give about 1,000 gallons per hour, and the Persian wheel about 500 gallons. Considering the cost, the single *mot* is to be preferred to all others for great depths, and to adapt ordinary ring wells of only 3 ft. diameter, and to avoid spilling of water, the bucket can be made to slide up two steel ropes stretched vertically from the bottom of the well up to the beam whence the pulley is suspended."

FERTILIZING BANANAS.

Experimenting on a banana plantation under irrigation, and where bananas have been grown for 12 years, sulphate of ammonia applied alone very quickly gave an impetus to vegetative vigour; the tree grew very large, but produced bunches of very disappointing size relative to the huge plant. On another piece basic slag was applied; this fertiliser is rich in phosphate and lime, the trees were not forced to huge growth as with the sulphate of ammonia, but the bunches produced were very good and well repaid the cost of fertilizing. The bunches were about equal with both fertilizers, but the trees with sulphate of ammonia were the best looking. However, as the basic slag only cost £4 10s. a ton and the sulphate of ammonia cost £15 a ton, the best net return was of course with the slag. An application of lime alone did not show any results where two tons and a half were applied per acre, but where five tons were applied the trees at once responded, the stems were stouter than on the rest of the plantation, and seemed very firm with very strong roots, and the fruit was much improved. Further experiments will probably be carried through with simple fertilizers like bonemeal, which contains an appreciable amount of nitrogen, and is especially rich in phosphates; and with cocoanut meal from the Oil Factory, which contains nitrogen, phosphate and potash, but is richest in the first named. Then complete commercial fertilizers may be tried, that is, compounds of the different elements containing nitrogen, phosphoric acid and potash, calculated on the needs of the plants, and the soil as indicated by the first simple experiments with single fertilizers. To get the maximum of crops the soil must be perfectly adapted to the needs of the plant, and the experiments are being carried through at some expense in the hope that a combination will be hit upon that will cause the fields to yield fruit quicker and of a higher grade when, as in the case with fruit-growers generally in other lands, the result may give a good return on the outlay for fertilizing. The soil being already fairly rich in potash as shown by chemical analysis, no experiments have included potash, but in the great majority of soils every fertilizer for fruit trees should be strong in potash. — *Jamaica Agricultural Society.*

THE VALUE OF MANIOC AS FOOD.

In view no doubt of the attention being given (in America as well as in India) to Manioc or Cassava as a food, a useful paper dealing with the nutritive value of the article as such appears in the January number of the *Queensland Agricultural Journal*, from which the information given below is gathered:—

It is generally understood that there are two distinct varieties of manioc, viz., the sweet (*Manihot aipi*) and the bitter (*M. utilisissima*), but the difference is believed by many to be induced by the character of the soil.

The so-called sweet cassava is largely grown for human and cattle food, and the starch from it is the source of commercial tapioca. This starch, which is its chief constituent is found to the extent of from 60 to 70 per cent, the Nitrogen from 1 to $\frac{1}{2}$, and proteids from $7\frac{1}{2}$ to $3\frac{1}{2}$ per cent, that is in the dry materials; the higher the percentage of starch, the lower that of nitrogen and proteids; so that the richer the soil, the more nitrogenous matter and less starch. In comparison with wheat and even Indian corn, cassava is inferior owing to the low proportion of proteids.

The most serious point, however, in connection with the use of manioc as a food is the presence of Hydrocyanic or Prussic acid, which, though equally present in all forms, is in the sweet cassava located chiefly in the outer skin and rind. This poison, which makes the root dangerous for food in the natural state, can fortunately be completely eliminated by thorough boiling and after washing, and it is advised that this treatment should be carried out in the preparation of any form of human or cattle food made from it.

According to Dr. Wiley, the well-known American chemist, the amount of Hydrocyanic acid in the roots is relative to the amount of nitrogen contained in them, and as this element varies according to the nature of the soil, the poorer the soil, the less nitrogen and less poison.

It has been found by chemical examination that the dangerous element is on an average found to the extent of 2.04 grains per lb. in the fresh, and 5.39 grains per lb. in the dry material, so that a horse would only need to consume 3 lbs. of the dry or 8 lbs. of the green root, and a man 3 oz. of dry and 8 oz. of fresh material for a fatal dose. So that in the natural state manioc must be consistently avoided.

BY HIGHWAYS AND HEDGES.

It is not, I think, generally known that among native plants we have two species of vanilla, viz., *V. Walkeria* and *V. Moonii*. I fancy it is the latter that I have seen between Dandugamuwa and Pannala in the N. W. Province, near Kankaniyamulle, where a resourceful local resident has cured the beans after his own fashion for flavouring his favourite liquor!

A notable specimen of *Pithecolobium saman*, the "rain tree," is the one in the Bilhul Oya

Resthouse compound, no doubt one of the first plants put down when the tree was introduced into the Island. It is an enormous specimen, and is said to have been planted by some G. A. or A. G. A. of the olden time.

In some villages, as in the Kalutara district, one sees exposed for sale on the way-side fairly large-sized catkins of what is locally called wel-mal, Siribo, and Ratabnat-wel, botanically known as *Piper Siriboa* (a variety *P. Betle*). These catkins are used for chewing with betel and its concomitants, in order to impart a pungency to them, just as the root of *Kaempferia galanga* (Sin. Hinguru-piyali), the flower buds of *Alpinia nutans* (Rankiriya), and the seeds of the cardamou, are used.

When cutting up the yam called ratala, a bright red dye may be seen just beneath the outer cuticle, imparting to the yam itself, on its outside surface, a purplish tinge somewhat like that of the well-known "Jaffna yam." This dye is readily extracted by methylated spirits, and on evaporation leaves a sediment. So that it is possible to use the dye for colouring food in place of cochineal, which I have known people object to, owing to its animal origin.

Memecylon umbellatum, called in Sinhalese korakaha, is well known as a source of a yellow dye got from its leaves, but I was not aware till lately that the beautiful bosses of bright blue flowers which make this tree so conspicuous an object amid forest flora, are made to yield a blue colouring matter used in Sinhalese paintings.

A very handsome tree is mas-mora (*Adenanthera bicolor*) next door neighbour to the well-known and common madatiya with its bright red seeds, a favourite plaything with children from its resemblance to red coral, and used also by gold and silversmiths; as weights of about 4 grains each. (Roasted madatiya sometimes hawked about for sale is a thing to be avoided owing to its extreme indigestibility). The young foliage of mas-mora, which is coloured pink, is a pretty element in forest vegetation. The tree is common near Matugama.

In the neighbourhood of Pelmadulla and Rakwana are to be found some of the largest specimens of the *Entada Scandens* (paswel) with its huge polished leathery seeds brought down by streams (along which the climber is generally found) into the sea and cast up on the beach, where it is picked up and used as a toy. This seed (called "Bataug" in Sinhalese) is a good instance of seeds designed by nature to retain their vitality, in spite of long immersion while being transported through the agency of water. I have a specimen of the bean 50 in. long gathered near Welandura.

The leaves of a plant of the Caper family known as Wela (*Gynandropsis pentaphylla*) emit a strong and by no means pleasant odour,

Though put down as a common weed by Trimen, it is not very frequently met with, and is sometimes searched for in the neighbourhood of Colombo for its medicinal properties, being highly esteemed as a remedy for flatulency. It is generally grown by Tamils near their dwellings. A strange method of employing it as a remedy for hydrocele is said to be by tying a poultice made of the leaves round the upper arm! The leaves are also cooked and eaten.

It is not often one hears of flowers being used for food. The most common instance is that of *Sesbania* (*Agati grandiflora*, known in Sinhalese as *Katuru-murunga*, the flowers of which fried in butter with seasoned batter is a tasty vegetable dish. Another flower or rather flower bud, used as food in the villages is *Careya Arborea* (*Kahata*) also known as the "Patana oak" which yields fibre and tanning bark. I have seen the buds being collected for food along the canal road to Chilaw near Walahapitiya.

DISEASES INCIDENTAL TO PREGNANCY AND PARTURITION.

(A. M. CREIGHTON, M.R.C.V.S.)

Concluded.

METRITIS AND METRO-PERITONITIS.

Definition.—Inflammation of uterus, inflammation of uterus and peritoneum. I shall consider these diseases under two heads—(1.) Simple metritis is the simple inflammation of the organ; (2.) Septic metritis inflammatory action due to the presence of a bacillus in the uterus and in the discharges therefrom.

Causes.—Unskilful and rough usage at calving, injuries, colds, draughts, retention of placental membranes, external violence, septic infection.

Symptoms.—Usually ushered in with rigors, pain on pressure over region of womb. Tumefaction of the vulva, with heat and dryness; then follows a discharge of purulent offensive matter from the vulva, increase of temperature, quick small pulse, increased respirations, grinding of the teeth, secretion of milk suspended, bowels constipated; on passing feces animal evinces pain: on examination per vaginam, os uteri will be found hot and sensitive; sometimes discoloration is seen on examination per vaginam.

Treatment.—Explore vagina if possible and ascertain if foetal membranes are away; there may be some shreds left which may be putrefying in the womb. If so, wash out with a reliable disinfectant and antiseptic, give a mild laxative with anodynes, and apply hot water blankets round the abdomen, and see to the general comfort of the animal. If we fear the metritis is of a septic origin, try the administration of internal antiseptics and stimulants with nutritious diet, and thorough irrigation of the uterus and vagina every day at least with suitable antiseptic solution. Some recommend packing the womb, but I have never resorted to this in cattle practice.

POLYPUS IN THE VAGINA.

These are frequent in the cow, attached to the mucous membrane a little distant from the orifice;

the shape is generally that of a pear. I removed one weighing 4½ lbs. from the vagina of a cow lately by ligature and excision, and used a simple antiseptic dressing for a few days; the cow did all right.

PARTURITION.

Now, gentlemen, I just wish to say a few words in regard to parturition in the cow. As a rule the messenger that comes for us in these cases is sweating and out of breath, and will gasp out that Mr. So-and-so wants you to come to a cow that can't calve. After asking a few questions we pack up a few necessary instruments, ropes, and the usual paraphernalia, and proceed with all speed to the scene of action. When we arrive there, and begin to explore the case, we generally find that Mr. Handyman has been there before us, and has spoiled the case and left it, because he could not do it. There are just a few positions that I wish to say a few words about. (1.) Breech presentation. (2.) One fore and one hind limb. (3.) Two fore limbs with head away back. (4.) Twist of neck of womb.

In breech presentation, push back buttocks of calf right as far up and back as you can, then get hold of foot and turn sideways and upwards, and you will get it into passage quite easily. Do likewise with other foot and the calf generally comes away quite easily.

If one fore and one hind you require to be able to judge which way the foetus will come away easiest. Generally to push back the fore limb is safe practice, as by doing so you have no trouble to look for the head. Then get up the other hind limb and the foetus comes away with little trouble.

In the case with the two fore legs with the head back, the position is generally the result of long-continued straining of the cow without delivery. If the head cannot be searched by the hand try a blunt hook, and if unsuccessful then try and remove one fore limb, which is sometimes a very difficult job. You should then be able to reach head and get foetus away. Then as regards twist or torsion of the womb, this generally involves the cow to be thrown and rotated from one side to the other until the twist is undone, and then delivery is usually easily enough accomplished. Some veterinary surgeons recommend jamming foetus in passages and take it away that way. After-treatment is anodynes if necessary and fomentations if needful.

PARTURIENT APOPLEXY.

This disease used to be very fatal in the cow until Herr Schmidt, of Kolding, found out the pot. iod. treatment. There are a good many theories put forward as to the cause, such as clean milking immediately after calving; by ptomaines, the products of decomposition of food in the stomachs and intestines (but I look upon this as the result, not the cause of the disease); by anæmia of the brain; and by auto-intoxication. I favour this view and believe milk fever is due to some toxic material that gains entrance or is manufactured in the animal economy and thus gaining access to the blood-stream. It may be due to some bacillus, but for that I can't say. By some it is supposed to arise from the liver not

being able to cope with the waste products in the blood during the time of rapidly rising lactation, especially as the liver and in fact all the glands in the animal economy have been in a state of comparative quiescence during the dry period—the light food the animal gets when dry is suddenly altered to stimulating food—and this condition may give rise to the auto-intoxication that produces the symptoms that we all so well know, and the eight principal symptoms have been put before you when contrasting them with puerperal eclampsia, so I will go on to the treatment and sequelæ. This much then can be said of milk fever, that it may be considered a genuine auto-intoxication caused by the accumulation or manufacture in the system of toxic material during the first stages of lactation. This circulating through the blood causes the symptoms of poisoning of the whole system of the animal. In relation to this theory I would point out that only good milkers are attacked, and that those which have been dry for some time are more liable, especially those that have been fed on rich food when dry, and cows that are hardly ever outside the byre. These sort of cattle, after an easy calving, go at the milking in a hurry (as we may say), and arrive at the height of lactation very quickly, and in this way the intoxication occurs, owing to the overburdening of the liver and kidneys with work. Just as when the air we breathe is polluted with a certain amount of Co2 we show the effects of Co2 poisoning, so, when the toxic material gets to a certain percentage in the blood of the cow she shows the symptoms of poisoning. Of the percentage that it takes I can't say, but this is the theory I hold in regard to milk fever, and upon this I base my treatment, and whether it is a product of casein, neuclein, albumen, or what, I am not prepared to say. Clearly it is the province of our scientists to elucidate such problems, for the general practitioners have neither time, money, nor appliances to do so.

Treatment.—I have tried a lot of remedies in milk fever; I have tried the following injections into the udder and they have proved fairly efficacious.

℞ Chinosol from 40 to 60 grs., according to size and weight of cow; boiled water 2 quarts.

And after milking the cow, clean and disinfect the udder and teats, when about the blood-heat I inject one-fourth into each teat. I also give the following every three hours alternately if the cow can swallow, and if in a weak state I give 4 oz. spt. ammon. arom. in 1 pint cold water, and if she can't I inject with the stomach pump.

℞ Liq. ammon. acet. conc. (1 in 7) ℥ii.
 Spt. ether nitrosa ℥ii.
 Aqua ℥xii.
 Then ℞ Whisky ℥iij., or spt ammon. arom. ℥iij.
 Aqua ℥xii.

I sometimes use the following injection, which is also very good:

℞ Iodine resub. grs. iv.
 Pot. iodide 4 to 5 drs.
 Boiled water 2 qts.

To be used ns the foregoing. The drenching part of the treatment must be done with great care.

The sequelæ are: mechanical bronchitis from regurgitation of the food, mammitis, metroritonitis, from giving drastic purgatives; pneumonia, bruised knees and hocks, fatty degeneration of the muscles of the thighs from bruises, paralysis, choking at drenching. If a cow has tuberculosis in a latent form and takes milk fever she is sure to die. I sometimes empty rectum and bladder, and this sometimes gives the animal relief; I also sheet up the animal well, as there is a tendency to a sub-normal temperature. I have tried stimulating embrocations along the spine when the cow was long in getting up, and when symptoms of paralysis are shown I prescribe doses of nux vomica. A great deal of success lies in the manner in which the cow is nursed. I give the attendants orders to turn the animal every four hours or so, but sometimes they neglect to do this very necessary part of the treatment, with the result that the cows get knees, hocks, &c. bruised, and then when she wants to rise she can't because of the sores and bruised condition of the muscles. There has been more success in the treatment of this disease in late years than before.

Now, gentleman, I think I have taken up your time sufficiently, and I will come to a conclusion by saying that the lot of a country veterinary surgeon has its bright side as well as its dark side. He generally gets his clothes more soiled and is generally not so stylishly got up as his city brother; we have as a rule more dirty work and smaller pay for it, and we must appear in harmony with our work.

I beg to thank you all for your patient hearing, and I trust that my effort will be rewarded by the members all participating in a good discussion.

GENERAL ITEMS.

The following descriptions of methods by which bones may be more or less readily reduced to powder without the aid of a crushing mill deserve quotation: "A simple plan is to pack the bones, layer by layer, with freshly calcined wood ashes in a barrel and keep the mixture moistened for some months. * * * * A quicker method is to boil the bones in an iron or copper boiler with strong caustic lye. The proportion of bones and lye to be used is roughly 15 parts by weight of bones to 5 parts by weight of caustic soda, or 7 parts by weight of caustic potash, dissolved in 15 parts by weight of water. The boiling should be done for two or three hours. But even without boiling, the bones will become disintegrated by being simply kept in the caustic liquor for about a week. Another method of softening bones is by mixing them in heaps with quicklime and loam. A layer of loam 4" deep is first spread, and on this is put a layer of bones 6" deep, and above this a layer of quicklime 3" deep. The layers of loam, bones, and quicklime are repeated until the heap reaches a convenient height, when it is covered all over with a thick layer of earth. Holes are then bored in the heap from the top and water poured down them to slake the lime. The mass will become hot and remain so for two or three months, after which the bones will become friable, and the whole heap may then be mixed up and spread as manure on land."

It is stated that the Government of India have finally decided to organise the proposed Commercial Bureau from the next official year. The Bureau will be independent of all semi-official intelligence bureaus and other agencies which carry on business in commercial intelligence.

Cape Colony has followed the example of Australia in restricting the immigration of Asiatics. The test imposed—that of ability to write English,—will have the effect of excluding a large porportion of Indian traders. Unlike Natal, Cape Colony is not one of the territories to which coolies proceed, so that the newly-imposed rule is not expected to affect the labour market.

From an external source we learn that a syndicate of planters in the Kelani Valley have concluded negotiations for the purchase of 600 acres of land for the cultivation of para rubber at Bulat Kohupitiya, not far distant from Ruanwela, in the Three Korales of the Kegalle district.

According to the general memorandum on the ground nut crop in Bombay and Madras, 1902-03, we learn that in Bombay the total area, according to the latest reports, has risen from 39,500 acres in October to 46,650 in November, but is still less than half of last year's area and of the average, the decrease being due to deficiency of rain. In Madras, where the crop is grown in only nine districts to any appreciable extent, the total area at the end of December was 421,900 acres. This is a considerable increase on the cultivated area of recent years.

The latest addition to periodical agricultural literature is the "Transvaal Agricultural Journal," published under the direction of the Transvaal Government, and edited by Mr. A. R. E. Burton. The journal is for the present issued quarterly.

Mr. Gerard, the well-known chemist and chief of the Paris Municipal Laboratory, pronounces citric acid a prophylactic against cholera. He experi-

mented on the bacillus of both cholera and typhoid fever, and found that in the acid the microbes cannot live. The same competent authority says that 15 grains of citric acid added to a quart of tainted water will effectually destroy all germs of microbes. With this view of the beneficial effects of lemon juice he recommends the drinking of lemonade during the prevalence of any disease or during epidemic. Citric acid is believed to owe its great virtue to its strong affinity for and solvent powers over urea, with which it unites to form a soluble salt. Uric acid is the bane of civilized man, and to this chemical body in some form or other we are most indebted for our various forms of rheumatism, gout, neuralgia, and kindred diseases.—*Agricultural Journal*, Natal.

Here is a new method of planting tomato seedlings:—Make a case of stiff paper with a small hole at the apex. Pass the root of the plant outward through the hole, the stem remaining within the case. Some earth is put round the stem and the plant thus removed is put in the hole in the soil, so that the rim of the case is an inch or two above the surface. The case protects the plant for cut worms and prevents the drying of the earth around it.

When sweet potato and other leaves are attacked by red spider, use kerosene emulsion or dust with a mixture of lime four parts and flowers of sulphur one part. Either will prove successful if used at the commencement of the attack.

A simple home-made liniment says the *Australian Farm and Home*, that is almost magical in effect is composed of kerosene, camphor gum and sweet oil. Into a quart bottle put one pint kerosene, and add as much camphor gum as will dissolve, add a little more day by day, shaking thoroughly. Now add half pint sweet oil and shake well, and the liniment is ready for use. Cork well and keep away from children. It is excellent for cuts, burns, bruises, slipperies, sore throat, &c.

"NEW MEXICO."

It is difficult to say which is presented in more attractive colours to American capitalists and pioneers, the rich undeveloped resources of the Philippines in the Far East, or the productive wealth of what is now known as "New Mexico." The former has the advantage of being under American law, currency and Government; while the latter has the great attraction of proximity to a grand market close by for all that can be grown, whether coco palms, rubber cacao, sugar or a host of other products. "The silver dollar" is a further attraction to investors in Mexico—labour and all expenses being paid in silver, while the crops can be realised in gold. These remarks have been suggested by the receipt of a copy of a profusely illustrated New York Journal (printed in English and Spanish) entitled "Modern Mexico," from which we learn much of the silver and gold currencies, the buildings (ancient and modern) the railways, irrigation works, the electric trams, the education, the pottery, bull-fights, the legends, sheep and cattle raising; but above all the tropical agriculture in Mexico. The illustrations in the latter show in one group:— oranges, (Mexican oranges sell in New York) banana, coconut, rubber, and plum trees, We do not admire the palms in any of the pictures; but the growth of rubber for 18 months and sugar-cane for 10 months, is phenomenal. "Forest cut ready for burning on San Miguel plantation," points to a

Ceylon man being on the scene—perhaps John Darley of the Knuckles as V. A.? In writing about "Money in Coconuts," George D. Coleman of Orizaba gives the most posterous estimates—figures which show he can have no practical experience beyond a stray group of trees. He writes:—

"A coconut tree will yield from 150 to 250 nuts per year when in full bearing, as every lunar month a new branch of blossoms comes out, and only a hurricane will destroy them. As from three hundred trees to the acre is fair number (I have seen 500 trees in fine condition on an acre), the yield of nuts would be, calculated on the basis of 200 nuts and 300 trees, 60,000 nuts to the acre, which at 1 cent per nut would mean \$600. At Tlacotalpan, in the State of Vera Cruz, where there are three small groves, I have been asked *un real*, or 12 cents at retail for one single nut, and in other places I have never seen the ripe and fully developed sold for less than 6 cents each. The half-ripe nut is sold in quantities for half that sum for making the favourite refresco or drink of the hot country. But the owner of the coconut grove who is content to receive 1 cent per nut for the nut on the tree or ground is losing much money."

[One cent of a dollar or 3 of a rupee is certainly a low price, even for Ceylon.]

Mr. Coleman is supposed to be a traveller who knows something of India and the Philippines and yet what will he say when told that Ceylon, which can boast of the most regularly planted and best cultivated coconut plantations in the world, can nowhere show more than 100 trees per acre, that 70 to 75 is the rule, and that only an ignoramus would dream of planting more than 100 trees. To do justice

to each palm, 75 trees per acre should be the maximum; and where then has Mr. Coleman seen 500 coco palms "in fine condition" on one acre? Then again 200 nuts per tree or 60,000 nuts per acre instead of the 3,000 to a maximum of 6,000—which is the heaviest crop per acre in Ceylon—famous all over the world for its coconuts. Verily, if this is the information which our American cousins have to swallow, some enlightenment is required from a Ceylon authority. We do not contradict Mr. Coleman when he says "the coconut needs two things especially—lime and salt; for—

"Lacking the first it delays its growing and time of fruitage, and lacking the second, it either remains entirely barren or gives few nuts, and those small and of poor flavour and deficient in oil, the main constituent giving it commercial value. It is a prevalent opinion that the coconut will not thrive except in sandy land and on the borders of the sea. This is due to the fact that the currents of the sea float the ripe nuts for long distances, and then the waves wash them upon some beach, where they sprout and take root. As these beach sands are generally full of shells, as well as salty, these two requisites give a fine growth even in pure sand, but where lime and salt exist in the soil, the better and richer the soil the better the coconut. One of the most luxuriant coconut trees I ever saw grew 100 miles in a straight line from the sea or salt water and in a rich chocolate loam, but the soil contained lime in abundance, and the owners had supplied a sufficient amount of salt."

And we are quite prepared to agree that a "coconut grove" (say of 100 acres) in Mexico is as good as a gold mine, even though we do not believe that, when it is at its very best, more than 500,000 nuts can be plucked in the year. But if these sold at 3 cents of a dollar each (or R90 per 1,000 in our Ceylon currency) the net income should not be less than 10,000 dollars or 30,000 rupees, or £2,000 sterling from the 100 acres which would be quite phenomenal in Ceylon, where such a return would be welcomed from 400 acres of well cultivated palms. So, we can quite see that "New Mexico" under the stimulus of American capital (and if possible, Ceylon experience in tropical products) has a great future before it and we shall be glad to hear again from our New York friends who, meantime, are going to study the *Tropical Agriculturist*.

REPORT ON HEVEA BRASILIENSIS IN THE MALAY PENINSULA.

By STANLEY ADEN,

Superintendent, Experimental Plantations, Federated Malay States, 1902.

(Concluded from page 583.)

TABLE XIII.

10 trees tapped every day (6 days).

Total weight of wet rubber 123½ ounces. Averages yield per tree 12.35 ounces.

In nearly every case the yield as slightly better than that when the same tree was tapped at weekly intervals, notwithstanding that an average of 10 ounces of rubber had been extracted from each tree immediately previous to this experiment.

The comparatively large yield on the first day is very noticeable and was probably due to the fact that

the trees had recently been tapped, a point to which attention has recently been drawn. The result of this last experiment supports the argument that there is little, if any, advantage in allowing the trees to "rest" before renewing the incisions.

YIELD.

Most of the points with reference to the yield of latex, the season to tap, the yield at various stages of growth, the time that should elapse before tapping operations are repeated, the age at which tapping can profitably commence, the cost of extraction, and other matters relating to this most important question, need much further investigation, the information obtained up to the present being far from complete.

The season to tap.—The "resting" season of *Hevea* spp. is very short, the trees not being devoid of foliage for more than about 10 or 14 days generally during the early part of February. This, however, is by no means always the case, and it is a common thing to see a tree here and there in the midst of a plantation, absolutely leafless and remaining in this state for two to three weeks although surrounded by others clothed with luxuriant foliage. In the case of young trees, this short "wintering" results in the production of a large number of auxiliary branches, where hitherto a tree of three to four years old consisted of a single whiplike stem 30 to 40 feet high.

Advantage was taken of this short resting season during the early part of the present year with a view to determining whether the different stages of growth had any effect on the flow of latex, the experiments being carried out on the Evelyn estate Selangor. In the first experiment some eight to nine year old trees were selected, whose foliage having turned yellow, was just commencing to fall. After being tapped on eight occasions at intervals of two days, most of the trees began to push forth new leaves, so operations were suspended.

The following table shows the amount of dry rubber obtained per day, from 20 trees tapped on the herring-bone system; the weather at the time being unusually hot and dry.

TABLE XIV.

Twenty trees, tapped on eight occasions:—1st tapping gave 10½ ounces of dry rubber, 2nd, 21¼, 3rd, 24¼, 4th, 23, 5th 22½, 6th 23¾, 7th 25¼, 8th 22½. Total 173½ ounces of dry rubber.

In the next experiment 20 trees growing on the same estate and as near as possible of the same dimensions, were selected, which were just commencing to push forth new leaves and flowers, which in this species are produced simultaneously. The tapping was on the same principle as in the previous experiment, but was carried on over a period of 24 days, by which time the leaves had mostly attained their full size, and the seeds had begun to form.

The result was:—

TABLE XV.

Twenty trees tapped on occasions gave:—1st tapping gave 17 ounces of dry rubber, 2nd 23, 3rd 20¼, 4th 21, 5th 22½, 6th 14¾, 7th 16¾, 8th 24, 9th 19½, 10th 17¾, 11th 20, 12th 20¼. Total 236¼.

The climatical conditions had altered considerably at the time the third experiment was made, which was during the month of April, rain falling almost daily during the whole time the operations were in progress. Twenty trees were again selected and were now in full growth and the fruits about the size of marbles, the result being shown in Table XVI.

TABLE XVI.

Twenty trees tapped on 12 occasions:—1st tapping gave 8½ ounces of dry rubber, 2nd 11¼, 3rd, 14¾, 4th 16½, 5th 15½, 6th 15¾, 7th 16¾, 8th 18, 9th 14¾, 10th 17¼, 11th 16¾, 12th 16¾, total 181¾.

If the yield of those trees tapped when leafless be compared with that obtained on the first eight occasions in the second experiment, when the trees were just commencing to grow, and the third where the trees were in full growth, the result will be found to be distinctly in favour of those trees tapped during the "resting" stage.

The figures are:—

	ozs. of dry rubber
1st experiment eight tappings on 20 trees gave	73½
2nd „ „ „	59½
3rd „ „ „	116

As this is the result of a single experiment it is impossible to conclude what was the real cause of the increased yield obtained whilst the trees were resting. It possibly might have been due to the difference in the atmospheric conditions or more probably, I think, to the inclusion of one or two trees which for some unknown reason had given a much better return than their neighbours. It may be remarked in passing that the results, so far as they go are directly opposed to the theory recently promulgated, as to the effect of tension on the flow of latex; or even if it be accepted that the thickening of the *bast* tissue was nearing completion, and that the tension was therefore approximating the maximum, what is there to account for the decided decrease, only a fortnight later, at a time when the sap was rising in the stem?

The cause of the increased or decreased flow, however, does not effect the producer to any great extent and seeing that most of the experiments previously referred to were conducted during the months of June, July and August, when the trees were bearing a heavy crop of seed, it would appear that tapping operations might be prosecuted with advantage during all stages of the plant's existence. It is to be hoped that further experiments will bear this out, otherwise, if tapping is to be restricted to certain seasons, the question of labour will prove a serious problem.

A dry season nevertheless has advantages over a wet one, in-as-much as the work is greatly facilitated but the flow of latex is affected to a slight extent, owing to the fact that it dries more quickly on the wound. I have found that by simply removing the coagulated rubber from the wound an hour after the incision had been made that a further flow of latex occurred. Though only a very small flow it shews that probably a greater yield would have been obtained previously had not the coagulation of the latex on the wound prevented a further exudation. The variations in yield from day to day, of the same tree, noticeable in all the foregoing Tables, are no doubt due to some extent to the prevailing climatical conditions, it having been noticed on many occasions; that a larger yield was obtained on a dull, still day.

It is of the utmost importance to get the tapping finished as early in the morning as possible, and with this object in view all preparations should be made the previous evening, so that a commencement can be made at daylight. On estates where the cultivation is divided between rubber and other products, I would advise that no tapping should take place later than 9 a. m., but where rubber is the sole cultivation, such a course would probably be found impracticable.

The number of times a tree can be tapped and the length of time which should elapse before tapping can be repeated, depends, I consider, not so much upon the amount of latex extracted at the first tapping as it does upon the injury inflicted upon the tree during the extraction of that latex. It has been seen in the experiments dealing with the area of trunk to be tapped that an equal amount of latex was obtained immediately after the first tapping by continuing the operations on the opposite side of the trunk, and although by this means over 5 pounds of dry rubber has been taken from a single nine year old tree, the supply was by no means exhausted, but the injury inflicted must be considered as severe and cannot therefore be recommended. Moreover it is probable that an equal amount of rubber might have been obtained had the labour expended on this one tree been divided between say four trees, in which case the wounds at the finish would be reduced by three-fourths and consequently would heal up much quicker.

I would lay down as a general rule to follow, that having regard to the welfare of the tree, it is advisable to postpone further tapping until the old wounds

are completely healed up. This remark applies more especially to young growing trees, in which case there would be a considerable risk of arresting the growth of the tree, if it be tapped first on one side and then on the other, before the original wounds are completely healed up.

I have found that nine year old trees on which the incisions had been renewed on nine or ten occasions had completely recovered, i.e., the wound was quite covered over with new tissue, on the occasion of my next visit, exactly twelve months afterwards, and were therefore ready for further tapping. On the other hand, those wounds which had been renewed 14 or 15 times were far from being healed up and in some cases there was still 1½ to 2 inches of wood exposed even after a lapse of 12 months. Although these trees were again tapped and in most cases a yield equal to that of the previous year was obtained, it was I consider a risky proceeding. Far better work through the whole estate, selecting the best trees and tapping them lightly—renewing the incisions eight or nine times, by which time the trees operated upon first will probably have completely recovered and will be ready for further tapping.

Age at which tapping can profitably commence.—Experiments for the purpose of ascertaining the age at which tapping can profitably commence are necessarily very incomplete as there are hardly any trees available between the ages of four and nine years. Recently some three-and-a-half and four year old trees growing on one of the largest rubber estates in Selangor, have been tapped, but the results clearly indicate that this is too young. I append the result of tapping 50, three-and-a-half year old trees. These were planted 14' x 14' (222 to the acre), the average girth of all the originally planted trees being 17.51 inches at 3 feet from the ground, and that of the 50 trees selected 21.24 inches. The tapping was on the herring-bone principle and the incisions, which were confined to the first 2 feet of the trunk, were renewed on 12 alternate days.

TABLE XVII.

Result of tapping 3½ year old trees.

Field Number of Tree	Girth at 3 feet from Base.		Total yield of dry rubber in Ozs.	Field Number of Tree.	Girth at 3 feet from Base.		Total yield of dry rubber in Ozs.

78	1	9	.75	153	1	10	1'
27	1	10	1.5	161	1	8	1.75

The total yield including scrap (17 ounces) was 77 ounces being an average of 1.54 ounces of dry rubber per tree.

Four year old trees.—The four year old trees selected for tapping were all 2 feet or more at 3 feet from the base, the mean girth being 26.65 inches, and that of the whole of the originally planted trees 12.45 inches, the largest tree having a girth of 31 inches at a yard from the ground. The trees were planted 24' x 24' or 75 to the acre and 21 trees were selected from two acres, representing 14 per cent of the total. As in the former case the herring-bone system of tapping was adopted and the incisions renewed on 12 alternate days.

The total yield per diem of 21 trees was as follows:—

TABLE XVIII.

Result of tapping 4 year old trees.

June 1902.

Total Yield per Diem	} Scrap		} Scrap		} Scrap		} Scrap		} Scrap		} Scrap	
	} 9.75		} 47.25		} 47.25		} 47.25		} 47.25		} 47.25	

Average yield per tree 2.25 ounces.

These trees which are growing under most favourable conditions, are a perfect picture of health and probably equal anything that can be found at this age in this part of the world; and I doubt whether, even in its native habitat, the rate of growth exceeds, or indeed equals this. It is apparent, however, that there is very little profit to be made if a tree must be tapped on twelve occasions in order to obtain a yield of 2½ ounces of rubber.

Seven year old trees.—At S'tiawan there are about 20 trees owned by the natives and, as is usually the case with native cultivation, they have been much neglected. They are growing on a dry sandy soil, which is covered with 'Lalang' (*Imperata Sp.*) a vigorous growing grass and although said to be seven years old have an average girth of 26.2 inches only, at 3 feet from the base, which is but slightly in excess of the average girth of the four year old trees, referred to above, and even a trifle less than the four year old trees selected for tapping.

These trees were also tapped with herring-bone incisions but the operation was more severe than in the two previous experiments; the vertical channel extending to a height of 4 feet, while the oblique incisions extended half way round the trunk, there being four on either side the vertical channel at distances of 1 foot. The incisions were renewed on 12 occasions at intervals of two days, the yield from ten trees being shown in the following Table.

TABLE XIX.

Result of tapping 10 trees 7 year old, 12 tappings every 2nd day.

Weight when dry	Ounces.
Scrap	119.75
					25
				Total	142.75

Average weight of dry rubber per tree, 14.275 ounces.

The fact that these trees yielded nearly six times the amount obtained from four year old trees, of a similar girth but growing under more favourable conditions, is partly due to the more severe tapping to which they were subjected, but only partly. I think, for I am inclined to regard this as sufficient proof that age is the most important factor to be reckoned with when considering whether a tree is fit to tap or not, and that it cannot be argued that because a tree say ten years old, gives 3 pounds of rubber, that half this amount might be obtained from a tree half the age. As instancing the fact that an annual yield is procurable, it may be remarked here, that although

tapped very severely, these same trees, when tapped exactly 12 months later, gave an average return of over 9 ounces of dry rubber per tree. On this occasion the incisions were much smaller and were renewed on eight occasions only; still the yield exceeds that obtained on the first eight occasions at the previous tapping.

Eight to nine year old trees.—Only five trees were available of this age, all of which were tapped on a system previously explained, viz, three small herring-bone incisions to each tree. These trees were also native property, but were growing under somewhat better conditions than the trees just referred to having been planted among old coffee trees, whose decayed roots and foliage had provided a small amount of humus, a constituent in which this soil was particularly lacking. The mean girth of these trees was 39.8 inches or 13.6 inches in excess of the seven-year old trees growing close by.

The total yield dry rubber per day from five trees is shown in Table XX.

TABLE XX.

EIGHT YEAR OLD TREES.

Trees 55, 56, 57, 58 and 59. Small herring-bone incisions (three per tree).

Tapped on eight consecutive days:—

1st day 4 ounces dry rubber including scrap. 2nd 7½, 3rd 10½, 4th 11½, 5th 10½, 6th 12½, 7th 13½, 8th 13½
Total Weight 83½. Average weight of dry rubber per tree 16.75 ounces.

Considering that the incisions were only renewed on eight occasions this may be considered a very gratifying return, being more than twice the amount obtained from the seven to eight year old trees when tapped on eight occasions, a strong argument in favour of good cultivation. It will be remembered however, that the system of tapping was different, and as this system has always given the best returns, the comparison may not appear quite a fair one.

Ten to eleven year old trees.—Tables VII and VIII which were given in the chapter relating to the area of the trunk to be tapped, shew the yield obtained from 10 to 11 year old trees growing under similar conditions. When tapped with V incisions and renewed on twelve occasions the average weight per tree of dry rubber was 28½ ounces. When tapped with small herring-bone incisions, exactly twelve months later, and the incisions renewed on eight occasions, the yield per tree was 19.1 ounces of dry rubber. Here again we have a large increase of yield with age, as compared with the 4, 7 and 8 year old trees, a very noticeable point in connection with all these experiments. These trees gave about ten times the yield obtained from the four year old trees, although growing under more adverse conditions, and twice the amount obtained from the seven year old trees with considerably less labour. The yield from other 10 year old trees will be seen on reference to Tables III, IV, V and VI, the aggregate results being 721.25 ounces of wet rubber obtained from 10 trees being an average of 72.12 ounces per tree, or after allowing for a loss of 50 per cent on drying 2½ pounds per tree.

The largest amount obtained from a single 10 year old tree was 16½ ounces of wet rubber, which when thoroughly dry weighed 5 pounds 6½ ounces. This tree, which does not figure in any of the foregoing tables, was 5 feet 3 inches in circumference, and was tapped with herring-bone incisions, renewed on 14 alternate days.

The cost of extraction of the latex depends firstly on the age and dimensions of the tree operated upon, secondly, on the instrument used. Assuming that the trees tapped are eight years old and of good growth, an average of two ounces of dry rubber per day may be relied upon, and with an ordinary pruning knife a coolie can easily tap three trees an hour, or 15 trees a working day of five hours. The remainder of his time would be partly employed by shaving off the rough bark and getting the trees ready for tapping on the following day, collecting the latex and conveying it to

a central shed to be coagulated, cleaning out the tins, etc., so that at the rate of 30 cents per day, the cost of collection can be put down at 15 cents per pound, a figure liable to modification if improved methods of extraction are forthcoming. The cost however, increases perceptibly when trees of a younger age are worked and in the case of five to six year old trees, where the yield will probably not exceed one ounce of dry rubber per day the cost is just doubled and it appears to me to be very doubtful, whether it is worth while tapping a tree unless an average of at least one ounce of dry rubber per day can be relied upon. With an improved tapping instrument, many more trees could be gone over, but even then the cost of extracting the rubber from younger trees will be considerable, to say nothing of the injury inflicted upon the tree, if the tapping be continued until an appreciable amount has been obtained.

PREPARATION OF MARKETABLE RUBBER.

Coagulation of the latex should be effected immediately after it has been collected, for if allowed to stand even until the following morning, decomposition of the proteid matter will often set in, and the value of the rubber will be decreased. This is easily detected by the putrid smell which is given off by the latex, or in the case of prepared rubber, by the dark coloured blotches, both of which can be entirely avoided by coagulating the latex immediately it is brought in from the trees. The rubber will then have only a slight, unobjectionable, characteristic odour, and will be of a light amber colour, deeping slightly with age.

The composition of the latex of Hevea, as given by Seeligmann, * is as follows:—

Caoutchouc ..	32 per cent	} in solution.
Nitrogenous matter (proteid)	2·3	
Salts	9·7	
Resinous matter ..	traces.	
Water, slightly alkaline ..	55·6 per cent.	

The quality of "Para" rubber is due to some extent to the very small proportion of resinous matter contained in the latex. The latex, however, differs perceptibly in the per-centage of caoutchouc it contains sometimes being of a creamy consistency with a yellowish tinge, while that from other trees has a more watery appearance and resembles skimmed milk; but as the latex from the various trees is not coagulated separately, this difference in the quality of the latex does not necessarily result in rubber of different grades. The Brazilian method of coagulating the latex by smoking it, has been described many times and need not be repeated here. Rubber prepared by this method still commands the highest price of all native cured rubbers in the market, but whether the "Para" rubber so prepared will continue to occupy the premier position when pitted against rubber coagulated on more scientific principles is very doubtful. There will probably be a certain amount of conservatism to break down, as is generally the case when a new product makes its appearance on the market, but we may rest assured that so long as rubber continues to be used for the manifold purposes it is at present, that it will always command a remunerative figure; and when prepared free from all foreign matter, and shipped in as dry a condition as possible, the probabilities are that it will eventually oust the "Para" rubber of to-day from its present position, for purity and freedom from moisture are what the manufacturer most desires.

The preparation of the commercial article is quite a simple matter, and the cost but slight. The method I have adopted is as follows:—Before tapping, a little water, about sufficient to cover the bottom of the tin, was placed in each tin, in order to delay coagulation until the tins could be collected, which is generally about an hour after the incision has been made. As soon as the flow of latex has ceased

the tins are collected, and their contents poured into a basin and an equal amount of water added. In this dilute state the latex was strained through a fine muslin cloth and practically all dirt, bits of bark, etc., were thereby removed: the latex is now ready to be treated with some coagulating re-agent such as acetic, nitric or sulphuric acid, corrosive sublimate, alum or other salts. All these substances and many others have the effect of collecting the rubber particles, which are suspended in a watery fluid, into a solid mass, which can then be pressed and dried.

The coagulating power of the various acids differs considerably, but in all cases a very small amount is required. Parkins gives the following approximate figures. (*loc.cit.*):—

100 c. c. of pure latex	are completely coagulated by
	0·1 gram Sulphuric Acid.
100 c. o. " "	0·1 " Hydrochloric Acid.
100 c. c. " "	0·3 " Nitric Acid.
100 c. c. " "	0·95 " Acetic Acid.

He also states that "if excess be added then coagulation ceases to be complete." This I have found to be the case with many of the acids I have employed though not so with acetic acid, even when ten times, the requisite amount has been added in which case coagulation took place instantly, so that it was impossible to pour the latex out into flat dishes. The residue, however, was quite clear showing that all rubber had been extracted. The great thing to remember is that the quantity of acid required depends upon the volume of *pure latex*, and no matter to what extent it is diluted the amount of acid required to bring about complete coagulation remains the same.

In actual practice I have found that acetic acid is by far the handiest to work with, as the range being so considerable, the quantity required to bring about complete coagulation is easily determined without going to the trouble of ascertaining the volume of pure latex to be coagulated.

When the latex had been strained as described above a small quantity—roughly about a tea-spoonful to a pint of latex—of acid (acetic) was added, and the whole stirred for a few seconds. If there were no signs of coagulation a few more drops of acid were added and stirred again, when usually it would gradually assume the consistency of thick cream, when it was immediately poured out into enamelled plates. The stirring and pouring out of the latex should be done as gently as possible, so as to avoid the creation of bubbles, which burst when the rubber is submitted to pressure, giving a roughened appearance to the surface. Enamelled plates are recommended in preference to tins, as the latter are liable to become rusty, and are also acted upon by the various acids.

After a lapse of three or four hours coagulation should be sufficiently complete to allow of the rubber now in the form of a thin solid cake and of a pure white colour, being taken out of the dishes and submitted to pressure, so as to express as much of the moisture as possible. Any kind of pressure may be employed, but something after the style of the old fashioned English wringing-machine will probably be found as effective and inexpensive as anything that can be devised.

The advantage of adulterating the latex and then coagulating by some re-agent may not at first sight seem quite apparent, but unless some such principle be adopted, it will only be found possible to prepare a small per-centage in the form of thin sheets, by far the greater amount coagulating in the tins before they are removed from the trees. Such rubber will be in the form of irregular lumps will be difficult to dry, and will contain a certain amount of impurity no matter how carefully the tapping be conducted. Moreover, unless some means of assisting coagulation be resorted to, difficulties are often experienced in wet or cloudy weather, decomposition setting in resulting in a discolouration of the rubber, an evil odour, and consequently a depreciated value.

* Seeligmann, Le Caoutchouc et la Gutta Percha.

In bright weather rubber prepared by the addition of acid can be dried in about a week or ten days, if placed on a rattan bench where there is a free circulation of air—assuming the cakes are not more than one-eighth of an inch in thickness, but on no account should it be placed in the sun, or the surface will be rendered permanently sticky. The producer, however should render himself independent of atmospheric conditions, by erecting a special house for this purpose. Something in the nature of a tea-withering house would suit admirably; or on those estates where rubber is supplanting coffee, a new use for the coffee-drier may be found. Unless some such arrangement already exists on the estate there is no necessity to go to any great expense in this direction; all that is required is a high temperature easily regulated, and a strong current of air with the object of driving out all the moisture as quickly as possible, thereby enabling the producer to realise on his rubber with the least possible delay.

Moulds are very troublesome and in damp weather will sometimes appear in the course of 48 hours, but their growth would be hindered to a great extent and probably entirely prevented if the rubber was kept in a drier, with a strong current of dry air passing through, until ready for shipping.

As compared with other tropical products, it will be seen that the preparation of commercial india-rubber presents very few difficulties, while the cost is comparatively small. Samples of rubber prepared by various methods are being sent home for valuation, and the result together with other remarks touching on this question will form the subject of a further report.

COST OF OPENING AND MAINTAINING A PLANTATION UNTIL PRODUCTIVE.

The following figures represent the cost of opening 500 acres of land, and planting with rubber 20' x 20' apart being 108 trees per acre.

Premium on 500 acres at \$ 1 per acre.	..	500
Quit-rent, first year, 50 cents	..	250
Survey fees, 25 cents per acre	..	125
Felling jungle, \$ 7 50	..	3,750
Clearing up, after burning off, \$3 per acre	..	1,500
Draining, \$ 10 per acre	..	5,000
Roads, \$ 1	..	500
Lining 1 50	..	750
Holing (holes 1½' x 1½') and filling with surface soil, \$1 per acre	..	500
Planting, with stumps from nurseries, 40 cents per acre	..	200
Weeding, \$ 1 per acre, per mensem (9 months)	..	4,500
seeds, 100,000 at \$ 5 per 1000	..	500
Nurseries, sowing, weeding and watering	..	150
Tools and implements	..	500
General transport	..	100
Coolie lines, to house 200 coolies	..	750
Conductor's bungalow	..	250
Manager's	..	750
Conductor's salary, first year, \$ 50 per mensem	..	600
Manager's " " " \$300	..	3,600
Contingencies	..	500
Total cost first year	..	25,275

This represents an average of \$50.55 per acre, although these figures are subject to a slight modification, varying with the nature of the jungle to be cleared and the land to be worked. The terms on which land may be acquired are dependent to a certain extent upon the situation and locality, and would not exceed the figures quoted above but, subject to certain conditions, may be had on more reasonable terms. The proximity or otherwise to a town, and the facilities for transport would necessarily affect the estimate for transport charges.

The upkeep for the second, third, fourth and fifth years would be as follows:—

Quit-rent, 500 acres, at 50 cents per acre (4 years)	..	1,000
Weeding, second year, 500 acres, at 75 cents per acre per mensem	..	4,500
" third year 500 acres at 65 cents per acre per mensem	..	3,900
" fourth year 500 acres at 50 cents per acre per mensem	..	3,000
Upkeep of drains, 75 cents per acre per annum (4 years)	..	1,500
" of roads 75 cents per acre per annum	..	1,500
Supplying vacancies, second year, 50 cents per acre per annum	..	250
" vacancies third year 25 cents per acre per annum	..	125
Insect pests 12 per acre per annum (4 years)	..	4,000
Repairs to coolie lines, second, third and fifth years 125 per annum	..	75
" to coolie lines fourth year (re-ataping)	..	150
" bungalows (2) second, third and fifth years, \$25 per annum	..	150
bungalows (2) fourth year (re-ataping)	..	150
Tools and implement, \$25 per annum (4 years)	..	100
General transport \$100	..	40
Manager's salary 3,600	..	14,400
Conductor's " \$600	..	2,400
Contingencies, insecticides " stationary etc., \$500 per annum	..	2,000
Upkeep until end of fifth year	..	39,600
Add first year's expenditure	..	25,275
Total expenditure	..	64,875

The total expenditure for five years is therefore \$64,875, being an average of 55.5 per acre for clearing and planting, and \$19.80 per acre per annum for upkeep, including the manager's salary. Taking the rate of exchange at 1s' 10d.—the average for the last two years*—this is equivalent to £5,946 17s 6d. sterling, or an average of £11 17s 10½d. per acre; to which must be added the interest on all money expended. Nothing has been estimated for weeding during the fifth year, as it is anticipated that the trees will give sufficient shade to prevent the growth of any rank growing grasses: the weeds which appear during the fifth and subsequent years will be of a harmless nature and will die out naturally as the shade becomes more dense. If it is considered advisable to weed beyond the fourth year, an additional estimate of 35 cents per acre per mensem should suffice to keep the estate perfectly clean.

Return.—On a good estate it will probably be found that a number of trees will be worth tapping during the sixth year, though lack of data prevents me from arriving at a definite conclusion on this subject; but I confidently anticipate a yield during the seventh year at least equal to that obtained from the seven year old trees previously referred to.

Assuming that 50 per cent of the five year old trees give an average yield of 8 ounces of rubber per tree which cannot be considered an unreasonable assumption, seeing that almost twice the amount was obtained from seven year old trees growing under very unfavourable conditions—albeit the tapping was somewhat severe—the yield per acre in the sixth year would amount to 25 pounds of rubber. Taking the selling price in London at 2s 6d. per pound (which is 1s 1d. per pound less than has recently been obtained for well cured samples from Ceylon) this would be worth £3 2s. 6d. sterling; but as there is always a certain per-centage of "scrap" rubber, it will be safer to estimate on an average selling basis of 2s., so that the yield per acre during the sixth year may be

* The rate of exchange for the present day is 1s 8½d

valued at £2 10s. From this must be deducted the cost of collection and preparation for market, which should not exceed 20 cents per pound—equivalent to 9s. 2d. per acre, also packing charges, freight and wharfage.

The average cost per acre per annum for upkeep being \$19.80 or £1 16s. 3½d. sterling, it appears probable that after deducting all expenses in connection with the preparation and marketing of the rubber, that the return during the sixth year will leave a small margin of profit, after allowing for upkeep, including the Manager's salary and interest on the outlay.

This, I am aware does not compare favourably with some estimates which have been published, but it must be remembered that this estimate is based on the assumption that there are only 108 trees per acre; had there been three times the number, the growth during the first four years would probably have been quite as good, and the yield trebled, but I anticipate a far better return from those trees when they attain the age of nine or ten years than from trees planted more closely. This however is a debatable point, and until there is some further opportunity of experimenting in this direction it is useless to attempt to arrive at any definite conclusion.

By the time the trees are six years old, 75 per cent should give an average yield of 12 ounces, which is equal to 56.25 pounds per acre. Valued at 2s. per pound, this gives a gross return of £5 12s 6d. per acre, so that after deducting the cost of harvesting and marketing there is every prospect of a fair return on the capital expended during the seventh year.

By this time the cost of upkeep will have reached a very low figure, while the yield will increase year by year, and should average at least 150 pounds of rubber per acre by the time the trees are nine years old, and probably 100 pounds the following year.

STANLEY ARDEN,

Superintendent, Experimental Plantations,
Federalated Malay States.

THE ALOE FIBRE INDUSTRY,

Mr. C. J. Greengrass writes to us from Puttur, North Arcot:—As the plantain fibre industry seems to be attracting considerable attention just now, perhaps a few remarks on the agave or aloe fibre will not be out of place and be of interest to those who are going seriously into the matter. The varieties of this plant grown to any extent in India, besides those grown for purely ornamental purposes, are the three varieties *A. vivipara*, *A. rigida*, and the species known as the Blue Aloe, to be seen along the Madras Railway. The last named, though producing a fair percentage of fibre, cannot compare in this respect with the other two, *A. vivipara* and *A. rigida*. The latter has the shorter leaf of the two, averaging about 2ft., and as its name implies, is stiffer and harder to manipulate than the leaf of the former. The percentages of fibre in both are about the same, of equal strength, but they differ considerably in length, one being only about half that of the other, an important feature in valuation.

From my experience, I found that the *A. vivipara* is eminently the most suitable for fibre producing. I do not see any of this species about this part of India, but towards the West of India generally it is very common, and is used as fencing by the Southern Mahratta Railway towards Poona and Belgaum. The plant resembles to a very great extent the West Indian variety, *A. sisalana*, out of which the West Indies are now making fortunes, the only difference being that the latter is somewhat shorter in leaf, and has of only the one terminal spike, and none along the edge of the leaf, as with the former. It is a very hardy plant and takes kindly to all varieties of soil and will thrive on land considered too poor for agriculture. When grown on rich soil the plant becomes somewhat longer in leaf, but the percentage of fibre is less the leaf becoming "fat." A drier soil with an admixture of *MOORUM* or sand is best suited for it

cultivation, for though the leaves produced are not quite so long, as otherwise, it produces more fibre and of a better quality. The plant requires a little looking after for the first year, but after this is well able to take care of itself, producing an annual crop of leaves after about the third year, for about 12 years, when, after it has produced its central stem and shed its bulbules, it decays and dies. The bulbules spring up around the parent stem.

From information gained of the methods of cultivation, in America and the West Indies, of the *A. sisalana* it would appear that the yield per acre is about one ton of fibre, allowing 10 ft. space between the plants. From my experience of the Indian variety I should say the same remarks apply to it. A sample consignment of fibre sent to Liverpool brought £11 per ton: the cost of manufacture freight etc., was about Rs 100 per ton. The leaves were procured from plant grown as fencing along the S.M. Railway at Poona, and the method of extracting the fibre was the usual primitive one of rotting the leaves in water and beating out with wooden mallets. This injures the fibre considerably, and I have no doubt, worked with proper decorticating machines, the price realised would be much higher, running up, I should say, to about £20 per ton.

The advantages the agave has over that of the plantain tree are many. It grows on any waste land thousands of acres of which may be seen all over the Madras Presidency, and which may be had at a nominal rental. The plant gives an annual crop of leaves for about 12 years, where the plantain tree has to be cut down *in toto* for the extraction of the fibre and, moreover, requires less looking after.

This industry has now been carried on in the West Indies and America for many years past, and large fortunes are being made out of it in exporting the fibre to England and other parts of Europe. Cannot some of this money be converted into rupees instead of dollars? I commend the question to those whose constant wail is the chronic poverty of India, and also to the Indian planters who now regularly meet at these Conferences and sadly contemplate, with hands in empty pockets, the darkening aspect of the planting horizon.—*Madras Mail*.

LIFE IN THE ANNAMALAIS.

COMPARISON WITH CEYLON.

The planting region of the Annamalais with the forest belts, Mr. Windle thinks, is about

50,000 ACRES IN EXTENT.

and of it some 15,000 to 16,000 acres are in private hands the whole of this, however, is not yet opened up. It is possible that further allotments of land would have been purchased readily enough, but Government stopped the further sale of land. The elevation is from 3,300 feet to 4,000 feet. The country is well watered and the rainfall averages about 130 in a year, most of it falling during the south-west and north east monsoons, while good "blossom" showers fall in the intervening periods. The monsoon rains, as in Ceylon are heavy, but without that characteristic feature of Ceylon rains, viz., wind. The Annamalais may truly be described as

A WINDLESS COUNTRY,

but, notwithstanding this, the weather is fine and cool with an even temperature. The soil as stated before, is exceedingly rich, and analysis have been taken by Mr. Kelway Bamber of Colombo; Dr. Van Garszel, Government Analyst, Madras; Mr. Hooper, Government chemist, Calcutta; Dr. Layman, Government chemist Mysore, and others, the result of which showed that the place was

EXCELLENT FOR CULTIVATION

of products. In this connection it is interesting to note that Mr. Windle was the first to make up but in the Annamalais. He applied for 2,300 acres by was allowed 1,000 acres, the maximum granted in Government to purchasers, and began opening in

1897 late in the season. He managed to plant about 60 acres in coffee by March 1898, but a jungle fire broke out during an exceptional dry season and destroyed all his labours. However, he planted up during the monsoon weather that year and the result showed the exceptionally good country for coffee. In the season 1900-01 he took his first crop of $1\frac{1}{2}$ tons from the young trees, 40 tons in season 1901-02, and 40 tons in the succeeding season, while the prospects for the coming crop were extremely good. Cardamoms were also doing remarkably well. In fact the place was the habitat of cardamoms, for Mr. Windle had found them growing wild in the jungle. He had opened out 130 acres in cardamoms from 1 to 3 years old and they were getting on famously. Messrs. Martin and Bannatyne, former Ceylon planters, had their cardamom plantations coming on well. Besides coffee and cardamoms, cinchona was another product that appeared to take to the Annamalais. Mr. Windle planted out *Ledgeriana* variety some 2½ years ago and the trees were quite sound and healthy. They grew extremely well, and it was hard to say which grew better coffee or cinchona. As regards rubber, which was quite a new product, and vanilla, which was given up, Mr. Windle has spoken of them before. Pepper he tried but without success. Roses grew particularly well, as also all flowers, which showed a luxuriant growth, and vegetables. Poultry thrived wonderfully which might be attributed to the absence of disease or pests; jackals, wild cats, hawks, etc., being unknown. The Annamalai hills for climate, soil etc., for growing products was wonderful and there is no doubt, if Government is only willing to sell further allotments.

LAND WOULD BE BOUGHT UP READILY.

The roads, Mr. Windle remarked, were in good condition, but not so well kept as the excellent Ceylon up-country roads. They sent their produce by cart to Podanur, a distance of 60 miles—distance by the way was no consequence to the Indiau planter—and thence by railway to Calicut. There was some talk of a railway from Dindignl to Palghat through Pollachi, which was only 15 miles from the foot of the hills. This if sanctioned will prove a great boon. As regards sport, there were elephant and bison in the Annamalai forests, and mahseer in the fine rivers. The only expensive item the Annamalai planter had was felling. It cost Mr. Windle R30 an acre; and sometimes it would cost more according to the nature of the forest. There was excellent timber in abundance, both white and red cedar, jak, toon, ironwood, and a little ebony.

LABOUR WAS PLENTIFUL

and easily obtained, and none of the difficulties that beset the Ceylon planter in this direction were experienced.—Local "Times."

ARTIFICIAL NITRATES FROM THE AIR.

The question of manures for keeping up the productive power of the soil must ever be of the first importance to planters and agriculturists. In the composition of all manures an element of the first importance is fixed nitrogen as contained in the various nitrates. But the supply of natural nitrates is limited by a variety of circumstances, and the expense of applying it in the form in which we now procure it is a very considerable item. Nature herself adopts another method of giving the indispensable nitrogen to the soil. The atmosphere consisting of four-fifths free nitrogen is a natural laboratory wherein by the effect of electric discharges nitric and nitrous acid are formed. These being dissolved and washed down by the rain form a perpetual fertilising agent quite sufficient for growth under natural conditions. Artificial culti-

vation however, is a much greater tax upon the soil and Nature's arrangement, admirable for her own purposes, does not suffice under conditions of continual cropping. The drain of material is too great to be compensated in this manner.

The balance of nature is in fact destroyed, and man who is responsible for the destruction must in his own interests set to work to reconstruct more suitable conditions and by applying an increased quantity of the vivifying agent restore the balance. Thus, in the long run, the supplying of nitrogenous fertilisers by the agriculturist becomes necessary. Hitherto he has been dependent on a comparatively limited number of mines, a fact which renders nitrates expensive; but some few years ago Lord Rayleigh showed that the artificial union of nitrogen and oxygen by means of the electric spark was so easy a thing to effect as to make the method worth trying on a commercial scale. This suggestion has now been acted on by two American inventors—Bradley and Lovejoy—and a company has been formed to work their process. Apart from commercial importance, the new process is of interest from the closeness with which it follows out Nature's method of production.

The apparatus employed consists of a fixed cylindrical metal box, inside which, but insulated from it a second cylinder rotates 500 times per minute. On the surface of each cylinder are six upright rows of metal pieces or "contacts" 23 in each row. These contacts are insulated from each other and each is connected through an inductance coil to one or other pole of a 10,000 volt dynamo, those on the outer cylinder to the positive pole, and those on the inner to the negative. As the rotation goes on the negative contacts come up to the positive, and each pair then "strikes" an electric arc; as they move away the arcs are drawn out and extinguished, only to be reformed when the next set of negatives comes up. About 40,000 acres are thus made and destroyed per minute. A steady flow of air amounting to something like 700 cubic feet per hour is maintained through the space between the cylinders. The arcs promote the chemical union of the oxygen, and nitrogen and the air leaves the apparatus having about one-fortieth of its mass converted into oxides of nitrogen. It is then conducted to absorbing towers. These are already well known in connection with other chemical industries, so we need only remind our readers that they consist of lofty "stacks" loosely packed with bricks or blocks of coke down which a stream of water is allowed to trickle. The mixed gases entering at the base of the tower meet the falling water, which dissolves out the oxides of nitrogen, forming dilute nitrous and nitric acids, which can be continuously drawn off below, and used for the preparation of the required chemicals.

Sufficient data have not yet been published to allow the efficiency of the plant to be calculated. Possibly the manufacturers desire to keep such information to themselves; but there is every reason to expect that the method will bring about a reduction of the cost of nitrates. Such a result would be of incalculable importance, not merely will the agriculturist be helped by cheap fertilisers—though this is probably the most important benefit to be expected—but many other industries will be assisted. To mention one only, the manufacture of sulphuric acid is only practicable on the large scale by the aid of the oxides of nitrogen. These are now derived from nitrate of soda, but it would be a great advantage to obtain them direct from the atmosphere. Even if it were impossible to utilise the new plant, cheaper nitrates would mean cheaper acid, which would be an assistance to nearly every chemical industry. Moreover, if the nitrates can be obtained by the new process in sufficient purity for gunpowder making, the public security will be enhanced by rendering our artillery independent of the Indian saltpetre mines.—*Indian Planting and Gardening.*

PRUNING FRUIT TREES.

By W. J. ALLEN.

Pruning is a means to an end. It is not intended in this article to enter into a discussion of the general theories of pruning, which are multitudinous: nor is it possible to give any advice for pruning until one has analysed the subject, and knows the object for which he is to work, and the underlying principle on which his practices must rest. The principles are universal, and the same might also be said of the practices which are primarily the shaping or training of the tree, and secondarily (after this object has been attained), to fruitfulness. Under natural conditions trees are being constantly pruned. Every fall nature strips the trees of their leaves. This is their regular annual pruning. In addition to this, there is a continual pruning of buds and branches. If every bud on a tree were allowed to develop, the latter would become a regular bush pile. Those buds which are most favourably situated as regards light get most nourishment, while those less favourably situated become starved and drop off. The lower limbs of trees and those within the crown become weakened, and die from lack of sunlight, then the wind, nature's pruning knife, comes along and removes the dead branch. In this manner trees are constantly ridding themselves of useless branches, and the pruning so effected is undoubtedly a benefit to the branches which remain and to the general growth and improvement of the tree.

Orchard trees, by virtue of selection, by hybridisation, and cultivation are in a highly specialised condition, and to be maintained so must receive special treatment. In a sense, the fruit tree is a machine for manufacturing fruit, and intelligent pruning is one of the means by which it can be made to manufacture the most fruit of the best quality in the shortest time, and to keep up the output for the longest possible period. A correct understanding, therefore, of this machine and all its working parts is necessary to its most successful manipulation.

Wickson, in his work on California Fruits, writes:—"One of the first things for the beginner to undertake as he approaches the practice of pruning trees and vines, is to form some conception of the purposes to be served. Imitation is not the foundation of intelligent pruning, though it yields many valuable suggestions. Satisfactory work rests upon a correct understanding of the reasons for each act, and to the attainment of this all study, observation, and experience should tend. Possessing this, one can proceed capably modifying method to meet condition, and producing desirable results. Receive all suggestions, and then go quietly to the tree and study your problem in its shade. The tree is the best revelator of its need. Some of our best pruners are men who were untrained to horticulture before they entered upon their orchard work. Reading discussion, systematic instruction, are all valuable. They save much time and many errors; but recourse to the tree affords the sovereign test of attainment. These may be counted among the practical purposes to be attained by pruning (a) Convenience of the grower; (b) health and strength of the tree; (c) regulation of heat and light; (d) attainment of strong bearing wood; (e) attainment of size in fruit; and (f) promotion of regular bearing."

"On examining the tree, it will be found to be composed aboveground of a trunk from which the main branches spring, which, in their turn, produce laterals, on which the shoots and spurs which bear the fruit are to be found. Taking these points into consideration, one can hardly fail to secure rays of light upon the subject of pruning which seems dark to so many.

"*Convenience.*—Trees which branch near the ground are mostly quickly and cheaply handled in all the operations of pruning, spraying fruit, thinning, and picking. Low trees with obliquely-rising branches are more easily cultivated than any form with hori-

zontal branches, unless the head is carried so high that the teams pass easily under the tree. To do this sacrifices all the other conveniences and economies which actually determine profit, and is really out of the question from a commercial point of view.

"*Health and Strength.*—It is imperative in most parts of this State that the sunshine be not allowed to touch the bark during the heat of the day. This protection is secured even for young trees by low branching. The low tree with properly spaced branches attains superior strength by virtue of thick, strongly knit, short growth between branches, and by its strong, stiff, obliquely-rising growth sustains weight which brings horizontal branches to the ground, and thus even high-headed trees are liable to continually increasing interference with cultivation, and the desperate grower has to raise the head of his tree higher into the air and farther above the profit line while at the same time he renders it more liable to sunburn, to bark binding, and to unthrifty by forcing the sap to flow an unnecessary distance and through wood and bark will impede its movement. Besides, a low tree escapes stress by strong winds, which a high tree invites, and at the same time is less able to withstand. Pruning for health and strength of the tree also includes the removal of unthrifty or diseased parts, which are not only an encumbrance to the tree, but many communicate to other parts the cause of their ill condition.

"*Heat and Light.*—The maintenance of strong bearing wood in the lower part of the tree is conditioned upon the proper pruning of the top of the tree. How far the upper levels or the shade layer of the tree can be safely opened depends upon the local climate in each fruit region. The rule must be the higher the summer heat, the denser the tree—the lower the heat the thinner the tree: but everywhere the proper condition of openness must be constantly in view in pruning. Not alone must this be done to maintain thrifty growth below, but it is also essential to the best growth and ripening of the fruit in the lower and interior parts of the tree. Fruit inferior in size, colour, and quality, results in part from lack of pruning to regulate the admission of light and heat, sometimes one, sometimes both, to the shaded portion of the tree.

"*Bearing Wood.*—Good fruit develops on good bearing wood, and good bearing wood is the product of proper degrees of light and heat as has just been urged; but bearing wood in the case of some fruits is new wood, and reduction of old wood for the purpose of forcing the growth of new wood must be constantly in mind. Renewal is more or less a consideration with all trees and especially the securing of strong new wood. This is a point upon which close study of the bearing tree will yield most satisfactory suggestions.

"*Size of Fruit.*—The size of fruit, providing the tree is healthy and vigorous, depends upon the character and amount of bearing wood which the tree is allowed to carry. Removal of part of the fruit burden is done by thinning after it is well set, this labour should always be minimised by antecedent pruning, which adjusts the retention of bearing wood according to the vigour, size and bearing habit of the tree. Thinning out of bearing shoots and spurs, when either are clearly seen to be in excess, should be the constant study of the pruner."—*The Indian Agriculturist.*

TURMERIC—GINGER.

Turmeric and ginger may be both profitably grown in Bengal, and like most other root crops are meant for, and are within easy reach of, small capitalists. Turmeric, *Curcuma Longa* requires soil of a rich and friable nature, to which has been added a good percentage of potash. High lands, not likely to be overflowed, should be selected for this crop, and should be well ploughed and cleared of weeds, etc. Manure should be freely applied and well worked into the soil. Sweepings of all kinds, pondrette, and ashes especially those from cowdung cakes are specially

valuable adjuncts towards fertilizing lands, in which turmeric is to be grown. This crop is often planted on lands, where sugarcane grew the preceding year, and it is considered an ameliorating crop. One of the special features to be noted in nearly every homestead in a Bengal village is the sight of a few clumps of ginger and turmeric plants growing, where ashes and other sweepings are thrown out. The small amount of tubers produced is generally sufficient for the frugal ryots yearly consumption. Turmeric is often grown under the shade, in orchards mango topes and such, but the crops produced cannot be compared to those grown on lands specially suited and prepared for it. The time for planting out turmeric varies a good deal but the best time for doing so is from the middle of April to the end of the following month. Before beginning planting it is advisable to wait until one or two north-westers have passed over, giving a certain amount of moisture to the parched soil. The tubers should be put down on ridges a foot or so high and 18 or 20 broad, with intervening trenches nine or ten inches broad. The cutting or sets, *viz.*, small portions of the fresh roots are planted on top of the ridges and about 18 inches apart. Three hundred such sets will be required for a *bigah* or nine hundred for an acre of land. The after-cultivation consists mainly in keeping off weeds and loosening of the soil between the ridges. Irrigation is not generally resorted to for by the time the monsoon rains are over, the tubers are already formed and only require ripening. Turmeric crops usually take ten months to come to maturity so should be taken up towards the latter part of January, and the plants be allowed to wither and dry up before doing so. When taking up the roots the *kodali* or spade should never be used, but only the digging fork.

The output of turmeric, like most other root crops varies a good deal but 16 to 18 maunds of fresh roots to a *bigah* or 3,800 to 4,000 pounds to an acre of land should be considered a very fair average. The roots are generally sold fresh to the middlemen, but they may be prepared and dried. To do this the roots must first be sorted out into two sizes, *viz.*, the smaller and larger ones, as these latter require more hoiling. After they have been sorted out, the roots are thrown into large earthen pots filled with water to which has been added an admixture of cowdung and tamarind leaves. The roots are then boiled for two or three hours according to their size and then taken out and spread out to dry. The boiling and drying makes the tubers shrink to half their original size and the loss in weight varies from 30 to 40 per cent. As the outlay required for raising turmeric crops is small, the returns obtained are generally very satisfactory. The price of turmeric, like most other such staples, varies a good deal according to the state of the crops and the time of the year; but from R 4 to R 6 *per maund* may be taken as a fair average for the dry roots, and R 2 to R 4 for the fresh ones. The following table will, I think, show that turmeric and ginger are among some of the miscellaneous crops that the would-be domiciled Anglo-Indian or Eurasian, may safely and profitably take up.

Expenditure and returns from one *bigah* turmeric

EXPENDITURE.		R.	A.	P.
Rent for 1 year with cesses	2	3	0
8 ploughs for ploughing and preparing land at 5 annas each	2	8	0

	R.	A.	P.
16 maunds fresh turmeric at R3 per maund	48	0	0
	48	0	0

Considering the small outlay, the returns obtained should be considered very satisfactory, and a great advantage that both turmeric and ginger have over other crops, is that they have practically *no enemies* to contend with, for nothing will touch their pungent and aromatic roots.

Like turmeric, ginger *Zingiber officinal*, may be grown very profitably in Bengal. Soil of an alluvial or loamy nature and heavily manured is the best suited to these roots. Old and well decayed cowdung or stable litter with an admixture of ashes and leaf mould, if available should be well worked into the soil, oil cake is also one of the best manures, I know of for ginger; but should be on *no account applied too freshly*. Ginger, besides potash, require phosphoric acid, so all manures containing the most of such properties, should always be made use of. The land after it has been *extra carefully* ploughed and manured should be laid out in ridges to facilitate irrigation, in the same manner as preparation is made for planting sugarcane. The best time for putting out ginger is from the middle of February to April. Pieces of the fresh end of the rhizome, about an inch or so long, should be planted one foot apart. When just planted the tubers should be protected from the sun until they have sprouted, the best way to do this is to cover them with pieces of plantain leaves, cut into suitable lengths and the ground should be freely irrigated for the first ten days or so, or until the plants have come up. Subsequent culture consists mainly in irrigating, weeding and keeping the soil open an applying manure once in four months. Like all *Scitamineaceae*, ginger require a very rich soil with plenty of moisture, and should be planted near enough so as to protect each other but not so thickly as to prevent access of light. Like turmeric, ginger takes a year to come to maturity; and though the tubers left underground will rot, they will sprout up again before doing so. With a little care a ginger plantation may be kept going for three years, the bulk of the roots being taken up, and a few left for the succeeding crops, the second year's outturn is said to be as a rule the heaviest. After the tubers have been taken up the plants should be manured, earthed up and freely irrigated. The average yield per *bigah* is about 10 maunds, and the market value may be taken R 6 as a fair average. Ginger is generally sold in its natural fresh state but it is also sometimes boiled and dried, in which state it is known as *soont*, and as such is greatly valued for its pharmaceutical properties.

Ginger and turmeric are some of the products the smaller capitalist should take up with every chance of making a success of it. The following table of expenditure and returns speaks for itself:—

EXPENDITURE.

	R.	A.	P.
Rent for one year per <i>bigah</i> with cesses	2	3	0
10 ploughs at 5 annas each	3	2
Manuring, including value of manure	8	0
20 coolies for preparing land at 5 for the rupee	4	0
10 coolies for planting at 5 for the rupee	..	2	0
After-culture, weeding <i>cher</i>	8	0
Taking up and sorting tubers, 15 coolies @ 5 for the rupee	3	0
Irrigating	6	0
		36	5

Ten mannds green ginger at R. 6 per maund	60	0	0
.. .. .	60	0	0
	<hr/>		
	60	0	0
	<hr/>		

The preliminary cost on raising one *biagh* of ginger crop is far in excess to that for turmeric, but as ginger is a crop that may be made to last for three years, the average cost will be found to be lower, and the return higher at the end.—*Indian Planters' Gazette.*

RECENT EXPERIMENTS WITH SWEET POTATOES.

Sweet potatoes (the enlarged roots of *Ipomea Batatas*) are among the most important agricultural products of the West Indies. As Mr. F. Watt's *West Indian Bulletin*, Vol. I. p. 271 states: 'So far as the sugar-producing islands are concerned the sweet potato occupies the foremost place in the list of home-grown foods and is, probably, next to the sugar-cane, the most important crop grown. . . . At present the crop is grown upon the sugar estates as a snatch crop and fulfils a useful purpose; owing to the short time it takes to come to maturity it can be planted after the (ratoon) canes have been cut when the potato crop will be ready for reaping from about December to February. After the crop has been reaped the land may be quickly prepared for a crop of sugar-cane. As the potatoes usually meet with a ready sale the crop is of value to the sugar planter and acceptable to the labourer. Sweet potatoes are largely grown by the peasantry themselves, the ease with which they are propagated, the poor soil in which they will thrive, the small amount of attention which they require, and the short time in which they come to maturity, all commend them to the peasant.' In the case of such a short time crop as the sweet potato it is difficult to obtain reliable information as to the actual acreage under cultivation. For Barbados the question was very fully discussed by Mr. J. R. Bovell in the *West Indian Bulletin*, Vol. I. pp. 204-12. He estimated that there were about 2,600 acres under sweet potatoes in the island as catch and rotation crops on sugar estates, of the annual value of about \$100,600 or approximately £21,000. In the islands other than those dependent on sugar, sweet potatoes also form a staple food, being to a great extent imported from those colonies in which the conditions are favourably adapted to their profitable cultivation. The sweet potato is also extensively grown in other parts of the world, for instance, the Azores, S. Africa, and the United States. According to the census return of 1890, the United States produce about 44,000,000 bushels per year. Recently considerable attention has been given to this crop by the Imperial Department of Agriculture and, as a result, a good deal of experimental work has been carried on and more is in hand.

EXPERIMENTS WITH DIFFERENT VARIETIES.

During the last season two sets of experiments were started to test the comparative value of the various varieties of sweet potatoes. These varieties are commonly recognised by local names, often indicative of some distinctive character of the potato, or of its place of origin. They differ from one another amongst other points in the shape, size, colour, flavour, and quality as a table vegetable of the root, in the shape of the leaf, in time of maturing, and in keeping power. In connection with the Botanic Station, Antigua, fifteen different varieties—some local, others introduced—were grown in separate plots under the same conditions. The crop from each plot was weighed separately. The full results have already been published by the Department in the *Report on certain Economic Experiments in connection with the Botanic*

Station Antigua, 1900-1901. The yields of each variety were calculated in tons per acre, and varied from 6 of a ton to 4.4 tons. Amongst the varieties which occupied the foremost places were 'Eliza' and two Trinidad kinds known as 'T. 1' and 'T. 2,' respectively. The latter, although beaten by the variety 'Eliza' in actual yield, were superior in shape. The experiments will be continued. Last year the ground was comparatively new, and the variation in the yield of duplicate plots necessitates caution in estimating the relative value of the several varieties. At Barbados a some what similar series of plots were laid out, under the charge of Mr. J. R. Bovell, on Waterford Estate. Twenty-eight varieties, mostly local, were obtained and 100 holes (5½ x 5½ ft.) planted of each. It was hoped that in the present crop season they would have been dug and weighed. A careful comparison was then to have been made as to quality as a table vegetable, shape, keeping power, etc. Unfortunately, during the past season insect pests have been more than usually prevalent on sweet potatoes in Barbados. The experiment plots were ravaged by red spider and other pests and the plants seriously injured. Even under such adverse conditions some useful information was obtained, concerning the comparative powers of resistance of the different varieties.

The field was examined by Mr. Maxwell-Lefroy in the middle of November. The sharp manner in which the plots of the different varieties were marked out owing to their varying powers of resistance to insect attack was most striking. Amongst those which had suffered the most at this time were 'Red Sealy,' 'Hurley,' and 'Caroline Lee.' About a month later many of those which were fairly free from attack in November had been damaged, but to the end 'White Gilkes' (both the three and six months varieties) and all the plots of mixed kinds, maintained their vigour in a surprising matter. From the result of this single experiment, 'Gilkes' and plots of mixed varieties seem to possess more than average powers of resistance to insect attack.

STORING SWEET POTATOES.

The usually low keeping power of the sweet potato is a great drawback to its usefulness. The question is discussed somewhat fully by Mr. Watts in the paper already referred to. The practical result is that shortly after the time of reaping the supply of sweet potatoes exceeds the demand. The greater number of the varieties will not keep long after being dug and they are sold at low prices to clear the ground for the succeeding cane crop. Hence for a brief period food is abundant and cheap. At other times the reverse is often the case.

'These home grown supplies are, as a rule, employed directly as food, little attempt is made to convert them into forms which will keep and thus equalise the supplies which are otherwise irregular; it seems probable that something will have to be done in this direction before much progress will be made in the substitution of locally grown for imported foods.' (F. Watts, *loc. cit.* p. 274.) The concluding words indicate the course which is pursued in equalising the distribution of food throughout the year in those communities which can afford it, namely the importation of foodstuffs, principally from America. Mr. Bovell (*loc. cit.* p. 211) gives the value of such articles imported into Barbados (for the year 1898) as £175,011. Towards this large total, starches, grains and meals of various kinds contributed no less than about £95,000. Most of these could be raised in the Colony. In the other sugar islands the situation is very similar. American food stuffs are largely imported to supply, during certain seasons of the year, the want of local food supplies, although at other times of the year such food materials are produced in the island in excess of the demand. Unsound as this policy undoubtedly is it will probably continue to be pursued until conditions arise which compel attention to be given to the more extensive cultivation of local food stuffs and to methods for preserving them so as to allow the supply to be

regular and uniform throughout the year. The question of the storage of sweet potatoes in a fresh state is one which has attracted a considerable amount of attention in different parts of the world. In the West Indies it has been found that some varieties keep fairly well if left in the ground and dug in small quantities as required. This method has disadvantages and a better one is very desirable. The problem of storing sweet potatoes is discussed in Farmers' Bulletin No. 26 of the U. S. Department of Agriculture entitled *Sweet Potatoes: Culture and Uses*, by Professor J. F. Duggar of Alabama. He says (p. 18) 'There is need for further investigation to determine the best method of storing sweet potatoes, for the losses occurring during storage are sometimes enormous. The conditions in the States are however very different to those obtaining in the West Indies and although it might be of interest to put on record the methods there employed, the contrast in climatic conditions must not be lost sight of.'

The best results are apparently obtained by storing the potatoes in dry cellars or rooms, in which the roots are placed either with or without packing of sand, straw, hay, or other dry material. Mr. Duggar in summing up says 'Sweet potatoes during storage should be kept in a dry atmosphere with ample ventilation, and a temperature between 50° and 60° F, except during the sweating period, for which time the temperature recommended by those who use artificial heat is 80° F.' Later (p. 29) he says 'The atmosphere of the storage room should be kept dry. The condensation of moisture on the roots affords conditions favourable to decay.' The essential points for success by this method of storage, namely perfectly dry conditions and a comparatively low temperature, are almost impossible to obtain economically in the West Indies where the air usually contains a very large amount of watery vapour, and the temperature is higher than in northern latitudes.

DESSICATED SWEET POTATOES.

Setting aside the possibility of keeping the whole potatoes in a fresh condition, it remains to be seen whether any other economical method is feasible. Mr. Duggar describes two modes of preserving sweet potatoes for use as a table vegetable. He says (*op. cit.* p. 25) 'Uncooked sweet potatoes may be sliced and then dried either in the sun or in evaporators. They are prepared for the table by soaking and baking. Dried sweet potatoes were exhibited among the products of Japan at the Colombian Exposition. Their preparation is described as follows:—"Cleanly washed potatoes are placed in a suitable basket and immersed in boiling water for a short time; when taken out of the basket they are cut into thin slices and spread over mats and exposed to the sun for two or three days. In order to make a superior quality, the skin of the potato is peeled off before slicing." As an indication of more recent developments it may be mentioned that a company has been lately started in New Jersey, America, with a capital of \$1,000,000, to make flour from sweet potatoes. The early results are reported as being very successful, and it is proposed to erect mills all through the sweet potato growing region. The more important States in this region are North and South Carolina, Georgia, Texas, Alabama, Mississippi, Virginia and New Jersey.

PREPARATION OF MEAL,

The remarks above, based on the irregularity of the supply of food throughout the year, apply with especial force to Anguilla, one of the Leeward Islands, situated about mid-way between St. Kitts and the Virgin Islands. Sweet potatoes are grown in Anguilla and are usually very abundant during one short season of the year. The peasants exhaust their stock during the two or three months following crop time, and for the remainder of the year are practically reduced to living on pigeon-peas (*Cajanus indicus*) and any other chance food plant which is capable of withstanding a six

months' drought. The possibility of preserving the potato in a palatable form is of the greatest importance to the peasantry of the island. The experiments recorded below are, to a large extent, the outcome of a request for information and advice made by Dr. J. Numa Rat, Magistrate of Anguilla, to the Department. Great credit is due to Dr. Rat for the trouble taken by him in the interests of the island.

EXPERIMENTS IN ANGUILLA.

In November 1899, Dr. J. Numa Rat requested advice from the Department as to a good method of preserving sweet potatoes. He was recommended to try slicing and drying, as described above, this process having been found to give satisfactory results in various parts of the tropics. *Early Experiments.* In May 1900, Dr. Rat forwarded a box containing sweet potato meal which had been prepared in the following manner:—The potatoes were peeled and grated, the pulp squeezed in a cloth and then dried in the sunshine for two or three days. The dried pulp was sifted and the coarse parts powdered in a mortar. By this method twenty pounds of unpeeled potatoes gave one pound of meal, that is, a return of only five per cent. The potato used for the early experiments was a variety known in Anguilla as 'Hug'em fast.' The cost of preparation was about 1s. per pound. One obvious objection to this method is the great loss of material caused by squeezing the wet pulp. This point was noted by Dr. Rat, and is emphasized in the following remarks by Professor A. H. Church, F.R.S., author of *The Food Grains of India*, etc., to whom a sample of the meal was submitted. Professor Church says: 'The method of preparation involves much loss or that one constituent which one can spare least—namely, the proteid or albuminous substance. . . . The expressed juice of succulent roots and tubers usually contains much soluble vegetable albumen.' A subsequent analysis of the meal by Professor Church confirmed his anticipations. The meal was found to be deficient in flesh-forming nutrients. 'The ratio of nitrogenous matter to digestible carbohydrates being 1:24.' Previous analyses of whole sweet potato roots had yielded the more satisfactory ratio of 1:13.

The detailed figures of Professor Church's analysis of the Anguilla meal are as follows:—

	per cent.
Water ..	12.6
Albuminoids and proteids* ..	3.6
Digestible carbohydrates ...	77.6
Oil or Fat ...	0.6
Fibre ...	3.5
Ash or mineral matter ...	2.1

Professor J. P. d'Albuquerque, Island Professor of Chemistry at Barbados also analysed a sample of the meal with very similar results.

Later Experiments.—In order to avoid if possible the loss occurring in the previous method, Dr. Rat prepared some more meal by grating the sweet potatoes and sun-drying the pulp without subjecting it to pressure. This method was found to be a practicable one. The yield of meal was from fifteen to twenty per cent. of the original weight of the roots instead of only five per cent. as in the earlier method. A variety called the 'Dominique' was used instead of the 'Hug'em fast.' The labour entailed being the same as before, but the yield four times as much, the cost of production was accordingly reduced to one quarter, namely, 4d. per pound of prepared meal. The meal so prepared was analysed by Professor Church. Its composition was found to be very similar to the former sample, but strangely enough it did not contain quite so much proteid matter. 'The results' Prof. Church says 'tend to show that the variety "Dominique" is inferior to "Hug'em fast" in this respect.'

* Calculated by multiplying the nitrogen by 6.25. By the phenol method 3.5 per cent was found.

† Of this ash 0.12 was phosphorus pentoxide,

EXPERIMENTS AT ANTIGUA.

At the time when the question of converting sweet potatoes into meal came into prominence owing to the necessities of Anguilla, Mr. Francis Watts, the Government Chemist for the Leeward Islands, obtained information from Mr. Spooner of Bendals estate in Antigua, concerning some experiments which he had previously carried out in this direction. Mr. Spooner's attention was drawn to the subject in 1898, when sweet potatoes were exceptionally abundant. The main points in Mr. Spooner's method were as follows:—

The cleaned potatoes were cut into slices, about 1/16 of an inch in thickness. The cutting was at first done by hand but later an old chaff cutter, temporarily adapted to the purpose, was employed with very good results. The slices were spread out on galvanised wire netting and quickly dried in the sun, until quite brittle. This state was reached in six or eight hours, when conditions were favourable. They were then stored in old flour barrels until sufficient had accumulated to be worth grinding, for which an engine on the estate was utilized.

The yield of meal by this method was 40.63 per cent. of the original weight of the potatoes; one ton of roots yielding 910 lb. of meal. Mr. Spooner estimated the cost at £4.9.7. per ton of meal, that is to say approximately 3d. per pound. Several tons of meal were made and used with great success for feeding mules and stock. The labourers ate it readily, and Mr. Spooner says that he personally found it a palatable and satisfactory form of food. It kept well, provided the slices had been thoroughly dried before being ground, but losses were incurred when for any reason, the slices were left at all leathery instead of being perfectly brittle. The meal made from such leathery slices quickly became tainted and spoiled. It is important to note how by the use of simple machinery the cost was reduced to such a low figure as 3d. per pound. The preparation was analysed by Dr. Voelcker who reported: 'The meal is well dried containing only 12 per cent. of water and should keep perfectly well. It contains practically 10 per cent. of sugar, with 67 per cent. of starch and digestible carbohydrates, 5 per cent. of nitrogenous or protein matters with a not inconsiderable portion of mineral (bone-producing) matter. The percentage of indigestible (woody) fibre is very small.

Dr. Voelcker's complete analysis is as follows:—

		per cent.
Moisture	..	11.99
Nitrogenous matter*	...	5.12
Oil	..	1.19
Sugar	...	9.90
Starch and digestible carbohydrates		67.01
Indigestible (woody) fibre	..	1.89
Mineral matter (ashy) †	..	2.90

* Containing nitrogen 0.82.

† Including sand, 0.03.

The comparatively high percentage of nitrogenous matter in this sample is noteworthy. This is the element which is lacking in the dietary of many of the West Indian natives, and of which so large a proportion was lost by the Anguilla mode of manufacture. From the above facts it will be seen that it is possible to produce from the sweet potato a meal which is palatable, digestible and cheap. It is essential that the potato should be quickly and thoroughly dried and then reduced to meal. By this treatment the greatest amount of nutritive material is retained. For such a locality as Anguilla it is important to determine whether a meal can be made at crop time and stored for use during the period of drought. To this end it is essential to know: (1) The food value of sweet potato meal, and (2) its keeping qualities.

FOOD VALUE.

In a perfect diet the ratio of the albuminoids or nitrogenous matter to the digestible carbohydrates and sugar together should be about 1:4. This relation is spoken of as the 'nutrient ratio.' The above analyses of sweet potato meal show that its nutrient ratio is low. The first sample of Anguilla meal gave a ratio of 1:2.1, and in the later samples it was even less. In the Antigua meal the ratio was much higher, about 1:15. In an analysis of fresh sweet potatoes, recorded by Prof. Church in his book on *Food* the ratio is given as 1:13. Specimens of a Barbados variety analysed by Professor d'Albuquerque gave as low a ratio as 1:50. This deficiency of the meal in proteid matter can easily be counterbalanced by supplementing it with such a food substance as pigeon-peas, which are rich in nitrogenous constituents, in common with the seeds of many other leguminous plants. In pigeon-peas the nutrient ratio is about 1:3. As has already been stated these peas are grown in Anguilla, in sufficient amount in fact to be an article of export. They are one of the staple foods during the dry season. Taken alone however they are not beneficial, containing too large a percentage of proteids in proportion to their carbohydrate and sugary contents. In conjunction with sweet potato meal they would make a good diet, capable of sustaining the inhabitants during the season of scarcity.

KEEPING QUALITIES.

Some of the meal prepared by Dr. Rat was sent to the Head Office of the Department at Barbados, in tins, and after about twelve months' ordinary storage was perfectly sweet and good. Mr. Spooner's testimony as to its keeping powers has already been given. There appears therefore to be no doubt that the meal, carefully prepared, will keep good for several months—a sufficient time to serve the immediate purpose of the people of Anguilla.

EXPERIMENTS IN PROGRESS.

In June of the present year (1901) the Department obtained for use in Anguilla a grinding mill and a vegetable slicer. During the coming crop season these will be tried, and it is hoped that an impetus will be given to the establishment of a regular industry in sweet potato meal, the importance of which to people situated as are the inhabitants of Anguilla, it is difficult to over-estimate.

OTHER USES OF SWEET POTATOES

Another method of preservation, namely, canning sweet potatoes has been tried on an industrial scale in America. Mr. Duggar says *op. cit.*, p. 25 'With in recent years sweet potatoes have been canned in a few localities. In 1893 a factory in Mississippi canned about 1,000 bushels using three-pound cans which sold in Chicago at 95 cents per dozen delivered. A bushel of sweet potatoes was sufficient for fifteen cans. Farmers were paid 40 cents a bushel. This firm expected to can about 8,000 bushels of sweet potatoes in 1894.' Such a method whilst of interest is hardly likely to be of practical importance under present West Indian conditions. Besides furnishing an important portion of man's diet, in many warm countries, sweet potatoes are very useful as fodder for cattle and stock. Both roots and vines (foliage) may be employed to this end. Mr. Duggar, in the pamphlet already referred to, compares the relative food-values of corn and sweet potatoes. His results are expressed as follows:—

Relative Food Value of Corn and Sweet Potatoes.

	Dry Matter.	Protein.	Nitrogen free extract & fat.
	lb.	lb.	lb.
100 lb. Corn contain	89.1	10.5	75
300 lb. Sweet potatoes contain	86.7	4.5	75.3

'Thus three pounds of sweet potatoes afford almost as much dry matter, quite as much carbonaceous material, but less than half as much protein, as is contained in one pound of corn. By using one-half pound of cotton-seed meal or one pound of cow-peas (seed) for every ten pounds of sweet potatoes this deficiency is fully supplied.' In the West Indies at present sweet potatoes are not usually regarded as a regular food for horses and cattle but rather as a special diet in cases of illness, etc. Mr. Spooner's testimony to the value of the meal as a food for stock has already been given. In the want of more exact data it would appear not improbable that it might be possible to utilise locally grown potatoes, peas, etc., as fodder for horses and stock in place of much imported corn. In England there is a certain demand for sweet potato meal for the manufacture of glucose. One firm has intimated its readiness to take as much as 1,000 tons per month, provided the price does not exceed about £6 per ton, delivered in London. This price it will be noted is very little more than 3 $\frac{3}{4}$ d. per pound including freight, etc. Even if the meal could be produced as cheaply as by Mr. Spooner in Antigua at 3d. per pound, it seems probable that it would be more useful and remunerative to the people in West Indies to prepare it for their own use rather than for export at such rates.

It is interesting also to note that, owing to the failure of the orange industry in St. Michael, the famous St. Michael orange is no longer to be found in the English market. Many of the former orange growers have turned their attention to the cultivation of sweet potatoes. A large portion of the crop is utilised in making spirit, which is shipped to Portugal and employed in fortifying wines, etc.

SHIPMENT TO EUROPE.

Another possible method of disposing of the surplus supply of sweet potatoes has been suggested. This is shipment to Europe. In May last the initial steps were taken to secure the introduction and establishment in favour of the vegetable in the home markets. To this end a circular letter was sent to several important firms, whom it was thought might be able to co-operate. The Department offered to supply them for a certain period, with fortnightly barrels of sweet potatoes entirely free of cost. The firms were requested on their side to give the potatoes away in small lots, or to sell them at nominal prices with the understanding that after say eight or ten weeks they should undertake to receive and sell a few barrels per month and sustain a regular trade in the article. The matter was actively taken up by two firms, and since October regular shipments of sweet potatoes have been made.

One great difficulty to be encountered in attempting to introduce a new vegetable is lack of knowledge as how best to cook it. To obviate this the Department prepared, with the kind assistance of Mrs. J. R. Bovell, a pamphlet entitled *Recipes for cooking Sweet Potatoes from the West Indies* which was issued as No. 6 of the Department's Pamphlet Series in July 1901. It contains fifteen different ways of preparing the vegetable for table use. Copies have been widely distributed with the potatoes. The Department has been fortunate in securing the hearty co-operation of several of the planters of Barbados in this matter, as also of the Royal Mail Steam Packet Company, who have agreed to carry the barrels of potatoes free of cost during the early stage of the experiment.

It remains to be seen how much demand there is for them in England. Supposing the trade to grow, many points as to the best modes of packing, the best varieties for transporting, etc., will require to be solved. The Army and Navy Auxiliary Co-operative Supply, Limited of London have regularly contributed valuable information concerning the condition in which the potatoes have reached England.

Preference has been already expressed in England in favour of small, red potatoes. One important point to remember is the comparative ease, with which the sweet potato can be bruised. It therefore demands careful handling.

The experiment has been commented upon in several of the English papers, and the following notice appeared in the West Indian Committee's Circular for Nov. 12, 1901:—

'With a view to popularising this vegetable in the United Kingdom Dr. Morris, the Imperial Commissioner of Agriculture for the West Indies, has arranged to send over by each mail for the present a few barrels of sweet potatoes. Samples of these potatoes with full culinary recipes may be obtained from Messrs. James Phillips & Co., 4, Fenchurch Street Buildings, E.C. Members of the Committee will greatly assist in the encouragement of what may become an important minor industry by bringing the sweet potatoes before the notice of their friends who have not had the advantage of sampling them in a 'tropical country.'—*Journal of the Imperial Department of Agriculture for the West Indies.*

MEXICO'S VEGETABLE PRODUCTS.

MOST OF THE KNOWN PLANTS AND TREES OF THE WORLD FOUND IN THE REPUBLIC.

Owing to the great range of latitude included within the borders of Mexico, as well as the extensive variations in altitude, the vegetation of all zones, from the frigid to the torrid, is to be found. More than 10,000 plants have been analysed and classified, and many yet remain awaiting the work of the scientist. In Mexico trees grow at an altitude of 13,054 feet and herbs at 13,715 feet.

Mexico is the land of striking contrasts, which is especially demonstrated in its vegetation—voluptuous growth varies with bare deserts, often within a short distance. There are luxuriant virgin forests, where the ground is overshadowed with creeping plants and brushwood and the branches are perfectly covered with parasites; near the coasts these forests are often as swampy and impenetrable as the jungles of India. There are immense prairies, thickly covered with grasses and fragrant blossoms; there are white alkali deserts, rocky and sandy plains, where nothing but the curious cacti and agaves grow. The traveller who enters Mexico from the North during the winter, over the Central plateau, is at first disappointed, and thinks it the country of sand-whirls and cacti, but even a few hours' ride to the east or west would change this idea. In a couple of hours you can be transferred from pine forests to palm groves. Most luxurious is nature in the hot and temperate zone of Mexico, especially in sheltered valleys, in the ravines and on the banks of the rivers. In the cool zone the gigantic Mexican cypresses, covered with Spanish moss or orchids demonstrate the productive power of the soil, competing with the giant chestnut trees of Sicily and the red-wood or mammoth trees of California. Stately trees are the shuacates, mangoes, amates, ashes, eucalyptus, palms, etc., curious trees are the "weeping tree," the "phosphoric tree," the "caustic tree," the "claw tree" and the "sensitive plants." The principal agricultural products are according to quantity: Indian corn, wheat, barley and Mexican beans, further straw, sugar, sisal, hemp and ixtle; cotton; garden beans, rice, vetch, chick-peas and potatoes. Indian corn and Mexican beans are the principal food, red pepper the principal condiment of the people.

The productivity of certain plants is wonderful; Indian corn, for instance, yields in certain cases up to 800 times, wheat as much as 110 times. Corn and wheat of Mexico are of the finest quality. In some parts of the country two and three crops can be harvested in one year. The most productive plant is probably the banana, one acre of these plants being able to sustain

about forty persons; the most productive, however, is the century plant, which furnishes the drink (pulque) fiber, food, fuel, etc. This enormous productive power of certain plants is the reason why the Indians cultivate but a small space of land.

In the following table Emil Riedel gives an index of some of the most useful and interesting plants arranged alphabetically, according to their Mexican names, with English equivalent, scientific name, classification and some curious items:

Aoelga, beet, *Betta vulgaris cyclo*, Salsolaceas.
Ahnacate, *Persea gratissima*, Laurineas: In four varieties in warm and temperate zones; nutritious fruit; principal harvest, April-June; wood for timber.
Ahnehnete or Sabino, Mexican cypress, *Taxodium distichum*, Coniferas: Grows to gigantic size, as in Chapultepec, Popotla, Texcoco, Atlixco and Oaxaca (Santa Maria del Tule). The latter, admired and described by Humboldt, has a circumference of 170 feet and a height of 124 feet. These trees are very often covered with Spanish moss or with orchids.
Ajonjoli, benesed, *Sesamum orientale*, Sesameas
Oil plant, introduced from Africa.
Alacle or hulnar, *Malva scoparia*, Malvaceas: Textile and medicinal plant.
Algeria, oily grain (*Sesameas*): Seeds used by the Indians for candy and oil.
Alfalfa, *Medicago sativa*, Leguminosas.
Algodon, cotton, *Gossypium herbaceum* and *arborescens*, Malvaceas: A native plant, cultivated in herbs and trees in many varieties, especially in the northern states of Coahuila, Durango, Chihuahua, but also in Vera Cruz, Colima, Yucatan, etc.; generally sowed from March to June, harvested from September to December.
Alpiste, canary seed, *Phalaris canariensis*, Gramineas.
Amate, shady tree of the hot zone, whose green fruit is eaten by the Indians.
Anil (the Aztec "Xihquilitzahuac"), indigo, *Indigofera tinctoria*, etc., Leguminosas: A native dye plant of hot zone for blue color, especially in Chiapas, Oaxaca, Colima; sowed from December to May; article of export declining in importance.
Anis, anise, *Pimpinella anisum*, Umbelliferas; introduced from Egypt, article of export.
Anacahuite, *Cordia Boissieri*, Borragineas; Native medicinal plant.
Anona, onstard apple, *Anona reticulata* and *glabra*, Anonaceas.
Arbol de fierro, iron wood, *Robinia*: Cabinet wood.
Arbol de hule, caoutchouc tree, *Castilloa elastica*: Native tree of hot zone.
Arbol de las manitas or Macpalcxochitl, claw tree, *Cheirastemon platanoides*, Bombaceas; Venerated tree of the Aztecs, grows in Valley of Toluca and Oaxaca; is medicinal.
Arbol del Peru, pepper tree, *Schinus molle*, Terbinaceas: Introduced from Peru; furnishes gum, medicine, etc.
Arrayan, myrtle, *Myrtus arrayan*, Mirtaceas: Furnishes fruit and medicine.
Arroz, rice, *Oryza sativa*, Gramineas: Introduced by conquerors, cultivated in warm zone, best in Morelos; sown in March and April; harvested in September and October.
Arvejon or Alverjon, vetch, *Pisum sativum*, Leguminosas.
Biznaga, *Mammillaria manimama* and *parvimama*, etc.: Cactus used for preserves.
Cacahuate or Mani, peanut, *Arachis hypogae*, Leguminosas: Native plant, planted in March and April, harvested in October and November; beans eaten roasted.
Cacaloxochitl, "raven flower," *Plumiera alba* and *rubra*, Apocinaceas: Beautiful Mexican flower of the hot zone; used for medicine and preserves.
Cacao (from the Aztec "cacahuatl") cocoa, *Theobroma cacao*, Butneriaceas: Native tree in hot zone of seven varieties, in Tabasco, Chiapas and Colima;

bears fruit after five year for twenty to thirty-five years; harvested from November to January; important article of export. The Aztecs used the beans as money.

Cacomite or Oceloxochitl, *Tigridia pavonia*, Irideas: Nutritious root, food for the Indians, toasted tastes somewhat like the chestnut.

Cafe, coffee, *Coffea arabica*, Rubiaceas: Introduced from Africa at the end of the eighteenth century; grows in elevated places of hot zone, in Vera Cruz (famous Codoba,) Michoacan (famous Uruapam) Colima, Chiapas, Guerrero, Oaxaca, etc., generally cultivated under the shade. Tree begins to bear fruit after the second year for fifteen to over twenty years. The "Mocha" is select fruit of the same trees. Two harvests yearly, first and best in June and July, second in December and January.

Calabaza, pumpkins or gourds, *Cucurbita melopeo*, Cucurbitaceas: In many varieties, flowers and fruit very popular food; the calabaza trompeta, guaje or acocote, *Lageneria vulgaris*, is used as instrument for the extraction of pulque.

Camote, sweet potato, *Batatas edulis*, Convolvulaceas: A native plant growing in many varieties in temperate zone, with white, yellow or red roots; planted from March to May, harvested from August to October; finest and largest are the yellowish roots of Queretaro; in Puebla and Morelia the white root is used to prepare a very fine preserve.

Caoba, mahogany, *Swietenia mahogoni*, Cedrelaceas
Cabinet wood, exported.

Cana de azucar, *Saccarum officinarum*, Gramineas: Cultivated in three varieties since middle of sixteenth century in hot and temperate zones. The molasses furnishes alcohol (refino) and brandy (aguardiente).

Canafistula, purging cassia, *Cassia fistuloides*, Leguminosas: Medicinal.

Capulin, American cherry, *Cerasus capollia*, Rosaceas: Native fruit tree in temperate and cold zones, cabinet wood.

Cardo, garden artichoke, *Dipsacus fullonum*, Dipsaceas.

Cardo santo, holy thistle, *Cirsium mexicanum*, Sinanterias: Medicinal.

Carrizo (cana vernal), reed grass, *Arundo donnas*, Gramineas.

Cascalote, *Coesalpima coriaria*, Leguminosas: Medicinal.

Cassahuate, *Ipomea arborescens*, etc., Convolvulaceas.
Cedro, cedar, *Cedrela odorata*, Meliaceas: Medicinal gum and timber.

Cedro blanco, white cedar, *Cupressus Lindley*—*Cedro de la Sierra*, mountain cedar, *Chamocypariss thurifera*: Timber.

Ceiba or Pochote, silk cotton, *Eriodendron anfractuosum*, Bombaceas; Native tree of the hot zone, medicinal.

Cevada, barley, *Hordeum vulgare*, Gramineas: Introduced by the conquerors, next to Indian corn and wheat, the most important grain, cultivated in temperate and cool zones, generally sowed November to January; harvest in spring; produces as much as twenty-four times.

Chavacano, apricot, *Armeniaca vulgaris*, Rosaceas.
Chayote, *Seschium edule*, Cucurbitaceas: Several varieties, a vine which produces a green or white vegetable, the green kind is thorny and boiled tastes like calabash.

Chia, lime-leaved sage, *Salvia chian*, Labiadas
Mexican condiment for drinks, etc.

Chicozapote or zipotillo, *Zipota archas*, Sapoteas: Fruit tree of hot zone.

Chile, Cayenne or red pepper, *Capsicum annuum*, Solanaceas: Principal condiment of the Mexicans, in many varieties, used fresh and dried.

Chirimoyo, *Anona chirimolia*, Anonaceas: Fruit tree of hot zone.

Cidra, citron, *Citrus medica cedra*, Auranciaceas: Introduced from Asia.

Cirnelo del pafs or atoyacocotl, Mexican plum, Spondias myrobolanus, etc., Terebintaceae; in many varieties, in temperate and hot zones.

Comino, cumin seed, Cumminum, Umbelliferae: Production in 1880, \$23,500.

Copaibo, copaiba, Terebinthina copaiferæ, Leguminosae: Furnishes medical balsam.

Copalillo, Elaphrium copaliferum, etc., Rutaceae: Mexican gum-tree; the gum of this tree was the incense of the ancient Mexicans.

Coquito de aceite, oil-palm, Elaeis melanococca: Palm of the hot zone; produces oil, article of export.

Ebano, ebony, Diospyros ebenum, Ebenaceae; Cabinet wood.—*Modern Mexico.*

(To be concluded.)

NUTMEGS AND CLOVES.

CROP PROSPECTS IN THE EAST INDIES.

Through the kindness of Dr. H. A. Nicholls, C.M.G., of Dominica, we are enabled to publish the following important communication received by him from his London agents Messrs. Boddington & Co.

"We have received through the London Correspondent of an Amsterdam house the following:—"In our last Dutch auctions high prices were paid for all kinds of nutmegs and mace and everything was sold with a good demand. The advance has already partly discounted the bad outlook of nutmegs during the next few years but certainly to a small extent only. The low prices ruling during the last few years have been the cause of a decrease in the production which has fallen off more and more on Banda Island since 1901 and feel sure that the effect of it will be more acutely felt in 1903 and during the next few years, as not only is a small and late crop expected on the Banda Island in 1903 (November instead of May to June) but it is anticipated that the crop will not yield more than one third of the average quantity on account of the drought from which the East Indies have suffered throughout this year. Beside this, the quality of nutmegs and mace will be poor. Considering that values ruling at present are only one third of what they were in 1872 in which year nutmeg prices in Holland reached 215c. for 110's to 115's, and taking into account that the consumption is increasing steadily and will continue to do so independently of the price, it seems that present values are ripe for a further advance."

"The Amboyna clove crop is also reported to be affected by drought and it is a total failure and will not yield this year more than 200 piculs † against 6,000 last year."—*Agricultural News*, Feb. 14.

GOVERNMENT QUININE FACTORY, NEDIVATAM.

(To the Editor, "Madras Mail.")

Sir,—The following case may interest cinchona growers who have supplied this factory with cinchona bark and those who may contemplate doing so. For twenty years the bark from a well known estate near Ootacamund has been analysed in England and found to contain 2½ per cent and 3½ per cent respectively of sulphate of quinine in its natural and renewed barks. For the first time in the history of this estate it sent a consignment of about 30,000 lb. in three lots to the Nedivatam factory. The owner of the estate accepted the departmental rules. Shortly after the bark had been delivered Mr Standen informed the supplier that his bark only contained, natural 1.48 per cent and renewed 2.55 per cent sulphate of quinine. On hearing this astonishing result the supplier sent a sample of

natural bark, which had been obtained from the Nedivatam factory sample bag, to Dr. Schulten of Calcutta, for analysis. Dr. Schulten certifies that it contains 2.25 per cent sulphate of quinine, and upon this basis the renewed bark would contain 3.25 per cent which practically confirms the English analysis of 20 years. This was represented to Mr Standen, who replied that he had submitted another sample to Mr. Hooper for analysis from the same sample bag, and that the second analysis worked out nearly 0.25 per cent, worse than the first. Your readers may not be aware that the samples sent to Mr Hooper by Mr Standen are not cinchona bark in its original quill or chip state but merely so much disintegrated powder, which it is impossible for any public analyst to say was a genuine or manipulated sample of bark. In this case the loss to the supplier is about 1 per cent. of sulphate of quinine on 30,000 lb. supplied at 1½d. per unit, which represents about £2,000. Now, Sir, this is a very serious matter. If this was an isolated case it might be capable of explanation, but it is no exaggeration to say that the whole District is seething with discontent, and it is difficult to meet the supplier who does not feel that he has been made the victim of an *appalling mistake* of the factory. It may be remembered that when Government opened the Nedivatam factory it was with the avowed intention of assisting growers to obtain the rates ruling in the London market without incurring the formidable expenses of sending the bark Home. The previous crop from the same estate has just been sold in England as follows:—

Natural bark, 4½d. per pound; renewed bark, 5 3-8d. to 6½d. per lb. It was analysed by T. R. Vizey and certified to contain, natural 2.48 per cent and renewed 3.42 per cent. sulphate of quinine, and the brokers' account sales show that the bark was all round richer than the analysed samples.

There is no question that it pays better to send bark (even the poorest) to London than to sell it to the Government quinine factory at Nedivatam! The only alternative cinchona growers have is to open a small quinine factory of their own. For some years past the Government factory has been practically run with supplies from private growers, yet large profits have been made. The actual process of manufacture is mere child's play. What cinchona growers want is a quinine factory of their own on the co-operative supply system where they can go and see their barks worked up, and what is more to the point, get the full value of what their barks contain. The following table compares the results of bark from the above estate when sold in England and when sold at Nedivatam:—

Sold in England.		Sold at Nedivatam.	
Analysis	Price obtained	Analysis	Price obtained
Natural 2.48	4½d per lb	Natural 1.48	2d
Renewed 3.42	5¾d to 6½d per lb	Renewed 2.55	3d

ANOTHER VICTIM.

—*M. Mail*, March 30.

EGGS.—Over five millions pounds worth of eggs are now annually imported into England, but not one half of these are used for culinary purposes. The calico Print works use over 40,000,000 eggs a year, photographic establishments use millions of dozens, and wine clarifiers 10,000,000 dozens in the year; bookbinders, kid glove makers, and leather finishers use them in abundance, as well as other trades. The general public appear to have but little knowledge of the magnitude of the numbers wanted for practical commercial uses, apart from those of food, though in the latter respect not a few of the figures are absolutely startling; as an instance one of the London clubs alone contracts for more than 100,000 eggs a year.—*Agricultural Gazette of New South Wales*, March.

* Presumably reference is made to the Dutch coinage. 100 Dutch cents=1 guilder=1s 8d.—[*Ed. A. N.*]
† 1 picul or picul=136 lb. avoird., nearly.—[*Ed. A. N.*]

H E KNAVESMIRE ESTATES CO., LTD.

The Directors have the pleasure to submit the Balance Sheet and Profit and Loss Accounts duly audited for the year ended 31st December, 1902.

The surplus on Revenue and Expenditure account is R23,546.80, to which has to be added the balance R2,979.96 carried forward from season 1901.

The Profit and Loss Account after providing for Depreciation, Irrecoverable Coast Advances and Superintendent's Commission and other charges shows an available balance of R18,560.29, out of which the Directors propose to pay a Dividend of 4 per cent. That will absorb R16,600 and leave, subject to the payment of Directors' fees, a sum of R1,960.29, which it is proposed to carry into the current season's accounts.

The Profit earned represents a return of R48.45 per acre on the area of Tea in bearing as against R56.72 per acre in 1901.

The Crop secured from Estate Leaf was 279,661 lb. or 20,339 lb. under the estimate. The Plucking area was 486 acres, and the yield per acre 575 lb. of made Tea. Had the last four months of the year been up to the average with regard to weather, the full estimate should have been secured, but total want of sun stopped the bushes flushing freely. The total quantity of Tea dealt with amounted to 316,435 lb., which included 36,774 lb. made from bought leaf.

The Tea sold to end of December was 292,200 lb., the net proceeds of which equalled 27.62 cents per lb., leaving unsold 24,205 lb., which has been estimated to produce 31.75 cents per lb.

Including the cost of Tea made from bought leaf, the twelve months' crop was put on the market for 20.48 cents per lb.

The Company's property on 31st December, 1902, consisted of:—

Tea in bearing	..	486	acres
Tea not in bearing	..	30	do
Jungle	...	73	do
Buildings & Waste land	...	5	do
Total	...	594	acres

The question of Green Tea manufacture has been under consideration, and the Board is making arrangements to have the necessary plant installed as soon as possible.

The Crop expected in 1903 is 300,000 lb. of made Tea, and the Estimate cost is 20.66 cents per lb. The Expenditure Estimate provides for the upkeep of 30 acres of unproductive land as also for the purchase of Green Tea making machinery, and allowance has been made for starting manuring on a small scale.

The Royalty payable to the Company by the Syndicate which leased the right to work Plumbago on the Estate has not yet been recovered, but all the mineral has now been realised and the small amount coming to the Company will shortly be available. There has been no mining in progress during 1902.

In terms of the Articles of Association Mr Payne Gallwey retires from the office of Director, and is eligible for re-election.

The appointment of an Auditor for 1903 rests with the meeting. By order of the Directors.

GEORGE STEUART & CO., Agents & Secretaries. Colombo, Jan. 13, 1903.

THE KELANI TEA GARDEN CO., LTD.

Following is the report submitted at the annual meeting at noon today, the minutes of which are held over for Monday:—

REPORT OF THE DIRECTORS.

ACREAGE:

398	acres	Tea in full bearing
10	"	" " " " 1899
14	"	" " " " 1900

422	"	" " " "
313	"	reserve
11	"	Ravines, Waste, and Grass.

Total 746 acres

The Directors beg to submit to the Shareholders of the Company the Accounts for the year ending 31st December, 1902, duly audited.

The Crop for the year amounted to 151,145 lbs. of made Tea as against the estimate of 200,000 lbs realising R43,325.15, or an average nett price of 28.66 cents per pound, and in addition to the above 112,420 lbs. of made Tea was manufactured for others, making a total of 263,565 lbs. made tea dealt with in the Factory.

The expenditure, exclusive of items under Capital Account, amounted to R44,662.79, equal to 25.98 cents per pound of made Tea, and included R2,901.99 spent on manuring representing 1.92 cents per pound made Tea.

The balance at credit of Profit and Loss Account after providing for depreciation on Building and Machinery, interest and other charges, and including the amount R6,807.30 brought forward from the previous year is R8,178.36, which amount the Directors recommend should be carried forward to next account.

The result of the year's working has been most disappointing, the crop falling short of the original estimate by 48,855 lbs. This shortage may be attributed to an unusually severe attack of Helopeltis affecting some 203 acres of the Tea in bearing, and also to an exceptionally wet and sunless North-East monsoon.

During the year arrangements were made with the proprietor of Kiriporuwa Estate for the manufacture of his Teas under a contract extending over two years, and to enable the Superintendent to cope with the additional leaf in the Factory, two Davidson's Sirocco Fans were erected in the withering lofts. This expenditure has already been more than recouped by the profit on outside leaf manufactured during the past season.

The estimate for the current season is 200,000 lbs. made Tea to be delivered in Colombo at a cost of cents 22.72, which includes R3,358, or the equivalent of cents 1.68 per pound to be spent on manuring.

In the terms of the Memorandum of the Articles of Association, Mr. Shakspeare retires from the Board, and as he is leaving the island does not seek re-election. It is proposed that Mr. E R Waldock be elected in his place. Mr. Hoseason also wishes to retire from the Board, and it is proposed that Mr. C L Davis be elected in his place.

The appointment of an Auditor rests with the Meeting.—By Order of the Board of Directors, CARSON & Co., Agents and Secretaries.

THE TEMPLESTOWE ESTATE CO. OF CEYLON, LIMITED.

REPORT OF THE DIRECTORS.

DIRECTORS:—Messrs H G Bois and F W Bois.

The Directors have the pleasure to submit their report and accounts for the year ending 31st December, 1902.

The Tea Crop amounted to 193,250 lb., which was short of the Estimate by 26,750 lb., and 957 lb. of Cinchona bark were also harvested. The heavy shortage in the tea crop is much to be regretted, but is in accordance with the experience of a large number of estates during 1902. The Tea cost 28.08 cents per lb. and netted 38.57 cents as against 27.57 cents and 38.11 cents for 1901. The increased cost can be mainly attributed to the shortness of crop and the price realised for the tea may be considered very satisfactory in view of the state of the tea market during the season.

The acreage of the Estate now consists of:—

479½	acres	Tea 5 years old and upwards.
28½	do	4 do
56½	do	3 do
6	do	2 do
110	do	Forest.
342½	do	Chena and Patna.

1,023 acres.

The profit on the year's working after paying interest on the mortgage for £4,500 and other loans, is R15,963.38 which includes the balance brought forward from last year of R1,591.30. The Directors recommend that this should be disposed of as follows:—By the payment of the Dividend on the Preference shares absorbing R6,516.00. By the payment of a Dividend of 3 per cent on the Ordinary Shares absorbing R4,926.00. By transferring to Depreciation account R4,000.00. By carrying forward a balance of R521.38. Total R15,963.38.

The estimate for season 1903 provides for a crop of 210,000 lb. at a cost of 26.36 cents per lb. exclusive of capital expenditure.

Mr F W Bois who was appointed a Director in the place of Mr G F Walker, retires in accordance with the Articles of Association, but being eligible offers himself for re-election. Mr Guthrie who was appointed Auditor for season 1902, died before undertaking the audit, and the Directors appointed Mr F M Simpson in his place. It will be necessary to appoint an Auditor for season 1903.

THE COLOMBO BRICK AND TILE CO., LIMITED.

REPORT OF THE DIRECTORS.

DIRECTORS:—Messrs. G W Suhren, W Shakspeare, and E M Shattock.

The Directors now beg to place before the Shareholders the Statement of Accounts of the Company's working for the year ended 31st December, 1902. The Works were taken over on January 3rd, 1902 and the first few months were occupied in repairing and overhauling the Plant &c, and in getting everything in readiness for the New Brick Machinery which had been ordered from England. This machinery arrived at Works in August but the Works were ready for a steady start at end of July. From that time forward until the end of the year, however, the weather was so abnormally and consistently wet that it was found quite impossible to obtain an adequate supply of clay from the pits to keep the works going. Consequently the monthly output of Bricks from August to Decem-

ber was extremely small and the Works were therefore carried on at a loss. It will be seen from the Accounts that the amount at debit of Profit and Loss Account is R10,473.17. Great efforts were made to maintain the brick output but it was found that the incessant rains prevented any possibility of profitable working. Other difficulties which had to be contended with were the irregular supply of labour and firewood, but it is hoped that these have now been overcome, and as, since the beginning of the year, fine weather has prevailed a start has been made with regular work. No fees to Directors have been included in the accounts and it remains for the meeting to decide whether the Directors are to receive any remuneration. In accordance with the Articles of Association the Directors retire and it will be necessary for the Meeting to elect a new Board. It will also be necessary for the shareholders to arrange as to the further carrying on of the Secretarial work.

THE CEYLON GAME PROTECTION SOCIETY.

REPORT FOR 1902-3.

I once more place before the members of the Ceylon Game Protection Society my annual Report and its chief feature will I think be its brevity. Not that the Society has been idle or that interest in its work and responsibilities has flagged, but thanks to the steady and consistent co-operation of Government—the work before us except the matter of appointing watchers diminishes each year. I do not say that it need or should diminish, for importation and acclimatisation of deer, antelope and wild guinea fowl might easily and beneficially occupy our attention, but with the limited funds at our disposal our scope is confined to the protection of the animals we already possess around us. Nor do I say that protection is in any way adequate. In spite of restrictions imposed by Government by the prohibition for the last nine years of the export of hides of sambur and spotted deer and the recent prohibition of the export of horns, the slaughter of those animals continues and exists far beyond the limits of expediency. The difficulty of dealing with this evil in a sparsely populated country presents a problem to this Society and to Government far more difficult of solution than landowners in the British Isles have to face, and I would ask, has poaching come anywhere near being abolished there?—in Ireland for instance where a Game Protection Society exists—our Bete Noir is the itinerant moorish trader, the game butcher. It is he who subsidises the villager, it is he who takes his carts into the low country forests, it is he who supplies the hide and horn markets, and it is he who carts back to us of dried meat into the populous villages of the more civilised villages. He does not do much shooting himself, but he is the robber who by means of a few handfuls of rupees which probably do not reach the hands of those who have earned them, takes away the meat out of the mouths of the villagers and, in the form of stud horns of deer, part of their legitimate means of subsistence. During the year under review the export of cut horns of sambur and spotted deer was prohibited by proclamation for a period of two years dating from September 1902, and it will be for the Society to watch whether any marked diminution in this export takes place. The period appears to me to be too short to effect its object, and horns being imperishable will be stored against the possible withdrawal of the prohibition. In addition to this many hundred of deer horns having all the appearance of stud horns with the occasional exception of a fragment of bone being attached are undoubtedly the horns of shot animals or "cut" horns. As the horn reaches perfect maturity and the season for its annual studding approaches it may be wrenched or knocked off its base of bone and so pre-

vent the appearance of being naturally stud. In the course of a hunting run stags have known to knock their horns off against trees. This proclamation, therefore, welcome as it is to the Game Protection Society, will hardly act as a serious deterrent to slaughter for trade purposes, for there is always the meat of the carcass as well. I am indebted to the Hon. the Collector of Customs for the following return of export of sambur and spotted deer horns during 1901 and 1902:—Taking the average weight of a pair of antlers of the two species to be two pounds (2 lb), the export of 1,233 cwt during these two years represents the product of 69,328 stags. I will not attempt to calculate the number of hinds killed in the same period. Statement showing the exports of Deer and Sambur horns for the Island of Ceylon (Colombo) for the two years 1901 and 1902.

H M CUSTOMS, (Signed) H L CRAWFORD, Colombo, 6, Jan. 1903. for Principal Collector. No. 9. H M Customs, Colombo Jan. 6th, 1903.

SIR,—With reference to your letter of the 28th ultimo, I have the honour to forward a return of the export of horns during the years 1901-1902, and to state that no horns have been shipped from our ports since 1899.—I am Sir, your obedient servant (Signed) H L CRAWFORD, Principal Collector. To Thomas Farr Esq., Honorary Secretary. Ceylon Game Protection Society.

The GAME SANCTUARIES—are doing good and when the Food Supply in these runs short, the game will overflow into adjacent forests and here the Society should exert itself to afford protection by means of watchers. I dealt with this subject fully in my last report and since then no further developments are to be recorded beyond an improved Water Supply by means of drains in the proposed Puttalam Sanctuary and a considerable restriction in its area (112,000 acres to 75,000 acres) (37,000 for villages.) In the Hill Districts the amount of good that has been accomplished by the refusal of shooting licenses to Tamil coolies and squatters about Nuwara Eliya together with an organised system of watchers is very marked, and where a year or two ago sambur had practically ceased to exist the old Game Paths again show signs of use. We have been fortunate in having the sympathy of his Excellency the Governor as well as that of the Government Agents of the adjacent Provinces and as a Society for the Protection of Game we have reason to congratulate ourselves upon the results of our efforts.

The New Ordinance No. 11 of 1901, to amend Ordinance No. 10, of 1891, has now become law and if applied in prosecutions with common sense and discretion; it should be of very material assistance in bringing to justice those persons who although in search of game, are not caught red-handed in killing for by its terms, pursuing or attempting to pursue, capturing or attempting to capture game are made punishable offences. It will, however, be necessary to prove that these persons are in pursuit of game and not of monkeys and pigs.

BRANCH SOCIETIES—appear to be in a fairly flourishing condition, judging by the reports of the two energetic Honorary Secretaries of the Nawalapitiya and Haputale Branches. Mr. P R Shand informs me that he has some 40 members on the list, and Mr. Ormiston some

26 members. Considering how favourably Uva residents are situated with regard to sport it is a matter for surprise and regret that the number of members is not far greater. During the year I have received from the Honorary Secretary of the Nawalapitiya Branch a sum of R26'25 being 25 percent of subscriptions collected by them in 1901, whilst from the Honorary Secretary of the Haputale Branch I have received nothing, but have on the other hand disbursed R20 collected by myself in the form of subscriptions, as well as R15 to pay a game watcher in Uva. There is one more subject of a general nature which I must briefly allude to in this report, and that is the inadequacy in my opinion of the fines and penalties imposed in Ceylon in cases of breaches of our Game Ordinance. Through the courtesy of Mr. JOHN FRGUSON of the *Ceylon Observer* I have received a copy of the Perak Government Gazette in which I notice an enactment in the Federated Malay States to provide for the protection of wild animals and birds. The penalties range from five dollars in respect to birds up to 500 dollars in respect to big game. During the year 1902, two meetings were held, one a general meeting on April 2nd, and the other a general committee meeting on the 20th September, at the former the following Committees were elected.

GENERAL COMMITTEE: SUB COMMITTEE.—A Resolution giving Honorary Secretaries of Branch Societies control over the subscriptions collected by them to the extent of three-fourths thereof with the proviso that annual accounts be rendered to the Honorary Secretary of the Parent Society was carried. Mr. P R Shand, the Honorary Secretary of the Nawalapitiya Branch, has kindly complied with this proviso and sends me the following very satisfactory balance sheet E together with a cheque for R45, and a list of members numbering 46. The Balance Sheet E referred to.

Whilst upon this subject I would point out that the establishment of these branch societies tends to impair the strength of the Parent Association financially. Subscriptions are necessarily diverted from it, but at the same time the principle is very sound and fair in most respects. There is, however, another side to the question and it is my duty to draw attention to it. Sportsmen in search of big game in Uva and other areas protected by funds from the Parent Society do not hesitate to seek for their sport in those localities, although they may have contributed but an infinitesimal sum towards protecting them. I would, therefore, appeal to the Hon. Secretaries of these branches not to adhere too closely to the rule giving them the right to three-fourths of their collections, but to err if possible on the side of liberality. I anticipate a falling off in revenue this year owing to the above cause and I trust too much will not be expected of the Parent Society financially.

PROXIES.—It was decided that proxies were not desirable at Game Protection Society meetings owing partly to the fact that the non-attendance of members were bad enough as things were, and partly to the fear that by their means resolutions might be carried which might affect the prestige of the Society in the eyes of Government. By this it was intended to be understood that certain members who seldom or never attended meetings might in

ignorance of the previous history of any question at issue, upset any annual measures that had been decided upon after mature consideration by those active members whose attendance was regular and continuous; and as the status and usefulness of the Society depends much on its consistency in its relations with Government there would be the fear of loss of influence in that quarter. The rule prohibiting shooting sambar and spotted deer in the Hill Reserves was again brought up and the following resolution was carried:—"That the present rule prohibiting all shooting of game above 4,000 feet should be altered in accordance with the resolution passed at last meeting, viz.—"That when registered packs are hunted, the killing of sambar be confined to stalking with the rifle at any elevation and to killing with the knife and hand." At the General Committee meeting held on the 20th September which was but poorly attended, Messrs C O Wilson and M J Kenaway were added to the Committee. At the same time correspondence with the Hon the Colonial Secretary on the subject of shooting in the Hill reserves and conditions to be attached to game licenses was submitted with a copy of conditions proposed by the Hon. Secretary. They were as follows.—1. Shooting at night and netting are prohibited. 2. This license is not transferable. 3. Hunting by men in gangs carrying sticks or guns, with or without dogs, is prohibited. 4. Shooting elk and spotted deer within the Hill reserves above 4,000 feet is prohibited, except with the permission of Government in writing. The only modes of hunting elk and spotted deer within such reserves, is hunting with dogs, to the knife and killing with the rifle. I greatly regret that through inadvertence on my part the words "above 4,000" instead of at any elevation were inserted in condition No. 4. This was most unfortunately not noticed at the meeting. I say unfortunately because it has given rise to some discontent as well as charges of want of *bona fides* on the part of the committee. It certainly on the face of it appeared that the committee had acted in an arbitrary and unwarrantable manner, in upsetting a resolution passed at two general meetings, and I took upon myself the whole onus of this inadvertence and trust that the explanation will be accepted in the same spirit in which it is made. However, the following letter from the Hon. the Colonial Secretary will show that the conditions proposed by all were not acceptable to Government in their entirety and it will now be competent for me to propose that the words at any elevation be substituted for above 4,000 feet:—

No. 017338—Colonial Secretary's Office, Colombo, 28th October, 1902.

Sir,—With reference to your letter dated 27th ultimo, submitting for approval conditions proposed to be noted on the back of licenses to kill game, I am directed to state that there is no objection to conditions 1 and 2 being endorsed on the license the sections of the ordinance 12 or 10 of 1891 and 11 of ordinance 10 of 1891 under which these rules are framed being inserted in brackets. I am to point out that condition "3" cannot be adopted, as there would be legal difficulty in exactly defining the term gang and in distinguishing a gang from a legitimate shooting. In condition "4," it will be necessary to insert "sambar" for "elk," and it is suggested that the condition may read thus:—"This license does not authorise the holder to shoot or attempt to shoot sambar or spotted deer at any place above the elevation of 4,000 feet, otherwise than stalking with the rifle when the holder has obtained permission in writing from the Government Agent for the purpose.—I am to invite you to be good enough to reconsider the rules and to state that on your furnishing me with revised rules to obviate the difficulties pointed out, they will be considered by Government.—I am, Sir, your obedient servant.

E. R. CUMBERLAND, for Colonial Secretary.

Thomas Farr, Esq., Hon. Secretary, Ceylon Game Protection Society, North Cove, Bogavantalawa.

The meeting requested the Honorary Secretary to endeavour to ascertain from the Government Agent, Sabragamuwa how the two watchers of the Meda and Kadawatte Korles were being employed and to obtain a return of cases instituted. The following letter in reply to the Government Agent, Sabragamuwa and the annexed return of cases were received by me in due course:—

No. 141.

Nov. 10, 1902.

In reply to letter from Government Agent, Sabragamuwa.—The two watchers are employed in the Kadawatte and Meda Korale under my own supervision. They are for the most part engaged in going about the country lying between the Walaway on the North and East Balangoda and Welgepola on the West and Atskalan Korale on the South where game is plentiful and where years before elk and spotted deer used to be killed by the hundred. This being dense jungle with small villages situated here and there watching is rather difficult. But it is a fact admitted that killing game is certainly reduced by nine-tenths from what it was five years back. I do not as a rule prosecute at the instance of the watchers alone when I do get information I hold an enquiry and get the chance to work up the cases. The watchers presence in the District act as a prevention to a great degree. (Signed,) S. D. MAHAWALATENNE.

Return of cases instituted under the game protection Ordinance.

No. 20,747 6th June, 1901, killing game without license S. D. Mahawalatenne, R. M., M Dingirihamy fined Rs.—No. 20,884 5th July, 1901, killing game without license S D Mahawalatenne, R.M. Mudalihamy and 2 others acquitted and discharged.—No. 22,362 12th October, 1901, having meet of game during close season S D Mahawalatenne, R.M., M Mothahamy accused under concealment.—No. 22,580 8th November, 1901, killing an elk without license S. D. Mahawalatenne, R. M., V K A Kiri Menika accused discharged.—No. 22,579 8th November, 1901, killing an elk without license S. D. Mahawalatenne, R. M., accused discharged.—1902 nil.

Taking into consideration the circumstances revealed by the letter I considered myself justified in discontinuing the services of those two watchers forthwith. It will be noted that no cases have been instituted since November 1901, and the presumption is that the villagers in those two Korales, are such reformed characters that to watch them further would be to insult their respectability. Owing to the close season for game in the Eastern Province having been attended without reference to this Society. I was requested to approach Government upon the subject, and received the following reply from the Hon. the Colonial Secretary:—

No. 017337. Colonial Secretary's Office, Colombo, October 6th.

Sir,—In reply to your letter of the 27th September, 1902, I am directed by His Excellency the Lieutenant-Governor to inform you that the Game Protection Society will be informed before any alteration is made of the proclaimed close season in any Province.—I am Sir, yours obedient servant (Signed) A CLAYTON, for Colonial Secretary.

Thomas Farr Esq., Honorary Secretary, Game Protection Society.

The Government Agent of the Eastern Province has since kindly furnished me with the following particulars:—

No. 336. Batticaloa Kachcheri, Sept. 13th, 1902.
Sir.—Referring to your letter dated 6th instant I have the honour to inform you that the close season for deer in this Province is from 1st June to 31st August for the current year. Please see my notice dated the 11th March last in Government Gazette No. 5838 of 22nd idem. It is the same as that for the Southern Province and was declared by one under Section 13 (1) of Ordinance 10, of 1891, No close season is provided for the shooting of Elephants or Buffaloes under the Game Ordinance of 1891. Govern-

ment notification dated 15th November, 1900, in Government Gazette No. 5735 of 16 idem regulates the rotation of districts for the issue of licenses for the Capture of Elephants.—I am, Sir, your obedient servant (Signed) S HAUGHTON, Government Agent, Eastern Province.

The Society at this meeting through their Committee expressed its appreciation of the Government Proclamation prohibiting the export of sambar and spotted deer horns, and duly recorded its thanks. It will be noted that no mention is made in this report of elephants or buffaloes, but from all I can learn the destruction of these animals is upon a very limited scale and previous reports have dealt thoroughly with the subject. I annex my balance sheet which I think explains itself. It brings the accounts up to the date of this meeting with the exception of those subscriptions for 1903 viz. R15 and Mr Stand's cheque for R45 from the Nawalapitiya branch. There is a credit balance in the Mercantile Bank of India of R1,839.26—irrespective of the two items just mentioned viz. R60—which after two years expenditure is in excess of the balance taken over by one or two years ago, by R44.77 plus R60 subsequently received.

BALANCE SHEET 1902—1903.

Balance from last year R2,026; Donations R130 Fines R375; Government Subsidies R405; Subscriptions R620; Interest R37.70. Total R3,222.45.

By paid Game Watchers R879; Forest Peons Game Watchers R158; Uva for Hon. Secretary Hapntale Branch R115; 4 Subscriptions from Uva Residents R20; Stationery Stamps and Commissions R69.89; Advertisements R76.40; Legal Fees &c. R27.50; 100 Copies Report for 1901-1902 R35.40; Balance R1,839.26. Total 3,222.45.

MATURATA PLANTERS' ASSOCIATION.

FIRST ANNUAL REPORT: 1902,

REGISTER.—The number of estates on the register is now 16 against 17 last year (1902). Wellakelle and Ellamulle estates have been made into one.

MEETINGS.—Three general meetings were held during 1902, at which most members were present.

FINANCES.—There is a balance of R13.10 to the credit of the Association.

ACREAGE AND TEA ESTIMATES.—4,810 acres in tea; 4,758 acres in bearing; estimate 1,700,000 lb. Black Tea for 1903: equal 357 lb. tea per acre. The manufacture of Green Teas has not been tried in the district.

CROP AND PRICES.—Generally this district has not had a bad year, as regards crop; the shortage was less than in most districts. Prices have been scarcely so well maintained, as in former years.

ROADS.—The district minor roads in Maturata have never been famed for their excellence. The natural configuration of the district and original bad traces are chiefly responsible for this. The best has been done with the money available. Four new bridges have been built and two have been renewed. Another bridge is urgently required on the Mandara Nuwara-Ellamulle Road. The road from Alacolawewa to Padiapallella is a constant source of expense and trouble; land-slips and subsidences are of frequent occurrence, but as this road is by far the most important in the district, it must always be kept in good order. It is hoped that Government will construct a first-class metalled cart road from Brookside to High Forest, at an early date. The erection of Sign-posts is a matter of urgent necessity, and your Committee are desirous of obtaining a special grant from the D R C for this purpose.

HOSPITAL.—The new Maturata Hospital was opened on March 1st, 1902, and from that date to December 31st, 261 in-door patients and 2,975 out-door patients were treated, which figures show how necessary this Hospital was.

POSTAL.—The work of the Post-master at Maturata has given satisfaction throughout the year.

POLICE.—Your Committee consider that the establishment of a branch station in the neighbourhood of High Forest, worked from Ragala, with a guard-room and a regular system of Police patrol, will meet the requirements of the district.

LABOUR.—This can scarcely be said to be in a satisfactory state. A general restlessness is apparent, and advances appear to be rising.

TIN TICKETS.—This scheme works satisfactorily, but very few coolies came in from the Coast to this district during 1902. Your Committee would recommend special efforts being made, during 1903, to recruit labour from the Coast, with the aid of Tin-tickets. New districts must be tapped, and a special Recruiting Agent established.

C.P.R.C.—The local section consists of 12 members. A Rifle-range has been completed on the Government Patanas adjoining Gonakelle estate.

GENERAL.—Your Committee regret the apathy of certain Superintendents in the district, who have not supported or joined the Association, and consider that such show a great lack of public-spiritedness.

F. G. HARVEY, Hon. Secretary.

HEWAHETA PLANTERS' ASSOCIATION.

ANNUAL REPORT

as follows, which was adopted.

MEMBERSHIP.—The number of estates on the register is 9 as compared with 7 in 1902.

FINANCE.—The balance to credit of the Association at the end of the year is R309.70 as compared with 263.33 at the end of last year.

CROP ESTIMATE FOR 1903.—The official returns received show 9,142 acres in tea and 8,852 acres in bearings. The estimated crop is 3,909,800 lb, including 16,000 lb. of green tea, giving an average yield of 427 lb. per acre. The foregoing figures do not include 535,500 lb. of green leaf from various native gardens, the acreage of which it is difficult to estimate.

SEASON.—The tea crop was short owing to the unfavourable weather during the latter part of the year, but in several instances estimates were obtained. The prices generally have been fair.

MAIN ROADS.—The main road from Peradeniya to Deltotta, especially from the 17th mile post downwards as also the main road from Kandy to Hangurankette leave much room for improvement, and your Committee trust these roads will have more attention in the near future. Your Committee would once more urge upon Government the desirability of joining Upper and Lower Hewabeta districts by joining the cart roads ending at Loolecodera and Rahatnugoda.

TELEGRAPH.—Your Committee have much pleasure in recording the opening of the Deltotta Telegraph office, which has proved a great boon to the district, and they trust that Government will shortly extend the service to Upper Hewahetta.

HOSPITAL.—The working of the hospital has generally been very satisfactory, but your Committee would specially urge on Government the necessity of a waiting-room for outdoor patients being built at once, as during the S.-W. monsoon the only accommodation at present is an open verandah, which is open to the full force of the wind and rain.

LABOUR.—Continued scarcity of labour causes much anxiety and your Committee would like to see Mr Westland's scheme given a fair trial.

POLICE.—Your Committee regrets to have to report that illicit sales of arrack and toddy are still carried on with impunity in the district, and the Police seem to be quite incapable of coping with the evil.

C.P.R.C.—The C.P.R.C has been well supported during the year, and it is hoped that more will join in the new year. The keenness of members in Rifle shooting has been well maintained.

THE HORREKELLY ESTATES CO., LTD.

REPORT OF THE DIRECTORS.

Managing Director:—Mr C E H Symons. Directors:—Mr F J de Saram, Hon Stanley Bois, Mr F W Bois, Hon F O Loos and Mr Fred Dornhorst. Secretaries: Lewis Brown & Co.

The Directors have pleasure in submitting the accounts of the Company for the year ending 31st December, 1902, which they trust will be considered satisfactory. The sum of R5,997.28 has been written off as depreciation on buildings, plant and machinery, and the 1903 manure account has been reduced to R5,000 by transfer of R3,884.68 to "1902" Estate expenditure. It has been decided to place R15,000 to a Reserve Fund Account, and the Shareholders will be asked to approve of the Directors' investing the sum so reserved upon the security of immovable property. The balance available for distribution (including R899.51 brought forward from 1901) is R44,002.45, from which the Directors recommend payment of a dividend at the rate of 10 per cent which will absorb R400,000, and leave R4,002.45 to be carried forward. The working of the estate for the years 1900, 1901 and 1902 compares as follows:—

Expenditure on Est. and 1900.	1901.	1902.	
in Colombo office	R35,761.59	R39,756.93	R43,098.52
Number of Coconuts produced	1,502,298	1,439,218	2,146,825
Quantity of Coir Fibre made	Ballots 22,592	24,876	21,209

Two Directors—The Hon Stanley Bois and Mr F W Bois retire by rotation, and are eligible for re-election. The Shareholders have to appoint an Auditor for 1903. The current year's prospects are favourable.—By order of the Directors, LEWIS BROWN & Co., Secretaries. Colombo, 31st January, 1903.

THE UDABAGE COMPANY, LIMITED.

REPORT OF THE DIRECTORS

335 acres in full bearing
164 „ 4½ years old

499 acres cultivated
641 „ reserve suitable for Tea and Rubber

1,140 acres more or less.

The Directors beg to submit to the Shareholders a statement of the accounts duly audited for the year ending 31st December, 1902. The crop secured amounted to 218,763 lb. made Tea as against an estimate of 240,000 lb, and realised an average of cents 34.65 per pound nett including the Bonus on Green Teas as against an expenditure of R52,936.66 or cents 24.08 per pound. Of the total crop 215,180 lb was manufactured into Green Tea and 3,715 lb into Black. The crop results for the year were somewhat disappointing, owing in common with other estates in this district to the abnormally wet season experienced, and yield was in consequence affected. The estimate for the current year is 250,000 lb of made Tea to cost cents 23.18 per pound, and it is proposed to spend a sum of R1,022 on manure during the season. The increase in crop necessitates an extension to the Factory, and the provision of a Down-Draft Sirocco involving an expenditure estimated at R6,000. In terms of the Memorandum and Articles of Association of the Company the Hon. Mr J N Campbell retires from the Directorate, but is eligible for re-election. The appointment of an Auditor for the current year rests with the Meeting.

BATTICALOA PLANTERS' ASSOCIATION.

ANNUAL REPORT.

The third annual report was as follows:—

Your Committee has pleasure in submitting the third annual report and in so doing congratulates you upon the satisfactory position of this Association.

The number of estates and voters on the register has increased during the year. As regards finances there is an appreciable balance to the credit of the Association.

During the year three meetings have been held.

OBITUARY.—It is with deep regret that your Committee records the death of Mr J J O'Dowd, who joined this Association from its commencement and was one of its most valued supporters. A donation has been made from the Association funds towards the proposed memorial brass to be placed in the R C Cathedral.

COCONUTS.—The crops for the year have been up to the average, and the weather throughout the latter end of the season has been such as to justify hopes of a fair crop during 1903.

The price fetched by copra during the year has been far above the average, and in July a highwater mark in prices was reached—one hardly hoped for by the most sanguine of us.

PESTS.—It is satisfactory to be able to report a decided check in the spread of the caterpillar pest. As much trouble as ever has been experienced in dealing with both black and red beetles, and until the native garden owners are either persuaded or compelled to attend to the proper beetling of their trees, the pest is not likely to decrease.

PADDY.—The *minnari* crops were good owing to the timely rains; the knlum velami crops were up to the average and good prices were realised.

WARD FOR PAYING PATIENTS.—Though in January, 1901, we were informed that H. E. the Governor had instructed the Director of Public Works to submit a plan and estimates for this work, and though provision was made in the annual estimates for 1902 for construction of same, January 1903 sees us with no signs of a ward. We are informed by Government that the money voted "had to be utilised for other more urgent works." That a sum of money voted for an urgent want of such vital importance as this is to the residents of the district, should be used for another work (we believe in the Western Province) is most unjust.

ROADS.—On the South Road the Periya Motuwanne and Mohidee Tandu causeways have at last been finished. The causeway at mani has been commenced and is likely to be completed during 1903. This Association ventures to hope that the most important bridge over the Randany Odai at the 32nd mile post, which when in flood cuts off all communication from the south, and which bridge was washed away as far back as December, 1901, will have the earnest attention of the P W D, and that instructions will be given that every effort be made to ensure its completion as soon as possible. Special attention might be called to the Batticaloa-Kalkndah road, which, owing to the very heavy traffic, is generally in an unsatisfactory condition.

MAIL SERVICE.—This Association regret that the motor-car service has met with such misfortune. Our thanks are due to the Postmaster-General for having so promptly substituted a through horse-coach service.

C. P. R. C.—During the latter end of the year a section of this corps was formed, and, considering the short time of enrolment, is in a high state of efficiency.

BADULLA PLANTERS' ASSOCIATION.

ANNUAL REPORT.

Your Committee has pleasure in submitting their report for the year 1902—the 19th since the formation of the Association,

MEETINGS.—During the year three General meetings and three meetings of Committee have been held. There have also been two meetings of the sub-Committee on minor roads.

MEMBERSHIP.—There are 46 estates registered on the roll of membership against 48 in 1901. There are also two private members against the same number in the previous year.

FINANCE.—The books and accounts of the Association are laid on the table for the inspection of members. The balance at credit of the Association at 31st December, 1902 amounts to R36'61 cents.

TEA.—Crops generally in the district have been well up to estimate. The weather throughout the year was favourable, and the rainfall good and well distributed.

The SOUTH-WEST MONSOON was late in setting in, and tea in consequence flushed very finely in June and July. However, though leaf was abundant, much of the fine flavour and quality characteristic of the tea from these districts during the dry months from June to October was absent, and there was less fine tea sent from the districts this year than usual.

The TEA CROP for 1903 is estimated at 7,080,975 lb. and 91,000 lb. from native gardens. The acreage under tea is 17,458 acres, of which 15,829 acres are in bearing; the yield per acre on tea in bearing is estimated at 447 lb.

LABOUR.—Labour has not been quite so plentiful in the districts generally, and advances have been rising considerably. More coolies from the coast are required, and your Committee would be glad to see immigration encouraged to the fullest extent.

TIN TICKETS.—This system has worked well and will, your Committee believe, be of great service to the planting community as well as to the cooly.

MAIN ROADS.—The principal roads have been kept in good order, but on some roads, notably the Madulsima Road up to the 11th mile, the quantity of metal laid down is scarcely sufficient to maintain the road in good order for a year. The traffic on this portion of the road has increased considerably of late years.

MINOR ROADS.—These have been kept in a fairly good state of repairs, but more liberal votes are in some cases required for the improvement of these important roads, the bridging of stream and other works. A new road has been cut to connect the minor road at Kudnoya with the bridge at Badulla. This will be of some service to the Badulla district, but your Committee regret that Government was unable to grant the bridge across the Baddullu-oya at the ford on this road.

Your Committee are urging upon the Provincial Roads Committee the necessity of constructing bridges across the streams at Pilpola and Nahavilla, and they hope that these will be made before the close of 1903.

NEW TELEGRAPH OFFICE.—Your Committee are pleased to report that a sum of R20,000 has been included in the estimates for 1903 for the opening of a telegraph office at Madulsima. This will be a great boon to the district interested.

RAILWAY EXTENSION.—In December last a resolution was passed by your Association asking Government to survey a light line of railway from Bandarawela to Badulla and Passara. Your Committee feel that these important districts should no longer be left without the benefit of a railway through them. Many of the estates are from 40 to 50 miles from the nearest station, and the heavy cost and uncertainty of transport form a severe handicap upon the tea enterprise of Badulla, Passara, and Madulsima. Your Committee sincerely hope that Government will be pleased to carry out this survey, and that the railway will be constructed at no distant date.

OBITUARY.—Your Committee records with much regret the death during the year of Mr Norman Rettie and Mr F G Hoste, both esteemed members of the Association.

In conclusion your Committee are pleased to think that better times are in view for the tea industry of

Uva, and that with a continuance of the same careful system of plucking, which has always been characteristic of these districts, a bright future is before the planting enterprise of Badulla and Madulsima.

COCONUT PEARLS.

The following extract is taken from *Chemical Studies of the Coconut with some notes on the changes during germination*. By J A Kirkwood and William J Gies, reprinted from the Bulletin of the Torrey Botanical Club, 1902, pp. 321-359, and issued as No. 26 of the Contributions from the New York Botanical Garden for June 1902:—

Within the nut there is occasionally found a small stony substance of a bluish white colour, a kind of vegetable bezoar, called in India *calappa*, which is eagerly purchased by the Chinese, who ascribe great virtues to it as a sort of amulet to preserve them from diseases. The cause of its formation in the nut is unknown.

According to Harley and Harley these pearls, like those of molluscan origin, appear to consist almost entirely of calcium carbonate, with water and organic matter in smaller proportion. Riedel, quoted by Harley and Harley, states that in 1886, while in North Celebes he found a pearl in the endosperm of the coconut. One such pearl was pearl-shaped in form and 28mm. long.

We are greatly indebted to Dr. D Morris, C M G, Imperial Commissioner of Agriculture for the West Indies, for the following very interesting quotation from a letter to Dr. MacDougal:—

“More than two hundred years ago Rumph, an eminent botanist in the East, sent as a present to the Grand Duke of Tuscany a ring in which a coconut pearl had been set. Further, Rumph himself described coconut pearls in his great work with considerable minuteness and gave illustrations of two of them. One was perfectly round, the other was oval or egg-shaped. Travellers in the Philippine Islands have heard of coconut pearls, but seldom or ever have seen them. The natives, it is said, keep ‘coconut stones’ as charms against disease and evil spirits. The Rajahs, we were told, highly prized them and wore them as precious stones. It was only a few years ago that real coconut pearls were at last brought to England. One is now at the Museum at the Royal Gardens at Kew, brought by Dr. Hickson. It is almost egg-shaped, perfectly white, and composed almost entirely of carbonate of lime. It has, in fact, a somewhat similar composition to the pearl of the oyster, and yet there is little doubt it is a purely vegetable product” (See Harley and Harley: *Proceedings of the Royal Society of London*, 43, 464, 1887-11.—*Agricultural News*, Barbados, Jan. 3.

TOBACCO IN JAFFNA.

The planting of tobacco has been completed in all parts of the District. The area under cultivation is annually on the increase and the cost of labour and manure is almost double of what it was about half a dozen years ago. But the demand for this tobacco in the Travancore market which is the only one outside Ceylon is not so great as it was some years back.—“Hindu Organ,” Feb. 8.

PRODUCE AND PLANTING.

A correspondent who has had an opportunity of observing the development of this slight

MOVEMENT IN FAVOUR OF CHINA TEA, which has extended from the Westend to the suburbs, and is almost accepted as a domestic creed by a few of the second-hand devotees of fashion, mentions an incident which recently came under his notice. One of these champions of China tea recently offered her cook some choice tea from the Flowery Land as an especial treat. It was the real thing, and too exquisite for ordinary consumption, but as it was the cook's birthday the occasion was considered a suitable one for astonishing the kitchen by a display of taste, and some of the "real tea" from China was presented amidst a flutter of excitement. Never doubting that a sensation had been created, the donor in due time asked her servant how she liked the delicacy, expecting a reply indicative of the enthusiasm she had sought to arouse. But in the kitchen the taste runs on something with a fuller flavour. The humble recipient of the gift, instead of becoming ecstatic over it, had to confess that in the kitchen they could not drink the delicacy because its flavour suggested "smoked hay." This was both ungracious and unappreciative, for doubtless the tea was of a delicate and subtle flavour, but it serves to show some of the difficulties attending the regaining of a lost trade, and it is also evidence that the present generation of tea drinkers are oblivious of the past fame of China teas, and are content with the teas which the gods in the form of the blenders send them. It may be very dreadful from the point of view of the self-styled epicure, but it is clear that before China tea again finds favour with the masses the consumer will have to acquire a taste for it, and so long as the blenders continue to exercise their skill and succeed in pleasing the majority there is not likely to be any feverish desire on the part of the consumer to take his China tea neat except at a few ladies' clubs or gatherings where they possess profound knowledge and taste, or imagine that they do.

We take the following from "Tea, Coffee, and Sugar" of New York: "The position of

TEA IN THE UNITED STATES

is so strong and the consequent activity so intense that there is probably no other line of business endeavour in the land in a condition so satisfactory to itself. Certainly, no one hears of anyone going out of the tea business, as in coffee, for instance, according to rumour, and the envy of the coffee men is often heard. A 'slump' by this time has often been prognosticated, but with 8-10ths of the stock sold, leaving only 2-10ths to do a half year's business in, this seems improbable. The tea men have disposed in the main of their stock, and it is up to the consumer to pay the bill. Here he should not grumble very much, if at all, for on effecting the purchase of his favourite leaf he will find it cheaper, even though only a little. Thus he will not feel he should stint himself in tea drinking, and the largely increased stock of tea in the land should find its way into the teapot, making room for the 1903 crops. An oddity and at the same time a somewhat portentous sign is the presence of England in our own market as purchaser of tea. The Englishmen even outbid us in our fancy bidding, and the fear is that they will leave us no tea of the kind so much liked here—the greens. The market is certainly being complicated and into unusual strength, and that too from a source that has been a fretful complainant of a plethora of tea of Colonial growth. Surely this world is one of strange and unexpected compensations, and if the consumer does not object too hard, why, as they say, 'let her go Gallagher.'—With reference to

THE DEATH OF MR NORMAN LAYTON

should be noted that on the assembling of the members of the tea trade at the opening of the auction last week, Mr W T Wilson (of Messrs Gow, Willson, and

Stanton) said: "Since we last met in this room death has claimed one of the most respected men in our trade. I refer to Mr James Norman Layton, who died on Thursday, January 22. I am sorry that fate has so decreed that I should be the first to occupy this chair today, as I feel sure that there are many gentlemen who will be following me who are far more eloquent, and therefore better able to extol the many virtues of this most estimable gentleman. I understand that Mr. Norman Layton has had a career in the tea trade extending between fifty and sixty years, and, speaking for the latter half of that time, I know, from personal experience, that he has made none but friends. Gentlemen, when I say that he was a just and honourable man, a friend to his fellow-workers when in trouble or distress, and a perfect gentleman in the highest sense of the term, I feel that I have but inadequately expressed the views and sentiments we all hold of our dear friend Norman Layton." It was the wish of all present that a letter should be sent to the widow and family of the deceased gentleman, expressing the deep sympathy felt for them by the entire trade in their sad bereavement. This was accordingly done.—*H and C Mail*, Feb. 6.

COFFEE GROWING IN NEW SOUTH WALES.

A new industry is now started in New South Wales, and one that should prove very profitable—coffee growing. It is an industry that might be well gone in for in the northern portion of this state, where it might do well, as there is a good summer rainfall. The coffee plantation in New South Wales is at Walbin Island, on the Clarence river. This year the harvest is about 40,000 lb. of berries. The trees are now about ten years old, and yield about 50 lb. of berries per tree, or about 15 lb. of the prepared article. The trees begin to give a return at about four years old.—*Western Mail*, Feb 14.

TEA COMPANY MEETINGS.—Several Tea Companies held their annual meetings on the 21st Feb., and in some cases at any rate the results for the past year were not up to expectations. The Kelani Valley Tea Garden has had a very disappointing year and was no less than 48,855 lb. short of the original estimate of crop. This was due to a very severe attack of *Helopeltis* affecting some 203 acres of the tea in bearing and also to the unfavourable character of the N. E. Monsoon. No dividend was declared but R8,178'36 was carried forward. The Knavesmire Company Ltd. had three bad months but were able to declare the same dividend as last year, namely four per cent. Green tea is to be started here and with the prospects of rubber the future of the company looks encouraging. The Templestowe Company Ltd. also, in common with many other companies, experienced a shortage in crop but were nevertheless found at the end of the year with R15,963'38 for disposal. Of this R651,6'00 went in the payment of a dividend on the Preference shares, R4,926'00 in the payment of a 3 per cent dividend to the ordinary shareholders. R4,000 was transferred to Depreciation account and a balance of R521'38 has been carried forward. The dividends of these companies, with those of last year, for the purpose of comparison, are:—

THE DONNYBROOK TEA COMPANY, LIMITED.

REPORT OF THE DIRECTORS.

The Directors beg to submit a Statement of Accounts for the year ending 31st December 1902, duly audited.

	ACREAGE.	
	Donnybrook	Mitford
Tea in full bearing	112 acres	37 acres
Tea in partial bearing	40 acres	108 acres
Tea not in bearing	—	7 acres
	152 acres	152 acres
304 acres cultivated in Tea		
4 acres forest		
67 acres Chena, Patua and Waste land		
Total... 375 acres		

The Crop secured amounted to 146,199 lb of Green Leaf as against an estimate of 200,000 lb. Of this 126,244 lb was sold as Green Leaf realising R8,205.75 while the balance was manufactured in the Norton Factory and sold in the local market, viz. 4,989 lb made Tea, at an average price of 38 cts. per lb. nett. The balance at Debit of Working account after providing for Legal expenses, Visiting Agent's fees, and all other charges, amounts to R3,531.60, which amount has been transferred to Property Immoveable. The estimate for Crop season 1903 is 50,000 lb of made tea to be produced at a cost of 37.02 cts. per pound, and the result of the year's working, estimating the Crop to nett 32 cents per pound is likely to show a loss of R2,510, for which provision will have to be made. In terms of the Memorandum of the Articles of Association of the Company Mr G P Fuller retires from the Directorate but is eligible for re-election. Mr Shakspeare who is leaving the Island also retires and does not seek re-election. The appointment of an Auditor for the current year rests with the Meeting.

KIRKLEES ESTATE COMPANY, LTD.

THE REPORT OF THE DIRECTORS.

DIRECTORS:—Messrs, G H Alston, John Gordon and Hon. Mr. W H Figg.

ESTATE SUPERINTENDENT:—Mr. J Armitage Ogden.

ACREAGE: 31st December, 1902.

Tea in bearing ..	435 acres.
Do partial bearing ..	13 "
Tea clearings ..	10 "
Timber and Cardamoms ..	129 "
Grass and uncultivated land ..	140 "
Total ..	727 acres.

The Directors now have to present to the Shareholders the accounts of the Company for the past year. The Crops secured amounted to 175,591 lb. Tea, including 6,996 lb. manufactured from purchased leaf, and 2,887 lb. Cardamoms. The nett price realised for the Tea was 36.34 cents per lb., as against 34.18 cents in 1901, and the Cardamoms sold realised 83.10 cents per lb. nett. After providing for depreciation of buildings and machinery and paying the 7 per cent dividend on the preference shares, the profit on the year's working amounted to R13,024.48, equal to 12.02 per cent on the paid up Capital of the Company, to which has to be added the balance of R976.47 brought forward from 1901, less R140.79 over-estimated for produce unsold at the end of that year. There is therefore available a sum of R12,860.16, out of which the Directors have decided to set aside a further sum of R500 to the coast advance reserve account as a provision for doubtful debts, and out of the available balance of R12,360.16, they now recommend the payment of a final dividend of 7 per cent, making with the interim dividend of 3 per cent paid, on 5th August last, a total of 10 per cent for the year, leaving a sum of R2,360.16 to be carried forward to the current sum of R2,360.16 to be carried forward to the current season's accounts. The only expenditure on capital

account during the past year was R292.50 for the purchase of ac. 9: 3: 38: land. The estimated crop, this year are 165,000 lb tea and 3,000 lb cardamoms on an expenditure of R46,300. In terms of the articles of Association, Mr G H Alston now retires from the Board, but is eligible for re-election. The appointment of an Auditor for the current year rests with the meeting.

THE VOGAN TEA COMPANY OF CEYLON, LTD.

DIRECTORS:—Messrs R W Harrison, V A Julius and E M Shattock.

The Directors now beg to submit to the Shareholders their Report and Accounts for the year ended December 31st, 1902. The Estimate of crop on Vogan and Iddagodde was 400,000 lb. of Tea, while the actual quantity secured was 362,355 lb., the shortfall being due to the abnormal absence of sunshine experienced during the last four months of the year. From bought leaf 15,231 lb. were also manufactured, making a total of 377,586 lb. which cost to place in Colombo 23.43 cents, and realized a nett average price of 32.92. Included in the Expenditure is a sum of R1,700.99, which has been spent in the upkeep of the Rubber clearings, and in laying down Albizzia nurseries. On Stamford Hill and Barkindale the crop for the year was 100,752 lb against an Estimate of 100,000 lb., the Tea costing, after deduction of profit on manufacture of outside leaf, 22.83 cents in Colombo, and realizing a nett average price of 33.13 cents. The following table, shewing the crop, cost and average price realized for the past five years, is appended, and will no doubt be found of interest.

	Crop.	Cost.	Price realized.
1898			
Vogan and Iddagodde ...	353,837	20.22	34.00
Bought leaf ...	30,929		
Stamford Hill and Barkindale ...	100,712	25.53	43.90
1899			
Vogan and Iddagodde ..	386,609	20.15	36.81
Bought leaf ...	2,523		
Stamford Hill and Barkindale ..	95,286	22.17	45.30
1900			
Vogan and Iddagodde ..	462,899	21.40	30.34
Bought leaf ...	20,268		
Stamford Hill and Barkindale ..	107,474	23.42	39.94
1901			
Vogan and Iddagodde ..	334,448	23.62	32.23
Bought leaf ...	15,383		
Stamford Hill & Barkindale ..	82,640	20.90	42.20
1902			
Vogan and Iddagodde ...	362,353	23.48	32.92
Bought leaf ...	15,231		
Stamford Hill & Barkindale ..	100,752	22.88	38.13

After payment of Interest on Debentures and all other charges, the amount of profit earned is R11,834.55 to which must be added the balance of R120.10 brought forward from the previous year, making a total of R11,954.65 available for distribution. This amount the Directors recommend should be apportioned as follows:—

By the redemption and cancelment of R. c.	
20 Mortgage Debentures of R500.00 each absorbing ..	10,000 00
By the payment of a Dividend of 4 per cent for the year ..	23,000 00
By the payment of a bonus to the Vogan Superintendent of ..	500 00
By the payment of a bonus to the Stamford Hill Superintendent of ..	500 00
By placing to Depreciation Account..	2,500 00
By carrying forward to next Account..	451 65
	41,954 65

Rubber continues to make satisfactory growth, and it is proposed to plant up a further 15 acres in this product during 1903. The acreage of the Company's properties is as follows:—

	A.	R.	P.
VOGAN AND IDDAGODDE.			
Tea in full bearing over 4 years ..	658	3	33
Tea in partial bearing under 4 years	119	0	10
Tea under 2 years old ..	25	0	0
Rubber ..	10	0	0
Reserve ..	515	1	38
	1,328	2	1
STAMFORD HILL AND BARKINDALE.			
Tea in full bearing ..	220	0	0
Total Acreage..	1,548	2	1

In terms of the Articles of Association Mr. R. W. Harrison retires from the Board of Directors, but being eligible, offers himself for re-election. It will also be necessary to elect an Auditor for 1903.

UNION ESTATES COMPANY, LIMITED.

REPORT OF THE DIRECTORS.

DIRECTORS:—Messrs W D Gibbon, F L Clements, G H Alston. ESTATE INSPECTOR.—Mr W D Gibbon. ESTATE SUPERINTENDENTS.—HAYES GROUP: Mr R J Trimen. DEE ELLA: Mr W L Vanderslott.

ACREAGE.

	Tea in full bearing.	Tea in partial bearing.	Cocoa.	Cardamoms.	Total Cultivated.	Grass Jungle and Waste Land.	Total.
Hayes Group	509	3	...	30	542	1,669	2,211
Dee Ella	243	..	81	..	324	162	486
	752	3	81	30	866	1,831	2,697

The Directors submit herewith to the Shareholders of the Company the Report and Accounts for the past year. The Crops secured on Dee Ella were 65,606 lb Tea, 162 : 3 : 17 : cwt Cocoa, 21,173 Coconuts and small quantities of Vanilla and Pepper; the Tea realized 30.81 cents per lb and the Cocoa sold R31.04 per cwt nett as against 30.69 cents and R33.15 respectively in 1901. The crops from Hayes Group amounted to 253,787 lb. Tea and 1,741 lb Cardamoms realizing nett 27.45 per lb Tea and 81.20 cents per lb Cardamoms sold, as against 30.71 cents and R1.14 respectively in 1901. The shortfall in tea crop was due to the very unfavourable weather experienced on both Estates during the last four months of the year and to attacks of Helopeltis on some of the lower fields on Hayes Estate, which seriously affected the crop there. Every step is being taken to deal with this pest. The amount at debit of Profit and Loss Account at the end of 1901, R830.55 was reduced by R450.08 realized in excess of the estimated value of balances of crops then unsold, leaving R380.47 to be brought forward to debit of 1902 accounts. To this must be added the balance of R1,638.74 loss on 1902 working account. The only Capital expenditure during the past year has been the instalments due for the construction of the Hayes Road amounting to R6,776.07. There is now only one further instalment of R3,291.24 due on 30th June, which will complete all expenditure on this Account. The Estimate for 1903 is 323,820 lb Tea, 180 cwt Cocoa, 30,000 Coconuts and 2,000 lb Cardamoms, on an expenditure on Working Account of R91,509.99. During the past year the Hon Mr W B Figg resigned his seat on the Board of Directors and the vacancy has been filled by the appointment of Mr F L Clements. In terms of the Articles of Association, Mr W D Gibbon retires from the Office of Director, but is eligible for re-election. The appointment of an Auditor for the current year will rest with the Meeting.

THE COLOMBO TEA TRADERS' ASSOCIATION.

INCREASED SAMPLING ALLOWANCES; THE WEIGHT OF PACKAGES, AND FALSE PACKING.

The Annual General Meeting of the Colombo Tea Traders' Association was held at the Chamber of Commerce Rooms on Feb. 27th. The Hon. Mr. Stanley Bois, Chairman of the Association, presided, and there were also present:—Hon Mr J N Campbell, Messrs G H Alston, J G Wardrop, A Thomson, A H Ayden, H J Scott, J H Adams, S Brown, A Pridaux, W Shakspeare, E R Waldock, G Croll, A W Willis, S O Jones, A F West, O M Aste, F M Maekwood, W Somerville, H M Waldock, W E Keell, W P Ampenoff, A O'dell Figg, W E Mitchell, A R A Heath, H B Phillips, Gordon Frazer, A H Barber, H E Day, Seymour P Jeffery, Dyer, A O Rainnie, D Edwards, H Walthew, C W Booty, Alexander Fairlie, A E Lubbock, L O Leefe, C M Wright, G A Ginn, E Webb, E B Walker, W E Drury, J Lochore, R Davidson, W R Sands and W Bartlett.

The minutes of the previous meeting were read.

THE ANNUAL REPORT.

Your Committee have now pleasure in presenting to you their Report and Accounts for the past year.

MEETINGS.—Three General Meetings have been held during the period under review, the first being the usual Annual General Meeting, a report of which appeared in the local press, on the 28th February last; the second being an Emergency Meeting on 30th May to discuss the operation of the increase in the Cess, which was to become law on the 1st June; and the third also an Emergency Meeting on the 9th December, to decide the dates of the two last Sales of the year. Your Committee have, in addition, met frequently to consider several matters of interest which have been brought to their notice.

PROSECUTION OF MELBOURNE TEA IMPORTERS.—This incident, which has been ventilated in the local press, was directly dealt with by the Chamber of Commerce, with whom, however, your Committee have kept closely in touch. From correspondence which the Chamber has had both with the Ceylon Government and the Melbourne Chamber of Commerce, it would appear that the prosecutions referred to were the immediate effect of a Custom's Ordinance which is open to criticism, rather than of an arbitrary interpretation of such Ordinance by the Melbourne Minister of Customs. The Australian and Colombo Tea Trades are in sympathy on this question, and it is to be hoped that further efforts to secure an amelioration of so stringent an Ordinance will meet with success.

PATENT PACKAGES.—The Agents of Australian Mail Steamers have been approached with the object of securing an alteration in the Bill of Lading. Instead of the weight of a package being limited to 100 lb. nett, it is suggested that it should be 130 lb. gross, thereby removing a disability from patent packages, which are constructed to contain over 100 lb. nett. The proposal was referred to your Committee, but did not meet with its support.

SAMPLING ALLOWANCE.—Owing to the increase in the number of buyers and the larger demand for samples for foreign countries, there is a feeling that the small samples now being distributed in the Port are insufficient, and a suggestion has been put forward that the sampling allowance should be increased from 3 to 5 lb. A resolution to that effect forms part of the business to be brought forward at the annual general meeting.

FALSE PACKING.—A flagrant case of false packing, which was fortunately discovered before shipment, was brought to the notice of your Committee lately, who decided upon legal action if such could be pursued with any hope of success. The lawyers were, however, not encouraging, with the result that two further measures will be introduced at the general meeting, intended to protect the Trade against a recurrence of false packing or cognate malpractices.

GREEN TEAS.—A noteworthy feature of the past year has been the increasing demand for Ceylon Green Tea which has been greatly stimulated by the high prices ruling in America for China and Japan Teas. While 2,796,844 lb. were exported during 1902, it is estimated that over 10 millions will be shipped this year; and there is every probability that, in future, Green Teas will become an important factor in the Tea Trade of Ceylon.

The total exports for the year were, as per Chamber of Commerce Returns:—

	1901.	1902.
United Kingdom ..	103,543,932 ..	105,734,570
Australia ..	13,718,794 ..	20,641,134
Russia ..	11,727,068 ..	9,653,896
America ..	7,016,593 ..	4,502,131
Other Countries ..	7,984,854 ..	5,767,237
Total ..	148,991,241	146,299,018

Totals for 1900 and 1899:—

1900 ..	118,431,639
1899 ..	129,894,156

The following figures show the quantity offered locally in public sale for the last four years, with the average prices obtained for complete invoices sold:—

1899	33,377,318 lb	Average 38 cents
1900	47,681,826 do	do 34 do
1901	51,044,000 do	do 33 do
1902	55,835,478 do	

The following formed the Committee for 1902—The Chairman of the Chamber of Commerce (*ex-officio*). **BUYERS.**—Messrs Tarrant, Henderson & Co., Messrs Rodewald & Heath, The Trading Co. (Successor to A G A K & Co.), F F Street, Esq. **SELLERS.**—Messrs J M Robertson & Co., Messrs Whittall & Co., Messrs Bosanquet & Co., Messrs George Steuart & Co. The number of members belonging to the Association is 45, same number as in the previous year. The accounts for the past year made up to 31st December, 1902 and submitted to you duly audited, shew a credit balance in hand of R1,564 34. Mr J A McGillivray deserves the thanks of the Association for his voluntary audit.

THE CHAIRMAN'S SPEECH.

The CHAIRMAN said:—In rising to move the adoption of the report and accounts for the past year I do not need to detain you long, fortunately, because there is a considerable amount of business before us today. A retrospect of the past is always interesting, but it is the future towards which our eyes continually turn and it is with great satisfaction I am able to congratulate the Trade generally and producers, and sellers in particular, on the improved prospects of the tea trade, though I am sorry Reuter has not enabled me to announce the eightpenny average. We should soon be getting it as it is now in the immediate vicinity and, perhaps, before long we may be able to top that figure even. The report before you first treats of the question of the

PROSECUTION OF MELBOURNE TEA IMPORTERS, which was a matter which the Chamber of Commerce and also this Association has had before them, and it has been thoroughly ventilated

in the local press. From a perusal of the voluminous documents sent us in connection with the case, it seems evident that in the wording of one of the local Acts, tea was pronounced as unfit for human consumption if it contained anything over 8 per cent ash. The tea in question was alleged to have contained 8½ per cent ash and consequently there was no course but to put it out and that was done. I think we can depend on the tea dealers of Melbourne taking all the necessary steps. The Chamber of Commerce and this Association have not, however, lost sight of the matter and will act as they see best. It is a delicate question to interfere with the fiscal arrangements of any Colony, or appear to interfere with them. As regards the

PATENT PACKAGES

notice of a special resolution has been given for discussion at this meeting and I will not anticipate discussion on the matter. I would only say with regard to the resolution that there are various difficulties in the way when we bear in mind that the object of the steamship Companies is strictly to limit the amount in a tea chest to 100 lb net, and this resolution does not adequately provide for that difficulty. That will no doubt be fully discussed. A similar remark might also be applied to the question of

SAMPLING ALLOWANCES

in regard to which a special resolution will be brought forward. I think, however, there can be no doubt this resolution is brought forward in conformity with the growing requirements of the trade. There seems to be no doubt that the quantity sent to each buyer is inadequate to enable him to arrive at a fair valuation of the tea and in these circumstances, speaking as a seller, I would be prepared to agree to an increase in the quantity, but whether that increase should be from 3 lb to 5 lb remains to be seen. As regards the paragraph in the report

"FALSE PACKING"

there is also a special resolution to be brought forward to deal with the matter, and I do not need to anticipate discussion on the matter.

GREEN TEAS.

The growth in the trade has been most marked and most satisfactory. It is regrettable—I think this is a matter I referred to at last annual general meeting of the Association—that we do not seem to get the figures from the Cus toms to tally with the amount on which cess is paid by the Planters' Association, and I can only suppose that it is due to the carelessness of Firms, exporting clerks, or some other reason. The difference between green and black tea is not mentioned in the Bills of Lading, and I would ask you to assist us in getting accurate figures in by seeing that your subordinates discriminate in the Bills of Lading between Green and Black Tea.—Proceeding next to deal with the

TEA EXPORTS FOR THE YEAR

the Chairman said:—We exported 2 million less to the United Kingdom and 2 million less to Australia, but against this we sent 2 million more to Russia, 2½ million more to America and 2 million more to other countries. Taken in conjunction with the considerable increase over last year in the local sales is very gratifying. The local sales in Ceylon were during 1902, 6½ million lbs. above that of 1901 which was in turn 3½ millions in excess of 1900. It is evident we

have to congratulate ourselves on the very healthy state as regards the local market and I trust its extension will continue as, I think, it doubtless will if justified by the results obtained by those offering tea locally. As regards

YOUR COMMITTEE

the voting papers have just been opened by the Committee in virtue of rule 8, and have resulted in the election of the following:—Buyers: Messrs Rodewald and Heath, the Russian Trading Company (Mr Ampenoff); Cro-field, Lunpard & Co; Mr F F Street. Sellers: Messrs J M Robertson & Co.; Messrs George Stenart & Co.; Messrs Whittall & Co.; Messrs Bosanquet Bros. which, I think, is substantially the same Committee you had last year.

THE ACCOUNTS

are of the simplest description and leave no comment for me except to point out their satisfactory condition. The last matter—or practically the last matter dealt with is the

NUMBER OF MEMBERS BELONGING TO THE ASSOCIATION,

which is 45 and, I am glad to say, there are six further firms which have been elected at last meeting of the Committee making in all 51 members. On looking into the constitution of the membership of this Association—I took the trouble to analyse the constitution this morning—I find there are 5 brokers, members; 16 firms, who are solely and simply buyers; 9 firms solely sellers and 15 firms, who are both. Now I have no hesitation in saying the bulk of these firms are interested, both buyers and sellers are interested, in every stage of the tea planting industry of Ceylon. It nevertheless occurs to me that we might with great advantage to ourselves

BROADEN THE BASE OF OPINION

on which this Association rests and on which it formulates the requirements of the trade; and I would suggest as the best means to this end that we should invite the Chairman of the Planters' Association and the Planting Member of Council to become in future as *ex officio* members of this Association. I am sorry this did not occur to me in time to put it forward as a resolution today at this meeting, but I throw out the suggestion now as I feel it would strengthen our hands materially and keep us better in touch with opinion upcountry. On the other hand it would enable our upcountry friends to keep in touch with the conditions of the trade in Colombo and prevent many misunderstandings arising—which, although, I am glad to say, we have successfully avoided them in the past, we wish to give every facility for avoiding in the future. I need hardly point out, gentlemen, that we owe our

PRESENT POSITION IN THE MARKETS OF THE WORLD

to the unity, combination and to the heartiness with which every one—from the producer and seller to the buyer and distributor—has worked together in the past to put the Ceylon tea trade at the head and front of the tea trade of the world and I feel sure everything we can do to assist this policy will be of the greatest service to the trade in the future. With these few remarks, I beg to move the adoption of the report and accounts for the year ended December 31st, 1902. (Applause.)

Mr S P JEFFERY—(of Messrs Lipton, Limited)—I have much pleasure in seconding the adoption of the report and at the same time congratulating the Chairman and Committee on the satisfactory year that has just passed. (Applause.)

THE GENERAL COMMITTEE.

The General Committee was formally appointed, the names of which were given by the Chairman in his opening speech.

TEA TRADERS' HOLIDAYS.

The CHAIRMAN:—The next item on the agenda is the question of the Tea Traders' Holidays for the present year. It is proposed in accordance with our usual practice for the past year or two, to omit the sales on 15th April and 30th September. On December 16th the sale will be held as usual and a supplementary sale on December 18th, closing the catalogue on the 14th and making the first sale of the new year on 5th January, the catalogue to close on 30th December at 4 p.m. If you recollect some little time ago we decided that these dates should be settled at the general meeting, and I trust that if you have any objection to these proposals of the Committee—they are merely proposals—you will take this opportunity of putting them forward.

Mr DRURY—(Messrs Forbes and Walker)—Mr Chairman, in connection with these holidays, I would like to suggest that we revert to the system of the holidays being settled by the Committee—with the exception of one point—the December holiday. At X'mas last year a great deal of trouble arose which is still fresh in the minds of us all. I think, the Committee arrange the holidays, it will be much more satisfactory.

The CHAIRMAN—said that these dates were fixed now in order that they might be advertised well in advance. There was some trouble last year in the December holiday, but that was due more to a mistake in regard to the closing of the catalogue. There was also the question of writing home, because if there was no sale their home houses would require to be informed and it might save telegraphing and other expense. The Committee would have no objection to undertaking the responsibility but at the same time it was discussed in a general meeting and considered these holidays should be fixed at the general meeting.

Mr. ALSTON—(Messrs Whittall & Co.)—seconded the suggestion of the Committee as put forward by the Chairman.

The CHAIRMAN:—I take it you are seconding the original proposal. Mr. Drury, previous to that being seconded, made a suggestion which I believe is to be an amendment—that the matter should be left to the Committee. If nobody seconds that, it falls to the ground and we deal only with the original motion.

No seconder to Mr. Drury's amendment being forthcoming the original motion was put to the meeting and carried.

INCREASED SAMPLES.

The CHAIRMAN:—Before calling on Mr. F. F. Street to propose the resolution standing in his firm's name I would like to read the following letter received from the Planters' Association:—

The Secretary, Colombo Tea Traders' Association Colombo.

DEAR SIR,—Your letter of the 16th instant having been duly read and considered at a recent meeting of the Committee of the Planters' Association of Ceylon, I now write to ask you to bring under the notice of your Association the annexed copy of resolutions passed on the subject of the resolutions to be brought forward at the annual general meeting of the Colombo Tea Traders' Association.—I am, dear Sir, yours faithfully,
A. PHILIP, Secretary to the Planters' Association of Ceylon.

Kandy, Feb. 23rd, 1903.

(Resolution referred to.)

"That as regards Resolution 4 in the advertisement notice of the meeting of the Colombo Tea Traders' Association the Committee of the Planters' Association considers that the value to be deducted from the sale proceeds should not exceed the present charge. (11). That as regards Resolutions 4, 5 and 6 the Committee of the Planters' Association considers that in their present form they appear to be detrimental to the interests of the Producers."

Mr J. H. ADAMS—(Messrs F. F. Street and Co.)—with your permission I should like before moving the motion to alter the increase to read from 3 lbs. to 4 lbs.

The CHAIRMAN:—I suppose the Association will have no objection to permitting the mover to substitute 4 lbs. instead of 5 lbs?

Mr. J. H. ADAMS—then moved the motion standing in the name of Mr. F. F. Street, which amended read as follows:—

"That in view of the increased number of buyers and the demand for extra samples for foreign markets, it is desirable that the sampling allowance for big breaks be increased from 3 lbs., as at present, to 4 lbs."

In doing so he said that since the resolution had been published there had been a lot of discussion on the matter and he thought sellers generally had come to the opinion that 4 lb. would be quite enough for the trade but at the same time they allowed that 3 lb. was hardly a sufficient quantity to give adequate samples. In Calcutta the sample was $\frac{1}{2}$ lb. and he believed buying brokers got 1 lb. each. In London they got larger samples and in China they used to get 1 lb. At the present moment in Ceylon there was never a sample left after the sale for the buyer or for other firms who wanted to send a sample away.

Mr. S P JEFFERY—(Messrs. Lipton, Ltd.)—in seconding the motion, said that he thought from the resolution passed at the Committee Meeting of the Planters' Association that they were inclined to overlook the fact that all the tea sold on the local market contained absolutely net weight. He had some experience in re-packing and his experience was that if there was a gain it was on the wrong side. With regard to tea packed for London he thought it was the custom to pack a little for what weight may be lost. His chief reason for supporting the resolution was, however, that the sample they got as buyers was in his opinion too small and he thought that was the opinion of many others. A large sample looks much more attractive, and he thought if they had larger samples to value the teas on, it would be in the producers' favour. On looking at a large sample they were inclined to see the tea in a better light. It is very difficult to get a sample of tea after the sale. He had often tried to get a sample to offer where he thought he could get orders and

he had to leave it because he could not get samples big enough to offer to customers. That was his chief reason and he strongly supported the resolution. He hoped both sellers and buyers would see it was to their interests to support it.

Mr. DRURY—at some length, explained the system of distributing samples and showed the sizes of the tins and the sizes of the packets in which the samples were contained. The brokers drew 3 lb. of tea and they distributed in large breaks 37 samples and in small breaks 39 samples in the trade. They were distributed in this way. 20 of the buyers sent round tins of this sort (showing one) some larger and some smaller. These buyers expected these tins to be filled and for 18 buyers who have no tins they sent samples in paper. The complaint was that if only these 3 lb were to be used they could not fill these tins. In fact some of them are only half filled, and that was where the complaint arose. If filled, 3 lb. would not even go round. That meeting could fix on a standard size of sample or fix a limit. He would suggest a size of box—that used by Messrs Crossfield, Lampard & Co. They could have 38 samples out of the quantity allowed if that box was adopted. A large sample looked better than a small one and it was most certainly to the interests of the seller and also to the interests of the buyer that larger samples be allowed. He would strongly support this motion that 4 lb be drawn and they could get a sample that would please everybody. After they bought, they could get a sample to send to their constituents and a sample which could be used for pushing tea in the various parts of the world, which was a very necessary thing indeed.

THE VIEWS OF THE P. A. REPRESENTATIVES.

The Hon. Mr J N CAMPBELL—said he was not altogether satisfied with the demonstration made by Mr Drury. Of course, he did not put his opinion against Mr Drury's or any of theirs; but he thought the trade hitherto had been supplied by the brokers in Colombo with a sample such as was sufficient and if all the brokers had supplied similar samples he did not think that agitation would have ever been brought before the Association. He perfectly agreed that a good sample ought to be given to the trade and if it was actually necessary that more than 3 lb should be taken he personally had no objection; but the question was "Who is to provide this sample?" Hitherto the seller had borne the whole of the cost of the sample supplied to the trade. Some years ago there was no such deduction made from the invoice as was made now, and that in a way without consulting the producer. When he said "without consulting" the producer he meant that apart from consulting him in that Association the producer was not invited to express his opinion and the result was that buyers received a sample of 3 lb which was paid for by the seller. A further allowance of 1 lb was asked from them, but he wanted to know what became of the 3 lb they already supplied. At present they gave about 100,000 lb to the trade per annum in sampling allowances and now 33,000 lb were asked for the same purpose. He thought it would be only fair that the buyer would be willing to take his share of that responsibility and in future that they (the producers) should be limited to the 3 lb and if further sampling allowance was necessary, the 1 lb or $\frac{1}{2}$ lb—as he was told by some was sufficient—should not be

deducted from the invoice. The buyer, he proceeded, invariably got more than the nominal amount of the invoice. Beside that he got his proportion of the samples drawn amounting on an average to a fortieth part of 100,000 lb. a year, so that it was perfectly reasonable the buyer should allow them 1 lb. against the 3 lb. they were willing to allow. He would ask them to allow him, to add the following words as a rider to the motion:—

“And that the value to be deducted from the sale proceeds shall not exceed the present charge.”

That was the view taken by the Planters' Association and as one of their representatives there he was bound to bring it forward. But it was also his own opinion. With these few words he begged to move that rider which he had just read and he asked them in all fairness to the producer and seller, who was not so largely represented there as the buyer to give that their earnest consideration.

Mr E WEBB—supported Mr Campbell's rider. With regard to extra sampling allowance he thought there was no doubt that more was required by the trade. He had been a couple of years in Mining Lanc himself and knew what was required for a sampling allowance. He thought the brokers should have something to hold over for show. He did not see why the buyer should not bear some of the charge of the sample. As a rule the buyer did not get more than the actual amount of the invoice. He thought that everyone, in order to prevent loss in weight, put in a little more than the actual amount and counting what the buyer annually drew from other samples, he did not think, it would be any unreasonable charge on buyers to let them be responsible for the extra samples.

Mr A R A HEATH—(Messrs Rodewald & Heath)—said he would like to point out the fact that in London they had a pound draft given to them on all teas sold whereas in Colombo they got nothing whatever, but the sample given by the broker and the small sample they got after buying tea. Planters were very anxious to encourage that market, and, therefore, he did not think it was at all an unreasonable suggestion that they should get this sample given them to judge by and also to send samples away to customers. At present in London the buyers got a pound, but here there was nothing at all, and he had many claims for short weights from Australia &c. He was sure there were many buyers there who could bear him out in that. He did not think the present resolution was at all an unreasonable one.

Mr JEFFERY:—I should like very strongly to endorse the point about the draft on teas given in London.

The CHAIRMAN:—I am afraid you cannot speak a second time on the same subject except by way of explanation.

Mr JEFFERY:—I was not going to speak except to endorse Mr Heath's remarks.

Mr G H ALSTON—said that it appeared to him as in the way of every other business, the sellers gave samples of his produce to the buyer. For the trade it was the same. Of course, it was brought forward as regards the London trade that they had to put back a return, but that was not really a return for, in addition to that, 1 lb. was allowed. After the lucid explanation given by Mr Drury of the amount required to give a

fair sample by which buyers could judge tea he did not think sellers should grudge them that sample.

The CHAIRMAN—said with regard to the weight of teas offered in the local sale he had there a letter before him which arrived at the last Committee Meeting, but not in time for any resolution to be brought forward in connection with it. The letter was from Messrs. Tarrant Henderson & Company who stated:—

The Chairman, Tea Traders' Association, Colombo.
Dear Sir,—For some time past we have noticed that the packages of tea offered for local sale, particularly under initial marks, are very often of very inferior wood and the tea on examination proves to be badly fired and is frequently short in weight.

We shall be glad if you will circulate this letter with the object of eliciting from other buyers if their experience is the same as our own, and if this is so would ask the Association to endeavour to take such steps by making this known publicly, as will improve matters.—Yours faithfully,

TARRANT, HENDERSON & CO.

Colombo, 13th February, 1903.

Proceeding the Chairman said it was an advantage to have that before them, so that if such a state of things existed they might do something hereafter to remedy it. He would also like to state—though it might not be absolutely in order it appeared in an interesting manner on that subject that a letter had been received from Mr Edgar Turner, who was a member of that Association. He says with regard to this particular question:—

In your rules and regulations corrected to March 1896, I find 39 members, corrected to April, 1902, 43 members (including 3 up-country members who do not draw samples), so that we do not see the necessity of increasing the sample allowance. You may remember that the sampling allowance when initiated was not liked by the sellers, on the ground that in a few years the trade would be asking for more and more.

Our fears were justified, and unless the movers of resolution No. 4 can show strong reasons for the increase it will cause dissatisfaction.

Should, however, it be the general wish of the trade, and they show the necessity of the increase in the seller's interest I trust it will be on a sliding scale. Say all breaks of 300lb. and under 1lb. samples be drawn, and samples seen at selling broker's office.

2 lb. allowance up to	...	800 lb.
3 " " "	...	1,200 lb.
5 " " " over	..	1,200 lb.

This sampling allowance he thought—he was subject to correction by the mover of the resolution—was intended only to apply to breaks of 1,000lb and over.

Mr. ADAMS—signified that that was so.

The CHAIRMAN proceeding said the amendment suggested by Mr CAMPBELL and seconded by Mr WEBB would read:—

“That in view of the increased number of buyers and the demand for extra samples for foreign markets, it is desirable that the sampling allowance for big breaks be increased from 3lb. as at present, to 5 lb. and that the value to be deducted from the sale proceeds shall not exceed the present charge.”

The amendment was first put to the meeting when there voted for it only the mover and second.

The original motion was then put and declared carried.

A MEMBER—asked if the style of sample suggested by Mr Drury was to be agreed upon. He thought it would simplify matters for the Brokers if it were adopted now. The tin, Mr Drury had shown them, was he thought generally considered a good one.

The CHAIRMAN—replied, he thought that was a matter that might safely be left to the Committee. It was a matter that could not very well be determined at a general meeting.

FALSE PACKING.

Mr. GORDON FRAZER—(MESSRS. GORDON FRAZER & Co)—moved the following resolution standing in his firm's name :—

“That no teas may be put up for sale at the Chamber of Commerce Sale-rooms except through members of the Colombo Tea Traders' Association. Other teas may, however, be offered on sale provided that they are guaranteed by the selling Broker as first hand teas on Garden Account, or provided that they be first bulked and repacked in the store of a *bona fide* member of the Association and there remain pending delivery.”

He said that his experience in regard to a lot of tea purchased by him at the sale on 21st January made him consider the steps of which that resolution was the effect and he thought when they heard what these experiences were they would agree with him that some such thing as was provided by that resolution was absolutely essential for the credit of shippers, the good name of Ceylon generally and the tea estates of the Island particularly. Briefly the circumstances were these. At the sale on 21st January he purchased 18 chests of tea, containing 1,780 lbs. The sample on which this purchase was made was a tippy, well made broken pekoe. Some of the packages were opened in his stores and the tea appeared perfectly up to sample, but by what he might term a dispensation of Providence that tea was required for blending and it became necessary to turn up the whole of it. This turning up displayed a most flagrant example of false packing. For the first 4 inches from the top of the chest the tea was perfectly the same as the sample, but underneath was the mixture of cheap souchong and dust. A deliberate fraud was attempted. The packages were treated in the same way at the bottom so that in the event of the chest having been opened the wrong way up the fraud would not have been detected. Now he asked them what would be the effect on the kind of an American or colonial buyer, if that tea had been opened by him in that condition. His credit in that quarter would receive a severe shock and also the credit and good name of Ceylon through him would similarly suffer. They could not tell how many cases like this had actually gone through and he thought that to think that was a singular case would be assuming too much. He might also tell them that instead of 1,870 lbs. the actual contents of these chests was only 1,820 lbs. That showed the disease, now for the remedy. The Committee of that Association obtained legal advice on the matter and the advice so obtained was such that no action was taken. It was considered difficult to secure legal proof. It, therefore, behoved them to take some steps for the protection of individual shippers and Ceylon tea estates and the reputation of the trade in the Island generally and he thought that resolution the best way of meeting the difficulty. They would observe that tea sold on garden

account was, in no way, affected by that resolution. If they adopted that resolution they did so as much on behalf of the estate proprietors as the merchants whose interests in that matter he considered, were identical. (Applause). Personally he did not think they should do much to encourage mixed lots of tea, once they had passed the hammer, to make their appearance on the catalogues again. He did think buyers should have some guarantee as to where the lots they purchased were packed. In the case of estate teas they knew they were packed in the estate factories and with that guarantee they were perfectly satisfied, but in the case of other teas they had no such guarantee. That was the reason for the resolution, and he did not think its terms were too strong. Another advantage it would have was that it would make the disposal of stolen tea more difficult to those exploiters of this particular branch of the tea trade in Ceylon. (Laughter). He remembered one fine day a cart-load of tea going a missing between the Colombo godowns and his stores. Unfortunately they knew that was not an unique case. From all points that resolution was calculated to benefit both producer and seller and both in their own individual interest and for the credit of Ceylon which they all prized so highly, he moved that resolution which he strongly recommended to their support. (Applause).

Mr. HERCULES SCOTT—(MESSRS. BOSANQUET & Co)—said he had much pleasure in seconding the resolution. He was extremely sorry to hear from the letter read by the Chairman that the Planters' Association Committee had passed a resolution that resolutions 4, 5 and 6 were opposed to their interests. He could assure the representatives of the Planters' Association present that in seconding that motion, he had done so he considered more in the interests of the producer and the sellers than he had in the interests of the buyers. He could not see anything opposed to the producers or the sellers or anything that put the slightest resolution upon them. (Hear, hear.) He spoke approvingly of the terms of the resolution and the advantages it offered and concluded by stating that they had not brought forward that resolution except with the idea that it was in the best interests of producers. (Hear, hear.)

Mr. E WEBB—said he did not see any objection why that motion should be opposed by the producer. It seemed in their interests.

Hon. Mr. J N CAMPBELL—said that as the name of the Planters' Association had been mentioned he might explain that when their resolution was passed the second part of the motion before the meeting had not been published. Very naturally they objected to the first part of the resolution by itself because that would confine the sale to the Tea Traders' Association, but with the addendum they had now added, he did not think the Planters' Association would object. He would like to ask what was a *bona fide* member? He did not see the difference between a *bona fide* member and an ordinary member of the Association. (Laughter.)

The CHAIRMAN—I don't think the mover of the resolution will have any objection to those words being deleted.

Mr. GORDON FRAZER :—Not at all, Sir.

The CHAIRMAN—said that before he put the resolution to the meeting he thought it was only

fair he should read to them a few remarks from a letter which had been sent to them by Messrs. J T de Saram and D B Seneviratne who were native buyers, in that market. Proceeding the Chairman quoted largely from the following letter:—

A PROTEST BY NATIVE BUYERS.

63, Maliban-street, Pettah, Colombo. 16th Feb. 1903.
F W Waldoek, E-q, Secretary,

Colombo Tea Traders' Association, Colombo,
Sir,—On behalf of the native sellers and buyers who patronise the Weekly Tea Sales held at the Chamber of Commerce, allow us to take objection to the suggested introduction of certain new rules forming the subject of the 5th and 6th Resolutions to be proposed at the Annual General Meeting of the Colombo Tea Traders' Association to be held on the 27th inst. We humbly beg to submit that if the proposed rules be passed and adopted by your Association they will involve great hardships on native sellers and buyers of Tea, and such rules will not in any way improve the Tea market, nor will they on the other hand be conducive to the benefit of the European Tea grower or planter.

As far as we could see, the adoption of these rules will only benefit the Broker, who will have to be paid an extra commission for buying Tea at the Chamber of Commerce Tea Sales for native dealers. The other alternative allowed for the native seller is that their Tea should be bulked and re-packed in the stores of a *bona fide* Member of the Colombo Tea Traders' Association, which would be an expensive process as far as the native seller is concerned, and ultimately the benefit accruing from this will also result only in the advantage of the European Storekeeper. The native dealer has to sell his Teas cheaper than his European brother, and that he should be mulcted in extra brokerage or commission as a result of these rules coming into force would be very unfair and would absorb altogether the little profit he makes. These rules would therefore be an infliction principally on the Colombo Tea Traders' Association, on the native sellers and buyers, and they appear to be framed with the object of restricting natives dealing in Ceylon's staple without any justification whatever for so doing. A good proportion of the Teas purchased by the natives at the auction sales are used for local consumption. The local retail dealers get their supplies of Tea from those who purchased at the Tea sale of the Chamber of Commerce. And under the new rules, Tea for these dealers could only be obtained at an extra expense. This would be an unnecessary additional tax on the local consumer. Finally, we beg to submit that there is no necessity for the innovations contemplated. It has been the custom for many years for natives to offer and buy Teas at these Sales. The conditions of sale which now obtain at these Sales have not been found wanting—wanting in the sense as to make any invidious improvements affecting the native dealer only. If these rules have been suggested by any other motive, such as the prevention of fraud and deception in the packing and bulking of Tea by the *native seller only*, we beg to state that the 7th clause of the existing conditions of sale is quite ample to meet the case, and that under this clause any Tea not properly offered could be rejected. (We beg to inform you that a copy of this letter has been sent to the Chairman of the Ceylon Chamber of Commerce and for the reasons already urged, and for other reasons, we trust that the proposed rules will not be passed by your Association towards which end we solicit your co-operation by duly presenting this letter before the meeting on the 27th instant.—We beg to remain, Sir, Yours faithfully,

(Signed.) J. T. DE SARAM.

{ " } D. B. SENEVIRATNE.

Proceeding the Chairman said he felt perfectly certain that no native trader, who was carrying on a legitimate trade, would be hampered in any way by that Association. He could only further

say that he welcomed with pleasure the remarks of Mr. Webb and Mr. Campbell on the subject of the position of the Planters' Association for he felt sure any opposition they could possibly have could only be due to their not thoroughly understanding the object of the resolution. (Applause.)

The resolution was put and carried *nem con.*

The CHAIRMAN:—Before going further I might ask when this new regulation is to come into force.

Mr. DRURY:—I would suggest first sale in April.

Hon. Mr. CAMPBELL:—Is that the first of April? (Laughter.)

The CHAIRMAN:—These regulations will be printed as conditions of sale, I suppose.

Mr. DRURY:—Yes.

A RESOLUTION WITHDRAWN.

The CHAIRMAN—who was to have moved on behalf of Messrs. Bois Bros—"That admission to the Tea Sales at the Ceylon Chamber of Commerce Rooms shall be strictly confined to Members of the Association, their accredited representatives, and visitors introduced by them" said that in view of the previous resolution he did not think it was necessary to put that before them and with the permission of the meeting he begged leave to withdraw the same.

WEIGHT OF PACKAGES TO AUSTRALIA;

FREE TRADE IN TEA BOXES WANTED.

Mr. J G WARDROP—(COLOMBO COMMERCIAL COMPANY, LTD.)—moved the following resolution standing in his firm's name:—That the Steamship Companies be asked to substitute for the existing clause inserted on all Bills of Lading for Tea shipped to Australia, which is as follows:—

"No package to contain more than 100 lb tea; otherwise the steamer is not responsible nor liable for damage."

The following, viz:—

"No package of tea to weigh more than 129 lb gross; otherwise the steamer is not responsible nor liable for damage."

The original clause referred to in that resolution was inserted 7 years ago with the object of minimising the claims of the shipping Companies with respect to that tea. He thought they must admit it as a fact that the producer in the past had not been as careful of packages to send Colombo for sale as to the sale in London and hence the necessity for that clause in the Bills of Lading. At the time that clause was brought into operation patent packages were used to a very small extent. Now a patent package can be legitimately said to contain 110 lbs. of tea against 100 in the wooden packages and the consequent effect of that stipulation of the Bills of Lading is to penalise the users of the patent boxes. If they adopted that resolution he was now moving it would inflict no hardship on the wooden packages and it would put the patent packages in a more fair position. There was no restriction in the amount packed from Colombo to London or to any country except Australia with regard to the value of the patent packets, he could only mention the case of a Company doing business in Ceylon with Russia. Their Russian friends found the patent boxes useful and well adapted to their trade, strong, light and capable of standing long and varied transport. He thought they were sufficiently used to warrant their taking this action.

Mr. A R A HEATH—seconded the resolution. He thought if the shipping Companies could be induced to make the alteration in the present clause and allow 129 lb gross instead of as previously 100 lb net it would be a distinct advantage from a buyers point of view and he could not see that looking at it from the planters point of view there could be any objection to it. He understood that the shipping Companies might consider the matter favourably if brought before them by that Association, and, therefore, he seconded the resolution.

Mr. HERCULES SCOTT—said they had heard a great deal on that matter lately which all went to attempt to popularise the Venesta Chest. Some of them were, perhaps, not aware that the matter was very fully discussed last September at a Committee meeting of that Association, and in January last it was brought up in a Committee meeting of the Chamber of Commerce and a resolution was unanimously passed at both meetings, condemning the principle of this resolution. If he had their permission, he might read the resolution passed by the Committee. Proceeding Mr. Scott read the minute of the Committee meeting with regard to this matter and went on to say that at the Chamber of Commerce meeting in January over a month ago that resolution came before them and was unanimously condemned. He hardly thought that the annual general meeting of that Association should upset the decision of both their own Committee and that of the Chamber of Commerce. The Colombo Commercial Company were, as they were well aware, agents for the Venesta Tea Packages and he thought Mr. Wardrop would agree with him that the primary object of the resolution was to push the sale of Venesta tea packages. That, from the Colombo Commercial Company's point of view was quite right, but he thought it was different for the Tea Traders' Association to come forward and give a gratuitous advertisement to a package which is protected by patent. After alluding to the difficulties that would arise in repacking, &c., were the resolution adopted, Mr. Scott went on to say that he was told several present were to vote for the resolution just to give free trade in patent boxes. If they admitted the Venesta chest into general use, what was to prevent the makers of them doubling the price? They were protected by patent. If the Venesta chest became universal, they put the whole situation in the maker's hands.

Mr. W E MITCHELL:—I think the Venesta Company have the remedy in their own hands if they make a package that will hold 100lb. (Hear, hear.)

Hon. Mr J N CAMPBELL—said he had great pleasure in supporting the motion put forward by the Colombo Commercial Company. He had to say he was very much surprised and astonished when he heard the Committees of the two Associations had agreed to have nothing to do with the proposal that that alteration should be made on the Bills of Lading. Mr Hercules Scott's remarks had been entirely a diatribe against the Venesta package and in favour of the Momi chest. He (Mr Campbell) was not in any way interested in the Venesta packages. He had nothing to do with the Venesta Company and he was not a shareholder in it, but he did use for the London market a large number of Venesta packages and

he was always very well satisfied with them. There was no free trade in packages in Colombo. They were not allowed to ship more than 100lb. in one package to Australia. Why should they not be allowed to use any package they liked? He did not know why there should be any difference in what was packed for London and for Australia. Why should there be a limit in the quantity packed to Australia? There was no limit in the quantity packed to London. It had always been said by the shipping Companies when they were approached "Let the trade approach us and then we may consider the matter. As long as the Traders' Association is against the change we will take no action." He asked that the Traders' Association should now give them an opportunity to put all boxes on an equal footing. (Hear, hear.)

Mr SCOTT—repudiated the suggestion made by Mr Campbell that his remarks were a diatribe against the Venesta packages in favour of the Momi. The great proportion of their teas were packed in country wood. He had no interest in the Momi chest and held no brief for them.

Mr AMPENOFF—said that the Company he represented had been trading with Ceylon for the past four or five years. Their experience was that tea packed in the ordinary boxes arrived broken and half the tea lost and his Company had given him instructions that the tea he bought now was to be packed in Venesta packages which they found strong and serviceable. He could not see why objections had been raised to the Venesta Chests. Russian buyers—

Mr SCOTT:—May I rise to a point of order? This is not a question of shipments to Russia; it is a question of shipments to Australia.

Mr AMPENOFF—resumed his seat.

Mr WARDROP—in reply—said he had nothing to add further than that he was equally interested in Momi boxes as in Venestas and all he wanted to see was free trade in tea boxes. What they were aiming at there that day was to forward the interest of the Tea Traders.

The CHAIRMAN—said he would only say one word, in regard to what fell from Mr Scott, and that was that although the Committee of the Chamber of Commerce or that Association had decided against this, it was not *prima facie* evidence that it had been settled for all time; and if any new facts were brought forward, it was quite competent for the Association to reverse that decision at any time. He just mentioned this unless any member might think that it would be a slight on the Committee to reverse their decision.

THE MOTION LOST.

THE CHAIRMAN—then put the motion to the meeting and it was lost by 14 to 12 votes.

This was all the business.

SANITARY INSTRUCTIONS FOR THE TROPICS.
—We invite the attention of our readers to the list of Sanitary Instructions for the use of people in the Tropics which have just been issued by the Liverpool School of Tropical Medicine. These simple rules are of the greatest importance to all residents in Ceylon and should be perused carefully, in view of the latest discoveries in medical science affecting tropical countries.

A NEW USE FOR SUGAR.

VULCANISING WOOD.

As the result of experiments, a method of so treating timber as to secure even from soft wood a largely increased toughness and hardness is reported to have been invented by Mr Powell, a Liverpool merchant. The treatment to which the timber is subjected is that of saturation at boiling point with a solution of sugar, the water being afterwards evaporated at a high temperature. The result is to leave the pores and interstices of the wood filled in with solid matter, and the timber "vulcanised," preserved, and seasoned. The nature of moderately soft wood, it is claimed, is in this way changed to a tough and hard substance, without brittleness, and also without any tendency to split or crack. It is also rendered remarkably impervious to water. Hard woods, similarly treated, derive similar benefits. Moreover, it is claimed that the process may be completed and timber turned out ready for use in a few days. The invention, which has been patented, is to be brought before the attention of the timber trade by a series of practical demonstrations and lectures.—*H. and C. Mail*, Feb. 20.

RUBBER FORESTS IN PORTUGUESE AFRICA.

The Portuguese investigator, Dr. Pereira, on a journey through Africa, telegraphs from Mosamedes that he has found large forests of rubber trees in the regions of Pungo-Andongo, Bardo and Quanza. The natives there have no idea of the way how to get the rubber.—"*Gummi Zeitung*,"—*India-Rubber Journal*, Feb. 16.

PRIMEVAL CAMPHOR AND OAK FOREST DISCOVERED IN FORMOSA.

An interesting and unusual discovery is that of a primeval forest which has been found in Southern Formosa. The forest is of vast extent, covers, it is said, 50,000 acres, and contains 120,000 camphor trees, each measuring from 7 to 18 feet in girth. These are roughly estimated to yield ten million cattles of camphor, which, purchased by the monopoly office at 18 yen per 100 cattles, will be worth 1,720,000 yen approximately. Besides, the forest abounds in "red-grained" oak, excellently suited for making Japanese oars, and also in *tenge*, valuable for cabinet work and other purposes. On the whole, therefore, the trees in this newly-discovered but ancient forest may be valued at some tens of millions of yen. There is one big obstacle, however, in the way of their being utilised, and that is the excessive cost of transportation. Mr. Ishibashi, chief of the Aborigines district office, is the lucky discoverer of this forest. He has also discovered in the same remote district a peak standing 12,081 feet above sea-level, the next highest peak therefore in the island, the highest being Mount Nitaka.—*Hongkong Weekly Press*, Feb. 23.

RED COCONUT BEETLES IN SINGAPORE.

With regard to the inspection of coconut trees, Mr Ridley, in the Gardens Report for 1902, says that, during the year, notices to

cut down infested trees were served on 233 persons and 1,039 dead trees and 35 piles of rubbish were destroyed. There were no prosecutions. The number of red beetles, especially, has greatly diminished in Singapore, so that it was some time before Mr Ridley could get a couple for a correspondent in Madagascar who wished to see it.—*Straits Times*, Feb. 28.

NETHERLANDS INDIA.

The *Batavia Nieuwsblad* tells of the steady march of improvement in Pulo Way, at the harbour of Sabang. Jetties and storehouses are being rapidly built for the Dutch mail steamers calling there. It is expected that the N D L steamers will follow the example.

THE NUTMEG PLANTERS

at Banda in the Moluccas are now in the hands of a shipping ring which deals with them on ruinous terms. The planters look now for better times from Australian ships beginning to call at Banda, and readily buying up local products. The supercargoes of these vessels have promised to call again.—*Straits Times*, Feb. 28.

EAST AFRICAN PEARL-SHELL.

Dr. Aurel Schulz, F R G S, the well-known South African explorer, has secured two concessions over the whole of the German East African Coast—one for mother-of-pearl and pearl fishing, and the other for the exploration of trepang, also called *Beche-de-mer*, both of which in other countries have developed into great industries and given large returns. The discovery of genuine mother-of-pearl shell on the German East Coast of Africa is expected to result in the development of a solid industry. Dr. Schulz states that the islands lying off the coast from coral banks of enormous extent, which fulfil all the natural conditions requisite for the maturing of mother-of-pearl shell in large quantities, while the conditions for diving are very favourable, as the water lies shallow over great areas. Red mussel, out of which he extracted some good white pearl, is plentiful over a distance at least 400 miles in length. South of the island Mafia, off Ras Kisimans, and in other places, he found beds of the large pinna shell (of extraordinary size) which yielded black seed pearls. Trepang is present in considerable quantities.—*African Review*.

ESTIMATE OF COST AND REVENUES OF A CACAO PLANTATION.

[Estimates of expenses in establishing a cacao farm in the Visayas, Philippines, and profits after the fifth year.]

The size selected is 16 hectares, the amount of land prescribed by Congress of a single public land entry. The cost of producing such a tract of land is as yet undetermined and cannot be reckoned in the following tables. The prices of the crop are estimated at 48 cents per kilo, which is the current price for the best grades of cacao in the world's markets. The yield per tree is given as 2 cattles, or 1.25 kilos, a fair and conservative estimate for a good tree, with little or no cultivation. The prices

for unskilled labor are 25 per cent in advance of the farm hand in the Visayan islands. No provision is made for management or supervision, as the owner will, it is assumed, act as manager.

Charges to capital account are given for the second, third and fourth year, but no current expenses are given, for other crops are to defray operating expenses until the cacao trees begin to bear. No estimate of residence is given. All accounts are in United States currency.

EXPENDABLE THE FIRST YEAR.

Capital account :—

Clearing of <i>average</i> brush and timber land at \$15 per hectare	... \$340.00
Four carabaos, plows, harrows, cultivators, carts, etc.	.. 550.00
Breaking and preparing land, at \$5 per hectare	... 80.00
Opening main drainage canals, at \$6 per hectare	... 96.00
Tool house and storeroom	... 200.00
Purchase and planting 10,000 abaca stools, at 2 cents each	... 200.00
Seed purchase, rearing and planting 12,000 cacao, at 3 cents each	... 360.00
Contingent and incidental	... 174.00

Total	... 2,000.00

SECOND YEAR.

Interest on investment	... 200.00
Depreciation on tools, buildings and animals (20 per cent of cost)	... 150.00

	350.00

THIRD YEAR.

Interest on investment	... 200.00
Depreciation as above	... 150.00

	350.00

FOURTH YEAR.

Interest on investment	... 200.00
Depreciation as above	... 150.00
Building of drying house and sweat boxes, capacity 20,000 kilos	... 450.00

	800.00

Total capital investment ... 3,500.00

FIFTH YEAR.

Income account :—

From 11,680 cacao trees, 300 grams cacao each, equals 3,500 kilos, at 48 cents...	1,680.00
Expense account :—	
Fixed interest and depreciation charges on investment of \$3,500	... 350.00
Taxes $1\frac{1}{2}$ per cent on a one-third valuation basis of \$250 per hectare	... 60.00
Cultivating, pruning, etc., at \$5.50 per hectare	... 88.00
Fertilising, at \$8 per hectare	... 96.00
Harvesting, curing, packing 3,500 kilos cacao, at 10 cents per kilo	... 350.00
Contingent	... 86.00

	1,030.00
Credit balance	... 650.00

SIXTH YEAR.

Income account :—

From 11,680 cacao trees, at 500 grams cacao each, equals 5,840 kilos, at 48 cents	... 2,803.20
Expense account :—	
Fixed interest and depreciation charges as above	... 350.00
Taxes as above	... 60.00
Cultivating, etc. as above	... 88.00
Fertilising, at \$8 per hectare	... 128.00
Harvesting, etc., 5,840 kilos cacao, at 10 cents per kilo	... 584.00
Contingent	... 93.20

Credit balance	... 1,500.00

SEVENTH YEAR.

Income account :—

From 11,680 cacao trees, at 750 grams cacao each, equals 8,760 kilos, at 48 cents	... 4,204.80
Expense account :—	
Fixed interest charges as above	... 350.00
Taxes as above	... 60.00
Cultivating, etc., as above	... 88.00
Fertilising, at \$10 per hectare	... 160.00
Harvest, etc., of 8,760 kilos of cacao, at 10 cents per kilo	... 876.00
Contingent	... 170.80

Credit balance	... 2,500.00

EIGHTH YEAR.

Income account :—

From 11,680 cacao trees, at 1 kilo cacao each, equals 11,680 kilos, at 48 cents...	5,606.40
Expense account :—	
Fixed interest charges as above	... 350.00
Taxes as above	... 60.00
Cultivating, etc., as above	... 88.00
Fertilising, at \$15 per hectare	... 200.00
Harvest, etc., 11,680 kilos of cacao, at 10 cents per kilo	... 1,168.00
Contingent	... 240.40

Credit balance	... 3,500.00

NINTH YEAR.

Income account :—

From 11,680 trees, at 2 'catties' or 1.25 kilos cacao each, equals 14,600 kilos at 48 cents	... 7,008.00
Expense account :—	
Fixed interest charges as above	... 350.00
Taxes at $1\frac{1}{2}$ per cent on one-third valuation of \$500 per hectare	... 120.00
Cultivating, etc., as above	... 88.00
Fertilising, at \$15 per hectare	... 240.00
Harvesting, etc., of 14,600 kilos of cacao at 10 cents per kilo	... 1,460.00
Contingent	... 250.00

Credit balance	... 4,500.00

In the tenth year there should be no increase in taxes or fertilisers, and a slight increase in yield, sufficient to bring the net profits of the estate to the approximate amount of \$5,000. This would amount to a dividend of rather more than \$312 per hectare, or its equivalent of about \$126 per acre.

These tables further show original capitalisation cost of nearly \$90 per acre, and from the ninth year annual operating expenses of rather more than \$60 per acre.

It should be stated, however, that the operating expenses are based upon a systematic and scientific management of the estate; while the returns or income are based upon revenue from trees that are at the disadvantage of being without culture of any kind, and, while I am of the opinion that the original cost per acre of the plantation, nor its current operating expenses may be much reduced below the figures given, I feel that there is a reasonable certainty that the crop product may be materially increased beyond the limit of two 'catties.'

In Camerouns, Dr. Preuss, a close and well-trained observer, gives the mean annual yield of trees of full-bearing age at 4.4 pounds.

Mr. Rousselot places the yield on the French Congo at the same figure. In the Caroline Islands it reaches 5 pounds and in Surinam, according to M. Nichols, the average at maturity is 6½ pounds. In Mindanao, I have been told, but do not vouch for the report, of more than ten 'catties' taken in one year from a single tree; and, as there are well-authenticated instances of record, of single trees having yielded as much as 30 pounds, I am not prepared to altogether discredit the Mindanao story.

The difference, however, between good returns and enormous profits arising from cacao growing in the Philippines will be determined by the amount of knowledge, experience, and energy that the planter is capable of bringing to bear upon the culture in question.—*Philippine Bureau of Agriculture, Farmers' Bulletin, No. 2, 1902.*

"SWEET POTATO" SUGAR IN FORMOSA.

[WHY NOT IN N. AND E. CEYLON?]

The Island of Formosa will soon become, under the wise economic administration of Baron Kodama and Dr Goto, one of the great sugar producing regions of the world. Sugar is made there from the sweet potato. There is an almost unlimited market throughout the Eastern world for sugar, and the Japanese administration in Formosa is wisely availing itself of the splendid opportunity for developing and supplying this market. It is estimated that at least one-half of the island is adapted to the growing of the sweet potato for sugar manufacture. The climate is moist and favourable, and the soil is as fertile as that of the Hawaiian Islands or of Java. The range of temperature is from 75 to 100 degrees Fahrenheit. The sugar section extends from the middle to the southern end of the island, and in this section rain occurs every day from May until the latter part of September, which is the growing season, and then there is no rainfall whatever until the following May, affording a perfect season for harvesting. The first sugar company was established about two years ago. In 1901 the product of sweet potato sugar was 20,000 bales, and last year it was estimated that it would reach 60,000 bales. The profits of the industry are encouraging, as one acre of land will produce 40,000 pounds of potatoes—worth about 80 yen, or \$40 (gold)—and manufacturing expenses is only 75 cents for 1,000 pounds of sugar. Wages are low, a labourer receiving only about 12 to 16 cents a day. In such circumstances there is no reason for astonishment at the rapid development of the industry.—*Straits Times, Jan. 24.*

THE ACTION OF BASIC SLAG ON POOR PASTURES.

It will only be after many years of continuous research that we shall know fully the real action of this cheap and comparatively new source of phosphate (Basic Slag) and the actual limitations to its use. At present we know that on many poor pastures its application has an almost immediate beneficial effect, and that in such cases its influence is very lasting. The Bath and West of England experiments would almost lead us to regard the application of this manure as a permanent improvement to such pastures as benefit from it at all. The six years' experiments at Gockle Park indicate limits which are more in accordance with what we know to be sound and practical agricultural maxims. According to these North Country results, basic slag only indirectly benefit the grasses in a pasture. The slag is found to improve the white clover; the flourishing clover improves the soil by increasing the supplies of nitrogen; while, as a result, the better grasses are strengthened and the worthless bent is displaced. Basic slag, in point of fact, seems to be of benefit only so long as it maintains or increases the white clover; and during the whole of this time both the soil and the better grasses are being indirectly improved. But when the white clover ceases to be the predominant crop—usually from three to four years after the first application of slag—the use of this manure in any quantity should cease, and its use followed up by the application of a mixed manure. Farmyard manure can then be applied with good effect. If artificials are preferred; these experiments show that the best results are obtained by their application in two dressings. In November, 1½ cwt of slag and ½ cwt of bone meal, should be used. This should be followed in February or March by a dressing consisting of 1 cwt. of superphosphate, ¾ cwt of fish meal, and 1½ cwt of kainit. These two dressings will cost about 15s and is enough to apply to one or two acres over such portions as need it—i.e., where the white clover is giving place to a more mixed herbage. Such dressings as these, especially if followed by cake feeding, will greatly assist the better grasses of the pasture, and complete the work of improvement commenced by the basic slag.—LAND AGENTS' RECORD.

COCONUTS: COSTA RICA'S POSSIBILITIES.

Every fool with his scheme, and we with ours. It been brought forcibly home to us that as very little is known as to utilising many of the riches in which our fertile soil abounds, and for the present we bring to the front Coconuts, which—if we were poets—we would compare to weeping willows who are mourning their misfortunes and abandonment. By order of the Governor of Limon a recount has been made of the coconut trees existing in the Comarea, and although not effected with any minuteness, it has been shown that there exist between 40,000 and 50,000 trees of this class. Each one of these produces a minimum of 50 nuts yearly, so that without exaggeration of any kind it can be assumed that two million coconuts represents the annual production. Each 40 coconuts produce on an average one gallon of oil, and therefore the two million nuts would produce 50,000 gallons of oil yearly which is less than half the quantity of grease imported into this country for soap alone as will be seen from the figures: In 1901, 373,352 kilogrammes of grease for soap were imported with an invoice value of \$18,431.19. The 50,000 gallons of oil that we have calculated as the product of the Limon coconuts would scarcely give 3703 quintals, or, say 170,338

kilogrammes, which are not, as we before said, even half of the 373,352 kilogrammes of fat imported, among which, we do not include 28,055 kilogrammes of machine oil that are also imported, which we could manufacture here—taking for the raw material the coconut or wild fig, for the oils of both plants are very good lubricants and only need a little mixing with petroleum for thinning it. In the calculations that we have made, we have taken into account only the Comarca of Limon, without considering the other extensive territories of the republic in which coconuts can be extensively produced. What is being done, today with all these products? Only a few hundred coconuts are exported that scarcely pay the cost of picking and transportation. What can be done? Much—by arousing the existing apathy before necessity, which is the supreme law, compels us by a more painful process. We know that there exists in this country the necessary machinery for the manufacture of coconut oil, machinery that cannot be utilised because the owner lacks capital for exploiting the business. Perhaps someone may be found with aptitude, having capital and lacking the material elements. Is it so difficult to realise this result? We think not; and in whatever form it is effected it may be the base for a productive and regenerative industry, a germ of the future commercial emancipation of Costa Rica. —*Limon Weekly News*, Dec. 1902.

MARKET VALUE OF VANILLA.

Messrs Brookes & Green, the well-known firm of Brokers in London, writes:—

Concerning Vanilla market and artificial substitutes, we beg to inform you that owing to a very large crop of vanillas from Seychelles, the price dropped very considerably from September 1901 to March 1902.

At the time of writing this letter prices are rising, and we think will keep firm through the summer. You may contradict authoritatively, that either 'Vanillin' or any other artificial competitor was the cause of the decline.

Referring to our letter of July 21st 1902, giving values of the sample vanillas you sent over, these valuations we repeat today, viz: from 3s to 7s-per lb, the mention of 6d per lb as a rumour, is altogether wrong.—*Barbados Agricultural News* Jan. 3.

JAVA PRODUCTS IN 1902.

At the opening of the first meeting of the Commercial Chamber of Amsterdam in the New Year, the President delivered the customary review of the trade in the preceding year. In general the results were not brilliant, the course of prices being mostly downward. Java coffee, which opened at c.33, declined to c.34 for good ordinary and Santos from c.23½ to c.18½. Java tea followed a downward tendency until July, and then improved for the greater part. The Amsterdam market maintained its excellent position, and in the last ten years arrivals and deliveries are about 150 per cent. more. As regards Cinchona bark, the large supplies caused a fall in value from c.7½ to c.6 per unit. The imports of rice were respectively c.10 and c.25 per cent, more compared with 1901 and 1900, but prices were maintained. The prices of Java tobacco were on the average c.5 per half kilo. lower, which means a loss of fl.2,500,000 on the crop.—*London and China Express* Jan. 16,

"DEANE-JUDGE" SAMPLES OF GREEN TEA.

We received a few days ago (and regret we did not notice them sooner) a few samples of green tea, from Mr. Drummond Deane, handed to us by Mr. Grieve of Messrs. Brown & Co. These samples, we may mention, have been seen by several testers in Colombo and were said to be very good and very like in appearance to China teas. The teas are an original ordinary green tea sample and a polished sample made in the New Polisher called the Deane-Judge Polishing Machine. They are, at present, at our office and can be seen by any callers interested.

CACAO CULTIVATION IN THE PHILIPPINES.

There can be no doubt of the rapid development of the Philippine islands under good Government, so soon as the Americans establish "the Roman peace." A "Philippine Bureau of Agriculture" has already been established and we have just received its "No. 2 Bulletin," which deals with "Cacao Culture in the Philippines," by Wm. S. Lyon in charge of Seed and Plant Introduction." Mr. Lyon mentions that cultivated cacao already exists in nearly every province of the Archipelago; but without much commercial success so far, while manuring is quite unknown. Very practical advice is given to intending planters, and an accomplished Entomologist is already at work as to insect enemies; while the following paragraphs are of interest in themselves, and a showing of the good sense of the compiler:—

The Philippine Islands appear to be so far singularly exempt from the very many cryptogamic or fungous diseases, blights, mildews, rusts, and cankers that have played havoc with cacao-growing in many countries. That we should enjoy continued immunity will depend greatly upon securing seeds or young plants only from non-infected districts or from reputable dealers, who will carefully disinfect any shipments, and supplement this by a close microscopical examination upon arrival and the immediate burning of any suspected shipments.

Another general precaution that will be taken by every planter who aims to maintain the best condition in his orchard is the gathering and burning of all prunings or trimmings from the orchard, whether they are diseased or not. Decaying wood of any kind is a field for special activity for insect life and fungous growth, and the sooner it is destroyed the better. On this account it is customary in some countries to remove the fruit pods from the field. But unless diseased, or unless they are to be returned after the harvest, they should be buried upon the land for their manurial value.

The climate of the Philippines, where cacao can be grown, is specially praised, and the following contrast offered:—

Malarial fevers are relatively few, predacious animals unknown, and insects and reptiles prejudicial to human life or health extraordinarily few in number. In contrast with this we need only call attention to the entire Caribbean coast of South America, where the climate and soil conditions are such that the cacao comes to a superlative degree

of perfection, and yet the limits of its further extension have probably been reached by the insuperable barrier of a climate so insalubrious that the Caucasian's life is one endless conflict with disease and when not engaged in active combat with some form of malarial poisoning his energies are concentrated upon battle with the various insect or animal pests that make life a burden in such regions.

Finally we have estimates given, which will be closely scrutinised by Ceylon planters, who can readily compare the figures with their experience by remembering that the American dollar is equal to about three of our rupees in value—the hectare being 2½ acres, the "cacao farm" estimated for, is one of 40 acres. The outlay, therefore, to the end of the 4th year is R262 per acre, but the cost of land is not counted and other expenses are expected to be defrayed by "catch crops." We make no further comments, save that so early as the fifth year, an "income," or rather gross return from the cacao crop of over R5,000 (or R125 per acre) is expected, which rises by the 9th year to R21,000 or over R500 per acre, resulting in a net profit of R337 per acre. Very rich must be the soil and flourishing the cacao trees that can give such results.

INDIA-RUBBER.

THE CHEMISTRY OF INDIA-RUBBER.—By Carl Otto Weber, Ph.D. Pp. x + 314. (London: Chas. Griffin and Co., Ltd.). Price 16s net. In the volume before us, the author has applied himself specifically to the chemistry of India-rubber, and incidentally to that of its various substitutes. It may be said at once that the result is an eminently useful contribution to the literature of India-rubber and its congeners. The book contains nine chapters and an appendix. In the first chapter, which forms more than a third of the work and gives its title to the whole, Dr. Weber deals with the constituents of India-rubber, discusses their physical and chemical properties, and propounds in outline a theory of vulcanisation. The carbohydrates present in crude "unwashed" rubber are first referred to, and then follows a useful little table showing the proportions of resinous extract obtained from the various commercial brands of technically-pure rubber by treatment with acetone. It may be explained that the importance of these "resins" lies in the fact that they allow the chemist to discriminate between a high-quality rubber, such as Pará, and an inferior product like some of the African kinds. Passing on to india-rubber proper, the author summarises the evidence which goes to prove that the pure rubber substance is a hydrocarbon of the terpene type. Oxygen, it is true, is always present in commercial specimens, but it is partly accounted for by atmospheric oxidation and partly by the presence of an "insoluble" compound having the empirical formula of a hydrated terpene. This last, the author suggests, may be an intermediate product between india-rubber itself and the carbohydrates from which, perhaps, the various terpenes are manufactured in the cells of the rubber plant. Organic chemists have apparently found the chemistry of india-rubber somewhat unattractive.

No doubt this is largely due to the intractable nature of the compound; for india-rubber, from this point of view, certainly possesses the defects of its qualities. It has few points of attack; there are none of the carbonyl-, carboxyl-, amido-, imido-, hydroxy- or methoxy-groups in which the organic manipulator delights; it cannot be readily dissolved; and *a fortiori*, being a colloid, it cannot be crystallised. Nevertheless, it has one vulnerable spot, and the Achilles' heel in this case is found in the existence of the 'ethylene bonds' pointed out by Gladstone and Hibbert. Much stress is laid upon the colloidal properties of rubber as being the clue to a proper understanding of its behaviour during manufacture—a disquisition on the colloidal state, leading up, however, to an interesting study of the phenomena of vulcanisation. In the author's view the vulcanisation of india rubber by means of sulphur consists essentially in the direct addition of sulphur to the india-rubber hydrocarbon (poly-prene), with the formation of various polyprene sulphides. Combating the theory that the action of the sulphur is one of substitution instead of addition, the author rightly points out that if the former were the case the vulcanisation of a ton of rubber would mean the production of about 18,000 litres of hydrogen sulphide—a daily amount which would make the vulcanising rooms fairly reek with the gas. In reality, only insignificant traces are found there. The cold process of vulcanising by means of sulphur chloride is also discussed in detail. In the succeeding chapter the technical examination and valuation of india-rubber and gutta-percha are dealt with. But in this industry, as in so many others, our manufacturers cling hard to rule-of-thumb methods; stocks are bought on the strength of a cursory empirical examination; and we read that, in consequence, different lots, supposed to be of identical quality, "often show the most absurd variations" when properly appraised by analysis. The following quotation speaks for itself:—

"Pig iron, caustic soda, wood pulp, and scores of similar articles, costing comparatively speaking, a few shillings per ton, are brought and sold on the basis of strict analytical standards; but india-rubber, costing from £150 to £500 per ton, changes hands without either buyer or seller having more than a vague knowledge of its intrinsic value."

A full description is given of the various india-rubber substitutes now so frequently used, and which consist either of recovered rubber from cast-off articles or of the products obtained by the action of oxygen, sulphur or sulphur chloride upon such substances as linseed or colza oils. Inorganic compounding materials, vulcanising agents, solvents, colouring matters and textile fabrics each claim a chapter. Analysts and technical chemists who are called upon to examine india-rubber will be grateful for the chapter on the analysis of rubber articles, with which the volume proper closes. Chemists should note that nitro-naphthalene is recommended as a "solvent" for india-rubber in preference to the nitro-benzene hitherto generally employed. The author is to be congratulated upon a very useful contribution to a somewhat obscure and difficult branch of technical science.

C. SIMMONDS.

—*Nature*, Feb. 5.

ZANZIBAR NEWS.

MR. D. G. FAIRCHILD, RECENTLY IN CEYLON
Mr. David G Fairchild, of the United States Department of Agriculture, passed through here on January 21st. He was on his way South in the "Herzog." He had been to Dar-es-Salaam to inspect the Botanical station there and had thus only a few hours to devote to Zanzibar. Mr. Fairchild is well known in Planting circles in Ceylon, Singapore and the East and West Indies. He is especially interested in fruit and one of the principal objects of his mission is to discover the best fruits that are grown and to collect seeds and plants of them for his Government. He visited the fruit market here and took away with him samples of our oranges, mangoes and bananas. He has promised to send us a brief report upon their quality. Mr. Fairchild was much interested in all that he saw in Zanzibar and was especially struck with the signs of life and vitality that are to be witnessed here in our busy centres.

SIR JOHN KIRK, OF RUBBER FAME.

Sir John Kirk, G.C.M.G., K.C.B., F.R.S. arrived here on January 27th by the "Yangtse" and proceeded to Mombassa by the "Juba" the next day. He goes up the line and returns here it is hoped by about the 20th February to allow him a few days in Zanzibar before proceeding home by the February French mail. Sir John Kirk was British Agent and Consul-General here, but retired in 1887, in 1858 he joined Livingstone's first great Zambesi expedition as chief officer. It was in this Expedition that Lake Nyasa was rediscovered and laid down, the lower Zambesi, the Shire and Rovunia explored. In 1895 Sir John was appointed a member of the Government Committee for the construction of the Uganda Railway and he is now on his way to inspect the line. It is, however, as a naturalist and especially a botanist that Sir John Kirk is perhaps best known. His contributions to the Flora of Tropical Africa have been considerable. The greater part of what is known of the Flora of Zanzibar is due to the investigations of Sir John Kirk. He practically created the Rubber trade of the East Coast of Africa and the best-yielding species, *Landolphia Kirkii*, is called after him.—*Zanzibar Gazette*, Feb. 4.

TEA IN 1902-3.

AN INDIAN END-OF SEASON VIEW

The 1902-03 season is now drawing to a close and it is time to form an estimate of what has been done in the way of lightening the burdens of the tea producer in the immediate past. In the first place the results of the present season have been disappointing so far as we have gone, and there is not time enough left of the London selling season for last year's crop, to materially alter the aspect of affairs. The general average of all tea sold in London on garden amount for the eight months of the season that have elapsed is lower by nearly a half-penny than the average for the corresponding period of the 1901-02 season, and even below the average for the eight months of the 1900-01 season to end of January. We have during 1902-03 averaged a little over 7½d against nearly 8d in 1901-02 and 7½d in 1900-01. At the end of two years of short crop this result would be disheartening were it not a mere indication that our efforts have not been commensurate with the magnitude of the evil. Our demand needs to be put on a much broader basis, if we desire to make it

firm and constant. There is yet time in the four months of the London selling year remaining, for the averages to advance comparatively, but it is clear that they have fallen too far behind to more than catch up with 1900-01, an admittedly disastrous year for prices generally. Those who pin their faith to the natural flow of trade would do well to note that though advance has been made in the last two years, it has not been sufficient to enable us to contemplate with equanimity the recurrence of another crop of the magnitude of 1900.

On the other hand, having come through so much the future certainly looks brighter, perhaps by contrast. London, fairly indifferent for three years, has woken up to the growing scarcity of tea, and it looks as if the boom in common teas which prevailed in the early days of 1899 were to be repeated. Having in memory the time of depression that was ushered in by that abnormal rise in rates for teas for price, we cannot think the whole battle won by the attainment of inflated prices for this class, even if they should come to pass in the immediate future. We cannot forget that these prices for a particular class of tea were explained at the time as subversory of all true values in other grades and not to the general interest of the industry as a whole. It is to be hoped that when the short excitement of a "boom" is past, we may be able to prevent the reaction and settle all teas on a firmer and truer basis of prices than before.

For the rest 1902 has been replete with good work. The Russian buyers have been attracted to the merits of the Indian article and an important trade has come, we believe, to stay. There has been a general quickening of demand for many minor centres, in the aggregate compensating for the Australian trade which in some unaccountable manner we continue to lose. In America, British grown tea has at last a chance of making further inroads upon the Far Eastern article, our previous expansion having checked upon reaching the limit of the black tea consumption of the Transatlantic countries, British and Yankee. During the year suit-advances in machinery for making the "true" green article, as approved by the Americans, have taken place, and though Ceylon and India by the application of the patent laws appear likely to be served with different machinery for the purpose, it seems that both countries are equally advanced, and time alone can show if either possesses an advantage over the other. Further ingenuity will no doubt be called out to overcome details in the process and place us mechanically equal with the hand labour of China and Japan. Even now we are able to undersell those countries with ease, and in these days of cheapness the result should be a foregone conclusion. In two important markets, therefore, Russia and America, our advance seems certain, and if the crop does not unduly rush forward this circumstance should render prospects for 1903-04 much brighter than any presented to our view for years past but only if the situation is treated with continued prudence.—*Indian Planting and Gardening*, Feb. 23.

COFFEE IN QUEENSLAND.—In a letter from Queensland dated February 2nd, the continued drought in that colony is spoken of as very serious. "We have only had one half crop now in four years," says the writer, "and last year was a total failure. This year promises to follow suit."

MOSQUITO BLIGHT ON TEA RUSHES.
REMARKS BY MR. C. R. NEWTON, OF
"TEA ENZYME" FAME.

(To the Editor of the "Englishman.")

Sir,—Neither of your correspondents, Mr Harold Mann or R P Mougoo seems to have noticed one constant habitat of "Helopeltis theivora" or the tea mosquito, viz., the cardamom fields. In the greater part of the Darjiling District it is known by the natives as the alinchee kera or cardamom insect, and is found throughout the year on the young cardamom shoots. I have delayed this communication in order that the result of previous observations might be confirmed and from Christmas to the end of January this year, when nearly all trace of it had disappeared from the tea except in a few unpruned portions which were flushing slightly, I have always with the aid of some sharp native children who had been employed throughout the year in capturing the insect on the tea, been able to obtain a number from the cardamoms, as also from other sheltered places where there was succulent jungle. In fact in my opinion it is rather an omnivorous feeder than a special tea one as described by Mr Mann. In artificial experiments the tea insect when fed on cardamoms acquires a lighter colour resembling those bred on the cardamoms. In fact, the insect seems to vary in colour within certain limits according to what plant it has been feeding upon. From observations during a number of years made by several planters, it always appears first on their tea in the neighbourhood of cardamoms or of special pieces of sheltered jungle and then spreads very rapidly. The crushed insects caught in the tea have also generally a decided smell resembling cardamoms. The reason I imagine that Helopeltis has not often been noticed on other jungle is that that the planter invariably looks for the black spots so typical on the tea, but not so on other plants. The blackness is due to the tanning. The shape of the marks depends on the shape of the plant cell in cardamoms where the cell is oblong, and the cell walls are longitudinal straight lines, rather hard. Several punctures generally occur together, often involving three or more cells; hence the mark, instead of being round as on the tea, may be oblong a quarter of an inch long by one thirty-second broad. Mr Stebbing, the Forest Entomologist, has I see recently recommended the burning of all jungle in the neighbourhood of cultivated crops, as a protection against blights. This I have advocated for years. There is no doubt that the blights have increased and the health of the inhabitants decreased in many districts since the Forest Department took steps to prevent the annual fires which used to take place every cold weather, consuming a lot of noxious jungle, that is now allowed to rot on the ground and harbour any amount of insect pests and fungus blights.

C R NEWTON, F R M S.

—Englishman, Feb. 26.

TEA IN UGANDA.

In a report on Exotic Plants of Economic Interest in the Botanic Gardens at Entebbe, Uganda, Mr J Mahon states that tea grows with but moderate rapidity. The rainfall is not great enough. During a period of rains it flushes nicely, but its cultivation on even a moderate scale

would necessitate resort to irrigation. Mr Scott Elliot, the naturalist and traveller, seemed satisfied from his exploration in the Ruwenzori country that large areas there offered a fine field for the cultivating tea on a large scale.—*Planting Opinion*, Feb. 28.

PLANTING NOTES.

ELDORADO FOR YOUNG MEN WITH MODERATE CAPITAL—is the attractive opening of an advertisement in an Indian paper referring to Alabama and it runs on as follows:—"Productive fruit land for sale in the beautiful and fertile State of Southern Alabama, U.S.A. Also good grazing land in the heart of the cattle belt. A few thousand acres going cheap in the rapidly enlarging colony of Beaver Meadows, the Chislehurst of the Southern States, situated 400ft. above gulf level, and six miles from the famous health resort of Citronelle. Lovely climate. Pure water good hunting and finishing, one mile from station, 25 from the City of Mobile."—We should think South Africa or Australasia would have the preference with Britishers.

"THE BOTANICAL MAGAZINE" for February contains coloured figures and descriptions of the following plant:—*Sansevieria grandis*, J D Hooker, tab. 7877.—A supposed native of tropical Africa, but introduced into Cuba in the hope that the fibre it contains, which is of extraordinary strength, might be turned to commercial account. The plant is growing in the temperate-house at Kew, and has a tuft of broad, obovate, oblong, acute leaves three to four feet long, six inches wide, pale green, with transverse stripes of a deeper colour, and a central stalked raceme some three feet high of numerous regular, erect, funnel-shaped, greenish flowers, each about two inches long, the linear perianth-segments as long or longer than the narrow tube. As an ornamental plant, it has high claims on the attention of gardeners, and its cultivation would seem to present no difficulty.—*Gardeners' Chronicle*, Feb. 7. [Can this be very much the same as our *Sansevieria Zeylanica* which also gives a good fibre?—ED. C.O.]

ARAMINA FIBRE.—In the Rio de Janeiro district of Brazil experiments have given proof of the excellent qualities of aramina fibre. Steps were taken to manufacture certain goods from it, and in June last year an exhibition of these goods, which consisted of rope and other woven products, took place in the city of S. Paulo. A factory is in course of construction in S. Paulo exclusively for the manufacture of goods from aramina fibre. The weaving machinery has already been erected, and other materials, which are being imported from the United Kingdom, are expected to arrive shortly, and the factory will then be in a position to begin work. The aramina plant is being extensively cultivated at two estates in S. Paulo. It is expected that the annual production of these two estates, which extend over about 325 acres of land, will yield from ten to twelve tons of dry husk, or four and a half to five tons of fibre for every six acres cultivated. The growth of the plant is rapid and it needs no special care. The price paid by the S. Paulo factory for clean aramina is about 1d. per lb.—*British Trade Journal*, Feb. 1. [What is the scientific name of the Aramina plant?—ED. T.A.]

TO THE PLANTING WORLD.

Seeds & Plants of Commercial Products.

Hevea Brasiliensis.—Orders being booked for the coming crop August-September delivery 1903, booking necessary before the end of April, quantities of 100,000 and over at special low rates. Plants available all the year round, 100,000 and over at special low rates. A leading Rubber planter in Sumatra, who purchased 50,000 seeds in 1899, and 100,000 in 1900, writes us, under date 15th November, 1900:—"I received your letter of 20th October, from which I learn that you added another case of 5,000 seeds to replace the loss, &c. I am satisfied hereby, and even after this adding I am satisfied by the whole delivery of this year." Special offer, post free on application.

Castilloa Elastica.—True superior variety cultivated in Mexico, seeds from specially reserved old untapped trees. Orders booked for October-November delivery 1903, immediate booking necessary; large quantities on special terms; Plants in Wardian cases.

A foreign firm of Planters writes under date 11th October, 1901:—"We beg to enquire whether you would procure us 100,000 Castilloa seeds, in which month we might expect them, and what would be the average price." Special offer, post free on application.

Manihot Glaziovii.—Seeds and Plants available all the year round, 100,000 and over at special low rates. A Mexican planter in sending an order for this seed wrote on the 22nd August, 1900:—"If they arrive fresh and germinate easily I may send you larger orders, as they are for high ground where the Castilloa does not thrive."

Ficus Elastica.—Seeds available in May-June; booking necessary before the end of March; also plants.

Mimosa Giobosa (Balata) wood of the tree is much sought for buildings, fruits sweet like a plum and eaten, oil from seeds, said to yield as much as 45 lbs. of dry rubber per tree per annum, the milk is drunk and when diluted with water used as cow's milk, grow from-sea-level up to 2,000 feet, orders being booked for seeds and plants, price on application.

Cinnamomum Zeylanicum (Cinnamon superior variety).—New crop of seed in April to June; booking necessary before the end of February, also plants.

Coffea Arabica-Liberian Hybrid.—A highly recommended leaf-disease resisting hardy new variety of Coffee (cross between Arabian and Liberian). New crop March-April; immediate booking necessary.

A foreign Agricultural Department writes dating 9th September, 1901:—"Please accept our order for 175 lbs. of Tea seed and for 2,000 Coffee beans. In regard to Coffee seed I would say that this will be the first importation made by this department, and we will leave the selection of the varieties to be sent to your judgment."

OUR DESCRIPTIVE PRICE LISTS.

The following six Descriptive Price Lists are now being forwarded with Circulars and special offer of Seeds and Plants of Rubber and other Economic Products:—

1. Tropical Seeds and Plants of Commercial Products, enlarged edition for 1902-1903.
2. Seeds and Plants of Shade, Timber, Wind-Belts, Fuel and Ornamental Trees, Trees for Road-sides, Parks, Open Spaces, Pasture Lands, Avenues, Hedges, and for planting among crops (Tea, Coffee, Cacao, Cardamoms, &c.)
3. Seeds and Plants of Tropical Fruit Trees including Mango grafts.
4. Bulbs, Tubers and Yams.
5. Orchids—Ceylon and Indian.
6. Seeds and Plants of Palms, Calamus, Pandanus, Cyeads, Tree and other Ferns, Crotous, Roses, Draeinas, Shrubs and Creepers.

Special Arrangements made with foreign Governments, Botanical and Agricultural Departments, Planters and others for supplying seeds and plants of Commercial Products in larger quantities.

"SOUTH AFRICA."—The great authority on South African affairs of 25th March, 1899, says:—"An interesting Catalogue reaches us from the East. It is issued by WILLIAM BROTHERS, Tropical Seed Merchants of Heuaratgoda, Ceylon, and schedules all the useful and beautiful plants which will thrive in tropical and semi-tropical regions. We fancy Messrs. Williams should do good business, for now that the great Powers have grabbed all the waste places of the earth, they must turn to and prove that they were worth the grabbing. We recommend the great Powers and Concessionaries under them to go to William Brothers."

Agents in London:—MESSRS. P. W. WOOLLEY & Co., 90, Lower Thames Street.

Agent in Colombo, Ceylon:—E. B. CREAMY, Esq.

Agent in British Central Africa:—T. H. LLOYD, Esq., Blantyre.

Telegraphic Address:

J. P. WILLIAM & BROTHERS,

WILLIAM, HENARATGODA, CEYLON.

Tropical Seed Merchants,

Liber's, A.I. and A.B.C. Codes used.

HENARATGODA, CEYLON

Correspondence.

To the Editor.

THE LIVERPOOL SCHOOL OF TROPICAL MEDICINE.

Liverpool, Jan. 1903.

DEA SIRs,—In compliance with a suggestion made at a Conference with His Excellency the Governor of Lagos, Sir William MacGregor, K.C.M.G., C.B., M.D., held in Liverpool on November 17th, 1902, under the auspices of the Liverpool Chamber of Commerce, and in accordance with the advice given by His Excellency on that occasion, the Liverpool School of Tropical Medicine have drawn up a set of simple instructions for the preservation of health for the use of agents of firms trading in the Tropics. I am requested to send you copies of the instructions in question. The Chairman of the School (Sir Alfred Jones, K.C.M.G.), and the Committee, are convinced that the adoption of the recommendations contained in the instructions would tend greatly to improve the health of Europeans living in the tropics. They trust, therefore, that the Principals of firms at home, having houses in the Tropics, will act on the advice of Sir William MacGregor, and will send copies of the enclosed instructions to their agents or responsible clerks in the Tropics, with strict injunctions that the recommendations are to be carried out.—Yours faithfully,

A. H. MILNE, Hon. Secretary,

P.S.—Additional copies of the instructions can be obtained.

CONCERNING SNAKES.

Padukka, Jan. 15.

SIR,—In answer to Virus *re* "Snake against Snake," my belief is that snakes devour each other for its food. The undermentioned incidents are the datas from which I draw my conclusion.

One day whilst fishing at a pond, I saw a large rat-snake glide into the waters and in a short time it re-appeared with a large water cobra and, dragging its victim ashore, swallowed it up and again went in search of prey, coming to the surface again with a similar one. This time the poor thing clung to the grass and I, through compassion, aimed a blow at the rat-snake with my fishing rod, which made it hook off abandoning its prey and again I have myself killed a cobra and as it seemed to have gobbled up something unusual, I got my cooly to rip it up. When lo! to my astonishment I found that it had swallowed up a rat-snake. On measuring the snake I found the former 5 ft. long and the latter 4 ft. long. *Re* venom of one snake being fatal to another, I have no experience.—Yours truly,

B. S. R.

FEEDING MILCH COWS AND BUTTER-MAKING.

London, Feb. 13.

DEAR SIR,—I should like to tell "A Planter's Wife" that she has not quite appreciated the process for producing butter by the absorption of the moisture contained in the cream. The whole action is to take

away this moisture as rapidly as possible, and a new paper is to be introduced of a considerable thickness, with an absorption much higher than that of the best blotting paper, so that as the cream is poured out on to this paper it will be immediately dried. This process should be of great value for a much larger percentage of butter can be obtained from the cream, as there is no waste whatever of fatty matter. So that your readers may quite understand the theory, I would suggest their pouring—say, a tablespoonful of cream—on to three or four thicknesses of good blotting paper. The latter must be completely dry.

I would suggest to "A Planter's Wife" that she can increase the yield of cream from cows if it is possible to procure linseed at a reasonable rate in your country. - The plan to be adopted is to put the linseed into a large stewpan with plenty of water, and let it simmer very slowly throughout the day. In this country I mix bran or crushed oats, but I am not sure whether you have any such meal which could be used to take its place. There is nothing which will so improve the quality of the milk as this mixture.—Yours truly,

THOS. CHRISTY.

[We thank Mr. Christy on behalf of many planters' wives as well as other residents in Ceylon for his most useful hints. Cotton seed with poonac—coconut cake—is largely used for milch cows in Ceylon. Is linseed better, and has one used it out here? As regards butter-making, Mr. Christy must favour us with a few sheets of the new "patent" paper when it is ready.—ED. T.A.]

MANA GRASS FOR MANURE.

DEAR SIR,—Could you or any of your readers kindly give the chemical constituents or manurial value of Mana Grass as a green manure buried with

PRUNINGS.

[The following is the analysis of Ceylon Guinea Grass, grown near Kandy, made by Mr. Cochran, after it had been dried in the sun:—

Moisture, 9.06, Albuminous compounds, 8.10, Fat (either extract), 2.80, Sugar, 4.70, Mucilaginous compounds, digestible fibre, &c., 41.07, Vegetable fibre, 22.50, Ash, 11.77.—Total 100.00. Containing nitrogen, 1.295, ditto 1.455.—Total nitrogen 1.750.

As regards mineral matters guinea grass is very rich in potash and has also a considerable proportion of phosphoric acid.

—ED. T.A.]

"THE CURE FOR MOSQUITOES."

Tangalla, Feb. 23.

SIR,—I was much interested in the article "The cure for Mosquitoes" which appeared this month. These pests make life unbearable here and anything appearing regarding a cure is of great interest to me. I enclose under separate cover two varieties of *Ocinum* growing here. One is called Maduru Tala and is used by the natives here as a cure for mosquitoes. The pungent odour is not lasting; it only keeps away the mosquitoes for a few hours and

through a whole night. But there is no doubt that this plant does keep away mosquitoes to a certain extent. The mere fact of the plant growing in a bed room will not, I am afraid, keep away the insects. The leaves have to be bruised between the hands and placed under the bed and scattered about the room. The other variety is called Tala and is used by the villagers here for chewing when the betel leaf is not procurable.—Yours faithfully,

A. D.

GROWTH OF RUBBER IN MATALE DISTRICT.

Colombo, March 4.

DEAR SIR,—The following information re the growth of *Castilloa Rubber* on the Ambanganga Estate in the Matale District may be of interest and merit inclusion in your next issue of the *Tropical Agriculturist* :—

No.	Height.	Girth.	No.	Height.	Girth.
1	19'3	23	8	16'6	23
2	21'11	25	9	16'8	24
3	18'7	26½	10	12'9	24
4	23'	24	11	14'	23½
5	21'4	26	12	15'3	22
6	18'7	25	13	18'3	23
7	18'3	23½			

All the above are in a clearing planted in November-December, 1900, and so 2½ years old only. Can the Straits beat this? It is interesting to compare these measurements with those of the same clearing published by you some six months ago, where the average girth was 16 inches only and average height 12½ feet only.—Yours faithfully,

W. E. GILDEA.

THE TROPICAL AGRICULTURIST.

March 12.

DEAR SIR—What a convenience it is to have all the Directors' Reports of Ceylon Companies given in the *T. A.* They are so handy for reference that I, for one, much appreciate your monthly on this score alone. All the London and Ceylon Tea Sales is another easy bit of reference for our estates.—Truly yours,

TEA-BUSH.

THE FEDERAL MALAY STATES.

Resident General's office, Selangor, Malay Peninsula, 21st February 1903.

The Editor "*Ceylon Observer*" and "*Tropical Agriculturist*," Colombo.

SIR,—In reply to your letter of the 5th instant, I am directed by the Resident-General to furnish you with the following information :—

FEDERATED MALAY STATES.

Revenue. Expenditure.

Actual 1901 \$17,541,507'23 \$17,273,158'57.

„ 1902 Returns not yet completed.

Estimated 1903 \$18,377,421'00 \$18,561,465'00

(Inclusive of Expenditure on Capital Account \$3,638,868).—I have the honour to be, Sir, your obedient servant,

OLIVER MARKS.

Acting Secretary to Resident-General, Federated Malay States.

PLANTING NOTES.

BANANAS.—Messrs. Elders and Fyffes inform us that, in round figures, the consumption of Bananas during the past two years—i.e., since Mr Chamberlain's effort to aid Jamaica—has risen from 1½ million to 3½ million bunches per annum, which speaks eloquently for the growing popularity of this fruit.—*Gardeners' Chronicle*, Feb. 14.

BLUE HYDRANGEAS.—It appears from a communication of M André to the *Revue Horticole*, that a certain soil near Augers, consisting of sand and humus, is made use of for the production of blue Hydrangeas with more or less success. The soil has been analysed and found to be chiefly silicious in its nature, but very rich in humus and organic matter including nitrogen and with a fair proportion of phosphoric acid and iron. Potash and lime are in very small proportions, so that it is recommended to grow the plants in soil destitute of lime.—*Gardeners' Chronicle*, Feb. 14.

AGAVE AMERICANA.—I was much interested with the supplementary illustration in the *Gardeners' Chronicle*, January 31, and the article on the Agave in Britain. I have observed some good specimens of the Agave in the Scilly Isles, but I was of the opinion they were much too tender for planting out near London. There are two fair specimens planted in a garden near Farnham Station, which up to the present look well, although 17° of frost have been experienced. I shall note their appearance later on, for if they survive I shall try them in different positions in the gardens here.—*W J P, gr, Frenshaw Farnham.*

TEA GROWING IN AMERICA.—Some parts of America are still under the delusion that theirs is a tea growing country. The professional tea taster who said that teas of Yankee origin were superior in bouquet and flavour to the finest Assams must have been fond of a joke! This is the latest from the *Galveston News* :—

Commissioner of Agriculture LeDuc, who introduced the ensilo and sorgo, or, as they prefer terming it, sorghum cane, once experimented with tea in South Carolina. The cash sunk in that enterprise would have floated a daily, but the tea materialised. We once tried to introduce the yerba tea of the chapparal into London; we were running a rural weekly in the Parish of St. Pancras at the time and the sanctum was a sort of Texas museum—jerked buffalo, chile, gum, cochineal, iftile, madder and cotton. We introduced it secretly among the samples of a professional tea taster, and awaited a verdict. He said afterwards that the bouquet and flavor was superior to the finest Assam teas, but its Yankee origin would condemn it. Its Yankee origin condemned it abroad and its Texas origin condemned it at home. It reminds us of the early reception of the American book and American wine. Someday we will all become more reasonable, if not patriotic, and instead of looking towards Battle Creek, Mich., for the correct thing in daily sustenance we will live like plain folk at home.

THE YATADERIA TEA COMPANY, LTD.—All concerned in this well regulated Company are to be heartily congratulated on the excellent results divulged at the last annual meeting. A 25 per cent dividend plus a 5 per cent bonus is certainly an exceptionally high return. The Directors too deserve credit for the very full and comprehensive report (on page 698) which through their agents and secretaries they submitted to the shareholders, and to which we direct the attention of our readers.

TOMATOES IN MEXICO.—More than 1,200,000 pounds of tomatoes were sold last year by the Bernal Orchard Company, Forlon, Tamaulipas, according to A E Graham, vice-president and general manager of the Company. The tomatoes were produced from a tract of 177 acres between the months of December and May. Mr Graham said that 220,000 pounds were shipped by express to the States, a large portion of them going to the New York market; 800,000 to the States by freight, and 200,000 to the markets of Mexico.—*Modern Mexico*, for February.

A REVOLUTION IN MINERAL PROSPECTING.—One of the latest inventions, news of which we publish today, is calculated to revolutionise the work of the prospector for valuable minerals. This is an electrical ore-finder brought out by Messrs. L. Daft and A. Williams of Meadow House, Ealing, by means of which the location of lodes of ore can be effected. The numerous experiments already made prove that its usefulness is no imaginary thing and that even tin sunk at no small depth can be located by means of the instrument. If there is gold in Ceylon—and we have so often said it is to be found in unworkable quantities—prospectors might well wait until the instrument is available for local use. Meanwhile, in finding new veins of plumbago, it should become useful at an earlier date?

WHY WE SHOULD EAT APPLES.—German chemists have established the fact that apples contain a large per cent of phosphorous, the element essential to the removal of the nervous matter of the brain and spinal cord, while the acids are of signal use to persons whose livers are sluggish owing to sedentary habits, the acids serving to eliminate from the system noxious deposits which would retard the action of the brain and induce skin ailments and produce boils. Hence the wisdom as well as relish of taking apple sauce with roast pork and goose. The malic acid of ripe apples, either raw or cooked, will naturalise any excess of chalky matter engendered by eating too much meat, says the *St. Louis Republic*. It is also a fact that such fresh fruits as the apple, the pear, and the plum, when taken ripe and without sugar, diminish acidity in the stomach rather than provoke it. Their vegetable salts and juices are converted into alkaline carbonates, which tend to counteract acidity. A good, ripe, raw apple is one of the easiest of vegetable substances for the stomach to deal with, the whole process of its digestion being completed in eighty-five minutes.—*Journal of Agriculture of Western Australia* for Feb,

“**HYPOPELTIS**”—is the name given (!) to the local insect-pest, by *Nature* in the issue of Feb. 5th, in which a short summary appears of Mr. E E Green's recent studies on the subject.

MOSQUITO SCREENS IN LORENZO MARQUES.—Portuguese East Africa. The United States Consul at Lorenzo Marques, under date of 16th December, 1902, reports that there is an opening for the sale of mosquito netting in that district. The Consul says:—“This place has long been noted for its mosquitoes and for its malarial fever. Until a year ago, the only nettings used were the canopies for beds. Recently, some of the foreign residents have had mosquito screens put in their doors and windows, and this idea is now beginning to gain popularity. I would suggest that manufacturers of mosquito nettings, as well as manufacturers of screen doors and window screens send samples of their different makes, with complete price lists.”—*Board of Trade Journal*, Feb. 19.

PAPAW TREE AS MOSQUITO BANE.—In a recent number of *Nature*, Mr Shipley called attention to the influence of the leaves of *Ocimum viride* in banishing mosquitoes. Following up this subject, Mr. Percy Groom narrates how his house at Whampoa was comparatively free from the invasion of these insects, a circumstance which he attributes to the presence of a line of Papaw-trees which intervened between his house and the river. Other houses in the same island were more or less infested with these insects. Once, after a typhoon had blown two of the trees, and left a gap, the number of mosquitoes in the house increased. Mr Groom further states that he never saw an insect on these trees, though he frequently examined them, and observed flies and other insects upon the Bamboos and Bananas near by. As the Papaw has usually unisexual flowers, and is in fact generally dioecious, it becomes interesting to know by what means fertilisation is effected.—*Gardeners' Chronicle* Feb. 7.

“BUYERS, BLENDERS AND DISTRIBUTORS. The economics of tea. Facts and fallacies about competition and combination,”—is the title of a paper in “Tea” for February by W Forbes-Laurie. We make two interesting extracts:—

To prove to what a low ebb tea-growing has reached, I annex a table showing the apportionment of cost in making an average pound of tea:—

Government duty	6 00
Cost to producer laid down in London, including office and all expenses*... ..	6 10
Growers profit	1 00
Dealers profit	0 60
Retailers profit	3 00
Average cost to consumer	16 70

One undoubted conclusion all agree in, that a low Market grinds down, until grower, dealer, broker and employee from manager to assistant, are in the lowest form of remuneration; and from this cause alone arises mutual recriminations. The market for producer and dealer is at its lowest ebb, neither are wrong, except in not seeking mutually to relieve the pressure at the right spot—they are on the horns of a dilemma. *Yet it has its remedy.*

MATALE AND ITS SURROUNDINGS.

A MODEL COUNTRY TOWN.

"What a charming country station is Matale"—says a recent visitor—"and how great the improvements since I first saw it in 1864 (!) or even since my last visit in 1891. I should scarcely know the place save that the Rest-house and Residency are in the same situations and that the mile-of-street-and-boutiques (like the lang toon o' Kirkaldy) along the North Road, shows as busy a scene as in the most prosperous of

COFFEE DAYS.

Alas! how are the mighty fallen—since the day when Ectapolla, The Borders, The Glen, Asgeriya and even Hampshire and Wiltshire were among the "crack" plantations of the island—all in their pristine vigour as I saw them in the early sixties; after which I rode across to Sylvakande (E J Young), Dambulagalla (D Watson), and on to "The Valley" (*par excellence*)

OF KELLEBOKKA

to see D Webster on Greenwood, and by Goomera to the centre of Rangalla at Battalagalla—now Duckwari. Some years later, a start from Matale led to Rattota, Opalgalla and Gammadua and back to join W D Gibbon and C Catto (who long ago passed the last bourne) in an expedition from Hoolankande across the Knuckles range to new clearings on the Eastern spur; and later still, Matale was the starting-point of a memorable expedition I made with poor A G K Borron right over

LAGALLA

and down on the other side through the region where Wingate, Hope, Mackie and a host besides buried many British sovereigns, bright anticipations and much labour and health in the vain hope that coffee crops would mature where the soil was rich and the rainfall good, even though for three months every leaf was blown off the bush by the swirling South-west winds rushing over and down from the high mountain range into the hot low-country of Bintenne. Our expedition was, however, for a goal much farther on—to inspect an arnatto clearing on one of the blocks at the back of the Knuckles which, when originally surveyed by Mr Vetch, of the Survey Department, he thought so much of that he induced his own brother to invest and settle, with disastrous results. Neither did the arnatto prove a success. When ever "new products," without over-production warrant attention to outlying forestland there are many lots privately owned, on the Eastern slopes between Lagalla North and Nitre Cave, available for the exploiter.

But my theme is "Matale" as a centre and starting-point and I have yet to refer to expeditions to North Matale towards Nalande, over land newly developed by Messrs. Ross, Milne, Taylor, Davidson and others, and where so much rich cultivation in cacao, tea and coconuts now prevails. The way in which the

COCONUT PALM

has flourished in response to extensive planting all along the Matale valley is quite surprising and the total crop must now supply no inconsiderable part of the annual food requirements of the town and surrounding country; for, we suppose, none of the nuts are, as yet, turned into oil or used for export? We visited only one plantation on the present occasion: the young extensive and promising property of

CLODAGH

where we were not only gratified at the evidence on every hand of careful substantial work but truly surprised at the extent and magnitude of the operations of the enterprising proprietor, who has as much at heart the good of the people in his employ as well as of the surrounding villagers, as the success of the plantation in which he has invested so much capital. Clodagh is made up of many lots of forest and waste chena land bought from Government and the natives to a total extent of quite 1,000 acres, and of this over 400 are planted with flourishing cacao, and over 300 with tea, very fine in parts—all equal, healthy fine jät from Norwood seed—the oldest field giving probably 500 lb an acre—while in some clearings, the work of "supply" has been a heavy, continuous one. We should be afraid the country was too dry here; but the record shews a fairly good, well-distributed rainfall, and certainly at our visit, everything looked vigorous—not the least, the really splendid coconut-palms (grown from Goluapokuna seed nuts), of which Mr. Malcomson has (or is to have) some 20,000 distributed, at wide planting distance apart, through his property. Nevertheless, if they all succeed,—as with such large holes and careful planting and attention they certainly should,—he should have the equivalent of an ordinary coconut estate of over 25 acres fully planted!

WHITE ANTS

have been a great trouble hitherto; and to get rid of them, Mr. Malcomson began by paying 25 cents for each "queen-ant" brought in; but he soon found this was extravagant and gradually came down until now the rate is as low as 3 cents; and yet from first to last, 1,000 queens have been disposed of and still they come from the latest clearings! All the works on Clodagh—roads, drains and especially buildings—have been executed after, the "pucka" fashion that would have delighted the late Messrs. Worms and Sabonadiere of Fussellawa. Bungalow and Factory are exceptionally well-finished, the proprietor being his own architect and very much his own engineer. The steam engine and boiler (a "Shanks") we were interested to learn was that imported by the ill-fated European Gemming Company to Rakwana; while Jackson's most improved tea machines are in use. We found a Cacao-drying Barbaque and Store in course of construction as also substantial "caddies" where the coolies can be supplied with good curry-stuffs, &c., at fair prices or rice-barter, without having to rush into Matale, or to villages *en route*. Not the least conspicuous, or commodious building on the property is the School-house where also services are held under the auspices of the "Friends' Mission" of which Mr. and Mrs. Malcomson are honoured members; while they have now got colleagues set apart entirely for Mission work in Matale and elsewhere, in Mr. Long (an experienced Missionary with many years of work among the Tamils in Coimbatore district, S. India, behind him), and Mr. Arden and Miss Cheale. It was certainly a fortunate day for Ceylon—and especially for much of the Matale district—when Mr. Malcomson decided to remove from his Irish ancestral home on the pleasant banks of the Clodagh in County Waterford, to establish himself and family in old Lanka.

Never did pioneer, planter and missioner deserve a fuller measure of success in all he has set his hands to, or his heart on.

It only remains to remark on the wonderful growth of introduced trees at this elevation: a four-year-old "Albizia" quite astonished us by its size, while young "Pehimbias," with their graceful foliage, and the Na ironwood, with its white flower in contrast to scarlet leaves, remind planters that they need not go beyond local jungles for handsome ornamental, as well as useful, timber trees. Clodagh tea-fields are planted all over with the grevillea—the "silky oak" of Queensland—which indeed is a distinguishing feature on all the plantations and clearings around Matale. The scenic outlook from Clodagh is very charming—the front view embraces Hunasgeriya peak and the range right along to the end of Laggalla, terraced rice valleys in the foreground adding variety, and only "water" in river or lake being wanted to complete the picture. There is a river running through one part of the property which (like so many of the Matale streams,) rises so rapidly as often to endanger life; but a useful suspension bridge, thrown across it, is not the least of Mr. Malcomson's improvements. From a point behind the bungalow, Adam's Peak and the False Pedro range are often visible; while the West Matale hills up to old Ambokka and the valley leading out to Nalande and Tamankaduwa are very near. The minor road as well as the main Rattota road we found in excellent order and Mr. Malcomson had only praise for the present active Assistant Agent in this and other connections.

But we must return to

MATALE TOWN

which we left with one long street, whereas it has now developed a back street quite as fully occupied with several busy cross streets; while the amenities—in parks, tennis greens, well-kept roads for the carriage, bicyclist or pedestrian, circling round the town, surprised us by their attractiveness and convenience. The Local Board and its President deserve much praise for these and other improvements in Lighting, Water Supply (not yet complete) and Sanitation. The town altogether has become a model outstation for Ceylon; but nature has richly endowed it in umbrageous and flowering trees and grassy glades,

So fair a scene, so rich a sod

Our English fairies never trod.

The most conspicuous building in Matale is the new "Club-house," erected by the enterprising Mr. Perera, formerly resthouse-keeper, and which he has built all at his own cost, immediately opposite the resthouse which it dwarfs and dominates. The planters are expected to make the investment a remunerative one. "The Borron Hall and Library" near the green, the Roman Catholic Church and Convent (the "sisters" being all Ceylonese) in the back street, the neat little Anglican Church on the Hill in the midst of the well-kept Cemetery, the Baptist Chapel and Hall in the middle of the town are farther institutions, not to mention the time-honored Kachcheri and Police Court with its, no doubt, indispensable "Lock-up" (Was it not an Englishman who, washed ashore from a wreck on a strange land, returned thanks that he was among a civilised people because the first object he saw was a gallows!) The airy-

situated, neat-looking Hospital and grounds are a special feature near the old coaching entrance to the town; while the Railway Station, though not attractive in itself, has two of the finest flower-gardens we have seen anywhere along the line—the show of chrysanthemums is specially striking. Much good work is being done by the "Padres" in and around Matale, through in-door and open-air services, in schools and in other ways. The climate we found in February to be truly pleasant—never too hot nor too cold—a happy mean between Colombo and Nuwara Eliya.

A CEYLON PLANTER IN CALIFORNIA.

MR O. H. GREENSLADE: HIS NOTES ON CEYLON PRODUCTS.

A letter has been received by a Colombo merchant from Mr O H Greenslade, formerly of Dehiowita, Kelani Valley, dated "Kern County, California, January 30th." He had been at work there, without moving once from the town since he last wrote in July, 1902; the railway is just across the road, where he lives. From his letter we are permitted to make the following extracts:—

"We live a very quiet life, to bed at 9:30 every night. I am greatly improved in health, and feel very strong and young, and fit to do any work. A travelling 'bed renewer' (a man who re-stuffs mattresses) was working here yesterday. I showed him the sample of 'mattress fibre.' He said 'Yes, I know it; it costs 22 to 24 cents per lb' at the lower price. The ton of 2000 lb, equals \$140.00, against your quotation. Mattress fibre, £2 per ton, equals \$10. The Collector of Customs, San Francisco, writes me the following on *Import duty*: on Mattress and Palmyra fibre, he answered 'Don't know what this is'; Desiccated Coconut, 2 cents per lb. Cocoa, answered "prepared" 2½ cents per lb up to 50 per cent.—"raw" free. Plumbago free. Cardamoms free. Gum, unrefined free. Cigars \$1.50 per lb and 25 per cent. Tea free."

"You notice that Coconut fibre is not imported at San Francisco—also that there is a very fine margin on the retail price.—Import duty on Cigars is quite prohibitive (I got a lot of samples from Madras).—I believe there is quite a fine trade, to be done in Ceylon products, and only wish I could travel, or start in, and sell them. Brushes are made here, with 'broom-grass,' which makes a very good brush. Straw, and hay, is bailed up with wire; if the coconut fibre rope would hold the bail together, it would soon be in great demand. [Wire is cheaper and better for bailing.—Ed. T. A.]—Tea sells retail from .50 to \$1.00 per lb; it can be landed here for under 25 cents.—Railway travelling is high; commercial travellers are allowed ten dollars a day.—Is there much 'gum' to be found in the forests of Ceylon? Every body (boys and girls) chew gum here. Note that there is no import duty on raw gum. There should be a big trade in this article, for I have seen gum frequently in Ceylon."

"Snow is thick all over the country, the first good fall for ten years in this part. Prospects for a good crop are good; but the rainfall is very small eight or ten inches a year, and unless spring rains come, the prospects fall flat."

THE ROEBERRY TEA COMPANY OF CEYLON, LIMITED.

DIRECTORS:—Hon. Mr Stanley Bois, Mr G H Alston and Mr H O Hoseason.

ACREAGE :	
Tea in bearing ..	497 acres
Tea 5 year old ..	109 do
Tea 4 do ...	36 do
	642 acres
Cardamoms ..	4 do

646 acres in cultivation

The Directors have now the pleasure to submit their Seventh Annual Report and Accounts, being those for the year ending 31st December, 1902. The yield of tea during the period has been 301,545 lb. costing 24.10 cents per lb., against 291,324 lb., costing 24.42 cents per lb last year, and realising 36.39 cents per lb., against 37.66 cents for the same period. After providing for commission due Superintendent and making a liberal allowance for depreciation of buildings and machinery, the amount at credit of profit and loss is R27,052.29. To this must be added the sum of R461.82 brought forward from last year, making a total of R27,514.11 now available for distribution. The Directors recommend the payment of a dividend at the rate of 5 per cent on the paid up capital of the Company, which will absorb R15,000; that a sum of R12,000 be placed to extension account—thus bringing it to R32,000; and the balance R514.11 be carried forward to current season's account. The Directors are pleased to state that the mortgage has been finally liquidated. The estimate for the current year is 320,000 lb. of tea on an expenditure of R75,170 which includes the cost of clearing and planting 10 acres of tea. The retiring Director is Mr G H Alston, who is eligible for reelection. The appointment of an Auditor for the current year rests with the meeting.—By order of the Board,

Bois Brothers & Co., Agents and Secretaries.

TALGASWELA TEA COMPANY OF CEYLON, LIMITED.

DIRECTORS:—Messrs. W Rae Sands, W Macgregor, Hector Van Cuylenburg and J W Erskine.
AGENTS AND SECRETARIES:—Baker & Hall.

Forest	1,229

Total Acreage .. 2,028

The Directors have much pleasure in placing before the Shareholders their Fifteenth Annual Report with a duly audited Statement of the Company's affairs to the 31st December, 1902. During the past season 143,131 lb of tea have been secured against 133,760 lb. last year. 30,151 lb. of tea were manufactured and sold on behalf of the Gallinda Estate. The cost of tea this year laid down in Colombo is cents 23.12 per lb. and same has realised cents 30.68 nett against cents 28.39 last year all tea having been sold in the local market. Profit and Loss account shows a profit on the year's working after writing off R2,388.07 to Depreciation, of R7,735.52 from this has to be deducted debit balance of R22.42 brought forward from last year and after payment of interest to preference shareholders viz. R2,100 there remains the sum of R5,313.10 which the Directors suggest should be dealt with as follows:—Payment of dividend 2½ per cent on ordinary shares absorbing R5,000; Carrying forward to current season R313.10. Since the last meeting Mr. J W Erskine has joined the Board; Mr.

Hector Van Cuylenburg retires from the Directorate by rotation and being eligible offers himself for reelection.

The appointment of an Auditor rests with the meeting.—By Order of the Directors, BAKER & HALL. Agents and Secretaries.

Colombo, 26th February, 1903.

THE CLYDE TEA ESTATES CO., LTD.

REPORT OF THE DIRECTORS.

DIRECTORS:—Messrs. F M Laurie, E D Harrison Robt. Davidson. Agents and Secretaries:—Messrs. Lewis Brown & Co.

ACREAGE :	
Tea above 4 years old ...	525 acres,
Jungle, &c.	190 "
	Total .. 715 "

Your Directors beg to submit their Report and the Accounts for the year 1902. The quantity of Tea made was:—From Estate leaf 170,647 lb and from bought leaf 5,395 lb. against original estimates of 175,000 lb. and 5,000 lb respectively. The shortage in Estate leaf is due to the very unfavourable weather experienced during the closing months of the year, but for which the estimate would have been exceeded.

The expenditure on Manuring during the year amounted to R3,732.70 which, along with sundry items for Rubber extensions &c. totalling R1,907.80 have been charged against revenue. The cost of Estate tea exclusive of these, but including transport to Colombo and selling charges was R46,587.57, equal to 27.30 cents, per lb. The average price realised for 27,601 lb black tea was 33.71 cents and 148,432 lb green tea (inclusive of Thirty Committee bonus) 36.24 cents per lb. The Capital Expenditure during the year on additions to buildings and machinery was R344.70 and R4,336.61 respectively. Depreciation on buildings has been written off at the usual rate of 2½ per cent, and on machinery at 5 per cent on the total book values thereof. Including the balance of R499.89 brought forward from last year, the sum now available for distribution R6,084.61, from which the Directors recommend the payment of a dividend at the rate of 2 per cent. This will absorb R5,400 and leave R684.61 to be carried forward. In terms of the Articles of Association, Mr. F M Laurie retires from the Board, but is eligible for re-election. The Shareholders have to appoint an Auditor for 1903.

THE CLAREMONT ESTATE CO., LTD.

ANNUAL REPORT.

The Directors submit herewith their Report and Accounts for the year ended December 31st 1902.

Crop for the year proved very short indeed. 63,383 lb only being realised against estimate of 85,000 lb. This great shortage may be attributed to the very unfavourable season, which was general, and also to the scarcity of labour, which however has since been remedied.

The cost of production was 28.09 cents per lb as against 26.47 cents the previous year, the small crop accounting for the enhanced rate. The Teas netted 33.67 cents as against 29.35 cents in 1901.

It will be seen that after taking into account Interest and all other charges, the balance at debit of Profit and Loss is 10,008.83. Interest on Mortgage has been paid to September 30th, 1902, but the interest on the mortgage Debentures still remains unpaid. The Directors have again waived their fees.

The existing mortgage of £3,000 has been called up, but the Directors hope to be able to effect a fresh mortgage on suitable terms.

Mr R H Elliot retires from the Board of Directors by rotation, but, being eligible, offers himself for re-election. Another Director has also to be elected to make up the number to that required by the Articles of Association.

It will also be necessary to appoint an Auditor for 1903.

THE NAHAVILLA ESTATES CO., LTD.

DIRECTORS:—Messrs. J M Mason, E S Grigson, W Anderson, Gordon Pyper; Agents and Secretaries:—Messrs. George Steuart & Co.

NINTH ANNUAL REPORT OF THE DIRECTORS.

The Directors have the pleasure to present their Report for the year ended 31st December, 1902, the accounts in connection with which show the Company to be now in a sounder financial position and afford ground for a better dividend than last time. The surplus of Revenue over Expenditure (R45,440.59) is much the same as for the previous season, but there is now less need to make provision for further improvements. After placing R7,500 to Depreciation Account, and the payment of Interest on Mortgages and Sundry other charges, the Profit and Loss Account shows a sum of R23,482.49 available for distribution, out of which the Directors propose to pay a dividend of 5 per cent on the paid up Capital of the Company. This will absorb R19,825.00, and the balance R2,657.49 after payment of Directors' Fees they propose to carry forward to next season's account. The Tea Crop fell short of Estimate, and only amount to 515,611 lb against 524,840 the previous year. The Average Price realised was however, somewhat better, being 35.43 cents as compared with 34.84 last year. The cost of Production including 1.22 cents for Manuring and Burying of Prunings was 28.11 cents against 28.06 last year. Coffee realised only R6,789.40 as compared with R8,846.11 the preceding year. The Water-Power Installations recommended in last Report have been completed on both Ury and Nahavilla, and are working satisfactorily. A new Roller and a Drier have also been placed in the Nahavilla Factory, besides Fans; but Fans are still required for the Ury Factory to improve the condition of the wither in the busy months. The Tea Crop for the coming season is estimated as 590,000 lb to be produced at a cost of 25.65 cents per lb exclusive of any manuring or capital expenditure that may be decided upon. The manufacture of Green Tea at certain seasons of the year is under consideration.

Mr J M Mason retires from the Board by rotation, and does not seek re-election, as he is about to leave for England. The appointment of an Auditor for the ensuing year rests with the meeting.

YATADERIA TEA COMPANY OF CEYLON, LIMITED.

DIRECTORS.—Messrs. Frank Liesching, David Fairweather and Henry Valentine Masefield (Managing Director); Agents and Secretaries—The Eastern Produce and Estates Co., Ltd.; Superintendent of Estate—Mr. J R Fairweather; Bankers—Bank of Madras; Solicitors—Messrs. Julius & Creasy; Auditor—Mr. J D Forbes.

The Directors have pleasure in submitting the Balance Sheet and Profit and Loss Account for the year ending 31st December, 1902.

The Profit for the year is R72,657.16 to which must be added R1,245.99 balance from 1901, and the Directors recommend that a Dividend of 25 per cent and bonus

of 5 per cent absorbing R57,000 be declared, R9,500 reserved for Working Capital and the balance R7,403.15 carried forward.

It will be seen that the Property representing Capital stands in the Balance Sheet at approximately R194 per acre cultivated as compared with the same figure in the previous year's accounts, and that the Profit is R75.21 per acre in bearing and 38.24 per cent on the Capital.

The total Tea Crop was 656,820 lb (630,643 lb. Black 26,177 lb. Green Tea) or 76,820 lb more than the estimated quantity, the heavy crop being attributed to improvement in the bushes under the system of allowing them to get well up from pruning before tripping; the appearance of the Tea is good and prospects of crop for 1903 fairly satisfactory; the Superintendent estimating an outturn of 541,512 lb. Green Tea from Estate leaf.

The total quantity of Tea for disposal was 695,374 lb including 38,554 lb made from purchased leaf, of which 541,002 lb were sold locally averaging 29.17 cents per lb and 154,372 lb shipped to London in the earlier months of the year averaging 27.85 cents per lb.

The cost of Tea per Superintendent's Estate Report was 15.27 cents per lb and the total cost delivered to buyers or put on board ship including all charges was 18.02 cents per lb; or exclusive of Depreciation 17.11 cents per lb the net value realised from sales was 28.88 cents per lb. R14,084.43 was spent in 1902 on New Machinery and Factory Extension and further outlay estimated for at R12,500 on New Engine and Boiler and a Dryer will be incurred in 1903. Manufacture of Green tea was commenced on 8th December, 1902, 26,331 lb being made by the end of the year which realised with the bonus 37.82 cents per lb; Green Tea manufacture will be continued for the first six months of 1903 the crop for that period not exceeding 300,000 lb having been sold on Contract at 35 cents per lb, the bonus accruing to the sellers.

The Company's Property consisted on the 31st December, 1902 of:—

Acres Tea	Planted in	Yield in 1902 tea per acre lb	Compared with lb in 1901

PARA RUBBER.—During 1902 some 42,647 plants were put out, the growing plants and trees on the Estate of all ages being estimated at 55,000, of which 843 trees have been tapped.

Mr David Fairweather retires from the Board, and being eligible offers himself for re-election and the shareholders will be requested to elect an Auditor for the current year. By order of the Directors,

THE EASTERN PRODUCE & ESTATES CO., LTD.,
Colombo, March 2, 1903. Agent & Secretaries.

RUBBER IN MEXICO:

OVER 8 MILLION TREES PLANTED
AND 1½ MILLION IN NURSERIES.

We begin to think that Mr. John Darley and some other Ceylon planters who have made their home in Mexico are right as to the great future before this favoured land, and that the London Deputation which included, if we remember rightly, Mr. James Sinclair and Mr. John Clark, among other practical men, were a little hasty in deciding against taking up land and establishing a plantation west of the Gulf of Mexico. The number and variety of crops that are successfully grown in a territory which extends from 7 to 32 degrees North Latitude is, of course, very notable; but the chief factor to financial success is found in the great and ever-growing market "next door" in the United States. Making due allowance for optimism and exaggeration, it is not possible to doubt the liberal returns got from coffee, cacao (indigenous) and the very rapid growth of the planted rubber trees. Plants (of Castilloa, the indigenous rubber, we presume) put out in July 1900, at a distance of 18 feet apart, had a girth of 8 inches by February 1901, of 20 inches a year later and of 25 inches in November 1902, and early this year, the branches were touching each other across the 18 feet. "Seeing is believing" and the statements are accompanied by illustrations which appear to bear out the figures given At Henaratgoda and Peradeniya it took 9 or 10 years for Castilloa trees to attain a girth of 40 to 43 inches; but they have done better with Major Gordon Reeves in the Matale valley; and Mr. Gildea the other day showed, for Ambanganga estate, a growth of Castilloa trees in 2½ years up to 26½ inches girth. *In this Ceylon beats Mexico, the indigenous home of Castilloa!*

On page 700 we give a letter to the New York periodical "Modern Mexico" (February 1903) from Mr. George Cullen Pearson, which bears the impress of truth; and he shows that Messrs. Lewis & Peat of London have valued his sample of rubber, taken from trees *three years old*, at 2s 8d per lb. and pronounced it "thoroughly marketable." We say nothing of the great things Mr. Pearson expects to do—nor of the anticipation of an income of £15,000 from 100,000 trees in their 7th year, to be doubled by the 9th year; but this is certain, that without the stimulus of such statements, rubber-planting has *already* become a vastly extended industry in Southern Mexico, although as yet there is probably not a single plantation which has arrived at the age for its rubber to be regularly harvested.

In other words, the rush into planting has taken place during the past four or five, and chiefly within the past two and three, years. Nevertheless, on certain of the coffee and cacao gardens there are old trees planted simply for shade purposes and

we are told that some of these, said to be 7 and 9 years old, when tapped experimentally, yielded 2 lb. of rubber per tree; another statement is that trees 6 to 8 years gave 1 lb. each on an average, of marketable rubber; while yet a third account mentions 350 trees (a few of them 20 years old) which yielded altogether 800 lb. of clean rubber.

But now to turn to the future of rubber in Mexico. Our contemporary of the "India Rubber World" of America has caused a census to be taken (by circular letter addressed to all the incorporated rubber-planting companies operating in Mexico) of these total plantings and they have had a response from 26 Companies (one beginning work in 1897, two in 1899 and the rest of 1900 or since.)

The number of trees per acre ranges from 200 to 2,000! 800 seems a favourite number. Here then we have 5,400,000 trees planted out, and over 11,400,800 plants in nurseries ready to put out, say in 1903-4. The work done, or to be done, by Companies not reporting may be taken to cover any over-sanguine estimates, or exaggeration, or failures in nursery plants; and our American contemporary reckons that numerous private planters in Mexico represent perhaps half as much again as the Companies. This would give us a total of over 8 million Castilloa trees planted out in Mexico, chiefly under three years old, apart from the indigenous forest trees.

We are naturally led to compare our progress in rubber-planting in Ceylon and the Straits Settlements with the wonderful start made in Mexico by American Companies, during almost the same period (the past three or four years); but our information is not sufficiently up to date as we write, for any but a rough estimate. We cannot suppose, at the most, that the planting in Ceylon of Para and Castilloa (or even if we count some Ceara and other kinds) exceeds 4 to 5 million trees; while the Straits and Borneo may also have 4 to 5 million trees planted out of all ages.

Is there anything in the Mexican and our Eastern figures to cause an alarm as to over-production in the future of five or six years hence? We do not think so. Suppose that the close of this decade, say 1909, sees 13 or 14 million planted trees yielding a pound of clean rubber each, what would this crop be, —however profitable to the growers as we expect it to be—to the growing requirements not simply of the world; but of the United States alone! The latter seems to require at present from 30 to 50 million lb. of rubber a year, for the manufacture of bicycle tires alone! When the numerous other uses for rubber are considered, and the immense development in new industries, which, we are assured, would follow a slight reduction in price, of the raw product, we may well bid good-speed to all the Mexican, Straits and Bornean, as well as to our Ceylon, planters of rubber trees —whether Para or Castilloa—and feel assured that there is "a good time coming" for most, if not all, of them.

AN EXPERIMENT STATION FOR INDIA. SOME LESSONS FROM AND FOR CEYLON.

(From a correspondent.)

The article in the *Indian Planting and Gardening*, just to hand, by Mr Harold H Mann, is one likely to attract attention in Indian circles and it is hoped that the Government will see their way to encourage the establishment of one or more Experiment Stations in the districts mentioned. The power of an Experiment Station with an agricultural people is very great and were it not for their existence in America, West Indies and Germany the vegetable economic products mentioned by Mr Mann would still have a very limited distribution.

The experimental cultivation of new products, the improvement in modes of cultivation and manufacture of products already existing, and the preparation of standard samples of products frequently adulterated, are subjects of vital importance to all planters and can only be dealt with by Government in places established for the purpose. It is a matter for congratulation to the people of this colony that Sir West Ridgeway has granted an Experiment Station, to be controlled by a recognised scientific staff of workers and assisted by some of our most prominent representatives of the Planters' Association. The constitution of

THE EXPERIMENT STATION AT PERADENIYA, the organisation of the staff and the work already in hand on the newly-acquired grounds, some 550 acres in extent, might very profitably be considered by our Indian friends. HE the Governor in his last annual speech informed us that Mr Herbert Wright had been appointed Controller of the Experiment Station and that a Committee comprising Messrs J C Willis, J B Carruthers, E E Green, M Kelway Bamber, the Hon Messrs E Rosling, Joseph Campbell, and S N W Hulugalla and Messrs J Fraser, T C Huxley and Edgar Turner, together with the Controller, had been formed. A stronger Committee could hardly be appointed and the Colony may confidently leave the future of Agriculture in their hands. There are several POINTS WHICH OUGHT TO BE CAREFULLY WATCHED lest the work turned out from the Experiment Station lack the fullness and vitality which we know Mr Herbert Wright would wish it to have. The first point, mentioned by Mr Mann, is that an Experiment Station is not a revenue-making place. Certainly nothing should be wasted, but, on the other hand, Government should be well aware of the fact that, in establishing new products or improving the old, many futile experiments must be made and these cost often large sums of money. Further, many experiments similar to those carried out at Rothamstead cannot possibly give any return in money to the station, but the agricultural community are placed in possession of knowledge which allows them to get more from their land and resist the ravages of insects and fungi in an intelligent manner.

A second point is *re* the subject of new products. It is a matter of

COMMON KNOWLEDGE THAT PRODUCTS COME AND GO

and the past few years have convinced us that tea is by no means sure of staying long. Cacao is becoming diseased in all parts of the island and cardamoms, citronella, cinnamon, and many other products appear to be passing through stages

familiar to those who have seen coffee bloom and fade away. In our opinion the Experiment Station should see that at least a $\frac{1}{4}$ acre plot of *e very* tropical product be established to show the planters what will grow and how best to grow it. Planters cannot afford to speculate on these products and it is a duty of Government to see that the *estate* in Ceylon is developed to the utmost. New products we must have and there are plenty which have never yet been scientifically cultivated in Ceylon.

We have heard from several planters of the work which is being carried on at the Experiment Station and though we must be patient and wait until the old cacao estate has been transformed into its proper form we should

LIKE TO SEE SOMETHING DONE WITH CACAO at an early date. No better place could be chosen for experiments with cacao and as Mr Wright knows, there is plenty of work to be done re fungicides and modes of attacking the cacao canker, with shade trees and wind belts, in methods of curing and fermenting and in manual work in general.

The first annual report issued from the Station should prove interesting and until it arrives further comment is scarcely required.

A MEXICAN RUBBER GROWER SPEAKS REGARDING PROFITS.

£15,000 A YEAR IN THE 7TH YEAR FROM 100,000
TREES.

Having planted and watched the growth of several hundred thousand trees for the past four years and a-half and having devoted much attention to the preparation of rubber in a series of experiments extending over the last three years, some marketable results I have obtained may be of interest to those who have taken up the rubber industry in Mexico. I may be permitted to state that my property is not in the market and that I can have no interest in deceiving myself. Two years ago, I sent a sample shipment of Mexican rubber prepared by myself from trees growing on the estate to the leading firm of rubber brokers in London, Messrs, Lewis & Peat. The rubber was valued at three shillings and nine pence, the best Para being then four shillings and two pence per pound. The quality was reported as excellent. This—I was informed—was the first sample of good marketable rubber ever sent from Mexico to London. Last year, when in London, I had sent me from the plantation a sample of rubber from three-year-old trees. The trees were only very lightly tapped, but sufficient rubber was obtained to enable me to present a sample on which a quotation could be made. It was valued by the same firm of brokers at two shillings and eight pence, and pronounced thoroughly marketable. I do not present this as a precedent to be followed, but it is interesting as showing that even at the early stage of the tree's growth, clean and careful preparation will produce a rubber which commands a price considerably over that yielded by mature trees when ignorantly and slovenly handled. I am now sending off a large sample shipment of rubber to London, prepared by an improved method (my own) which I, perhaps conceitedly, believe to be the finest rubber ever sent out of Mexico, and which will, I have no doubt, fetch the highest price next to best Para.

It is regrettable that statements should be irresponsibly made, disparaging an industry which will certainly become a source of wealth to those who give thought, care and patience to its development, by any one who has not studied its methods and is manifestly unacquainted with the principles which make for success. For my own part, I am more than satisfied with the growth and prospects of my own enterprise. Let us take the case of a man possessing a hundred thousand trees, and put the yield at the seventh year at one pound only—I believe this to be below what the result will actually be. Let us put the price of good, clean, sound rubber at three shillings per pound, which my brokers inform me it is quite safe to assume will be its value. The result would be £15,000 sterling—fifteen thousand pounds—for the first year, which would be doubled certainly by the ninth year, an income for which I, for one, am quite content to work and wait.

GEORGE CULLEN PEARSON.

Puebla, Mexico, January 4th.

PROSPECTS.

Again:—The following is taken from the letter of a gentleman residing in Mexico who has no interest in rubber lands, and may be considered an impartial statement:—

I am in receipt of your favour of the 15th inst. in which you ask me to give you the location of the various districts of sub-tropical Mexico where conditions are favourable to the cultivation of rubber, and stating that you contemplate establishing a plantation if available land can be found where rubber would likely prove a profitable crop. The rubber tree is found growing wild in the forests which cover a strip of country ranging from ten to one hundred miles in width, and extending from the port of Tuxpan on the north to the western boundary of the State of Campeche, a distance of probably five hundred miles. There are probably more rubber trees to a given acreage of forest in the vicinity of Frontera, in the State of Tabasco, than elsewhere in the rubber-producing country of the Gulf Coast. Near Belize, on the east coast of Yucatan, rubber trees are abundant. Around Soconusco, on the west coast of Chiapas, and in the vicinity of Pochutla, State of Oaxaca, rubber plantations have been started. As rubber grows only on the moist low lands of the coast, the width of the rubber belt varies greatly. In places it follows the river valleys for a considerable distance inland, but, where the mountains approach the sea, it is narrowed to a few miles of country lying along the coast. Nearly all the rubber produced in this Republic is collected by the Indians from the wild trees growing in the forests.

The rubber tree matures at the age of 6 years. They should yield from 6 to 48 pounds of milk annually. In the coagulation of the milk there is a shrinkage of about 50 per cent, leaving from 2½ to 3½ pounds of crude rubber, which is worth 50 to 80 cents per pound gold. The process of coagulating the milk is simple and inexpensive. The annual profit of a bearing plantation of 100 acres should not be less than \$8,000 Mexican money. However, up to the present time, the actual profitability of cultivated rubber is, in a measure, a matter of conjecture, as no one, to my knowledge, is yet making money from a bearing plantation in this Republic.

In the southern portion of the Republic, particularly in the rubber-producing districts of Chiapas

and Tabasco, a large number of rubber trees are annually being killed by too frequent tapping by the Indians. This is causing a great decrease in the rubber production of the country.

Capitalists seeking profitable investment in Mexico are fully warranted in going into this subject scientifically. Something is already being done in an experimental way, and a few years should do a great deal toward demonstrating what results are obtainable from the systematic cultivation of the rubber tree in Mexico. There has been a constant increase in the consumption during the past few years. The annual exportation of Brazil has reached \$100,000,000. The Central American countries are also largely exporting this commodity. The price of rubber is also advancing. The United States alone consumes \$30,000,000 worth of rubber in the manufacture of bicycle tires. It is my belief that the price of rubber will not materially decline. The increased use of electrical apparatus, the probable general adoption of rubber-tired vehicles, the extended utilisation of rubber in the manufacture of belting, clothing, etc., will prevent any notable depreciation in the value of this commodity. A decline in price will be quickly followed by an increase in consumption.—*Modern Mexico* for February, 1903.

A HARDY, RUBBER-YIELDING TREE

Eucommia ulmoides was figured and described by Prof. D Oliver in Hooker's *Icones Plantarum*, tt. 1950 (1891). 2361 (1895), from specimens collected in the Province of Hupeh, China, by Dr Henry. It forms a tree 20 to 30 feet high, with a branch-system resembling that of the common Hazel, the deciduous leaves resembling those of the Elm; the flowers small, and unattractive; and the fruit in clusters, samaroid, winged, about an inch long, ¼ inch wide, each containing a single oblong seed. The genus is related to *Trochodendron*, *Cercidiphyllum*, and more distantly to *Hamamelis*. A plant of it was presented to Kew in November, 1897, by M Maurice de Vilmorin, and in the space of four years it has grown from a small plant a foot high to a sturdy bush 7 feet high, and 6 feet through. It has stood the frost of that period in the open air without any protection, and appears to be quite as hardy as the Witch-Hazel. Cuttings of the branches root readily, and large branches of it may be successfully layered. This plant has a special interest from its caoutchouc-yielding property, as will be seen from the following note. "Tu-chung" (*Eucommia ulmoides*) is a native of Central China, where, according to Dr Henry, it is cultivated in the districts of Chang-yang and Patung, in Hupeh, N. lat. 35°; it is also, according to Farges, cultivated in about the same latitude in eastern Sze-chuen, in the district of Tchen-keow-tin. A singular feature about this plant is the extraordinary abundance of an elastic gum in all the younger tissues, especially in the bark, the leaves, and petioles. Any of these snapped across when dry, and the parts drawn asunder, exhibit the silvery sheen of innumerable threads of this gum. The bark itself (to which, according to Dr Henry, tonic, invigorating, and other properties are ascribed) is a most valuable medicine with the Chinese, selling at 4s to 8s per lb. Further, the leaves are eaten when young, and the fruit is astringent. The merits of the Tu-chung as a caoutchouc-producing plant are entirely unknown; it is, however, deserving of notice. It would be

likely to thrive in semi-tropical countries, such as Algeria and Florida, and in the mountainous parts of Southern India and the West Indies; it might also survive the winters of southern Europe (Morris, 1898). Messrs Vilmorin, Andrieux & Co., Paris, who offer young plants of the *Eucommia*, give the following particulars in their *Catalogue des Graines d'Orangerie, et de Serre pour 1903*:—"M J Dybowski, the eminent Director of the Colonial Garden at Vincennes, has called attention to this tree, which contains in all its parts a notable quantity of gutta-percha of good quality. Unlike all other caoutchouc-yielding trees which are confined to the tropics, the *Eucommia* may be cultivated with success in a temperate climate. We have a plant which has stood for five years in the open air without protection, which has not suffered in the least, although the thermometer has fallen to -8° Cent. (17° Fahr.), and we believe it will support a temperature still lower than this." Plantations of this tree are being formed in France. There is good reason for believing that it would be worth while to plant it in the warmer parts of the British Islands as a probable source of rubber, and also for its medicinal properties. The Kew plant is in a border near the Economic house (No 12.) *W. W., Kew.*—*Gardeners' Chronicle*, Feb. 14.

THE NATAL TEA INDUSTRY.

ITS FUTURE PROSPECTS.

[BY "NEMO."]

Few people are aware, notwithstanding the ever-increasing flow of immigrants to South Africa from all the world over, what small strides the Natal tea industry is making. Bearing in mind that Natal is the only tea producing Colony in South Africa, the large and steadily-growing market for tea, and the absence, up to now, of any keen competition from other countries, by reason of the protective duty of 6d a lb. on imported produce, there are only a dozen estates, or thereabouts, of any importance, and all of these manufacturing coarse, rough tea. So far, the public have had very little choice in the purchase of tea, and the local planter has taken advantage of this fact to turn out of his factory the greatest possible quantity, with little or no pretension to quality. This line of action, however, is at last beginning to tell on the industry, for, apace with the growth of the Colony, imported teas, from India and Ceylon chiefly, are fast making their way in every other household, while import statistics prove that year by year the quantity imported is largely increasing, and local planters cannot sell off their stocks as easily as in days gone by. Beside this, Government can hardly be expected to protect these few estates at the expense of the tea-drinking public, and, sooner or later, the duty will either be abolished or at least greatly reduced, unless the industry makes more rapid strides to increase both quantity and quality of its produce. There is absolutely

NO REASON WHY NATAL CANNOT PRODUCE AS FINE TEAS AS ANY OTHER COUNTRY.

The labour conditions are precisely the same, while the wages paid are not much more than is customary in Assam and Ceylon, and, if these countries can produce, ship, and, after paying a big duty, sell their teas at a profit, it does not speak very highly for the energy or

enterprise of our Colonists. There is a big future for tea in Natal, and, if more capital was put into the venture, care taken to produce as near as possible teas like either the Indian or Ceylon manufactured leaf, and at a price within reach of all, there is little fear of imported teas finding room in our market, especially as it has been proved scientifically that a good Natal tea contains less tannic acid, is less pungent, and therefore more easily digested, than the produce of any other country. The indentured

COOLIE IN NATAL DOES TWICE AS MUCH AS HIS BROTHER IN INDIA,

and gets a third as much again as wages for his work, so that, theoretically, Natal planters ought to produce their teas about as cheaply as their Indian or Ceylon competitors.

A further hindrance to the progress of the Natal tea industry has been the marked absence of men with the necessary experience as proprietors or managers. Not one of the owners of any Natal tea estate has had any practical training in a large tea-producing country, and few employ Indian men. Most owners have become so puffed up with their own importance by being able to make, so far, a good thing of their tea, that they are jealous of any Indian or Ceylon planter about the place, preferring, should they need a manager, or assistant, to select a candidate who knows nothing about tea, and less about Indian labour, and set up to teach him a profession they know little about themselves. This narrow-mindedness can hardly be expected to improve what promises to become a big source of income to the country, and it is to be hoped men with broader views start more estates on better lines. If men from India and Ceylon were imported, well paid, and properly treated and freely employed, and a better class of coolie than the weeds being brought into this country now indentured with all the facilities tea-growing offers in Natal, there is no reason why the finest quality tea should not be made, at prices everybody can afford.

THE SOIL IS EMINENTLY SUITED

to the tea plant, and every condition favourable to its growth. The writer has seen and tasted samples of Natal tea, specially manufactured by a firm of tea-planters employing an experienced manager with Indian training, which cost 4½d per lb. to manufacture and which compared very favourably with a fine Assam Broken Pekoe selling in London at 8d to 9d per lb. Allowing, say, 1d for packing and handling before it reaches the customer surely there is a big enough margin for a profit when there is no duty to pay. More experience and more capital is needed to give this pleasant and paying industry the impetus it requires, and we ought easily, with both these conditions to back us, be able to produce in Natal every ounce of tea consumed in South Africa. The life of a tea-planter will appeal to many, and the pure country air and congenial employment has a charm peculiar to itself which must be experienced to be understood. Coffee production went to ruin here because no one thoroughly understood the venture, and the trees, delicate at best and fond of light shade, were expected to crop out in the open, with no pruning, or any other attention so necessary to this tree. The result was: every known blight and disease soon made their appearance, and presently exterminated every plantation and then the country was blamed for the failure.

LUCKILY FOR NATAL, THE TEA PLANT IS HARDY, being an evergreen of the *camellia* family, so that it can stand to a large degree the rough usage it receives. Pruning of tea bushes—an art in itself, and the most important work on an Indian or Ceylon estate—is reduced to mere hacking down the bush with the largest sized pruning knife obtainable, and often in the hands of a raw coolie; and as a result a heavy mortality usually ensues on some estates. Plucking, another very important work, is done in a most primitive fashion, and it is a wonder the trees “flush,” or send out new shoots again, after the handling they get. By careful plucking—i.e., by removing two or three leaves with the “bud,” or topmost unformed leaf, and leaving an “eye” or embryo shoot below, carefully protected by the stalk of the last leaf picked, a new shoot soon forms, and springs out ready to be gathered in seven to ten days. The local fashion is to tear off the “flush” in handfuls, and in some cases the writer has counted no less than eight leaves on a single stalk, the stalk being torn away from the parent branch, and every chance of a succeeding flush lost. It can easily be understood, therefore, that, by careful and fine plucking, and nursing the next gathering—though the amount for the day be less than if picked by the local way—the former and correct method produces more flushes for the season than the latter, and in the long run a greater quantity is obtained per acre, while the quality is of course, incomparable.

SUITABLE LAND CAN BE HAD IN ANY QUANTITY at moderate prices, and a capitalist starting on a holding of, say, 500 acres, with 50 Indians as a beginning, and an experienced manager, if he is not one himself, could easily commence his tea garden, and by ordinary perseverance and imitating Indian and Ceylon methods of production, would soon develop it into a very paying concern, and the source of a very comfortable income.—*Natal Mercury*, Feb. 26.

A FERMENT OF THE TEA LEAF.

A most interesting paper on “Ferment of the Tea Leaf”—II.—reaches us today from the Secretary, Indian Tea Association, written by its Scientific Officer—Mr. H. H. Mann, B. Sc. His conclusions, from experiments dealing with the “enzyme” of tea, are:—

1. That, during withering, the amount of oxidising enzyme or ferment in the leaf increases up to a certain point corresponding under normal withering conditions with the point at which the leaf is ready for rolling.

2. That the two processes of loss of moisture and production of ferment by no means necessarily take the same length of time, and that the leaf may be withered (in very dry weather) long before it is chemically ready to roll, and in very wet weather may be ready, chemically, to roll long before it is withered.

3. That, at the temperature studied (76°–86° F) the normal time which the leaf requires in order to be chemically ready for rolling is 18 to 20 hours with normally withered and over-withered leaf, and several hours longer (it may be up to 25 hours) with leaf prevented from withering by a very wet atmosphere.

4. That the object of the tea manufacturer should be not merely to get his leaf in the best physical condition for rolling but also in the best chemical

condition, and for this purpose he should arrange, so far as is possible, to have the leaf soft for rolling when the chemical constituents of the leaf are at their best.

Other experiments in fermentation are recorded in the same paper and, being of high importance to all manufacturers of tea, we quote them at once in full:—

1. The time required for making the leaf chemically ready for rolling is independent, or nearly so, of that required to render it soft enough for this purpose and at a temperature of 76° F.—86° F. varies from 18 to 24 hours, according as the leaf dries normally, too quickly or not at all. Hence the object should be to wither the leaf in the time. If it be withered too quickly, as by heat and fans, the leaf is soft enough to roll before being chemically ready; if it be withered too slowly, as on a wet day, with a saturated atmosphere, it is chemically ready long before it is soft enough. I hope to be able to, later on, after further experiments, prepare a table giving the best time for withering at various temperatures and under different conditions.

2. The absolute cleanliness of every thing during the manufacture becomes more and more evident and the cleanliness necessary can only be reached by scalding every implement and machine, and the floor of the fermenting house with boiling water. There seems moreover considerable reason to suppose that by the addition of a small quantity of Salicylic Acid to the fermenting leaf the effect of outside microbes may be entirely eliminated (the salicylic acid being entirely driven off during the subsequent firing), and the tea correspondingly improved.

RUBBER IN UGANDA.

PARA PLANTS DOING WELL.

It is only a question of the activity of traders to determine the time during which our natural supplies of rubber will last. So says Mr. J Mahon, in a report to the Foreign Office on various exotic plants in the Botanic Gardens at Entebbe, in Uganda, and that being so, importance attaches to the efforts being made there to furnish by systematic cultivation supplies to meet the demands of the future. So far not a great deal has been done, but, despite some unfortunate circumstances, one of the Para rubber seedlings sent out from Kew in 1901 is now over 7 ft. high. It remains to be seen whether the climate and elevation. (4,000 ft.) will continue to prove favourable, but Mr. Mahon appears to have some hope that on the lake shores the Para rubber will do well. The Central American variety, *Castilloa elastica*, which is more or less highland plant, is likely to find suitable conditions at Entebbe, and a seedling Ceara rubber of eight months is already 4 ft. high. Satisfactory progress has also been made with plants of *Theobroma cacao*, and Mr. Mahon believes that since an excellent wild coffee flourishes, introduced sorts would do well.—*H and C Mail*, Feb. 13.

MAN—is born an agriculturist; and it is both bad morality and bad policy to invite him, by fortune or by honours, in other words, by avarice or by ambition, to leave the plough and the fields. It is a mistaken idea to give education to the children of peasants only to make them come out of their sphere. No one is too learned to be an agriculturist, hardly anyone is learned enough for it. (Alphonse Karr.)—*Agricultural News*, Feb 14.

PRIZE ESSAYS FOR TEA PLANTER :
THEORETICAL POINTS IN TEA
CULTIVATION.

The present age is not one which desires to obtain its knowledge through laborious research nor time-consuming experiment; but rather at second-hand in the concentrated form of hand-books and manuals. It matters not what aspect of truth with which the seekers desire to acquaint themselves, whether it be philosophy, theology, or history, the reading public demands its pabulum in a nutshell, and craves for mental stimulation in the form of literary tabloids. No province of literature exists without these royal roads to learning, and any student of fair capacity, can, by walking therein, cram a subject so successfully, as to make a very fair show, indeed, when he goes up for his examination. The result to the student may not exactly be what is meant by education, and to the man who stops at that point, who is content with a pass, and the smattering of knowledge he possesses, the benefits he has received are questionable. If, however, he is bent on widening his horizon, and recognises that education here ends only with life, the superficial knowledge which these rough sketch-plans afford, is not without its value when later on he labours to fill in the details for himself. To know the headlands may not mean an accurate knowledge of the coast; but it is useful in this way that you can locate your position, very nearly, and are not wholly at your wit's end as to what next to do. Tropical agriculture is not different from other studies in the demand for hand-books, and when any special culture bids fair to draw to its cultivation the money and brains of the West, the creation of a new manual is assured. The continued issue from the *Observer* press of complete treatises on almost every brand of tropical planting enterprise, and the steady call from all parts of the world for these cultural guide books, are evidence enough that they supply a needed want, and have a wide and appreciative public. But to attain to the full measure of their usefulness, the reader must be generally informed on tropical agriculture, and the wider his knowledge and experience, the more highly appreciated is the special manual. The Planters' Association—during its literary age—added considerably to the stock of tabulated information available for the outdoor worker in the tropics, and we suppose we may take, as evidence of the dawn of happier and better times, the readiness of the Committee today to accept the onerous task of adjudicating the merits of the Planting Essays to be sent in, in competition for Messrs. George Steuart & Co.'s handsome R500 prize. The principal point which the essayist will have to deal with is Pruning, and on this subject there will be ample scope for the ingenious mind. It will be hard, however, to make the theme intelligible or of much practical value without the aid of illustrations, but if these are employed "he that reads may

run." In the February number of *Country Life in America*, there is an article on Pruning, which, however, refers to the garden, and not to a tea estate; but the principles which guide the cultivator when he desires to bring, say, a peach or a cherry tree into prime condition, do not differ in any way from those which obtain when the planter has a field of tea requiring the knife. "Before one prunes a plant"—says the American writer "he (*sic*) should know why he (*sic*) prunes it." That statement may at once be accepted as the theoretical standpoint of the scientific cultivator. To successfully treat and advise on such a subject as Tea Pruning—where the plant thrives from sea-board to a six thousand feet elevation—it is clear that no rough and ready rule of thumb will avail; and when we add jāt, exposure, soil fertility, and the health conditions of the bush itself, a very complicated problem is evolved calling for special directions, which may modify any general principles before formulated. Root Pruning, which in Arboriculture is about as important as branch pruning, is a dark subject yet as regards tea; certainly what root pruning the tea bush gets, is done in a rough, blind and unintentional fashion; the tool, a mamotie, or a digging fork; and the rule of guidance, blind chance. Roots get cut in manuring operations, but the man has yet to arise who has made the root-pruning of tea a study and who can guide his brother-planters in the matter. He may make his advent among the coming essayists, and he is certain to be hailed when he appears above the horizon. In the early days of coffee-leaf disease, when no one would credit that what was in process before their eyes was a tragedy—the ruin of an industry, there were several men who claimed to have discovered a cure which, alas! on trials made, came to nothing. Some followed well-known remedial lines, but a few originals struck out in a wild way. A German chemist poulticed the stem of the trees with mud and carbolic, and the trees died! Another, an eccentric Frenchman, would have built a miniature paddy field around each individual plant. After a trial of his system in several parts of the country, and no beneficial results obtained, he still lost neither heart, enthusiasm nor resource. "The roots of the tea wanted attention," he said, "have them uncovered and white-washed and recovered afresh and then"—here his eyes blazed and rolled in the fine frenzy of the prophetic soul,—"mon Dieu, you will see!" Nobody ever did see; for men were sick at heart, and felt that to have decorated the roots with ribbons of the newest Parisian shade would have salted the tail of the deadly fungus as effectually as white-wash could have done, and been very much more artistic. The next coming authority on root culture who is to appear amongst us will be—let us trust—of a sane mind, and be able to give a reason for the hope that is in him, without requiring to fall back on Gallic hysterics, or the heroics of the Teuton. The

value of buried prunings in particular, and manuring generally is to be a supplementary branch of the essayist's theme. Accurate and reliable information on these subjects will, we feel assured, be very acceptable to the planting community; for the matter is not one where a solid vote would be given one way or another, there being still much variance of opinion especially in regard to buried prunings, while there are districts which are ready to tax all fertilisers. Let us trust when the information is available, it will not be of the technical nature which requires a chemical expert to interpret it; but rather that it may be of a nature easily assimilated by the mind of the everyday-planter, and the man of ordinary intelligence.

MESSRS. HECHT, LEVIS AND KAHN TO ROYAL BOTANIC GARDENS, KEW.

36, Fenchurch Street, London, E.C., Dec. 19, 1902.

DEAR SIR,—We have examined the samples of Para Rubber from Selangor which you submitted to us. We are of course not chemists, and can only judge the rubber from its elasticity, strength and freedom from dirt. With ordinary Hard Cure Fine Para worth today 3s 8d per lb., we should estimate the value of your samples as follows:—

No. 1 about 4s 4d per lb. Nos. 2 and 6 about 4s 3d per lb. No. 5 about 4s 2d per lb. No. 4 about 4s 1d per lb. No. 3 about 4s per lb. No. 7 about 3s 4d per lb.

Numbers 3 and 4 are decidedly weaker than the others, and on the whole we think the less acid used in coagulation the better. Sample No. 1, coagulated without acid at all, is certainly the best of the lot.—We remain, etc.,

HECHT, LEVIS AND KAHN.

REPORT ON SAMPLES OF RUBBER EXTRACTED FROM HEVEA BRASILIENSIS IN THE FEDERATED MALAY STATES.

STRAITS SETTLEMENTS, NATIVE STATES.—No. 432.

Downing Street, 31st Dec., 1902.

SIR,—I have the honour to transmit to you for your information and for communication to Mr Stanley Arden, Superintendent of Experimental Plantations, the papers noted in the subjoined schedule.—I have, etc.,

(Signed) ONSLOW, for Secretary of State.

(Copy.)

Royal Botanic Garden, Kew, Dec. 24th, 1902.

SIR,—I have the honour to inform you that I have received from Mr Stanley Arden, Superintendent of Experimental Plantations in the Federated Malay States, series of samples of Para rubber coagulated by various methods, with a request that I would obtain a commercial report upon the results. A copy of the brokers' report is enclosed. Without entering into unnecessary details it is sufficient to notice that Nos. 1 and 6 were naturally coagulated; No 2 was coagulated by the addition of acetic acid; No. 7 was "scrap rubber" collected off the tree; the remaining samples were coagulated by various mineral acids. It is quite clear from the brokers' report that natural coagulation affords the best results and that the only admissible artificial coagulating agent is acetic acid. The point, however, which it is important to notice, is that Para rubber can be produced in the Straits Settlements from ten years old trees, which is worth eightpence a pound more than the best equivalent Brazilian product. I may be permitted to feel some satisfaction at this result seeing that the trees which have furnished the rubber now reported on are the descendants of those transmitted from Kew to the Straits Settlements in 1877; these were part of the first consignment of Para rubber trees to the tropics of the Old World. I have no doubt that the Straits Settlements is now in possession of a new and important cultural industry. The facts stated above are therefore of sufficient importance to bring under the notice of the Secretary of State and to be placed on permanent record. Mr Chamberlain will no doubt cause them to be communicated to Mr Stanley Arden, in official course.—I am, etc.,

(Signed) W T THISELTON-DYER.

PRODUCE AND PLANTING.

The chairman of the Mazawattee Tea Company, like some other sanguine people interested in tea, is hopeful that the Chancellor of the Exchequer will be in a position to

TAKE OFF THE EXTRA DUTY ON TEA

imposed in 1900, when he introduces his next Budget. Tea is certainly much more entitled to relief than some of the other commodities whose vendors are clamouring for reduced taxation; but justice does not necessarily govern these matters.—Commenting on

THE DUTY QUESTION AND THE TEA MARKET

the *Grocer* says: "Operators in the tea trade naturally think that they ought to be relieved of part at least of the Customs' duty before anybody else, and have been inclined to abstain from clearing stocks out of hand faster than was necessary, so as to be in a better position to enjoy the full advantage of a reduction in the impost, should such a proposal be made and carried through. The actual state of the market for tea at the moment is so peculiar as to be almost beyond influences of a fiscal nature, and the change that has come over it within the last fortnight has created quite a surprise. Attributable in the first instance to the shortening of the supplies immediately on offer, by importers restricting the number of invoices to be catalogued for public sale every week for a long while past, the dealers and others have not been overburdened with unmanageable duty paid stocks as they were at this period last year. The consequence has been a great strengthening of the market, as time and opportunity have been given for all surplus quantities in the hands of the trade to be worked off; and as the principal blenders have again entered the market to renew their purchases and replenish stocks, a fresh and stronger stimulus has been imparted to the upward move of late, which has become so marked this week that prices for the common qualities have advanced fully 4d per lb.—a rally in no way connected with the question of the lowering or raising of the duty on tea."

If we may judge by the hints given in one of their trade organs,

GROCERS DO NOT KNOW ABOUT TEA

as much as they ought to do. The journal says: "It is a pleasant thing to see a grocer's window smartly dressed with samples and showhowls of tea, and in anyone connected with the trade such a sight generally arouses a feeling of admiration. But how rarely are such efforts to win back the tea trade shown by the one-shop and two-shop tradesmen of today! Yet it is not easy to blame them; there are excuses for this want of interest. The truth is that the retail tea trade has been so exploited, and in such a variety of ways, that numerous grocers have grown

indifferent about the cultivation of a tea trade. It is too large an order. They find it better business to push groceries and even brushes and hardware. If a customer wants tea they are content to sell a packet of an advertised proprietary article for a very small profit. The result often is that such tradesmen, though competent in every other branch of the business have little or no knowledge about tea. As an instance showing how ill-informed some grocers are on the subject, a grocer said, in all seriousness, last September, 'I suppose now is the time for autumnal teas'—imagining that the autumn of the tea gardens was the same as the autumn of the English harvest field."

According to the Bureau of Statistics of the United States Treasury Department, the value of the TEA IMPORTED INTO THE UNITED STATES was 14,570,285 dols in 1902, 8,744,190 dols in 1901, and 11,783,317 dols in 1900. The exports of tea during 1902 amounted to 924,544 lb, making the net imports 107,822,920 lb. The Chinese imports were 56 per cent of the total, and Japanese 32.1 per cent. The imports for December, 1902 were 16,479,579 lb, against 7,565,451 lb for December, 1901.

The *Daily News*, quoting the current issue of "India" calls attention to

THE PLANTERS' LABOUR BILL, now being considered by the Madras Legislative Council. "India" declares that this measure "might more truly be called the Madras Slavery Regulation Bill," and that it will be a public scandal if it is allowed to become law: and the *Daily News* thinks that while the question of forced labour in South Africa is under discussion the Madras Bill should be given a share of attention.—*Hand & C Mail*, Feb 27.

PLANTING NOTES.

PLANTING IN NYASSALAND.—For a chatty hopeful letter from a Ceylon planter see another page. He says tobacco is to make the fortune of plantation owners, supplemented by tea grown for local sale at 3s a lb! We trust there is a good time before all Nyassaland and B C A. proprietors.

THE PEARL FISHERY.—In answer to a correspondent, we may say that the most elaborate and best account of the Pearl Fisheries ever published was contained in letters by the late A. M. Ferguson, C.M.G., to the *Ceylon Observer* in 1887, summarised and reproduced in "Ceylon in the Jubilee Year."

SEA COCONUTS.—Amongst the many curiosities cast up on the shores of the West Indian islands by the sea are numbers of brown, globular fruits, with a hard rind or shell, about the size of a hen's egg. These are popularly known as 'sea coconuts. In reality they are fruits of the Timite palm (*Marcaria saccafera*, Mart.) which grows abundantly in the swampy lower districts of Trinidad and along the river banks of the South American mainland. The tree produces large quantity of seed, which falling into the water are borne by ocean currents to the shores of the West Indies. Dr. Morris in his article on 'A Jamaica Drift Fruit' thus refers to this sea waif:—"In the West Indies the ripe fruits of a palm unknown in the greater Antilles are continually brought up by Gulf Stream from the South and washed ashore at Jamaica and other places. They are locally called [in Jamaica] sea-apples or sea coconuts. They are the fruits of the 'Bussu Palm.' The white kernel is sometimes fresh enough to be eaten after long immersion in salt water. The fruit was gathered by Sloane as long ago as 1687, and he remarked that it was frequently cast on North-west islands of Scotland by currents in the sea."—*Agricultural News*, Jan. 17.

VANILLA.—Only 43,991 pounds of vanilla were exported from Mexico in 1901, with a value of £57,426, as against 64,921 pounds in 1900 valued at £62,565, due to a failure of the crops by heavy frosts in the early part of the year. The value of the exports as here given makes the value of each pound £1 6s whereas in the previous year it was only £1 0s 6d, a difference which coincides with the silver value declared at the custom-houses.—*B. and C. Druggist*, Feb. 27.

THE TONACOMBE ESTATES CO. OF CEYLON.—The annual meeting of this Company was held today and the report submitted by the Directors, as will be seen elsewhere, is a model in respect of the comprehensive and interesting information it offers to the shareholders. A dividend of 5 per cent was declared besides a balance of R5,654.06 standing to the debit of Buildings account being written off and a sum of R8,642 carried forward. Other announcements which ought to please the shareholders were made—that the Debenture Debt has been further reduced by £500 during the year and that the Kalugalla estate has been purchased during the year for R17,500. A report of the meeting will be found elsewhere.

MERIT OF ORANGE JUICE.—Professor Kiosto, an eminent Japanese bacteriologist, also Prof. Koch and others, have shown that the acid of lemons, apples, and other fruits, citric acid and malic acid are capable of destroying all kinds of disease germs. Cholera germs are killed in fifteen minutes by lemon juice or apple juice, and typhoid fever germs are killed in half an hour by these acids, even when considerably diluted. If you squeeze a lemon into a glass of water containing cholera germs and let it stand 15 or 20 minutes, you may drink the water with impunity, as the germs will be dead. These juices will kill other disease germs. Instead of telling a man to have his stomach washed out, we can now tell him to drink orange juice, which will cleanse the stomach as thoroughly as a stomach tube, providing it is not a case of gastric catarrh. The fruit diet will cleanse the stomach and the alimentary canal, and drive off disease germs, which are responsible for a large share of our ailments.—*Journal of Agriculture* of Western Australia for Feb.

A RIVAL TO KANDY.—Mr. W. R. TOWNSEND, a recent visitor to Java, writes a description of that country which appears in the *San Francisco Argonaut Inter alia* he says:—"At Buitenzorg thirty-three miles from Batavia, at an elevation of one thousand feet or so, with towering volcanoes to the east and west, the climate is much cooler than at Batavia, and the place is a popular resort for Batavians. Here the governor-general's residence is located in what is claimed to be the finest botanical garden in the world. It certainly is ahead of anything we have seen, greatly excelling those at Calcutta and Kandy in Ceylon, both of which are famous. There is an avenue of kanary-trees, each tall trunk covered with a different species of giant creeper, some of them orchids, which are wonderfully fine. The collections of palms, orchids, water lilies, bamboos, and innumerable other trees and plants embrace almost every known variety, and are beautiful beyond description."

Correspondence.

To the Editor.

COCONUT PLANTING IN FIJI.

ENORMOUS FRUITING ON OUR PALMS.

Tavanni, Fiji, Feb. 5.

DEAR SIR,—Just a line to describe a very peculiar freak I have just seen. A young coconut tree, 5 years old just coming into bearing: It has three spathes or blossoms and on the largest of the tree I counted 30 spears to the spathes and on one of the spears I counted 51 nuts, making a total of about 1,500, on the one spathe. There are about 1,000 each on the other two so that at the present time there are about 3,400 nuts on the tree. There are two more tremendous spathes that will be blossoming in a few days when we expect to see over 5,000 nuts on the tree—nearly a ton of copra. Now can you Ceylon chaps beat that? When you can let me know, will you? I can assure you it is a positive fact I have often seen from 1,000 to 1,200 nuts on a tree, but this caps all.

We are having a magnificent year—better, in fact than last, I think. I am trying to get hold of some averages this year and will let you know result bye-and-bye. The whole country is looking very well.—Yours faithfully, H. V. TARTE.

[A practical coconut planter's remarks on the above are:—

“The degree of ‘proliferous’ of the coconut palm varies greatly and although an average of 60 nuts per tree per annum in Ceylon is considered a good yield; yet there are individual trees which bear 400 to 500 nuts a year. However, I have never seen or heard before of such a phenomenon as a coconut spathe with 1,000 to 1,500 fruit on it. I doubt whether such a huge cluster of nuts would reach maturity, as the stalk is sure to break down with their weight before the nuts are even half ripe. Trees of vigorous growth send forth a spathe once a month. The wonderful 5-year old tree, your Fiji correspondent refers to, has already produced 5 spathes, all of abnormal size, and we may expect at least 3 more before the oldest nuts are ripe enough to be gathered.

“The tree should then carry over 9,000 nuts, beside about 3 dozen fronds, but would the stem support such a ponderous load? Mr Tarte should have the tree photographed at once, so as to show the several clusters of young nuts of different stages. It would be interesting to know the length and girth of one of these extraordinary spathes. Mr Tarte says he has often seen 1,000 to 1,200 nuts on a tree. It will be of much interest if he will give the average yield of, say, 1,000 trees in full bearing on his plantation.”—ED. T.A.]

INFORMATION ON THE CASTOR OIL TREE WANTED.

Batticaloa, March 14th.

DEAR SIR,—Can you or any of your readers be so kind enough as to let me know, through the medium of your valuable paper, if there is any book in which the cultivation of Castor, is dealt with? If there is any, I shall be much obliged, if I will be informed by you or any of your numerous readers, where such a book could be procured. As an experiment is to be tried in the

cultivation of Castor in the Island, I shall deem it a favour if you or any of your readers could furnish me with the following particulars:—

- (1). Nature of soil required for the cultivation of castor.
- (2). How castor is planted? How many feet apart from each other?
- (3). In how many months will castor bear fruit?
- (4). How many years after, will the plants yield?
- (5). What will be the yield for a year, per acre?
- (6). How are the crops collected?
- (7). What should be the temperature of the place?
- (8). What is the average price of a bushel of castor in England, and in Ceylon?

Yours faithfully,

SUPPRA.

[We take the following from the “Treasury of Botany,” as the fullest information we can find:—

CASTOR OIL PLANT is botanically known as *ricinus communis*, the seeds yielding castor-oil. The plant is a native of India, but is now widely distributed over the warmer regions of the globe and throughout the Mediterranean region. It is even cultivated in England as an annual and is known under the name of Palma Christi. In the English climate the stems do not attain a height of more than from three to five feet; in India however, they grow from eight to ten feet, while in Spain, Crete, Sicily, and elsewhere the plant is stated to become a small tree. The stem is jointed of a purplish-red colour, and covered with a glaucous bloom like that of a plum. The leaves are large stalked palmate deeply divided into seven lance-shaped segments and at the junction of the blade with the stalk of the leaf is a small saucer-like gland. The flowers are in spikes, the males being placed below, the females above. There are several varieties of this plant, differing in sundry slight particulars and amongst others in the size of the seeds. These latter are oval flattened of a greyish colour mottled with brownish blotches. At the upper end of the seed is a small sponge-like excrescence. It is stated that the best oil for medicinal purposes is derived from the small seeds that procured from the large seeds is coarser and in India employed for lamps and in veterinary practice. A still prevalent error is that the acrid purgative principle resides in the seed-coats and in the embryo only while the albumen is destitute of it. The oil is extracted by boiling the seeds and by pressure in an hydraulic press the latter process yields the most esteemed oil. After expression the oil is purified by being allowed to stand, by decantation, and by filtration. In India the oil after having been obtained by pressure is mixed with a certain proportion of water and boiled till the water has evaporated. In France the oil is obtained by macerating the bruised seeds in alcohol but the process is expensive, and the product inferior. The larger quantity of the oil used in this country is imported from India. Castor-oil is very largely used as a gentle and efficient purgative; its nauseous taste is however, a great objection to its use. This may partially be overcome by mixing it with orange-wine, gin, or peppermint-water, or by making it into an emulsion with the yolk of an egg or mucilage. The leaves are used for various purposes, for which their size and coolness render them serviceable, and topically as an application in rheumatism.—ED. T.A.]

CEYLON GROWN RUBBER IN LONDON.

London, Feb. 27.

DEAR SIR,—We wrote you re Ceylon grown Para Rubber a few weeks ago and now have to

report further sales which, we think, will be of interest to your readers:—

Mark	Cases		Sold at per lb
Culloden	6	Fine thin biscuits	4/2
do	2	Good scrap	3/4½
do	1	Large balls scrap	3/0½
do	1	Scrap good	3/2
do	1	Scrap fair	3/0½
Edengolla	3	Fine thin biscuits	4/2
do	1	Good scrap	3/1½
Clyde	2	Fine thin biscuits	4/
do	2	Scrap	3/
Kumaradola	1	Fine in small biscuits	3/4½
Yatipauwa	3	Scrap	3/0½
Igalkande	1 crate	Fine thin biscuits	4/2
Aberdeen	1 case	Fine thin biscuits	3/10
do	1 bag	Good scrap	3/1½
Tudugulla	5 cases	Fine thin biscuits	4/2½

The market is strong and prices seem likely to go higher. Kindly insert above in your paper, as planters are much interested.—We are, dear Sir, yours faithfully,

LEWIS & PEAT.

P.S.—Fine Para 3s 8½d to 3s 9d.

PLANTING NOTES.

THE NAHAVILLA ESTATE CO. LTD.—The directors and shareholders and the Agents and Secretaries of this Company have our warm congratulations on the return of prosperous times after some two or three years decidedly discouraging balance sheets. The report appears on page 698, and it will be noted a 5 per cent dividend is declared.

VANILLA.—An item that will have some interest to vanilla growers is the following:—A consignment of about 300 kilos of vanilla cultivated in German East Africa arrived in Hamburg a short time ago. The beans are said to be of fine dark chocolate colour and are commencing to crystallise. They are of various lengths, and are reported to compare favourably with the best Bourbon quality.—*Agricultural News*, Feb. 14.

FAILURE IN THE RUBBER TRADE.—At a meeting yesterday afternoon of the creditors of Messrs Kramrisch and Co, rubber merchants, of Liverpool, the liabilities were stated at £111,663 11s, and the assets at £7,089, leaving a deficit of about £104,000, in regard to the absence of Mr Kramrisch abroad, about which rumour has been busy, it is stated on good authority that he has been endeavouring to arrange matters for the benefit of his creditors and will shortly return. A committee has been appointed to carry out a deed of assignment.—*London Times*, Feb. 25.

GUM ARABIC.—The unsettled condition of several parts of the world, notably Somaliland and Morocco, has influenced the position of some well known products, one of which we may instance namely, gum arabic, a fact which shows the necessity, either of secondary sources for any indispensable product, or of some available substitute. Opposed as we are to substitutes generally, it would seem that out of the numerous species of *Acacia* known, a picked or sorted gum might yet be found to tide over a time of scarcity, which might perhaps end in establishing for itself a reputation of a lasting character, if not for use in food or medicine, at least for manufacturing purposes,—a remark that applies to products other than gums.—*Agricultural News*, Feb. 14.

THE FORMATION OF PEARLS.

A SEASONABLE ARTICLE.

By far the greater number of recent writers on pearls, whether scientific or otherwise, when discussing the cause of pearl-formation, have contented themselves with recapitulating what has already been written on the subject, without attempting to verify or refute the various hypotheses that have been propounded. The question is one which has called forth speculative theories since the earliest times of which we have any records; but, with the exception of the brilliant researches of Filippi and a few of his contemporaries, theory has prevailed to the almost complete exclusion of practical investigation.

In a recent paper, based upon an examination of large quantities of material comprising a number of the pearl-producing species of mollusca, I have tried to place our knowledge of the matter upon a more satisfactory basis. By observations upon pearl-bearing examples of the common mussel *Mytilus edulis* (which were confirmed in the case of all other species examined), I proved that the formation of the pearl takes place in exactly the same way as that of the shell, except that a true pearl is laid down in a closed sac of the shell-secreting epithelium, embedded in the subepidermal tissue of the mantle and completely cut off from the outer epithelium itself. Inside this spherical epithelial sac, the shell substance is laid down in the concentric layers that are so characteristic of the pearls, instead of in the parallel lamellæ which are found in the shell itself. Such a sac, with its contained pearl, may be compared to a human atheroma cyst. This makes it necessary for us to draw a sharp

DISTINCTION BETWEEN PEARLS PROPER AND BLISTERS OR PEARLY EXCRESCENCES

of the shell lining, which are secreted by the outer (shell-forming) mantle epithelium, to cover over foreign bodies that have intruded themselves between the mantle and the shell or to repair the damages done by shell-boring domiciliaries. "Concretions" are, again, distinguished from pearls as calcosphæritic bodies which have not a cuticular origin from an epithelium, but seem to arise by free crystallisation in the mantle or other tissues. The term "attached pearl" should be applied only to pearls which have become secondarily fused to the shell by absorption of the intervening tissues. From the facts of pearl-formation, it is easy to understand why the pearl presents the special characters of the particular species of shell from which it is taken, and also why, in the same mollusc, the characters of the pearls produced are determined by the part of the mantle in which they are formed. Thus, pearls formed in the extreme mantle margin are composed mainly of periostracum, e.g. the leathery pearls of *Modiola modiolus*, while those which occur in the part of the mantle concerned in depositing the prismatic substance are made up of concentric layers of rod-like prisms, as in the brown or "black" pearls of the Scotch river mussel, *Margaritana margaritifera* (Fig. 1). By far the greater part of the mantle epithelium deposits the nacre, and pearls which arise in this part of the mantle are the typical nacreous ones, to which the great majority of the marketable gems belong. Even the uncalcified substance of the hinge ligament of the shell may be represented in the pearls;

for example, in the great Australian mother-of-pearl oyster, *Margaritifera maxima*, Jameson, black leathery pearls are sometimes found in the dorsal body-wall. I next proceeded to investigate the

ORIGIN OF THE SAC IN WHICH THE PEARL

ARISES,

and also the nature and origin of the "nucleus" which is so often to be found in the centre of the pearl. In a great many molluscs, among which were several of the pearl-oysters proper, the remains of trematodes were found to form the nuclei, a discovery which confirmed the observations of Filippi, Möbius and others. In one or two cases, however, other parasites played the same part. By confining my attention to the common mussel, I proved that the epithelial sac, which is all-important for pearl formation, is first formed around the live trematode which enters upon a resting stage in the tissues of *Mytilus*. A similar sac, surrounding a trematode, was found in an example of the Ceylon pearl-oyster, *Margaritifera vulgaris*, Schumacher, which I examined. For the formation of the pearl, it is not necessary for the trematode to persist as nucleus, for it often happens that it migrates out of the sac; but the sac, caused primarily by the specific stimulation of the parasite, is essential to pearl production. In *Mediola mediolus*, and probably in some other forms, similar sacks are formed around Sporozoa. The next subject to be investigated was the origin and

LIFE HISTORY OF THE PARASITE THAT CAUSES THE PEARL-SAC.

The common mussel was found to be the most convenient species on which to study this, and the pearl-bearing mussel-beds of Billiers, in Brittany, and Piel, in the Barrow Channel, were selected as suitable sites in which to begin the observations (Fig. 2) The parasite, like most trematodes, passes through a regular cycle of three hosts, two of which are invertebrates and the third a vertebrate. It arises in sporocysts in the "tapestry shell," *Tapes decussatus* and the cockle *Cardium edule*, the former acting as first host at Billiers, the latter at Piel, where *Tapes* does not occur. The young tail-less Cercariæ or trematode larvæ leave the mother sporocysts in the first host and migrate into the mussel. The transmission of the parasite from *Tapes* to *Mytilus* was proved experimentally in a tank at the Brighton Aquarium. In the mussel, the parasite enters into a resting stage, in the sub-epidermal connective tissue, and gives rise to the epidermal sac or "epithelioma" in which the pearl arises (Fig. 3.) If the parasite dies in this sac, a pearl is formed around its remains, or if it migrates to another part of the tissues, a pearl may be developed in the empty sac. Although it was found impossible to secure live uninfected material of the final host for experiment, it is almost certain that the adult stage of the parasite is *Distoma (Leucithodendrium) somateriæ*, Lev., a worm which occurs in the intestine of the elder duck, *Somateria mollissima*, and the black duck or scoter, *Oedemia nigra*. Both these birds feed almost exclusively on mussels. A number of scoters caught or shot in the immediate vicinity of the Billiers pearl-beds were found swarming with this worm. Indeed, one example of the worm, in an immature condition, quite indistinguishable from the resting stage which occurs in

Mytilus, was taken from the intestine of a scoter. Our knowledge of the life-stories of other trematodes, or "flukes" as they are popularly called, enables us to fill in the life-history of this parasite with considerable detail. The worm reaches maturity in the intestine of the scoter and eider, and the eggs pass out with the faeces. These eggs, or possibly "Miracidium" larvæ derived from them, enter *Tapes* or the cockle and there give rise to sporocysts, in which the young flukes or Cercariæ are formed. These larvæ, unlike typical Cercariæ, are tailless, and when they escape from *Tapes* reach the mussel chiefly by drifting with the tidal currents. On entering the mussel, they pierce the body wall and settle down in the subcutaneous tissues, in which they become surrounded by the pearl-sacs. If the mussel lives long enough, pearls will be formed in these sacs. If, on the other hand, a mussel containing these resting Cercariæ is eaten by an eider duck or scoter, the Cercariæ develop into the mature worms, which produce eggs, and the life cycle is repeated. As an

ECONOMIC RESULT OF THESE INVESTIGATIONS, it would seem that the artificial production of marketable pearls in large quantities should present no great difficulties, if the conditions essential to pearl production in the particular cases be intelligently investigated. The fact that trematodes have been ascertained to be at least one cause of pearl formation in several of the molluscs that produce the marketable gems gives us every reason to hope that, by learning the life-histories of these parasites, we may be able to infect any number of pearl-oysters of pearl-mussels to any desired extent, without any operation on the individual molluscs, by simply placing them in the roper surroundings, in company with infected examples of the first host. Once infected, the molluscs could be bedded out on suitable grounds, and left to care for themselves, until the pearls formed in them were of marketable size.

FUTILITY OF OYSTERS TRANSFERENCE.

These observations show the futility of the proposal that has so often been made, viz., that young pearl-oysters should be transferred from their native grounds to more accessible in-shore waters, as it must obviously be the first object of the scientific expert, before laying down the beds of young pearl-oysters, to assure himself either that they are already infected or that the conditions essential to speedy infection are present on the grounds to which the oysters are to be transplanted.—H. LYSTER JAMESON in *Nature*, Jan. 22.

THE CACAO CROP OF TRINIDAD—is expected to be very large this season. The *Port of Spain Gazette* estimates that during the month of December, close upon 20,000 bags (of 130 lb each) will have been brought down by the railway. The *Grenada St. George's Chronicle* draws attention to the necessity of supplementing the cacao industry with others, in view of the rapid increase in cacao production in other parts of the world. The export of this crop from West Africa has risen from 166,054 bags in 1898 to 297,054 bags in 1902. From South America also increased production is recorded. Bahia for instance exported 192,000 bags in 1900, and 236,548 bags in 1902 *Agricultural News* Feb. 14.

CINCHONA AND QUININE.

Messrs. C. M. & C. Woodhouse afford a good deal of generally interesting information in their annual review of the above markets published in February. They say that the bi monthly exports of bark from Java continue to exercise the chief controlling influence on the quinine market; although the total shipments for 1902 were by no means excessive. But when shipments for a fortnight in August were telegraphed at $1\frac{1}{2}$ million lb., a panic occurred, only abated when news came of short exports afterwards. Now the Java planters are expected to regulate shipments; just as India and Ceylon tea planters are expected to try and control the offerings of their staple in the London market—rather a difficult task. The Java Cinchona men have resolved “to offer during 1903 at every Amsterdam Cinchona Bark Auction, not more than 1-10th of the yearly production of every estate.” The largest monthly export last year was 1,577,000 lb. in October, and the smallest 776,000 in May. A great feature of the market was the large orders for quinine during the past six months, and Germany has been a large exporter, sending away 232,200 kilogrammes in 1902 against 195,400 in 1901. United States, Russia and Italy are the chief customers. The unit value of bark, in London varied from $1\frac{1}{2}$ d. to 2d. per lb. Altogether, the estimated production of cinchona bark is given, as equivalent to 14,489,000 ounces of quinine in 1902; and Java makes up 12,457,000 ounces of this, leaving only 2 millions for the rest of the world, of which again India gave more than half. South America, the original home of cinchona, gave last year bark only equal to 620,000 ounces of quinine; Ceylon 195,000 oz.; Africa 86,000 oz.—Java exported 700,000 ounces of quinine locally manufactured, against 11,757,000 oz. sent away in bark. So that the Java quinine manufactory of which we heard so much, does not deal with much more than 5 per cent of the whole crop of bark. The United States is the greatest consumer, importing 3,400,000 oz. of quinine beside bark for local manufacture equal to 2,496,000 oz. France takes bark equal to 1,802,000 oz. quinine; Germany consumes a million oz. of quinine; but exports 6,195,000 oz. exclusive of what goes to the United States, Russia and Italy each use up over a million oz., and Greece and Turkey rather more. The British Empire makes up another million; and Netherlands, Austria and other countries about $1\frac{1}{2}$ million more. The world's consumption is slowly increasing.

 THE FUTURE OF QUEENSLAND:

A SAD PICTURE.

Writing from Dornoch Terrace South Brisbane, Queensland, on 16th February, Mr. Donald Mackay (so well-known in Ceylon) tells us in the course of a chatty letter:—“I am working my way back from New Zealand to Malaya. The disorganised state of trade

owing to the ravages of drought makes it more difficult to get along round the north of Queensland and through the Eastern Archipelago for the lines that were formerly regular have become quite irregular for want of loading. I don't know what this poor country is coming to—what with the visitations of Providence and the intolerance of the labour-ridden Government of the Commonwealth which decreed that even tropical Queensland should be the close preserve of the white labour which cannot labour to any purpose. Even now a Government Agent is going about, arranging for the deportation to the New Hebrides of the Kanakas, many of whom have been here for years, some of whom have been here for twenty. The Government or the labour party, which is one and the same thing, think that by bonuses of two pounds per ton, sugar can be grown by whites. Assuming it can, what can be said of a policy that keeps up the price of labour by simply taxing the rest of the population? This is only one of the many examples of labour class legislation, to the detriment of the general body, that has been passed by the Parliament of the Commonwealth. Both N.S.W. and Queensland have suffered already from the Federal protectionist tariff, but this state has suffered most and it is for it a cause for bitter regret that it went into Federation in blind faith, without any guarantees. It was quite open to Queensland to have made terms as West Australia had, but the wise men of the former State had not the foresight of those of the latter who did not pin their faith on the word of any man, much less on those of the colonial politician on the lookout for office. It is stated, and I think with a good deal of truth, that the present Premier of the Commonwealth—to gain the support of the labour party—ate his own words, spoken when bidding for office, and allowed his legislation to be controlled and virtually ruled by the labour minority in Parliament. Hence it is that indirect taxation on necessities of the multitude, which was really little felt, was sacrificed and as a consequence resulted in a highly protectionist tariff which is now being strongly agitated against by the Opposition. The labour party, though a small minority, hold the fort because of their organisation outside which is complete. The other and larger interests of agriculture and commerce are not organised and consequently are not able to assert themselves to substantial effect in the control of legislation and Government of the country. The arrogance of the labour party and the ruinous results of their narrow, selfish policy will assuredly lead to counter-organisation of rival interests in Australia as it did in New Zealand, where the farming interest is organised and ready to strike in when the pinch of adversity makes labour arrogance intolerable. Labour is having its day of power which, in its short-sightedness, it is using most arrogantly; the more so the better, for the quicker will come the reaction and the more crashing the downfall, I cannot discourse any longer on the politics of Australia which are none of the sweetest, so must say good-bye and with best wishes &c.

CEYLON TEA: MONTHLY SHIPMENTS TO UNITED KINGDOM AND ESTIMATE.

Estimate for	Mar. 1903—8½ to 9 mill. lb.
Total Shipments	Do 1903—7,500,000 lb.
Do Do	Do 1902—8,198,179 lb.
Do Do	Do 1901—7,982,090 lb.
[ESTIMATE for Apr. 1903—8½ to 8¾ million lb.]	

"PHILIPPINES AND THEIR RICHES"—is the heading of an article (in *The Manila Times*, February 28th), in which Capitalists are urged to "go East"!—and we read:—

There are hundreds of thousands of acres of the most fertile sugar lands in the world merely awaiting capitalists to take advantage of them, while there are some millions of natives, honest and experienced, who are only too anxious to cultivate them.

TEA IN NATAL.—The article we quoted the other day from the *Natal Mercury* has elicited two further communications, quoted elsewhere. The first writer's acquaintance with the general conditions of tea-growing in Natal was, it will be seen, greater than with up-to-date methods of plucking &c.

COLOMBO PRICE CURRENT.

Furnished by the Chamber of Commerce.)

EXPORTS

Colombo, Mar. 30th, 1903

THE AGRICULTURAL MAGAZINE, COLOMBO.

Added as a Supplement Monthly to the "TROPICAL AGRICULTURIST."

The following pages include the Contents of the *Agricultural Magazine* for April:—

Vol. XIV.]

APRIL, 1903.

[No. 10.

PRINCIPLES OF NUTRITION AND NUTRITIVE VALUE OF FOOD.

THIS is the subject of a learned paper by Prof. W. O. Atwater, of the United States Department of Agriculture, who as special agent in charge of nutrition investigations, speaks with authority on this very important subject. There is so much in it that should come within the knowledge of both grower and consumer, that we have decided to summarise the contents of the paper for the benefit of our readers who will no doubt be able to learn a great deal about the true value—nutritive and pecuniary—of food, as well as the general subject of diet, the errors of which has so much to do with the welfare of mankind.

It is well known that the chemical substances of which the body is composed are made up of the same elements as those of the foods which nourish it. The most abundant of the 15 or 20 elements occurring in the human body are oxygen, hydrogen, carbon, nitrogen, calcium, phosphorus and sulphur, which combine to form a variety of compounds. The most important among these latter are the substances distinguished as protein, fats, carbohydrates, mineral matter and water, whose functions stated generally are to build and repair the various tissues of the body, and to supply it with heat and muscular energy.

Water is among the most important compounds, forming over 60 per cent of the weight of the body of the average man, being itself a component of all the tissues.

Mineral matter or ash forms 5 or 6 per cent of the body weight, and is found chiefly in the bones and teeth, though also present in the tissues and fluids. Phosphate of lime is the mineral basis of bone, and compounds of potassium, sodium, magnesium and iron are found in the body and are necessary to life.

Protein includes the principal nitrogenous compounds and is familiar in the form of meat, white of egg, &c. It forms 18 per cent of the body weight in the average man. The albuminoid proteids include substances similar to white of eggs, lean of meat, curd of milk, &c. The gelatinoids occur principally in the connective tissues, and with the albuminoids are the most important constituents of our food, forming the basis of bone, muscle and other tissues. They yield heat on combustion, and are to some extent transformed into fat and stored in the body. Proteids are most abundant in the animal foods though also present in cereals, and, in large proportion, in legumes. It should be added that the gelatinoids are less valuable than the albuminoids for nutriment. The "extractives" though classed as proteids are very different from the two already mentioned. They are the chief ingredients in meat extracts, such as beef tea, &c. They are believed neither to build up tissue nor supply energy, but act as stimulants and appetisers. The nitrogenous compounds of vegetables contain more or less of the so-called amids analogous to the extractives of meat. Fats occur chiefly in animal foods, but are also found as oily matter in seeds. When the food supply is short, fat, and also protein, is drawn upon to supply heat. Fat forms 15 per cent of the average body weight. The tendency to fatness is not

decided by food and exercise alone, but depends also on personal idiosyncrasy or some other little understood factor. Sugar and starch of foods are charged into and stored as fat in the body.

Carbohydrates.—These include starches, sugars and cellulose which occur chiefly in vegetable foods, though, milk contains much sugar. The carbohydrates form less than 1 per cent of the body. Starches and sugars are important as being a source of energy, and are easily digested.

In discussing the nutritive value of food we must discard the refuse part of it, such as bones of meat, shells of eggs, skin and seeds of fruit, in order to find the actual cost of the nutrients.

The potential energy of food is transformed in the body into heat and mechanical power. The latter is required for work, the former is used to keep the body warm, and when more is generated than is needed for that purpose it is wasted. The body is indeed a machine, but unlike other machine it is self-building, self-repairing and self-regulating. It is, however, more than a machine in that it has a nervous organisation, sensibilities, and the higher intellectual and spiritual facilities, the right exercise of which undoubtedly depends upon the right nutrition of the body.

Shortly stated the uses of food are (1) to form the material of the body and supply its waste, (2) to yield heat for the warmth of the body and furnish muscular and other power for its work. The principal tissue formers are the proteids, especially the albuminoids which make the frame-work of the body, build up and repair nitrogenous materials (muscles, tendons) and supply the albuminoids of the blood and other fluids. The albuminoids of food are transformed into albuminoids and gelatinoids of the body. Muscle, tendou, cartilage, bone, skin, blood corpuscles, the casein of milk are all made from them. The gelatinoids of food, such as the finer particles of tendon and the gelatin (which are dissolved out of bone and meat in soup) though not believed to be tissue formers, protect the albuminoids from consumption. When the food contains gelatinoids in abundance, less of the albuminoids is used. The proteids can be so changed in the body as to yield fats and carbohydrates, and are also burned directly in the body like carbohydrates. The material of lean meat may be converted into muscle and its energy into heat and muscular power, but a one-sided diet of meal is unsuitable. Fats and carbohydrates (starch, sugar) are the chief fuel ingredients of food—the former being the more concentrated fuel. The fat stored in the body for food, and that formed in the body from carbohydrates, act as reserve supplies of fuel. While the functions of the different nutrients are interchangeable, only albuminoids can do the work of building and repair.

Heat and muscular power are forms of force or energy. The energy latent in food is developed as the food is consumed. When combustible matter is oxidised, be it meat or wood, bread or coal, the latent energy becomes active and is transformed into heat and power. Again, as various kinds of fuel differ in the amount of heat they produce, so various kinds of food give off

different amounts of energy, and hence have different values as heat-producing substances.

When a man does no muscular work (beyond respiration, circulation, &c.) all the energy leaves the body as heat; otherwise it is expended partly in this way and partly in muscular work. Any way, the interesting point is that the energy given off is exactly equal to the latent energy of the material burned in the body. The body thus obeys the great law of the conservation of energy which obtains in the physical world. In practically applying the principle of this law to the body, we have to take into account the chemical composition of food, the proportion of nutrients actually digested and oxidised, and the proportion of the whole latent energy of each which becomes active and useful for warmth and work. Taking our common food materials as they are used in ordinary diet, the following is a general estimate for the energy furnished by 1 lb. of each class of nutrients:—

Protein	fuel value, 1,820 calories per lb.
Fats	" 4,040 " "
Carbohydrates	" 1,820 " "

[One calorie is equal to very nearly 1.54 foot tons, that is to say, one calorie of heat, when transformed into mechanical power, would suffice to lift 1 ton 1.54 feet.]

It will thus be seen that a pound of protein of lean meat or albumen of egg is about equivalent to one of starch or sugar as regards fuel value, and that a little over 2 lbs. of either would be equal to a pound of meat or butter fat.

Thus the fuel value depends upon the amounts of the nutrients, especially fat.

Here are a few instances of the fuel value of common foods themselves:—

Wheat flour	... 1,625 calories per lb.
Butter	... 3,410 " "
Milk	... 310 " "
Cream	... 865 " "
Skin milk	... 165 " "

(To be continued.)

OCCASIONAL NOTES.

The flowering tree now pretty common about Colombo and popularly known as "Madre de Cacao" has at last been fully named *Milletia atropurpurea* by Sir Joseph Hooker. The seeds originally came to the late School of Agriculture from Central America in exchange for seeds of the Dhall or pigeon pea (*Cajanus indicus*). The tree is very easily grown from cuttings, and is rapidly spreading as a shade and hedge plant, while the blossoms, which appear in February-March, are really handsome.

The curious name "Arthapal" by which the English potato (*Solanum tuberosum*) is locally known is only a corruption of "earth apple" (pome de terre) not to be confounded with earth nut or ground nut (*Arachis hypogaea*). "Potato" is said to be derived from "batata" (the Spanish for sweet potato) which must therefore have been known before the former. By-the-bye has any one heard the term "rata-imala" applied to the

English potato? Watt mentions this as the Sinhalese name. Of course, the innala (*Plectranthus tuberosus*) is known as the "country potato."

The Sinhalese word *ala* is indiscriminately applied to all kinds of yams, including the potato, and is apparently equivalent to tuber or bulb. In some cases a prefix serves to distinguish different varieties as in "dehi-ala." The sweet potato is bathala, which some say signifies "the yam which is farinaceous like rice" (bath), and others consider as only a modified form of the Spanish and Portuguese Batata. The specific term *batatas* is believed to be the original South American name.

Some authorities, however consider the sweet potato a native both of the old and new world, that it formerly grew wild in the forest of the Malayan Archipelago, and that *batatas* is the Malayan name. Nicholls states that the plant was first mentioned by Pigafetta who visited Brazil in 1519, and found the Indians using the tuber. Soon after the plant went to Spain and spread over Europe, being introduced into England long before the English potato. Dr. Pavy says that the tubers were imported into England by way of Spain, and that it is the article referred to as the potato by writers before the middle of the 17th century.

With us the term "yam" is applied to the products of either the Araceæ or Dioscoreaceæ, but not so in the West Indies. The name *Tania* is applied to the tuberosus rhizomes of *Colocasia antiquorum* (Sin. Gahala,) while the term Yam is confined to the several species of Dioscorea.

The pineapples of the Matale district, where oranges also flourish, are becoming famous. Dr. Van Royen has succeeded in growing excellent pines that turn the scale of 16 lbs., and with the careful cultivation he is adopting we shall not be surprised if he beats the record of 20 lbs. reached by Henaratgoda, another pine-growing district.

The Colombo Agri-Horticultural Society's Show to be held at Henaratgoda Gardens in July next promises to be a great success. The Mudaliyars of the contiguous Korales are showing great enthusiasm over the coming Exhibition, the first to be held by the Society out of Colombo city, and the Honourable the Government Agent of the Western Province, to which the Show is to be confined, is not less enthusiastic than his chiefs.

One of the prizes offered is for the best School Garden in the five neighbouring Korales. This is an innovation, and is creating keen competition among the village schoolmasters. The first prize will be a large silver medal, a smaller silver medal going to the second best garden.

The renovation of "black cacao" by the aid of anatto (*Bixa orellana*) dye has now become quite an art, and it is a common sight to see

Moormen—dealers in cheap cacao—churning the seed in a sheet of coarse cloth together with the colouring medium, made up of cacao juice and anatto. Unfortunately the colour is not a fast one, and the Colombo Broker has, it is said, discovered a convenient and extremely simple means of distinguishing the genuine from the spurious "bold bright red," viz., rubbing the seed against a white substance,—when the dye (like similar capillary washes) comes off!

The greatest rainfall recorded in any 24 hours, on 31st March, 1903, 44 inches,

Recorded by ALEX. PERERA.

SCHOOL GARDENS IN WEST INDIES.

The following account of the efforts made in Trinidad to encourage a practical interest in plants by means of School gardens is taken from the Annual Report for 1901-02 of the Inspector of Schools for the Colony:—

Of the 82 Schools in operation on March 31, 1902, 67 had taken up Practical Agriculture previous to that date, and out of the 80 schools examined, 30, or 37.5 per cent. presented this subject, the results being in my opinion satisfactory for the first year.

In some schools, notably Mayaro Government, and New Gaand, E.C., to which the award of "Very Good" was given, the subject had been treated in a systematic and intelligent manner, whilst at other schools, notably—Hard Bargain, North Trace, New Grant and Princes Town Government, 5th Company, 6th Company and Neckchuddy Road E.C. the work deserves great credit.

My chief object has been to impress upon the teachers that a school garden is not for the purpose of merely growing vegetables, but to be cultivated in such a manner as to impress upon the children by means of experiments the benefits

to be derived from *true* Agriculture. I have also recommended teachers to try and induce the parents of children to come and see the results for themselves which will do more, I think, than anything else, to make them believe in the benefits to be derived from the proper training of this most important subject, and cause its more rapid spread and adoption amongst the labouring part of the community; and this I am glad to say has already commenced, as some of the parents of the children attending 5th Company, 6th Company, and Neckchuddy Road E.C. Schools, have been to the teachers asking for information as to the methods used to grow the fine vegetables obtained at these schools.

The chief faults in the school gardens are:—

(1) Overcrowding, and mixing of different plants, which renders 'rotation of crops' impossible.

(2) Planting only with a view to get as much as possible out of the land, without any regard to exhaustion of the soil, and without experiments.

(3) Insufficient use of green manure.

(4) Want of compost heaps.

(5) Insufficient mulching during the drying season.

In order to remedy these mistakes, I am advising the teachers:—

(1) To set aside a plot for each kind of vegetable, and plant at regular distances.

(2) To set aside a portion of each plot for experiments.

(3) To bury in each plot as much as they can of the plant refuse.

(4) To form compost heaps of any surplus vegetable refuse, weeds and grass.

(5) Always to mulch as far as possible in the dry season.

I have been careful to inform teachers that it is not the look of the garden on the day of examination for which the award is given, but for the general work during the year.

On the whole I am sure that, I think the outlook for practical agriculture in this district is very promising, and if an instructor could visit the different schools two or three times a year, and take practical work, as well as give lectures, the results would be marked, as I have no doubt that after a time some of the more intelligent adults would also attend sometimes, more especially if the subjects of the lectures were known beforehand.

I am sorry to say that the parents of pupils attending Russillac C.M.I. School have refused to allow their children to work in the school garden, and have threatened to take them away if they are compelled to do so. In consequence practical agriculture has ceased to be taught at this school.

VETERINARY NOTES.

Still another cure for tape-worm is powdered kamala. This is a dark ochre-coloured powder, consisting of minute glands and hairs obtained from the surface of the fruits of *Mallotus philippinensis*. It may be given in a little milk or

water, or as pills made with flour and water. Being very light it is difficult to mix it nicely with water. The dose for a lamb or kid is a teaspoonful heaped; calves twice that quantity; dogs half to a full teaspoon according to size and age.

Mallotus Philippinensis is an Euphorbiaceae plant called in Sinhalese *Himparilla*. It was formerly known as *Rottlera tinctoria*. Trimeu mentions that the powder of the seeds is used as an anthelmintic in cases of tape-worm and as a cure for itch. The bark is used for tanning, and the capsule yield a dye giving a permanent rich flame colour.

The following treatment for foot-and-mouth disease is taken from "Diseases of Stock and their Treatment" (Cape of Good Hope, Department of Agriculture): In the first stage, the internal administration of Epsom salts, one pound in three quart-bottles of water; followed by Epsom salts 1 oz., Hyposulphite of Soda $\frac{1}{2}$ oz., Chlorate or Nitrate of Potash 2 drs., given in drinking water for a few days. For a mouth wash: Carbolic acid 1 dr., vinegar 1 pint, water 1 pint, or borax 1 oz., alum 1 oz., water 1 quart.

For the teats: Permanganate of potash 20-grs., water 1 qt.; or tincture of myrrh 1 oz., glycerine 10 oz. to be applied twice daily.

For the feet, after thorough washing, and, where necessary, poulticing, apply sulphuric acid 1 oz, diluted with 4 oz. water to the abraded surface with a feather, and apply a bandage previously well soaked in Stockholm or Archangel tar.

An epidemic, recognised to be Indian "Surra" has been causing great mortality (estimated at from 75 to 80 per cent) among horses, mules, and oxen in the Mauritius, and as a result the cultivation of sugarcane has been seriously interfered with. The local Government has, it is reported, decided to apply for the services of Dr. Edington from the Cape of Good Hope.

Owing to the prevalence of Lathyrism in the Central Provinces of India, Major Buchanan, I.M.S. and Mr. Stockton, M.E.C.V.S., late Professor of Pathology in Edinburgh Veterinary School have been appointed to enquire into the cause and prevention of the disease. The malady is regarded as arising from the consumption of large quantities of the food grain known as *Lathyrus sativus* or teora, when not prepared in such a way as to eliminate the poisonous principle which it is believed to contain.

The following will give an idea of the disease: To begin with there is a feeling of weakness and drowsiness, with pains in legs and occasional cramps in the calves. Suddenly the patient falls, and being unable to rise, is confined to bed for a month or two. This is due to the paralysis of the lower extremities. The attempt to stand brings on spasms in the legs. There is also rigidity

of the muscles of the spine. Improvement is slow (assuming a change of diet) but gradual. There is no fever. Males appear to be more susceptible.

NEW VARIETIES OF SWEET POTATOES.

(*J. W. Mollison Inspector-General of Agriculture for India.*)

I imported three American varieties of sweet potatoes last year. These were first tried on the Bombay farms. The first Bombay crop was propagated from imported tubers, the second crop was propagated in the usual way from cuttings. It was planted on the 8th of April and was lifted at the end of July. A large number of cuttings were distributed from the first crop to various parts of India; therefore only about one-fourth acre was planted for the second crop. The area was too small for very reliable outturn figures. I give, however, the results as under:—

	lbs. per acre.
Nansemound	14,470
New Jersey	16,782
Virginia	21,413

The land was not directly manured but was in good condition. The produce from the whole plot ($\frac{2}{50}$ th acre) was sold for Rs. 90, or Rs. 303 per acre.

2. The crop also yielded a very large number of cuttings which have been used for distribution and for planting an extended area at the Bombay farms. I have now seen these varieties growing on various descriptions of soil in the Punjab, Bengal, Central Provinces and Bombay. The plants everywhere show great vigour of growth. I believe the introduction of these varieties to be an undoubted success. It is important, therefore, to have these American varieties tried in all districts where the crop is important. Cuttings can be supplied during October for experimental trials if applications are made to my office at Nagpur.

3. The crop does best on deep alluvial soil of a sandy or loamy character, but will also do well on any free working naturally dry soil of fair depth. The best crops are grown under irrigation in the rabi season; but in districts where the cold of winter is severe and the total rainfall is not excessive, the crop will probably do best if planted in June-July. The American varieties are not likely to thrive on deep black-soil.

4. The results reported from Poona show that the tubers were all sound and of good shape and size. They were proved to cook well and have good flavour. The Virginia variety produced 4 or 5 tubers from each plant. These tubers were larger than those usually obtained from indigenous varieties. The Nansemound and New Jersey varieties produced 16 to 18 tubers from one plant. These tubers were smaller than those from ordinary indigenous varieties, but were all of good marketable size. The tubers of each variety grew not far from the surface in clusters, and were much easier to dig than those of ordinary Indian varieties.

5. The cultivator of sweet potatoes is put to no particular expense for seed. He simply uses as cuttings the haulms of a previous crop. These cuttings may have to be planted in a nursery. A small nursery planted in March when the rabi crop is harvested will provide cuttings for planting a kharif crop in July, and this crop will, in its turn, provide cuttings for the next rabi crop which should be planted in October-November.

6. Full details regarding methods of cultivating this crop are given in Volume III of my *Agricultural Text-book*, but for easy reference I may refer to important points here.

7. The soil should be of suitable class and be well worked by repeated ploughings and harrowings. Beds should be formed if irrigation is required. The crop can be propagated from tubers, but more economically from cuttings or pieces of mature stem having four nodes to each cutting. The best cuttings are got from the middle portion of the stems. The date of planting the main crop will depend upon the usual custom in any particular district. The main crop is sometimes planted in flat beds and sometimes, in ridges made about 18 inches apart. The latter method is preferable. The cuttings, if planted in ridges, should be buried half way between the base and the apex and on each side of each ridge. Each cutting should be planted with two nodes buried and two ends above ground. A vigorous growth of long trailing stems is soon produced if the crop is healthy and very little hand-weeding is required. No irrigation is given in the rains, but if planted in the rabi season irrigation is necessary every 8 to 15 days according to the character of the soil.

8. The stems when in contact with wet soil after rain or irrigation become attached to the soil by rooting at the nodes. This must be prevented, otherwise small thin tubers of no marketable value form at each point of attachment. The tubers which form at the main root, moreover, will not grow so large as when the stems are kept quite free. The stems during growth must be repeatedly lifted clear from the ground and turned over to prevent the formation of these roots. These operations must be done often if the crop is good and the foliage luxuriant, and always with care, so that the stems and leaves are damaged as little as possible.

9. In a luxuriant crop the growing points of the long trailing stems may be pruned off without damaging the crop in any way. These prunings provide a delicate vegetable.

10. The crop should be lifted when the stems near the growing point get hard and fibrous and the leaves turn yellow. The vines should be reaped close to the ground and cuttings selected for a nursery. Such of the vines or portions thereof as are green and succulent can be used as cattle fodder. Irrigation water should be withheld as the crop approaches maturity. When the tubers are ripe they should be lifted at once, otherwise much damage will be done by rat and white-ants, &c.

THE CAROB OR LOCUST BEAN BEET.

This is also known as the Algaroba bean or St. John's Bread, and botanically as *Ceratonia Siliqua*. The seeds are said to be the original of the carat weights of jewellers.

According to the *Kew Bulletin* it is a native of Southern Europe. The tree is leguminous and usually grow 15 to 25 ft. high, with few branches and dark green pinnate leaves, composed of 2 or 3 pairs of leaflets of a leathery texture. The flowers are polygamous or dioecious (self-fertilising or unisexual on different plants). The pods are full of sweet mucilage, 6 to 10 inches long and contain many seeds. They are often eaten by the poorer people in the Levant and serve as a useful food for cattle. The seeds are also said to be used in the preparation of mucilage. In Italy and Southern Spain the tree is cultivated in dry strong localities and yields valuable crops. The value of beans exported from Cyprus reaches, in some years, £65,000. There are several cultivated varieties. As the tree is dioecious, male or female branches as is necessary must be engrafted to ensure fertilisation.

For cultivation in hot and dry districts, with strong soils, says the *Kew Bulletin*, there is little doubt that the carob is a valuable tree and deserves to be widely cultivated. It requires warmer conditions than the orange, and is said to prefer a calcareous sub-soil. We fancy it should therefore suit the northern part of the Island. It begins to bear about 3 years old, and a single tree may yield pods weighing in the aggregate about 2 cwts.

Dr. Balfour refers to the locust bean tree as the Husk tree, and mentions that the term locust in St. John's Bread (German: *Johannisbrod*) was given to the tree from a mistaken notion that its pods were the locusts referred to in Matt. iii. 4, and Mark i. 6, as forming part of the food of the Baptist.

The Greek word *Ceratia* or *Keratia* (which is given to the pods owing to their resembling a slightly curved horn, (*keras*) has been translated "husks" in the passage occurring in Luke xv. 16, "the husks that the swine did eat." The tree is common in the South of Europe as well as Syria and Egypt, and the pods were formerly used in large quantity to feed swine and cattle. Horace has the following reference to them: "Vivit siliquis et pane secundo" in *Epist.* II. i. 123. Perseus and Juvenal also allude to them, and Pliny describes them as food of pigs (*Lib.* xv. cap. 23, 24).

A tree will sometimes produce 800 or 900 lbs. of pods, useful for feeding horses, asses and mules. They were given to the British horses in the Peninsula war, and are to some extent imported into England for both horse and cattle food. Farmers mix the beans with oil cake and meal.

Another Algaroba bean tree distinct from, but closely related to the above is *Prosopis Julifera*, the mesquit or algaroba blanca, also with sweet succulent pods used as food. The tree is growing freely in the Government Stock Garden, and can be propagated by cuttings.

TOMATO WILT.

By A. DESPEISSIS.

This disease has been unusually prominent on tomatoes this season. The trouble is a bacterial blight. G. Delacroix, a French scientist, who has it under observation, first attributed it to an organism described *Bacillus solanacearum*; subsequent studies have since led him to state that the disease in question is not to be attributed to this organism, but to another apparently undescribed, to which the name of *B. solannicola* is given.

The attacked plants wilt suddenly and after a time leaves and stalks become discoloured and die. If a section is made of the stem, the pith channel is found brown, small warty spots on the stem, not unlike the water core of apples, let droplets of dirty white liquid exude. This liquid is full of bacteria. In potatoes this discolouration extends down the stalk to the tubers, which turn brown and rot. The disease is mostly spread by inoculation caused by the bite of insects; it is also associated with a web-like ground plant fungus, *Rhizoctonia Solani*, which extends its meshes from plant to plant, boring directly into the healthy cortical cell and thus giving and an entrance to the bacteria.

The first step to take is to spray with a poisonous mixture, and destroy those insects which feed from plant to plant, thus spreading the disease. One ounce of Paris green in ten gallons of Bordeaux mixture will effect this. Carefully dig round the diseased plants and prevent the spread of web-like fungus to healthy plants. Root up and carefully burn diseased plants.

The organism causing this trouble is believed to be present in the soil from which it spreads to the plants, and unfavourable meteorological conditions are a contributing cause of the infection. Sour ground aggravates the disease.

Tomatoes, potatoes, egg-fruit, black nightshade, Cape gooseberry, among other plants, harbour the germs of the disease, and for that reason should be avoided in the course of rotation over infested ground.—*Journal of the Department of Agriculture, Western Australia.*

CONDENSED MILK.

Few people have a clear idea of how condensed milk is prepared, and Mr. M. A. O'Callaghan's contributions on the subject in the *Agricultural Gazette* of New South Wales for January and March of this year (from which we summarise the information given below) are worth perusal by all consumers of the article in question. In Ceylon the use of Nestle's and the Anglo-Swiss Condensed Milk Co.'s milk is very extensive.

Condensed milk may be defined as new milk reduced by evaporation in a vacuum pan to about a third of its original volume. Before sterilising by heat was understood, the addition of cane-sugar was deemed essential; now, however, we have both sweetened and unsweetened milk

in the market. Many brands of condensed milk contain a very large amount of sugar—as much as 40 per cent in some cases. The result is that it is necessary to add a large quantity of water to dilute it sufficiently for use, and this is of course a serious objection.

Of eighty-six samples of condensed milk examined in the Government Laboratory, London, at the instance of the Committee appointed in 1899 to enquire into the use of preservatives and colouring matters in food, none were found to contain chemical preservatives. The use of such preservatives in condensed milk would thus appear to be unnecessary.

But for what is known as *concentrated milk* a preservative, and especially boric or boracic acid, is commonly used. The question will no doubt be raised as to what is concentrated milk, and what is the difference between it and condensed milk? The former is a product peculiar to Australia as far as the manufacture is concerned. It corresponds to the unsweetened milk of Europe. To state the difference clearly, condensed milk is milk from which a considerable part of the water has been evaporated and which has been *sterilised* by heat; it may or may not contain added sugar. Concentrated milk on the other hand is *pasturised* milk from which a certain proportion of water has been evaporated and which contains no added sugar. Condensed milk again is put up in 1 lb. tins which are filled and hermetically sealed. Concentrated milk is generally put up in gallon tins, and sometimes distributed from open vessels. Concentrated milk is not intended for long keeping, and indeed will not remain good beyond a few days, unless kept in cold storage. It is principally used on board-ship where it is much preferred to condensed milk. The question of using preservatives has been warmly discussed, and Mr. O'Callaghan is of opinion that .25 of boric might be allowed to be added before concentration, so that .5 or .75 will appear in the end according to the degree of concentration.

The following is given as the general technique of manufacture:—

(1) The milk is sometimes separated or centrifuged to remove all possible impurities before starting.

(2) The milk is now warmed (sometimes boiled) and sugar added when sweetened milk is to be made.

(3) Some factories heat it in open vats for some time before placing it in the vacuum pan. This is to help sterilisation.

(4) It is then evaporated till only a little over more than $\frac{1}{3}$ of the original amount remains, the evaporation being carried on in a vacuum pan, where the milk boils for a couple of hours. The temperature at which the milk is evaporated is an important point.

(5) After evaporation has been completed to the desired point the milk is drawn off, cooled, and packed in tin vessels.

(6) If the concentrated milk is required the process is now complete, but if sterile milk (condensed) is required, further heating is carried

on, and this is what is technically known as *processing the milk*.

(7) The milk is then held for some time to test its keeping qualities before sending it to market.

The following is given as the fat analysis of the better known milks:—

Ideal	... (unsweetened)	11.09	per cent.

POUDRETTE.

(J. W. MOLLISON, M.R.A.C.)

A practical and profitable method of utilising human excrement as manure is specially important in India. In the light of up-to-date sanitary knowledge there is no doubt that with a properly organised water-closet system and regular house-to-house connections the sewage drainage of any city can be so purified that it can be used as a source of irrigation and of manure for crops without producing unsanitary effects. The purification is effected by several processes, the most effective of which is a septic tank and filter bed system. Other effective processes are known as "Dibden's filters" and the "macerating tank system." We have had each system in experimental operation in connection with sugar-cane experiments at Manjri (Poona), and the results are fully reported in my annual report 1899-1900. It is unnecessary to enter here into full detail. The purification is brought about through the influence of bacteria, and in the space of 24 hours the whole of the solid matter of the sewage disappears. The organic matter is converted into soluble inorganic salts. The test of complete purification is the conversion of all the organic nitrogen into nitric acid. In the Poona experiments the purification were not quite complete, the nitrogen being converted mostly into nitrites. The effluent has been proved a most valuable and quick-acting manure for sugar-cane and other crops, and at present I believe that it can be used as continuously as canal water for irrigation without causing unsanitary conditions of any kind. It is proposed to apply the system to the whole of Poona; and the Poona sewage scheme as engineered by Mr. J. C. Pottinger, Sanitary Engineer, Government of Bombay, is described in two addresses to the Municipality which he has recently published. Pure sewage cannot long be used for irrigating and manuring one particular area because the land to which it is applied requires intervals of rest. If used continuously the pores of the soil get choked with slimy organic matter which obstructs aeration, and in consequence an unhealthy condition of vegetation is produced.

In rural districts in England the earth closet system is practised. The same system is common in Ceylon. This consists in covering the solid and liquid excreta with earth. The urine is absorbed, the solid excreta deodorized. Earth, particularly good loam, has this power. The effect is due to

humus and clay. In Poona and many towns in India the deodorizing power and absorptive effect of earth or carbonized material is taken advantage of in the preparation of poudrette. The night-soil is collected and also the town sweepings and leaves &c., and carted to a depot outside the Municipal limits. The sweepings are burnt or rather charred. The ashes still containing a good deal of carbon are mixed with the night-soil. The ashes, if used in the right proportion, exercise a disinfecting power in deodorizing the whole mass. The resulting manure is a source of handsome revenue. A decided caste prejudice existed for years against its use until its effect upon sugar cane and garden crops was made perfectly clear to the cultivators.

The following is a method of manufacture of poudrette at Poona:—A series of beds 18 feet long, 15 feet wide, and 1 foot deep are floored with *marum*. A layer of ashes about 1 inch deep is laid on this floor, and night-soil poured thereon to a depth of about 5 inches. The mass is immediately covered with another thin layer of ashes one inch deep, and thereafter allowed to stand 24 hours during the fair weather, and for three days during the rains. Wooden rakes are then used to mix the night soil with the ashes. Another layer of ashes is now added, and the whole allowed to remain from three to eight days according to the state of the weather. It is then removed from the beds and dried on dry open ground. In the hot weather it is dry in five days and ready for sale and use. In the rains the whole process is conducted under cover and takes a longer time. When moist poudrette is heaped up sometimes, as with farmyard manure, an excessive degree of heat is generated which causes loss of nitrogen.

In the cantonments of Poona another method is adopted which is decidedly more sanitary. Pits of convenient length and width are dug, sometimes five feet deep. Into these pits the night-soil and dry pulverized earth are put in alternate layers and equal proportions. A capital manure results, but it is not ready for use for several months. It is not of course so concentrated a manure as poudrette made in the ordinary Poona way: Poudrette is recognised as an active and powerful manure for all irrigated crops in which a rapid and luxuriant growth is desirable. It is very suitable for sugarcane, lucerne, vegetable and all fodder crops. It is too forcing for grain crops and fruit trees. The plant is stimulated into active growth at the expense of fruit or grain.

Poudrette is seldom applied except where irrigation is practised. It is worth at Poona as much as R3 per cart-load, but in seasons of scant rainfall when a supply of irrigation water cannot be guaranteed it falls in value to less than R1 per load. Poudrette is applied at the rate of 15 loads per acre, up to as much as 80 loads per acre for sugarcane.

Dr. Leather's analyses show that Poona poudrette contains about one per cent of nitrogen, and generally a slightly higher percentage of phosphoric acid. The percentages of these ingredients vary with the percentage of moisture. If Poudrette was generally manufactured through-

out India at all populous centres, it would probably be the cheapest and best manure procurable.—*Textbook of Indian Agriculture.*

SOME PROBLEMS OF THE RURAL SCHOOL.

(From an American Point of View.)

That there are many important matters in connection with our system of rural education requiring urgent consideration there is no denying; and the publication of a paper on the subject of rural educational problems by Dr. True is very opportune, as likely to direct attention to questions that are closely connected with the best interests of the island, at a time when a good deal is being said or written about educational matters.

We therefore summarise the paper referred to for the benefit of our readers:—

The elementary rural school, free to all children, has undoubtedly done much to raise the general level of intelligence. But in considering the benefits of the system, we have lost sight of its shortcomings, and it has, at times, been in danger of becoming a "petrified institution" deprived of the progressive spirit which can only enable it to adapt itself to changing environment and advancing knowledge. With the growth of large towns and cities, men of influence have succeeded in developing a public school system to meet the needs of the stronger and more active communities,—a complicated system of public education for the urban youth—in order to equip him for various professional and industrial occupations. On the other hand the progress among rural communities has been along very narrow lines. The chief effort of the educational forces in the rural districts has been to provide schools of some sort to meet at least the simplest educational needs of a widely scattered multitude of children. The motto of our leaders would seem to have been, "Let us put a school house in every valley and in every hill-top," but little attention was given to make the curriculum of the country school suitable to the condition of the children. The problem was put aside with the remark—"These schools are no doubt unsatisfactory, but we see no present hope of their improvement. Let us go on building school houses, and trust the future to bring forth some plan for the betterment of the schools."

Fortunately, however, there has at length been aroused an interest in plans for the improvement of country schools. In these plans are contained much that promises to work to the advantage of agriculture, as well as to the greater welfare and happiness of the rural population.

The character of Agriculture is rapidly changing in many particulars which need not be here specified, and wider knowledge and greater skill is now needed. It is very important, therefore, that the agricultural people should understand the relations of rural schools to the progress of their art. When every other industry is ally-

ing itself closely with schools and seeking changes in the school courses, it surely will not do for agriculture to hold aloof from the educational movements of our time. It is true that attempts are being made to improve the condition of the rural school, but this must not be left entirely to the "schoolmen." The patrons of the schools, and the land-owners in the neighbourhood, should take an active part in the movement, and impress upon the schoolmen their real educational needs, and help to adjust the schools to the advancing requirements of agriculture.

Obviously the fundamental problem of our public schools is to give all the people at least the simplest rudiments of education. But this primary task they have not established as census reports can prove. Indeed it is illiteracy among the agricultural classes that is one of the greatest obstacles to the progress of agriculture. This "inert mass of absolute ignorance" prevents the introduction of better crops and better methods of cultivation; and the effects of the few intelligent ones to improve matters are largely defeated by the stupidity of those who must be looked to, to give practical effect to suggestions for improvement. There is, then, yet a great work to be done by schools among our rural communities.

The great object before every school is to find a way of getting all the available children within its walls, and keep them there long enough to give them a satisfactory training. For this funds are necessary, and the greater part of the money required for the proper maintenance of schools must be raised by taxation. This may not sound well, but the fact cannot be got over. There are, however, certain general principles to be applied in levying school taxes: (1) The aim should be to provide every child of school going age with equal opportunities for an education. (2) The whole wealth of the "State" should be made available for educating all the youth of the State. (3) The individual communities requiring schools should contribute according to their means towards the support of their own school. The failure to observe these rules has resulted in keeping up the percentage of illiteracy, and has imposed too large contributions on the rural communities, or left them without proper inducements to contribute their share. The main object as regards maintenance, is to have such an adjustment of State aid and local self-help as will make the schools efficient and keep their patrons alive to their best interests. It is not necessary here to discuss the merits of laws to check the evil of non-attendance at schools because of the money value of the labour of school children; but it is sufficient to say that one of the important educational problems to be solved is the securing of more general attendance of children at the elementary schools provided for them.

Though in some respects urban schools have the advantage over country schools, in others the reverse is the case, and there are many natural advantages in the latter. The free and open life of the country imparts greater vigour of mind and body; the occupations of the country necessitate a more varied exercise of both mind and body, and

the country environment furnishes a much wider range of materials for interesting study, which (the greater the pity) is almost entirely neglected by the schools. Given a bright, energetic and well-trained teacher, and 25 to 40 healthy and active country children between 5 and 18, and we may easily have a school where educational results will be of great merit, though it lacks the organisation and equipment of the city school. There are such schools, and they are doing a grand work; but these serve at present only to brighten in a slight degree the glooming picture which portrays the unsatisfactory condition of the ordinary village school. The fact remains that if we are to improve our agriculture and compete with others on the best terms, if we are to make the conditions of country life attractive enough to keep the bright boys and girls in the country, if we are to equalise the advantages of country and town so as to maintain an intelligent, prosperous, progressive and contented rural population, we must give effective attention to the needs of our rural schools.

ON POULTRY AND EGGS.

At ancient feasting eggs were consumed in considerable numbers, for it is recorded that at one in the time of Richard II., no fewer than 11,000 were provided. In the reign of Edward I. 450 eggs were sold for eighteen pence. In that of Edward II. A.D. 1314, eggs and other foods being dear, the price was settled by Parliament at twenty for a penny. In A.D. 1316 Parliament abrogated their decree, and then food was to be sold at reasonable rates. The prices allowed for the household of Henry VIII. were "For eggs from Shrovetide till Michaelmas, the hundred, fourteen pence, Michaelmas to Shrovetide, the hundred twenty pence," which was evidence of their scarcity at the latter part of the year, and therefore of more value.

Over five millions pounds worth of eggs are now annually imported into England, but not one half of these are used for culinary purposes. The calico printing works use over 40,000,000 eggs a year, photographic establishments use millions of dozens, and wine clarifiers 10,000,000 dozens in the year; bookbinders, kid glove makers, and leather finishers use them in abundance, as well as other trades. The general public appear to have but little knowledge of the magnitude of the numbers wanted for practical commercial uses, apart from those of food, though in the latter respect not a few of the figures are absolutely startling; as an instance one of the London clubs alone contracts for more than 100,000 eggs a year.

Hens that are kept busy scratching a good part of the day will eat more and lay more. Layers want plenty of ground green, bone, broken shells, grit and vegetables. Albumen exists to a large extent in fresh meat and ground green bone than in any other food. The shell of the egg

is formed from bone, shells and grit. Of grains wheat, oats, barley and maize come in order. Of green foods clover, cabbage, carrots, turnips, &c.

Six large eggs will weigh about a pound. As a flesh-producer one pound of egg is equal to one pound of beef. About $\frac{1}{3}$ of the weight of an egg is solid nutriment, which is more than can be said of meat. There are no bones and tough pieces to be put away. Eggs, at average price, are among the cheapest and most nutritious articles of diet. Like milk, an egg is a complete food in itself, containing everything necessary for the perfect development of a perfect animal. It is easily digested, if not spoiled by cooking.

Fertile eggs with strong vigorous germs can only be secured from healthy well-cared-for birds. Despite the various theories and methods suggested, no one can tell which egg will hatch and which will fail till after a period of incubation. It is an impossibility to discern the sex of the prospective chick.

A fresh egg has a somewhat rough shell, while that of a stale egg is smooth. When cooked the contents of a fresh egg stick to the shell and must be removed with a spoon; but a stale egg, when boiled, can be peeled off like the skin of an orange.

Bran is an excellent food for poultry. It contains more lime than any other cheap food derived from grain, and in a more serviceable, because better digested, form than that in shells.—*Agricultural Gazette, N. S. W.*

GENERAL ITEMS.

The following is Prof. Church's analysis of the fresh kernel of the coconut: Water 46.6, albuminoids &c. 5.5, oil 35.9, sugar &c. 8.1, cellulose 2.9, mineral matter 1.0. The Report of the Agricultural Experiment Station, California, contains the following analysis of good coconut oil cake (poonac): moisture 12.87, pure ash 4.54, crude protein 20.06, crude fibre 11.50, nitrogen free extract (starch, sugar, &c.) 40.90, crude fat 10.13. Prof. Henry in his *Food and Feeding* gives a summary of experiments made by the French War Department in feeding with coconut meal, and says that the results proved that the meal was equal and even superior to the same weight of oats.

A contemporary writing about "What the Onion can do," says: To keep off disease eat onions raw, to cure spasms rub them on the spine, to cure typhoid fever bruise with a hammer and bind on the feet, to cure chills bind round waist and to the pulse, for diphtheria bind to the throat, for a burn wet with raw juice, to cure a cold boil and eat with butter, for croupy babies slice and sprinkle with butter and cover closely, and when the juice runs out give a spoonful every hour.

Prof. Koch has shown that citric and malic acids as they occur in apples, lemons, &c. are able to destroy all kinds of disease germs. We are told that cholera germs are killed in fifteen minutes by lemon or apple juice, and typhoid germs in half an hour by these acids even when diluted.

According to the *Agricultural News* (Barbados) the banana known as "Pisang maas" proves to be the same as the variety well known as "figue sucrée" or ladies' finger. This is one of the eight varieties received from Queensland for the Colombo Stock Garden. It remains to be seen how many of these are distinct from local varieties. The same contemporary says that special mention deserves to be made of the "Guindy" banana, which produces large bunches of fine flavoured fruit and is well worth growing as a dessert fruit.

The following simple method of making grafting, or budding tape is taken from the *Bulletin of Miscellaneous Information* for October, 1902, issued by the Botanical Department, Trinidad:—

"Materials:—(1) White cotton tape, $\frac{1}{2}$ inch wide;"

(2) Bees-wax	} equal parts.
(3) Ship's pitch	

Directions:—Put equal parts ($\frac{1}{2}$ lb. of each is sufficient for about 15 yards of tape) of bees-wax and ship's pitch in a small metal or earthenware vessel with a wide mouth, and heat over a fire, stirring as the two constituents melt together. Then plunge a piece of tape of convenient length into the liquid, keeping hold of one end with the finger and thumb. With the other hand hold two small pieces of wood on each side of the outer end of the tape, just in front where it is held by finger and thumb. Then pull the tape through between the two pieces of wood so as to remove extra wax and distribute it evenly over the tape. As each piece is dipped, it should be hung on a wire to dry. It will be cool and ready for use in a few minutes."

COLOMBO, MAY 1ST, 1903.

No. 11.

PRUNING OF FRUIT TREES.

By T. R. SM, Conservator of Forests.

CORRESPONDENT in this issue of the *Agricultural Journal* takes exception to Mr. Fred. Symons' statement that pruning is a debateable subject, and quotes American opinion as being entirely in favour of pruning. That, however, only

shows one side of the subject, while the fact that a very large proportion of the English orchards are still unpruned shows that there are believers in the opposite view, whether they have reasonable grounds or not for such a belief.

The position may be put thus;—A fruit tree, like any other animate object, naturally aims at reproducing itself, or rather its kind, and, in furtherance of that object, the production of seed is its chief end in life. To produce seeds the production of fruit is necessary, and with reasonable feeding and cultivation that fruit can be of very high quality, irrespective of pruning. A fruit tree in its natural condition does not, however, begin to fruit at an early age, it rather devotes its early vigour to growing into what is its natural size, and then, on reaching maturity, the fruiting commences in earnest. Fruits may be produced earlier, but these indicate precocity in the kind; the natural sequence in most fruit trees enjoying vigorous health being growth first and fruit afterwards. That being so, the production of a full crop from an unpruned tree usually occurs high up among the top branches, the fruiting buds in almost all fruit trees being produced on the branches most exposed to open air, which naturally are the highest and most spreading ones. These exposed branches often produce fruit-buds along their whole lengths, but if there is sap enough, those near the points flower first and secure fertilisation, and the rest then become abortive. The

result is that on unpruned trees of vigorous habit the fruits are produced at the points of rather long and fully exposed branches, barely fit to support them; they dangle about in the wind, and when mature are in inaccessible positions, and have to fall or be knocked to the ground, or be gathered from the trees by the use of long ladders. In suitable surrounding, however, they often get beyond the reach of ladders, and I have in mind many fine fruit trees, especially pears, in Cradock and other Karroo towns, which carry grand crops of good fruit 50 to 70 feet above the ground. The soil there is rich, deep alluvial, and is irrigated when necessary.

A pruned tree, on the other hand, is an artificial production, in which Nature is subdued, kept in check, and regulated only in accordance with the skill and persistence of the operator. The extent and object of the pruning may vary considerably, but usually the object is two-fold:—

1. To produce, in the first case, and afterwards keep in the same condition, a tree from which the fruit can be gathered direct into the basket and sent to market or table without a bruise.

2. To change the whole nature of the tree from one of wood production to one of fruit production; that is, to take the vegetative vigor out of it and to produce an unnatural and precocious tendency to fruit.

Now, abundant fruiting in a tree, whether pruned or not, usually has the effect of further checking the vegetative vigor and increasing the tendency to become reproductive. Any other circumstance which in a similar manner checks the wood growth usually hastens maturity and increases the fruit crop, such as, for instance, the root-pruning of an over-luxuriant tree, chopping incisions in the bark, or allowing rats or sheep to gnaw part of the bark away, and it is a common practice to use stocks of the less vigorous kinds on which to graft the stronger growers, and thereby produce a similar check.

Mr. Symons mentions that Nature supplies the necessary check in the case, when he says "The

climate here is dry, and the trees do not make anything like the wood which those nearer the coast do." The same thing occurs in many places, especially in the drier parts of Cape Colony, where, if irrigation is irregular, or not practised at all, the crops of good fruits are enormous from trees which in spring are too dried out to send sap to the points of the branches, and consequently fruit on spurs lower down. In such case, too, fewer twigs are produced, and consequently abundant air is admitted to all parts of the tree. It will be seen then that Nature in some cases prunes or checks to a considerable degree, and each orchardist has to study his own conditions and his own kinds in deciding whether or not he will prune. (All this, of course, refers to deciduous fruit trees only, and does not apply to citrus or other evergreen kinds, in which the treatment is different). But "pruning" is a wide term and is understood differently by different growers.

(1) The most advanced orchardists believe in a totally artificial tree, which is made, and continues to be such, simply through the unremitting attention paid to it in the matter of pruning, though much of that pruning is done with the thumb nail rather than with the knife, *i.e.*, summer regulation of the young green shoots, to such an extent as to fully mature, by free contact with fresh air every shoot that is left.

(2) Others, again, believe in pruning scientifically only for the first three or four years, that is, until the tree has assumed the desired shape, and there, after doing only a limited amount of pruning, especially if, as often happens, Nature assists by means of drought, hail, or other causes.

(3) Others again do not prune at all when the trees are young, but in after years saw out heavy branches and thereby admit air.

Of these various methods the first is distinctly the most profitable where climatic and soil conditions are altogether favourable, and where skilled labour is always obtainable at reasonable cost. The six Europeans of Mr. Symons could not do everything in 30 acres of orchard on these lines, and it then comes to be a debatable subject whether additional skilled labour will pay better than by adopting the second method, in which dwarfing stocks and natural checks do a good deal of the work after the first few years. In commercial orchard work skilled pruning usually pays, but it is no uncommon case also to find, taking all the surrounding conditions and circumstances into consideration, that skilled abstention from pruning pays better than unskilled pruning.

The third method suits the man who grows his firewood in his apple trees, at the expense of his crop, and who does not have sufficient skill or sufficient energy to do anything better. He is satisfied with second-rate fruit, in small quantity, and uses six acres to produce what one acre should do, and then gets lowest prices. Still it is the method used almost exclusively in all the cider and jam producing orchards in England and New England; it is a low-grade method, producing inferior fruit suitable only for low-grade industries and often unsuitable for market, but it pays the man whose low-grade ability would oust him altogether from the production of first-class market fruit.

For the production of first-rate market fruit one or other of the first two methods must be used, surrounding circumstances deciding in each case which it has to be, but in a general way it may be said that scientific pruning is the more successful costward, or on low alluvial valleys, while on high and fairly dry ridges and where labour is unobtainable the second method makes a fairly good substitute.

I trust no one will construe this into an excuse for slovenly negligence of necessary pruning; I also trust that your correspondent will see that there is room for debate as to how much pruning should be done, and in some places whether any at all should be done beyond producing the form of the tree at the start.

It is evident that market fruit cannot be successfully gathered from trees 70 feet high, but it is also as evident that where Nature and kind of stock keep the trees reasonably dwarf and productive of full crops of good fruit upon stem-spurs, very little, if any, pruning is wanted.—*Natal Agricultural Journal.*

PREPARING "PARA RUBBER" IN CEYLON.

"To the Editor of the India Rubber World."

I have much pleasure in complying with your request for full particulars as to the method of collecting and coagulating rubber up to the time of despatch for market, employed on the Kepitigalia estate [at Mutale, Ceylon]. After considerable experience, with several methods employed in other parts of the globe, I think there is none other equal to the one adopted in Ceylon, and if this were used in other countries it certainly would mean a rise in price of at least 6 pence a pound for rubber.

The tool employed for tapping rubber trees on this estate is not equalled by any other in use, for its clean cut and absolutely safe incision, the tree not being damaged in the least. The shape is indicated by an accompanying cut.

Tool for incising Rubber Tree.

In practice both hands are used to hold the wooden handle. Placing the corner of the angle *B* at the start of the cut, the tool is pulled downward two or three times in the same incision, care being taken not to cut into the wood. Though this may seem difficult at the beginning, a little practice will soon make the work easy. After two cuts have been made, converging in the shape of the letter *V*, another labourer places a small tin cup at the lower point of the *V*. Care should be taken that at this point the two cuts do not run together, but that a small space be left between them. The incisions should be about 4 inches long, with a space of at least 3 inches between them at the top. The same space (3 inches) should be left before beginning the next pair of incisions in going around the tree. This is absolutely necessary, for if the cuts join, the flow of sap to the tree will cease, and the tree will die. The first series of incisions should be made as far up the tree as a person standing on the ground can reach. Every second day a new band of incisions may be made lower down, as indicated in the drawing. About twenty rings or bands of incisions can be made around a tree within a distance of six feet from the ground. About five *V* shaped incisions may be made around a tree 40 inches in circumference.

Incision with tin attached.

The tin cup used are about two inches in diameter and two in depth. As the latex flows immediately after the cuts are made, the tapper's assistant at once presses the edge of a tin cup into the bark, no nails or putty or wax being required to hold it in place. A third labourer follows with a pail of water, putting a small quantity into each tin to prevent the latex from coagulating—a very necessary precaution, especially on a hot day. The tapping as above described is done early in the morning, and in this

way three men can place 400 cups in a half day, and attend to the rubber obtained.

The contents of all the tins are stirred once or oftener, besides which the laborers must see to it that none of them overflow. Work is started about 6 A.M. and by 11 A.M. all the tins have been taken off and emptied into a pail. While one cooly carries the pail of latex to the factory, the others wash out the tins and at once replace them under the same cuts. The tins are again emptied, in the same manner, at 3 P.M., which completes the yield of latex from a given set of incision. In the meantime, after the tins are washed, the coolies pick off any rubber that may have dried in the wounds made on the last round, which is called scrap. So much for the collection of the latex; we come now to the curing of the rubber, which is simpler still.

As the latex is brought to the factory in a liquid state (mixed with water, which is necessary to enable the latex to go through the process by which the rubber is preserved), it is strained through a very fine wire mesh—a milk strainer, for example—into shallow tin pans, 7 inches square by two inches in depth, in which it is left to stand overnight. By morning the rubber will have coagulated naturally, without the use of any chemicals, and most of the water will have become separated from the pure rubber. The lump of rubber is then taken out and placed on a table and gently pressed with the hand to exclude the water, after which a wooden roller worked by hand is passed over it, back and forth, until more of the water has been expressed, leaving a flat sheet of rubber about 8 inches square and $\frac{3}{8}$ inch thick. The lumps of rubber thus made are placed on caned trays or frames about 6 x 3 feet, caned like the bottom of a chair, though not so closely woven. After the rubber sheets have remained on the trays for four or five days, they are hung to dry on wires stretched across the room, after which they will require frequent attention to prevent mildew, a man being detailed to rub off all mildew spots with a rag. About two months are required for the rubber to become thoroughly dry and free from white patches. So long as these patches appear, it is an indication of dampness and further drying will be required.

When thoroughly dry the sheets of rubber are ready for shipment, and are packed in boxes about 18 by 18 inches square and 8 inches deep—usually about 50 pounds to a box. The secret of the high prices obtained for rubber from Ceylon lies (1) in the strain-

ing of the latex, by which every particle of dirt is kept out, and (2) in the thinness of the sheets of rubber, which permit any one to see that they are free from dirt, sand, etc. No chemicals are used, and no heating is required. On the whole this is the simplest method, when one knows how that could pos-

sibly be adopted. The rubber from most countries now comes to market in large pieces, and can conceal any amount of impurity, while in other cases the latex is allowed to dry on the stem of the tree and when pulled off contains a large percentage of bark and dirt, which mean loss to the buyer and extra work in the factory.

The last sales of rubber from this estate have brought probably the highest average price of any rubber sold in the world during the same period, and this is saying a good deal, namely: an average of 3s. 11d. per pound. The total output for Ceylon for 1903 will be about ten tons, of which this estate will send two tons.

FRANCIS J. HOLLOWAY.

Keptigalla Estate, Matale, Ceylon,

January 8, 1903.

KEPTIGALLA ESTATES AND ITS PRODUCT.

The Keptigalla Estate, situated in the Central province of Ceylon, in the valley of the Matale river, 8 miles from Matale town. THE INDIA RUBBER WORLD of December 1, 1902 (page 80) contained some details regarding the extent of the rubber tapping on this estate, to August 1902 by the manager Mr. Holloway. It was stated at the time that the trees were planted at the rate of 150 per acre, at a distance which fitted them for shading cacao. His experience to that date pointed to one hundredweight (112 pounds) as the average yield per acre, based upon a result of tapping about 4,000 trees. He gave then also an estimate of the cost of preparing rubber and forwarding it to the seacoast, which equalled \$17 per acre. At 3s. 11d. per pound, the product of an acre would realize \$106.73 which, after deducting freight to London and brokers' commissions, should allow a very good profit.

Mr. H. G. Tippett managing Director of the Liverpool Rubber Co., Limited, who has used some of the Ceylon rubber, says in regard to it, in a letter to THE INDIA RUBBER WORLD:

"The weight of the cases at present is irregular, roughly about 100 to 130 pounds, but they will probably settle down as the supply becomes regular to 1 cwt. 112 (pounds) cases. The rubber is excellent—made up in round pancakes (just like hick-wheat cakes), about $\frac{3}{8}$ inch thick, and 6 inches diameter; semi-transparent—absolutely clean and dry—loss about 1 per cent. Quality equal to finest (Bolivian Para)."—*India Rubber World*.

QAT OR ARAB TEA.

[Special for Indian Planting and Gardening.]

A specimen of *Qat*, usually referred to in botanical works as *Catha edulis*, is now in flower in the Royal Botanic Garden, Calcutta, to which it was introduced somewhat accidentally in 1892.

The genus *Catha* belongs to the family of *Celastrineae* or "Spindle-trees," and is at present limited so as to include only this one species, *Qat*; a shrub found in a wild state in Abyssinia, where it is said to be also cultivated. It is likewise found in Arabia, and according to Forskael, who first described the plant, the Arabs cultivate it along with *Coffee*. They eat the green leaves, he tells us, because they attribute to them the property of enabling a man to do 'sentry go' all night without wishing to sleep. He says, too, that they look on it as an antidote to plague, declaring that anyone wearing a sprig of this plant may go without risk among the infected, and believing that, wherever this shrub is planted, the plague cannot come. But Forskael adds that the taste of the leaves does not appear to indicate such virtues. Botta found that in Yemen just as much importance is attached to the cultivation of *Qat* as to that of *Coffee* itself. He speaks of wild as well as cultivated plants, but it is not at all clear from his account whether these wild plants are indigenous or only escaped and naturalised ones. It is true, as De Candolle says, that the interior of Arabia is nearly unknown to botanists; this makes it somewhat uncertain what plants are, and what are not indigenous to the Arab Peninsula. But as regards *Coffee*, it is almost certain, in spite of its popular

Relative Position of series of Incisions.

association with Mocha, and in spite of its being named *Coffea arabica*, that the plant is a native of the African side of the Red Sea, and is only an introduced plant in Arabia. De Canolle is therefore (*Origin of Cultivated Plants*) inclined to think that probably the two plants, *Qat* and *Coffee*, were introduced together from Abyssinia; and Boissier, who made a study of the plants of this region to a great extent the work of his life, clearly did not accept *Qat* as a native of Arabia, because he does not include the species in his celebrated *Flora Orientalis*.

Hochstetter in *Flora*, for 1841, says that in Abyssinia an infusion just like *Tea* is made from the leaves; but a correspondent of the *Gardeners' Chronicle*, for 1843, writing from Yaush in Shoa, November 1842, says very definitely that the Abyssinians only use it in building their houses mostly structures of wattle and daub, for which the thin stems and branches of this shrub must be very well adapted. No other use, this writer says, is made of the plant except by the Musalm merchants, who chew the leaves in order to prevent sleep. These merchants, he adds, have transported the plant into the country of the Yeajon Gallas, where it is largely grown, but is nevertheless not used as an article of trade. In Arabia on the contrary (*Treasury of Botany*) *Qat* forms a considerable article of commerce, large quantities, of twigs being annually brought to Aden from the interior of the Peninsula; some of these, according to Watt, even reach Bombay. For export the twigs are made up into compact bundles, varying in size according to quality; the best kind comes in bundles, 12-15 inches long by 3 inches wide, consisting of about 40 twigs neatly bound together by strips of fibrous bark or tightly packed in palm-leaves. A thousand camel-loads of these bundles, according to the *Gardeners' Chronicle* for 1890, reach Aden every year.

The plant seems, as a matter of fact, to be used chiefly as a stimulant and a food-accessory, just as *Coffee*, *Tea*, *Mate*, and *Coca* are. Of the four, *Qat* appears most to resemble *Coca* in its effects. It enables the user, so it is said, to undergo prolonged muscular exertion without fatigue or to sustain hunger without inconvenience. The use of the leaves which besides being chewed like those of *Coca*, fresh or dried, are also infused like *Tea*, induces a feeling of exhilaration and excites cheerfulness of spirits; for this reason, according to Botta, and to Deflers, the leaves are liberally distributed at religious rites, domestic festivities, and visits of ceremony; Botta speaks of one sheik, obliged to receive many callers who had to spend, on *Qat* alone, as much as 100 francs a day! The fresh leaves, which taste to the writer's mind, very like the leaves of *Coca* are said by Botta to be sometimes very intoxicating; the writer cannot corroborate this from his own experience. It is true that Botta credits this quality to the leaves of wild plants. In the *Gardeners' Chronicle* for 1843, a woodcut is given of a twig, said to be from a specimen gathered by Bové. This woodcut is used again by Lindley in his *Vegetable Kingdom*; it will be referred to critically below. In connection with this drawing it is remarked that leaves gathered when the plant is three years old are sold as *Qat mubarrreh* or "inferior"; a year later young shoots are gathered and fetch a higher price. The Abyssinian correspondent also refers to two varieties, but in a somewhat different way; he calls them the "red" and the "white," distinguished by the colour of the wood and young leaves, and (though of this he is not quite certain) the flowers also. To this question of different kinds, too, further reference will be made.

When it is a plant of economic importance that is under discussion, the writer's experience commonly is that there is some confusion as regards its name; *Qat* is no exception to this rule. The name usually given to the plant is *Catha edulis*; the authority quoted is Forskael, *Flor. Aegypt. Arab.* p. 63 (1775). The first writer to make this citation is Vahl, *Symbol.* i. p. 21 (1790), who himself named the plant *Celastrus*

edulis. The citation can only be explained as a *lapsus calami*, because in the place quoted Forskael does not use the name *Catha edulis*. He described the plant rather more carefully than most subsequent writers have done, but omitted to name it; so far as the writer can ascertain, Forskael never did publish a name for the species. Vahl's inexact citation has, however, been usually accepted as accurate, but it is not clear if *Catha edulis* be the true name of the plant. It certainly is not on Forskael's authority that it can be taken up if it be the true name. This is, however, a trifling matter. More important is the question as to the arrangement of its leaves and branches.

Forskael's account, which is rather more careful than some subsequent ones, states.—"Branches alternate, axillary; branchlets green, annual articulate; leaves opposite, on the large branches alternate." Vahl, copying from Forskael, but varying the expressions, says:—"Branches alternate; branchlets articulate, alternate; leaves alternate, on the branchlets opposite." Don (*Gen. Syst. Gard.* 1832) says briefly:—"Leaves opposite and alternate." Hochstetter *Flora*, 1841) says:—"Leaves opposite." Lindley's figure in the *Gardeners' Chronicle* for 1843 and in his *Veges table Kingdom* (1853) shows a pair of opposite leaves with flowers in their axils, at the base of the twig and two alternate leaves without flowers above. The *Genera Plantarum* (1862), apparently following Hochstetter says:—"Leaves opposite." The *Treasury of Botany* (1866) says:—"Leaves opposite on some branches and alternate on others;" Oliver (*Flor. Trop. Afr.*, 1868) says:—"Leaves opposite; or alternate on the leafy shoots." In the *Histoire des plantes* (1875) Baillon says:—"Leaves usually opposite." Finally Loesener, the last important author who has dealt with *Qat*, says (*Engler's Natürliche Pflanzenfam.* 1896):—"Leaves opposite on fertile twigs, often alternate on the sterile." Forskael's account is thus the fullest, and it may be added is also the most accurate on the point; that even it is not clear we can see from the indecision and the discrepancies of subsequent writers. It may therefore not be superfluous to explain exactly what does happen and what the conditions, as exhibited by plants that the writer has watched for eleven years, really are.

In 1892 some twigs were sent from Hodeida for identification; they were specimens of a kind very familiar to the Editor of *Indian Planting and Gardening* and to the writer, for they had neither flowers nor fruits, and had been placed in a letter without having been previously dried. They reached their destination a mass of pulp so far as the leaves were concerned, but as there seemed to be some vitality in the twigs, an attempt was made to strike them as cuttings. Of the twigs that had, as their leaf-scars showed, borne opposite leaves none survived; of those that had borne alternate leaves a fair proportion held. In, as was then supposed, (though now it is clear this was not exactly what happened, the axils of these leaves small buds broke and gave rise to nearly vertical shoots with red bark and alternate leaves. These shoots gave the plant a fastigate character; they increased in length for two seasons, retaining nearly all their leaves but not branching. In their third season the axils of the lowest leaves, corresponding to the first season's growth, gave origin to branchlets quite different in appearance from the branches produced by the original cutting. Instead of growing fastigiate these branchlets spread horizontally; instead of having alternate they had opposite leaves, slightly smaller and distinctly more cuneate at the base than the others, with moreover only a faintly red petiole and base of mid-rib, whereas the alternate leaves had red petioles, mid ribs red throughout, and reddish secondary nerves beneath. The following season the set of leaves corresponding to the next succeeding season of growth in turn gave out more horizontal opposite-leaved branchlets, while the horizontal branchlets of the preceding season increased

in length. It was observed, however, that these branchlets were now unlike the fastigiate and alternate^o leaved branches in other respects. Instead of being decidedly thicker at their bases and tapering upwards like the latter, the opposite-leaved horizontal branchlets remained of uniform thickness throughout; they were moreover rather markedly swollen at the nodes, which is not the case with the alternate-leaved branches; most marked difference, perhaps, of all, the redness of the youngest part of the shoot, instead of deepening with age into a rusty brown, as happens with the alternate-leaved branches, passed in these opposite-leaved branchlets first into green and ultimately into greyish white. After an interval of two more seasons a striking occurrence took place. Just above the oldest set of horizontal branchlets, now in their fourth season of growth, a new series of buds appeared which developed into a new set of branches, so that now in each axil were to be found two superposed axillary twigs. But every one of these new and accessory branches differed from the first from its subjacent opposite-leaved companion branchlet in having dark-red bark, with alternate and red-veined leaves, in being thicker at the base than it is above, and in growing fastigiate instead of spreading horizontally. This second set of branches was in fact a repetition of the system of branches that appeared originally in the cuttings.

Since then the same phenomena have repeated themselves, the branches last described have developed their own primary series of horizontal branchlets and are now beginning to emit their accessory series of fastigiate branches. Moreover, the primary horizontal branchlets of the second series are now in full flower and are setting fruits.

While the cycle described is the normal sequence of events it must not be supposed that it exhibits absolute regularity. To begin with, every leaf on a vertical alternate-leaved branch does not have a horizontal, opposite-leaved branchlet in its axil; most of them have, but not all. Again, by no means does every branchlet with opposite leaves become accompanied by a superposed vertical alternate-leaved branch. Not infrequently these opposite-leaved branchlets die and are shed before the corresponding vertical alternate-leaved branch has appeared. The buds of these alternate-leaved vertical branches, in spite of their greater vigour of growth when they do ultimately burst, often never show at all or lie long latent, and appear low down on the stem, long after the leaves and the horizontal branchlets that correspond have disappeared. But where a vertical alternate-leaved branch does this break, it is at once evident that just below its position there have formerly been a horizontal branchlet and a leaf. Again, though it is usual for only one vertical branch to accompany a horizontal branchlet, now and then two or even more than two branches arise at the same point. What, however, is certain in the case of *Qat* is that there are two branching moods, and that these moods alternate. Leafy branches of deliquescent type with alternate-leaves bear first a set of axillary branchlets of excurrent type with opposite-leaves. The latter are comparatively short-lived and do not again branch vegetatively but ultimately bear in their axils cymes of flowers. Later the leafy alternate-leaved erect branches produce, just above the branchlets a new series of branches which repeat the erect habit and the alternate leaves of the branches that bear them and in turn go through the same cycle.

The facts of the case explain all the divergent accounts of the authors who have been cited. In Herbaria only flowering or fruiting specimens as a rule find a place, hence as a rule only opposite-leaved twigs occur in collections. This explains the statements of Hochstetter and of the *Genera Plantarum*. The writers who say "leaves opposite or alternate" are more accurate no doubt, but they leave the true condition entirely unexplained. In the case

of Lindley's figure it can only be supposed that his artist had twigs of both kinds before him, and not grasping the significance of their differences had, to save space, combined their attributes. Loesener is much more nearly exact, and when he says "leaves on sterile branches often alternate," he is no doubt accurate, since all the opposite-leaved branchlets do not have flowers. He does not, however, bring out the fact that the branchlets with opposite leaves so far as we know, are the only ones that ever do bear flowers and fruits. Forskael's account, in the light of actual facts, now becomes clear. His large branches are the branches of the alternate leaved deliquescent type; his green branchlets are those of the opposite-leaved excurrent type. The expression 'articulate' is not strictly accurate; these branchlets are swollen at the nodes it is true, but they are not jointed; nor is he accurate when he speaks of them as annual, for though they do appear as a new crop each year, and though they are snott-lived as compared with the erect branches, they persist as a rule, for more than one season. Some of them in the case of a plant under observation at the Royal Botanic Garden, have persisted for 5 or 6 years. But when a branch of the erect alternate-leaved type appears just above a branchlet of the opposite-leaved type it grows so much more vigorously and rapidly than its companion that it seems to rob the latter of its nourishment, with the result that all save the leaves of its newest growth drop off and in a year or two it makes no more growth, loses the remaining leaves, dies and sooner or later snaps off close to this branch from which it originated.

In what has gone before, the writer has endeavoured to bring together all that has been recorded, and to state what he has been able to observe with regard to *Qat*. There are, however, not a few points that are still obscure; these it may be well to briefly review.

It has been explained that the writer has failed to get cuttings from the opposite-leaved branchlets to hold. It would be interesting to try in some locality more suitable to the plant than the Gangetic delta, whether this experience holds good elsewhere, and whether it is only from branches of the alternate-leaved type that cuttings can be struck. Again, in cuttings from branches with alternate leaves it was found that the buds which broke were all buds that gave rise to branches with erect habit and alternate leaves. They were supposed by the writer to be axillary; he now knows that they were really supra-axillary and that in theory a bud of the excurrent opposite-leaved type must have existed below each, but never became developed. No seeds have yet been obtained at Calcutta; those who have seeds at their command might observe what happens with seedlings, and record whether the first series of branches that appear on these are of the normal primary excurrent type, or whether with seedlings, as with cuttings, the first series of primary excurrent opposite-leaved branchlets is suppressed.

Then as to the name. Some writers give *Qât* or *Kâf* (*Bove*), *Kafta* (*Treasury of Botany*), or *Qafter* (*Watt*). In the *Gardeners' Chronicle* for 1813 Lindley publishes the explanation suggested by a scholarly friend that the variant *Kaf* for *Kat* is merely a mistransliteration. It very probably is, but the point has not yet been authoritatively settled. Nor, to come to the scientific nomenclature, is it certain that *Catha edulis* is the correct appellation; whatever the name may be authority universally cited for it is erroneous.

Then, is the plant wild in Arabia? Botta, we have seen, speaks of the plant as wild in Yemen. The matter is doubtful. The question whether *Coffea* is or is not wild in Arabia is one that every traveller in the Peninsula hopes to settle. The two matters hang together, and as the two plants are cultivated side by side both problems will doubtless receive the same attention.

That the reputation the plant enjoys as a plague-preventive is an item of folk-lore, and no more is sufficiently clear from what Forskæel says, but do the fresh leaves, as BOUTY states, ever have intoxicant qualities? As the property is associated especially with the leaves of wild plants, the absence of the property from the leaves of plants grown at Calcutta proves nothing. But the statement gives an added interest to the question whether the *Qat* is truly wild in Arabia, whence the property is reported; its accuracy should admit of being readily tested in Abyssinia, where the species is unquestionably wild. That the ordinary commercial *Qat* is not deemed intoxicant, seems fairly clear from the statement made in the *Treasury of Botany* that certain Arabs were induced to assume towards the species the attitude that the Wahabi sect assume towards *Tobacco* and, on account of its stimulant property, to class *Qat* among those intoxicants whose use is forbidden by the Koran. A synod consequently was convened to consider the point, and after due deliberation, having regard to the fact that it only caused hilarity and conduced to good humour, but neither impaired health nor interfered with attention to the duties of religion, this synod decreed that the use of *Qat* is lawful.

Forskæel, as we have seen, gently throws a doubt on the potency claimed for *Qat* by the Arabs; Lindley (*Gardeners' Chronicle* 1843), says:—"We have tried the quality of the infusion in hot water, but are unable to say anything in its favour." Were the writer to judge from the results of his own trials, he must consider the stimulant properties even of fresh leaves just as doubtful as their narcotic ones. Possibly, however, Forskæel, Lindley, and the writer have not gone on long enough!

The *Qat mubarrak* or "inferior" *Qat* of the *Gardeners' Chronicle* is clearly the leaves of alternate-leaved three-year-old young stems, but whether the young shoots gathered in the fourth year are alternate-leaved branches or opposite-leaved branchlets we do not know. Theoretically we should expect them to be the latter; we know, however, that with cuttings the opposite-leaved branchlets remain suppressed and alternate-leaved branches at once arise, and it may be that with seedlings this is also the case. Anyhow the matter, which might be settled by a simple observation in Abyssinia or Arabia, has never received the attention it demands. That the two kinds of *Qat*, the "red" and the "white," referred to by Lindley's Abyssinian correspondent, are simply twigs from young alternate-leaved and from opposite-leaved shoots respectively, will be obvious to those who have studied the branch-system of the plant. Unfortunately our certainty as to this throws no light on the problem as to whether good *Qat* has leaves opposite or alternate, because no reference has been made to the relative quality the "red" and the "white" kinds.

De Oandolle remarks on the fact that the use of *Qat* has not spread eastward to Beluchistan and India, where intoxicants are so much in request, in spite of the fact that the plant is likely to thrive well enough in both countries. The first question of course is as to whether *Qat* be really an intoxicant at all. Apart from this, however, a sufficient reason possibly is that the people of those parts of Beluchistan, Persia or India, where *Qat* will freely grow, did not require to trouble about so relatively innocent an article when they had at hand such potent intoxicants in *Hyoscyamus*, *Cannabis* and the like.

The *Gardeners' Chronicle* for 1890 speaks of *Qat* as a plant that it might be advisable to introduce into various British Colonies and Dependencies. In the writer's opinion *Qat* is a plant that deserves further investigation, but something more definite than we have yet been told must be known before its introduction as other than a curiosity need be advocated.

D. PRAIN.

As a supplement to the interesting article on Arab Tea, written by Major D. Prain, in last week's *Indian Planting and Gardening*, it would be well to give the results of the chemical investigations of this plant.

As the leaves are employed as a stimulant, it was naturally supposed that, like coffee, tea, and kola, the plant contained caffeine, but three independent observers searched for this alkaloid with negative results. Dr. Atfield in 1863, Professor C. Schloermer in 1884, and Dr. Paul in 1887 were unable to find indications of caffeine. Dr. Paul attributed the action of the drug to an ethereal oil or some other aromatic or volatile constituents. Professor Schloermer isolated from the leaves a small quantity of a kind of sugar which was apparently mannite.

A long paper was written in 1837 on the history and composition of *Catha edulis* by Professor Flückiger and Gerock, and the authors, as the result of a chemical investigation, detected the presence of an alkaloid existing in small quantity which they named "katine."

In 1894 the physiological and therapeutic properties of *Catha* were studied by M. E. Collin of Paris. He found that the drug has a powerful stimulating action on the nervous system, banishing sleep, restoring the physical forces and sustaining muscular activity.

In 1899 the leaves were again submitted to analysis to ascertain their proximate constituents, and Professor Schaer of Strasburg communicated the results to the Convention of German Naturalists and Physicians. The principal constituents were found to be—1. Physiologically active alkaloid, cathine, which forms rhombic crystals. 2. Large quantities caoutchouc. 3. A tannin, closely related to that of tea leaves. 4. Mannite. 5. Small quantities of an oxygenated volatile oil. From the seeds about 50 per cent of fixed oil, composed of glycerin-esters was obtained.

Dr. Albert Beitter, in 1901, found the alkaloid to exist in very small amount; the leaves from Aden yielding only 0.076 per cent., while those from Harrar yielded only one half as much. The alkaloid is associated with a new caoutchouc substance, which softens at 50 deg. C. and melts at 120 deg. C.; and the composition is represented by the formula $C_{10}H_{17}O$.

These particulars may be of interest to those who wish to know what are the constituents of Arab Tea. The plants grows well at Poona, and could no doubt be easily cultivated elsewhere in India. Dr. Zwemir, of Arabia, who visited Calcutta last December informed me that *Catha edulis* was one of the most useful drugs of the country and formed an important article of trade.

D. HOOPER.

MEXICO'S VEGETABLE PRODUCTS.

MOST OF THE KNOWN PLANTS AND TREES OF THE WORLD FOUND IN THE REPUBLIC.

(Concluded from page 666.)

Flor de Noche Buena, *Euphorbia pulcherrima*, Euphorbiaceae: A peculiar red Mexican flower, medicinal.

Flor de San Juan, *Bouvardia longiflora*, Rubiaceae: Beautiful native flower of the valley of Mexico, used for perfume.

Floripondio, *Brownsia suaveolens* and bicolor, Solanaceae: Large white or colored flower.

Fresno, ash, *Fraxinus juglandifolia*, Oleaceae: Especially on Central Plateau.

Frijol, Mexican bean, *Phaseolus vulgaris*, Leguminosae: Many varieties, best is called bayo gordo, sowed between the Indian corn, furnishes the principal food of the people.

Garambullo, *Cereus Garambullos*, Cactus with eatable reddish purgative berries.

Garbanzo, chick pea, *Cicer arietinum*, Leguminosae: Native plant.

Girasol or Chimalatl, *Helianthus annuus*: Introduced from Peru for the extraction of oil.

Gram or zacate, couch grass, *Triticum repens*, Gramineae: In many varieties, medicinal; furnishes straw and roots (zacaton), the latter used for brushes, etc.

Granada, pomegranate, *Punica granatum*, Granateae: Introduced from Spain.

Granadita, Chinese pomegranate, *Passiflora corulea*, Passifloras: Kind of passion flower, with eatable gourd, Guaco or Tecomate, *Aristolochia grandiflora*, Aristolochiaceae: Medicinal.

Guaje, *Crescentia caje*, Bignonaceae: Native fruit tree of hot zone; guaje is also a kind of gourd, *Lagenaria vulgaris*, see calabazas.

Guayabo, guava, *Psidium pyrifera*, Mirtaceae: Fruit tree of hot and temperate zones, cultivated and wild.

Haba, garden bean, *Vicia faba*, Leguminosae.

Heno, Spanish moss, *Tillandsia asneoides*, Bromeliaceae: Hanging from the cypresses, etc., in pendants and garlands as natural decoration.

Higo, fig-tree, *Ficus carica*, Urtiaceae.

Higuerilla, castor oil plant, *Ricinus communis*, Euphorbiaceae.

Huacamote, sweet cassava or yucca, *Jatropha manihot alpi*, Euphorbiaceae: Mexican farinaceous plant of three varieties (see *Yucca amarga*) grows in the hot zone, Vera Cruz, Yucatan, etc., furnished a kind of bread and tapioca.

Huamchil, *Mimosa unguisati*, Leguminosae: Mexican fruit tree of hot and temperate zones.

Huazontle, Mexican asparagus, *Blitum bonus Henricus*, Chenopodiaceae.

Huitlacoche, eatable corn mushroom, *Uredo maydis*, Fungus: Grows on the ears of Indian corn.

Huizache, *Acacia albicans*, etc., Leguminosae: Timber and fruit (beans).

Iflame, yam, *Dioscorea alata*, Dioscoreae: Nutritious root, kind of asparagus; introduced from Africa as food for negro slaves.

Ipecacuana blanca, white Ipecac, *Richardsonia scabra*, Rubiaceae: Native plant, grows in hot zone root medicinal, exported.

Jalapa or Purga, jalap, *Ipomoea purga*, etc., Convolvulaceae: Native vine of temperate zone, root medicinal; exported in considerable quantity.

Jamaica Hibiscus sabbdariffa, Malvaceae: Hot zone, red flower used for a febrifuge drink.

Jicama, *Dolichos tuberosus*, Leguminosae: Native sweet, farinaceous root; very much cultivated.

Jinicuil, Inga jiuicuil: Fruit tree.

Jitomate, tomato, *Lycopersicon esculentum*, Solanaceae: Native plant, cultivated in all zones.

Lenteja, lentil, *Ervum lens*, Leguminosae.

Lima, sweet lime, *Citrus limmeta*, Aurantiaceae, Limson, lemon tree, *Citrus medica limonum*, Aurantiaceae: Cultivated in many varieties; lemon real, royal lemon, etc.

Linaloe, aloe tree, *Amyris linaloe*, etc., Terebinthaceae: Wood used for perfume, exported.

Liquidambar, *Liquidambar styraciflua*: Native tree of hot zone, furnishes the sweat-gum.

Maguay, century plant, *Agave americana*, etc., Amarilideae: Most useful and peculiar native plant of Mexico, grows in many varieties all over the country, furnishes the intoxicating "pulque," the brandy "mezcal" and a strong fibre, the "ixtle." The finer fibre "henequen" and the finer brandy "tequila" are obtained from two other varieties. Lately a vinegar has been extracted from the "pulque." The Aztecs called the plant "metl" and used it besides for the extraction of "pulque (oculi), for the manufacture of clothing, paper, molasses and sugar; it furnishes further gum, food, fuel, needle and thread, household furniture and other useful utensils.

Maize, Indian corn, Zea mays, Gramineae: Native plant of Mexico, the 'tlaolli' of the Aztecs, principal grain of the country; cultivated in many varieties; yields from 30 to 800 times, at an average from 80 to 150 times. Sown usually from April to June, harvest from September to November. It furnishes the bread (tortillas) of the people, made in round, thin cakes and without yeast.

Mamey, mamee, *Lucuma Bomplandi*, Sapoteae: Temperate and hot zones, furnishes fruit (after eleven years) and cabinet wood, seeds are medicinal.

Mangle, mangrove, *Rhizophora mangle*, Rhizophorae: In forests of the east coast; gum and timber used.

Mango, *Mangifera indica*, Terebinthaceae: In temperate and hot zones in many varieties, fine shade trees, fruit after four years, best "mango de Cordoba" and "mango de Manila," harvest during spring and summer.

Maranta, *Maranta arundinacea*, Marantaceae: Root produces the starch called arrowroot.

Melon, *Cucumis melo*, Cucurbitaceae.

Membrillo, quince, *Pyrus cydonia*, Rosaceae: Cool and temperate zones, furnishes a palatable wine, "vino de membrillo."

Mezquite, *Prosopis dulcis*, Leguminosae: Native tree, sweet beans are used by the Indians as food and for a fermented drink; furnishes timber, gum, medicine.

Naranjo, orange tree, *Citrus aurantium*, etc., Aurantiaceae, cultivated in many varieties; fruit exported.

Nardo, tuberose, *Polyanthus tuberosa*, Liliaceae.

Nopal manso, prickly pear cactus, *Cactus opuntia*: Native cactus of many varieties, grows especially on the Central Plateau and furnishes the very refreshing and popular fruit "tuna." Harvest, from June to October. In San Luis Potosi a red kind is used for the favourite drink, "colonche."

Nopalillo, *Cereus phillanthus*, cactus.

Orchilla, archil, *Lichen rocella*: Red colour of this plant exported.

Organo, giant or candelaber cactus, *Cereus exelsus* Cactus: Used for fences, etc.

Oyamel, *Pinus religiosa*, Coniferae.

Palo de Campeche, logwood, *Haematoxylon campechianum*, Leguminosae: Native tree of hot zone especially in Yucatan, medicinal and dyewood (blue colour); exported.

Palo del Brazil, brazil wood, *Cesalpinia echinata* Leguminosae: Hot zone, used for dyeing and tanning exported.

Palo mulato, tawney wood, *Xantoxylon pentanome*, Rutaceae: Valley of Mexico, used for timber and medicine.

Palma or Izote, yucca, *Yucca gloriosa*, Cicadeae: Temperate and cool zones.

Palma de coco, coco palm, *Cocos nucifera*, Palmeras: Hot zone, furnishes fruit, wine and oil.

Palma de coyol, *Cocos guacuyule*, Palmeras.

Palma real, royal palm, *Oreodoxa sp.?* Palmeras.

Palma de datil, date palm, *Phoenix dactylifera*, Palmeras.

Papa or patata, Irish potato, *Solanum tuberosum*, Solanaceae: Introduced from South America.

Papayo, melon tree, *Carica papaya*, Papayaceae: Native plant of hot zone.

Patol, colorin or zompante, *Erycitra. coraloides*, Leguminosae: Flower eatable, seeds poisonous.

Pimicuto gordo or de Tabasco, *Eugenia pimentata*, Mirtaceae: Hot zone, especially in Tabasco; condiment exported.

Pinguica or gayuba, oil nut, *Arctostaphylos pungens*, etc., Ericaceae.

Pina, pineapple, *Bromelia aouana*, Bromeliaceae: Native plant of hot zone.

Pitahaya, giant cactus, *Cereus pitahaya*, cactus: Eatable fruit, kind of prickly pear.

Platauo, banana, *Musa paradisiaca*, etc., Musaceae: Introduced in many varieties in the sixteenth century, cultivated in the hot and temperate zones. Humboldt calls it the corn of the tropics and believes

it to be native. There is no other plant which produces so much nourishment in so small space. It is planted in sprouts and needs little cultivation; fruit can be gathered after the tenth month. One branch bears often from 160 to 180 bananas, and weighs from 80 to 100 pounds. One acre may contain 600 to 800 banana plants, which will yield annually about 800 cwt. of fruit, nourishment enough for about forty persons. The best varieties are the platano gordo, colorado, costarica and manzana.

Ramie, china grass, *Urtica Boehmeria*, *Urticaceae*: Textile plant, introduced from China.

Sandia, watermelon, *Cucurbita citrullus*, *Cucurbitaceae*.

Sauz and Sauz lloron, willow and weeping willow, *Salix pentrandra* and *babilonica*, *Salicaceae*.

Sempaschil or Zempoalxochitl, *Tagetes erecta*, *Compositae*: Yellow, favorite flower of the Indians.

Siempreviva, house-leek, *Aizoon canariensis*, *Craucaceae*: Many varieties, medicinal.

Tabaco, tobacco, *Nicotiana tabacum*, *Solanaceae*: Native plant of Mexico; the yel of the Aztecs, in many varieties in hot zone; wild in Tabasco, etc., best in Vera Cruz, Oaxaca and Tepic, further in Yucatan, Campeche, Chiapas, etc.; important article of export.

Talaycte, *Gonolobus pedunculatus*, *Asclepiadaceae*: Eatable green fruit; harvest in summer.

Tamarindo, tamarind, *Tamarindus occidentalis*. *Leguminosae*: Hot zone, fruit medicinal, exported.

Tejocote, Mexican thorn-apple or hawthorn, *Craetagus Mexicanus*, *Rosaceae*: Native fruit tree of temperate and cool zones, abundant in fruit; harvest, October to December.

Tepeguaje, *Acacia acapulcensis*. *Leguminosae*: Hot zone, furnishes timber and gum.

Timbiriche, wild pineapple, *Bromelia pinguin*, *Bromeliaceae*: Hot zone.

Tomate, *Phyalis pubescens*, etc., *Solanaceae*: Favorite Mexican condiment of many varieties.

Trigo, wheat, *Triticum sativum*, *Gramineae*: Introduced about 1536; next to corn, most cultivated grain, in Mexico; sown in November to January, harvested in April and May, yields on an average from fifteen to thirty and up to 110 times. Humboldt considers the Mexican wheat among the best of the world.

Trompetilla, *Bouvardia angustifolia*, *Rubiaceae*: Beautiful vine.

Tule, reeds, *Cyperus*, *Cyperaceae*: very prolific on the banks of the lakes; green, used as food for animals; dried to make mats, fire fans, etc., especially in the Valley of Toluca.

Uva, grape vine, *vitis vinifera*, *Vitiferas*: Introduced from Spain, best in Coahuila, Ohihuahna, Puebla, etc. In Parras is manufactured a light, good wine and cognac. Wild grapes grow in various places.

Vainilla, vanilla, *Epidendrum vanilla*, *Orchideae*: Native plant of hot zone, the tlilxochitl of the Aztecs; wild and cultivated; blooms in February and March; harvest, March to June; best fruit in Vera Cruz (Papantla Misantla); production in 1880, \$651,958; formerly exported exclusively from Mexico; still an important article of export.

Yoloxochitl or flor del corazon, *Magnolia mexicana*, *Magnoliaceae*: Very fragrant flower.

Yuca amarga, bitter cassava, *Jatropha janipha*, *Euphorbiaceae*: Native plant of the same kind as the sweet cassava or huacamote and although poisonous furnishes, too, after certain preparations, the same tapioca; the brown juice is used as sauce.

Zapote, sapota, fruit trees of many varieties. Zapote blanco, white sapota, *Casimiroa edulis*, *Rutaceae*; zapote borracho, yellow sapota, *Lucuma salicifolia*, *Sapotaceae*, especially in Morelos—zapote prieto, black sapota, *Diospyros obtusifolia*, *Ebenaceae*. The gum of the sapotas called "Chicle," is an article of export for making chewing gum.

Zarzamora, bramble or blackberry, *Rubus fruticosus*, *Rosaceae*: Wild in the temperate and cool zones, is used in the Valley of Toluca for blackberry wine.

Zarzaparilla, sarasapilla, *Smilax medica*, *Esparagineae*: Medicinal; native plant of hot zone, especially in Vera Cruz; root exported.—*Modern Mexico*.

PLANTING NOTES.

A NEW RUBBER-PRODUCING PLANT.—M. E. de Wildeman describes in the *Comptes Rendus*, 1902, p. 400, a new species of *Clitandra* (*Apocynaceae*), from the Congo. The species is called *C. Arnoldiana*, and the caoutchouc is obtained by boiling the latex or milky juice with water.—*Gardeners' Chronicle*.

THE NATIVE COUNTRY OF THE COMMON LILAC.—M. LOCHOT, in a recent number of the *Revue Horticole*, establishes the fact that the common Lilac is indigenous in the Balkan range from the Black Sea to Hungary, thus confirming the opinion of M. Andre, who found it growing wild in Servia and Bulgaria.—*Ibid.*

WEST INDIAN AGRICULTURE.—Under the energetic direction of the Commissioner, Dr. Morris, the Department of Agriculture is making satisfactory progress. Over 5,000 copies of official bulletins and other publications were distributed among those concerned last year, and although practically nearly everything is distributed gratuitously, yet the sale of publications reached nearly £100. Messrs. Dulau & Co., Soho Square, are the London agents.—*Ibid.*

THE DOUGLAS FIR.—A curious case of a woman being poisoned by handling the branches and leaves of this tree while gardening, and not washing her hands before eating, is recorded by Neudoerfer in the *Centralb. f. Innere Medicin*. The symptoms were spasmodic convulsions, dyspnoea, and coma. Other persons appear to have been more or less affected who were working at the same employment. It appears probable, therefore, that the tree which is cultivated for ornamental purposes, contains some poisonous ingredients to which some persons are more susceptible than others. *Nouv. Rem.*, 1903, 65—*Journal of the Pharmaceutical Society*.

GINSENG (*ARALIA QUINQUEFOLIA*) will not grow in this country. It has been tried again and again at Kew; the last time according to directions given by Mr. Stanton, who grows it successfully near New York; and I know of several other gardens in England where it has been tried. The directions given by Mr. J. J. Willis (p. 171) are, he informs me, taken from *Bulletin* 62 (1903) of the Pennsylvania State College, and are practically those given by Mr. Stanton. Mr. Budde, of Utrecht, in his note (p. 181) stated that Ginseng was easily cultivated in Holland, where it was grown as a market plant; but the plant he means, and of which he kindly sent me a leaf, is *Pseudopanax* (*Aralia*) *crassifolium*, a New Zealand shrub, of which there are large examples in the temperate-house at Kew. I have seen a plant of Ginseng in flower in the rock-garden at Kew, but it was the sole survivor of a large number that were planted a few months before. Evidently there is some condition, as in the case of (*Ipecacuanha*) (*Cephaelis*), *Manilla Hemp* (*Musa textilis*), *Sandalwood* (*Santalum album*), and certain other plants, which is essential, but as yet is unknown. Probably it is in the soil. Is it bacteria? I am told that attempts to extend the cultivation of Ginseng in the United States have proved unsuccessful. Ginseng has a perennial tuberous rootstock, not unlike a small Parsnip, annual stems a foot or so high with long-stalked palmatisect leaves, usually with five leaflets, hence the specific name. The flowers are in umbels, small, yellow, and they are succeeded by small Pea-like, bright red berries. The medicinal properties are in the roots.—W. W., Kew [*Bailey's Cyclopaedia of American Horticulture*, art. "Ginseng," may be consulted with reference to the culture of the plant in the United States.]—*Gardeners' Chronicle*.

Wilson, Smithett & Co.'s Ceylon Tea Memoranda for 1902.

LONDON, MARCH, 1903.

Although the year under review cannot be considered one of actual prosperity for tea planters generally, it may at least be regarded with more satisfaction than its three immediate predecessors, inasmuch as during its progress the industry would appear to have, at length, emerged from the period of storm and stress, resulting from over-production on the one hand, and on the other from the disorganisation caused by the additional fiscal burden imposed upon it in 1900, and the apprehensions on the same score in the two succeeding years, which found expression in the abnormal duty payments of the ante-Budget periods. Since the date of our last "Annual Memoranda," however, the clouds of doubt and depression, which so long obscured the outlook, have been almost dispersed, and we have, we believe, entered on a period which requires only ordinary care and prudence to ensure a return to comparative prosperity. If we cannot, therefore, absolutely congratulate planters upon a profitable season, we think we are entitled to indulge in more hopeful anticipations for the future. It was generally considered that the year 1902 would produce the heaviest yields yet recorded, both in INDIA and CEYLON, owing to the fact that it was the year in which the most recent important extensions would come into full bearing. The caprices of climate, however, had not been taken sufficiently into account, and the estimates made with regard to the crops both in CEYLON and INDIA proved, fortunately, to be excessive, and this factor, in conjunction with a further marked expansion in the demand for British-grown teas from extraneous markets, has resulted in a satisfactory re-adjustment of the balance between supply and demand. The problem for the future, which should now engage the serious attention of producers, seems to us to be that of securing the maintenance of this re-adjustment, and for its solution we look naturally to the steady following up of the successes already gained in the exploitation of new markets. In this connection we would strongly urge the desirability of developing, as far as possible, the characteristics peculiar to each district, so as to satisfy the varying demands, not only of foreign markets, but more especially of the United Kingdom, which, after all, constitutes the principal tea-consuming community of the world. One of the chief reasons, perhaps, of the periodical depressions experienced in recent years in the home-trade, apart from the question of over-production, has been the monotony and lack of character of a

large proportion of the supplies. Too often in the past has a temporary scarcity of common tea resulted in a universal resort to coarse plucking, or a superabundance of common tea has been followed by a general rush to the other extreme; and although in the past year plucking was evidently conducted with considerable care, we regard with some anxiety the exceedingly strong position of common tea at the present time.

The average Price of all Ceylon Tea sold on Garden Account in 1902 was 6 85d. per lb., against 6 80d. in 1901 and 7 25d. in 1900.

HOME CONSUMPTION of CEYLON tea during 1902 is somewhat disappointing, seeing that it only equals the figures of 1897, when the IMPORTS were almost 8,000,000 lbs. less. The true explanation seems to lie in the smaller proportion of common tea received, and the increased demand from Foreign markets, as well as the cheapness and abundance of INDIAN imports of a similar character. In the past year the deliveries amounted to 85,541,000 lbs. for HOME CONSUMPTION and 17,352,000 lbs. for EXPORT, whereas although 85,494,000 lbs. were cleared for HOME CONSUMPTION in 1897 the EXPORTS in that year only reached 10,684,000 lbs.

FOREIGN TRADE.—The development in this respect has again realised the most sanguine expectations, and is most encouraging for the future. The increase in the consumption of BRITISH-GROWN tea in RUSSIA is very remarkable, and now that CEYLON and INDIAN teas have gained such a foothold in that country, we may fairly look forward to an annual expansion in the quantity absorbed, and it is a most favourable feature that the demand is no longer confined to light liquoring delicate sorts and the whole-leaf grades, but that semi-broken Pekoes and ordinary fermented teas are now more freely taken, if not actually preferred. The AUSTRALIAN market has also again bought freely in COLOMBO to the extent of 19,000,000 lbs., and for AMERICA and CANADA the COLOMBO purchases of Black leaf tea shew an increase of 700,000 lbs. in 1902, having amounted to 4,365,000 lbs. against 3,654,000 lbs. in the previous year; in addition to this and to the direct EXPORTS from LONDON, transshipments from LONDON to NEW YORK shew a considerable increase.

GREEN TEA.—The ready sale of some 2,000,000 lbs. of GREEN tea in 1902 to the STATES and CANADA is of happy augury for the attempt to break down the monopoly hitherto enjoyed by JAPAN and CHINA for

this description of tea. The manufacture of this variety has materially increased since the date of our last Annual Circular, and though it must still be considered to a certain extent as experimental, there is every reason to congratulate planters on the success which this latest phase of their enterprise and energy has met with. The true Green teas, manufactured for the first time this year, are especially to be commended, and appear to us to compare most favourably with coloured JAPANS. It is open to question whether the substantial increase in the out-turn of Green tea, estimated variously at from 10 to 15 million lbs., contemplated this season is not too great, but there can be little doubt that the high rates ruling at present for JAPAN and CHINA Greens, which, as far as JAPAN is concerned, are likely to be maintained, owing to the advance in the value of labour following the development of manufacturing industries in that country, afford a most favourable opportunity for a successful assault upon the AMERICAN and CANADIAN markets, by supplying an equally good article at a more reasonable price.

PACKING.—Both wood and lead have occasionally left a good deal to be desired during the past year. The use of chests made of unsuitable or unseasoned wood has been responsible for a good deal of deterior-

ation in values, but to the increased use of thin lead is probably due the "woodiness" which has marred the flavour of many a good tea. The economy practised in the use of "two-ounce" lead is, we think, false, as in the case of good and fine qualities the particular point and flavour is often so neutralised that a loss of 1d. per lb. in value may easily result.

Our list of Estates this year gives the quantity sold in Public Sale and average price realised of 550 marks; a good deal of tea was again disposed of privately but not to the same extent as in 1901, when the agitation in favour of unreported sales was, for a time, in force. The chief feature to note is the rather better value generally realised for low-grown tea, despite the low rates ruling for this class during the summer and early autumn. With the exception of DIMBULA, which averaged exactly the same figure as in 1901, viz., 8.25d. per lb., high grown teas generally sold at a rather lower range, and the large proportion of medium tea also shewed some irregularity. Owing to the development of the UVA side of the island—BADULLA in particular—this group of districts shews a considerable expansion in yield, and it is very satisfactory to note that this expansion was accompanied by a substantial advance in the average realised.

Estimated relative YIELD and AVERAGE PRICE realised for the different CEYLON Tea Districts, compiled from the Public Auctions held in LONDON between JANUARY 1st and DECEMBER 31st, 1902:—

SUMMARY of CEYLON TEA sold at public auction in London between January 1st and December 31st 1902. Estimated quantity in lbs. and average prices realised:—

Average Price for the Year was 6·85d per lb., against 6 80d in 1901, and 7·25d in 1900.

The initial letters following the estate names refer to the mean elevation, as follows:—

L (low) sea level up to 1,000 feet. HM (high medium) 2,500 to 3,500 feet. HH (highest) above 5,000 feet.
M. (medium) 1,000 to 2,500 feet. H (high) 3,500 to 5,000 feet.

Over 750,000 lbs.

LABOUR AND PRODUCTS IN BRITISH CENTRAL AFRICA.

We have received on the above subject an interesting letter from the Rev A Hetherwick, D D, head of the Blantyre Mission in British Central Africa. With regard to the suggestion that Central Africa should be opened up from the Nile to the Zambesi as a recruiting ground for native labour for the mines Rhodesia, the Transvaal, and the labour markets of the South African colonies, Dr Hetherwick writes :—"The proposal has caused grave anxiety here to all whose interests are bound up with the welfare and progress of the Protectorate of British Central Africa and its people. These are so closely connected with the labour supply of the country, that any attempt to draft natives, out of the Protectorate will be fatal to the very existence of the agricultural and commercial interests that have done so much to open up Central Africa to the pacifying and civilising influences of legitimate trade. At present all recruiting of natives for service outside of the Protectorate is forbidden by ordinance of his Majesty's Commissioner. This ordinance was enacted in view of the fact that the supply of native labour has in past years barely sufficed for local needs." The necessity of a railway across the Shiré highlands to set free for the agricultural industries of the Protectorate the labour now absorbed in transport work between the upper and lower Shiré rivers has at last been recognised by his Majesty's Government, and a concession granted to a private company for the construction of a line from Chiromo to Blantyre, which it is expected will be commenced in April next. "For the construction of this railway a larger amount of labour will be demanded than the Protectorate is able to provide. As I write, the cry from the transport and planting companies is for more labour. The Labour Bureau, the one organisation sanctioned by Government for the proper distribution of the available labour imported from the outlying districts, has on its books at the present moment demands for upwards of 5,000 which it is unable to supply. In such circumstances, to allow any of the labour to be drafted out of the country to the mines of the south, is to cripple most seriously the commercial and agricultural institutions which are at present struggling to maintain their foothold in the country.

These institutions have invested during the past dozen years no small amount of capital. The three chief transport companies are valued at £330,000, while a new company which has secured the concession for the construction of the railway has been registered with a capital of £1,000,000. The necessities of the country itself demand the retention of the labour of its people for the cultivation of its soil and development of its own resources. Central Africa has no indigenous product such as will form a staple export. The supply of native rubber is exhausted, and so, too, is the ivory trade. Coal there is on the hills above Lake Nyasa and in the Lower Shiré valley. There is gold in the Machiuga mountains on the borders of the Congo Free State. But the true wealth of the country lies in its soil. There are thousands and thousands of square miles of land along the river, valleys and over the countless hill slopes now lying waste and arid, waiting for the hoe and the spade or the plough. Given labour and capital, together with easy transport and direct shipping connection with the home markets, and these wastes might become fertile fields of cotton, tobacco, sugar, chillies, &c. Without its labour Central Africa will never be developed, will never become a self-supporting asset of our Empire. The climate forbids any hope of the utilisation of the white man in manual labour, and all hope of advancement depends on a sufficient supply of native labour being always assured. To remove the native from the country, which itself needs his labour so sorely, is to throw an insuperable barrier across the future progress of the Protectorate."—London Times, March 24.

BLUE HYDRANGEAS.—The cause of the blue coloration has been the subject of multiple discussion, but so great is the conflict of evidence, that it cannot yet be said any satisfactory conclusion has been arrived at. In a recent number of the *Revue Horticole* we find a statement to the effect that certain plants whose roots were in contact with a fragment of slate had fallen from the roof of mansion produced blue flowers. Elsewhere, where fragments of tiles were mixed with the soil, the flowers were of a rose colour. Here is another experiment which might be tried at Chiswick.—*Gardeners' Chronicle*.

AUSTRALIAN PEARLS AND MOTHER- O'-PEARL OYSTERS :

AN EAST AFRICAN ISLAND AS A CENTRE FOR PEARL FISHERIES.

AMERICAN RIVER PEARLS.

At the time we visited Fremantle and Perth and made a short tour through Western Australia, in September 1875, very little was known of the Australian Pearl Oyster Fisheries. The more extensive fisheries were entirely on account of the shells:—some of the Nickoll Bay Shells (specimens of which we lodged in the Colombo Museum being 6 to 7 lb. weight the pair, thickly coated with mother-o'-pearl and often with noticeable raised "blisters"—of which more anon. The Shark Bay Oysters, on the other hand, about three times the size of those of Ceylon, were fished or rather dredged, solely with reference to pearls. Here then we may reproduce some manuscript notes drawn up 28 years ago; but for some reason not given at the time in the *Observer*. They are, however, of some interest at the present time.

"At first, there was no expectation of finding pearls, and indeed very few were discovered in connection with the West Australian fisheries. The great impetus to the trade in pearls was given by the discovery by Mr. Mason, a jeweller in Fremantle that the raised blisters which are rather common on the naere inside the larger mother-o'-pearl shells, usually enclosed pearls of great purity and value. This enterprising and skilful manipulator, with whom I had some conversation, assured me that he was first led to pick at these blisters which had never previously attracted attention, through the great scarcity of pearls such as usually came in from Shark's Bay. Peeling away at the blister he soon found that a very fine pearl was enclosed which could be removed without sustaining injury. Every blister was now an object of great interest and value. The secret soon oozed out and the trade in pearls became an extensive and valuable one. Occasionally large blisters or excrescences inside the shells, giving promise of enclosing fine pearls are found to be empty. But, the largest which have yet been seen in the market have been obtained from such blisters rather than from the fleshy body of the oysters. The best pearls got from the Shark's Bay oysters, I was told, averaged from 18 to 24 grains, while from the large Nickoll Bay Shells, pearls of 40 grains were the rule and some had been pricked out as heavy as 82 and 125 grains each. One of the finest pearls yet found is said to have been purchased for the Crown Princess of Prussia for the sum of £2,000 I was told of a small but select consignment of pearls recently sent to England by a private gentleman which was expected to realise a considerable sum, leaving a handsome profit. One pearl—double the size of a pea—was valued at £1,500. I heard of a dealer pestered at a time when pearls were not so much valued in Fremantle as they are now to buy a pearl by a man newly arrived from a Fishery. He did not care about it, but was importuned to give at least all the money he had about him—the encounter was in the street—and so he handed the large sum of

2d and received a pearl which afterwards proved to be worth over £100! A great many small and seed pearls are, of course, found and for these a ready market is found in England at so much per ounce. There is also a considerable proportion of yellow pearls. These are at present regarded as of little value; it being reported that they will not sell in London; but I found a rumour current that they were much prized in India. I could not say whether they are or not; but I have got one or two small specimens with me on which to get the opinion of competent judges. To get at any pearls in the oysters, the mode adopted is to boil down the flesh on the latter. Of pearls the quantity entered in the Custom-house as exported last year stand at a value of £6,600.

Since 1875, Saville-Kent has investigated—and he and others have written freely about—the Australian oyster fisheries. None of the Tahitian species, with black-edged shells, are found on the Westralian Coast.

There is an island some distance off the land from Portuguese East Africa which is believed to be surrounded by banks covered with Pearl Oysters, never properly fished—if fished at all. It was the subject of a Consular report some years ago, and with the South African war intervening, we do not know that any notice has been taken of it up to the present day.

It is not generally known that in America, pearls—and some of them very fine—are found in mussels in the rivers, just as in Scotland and Wales, mussels in the Tay and Conway have often yielded fine pearls. More than 10,000 dollars worth of pearls were sent from Wisconsin to New York in a few months of 1890-1; but the rivers there got worked out and now the States in which pearls are chiefly found are Kentucky, Tennessee, Arkansas and Texas. If limestone prevails near the rivers, it is noticed that pearls are more likely to be found. They are of all colours from pure white to that of a drop of molten copper. There are, of course, pearl-oyster fisheries off Southern California and west of Panama and attempts at culture have been made near the Gulf of California.

COFFEE, CARDAMOMS AND PEPPER IN COORG.

We are in receipt of a copy of the Administration Report on the Province of Coorg for 1901-2, with a note by Lieut.-Colonel Donald Robertson, C.S.I., Chief Commissioner of Coorg, in which he states:—"The province of Coorg is still suffering from the depression brought about by the deterioration of the coffee industry." To us it is wonderful that Coorg coffee has kept up so long as it has, and that there should still be 45,000 to 90,000 cwt. exported annually according to season. Coorg has an area of 1,500 square miles, a little more than our Western Province; but with a population of only 185,000—not much more than there is within the Colombo Municipality,—the total revenue being under three-quarters of a million of rupees. The following extracts are of some interest to our

planting readers; more especially the reference to Cardamoms, Pepper and Orange cultivation taking the place of coffee:—

The extent actually cultivated with coffee (58,393 acres) declined by over two thousand acres owing to the relinquishment of ruined coffee gardens owned by native planters, though the area cultivated under European methods exhibited a slight extension. Some idea of the depressed condition of the planting community may be gathered from the fact that of the total holding under the coffee tenure only some 57 per cent is now actually under coffee, cardamoms and oranges having taken its place over an area estimated at some 12,000 acres, while another 31,000 acres consists of abandoned coffee and unplanted jungle. Special concessions and reductions of assessment have been found necessary in regard to large areas; during the year under report alone, such reductions were sanctioned in respect of some 1,700 acres and orders were awaited in regard to similar proposals affecting a further extent of 2,800 acres. Prices revived somewhat as compared with the low rates prevailing in the previous year, but the variation, in no case material, was more than neutralised by the unfavourable season, heavy rain in the blossoming time having affected the crop so seriously as to reduce the outturn to little more than half the normal figure.

The cultivation of cardamoms enjoyed no more favourable conditions. The outturn was normal, but prices continued at the low figure which has for years past practically ruined the industry, nor were the numerous reductions and remissions of assessment continued from previous years efficacious in reviving the prosperity of the cardamom growers, whose operations extend over an aggregate area of upwards of sixty thousand acres, of which, however, only a portion is actually cultivated.

The only other agricultural features of the year which call for notice are (i) the increased attention devoted to orange-growing and the cultivation of pepper, chiefly on or near estates formerly worked only for coffee, (ii) the fall to normal rates of the prices of the principal food-grains, and (iii) a reduction in the mortality among cattle. Seasonally, the period under report was on the whole normal.

For further extracts bearing on planting in Coorg, see page 744.

ECONOMIC PRODUCTS IN THE STRAITS.

EXTRACTS FROM ANNUAL REPORT ON THE BOTANIC GARDENS, SINGAPORE, FOR THE YEAR 1902.

PARA RUBBER.—The demand for seeds and plants of this fell off materially as many of the trees planted in the Native States and Malacca are fruiting now, and the planters are now supplying themselves. The number of seeds sold or otherwise distributed was 126,210 young plants. Owing to the drought the crop was very late and smaller than usual; experiments were made in tapping but were not completed as owing to the drought, the latex escaped very slowly and in small quantities. Experiments were made in manuring young plants in pots, with various kinds of manures, including lime, cowdung, burnt earth, pouquette, etc. The evidence, was in favour of burnt earth and cowdung; lime and pouquette seemed not to benefit the plants at all.

BRUCEA SUMATRANA.—This new dysentery drug was introduced to Singapore from Pahang in 1892, by myself, and its use in cases of dysentery described in the bulletin of this year. There was a fairly good demand for it, from varied parts of the world especially India, and a piece of ground was planted up with it. The shrub fruited in 6 months after planting, and grew very readily. A bag of ten pounds weight of seed was sent to Messrs Burroughs and Wellcome, for experiment.

Among the plants of economic value received during the year were two species of Anona from Mexico with edible fruit, Eugenia owariensis "Nsali" with eatable fruit, the Nyassa Land Coffee, and the "Masanda,"—an Artocarpus with edible seeds, and some Amomums from Uganda, the Rotan Segar, Calamus sp. from Muar, the best rattan in the Peninsula: Seeds of Bambusa spinosa, Dendrocalamus strictus and 16 bags of Swietenia Macrophylla from Calcutta, Copernicia cerifera Wax Palm, from Guiana, Javanese vegetable seeds from Mr Cohen, American vegetable seed from U S A Department of Agriculture.

The chief demand for economic plants besides Para rubber, was for Fruit trees and Vanilla.

INSPECTION OF COCONUT TREES.

During the year notices to cut down infected trees were served on 238 persons and 1,039 dead trees and 35 piles of rubbish were destroyed. There were no prosecutions. The number of red beetles especially has greatly diminished in Singapore, so that it was some-time before I could get a couple for a correspondent in Madagascar who wished to see it.

FOR BOTANIC GARDENS, PENANG.

COCONUT TREE PRESERVATION.—The Inspector of coconut trees complains that in too many cases persons summoned for infringing the Ordinance are let off with a caution, or fined in so small amounts as to be non-deterrent. In view of the increasing importance of coconut cultivation, and the necessity for keeping the beetle in check, for which it has recently been found necessary to take steps in the Federated Malay States on the same lines as in the Colony. I think too lenient treatment is a mistake.

Name of District	The number of dead coconut trees destroyed	Notices, &c., issued for pieces of Coconut Trunks destroyed	Amount of Castle Manure removed from Paddy-bushes destroyed	Amount of Notices issued	Amount of Fines recovered	
Prov. Wellesley, N. District ...	480	2,770	168	89	383	15
Prov. Wellesley, C. District ..	149	1,089	103	54	185	83
Prov. Wellesley, S. District ..	49	231	35	22	85	Nil
Penang Island..	380	3,716	389	70	596	58
Total ..	1,058	7,806	695	235	1,249	101

PARA RUBBER.—Para Rubber still holds the field and bids fair to recoup Agriculturists some of the money that has been lost in other cultivations. The largest tree in the Waterfall Garden, of which mention has been made from year to year in annual reports, has been tapped for the seventh time, the yield of dry rubber being 2 lbs. 13½ ozs. which makes a total of 18 lbs. 7 ozs. from this tree in seven years, or an average of 2 lbs. 10 oz. per year; and I see no reason why this average should not be maintained or even exceeded without injuring the tree. According to a note in the Agricultural Bulletin, two of the oldest Para rubber trees in Perak that had not previously been tapped gave 50 lbs. of dry rubber at one tapping. Mr. Stanley Arden, Superintendent of Experimental Plantation Selangor, has just published his report on tapping of trees in various manners and at different ages, and I believe the conclusions arrived at coincide

in all material points with my own experiments, which though dealing with only a few trees have been spread over a much longer period. The extension of plantations is pushed on, especially in the Native States, and it is proposed to commence tapping this year on two Estates that I know of, but I fear that the return from very young trees will be disappointing after deducting cost of collecting.

RAMIE.—A short note on Ramie in the Agricultural Bulletin somewhat revived the interest in this fine fibre producing plant, and has resulted in eliciting some information that may be of practical value. A correspondent in Scotland who is thoroughly conversant with the methods of cleaning and preparing this fibre, and to whom a parcel of ribbons was sent for treatment, suggests that the kind we sent and which I believe to be the same that has been planted on the two or three estates in which the cultivation on ramie has been attempted on any considerable scale, is a very inferior variety which he terms black ramie. It is a very strong and quick growing form and on this account it has no doubt been selected in preference to others, but if our correspondent's views are correct this is its sole recommendation. We have in cultivation in the nursery here a smaller and shorter variety with hollow stems which will, I have little doubt give more than double the weight of fibre from an equal weight of stems as compared with the large growing kind. The nature of the stem too, I think, simplifies the decorticating process, for instead of stripping the bark from the wood which is never a complete process, there being always a certain amount of fibre adhering to the wood that cannot be removed with the bark, by simply beating the stems while in a green state and washing in water, every particle of fibre is obtained from this variety two pounds weight of green stems without leaves gave 4 oz. of roughly cleaned fibre which has been sent home to ascertain what further loss occurs in completing the process of preparing the finished article and the approximate value if shipped as per sample.

GUTTA PERCHA.—Gut'ta Percha trees growing in the Waterfall valley, from which a good crop of seeds was obtained in 1901, produced not a single fruit this year though one tree flowered freely. Import saplings both from Borneo and Sumatra are decided failures, and until seeds are obtainable the cost of forming large plantations is too great to justify the undertaking. This, however, is a matter to be dealt with more fully in a report on the Forest department which I have been asked by the Chief Forest Officer to write, and I merely refer to the subject here as the preparations of Gutta Percha plants for planting in the Forest reserves has hitherto been done in the Botanic Gardens.

C. CURTIS,

Superintendent of Gardens and Forests.

KANAN DEVAN HILLS, NORTH TRAVANCORE.

About 12 years ago, there was an account of a visit to these hills in the *Pioneer*. The country was then comparatively unknown and only a few estates had been opened out, principally with cinchona. This District known as the "High Range" is situated in the northern corner of Travancore near the British boundary, and is a portion of the Western Ghats from which it is separated by a barrier of precipitous mountains—the peaks of which are about 8,000 feet high, one of them, Anaimoody, being the highest point in South India—8,827 feet. These mountains shut in an area of about 300 square miles, consisting of hills and valleys ranging from 4,500 feet to about 6,500. Hidden amongst these hills' are extensive forests, which until recently were the haunts of elephants and bison, whilst on the summits of the hills there are still large herds of ibex. Altogether there must

be between 30,000 to 40,000 acres of forest, the remainder consisting of undulating grass hills and high mountain peaks. In every valley there is a small stream and the rainfall varies from about 250 to 100 inches, the portion lying to the west getting the full brunt of the south-west monsoon. About twenty-five years ago a concession for this District was obtained from the Travancore Government and was formed into a small company. A few experimental estates of

TEA, COFFEE AND CINCHONA

were opened out in different parts by the Company, and two or three independent planters also settled there, but owing to the inaccessibility of the place—it is even now 70 miles from the nearest railway station,—but few persons were attracted. Seven years ago, the whole of the concession was purchased by Messrs Finlay Muir and Company for a very small sum, about 65 per cent of the capital of the pioneer Company. A new company was then formed with a capital of £1,000,000 and operations were commenced on a very large scale. Altogether more than 13,000 acres have been planted out during this period, of which 11,000 acres consist of tea. The great drawback is the want of facilities of communication with the low country. Looking at the map the natural port of egress would seem to be Cochin, and although the western slopes of the Ghats present many engineering difficulties, it would have been quite possible to construct a road on that side. The Travancore Government, however, were not at first prepared to open a road, and have thus lost all chance of benefiting from the produce traffic which now finds its way to British territory. The two other points of egress from the planting district are to the north in the Coimbatore District, and to the west towards the South Indian Railway, running from Trichinopoly to Tuticorin. By the former route it is about 50 miles to the nearest town in the low country, Udumalpett, and from there as far again to the nearest station on the Madras Railway; whereas to the west it is only about 70 miles to Anmanayanaikanur, a station on the South Indian Railway. In both directions the only means of conveyance is by pack animals and cattle and the eastern slopes of the hills are so precipitous that it will probably never be possible to construct a cart road. By the route to the north it will be possible, and the Travancore Government has at last sanctioned and commenced a Ghat road to Udumalpett, to which town

THERE WILL SOME DAY OR OTHER BE RAILWAY

COMMUNICATION

by means of a branch railway from the Madras line to the South Indian Railway. Some years, however, must elapse before this project is carried out and in the meantime the produce is for the most part despatched by the eastern route. The hills are almost entirely uninhabited except by Malialies, and the whole of the labour employed has to be brought up from the Madras side. Altogether about 10,000 coolies find employment on these hills for about 10 months in the year. The produce sent down amounts to about 3,000 tons annually and probably about an equal amount of rice and food stuff has to be brought up for the consumption of the coolies. To carry all this traffic by head loads and pack animals would be well nigh impossible, and therefore at a very heavy cost the Company has constructed a tramway from its headquarters station Munnar to

the top of the Eastern Ghat a distance of 22 miles. The line is on the Ewing Mono-rail system, each truck carrying one ton and drawn by a pair of bullocks. The gradient is a fair one (1 in 40), but whatever the cause may be, it does not give entire satisfaction, the balance wheel being said to cut up the road way so much as to involve more expenditure than a double rail would cost. The terminus of the rail is at a pass between the enclosing mountains and is said to be 6,000 feet above the sea. From here the produce is sent down rather more than 4,000 feet by a wire rope worked by a turbine from the bottom. The rope is in two sections, the power being applied in the middle station by means of two dynamos (the second being in case of any accident to the first). The rope, an endless one, working round vertically placed wheels at both ends, carries about 150 loads either way each day, each load being 180 lb. The loads revolve with the rope at the rate of two miles an hour and are fastened to the rope by an ingenious grip which fastens automatically on to the rope and is held in position by the weight of the load. When the load reaches the terminus at the end, it is met by a horse-shoe-shaped rail which automatically lifts the load off the wire and releases the grip. The wire is $\frac{3}{8}$ inch in diameter and is capable of carrying 200 lb. At the middle station the two sections are connected by cog wheels, so that the load from one section can pass on to the other by the same contrivance. The turbine at the bottom is worked by a 9-inch pipe with a lead of about 1,200 feet and a fall of about 800. Here again there are double machines in case of accident, which are capable of working up to about 50 H. P. although the actual amount in use was only 20 H. P. From the lower terminus there is a cart road of 9 miles descending about 1,000 feet to the low country and from thence a good road 45 miles to the Railway Station of Ammayanaikanur. To construct this

TRAMWAY WIRE ROPE

involved an expenditure, I was told, of about £50,000 and it not only pays an interest on the capital expenditure together with all working expenses, but also effects a saving of about 4 pie in the rupee on what the cost would be by ordinary means of traffic. The great advantage, however, is that it makes it possible to get the produce away and to bring up the food supplies without having to depend upon coolies and pack bullocks. Of course, all the money spent in opening out this large area, and in the employment of labour has not been without advantage to the Travancore Government although the produce finds its way to British outlets. This is proved from the fact that the district, which was formerly an unproductive wilderness, is now made the headquarters of a Revenue and Magisterial official—a European officer,—and not only covers the cost of establishment but brings in a revenue of about R70,000 a year. All this productiveness, however, is at present confined to the forest land. There are at least 150 square miles of grass land which are absolutely unproductive and no attempt has been made to bring them under cultivation. It remains to be discovered what cultivation would be best suited to this land, but with a country so well watered, and so favourably situated for climate and rainfall, it should not be impossible to find a remunerative crop, and it would seem to be the ideal spot for a European colony. The district now

CONTAINS ABOUT SIXTY EUROPEAN PLANTERS, including the Company's supervising staff and a few independent planters, survivors of the pioneers. Some of these are married and are scattered about the district in outlying estates, most of them beautifully situated as regards position. At the headquarter station Munaar there is a large tea factory, an association store, a club, and gymkhana ground. There is, moreover, a Volunteer detachment, and finally during my visit a Masonic Lodge was opened. The District has evidently a future before it and shows what can be done by the judicious employment of capital and energy. The original shareholders have, I was told, already received back in dividends and bonus about 60 per cent of their capital and now that the estates are coming into full bearing there should be a permanent dividend, though of course every thing depends upon the price of tea, which at present is the staple product. Given an average net profit of £5 per acre, which does not seem an extravagant estimate, the return from the estates already opened out should give $6\frac{1}{2}$ per cent on the total capital. This is entirely apart from the latent possibilities of development and with improved facilities of communication and cheapness of transport there can be little doubt that there is a wide field open for further progress.—*Pioneer*, March 14.

J. D. B. G.

PLANTING IN COORG.

(From the Official Report for 1902.)

As an indirect consequence of the depression in coffee, there has been a growing tendency to devote greater attention to the cultivation of rice. The extent grown with this crop (79,930 acres) expanded during the year by nearly two per cent, the harvest being a good average one notwithstanding an unusually long break in the monsoon. *Per contra*, dry cultivation, to which much less recourse is had in Coorg, diminished; the total extent (14,512 acres), of which almost all relates to *râgi*, was some 13 per cent less than in the previous year, when the area under this crop was materially expanded by the irregular practice of *kumri* cultivation which has since been prohibited.

There are two main outlets to the Western coast through the valleys of the Sampaji and Perambadi Ghats. The high roads to the ports of Mangalore and Tellicherry run through these passes, which about thirty years ago were covered with dense forest. This gave place to coffee. Coffee succeeded for a few years and failed, the rainfall being so heavy that it washed away the soil no longer protected by the forest. *Lanthana (lanthana aculeata)* a shrub introduced in 1863, has now taken the place of the coffee and has overgrown the sides of these hills turning them into an almost impenetrable bush.

The evergreen forests on the Western Ghats contain poon (*calophyllum elatum*), ebony (*diospyros ebnaster*), ironwood (*mesua ferrea*) cedar (*cedrela toona*), sampigè (*mischelia champaca*). Owing to their inaccessibility, these forests are very little worked. The right of cultivating or collecting cardamoms in them is leased out, the area of the leased blocks known as cardamom 'males' or hills being no less than 35,240 acres. The cardamoms (*eleteria cardamomum*) are grown in small clearings, the size of which is strictly regulated in order to prevent injury to the forest. There is but

little regular cultivation, and the growth is for the most part a spontaneous consequence of the clearance of timber and undergrowth and the breaking up of the soil. Bamboos are cut in the valley of the Cauvery and exported to Mysore. Fine clumps of a large variety are met with in the extreme south of Coorg near Kutta and the foot of the Saupaji Ghat.

To a considerable section of the population, the cultivation of cardamoms was formerly second in importance only to that of rice. During the last 20 years, however, the price of this product has fallen to such an extent that it now scarcely pays to collect the berries, and many well-to-do families, who depended chiefly upon their cardamoms *mâës* for the purchase of articles required to supplement the produce of their rice fields, have been greatly impoverished.

Coffee is extensively produced in Coorg, and its cultivation forms the chief industry of the Province, every one, European and Native, being more or less interested therein. During the past decade however low prices combined with the ravages of leaf disease and borer have materially affected the industry with the result that many estates have been altogether abandoned and the majority hardly pay their way. The plantain (*musa paradisiaca*), of which there is a wild kind in the hill jungles, is commonly grown all over Coorg in the vicinity of native dwellings. The Coorg oranges are celebrated, and in South Coorg are as abundant as the plantain. Among dry grains the chief are ragi (*cyenosurus corocanus*), awaié (*dolichos lablab*), togari (*cajanus indicus*) and horse gram (*dolichos uniflorus*); these are mainly grown in those parts of the Nanrajpatna taluk which adjoin the left bank of the Cauvery.

The area shown in the statement under orchards and garden produce is made up of 231 acres areca-nut and 2,165 acres of orange groves. The assessment ordinarily levied on orange cultivation, which has materially expanded of late years, is from As. 8 to Rs. 2 an acre. The expansion is attributable to the gradual decline in the interest taken in coffee planting. An incidental consequence of the same factor is the impetus given to the cultivation of pepper. No statistics are available, but it is an undoubted fact that considerable areas have been cultivated with pepper on estates formerly worked only for coffee.

Coffee suffered severely from unusually early blossoming showers as also from the reaction after the abnormally heavy crop of the previous year. The combined effect of these causes was an out-turn roughly estimated at 2,250 tons, or little more than half the normal crop. The price of coffee revived somewhat from the low rates obtaining in the previous year, but the variation was so slight as to have no appreciable effect on the industry. The cardamom crop was also very poor; though slightly better than in the previous year, the out-turn was only estimated at the normal figure, nor was there any compensatory improvement in prices.

PLANTING IN BRITISH CENTRAL AFRICA.

A FORTUNE TO BE MADE IN TOBACCO—AND TEA.

(? FOR LOCAL CONSUMPTION) AT 3s PER LB.

A young Ceylon planter, who recently went across to the Nyassaland Districts, sends us a

chatty and cheerful letter from which we quote:—

25th January, 1903.—I arrived in Chinde after a fortnight's pleasant journey from Ceylon. The river Zambesi being so low, the paddle boat could not travel farther than the first Wooding Station, after which I had to go by small barge—no house boats being available. It took 10 long weary days from there to Chiromo. 13 natives paddled the barge, stopping at night time at different villages *en route*. The river got worse and worse until at Chiromo, I was told that I should have to travel by *Machilla team*:—that is, being carried by natives to Blantyre. I did not care for the idea, as the forests were swarming with lions, leopards and other wild beasts and only a short time since Mr Ray the Manager of Messrs Sharrer's Zambesi Traffic Company had a visit paid to his house by a full-grown lion. Well, I travelled all night through the forest—walking every now and again to stretch my legs; the natives meanwhile made as much noise as possible and imitated the lion to scare them away. They carry varieties of skins made into water bottles across their shoulders and run with great speed.

Thankful I was when "Chiromo" was reached after a journey lasting six weeks from the time I left Colombo. On the way up the Zambesi river I visited Mrs Livingstone's grave: she is buried near the Jesuit Missionary Station but they had not attempted to keep the grave in good order. It took 2½ days from Chiromo to Blantyre. The river has never known to be so low before by the oldest inhabitants and the river is swarming with Crocodiles and Hippopotami, but they did not prevent me from having my swim every evening coming up, a rather unwise thing to do, but after sitting huddled up in a barge all day in a sweltering hot sun one would risk anything, for a cool bath. I am 45 miles from Blantyre, up the hills and not far from Henry Brown, who used to be in Ceylon. Coffee, as you no doubt know, has had its day. Many firms have been ruined by it and are now all going in for tobacco and tea which pay a large profit at present. As for the land and soil, it is simply marvellous—not like Ceylon "clay", but rich dark soil. To give you an idea, the tea that Mr Brown planted two years ago I said at once when asked was "five years old." Another Ceylon man who saw it said the same thing. The labour is so cheap I could hardly believe the wages the natives receive. As for the climate being made out to be so treacherous, that is simply ridiculous. Where I am at present is quite equal to Hatton. The only thing is: food is very scarce; but when British Central Africa is properly known it will I am sure be the centre of Africa for growing Tobacco and Tea. Men with capital, not afraid to speculate out here, can I think make a fortune in a short time—very different from Ceylon in labour and competition. Although I was laughed at for coming over here to grow coffee, let me tell you at once that coffee is not reckoned on in future: tobacco and tea only. The tobacco grows here like a weed and I am planting 50 acres up this year and also tea is coming on splendidly, in fact better than I ever saw it in Ceylon. All that is required is machinery and that is coming as soon as enough tea is in bearing. At present I have to manufacture this estate's tea by hand and a steady sale is 3s per lb.—not so bad.

THE COTTON SHORTAGE: AND GROWTH IN NEW CLIMES.—Our weekly commercial report from Mincing Lane has been steadily urging the growing of cotton in Ceylon in view of the shortage of supplies to British sources. We should be glad to know if independent experiments are being made. It will be seen that Cyprus has sent some excellent samples, and that cultivation in that island is likely to be encouraged.

CINNAMON IN LONDON.

The particulars received by a recent mail confirm and explain the commercial telegram which we published, bearing on the first sale of the current year of Cinnamon held in London. The February auctions do not generally lead to much competition, as buyers lay in large stocks in anticipation of Christmas, which help the November sales. On the present occasion there were two reasons for expecting a good demand. The last quarterly sale of 1902 had a short catalogue—only two-thirds of what had been offered the previous November; and the offerings were all sold at advanced prices. The second reason was that the total export of Quills for last year fell short of that for 1901 by about 200,000 lb. and since then the exports had been restricted. As a result, the quantity offered was exceptionally small—less than one half of that brought to the hammer at the corresponding sale last year; and yet the demand was slack, and the competition spiritless. With all that, there is not much to complain of in prices. Though "Worked" spice experienced a drop of 1d., it was from a point which had seldom been reached in recent years; and 1s. 5d. to 1s. 8d. for Firsts, and 1s. 4d. to 1s. 6d. for Seconds, is decidedly good. What is more, the whole of the small quantity offered was sold under the hammer. Though about one-fifth of the "Unworked" Cinnamon remained unsold, the prices realised for its Firsts and Seconds were not only a penny higher than at the November sales, but also, we believe higher than "Unworked" had ever before realised. Altogether, the prices which ruled must be regarded as satisfactory, though the tone of the market was dull. It has not recovered yet from that state; and if prices are to be maintained the quantity produced will have to be moderate. But, after all, the United Kingdom now takes only about one-sixth of our Exports, Germany taking about double that quantity, though the best spice which the Island produces continues to go to London.

The Report of the sale from the leading spice firm, from whose notes we usually quote, will be found on this page.

COTTON IN CYPRUS.

The occasional shortages in the American supply of raw cotton have for some time past been the subject of a good deal of interesting discussion. The question of freeing the English mills from the exigencies of American speculators by substituting a supply of raw cotton produced within our own confines is an exceedingly important one; and the Government of several British colonies, notably of the Gold Coast, Lagos, and Sierra Leone, have professed a strong interest in the movement, and declared their willingness to undertake series of experiments with a view to the cultivation of cotton within their boundaries. This being the case, it is not a little surprising that Cyprus—a colony so near home, and one which has, moreover, for centuries been known as a cotton-producing country of no small reputation—should up to the present have been apparently overlooked. The Italian traveller and writer, Mariti, relates that as early as the 16th century, under Venetian rule, 30,000 bales, or 6,600,000 lb., of cotton were exported annually from the island. Of more recent years the export has been much lower, but

in spite of the depopulation and impoverishment of the island while under Ottoman rule, still eminently respectable. In 1865 it was put at 1,800,000 lb., in 1866 at 2,065,000 lb., and as late as 1871 at 1,120,000 lb. Since the British occupation the yield has further decreased, the average for the first 12 years being 854,551 lb., and for the last 11 years 550,664 lb. This decrease is to be attributed to three causes—namely, (a) swarms of locusts, (b) scarcity of water, and (c) want of good seed. Thanks to the energetic action on the part of the island Government, which has spared no expense to benefit the country in these respects, locusts are at the present time practically extinct in the colony, and during the last two years large areas of cultivable land have been laid under proper irrigation. The want of good seed continues, however, to make itself felt. Mr John Butterworth, examiner in cotton manufactures to the City and Guilds of London Institute, in his report on some samples of cotton which were sent to the Indian and Colonial Exhibition of 1887, comments very favourably on the colour and staple of Cyprus cotton which he considers equal to the best Smyrna. Practical experiment has demonstrated that by a judicious use of American seed the staple of Cyprus cotton can be materially improved, and in irrigated lands the American varieties of cotton thrive far better than the native one—that is to say, they produce more and better quality of cotton. What is needed for a few years is new seed in sufficient quantities for distribution at a low price to native cultivators. Let but the Manchester Association devote a little attention to this object and in a very short time the output of Cyprus cotton will again reach a figure more than respectable, and the Lancashire market should experience no difficulty in securing practically the whole supply.—*London Times*, Feb. 23.

CINNAMON QUARTERLY SALE.

9, King William Street, E.C., London, 24th Feb., 1903.

CINNAMON.—The first auctions of the year were held yesterday, when the small total of 567b was presented, comprising 116b "worked" good and fine quill, and the remainder "unworked" common to fair medium. At this period last year 1,311b Plantation were offered and 1,178b in November last.

There was a fair attendance of Buyers whose requirements for the time being were apparently fairly all ordered, as competition was spiritless throughout, and only about 415b changed hands in the room and immediately afterwards.

The "worked" spice was all sold, but at prices about 1d per lb. lower on average than at the November sales. "Unworked" for some of the best marks ruled dearer for firsts and seconds, but cheaper for the lower grades.

"Worked" firsts 1s 5d to 1s 8d, seconds 1s 4d to 1s 6d, thirds 8d to 1s 4d, fourths 6d to 11d per lb.

"Unworked" firsts 5½d to 1s 1d, seconds 5d to 11d, thirds 4d to 9½d, fourths 4d to 8d per lb.

CHIPS, &c.—947 bags offered and about 800 bags are sold at lower prices. Cuttings &c. up to 9d and good to fair Chips 3d to 2½d per lb.

BAK.—300 bags brought in. No bids at ¾d per lb. At the Spice Sales on 4th instant 1,301 bags "Wild Bark" were offered and cleared "Without reserve" at ¾d to ¾d per lb.

Stocks.—Ceylon	2,606 b	against	3,420 b	1902
Wild	1,817 b	do	2,282 b	do
Chips	1,801 b	do	2,318 b	do
Wild Bark	5,605 b	do	7,663 b	do

NEXT SALES, May 25.

INDIA AND THE CENTRAL ASIAN
TEA TRADE.

Mr. G Macartney, British representative at Kaskghar, writes:—An examination of the Leh Office Trade Statistics for 1900-1901 would show that in that year the total value of the trade

carried on *via* Ladak between India and Yarkand had increased by about 1½ lakh of rupees as compared with the previous twelve months.

Trade in Indian tea during 1901-02 does not strike one as having made any special progress—at least, if any has been made, it does not appear to have been proportionate to the general expansion of imports. The slackness is the more extraordinary because, as explained in this office 1900-1901 Trade Report, the quantity of Chinese tea, on account of transport difficulties in Kansu, has been diminishing in the market here, resulting in a gradual rise in price. The Indian tea brought to Yarkand last autumn consisted mainly of the three following sorts:—

'Green'—Forming about $\frac{2}{3}$ of total import price at Palampur about 7½ annas a seer. All obtained from native gardens.

'Bohea'—Forming about $\frac{1}{3}$ of total import Price at Palampur about 4 annas a seer. All obtained from native gardens.

'Black'—Forming about $\frac{1}{3}$ of total import Price at Palampur about 6½ annas a seer. Partly from native, and partly from European gardens.

It may be noted from the above that whatever be the trade in Indian tea with this country, it is almost exclusively in the hands of native growers, the European planters of the Indian Tea Association having apparently only had an infinitesimal share in it.

Regarding the present demand for Indian tea, the following information given by traders may be of interest:—The 'Green' tea is mostly taken by the Chinese, and penetrates to regions as distant as Kuchar and Li. This preparation is not in special request with the natives of Turkistan, who prefer the Chinese brick tea. Since, however, the latter has risen in price by reason of diminished supply, Indian 'Bohea' has gained somewhat in favour in Yarkand, where it is said a few Tunganis buy it up secretly, and mould it into bricks for native consumption. The reason why the 'brick' form is adhered to is that the people are accustomed to it, and that it permits of adulteration. A few maunds of Chinese tea, received *via* Bombay, came to Yarkand in the year under notice. The importation of this tea, though never large, has been a persistent feature in the Indo-Yarkand trade during at least the last decade. One cannot help remarking the sense of irony in the fact that, whilst our planters are trying to gain a market in these parts for their tea by competing with Chinese growers, our own traders should, all the while, assist the latter by importing the Chinese production.—*Indian Daily News*, March 17.

BORDEAUX MIXTURE.

Bordeaux Mixture if required for application to leaves or young branches should be made as follows:—*Materials*.—(1), 8 galls. water; (2), 1 lb. copper sulphate (blue stone); (3), $\frac{3}{4}$ lb. unslaked lime
Directions—(1). Put 7 gallons of the water into a tub, reserving one gallon to mix with the lime; (2). Put one lb of blue-stone into a small muslin or cotton bag and suspend it by a string to a piece of wood placed across the tub, so that the bag with the blue stone is just a few inches below the surface of the water; (3). Allow it to remain for about six hours or until all the blue stone is dissolved then remove the bag and pour in the lime which has already been mixed with the other gallon of water. The

formula given in pamphlet No. 17 of the Imperial Department of Agriculture is as follows:—(1), six lb copper sulphate; (2), four lb unslaked lime; (3), fifty gallons water.—*N. B.*—When required for dressing the old stems of trees so that the leaves or young branches are not touched by it, the solution of copper sulphate may be stronger and sufficient lime may be used to make a thin white wash. This mixture is usefully employed when trees are attacked by any kind of fungus, and it has also been strongly recommended for the removal of epiphytic growths.—*Trinidad Bulletin* for October 1902.

THE CULTIVATION OF CASSAVA—ITS CONVERSION INTO SUGAR.

I think the public of Jamaica owes a heavy debt of gratitude to Mr Robert Thomson for the great revival of the interest which is now taken in the cultivation of cassava in this Island. His interesting pamphlet relating to what has been done in Florida has aroused a well-merited attention, which it is to be hoped will not be allowed to subside without profitable result.

In the course of my professional avocations, I see much cassava growing in what would appear to be its natural haunts, namely Clarendon and Saint John. The long continued dry weather in these districts, lasting from August through September into October—for the autumnal rains have not yet fallen—has caused a retardation in the maturing of the crop. Cassava should have come into the market fully two months ago, and the tubers that are now being lifted are small in size, and so stringy by the development of fibro-vascular tissue at the expense of the starch, that they are scarcely fit for the table. However, the peasant-women continue their preparation of starch, and this article will soon make its appearance in the markets.

Cassava starch is much undervalued in the island as an article of infant's food. Prepared with boiled milk it is highly digestible and should be freely given to young children. Mixed with even a small proportion of ground malt its digestibility is increased, and it then vies with more expensive articles that are much advertised. To make a market for this starch, it should, I think, be converted into starch-sugar, or glucose. There is a demand for glucose which the Americans have found out, for brewers use it in brewing ales and beer, and confectioners employ it in preserving fruits, in making pastry, barley sugar and other sweet-meats. In the very valuable work on Sugar growing and Refining by Messrs Lock, Wigner and Harland, there is a chapter of some twenty two pages on starch-sugar and glucose, giving very clear directions as to the different processes in use for its manufacture, some of which are very simple, requiring no great outlay for apparatus. The most simple apparatus is that known as Anthon's, Sulphuric acid and bone-black are required in the process, but the other substances we have here in abundance, namely, starch—produced more cheaply than corn-starch can be produced in the Western States of America—quicklime and chalk, the latter existing here in the form of white marl,

What follows is quoted from the work mentioned:—"In Anthon's method for producing three to four cwt of starch sugar per twenty-four hours, the ingredients for boiling are:—

370 lb of air-dry starch.

11 lb of sulphuric acid of 66 degree Beaume.

3 lb and seven-tenths of bone black.

2.46 to 3.70 lb of pure burnt lime.

4.95 lb of prepared chalk.

The apparatus is very simple. It consists of a boiling pan, a vat of about eight and half bushels capacity, with a wooden spigot at the bottom, a Taylor's filter in a case four feet high and two feet wide and deep, arranged for the reception of nine bags, each about two and half feet in length, and six to seven inches in diameter when filled, and set up so that the thin liquor can be drawn off into a cask. The bags are made of grey linen of prime quality and of uniform weave and are fastened over funnels placed in the bottom of a syrup-containing box with a strong cord." It is stated in America the cost of manufacture is about one cent (half pence) a pound. Some 26 to 32 lb are made from a bushel of corn. It is sold by the manufacturers at three to four cents one penny to twopence per pound.

The authors quoted also give directions for the preparation of starch-sugar on a larger scale by Anthon's process, which it is stated, furnishes excellent sugar. They also state that starch-sugar is principally used for manufacture of table-syrups, candies, as food for bees, for brewing, and for making artificial honey. All soft candies, waxes, and toffees, and a large proportion of stick-candies and caramel are made of starch-sugar syrup. Small quantities of starch-sugar syrup are used by vinegar makers, tobaccoists, wine-makers, distillers, mucilage-makers, and perhaps for some other purposes.

All readers interested in the proper utilisation of cassava in Jamaica should consult the valuable work from which I have partially quoted. Old Harbour, Oct. 25, 1902. JAMES NEISH, M.D.
—*Journal of the Jamaica Agricultural Society*:

WEST INDIAN COTTON CULTIVATION A RICH FIELD IN PROSPECT.

Sir Alfred Jones has just received from Dr Morris, of the Imperial Department of Agriculture, Barbados, a letter stating that they had already 600 acres under cotton cultivation in different portions of the West India islands. In St. Lucia, Antigua, Montserrat, and St. Kitts encouraging results have attended the experiments, proving that the West Indies offer a rich field for cotton growing. The revival of interest in West Indian cotton cultivation, like that of the West African, is very marked in Lancashire. Further larger shipments of American cotton seed have been sent to the Governor of West African colonies as well as to Sir F Lugard, who is displaying great interest in regard to cotton growing.—*London Times*, March 2.

RUBBER IN UGANDA.

In a report on exotic plants of economic interest in the Botanic Gardens at Entebbe, Uganda, Mr J Mahou states that while some plants make only moderate pro-

gress in this country, which in other parts of the tropics are known to grow very rapidly, still, it may be said that, on the whole, the things mentioned in the accompanying lists thrive most satisfactorily, and are eminently suited to the climate for either useful or ornamental purposes.

It is well known there are large areas in Uganda containing abundance of rubber vine (*Landolphia*) yielding excellent rubber, but as it is practically impossible to systematically cultivate this plant, we are introducing all the celebrated rubber-yielding trees with the object of demonstrating that this country offers a field for establishing rubber plantations on a commercial basis. As I have pointed out before, it is only a question of the activity of traders to determine the time during which our natural supplies of rubber will last, and as the same circumstances apply to other countries, where rubber is found naturally, it follows that timely preparations require to be made to furnish supplies for the demands of the future.

The standard by which all rubber is judged is the Para (*Hevea brasiliensis*). When I came to Uganda in 1901 the director of the Royal Botanic Gardens, Kew, forwarded in my charge a consignment of plants, amongst which were several sorts of Para rubber seedlings with stems about as thick as a lead pencil, and 9 in. to 12 in. high. One of these, in the Botanic Gardens, is now over 7 ft. high, and otherwise of proportionate growth. As I reached Entebbe for one of the worst droughts remembered here, the young plants, after a trying journey of almost two months, had a hard battle to exist, and some of them succumbed, so that the success of the survivals is all the more satisfactory to record. But as this Amazonian plant affects low levels, it remains to be seen whether our climate and elevation will suit it. I am certain the lake will exercise a very favourable influence, and it would, in my opinion, be a mistake to experiments with these and other extra-tropical plants elsewhere in Uganda than on the lake shores.

Castilloa elastica—Central America rubber—was another item in the Kew consignment. This also has done very well, and, being more or less of a highland plant in its native country, it is reasonable to assume the conditions here will prove suitable. A considerable quantity of *Castilloa* plants have been ordered, and an experiment in introducing its seeds here direct from Mexico is being conducted.

Ceara rubber (*Manihot Glaziovii*) is growing with its accustomed vigour. A seedling of eight months is nearly 4 ft. high. It seems quite at home in Central African climates, but it is not a first-class rubber, and instances are on record where it was proved not worth the trouble of planting, still it might be a most suitable sort here.

A serious loss occurred last June in the burning down of a large nursery shed through native carelessness, when a fine batch of the celebrated silk rubber of Lagos (*Funtumia elastica*) was lost, in company with other valuable things.

They were raised from seeds I received from the Gold Coast, and we were waiting for a rainy spell to plant them out. I am expecting more seeds by every mail. A few seedlings are doing very well, but a plant brought from Kew, which at first made good growth, has, for some reason, become leafless and refuses to move at present. I feel certain Lagos silk rubber will prove a suitable culture here for plantations in the lake region.

We have a large number of *Landolphia* seedlings which were obtained from Sesse in 1900. Nothing is more puzzling than the slow rate at which this common native plant grows under cultivation. It is quite clear it requires to be sown where it is intended the plants are to remain. It resents transplanting, and some seedlings we put at the base of trees in a stretch of forest to grow "an natural" have remained practically as they were put out six months ago.—*India-rubber Journal*, March 2.

THE RAYIGAM COMPANY, LIMITED.

REPORT OF THE DIRECTORS.

DIRECTORS :—The Hon. Mr. Edward Rosling, Messrs. Albert Rosling, Gordon Frazer, F M Mackwood

ACREAGE :

Rayigam.		
Tea in bearing	628	acres.
„ partial bearing	68	„
Rubber not in bearing	20	„
Forest	484	„
Total		1,200 acres.
Annandale.		
Tea in bearing	250	acres.
Forest	8	„
Grass	38	„
Total		296 acres.

The Directors herewith submit their Report and Balance Sheet for 1902. After writing of R4,000-00 for depreciation on buildings and Machinery there remains at credit of Profit and Loss Account R15,046 01. Out of this the Directors propose to pay a dividend of 2½ per cent absorbing R15,000-0, carrying forward a balance of R46-01. The crop of Tea from Rayigam was 296,725 lb as against 294,110 lb in the previous year, and from Annandale 90,606 lb as against 85,929 lb. In the case of Rayigam approximately about one-third of crop 99,355 lb. was made into Green Teas which netted 34-02 cts. per lb exclusive of the Cess bonus. The Black Teas netted 29-56 cts. and on Annandale 41-85 cts. per lb. A contract has been made disposing of the first six months' crop of Green Teas from Rayigam Estate for 1903. The estimate of crop for the current year for Rayigam is 300,000 lb and for Annandale 100,000 lb.

Para Rubber.—About 20 acres were planted with Para Rubber during 1902. This, with what is already planted in ravines and through the Tea, gives an equivalent of 50 acres varying up to 10 years old. It is proposed to plant up about 20 acres annually. Mr. Albert Rosling retires from the Board of Directors by rotation, but being eligible offers himself for re-election. The election of an Auditor for 1903 rests with the Meeting.

PORTMORE TEA COMPANY OF CEYLON, LIMITED.

ANNUAL REPORT.

to be submitted at the sixth annual meeting held at 24, Rood Lane, London, E. C., on Monday 16th March.

The Directors have the pleasure to submit the General Balance Sheet and profit and loss account for the year ending 31st December, 1902, duly audited.

The net amount at credit of profit and loss after providing for general expenses, income tax, &c. £3,930 6d 9d. To which should be added balance brought forward from last year £260 5s 11d.—Total £4,190 12s 8d.

An Interim Dividend of 5 per cent, was paid October 18th, 1902, amounting £2,000. It is proposed to pay a final Dividend of 5 per cent, (making 10 per cent, in all, free of Income Tax) which will absorb £2,000. And to carry forward to next year £190 12s 8d.—Total £4,190 12s 8d.

In presenting their sixth annual report, the Directors have pleasure in recommending a dividend of 10 per cent, for the year ending December 31st, 1902. The Tea crop from the Estates has been 221,143 lb, being at the rate of 472 lb per acre, which is the smallest yet obtained, and is accounted for partly by the system which has been carried out of leaving a portion of the area unplucked, and partly by excessive rains in the latter months of the year, which prevented the usual flushings.

The cost of production has been £4,071 15s 5d, being at the rate of 4-42d per pound, and the crop has netted £3,459 5s 10d, being 9-18d per pound. The average rate of exchange has been 1s 4 3/16d against 1s 4 3/32d last year. Mr W Herbert Anderson retires from the Board by rotation, and being eligible offers himself for re-election.

The latest reports from the manager in Ceylon show that estates, buildings, and machinery are in good order, and the estimates of crop and expenditure give promise of continued good results. The directors feel that great credit is due to Mr R C Grant, the manager, and Mr H A Grigg, the superintendent in Ceylon, for the way in which they have cultivated the estates and maintained the high quality of the tea during the past year.

THE TONACOMBE ESTATES COMPANY OF CEYLON, LIMITED.

REPORT OF THE DIRECTORS.

Authorised Capital R600,000
Subscribed and paid up 230,000

DIRECTORS :—Hon. Mr. J N Campbell, Messrs. G H Alston and R S Templer. Agents and Secretaries:—Messrs. Cumberbatch & Co. Estate Superintendent:—Mr V Vicaresso.

ACREAGE.

The acreage of Tonacombe Group is as follows:—

Tea in bearing	532	acres
Tea not in bearing	8	do
Tea seed bearers	3	do
-----		593 do
Cardamoms in bearing	98	do
Reserve Forest	24	do
Fuel Trees	20	do
Chena and Patna	1,142	do
Total		1,877 acres

The total quantity of tea secured for the year was 214,566 lb being 14,566 lb in excess of the estimate. This was sold at an average of 35-63 cents per lb, as against 37-84 cent per lb. last year. The cost of production was 25-84 cents per lb, as against 26-50 cents in 1901. The cardamom crop was disappointing, the quantity secured being only 6,308 lb. Of this 4,220 lb, have been sold at an average of R1-07 per lb., and the balance is estimated in the accounts to realise 75 cents per lb. In 1901 a net average of R1-48 was obtained. The total expenditure amounted to R69,931-07 and, as in the previous year, there has been no outlay on capital account on Tonacombe Group. The balance available, after providing for depreciation on buildings, and including R5,004-38 brought forward from last season's account, amounts to R23,296-51, and the Directors recommend the payment of a dividend for the year at the rate of 5 per cent on the paid up capital of the Company absorbing R14,000, the writing off of the balance standing to the debit of Buildings Account R5,654-06 and the carrying forward of R3,642-45. The Directors have pleasure in stating that the Debenture debt has been further reduced by £500 during the year. An opportunity arose towards the end of the year of acquiring the Kalugalla estate consisting of 146 acres of tea, and about 227 acres of patna, &c. The Directors being of opinion that the purchase of this estate would be to the advantage of the Company decided to acquire the property at a cost of R17,500. Financial arrangements necessitated the payment of the purchase money by the last day of December, 1902, and the estate was taken over on the 1st January, 1903. The Coast Advances on Tonacombe Group stand at R3,116-84 on 31st December, 1902, being a slight decrease on this account since the same date in 1901. To meet the requirements of Kalugalla the labour force on that estate was taken over, and R1,846-70 has been advanced to meet their debt. The crops for 1903 are estimated at 210,000 lb tea from Tonacombe Group; 56,000 lb tea

from Kalugalla Estate; 6,000 lb cardamoms, against an Expenditure of R85,498-70. The Hon Mr W H Figg resigned his seat on the Board on leaving the island, and Mr G H Alston was appointed in his place. Of the Directors the Hon Mr J N Campbell retires by rotation, but is eligible for re-election. The appointment of an Auditor for the current year will rest with the meeting.

COLOMBO COMMERCIAL COMPANY, LIMITED.

REPORT OF THE DIRECTORS

presented to the eighth general meeting on Tuesday, the 17th March, 1903:—

The Directors have pleasure in placing before shareholders the profit and loss account for the year ended 30th September, 1902. Balance sheet made up to 30th September, 1902.

The above accounts shew the following figures:—
Profit for the year after debiting all charges, interest on debentures, &c.. £ 7,999 11 7
Add balance brought forward from last year 2,023 13 5

£10,023 5 0
Less transferred to reserve fund .. 1,500 0 0

Amount available for dividend, &c. £8,523 5 0

Interim dividends, of 3 per cent. on the preference capital and 2½ per cent. on the ordinary capital were paid on the 15th September, 1902, and the Directors recommend that the following dividends be now declared, viz.:—3 per cent. on the preference capital, making 6 per cent. for the year, and 5½ per cent. on the ordinary capital, making 8 per cent. for the year, the latter free of income tax.

After payment of the above dividends there will remain a balance of £1,832 3s 0d, which the Directors propose should be carried forward to next year.

The liquid assets in Ceylon appear in the Company's accounts at the same exchange as in last year's balance-sheet, viz.:—1s 1d. per rupee.

The general reserve fund stands at £7,000, including the amount transferred in the present accounts.

Hatberleigh estate, one of the Company's tea properties, has been sold, and its cost has been deducted from the amount at which those assets were represented in the last balance sheet.

Mr. P C Oswald, a member of the Board, retires from office on this occasion, and, being eligible, offers himself for re-election.

Messrs. Deloitte, Dever, Griffiths & Co., the Auditors also offer themselves for re-election.

TEA IN NATAL.

PAST AND PRESENT.

(By "Planter.")

I was much struck with the article on the "Natal Tea Industry" by "Nemo," in your issue of the 26th ultimo. Wholesome criticism from those who have been connected with industries attempted in Natal will at least show those who have the conduct of these affairs that there is still room for improvement in their products, while the facilities of climate, labour, soil, and proximity to markets are nine-tenths as great as the countries whence the whole world has obtained its supply for a century.

No Indian or Ceylon tea-maker would accept the carelessly-picked leaves that are sent in from the field here, and the class of machinery will have to be very much improved, and looked after by experienced men, before Natal can approach the standard these other countries attained ten years ago. I do not mean to say that it will take ten years to attain

this standard—it need not take ten months—but both the field and the tea-house must be under the control of competent men, and your field will then produce more and your machines will turn out better quality. What "Nemo" has pointed out was patent to me when I came to Natal three years ago, and I have had the opportunity of comparing notes with the sons of brother planters from India and Ceylon who have been brought up on tea and coffee estates, and know their business thoroughly: and they have gone back with little fear of any competition from Natal while the present state of things lasts.

(To the Editor of the "Natal Mercury.")

Sir,—With "Nemo's" article on "Natal Tea," as a planter of long experience with one of the largest tea companies in Assam, I fully agree. Natal planters will not have an experienced Assam, Indian, or Ceylon planter on their estates as I found to my cost when I arrived, thinking that with long and up-to-date experience and first class references I should have no difficulty in obtaining a billet. I was offered the handsome salary of £8 per month! Having a trade to fall back upon, I preferred to work at it, rather than give my experience and knowledge for such pitiful competence. The methods of pruning and plucking, as described by 'Nemo,' would not be tolerated even on a native garden in Assam, and might well be described as murdering the bushes. To hack at a tea bush with the 'largest size pruning knife available' can only result in a large percentage of the 'new wood dying back,' and forming knots, which it should be every planter's object to do away with. Plucking eight leaves and a bud is absurd, as the lower end of the shoot will have formed 'wood' by the time eight leaves are out, and it is not usual to make tea out of wood, although, of course, it will make up the bulk, and help to swell the quantity. Tea, with the quantity of 'sticks' that most Natal teas show, would be almost unsaleable on the London market. I have before me some Natal tea, styled 'Pekoe'; it should be styled Pekoe Souchong, a much inferior grade. Pekoe should be a clean, whole-leaved tea, free from 'sticks' and red leaf, and with a few 'tips'; this is partly made up of sticks and red leaf, the balance being a broken and coarse Souchong leaf—it would not be considered on the London market even a fair Pekoe Souchong. 'Nemo' is quite right in stating that, by plucking two or three leaves and a bud, the quantity is not sacrificed; this has been proved by experience, and the old custom of plucking four or five leaves and a bud has long been discontinued by up-to-date planters.—I am, &c.

ASSAM PLANTER.

RETURN OF MR. T. FAIRHURST FROM THE STRAITS.

RUBBER TAPPING FROM PARA TREES.

We have have to welcome back Mr. T Fairhurst, the well-known proprietor of St. Andrew and Ferham estates, Dimbula, who arrived by the P. & O. "Valetta" yesterday after a visit of some weeks to the Straits. Mr. Fairhurst goes up to Ferham on Saturday and will leave for Europe in about a fortnight's time—probably by the Bibby ss. "Lancashire" on April 7th.

In a conversation with Mr. Fairhurst today we learn that he had been seeing a good deal of rubber in the Straits and was everywhere struck with the fine growth displayed. He had not, however, seen rubber growing in Ceylon and so could not institute comparisons. Mr. Fairhurst assisted at the tapping of a specimen Para tree which was 32 inches in circumference, 3 feet from the

ground, and 5½ years of age. The incision was made at a height of about 4 feet (the height of the first branch, we may mention, was nearer 7 feet!), in a V-shape, and the rubber latex flowed freely into the cup fixed at the foot of the V. Making the incision in this fashion, one gets the rubber to flow well and the cut does not dry up quickly. Another common method is the herring-boning, in which a long central cut is made, perpendicularly, and then parallel incisions are made sloping into the central one; but in this case the channels are found to be too small and numerous and to dry up too quickly. The ideal instrument for making the incisions has yet to be found and something of the nature of a chisel has been mostly used so far; the tool should be a sort of gouge that would be pulled rather than pressed along the line of incision, the sharp portion being just deep enough to pierce the bark (which shall pass under the knife blade as it is cut) and not injure the inner wood. There is another kind of chisel-knife, with a double handle which is pulled along in cutting the bark; from its make it requires less energy to handle. It is from the bark, of course, that the latex flows.

DOCTORING TREES.

A new method of feeding trees and plants without the agency of the roots has been discovered by the well-known entomologist M S A Mokrshezki, who has explained his discovery in a lecture before the Imperial Botanical Society. He has invented an apparatus by which he can introduce into the stems of apple and pear trees salts of iron, either in the form of a solid or in solution. The effect of the chemicals is, on the one hand, completely to cure the tree of chlorose and on the other, to stimulate its growth in an important degree. Among other extensive researches the scientist has applied his theory to 800 fruit trees growing on the southern shore of the Crimea. By introducing dry sulphate of copper into the stems he produced an unusual development of the trees, as many photographs testified. M Mokrshezki considers that in this way the size of a fruit tree can be increased, its colour improved and varied, and its diseases removed. The discovery opens up a wide field of practical utility, and is regarded as most important.—*Indian Daily News*, March 26.

RAINBOW TROUT IN CEYLON.

(To the Editor, *Indian Field*.)

SIR,—Can any of your Ceylon correspondents furnish information of the success or otherwise attending the introduction of "Rainbow Trout" into the Island? Up here in South Sylhet we have small streams admirably suited for trout of all kinds, and on the northern side of the valley there is a pretty little fellow running about 2 to 2½ lb; a true trout. The upper part of the body is light sepia coloured, the under silver, but where these hues blend into one another there are three, sometimes four, longitudinal streaks of bright blue spots; the upper part is also speckled but with darker spots than the back ground. It is a hand-

some fish generally found in bright pools: can you identify it? It will rise to the black fly but a spoon or anything bright or glittering is ignored. Is this the rainbow?

Mulvee, 9th March 1903.

—*Indian Field*, March 26.

PISCATOR.

FINE GROWTH OF PASPALUM GRASS.

An interesting record of Golden Crown grass (*Paspalum*) growth is contributed to the *Gosford Times* (New South Wales) by a correspondent, who writes:—"Off 30 square yards land under the above grass I took 150 lb. of dried hay (which would be nearly 11 tons per acre), being the second cutting this season, and will probably get as much from the third cutting. This piece of land has never been manured. What other grass is there in cultivation will do as much and then keep green all through the winter? Granting that this particular piece of land is well suited for it, say, that an average acre of land would produce 3 tons per cutting—3 cuttings per season, 9 tons—which any ordinary land about Gosford can do, why grow couch? Both grass and hay (chaffed) are well suited for the cattle, improving the milk and butter yield."—*Melbourne Leader* March 7.

MALARIA AND MOSQUITOES.

GOVERNMENT COMPETITION: BOMBAY PRESIDENCY.

Bombay, March 19.—In accordance with a recent Government Resolution requesting the Surgeon-General with the Government of Bombay to furnish detailed proposals to give effect to the wishes of the Government of India that measures should be organised by private enterprise for the prevention of the spread of malaria by mosquitoes, a statement on the subject is published in today's Government *Gazette* in which the Surgeon-General points that whilst all Civil Surgeons express their readiness to promote organisations for the destruction of mosquitoes, so far as their time and opportunities will allow, the majority report that the collection of funds for this purpose from Municipalities or private individuals is uncertain and that they cannot hope to arouse much interest in the matter on the part of the inhabitants. On consideration of the views expressed by the Surgeon-General, the Government of Bombay have decided to offer four prizes of R400, R300, R200 and R100, for a year's observation on the distribution and habits of mosquitoes in any of the towns and villages mentioned in the Surgeon-General's letter. The competition is not restricted to Government servants.—*Pioneer*, March 21

THE CAMPHORTREE IN HUNAN.

March 10.—Formosa, which has hitherto been the chief supplier of the world in regard to camphor, will soon have a great rival in Hunan province. The soil of Hunan has now been found to be well suited for the extensive cultivation of the camphor tree, and the inhabitants are enthusiastically planting it everywhere they can. A Ch'angsha, capital of Hunan, dispatch states that there are innumerable camphor trees several feet in diameter in the province and it is expected that with care the province will soon be able to export annually several thousand piculs of the stuff.—*N. C. Herald*, Mar. 12.

THE PASTEUR INSTITUTE, KASAUJI.

We have received the report of the Director of the Pasteur Institute at Kasauli for the second year ending 8th August, 1902 (Punjab Government Press: Lahore). There were 543 patients treated during the year, as compared with 321 in the first year. Of these 543 patients 215 were Europeans and 328 were natives. As regards the latter, Major Semple, the Director, remarks, "I believe every caste in India was represented;" and he apparently means every main Hindn caste, as well as Mussalmans, Sikhs and others. - This is the only loose statement in the Report; and in view of the prejudice against anti-rabic treatment still prevalent amongst the Indians it would be as well, we think, if in future Reports a list of actual castes and nationalities were given, as an object lesson. As regards results of the treatment there were only five failures (all native) or 0.92 per cent of persons treated. In addition, four patients (three Natives and one European) contracted hydrophobia within 15 days after the last inoculation, and two patients (both Natives) during treatment. The European referred to was a lady in a delicate state of health, severely bitten on the upper lip, nose and cheek, and who came late for treatment. The Report remarks:—"It cannot be too forcibly impressed upon persons bitten by rabid animals the very great importance of early treatment, especially if the bites are multiple, or severe, or situated on the head or face." This emphasises the need for another Institute in Southern India; and it is satisfactory to know that this will soon be an accomplished fact, thanks to the beneficence of Mr. Phipps. It should then be possible for every patient in India to come under treatment before the fifth day. The Report makes an urgent plea that the Railway Companies should grant free return passes for. While 436 of the cases last year were from dog bites and 99 from jackal bites, there were also five from horse bites and three from cat bites.—*M. Mail*, March 24.

A CAMPAIGN NEAR LAHORE.

Lahore, March 20.—Endeavours have been set afoot in the cities of Gujranwala and Gujrat to suppress malarial fever by an organised campaign against mosquitoes. Hollows in the ground have been filled up to prevent accumulation of stagnant water, and water-holes, drains and malarious spots treated with kerosine oil. Larger drains are being flushed with phenyle. Huge swarms of both full grown insects and *larvæ* are reported to have been destroyed.—*Pioneer*, March 22.

INDIAN COOLIES PROSPER IN TRINIDAD.

737 BRING £10,000 IN SAVINGS.

An extraordinary instance of the prosperity of Indian emigrants in suitable Colonies has just been furnished by a shipload of these people who returned to Calcutta on the 24th February by the steamer "Mersey" from Trinidad. There were 737 returning emigrants on board, and they landed bringing nearly £10,000 in drafts, coin and jewellery. State-regulated emigration to Trinidad has gone on now for upwards of half a century; and the carefully kept records disclose to fact that since 1851, when the first Indians began to come back, the returned emigrants have brought with

them saving to the value of £386,000 actually declared. This is, of course, merely what they have carried back on their persons and in their pockets, and takes no note of the large sums that are remitted to India as they are saved. It is unfortunate that the Indian cultivator and labourer cannot do in his own country what he does in Trinidad, Mauritius and Natal. But before he will turn high wages to good account it seems necessary that he should be transplanted away from his village, his caste folk and all the influences which conspire to keep him in the traditional rut. Remove him from these and start him in a new country, and from Coolie to Croesus it is but a step, or at any rate a matter of few years.—*Pioneer*, March 18.

NEW ZEALAND TROUT FISHERIES.

Captain G D Hamilton, president of the Hawke' Bay Angling and Shooting Club, writes as follows on some points raised in a recent *Times* article on the above subject:—

1st. The anglers in the colony are not a few persons, they are thousands. They are not a class, and are chiefly working men, who, when they care for the sport; can for a small fee, necessary to keep up the supply of fish, have a recreation for seven months of the year which relieves the monotony of their work-life and gives them a variety of food. In Scotland nearly the whole of the rivers are open to the trout-fisher. There are in thousands working men living near rivers, who take care that their sport is not destroyed by the trout poacher and netter. Anglers are not always amateurs in knowledge; some of them have more general knowledge of the habits of fish than any of the people employed about fish hatcheries. I fancy few of the experts, have much, if any, experience of fish or game in the countries from which they have been imported. The anglers serve the useful purpose of keeping up the interest in acclimatisation, which is otherwise apt to flag. Were it not for the anglers, I question if there would be trout in New Zealand waters now. All this has been done at the private expense of the acclimatisation societies and anglers, who have worked without pay. I turned out trout in the North Island about 1870. This enables the Government now to invite tourists' to enjoy the sport thus provided—a very commendable project for the benefit of hotel-keepers and others, and for utilising about one-third of the country too sterile for industrial occupation.

2nd. It is argued that, under proper restrictions, netting can be done without injury to the rivers and lakes. I am aware that netting has been sanctioned in lakes, and it has been under certain restrictions. Who has ever seen these restrictions carried out, or who is going to see them carried out if amended restrictions are passed? I predicted when netting was sanctioned in Lake Wakatipu that it would ruin the fishing of the district. The lake is now hardly worth netting. It is not a well-known fact that the sanctioning the netting of Lake Wakatipu for fish for sale has caused all the rivers running into it to be cleared of fish and the rivers and lakes to within seven miles of Dunedin and Invercargill to be poached for fish and sold in those towns as Lake Wakatipu trout? Rotorna is an instance of the same kind. Allowing occupiers of land to fish without a license will be found to be very troublesome, particularly in native districts. So far the Government has not been in a position to protect the rivers and lakes, which would entail a lot of supervision, quite out of the power of the police, even in easily accessible places, but of course they can help. It is a quarter or half a century too soon for legalised netting of fresh-water-going fish in this country. Except in a few rivers, the brown trout, bull trout, sea trout (salino trutta) and salmon are barely established. The sea-going trout travel round the coast, thus stocking rivers and lake

that have been considered too inaccessible so far to stock in the ordinary way. If netting for trout is legalised in salt or breakish water, this supply for stocking the rivers naturally with a large breed of trout will be much reduced, and the stocking of the whole country retarded. It is not possible to avoid taking trout occasionally when net fishing for other fish off the coast or in the estuaries, but it is possible to return a great many alive to the water, and it is better to try this with some failures. I have for the last few years returned more than three-fourths of the trout of all sizes I have caught on the rod to the water, and not one has failed to recover and swim away. Among these were seven-pound fish. I did not want them. It is quite common to overfish a stream without using nets. The rivers of this country have become celebrated for their large sea-run trout. This is because there has been no organised netting for trout in or about the estuaries or lower parts of the rivers. The sea-run trout (not salino trutta or salino salar) in some of the North of England and Scotch rivers are just as large and in great number, but the salmon nets prevent nearly all of them ascending the rivers until close time, when it is illegal to take them, and so many anglers hardly know of their existence. I have caught them in the Tweed (Scotland) up to eleven pounds, and have seen them caught twenty pounds weight in the same river. Lately I saw a trout of 39½ lb. had been taken with a salmon fly at the outlet of a Scotch lake. I am not quite a novice in net and sea fishing. I have been through it all from herring to cod.

More caution should be exercised in allowing insufficiently informed people to deal with these things. The introduction of the poorest of anything that can be called game—the rabbit and other pests—has ruined the game shooting of the whole country. Now we are having 'white fish' introduced to our lakes already stocked with trout. They can only be taken in nets, so that if they are to be taken at all the trout must be netted. It is quite a different thing to accept and make the best of these things, where Nature has placed them, and to introduce doubtful things to a country in which they are not indigenous. A much more valuable fish for the table than the 'white fish' and a freer riser than the brown or even rainbow trout, in lake or river connected with the sea, is the white trout (salino trutta), and much more likely to remain on our coasts than the salmon.—*New Zealand Mail*, March 4.

GIANT LAND-TORTOISES.

"In the long-past days when the plains of India were the home of the mighty sivatherium and of still more gigantic elephants and mastodons, while its rivers were tenanted by hippopotamuses and huge long-snouted, gavial-like crocodiles, that country was likewise inhabited," writes Mr. Lyddekker in *Knowledge* for March, "by the most gigantic land-tortoise of which we at present have any knowledge. When fragments of its fossilised shell and more or less nearly complete specimens of its limb-bone came under the notice of its original describers it was thought, indeed, that they indicated a creature of truly colossal proportions, the length of the shell in a straight line being estimated at no less than twelve feet three inches. In a restoration of the shell made under the superintendence of the discoverers of the species, and still exhibited in the geological department of the Natural History Museum, the length was reduced to a little over eight feet. But even these reduced dimensions appear to be considerably in excess of the reality and it is probable that the maximum length did not much exceed six feet. A shell

of this size vastly exceeds, however, that of any modern land-tortoise, so that the Sivath tortoise, or 'Testudo atlas,' as it is scientifically called, is fully entitled to rank as the real giant of its kind. . . . In modern times the islands most famous for these tortoises are those of the Galapagos group, which take their title from one of the Spanish names (galapago) for a tortoise, and are situated on the equator, a comparatively short distance off the western coast of South America. All the other 'tortoise-lands' are in the Indian Ocean, where they lie (with the exception of the lower extremity of Madagascar) within the southern tropic, off the African coast. . . . In the Aldabra tortoises the only member of the group surviving in a wild state in its native habitat is the South Aldabra 'Testudo daudini.' A male of this species, received by Mr. Rothschild in 1897, is the largest known example of modern giant tortoises, the length of the carapace in a straight line being no less than 55 inches, or only 19 inches short of the length assigned to that of the extinct *T. atlas*."

NILGIRI PLANTING NOTES.

TEA PLANTERS FROM ASSAM.

A group of estates near Colacumbay has just been sold to two tea planters from Assam. The properties consist of the Terramia, Pembroke and Carshalton estates, comprising about 600 acres of land, of which about 200 acres are under tea and 100 acres under coffee. It is said that the purchasers intend to open out all the uncultivated land in tea and make a big concern. It is significant that planters long resident in that well-known tea-producing District should leave it to settle on the Nilgiris, and one is inclined to seek the reason. It must be that the labour difficulty in Assam is preventive of any profits being made in these times where large advances have to be made to the coolies, R75 per head and even more, and where Government interference is so irksome. The planters here will no doubt hail the advent of these newcomers as they will be sure to carry out economical methods and keep down the rates of pay which have a tendency to rise of late years, and would undoubtedly run high but for the fall in prices.

NILGIRI TEA.

Nilgiri tea is noted for its peculiar aroma, is delicious when used alone, and is bought by dealers to make a blend with the coarser-tasting tea, grown at a lower elevation, to give it flavour. Some good sales have taken place lately, the average from one estate realising as much as 9d a pound, a very remunerative price if the yield is fair.

SALE OF THE MOYAR ESTATES.

The Moyar coffee estates belonging to Lady Souter have just been bought by Mr E G Windle at a figure indicative of the low prices.—*Madras Mail*, March 28.

GREEN TEA MACHINERY AND MANUFACTURE.

(To the Editor, "*Indian Planters' Gazette*.")

SIR,—I thank you for your complimentary mention of my name (on page 272 of your issue of 21st February) in *re* the bringing about of what promises to be a solution of the problem of over-production of "black teas."...I now claim that we have solved the problem of Panning and Finish-

ing by machinery—the mere finishing by friction being an old and well known process often used in America and Java, but this though it gave the appearance, did not give the flavour or keeping qualities of the panned article. “Black tea” prices are up, thank goodness, but to keep them so, it should be the endeavour of every company to foster and promote the manufacture of “True” Green teas on such gardens as, owing to forcing climate and heavy flushes, cannot hope to stand out for special *strength* and *flavour* as Black teas. If India can dispose of ten to fifteen millions of Greens, and Ceylon a like amount, at remunerative prices, so surely will a better day dawn for Tea Companies and Proprietors. In conclusion I may state that the only two points, in which India, at any rate, is behind China and Japan, are firstly the rolling of “gunpowders,” which is affected in China by foot-rolling in bags, and secondly the “polishing” of coloured teas, which in China and Japan is done with “soap stone,” both these processes we hope and intend to adapt existing machinery to with but slight alteration.—I am Sir, Yours faithfully,

HORACE DRUMMOND DEANE.

Stagbrook, Peermaad, S. India, 16th March, 1903.

P. S.—Owing to complications of a business nature, by which my crops were hypothecated to London, I have had to abstain from making Green Teas on a large scale. These troubles, through the courtesy of my London Agents, Messrs. Rowe White & Co., are now removed, and I hope from July next to have a full installation of green tea machinery at work, including a novelty in boilers of the “Flash light” type, that are not only extremely portable but expensive, costing about £25 f.o.b. This is a most important item in the expense of an installation, to such Estates as have not “Steam power” as their motor.—*Indian Planters' Gazette*, March 28.

CONDENSED EGGS.

When condensed milk was introduced it was looked upon as a curiosity by the public, but it has become a staple article of food now, and milk factories exist in the agricultural districts for collecting the milk from the farms and condensing it at once; by this means much of the prejudice against condensed milk has been overcome. Eggs are used in enormous numbers in this country, and somewhere about £7,000,000 represents the annual value of eggs imported into Great Britain. When an abundance of eggs can be procured in the summer they quickly go wrong and many methods have been suggested for preserving them, but these all entail some trouble and small expense, and the public do not care for preserved eggs. For some years now eggs have been deprived of their shells and a preservative added, liquid egg is an article of commerce for manufacturers, but hardly suitable for domestic use. The Condensed Egg Syndicate, Limited, have, however, overcome the difficulties which beset the question of preserving eggs, and supply egg in a condensed form mixed with sugar as a preservative. We have examined the product, and find it contains all the constituents of ordinary fowls' eggs, and further, we are able to state that it is in an excellent state of preservation, and free from organisms which would induce decomposition in keeping. The product is about the consistence of

treacle, and is supplied in hermetically-sealed glass jars. Like condensed milk, it will remain good as long as it is unopened, but when once opened it should not be closed up again. Three forms of the preparation can be had for domestic purposes—(1) the entire contents of the egg; (2) the yolks only; (3) the whites only; and the uses of these are as unlimited as those of fresh eggs. For pharmaceutical purposes condensed egg and extract of malt ought to find a ready sale to replace the preparations with cod-liver oil for patients who cannot take the latter. In the preparation of emulsions the condensed yolk ought to find a wide field of usefulness. Emulsions of petroleum, hypophosphites and egg, or cod-liver oil and egg, would be useful adjuncts for retailers; while, for prescribing purposes, equal parts of port wine and an entire egg should be of especial value to invalids when given in suitable quantity. A tablespoonful of the condensed egg represents one entire fresh egg, and it can be used without any doubt of its freshness or soundness.—*British and Colonial Druggist*, March 6.

INDIAN COMPANIES AND GREEN TEA.

We note from the accounts of the North-Western Cachar Tea Company now published that green tea did pretty well for the Company last year. Out of a total of 318 645 lb. of tea manufactured, the proceeds of which totalled R89,416, the amount of green tea made was 145,108 lb. producing R44,936 and black 173,537 lbs. producing R44,480. The average price of green tea in the above account works out to 4 annas 1½ pies per lb. against 4 annas 1¼ pie per lb. for black. Another Company which shows good results from having undertaken the manufacture of green tea last year is the Manabarie Tea Company. Out of a total of 247,944 lb. manufactured, 195,633 lb. of green tea were made, 182,522 lb. of which were sold in Calcutta, producing R59,790; and 13,111 lb., were sold in London, producing £403. The average works out about 5 annas 3 pies for the Calcutta, sold green tea and 7½d for the green tea sold in London, against 6½d per lb. for the black tea sold by the Company.—*Indian Planting and Gardening*, March 28.

THE BAOBAB TREE IN UGANDA.

It seems a pity that so far no practical use has been found for the baobab tree, beyond the conversion of its fruit shells into calabashes by the natives. The wood of its stem is said to possess qualities suitable for the manufacture of paper, so possibly this, together with the undoubtedly large supply of rags obtainable from the natives, will one day form a nucleus for the material required by a local paper manufactory. The consumption of paper in East Africa must already be very considerable, and is constantly increasing.—*African Standard*, March 10th.

VICTORIA REGIA IN NATAL.—The water plant in the Durban Botanic Gardens is now in four buds, and the first bud is expected to open on Sunday or Monday—the first event of the kind in South Africa. The flowers last only one day.—*Natal Mercury*, March 7.

PRODUCE AND PLANTING.

INSURANCE OF TEA CROPS.

An interesting and important departure is, we understand, being made in connection with the insurance of the new season's Indian tea crop. The risk of damage from the time the tea is plucked until arrival in the United Kingdom has always been readily undertaken by marine underwriters at reasonable rates, but injury to the leaf before plucking, from whatever cause, has had to be borne by the planter. Hail storms are amongst the worst enemies which threaten the growing crops, and extensive damage can be done by a visitation of this nature. Cases are on record where over 20 per cent of a whole crop has been destroyed in a few minutes, and instances of damage amounting to 10 per cent. are legion. So urgent has the matter become that the Tea Association, having been appealed to, took steps with a view to find a workable basis for the insurance of the risk. It circularised the trade asking for statistics to enable a comparison to be made between total outturn and losses due to hail, and the immediate response of a large section sufficiently indicated their appreciation of the importance of the matter. A number of concerns, however, had to refer to Calcutta, as the required figures were not available in London; meantime, the statistics which had been secured covered sufficient ground to enable inquiries to be made in the insurance world, with the result that a favourable rate of premium has been obtained with a workable clause to govern the assessment of losses. We should imagine the industry will largely avail itself of the new facilities, especially as the statistics of losses due to hail prove without any doubt that no district or garden can consider itself safe from a visitation, whatever may have been its experience in the past; the figures show that the longer the immunity the greater the disaster when it arrives. Under such circumstances no prudent planter can afford to ignore such an opportunity to replace, in his calculation, the very real risk of a calamity with a reasonable annual charge in the form of an insurance premium. The rate is of necessity experimental to some extent, but should experience show it to be too high, competition will no doubt afford a ready and effective remedy. In any case the Tea Association, by its efforts which have led to the establishment of insurance facilities, has earned the thanks of the tea-producing industry.

MARKET VALUE OF TEA SHARES.

From the following figures, compiled, as usual, by Mr George Seton, of the Indian Tea Share Exchange, 120, Bishopsgate Street, E.C., it will be seen, says the "Financial Times," that the market value of the shares of the forty five representative companies has again advanced to a moderate extent. With one or two exceptions, the advance has been "all along the line":—

Face value of 45 companies' shares	9,500,000
Market value July 1, 1897 (top point)	12,000,000
Do Jan. 1, 1902	7,000,000
Do Sept. 1, 1902 (lowest point)	6,050,000
Do Jan. 1, 1903	6,600,000
Do Feb. 1, 1903	6,800,000
Do Mar. 1, 1903	7,000,000

So that the recovery has been just to about the level of the beginning of 1902. As the grand total of the share and debenture capital of the one hundred and seventy tea companies registered, with sterling capital, in the United Kingdom (exclusive of private-owned estates and companies registered, with rupee capital, in India and Ceylon amounts to about £19,000,000, the fluctuations of the entire volume, based on the above figures, may be thus roughly estimated:—

Face value of (about) 170 companies	..	19,000,000
Highest market value, July 1, 1897	..	24,000,000
Lowest market value, Sept. 1, 1902	..	12,100,000
Present market value, Mar. 1, 1903	..	14,000,000

This shows a rise in value from the lowest point of nearly 16 per cent, but there is still a depreciation from the highest point of nearly 42 per cent, or, taking 100 as representing the top value, the lowest level would be represented by just over 50 and the present level by 53.

Notwithstanding the present rather uncertain outlook as regards dividends for the producing year 1902, Mr Seton considers that, with the restoration, or partial restoration, of public confidence in the stability of the industry, a further moderate hardening of values is to be expected. It may be noted, however, that the better prices now ruling in Mincing Lane, coming, as they have done, late in the selling season, are just barely compensating for the very low prices at which the first half or two-thirds of the crops were sold during the summer and autumn of last year.

The following letter appeared in the *Produce Markets Review* of February 28, and was signed "Home Tea Trade." This correspondent wrote: "It seems to me that

THE TEA POSITION, FROM THE DEALERS' POINT OF VIEW,

is left entirely without an exponent. In the trade and daily papers we have constantly brought before us the importers' and growers' side of the question in the reports emanating from such brokers' firms, and their policy at present seems to be to write so as to foster the idea of an advancing market. To do this they have to introduce statistics which may be very interesting and instructive, but which should have very little real bearing upon the condition of the market in London. Some two or three years since these same firms were asserting that the accumulated over-production of the previous year amounted to fifty million pounds, and, seeing that the present stocks in bond are, if anything, larger than they were at that time, it is at least doubtful if that overplus has been worked off, and when it is remembered that there is sufficient tea in bond—let alone duty-paid stocks in the country—to supply about five months' consumption, it seems very reasonable to suppose that production is still outstripping consumption. At any rate, it will be pretty generally admitted that five months' stock of tea is quite an unnecessary amount to carry, having regard to the heavy supplies reaching us month by month all through the year, and bearing in mind the fact that much of the tea deteriorates rapidly after reaching this country. A five month's stock must mean that much of the tea becomes eight or nine months old before being used, it will lie for several weeks in the distributors' hands after leaving bond. Values have been forced upwards by a sort of cornering process described as regulating the supply, presumably with the object of enabling dividends to be paid on the capitals of the tea-growing companies, and advantage is being taken of a rather poor season to try and make out that at last consumption has overtaken production, but the asserted smaller production of this season over last seems quite problematical; and, given favourable conditions in the coming season, there will again be an enormously increased outturn, as it appears from the reports of the various companies that no determination has been reached to reduce the area under cultivation, and in some cases mention is made of increased plantations coming into bearing this season. With an expectation of more tea to sell it is probably bad policy on the part of producing interests to push the price of lowest teas upwards, as with common tea about six pence per pound the retailers will soon abolish their shilling canister, which will mean materially reduced consumption, as poor people will buy one ounce for a penny instead of two ounces for three halfpence; also, dear common tea has the effect of bringing down the values of medium tea through the blender being unable to use the higher cost teas so freely in his lower-priced blends. Also, of course, he uses China

teas to the exclusion of Indian and Ceylon, so that it seems as if it would be more to the advantage of the grower to retain the larger consumption by keeping down the price, and to seek for profit in reduced cost of production and the other heavy charges which tea has to pay. That low-priced teas can be made remunerative to the grower appears to be a fact, as some estates, with the lowest average price per lb., are able to pay dividends."

U. S. A. NATIONAL TEA ASSOCIATION.

A New York paper says, apropos the tea trade of the United States: "Nearly two hundred members of the tea trade have consented to become charter members of the proposed national tea association, which will probably take shape in the early spring, but unless this federal organisation can reach down to the extreme fringe of the business and control the actions of the retail cutters who have a weakness of cheap tea, with an 'inducement' thrown in, the tea puddle will hardly be disturbed by any ripple the national association can cause. It is 'getting together' that the tea trade needs so much as an active competition between packers of fine blends, assisted by extensive and expensive advertising. It is 'up to' any wholesale of retail grocer with fair capital to be the tea trade's Moses and lead it out of the house of bondage—the bondage to 'tea for price,' with trading stamps, a cup and saucer, 3½ lb. of sugar thrown in. Who'll be the trade's Moses? Not Uncle Sam, with his tea standards and board of inspectors; not the blender of 'something just as good,' not the tea-store chain-system, with its cut prices and very ordinary goods; not the tea peddler who goes from house to house; not 'Lancelot not another,' but just the plain old-fashioned family grocer, who has the wit to see the possibilities in the tea department when it is properly developed and pushed."—*H. and C. Mail*, March 13.

TROPICAL PRODUCTS IN JAVA.

In the districts around Batavia, coffee-planting is on the down-grade owing to low prices, disease among the plants, and exhaustion of the soil. Should prices continue to be low for the next few years, very few estates will be left to profit by any considerable rise in quotations. Tea-growing has met with a check owing to low prices and over-production. Rubber-growing is extending there, and bids fair to prove profitable.—*Perak Pioneer*, March 24.

THE MANUFACTURE OF GREEN TEA.

(To the Editor, "*Home and Colonial Mail*.")

Sir,—With reference to the manufacture of green tea in India and Ceylon, it appears to me important to consider how this can be made self-supporting at as early a date as possible, so as to relieve those gardens which are making black tea of the necessity of aiding, by bonus, those engaged in exploiting this new manufacture. It will no doubt be necessary for a few years to help those planters who are willing to undertake the manufacture and exploiting of this article, for the capital required to properly alter existing factories and equip the same for the scientific production of green tea must be considerable. There are two methods of distributing this bonus:—

1. Indiscriminately to any factory which makes experimental or small quantities.
2. To bind the planter to produce a season's crop and ensure to him the bounty on a given quantity.

The first we may dismiss at once, for it will only encourage amateur and spasmodic efforts which will waste money, and it will not give sufficient continuity of supply to ensure confidence amongst

buyers. The second is the only practical way, for the planter will then study the question of manufacture, and also the markets, &c., and this should enable him in time to build up a sound business in green tea of British growth, independent of bonuses and outside help.—Yours faithfully,
EXPORT.

London, March 12, 1903.

—*H. and C. Mail*, March 13.

PLANTING LABOUR ON THE NILGIRIS.

(To the Editor, "*Madras Mail*.")

SIR.—Sometime back a meeting of the planters in this District was called to talk over the local labour conditions. It was then decided that the rate was in future to be cut down from four annas per day per man cooly to five days for the rupee. One would have thought that this was a blessing to the planter, but it has by no means been so, and the only people we have to thank for the present state of things are ourselves. Before we cut down the rates for labour the coolies used to come to the estates from their villages between 8.30 and 9.30 a.m. and do a fair day's work. But of late it has been getting later and later, and only last week I saw a gang going down to work at 10.45 a.m. Now, these coolies could not have started work till 11 o'clock at the earliest, and they leave off at 5 p.m., making six hours per day or 30 hours work per rupee at present rates. Under the old rates when they came at 9 they did eight hours per day or 32 hours per rupee. But the loss of two hours is not the greatest loss. When we have crop coming in it takes us now 5½ days to do the same amount of work that under the old system we got done in four days. Not very long ago I happened to see a case of this cut-throat policy going on. Some coolies arrived at 10.15, but the manager, who is trying to get back to the old time of 9 o'clock, refused to give the coolies work. They straightway went on to the next estate and were given work, although they could not possibly have arrived there before 10.30. The estate that had refused the labour has now got to take them at their own time or they go. If they are refused they only have to go on to one of the surrounding estates and are sure of being taken on.

BERRY.

Kil Kotagiri.—*M Mail*, March 31,

KANAN DEVAN HILLS.—The most complete, up-to-date and interesting account of this favoured district in North Travancore appears in a recent "*Pioneer*" and is given on page 743. Everything promises well and good returns are expected; only the mono-rail tramway is not quite the success hoped for.

THE OLIVE IN SOUTH AUSTRALIA.—From a report just published, we learn that the cultivation is much in favour, the climatic conditions, nature of the soil, and the introduction of the best varieties, all tending to the success of a highly remunerative industry—of the production of fruit and oil of the best quality. The number of trees returned for 1902 is 66,852, against 61,740 in the preceding year.—*Gardeners' Chronicle*, March 21.

GEORGE WHITE & CO'S ANNUAL TEA REPORT.

(Extracted.)

London, 31, Fenchurch Street, E C, March, 1903.

When just a year ago we ventured in our Annual Report to dwell on the gradually improving prospects, it seemed scarcely possible that the hope then put forward of better times could be so quickly realised. As it is, owing to a variety of causes, some of which could not have been foreseen, the tea trade has within the last few months attained a measure of health and general soundness on which it may well be congratulated. The Clearing House dispute which arose in September for some time demoralised the trade, and no doubt retarded the development of the situation. On the other hand, had it not then occurred, more of the crop would have been quitted on the lower level of value, as during the dispute every day was adding to the strength of the position, owing to the reception of confirmatory cables of the shortage and the eventual result was combined action on the part of sellers. The chief causes of the altered situation are to be found, first in the crop falling far short of expectations, and secondly in the marked expansion in the demand for the British-grown article, especially in America, Canada and Russia, and also in less degree, to the displacing of black by green tea particularly in Ceylon.

CEYLON.

Participates with India in the greatly improved position above referred to. Similar agencies have been at work, viz.:—a stationary output and largely increased shipments to markets other than the United Kingdom, together with a very appreciable displacement of black by green tea. In both cases the recent removal of the import tax in America has had a very stimulating effect on business with that country. Quality.—Has been a good average, if not quite reaching the unusual excellence of the preceding year. Really fine high-grown tea has throughout been comparatively scarce and where the standard was fully maintained good prices resulted; on the other hand when it has just been missed the shrinkage in value even in well known marks has been very apparent, as buyers when dealing in high cost tea are extremely sensitive. It is satisfactory to note that really low common, no doubt largely due to the increased manufacture of green tea in the lower districts, has again been practically eliminated from shipments to London and the supply in the inferior grades has, on the whole, been of a useful description. Possibly it is in a measure owing to this that the difference in value looked for between tea grown on the higher and lower levels has often been disappointing to owners of the former, who have not the advantage of a large output per acre.

STATISTICAL POSITION.—Although during 1902 there was a falling off in the deliveries of some 7 million lb, partially accounted for by the reduced imports, the stock of 19½ millions on 31st December as against 68½ Indian shows the situation as relatively stronger. Shipments to United Kingdom for the past year totalled 103½ millions, or a decrease of nearly 3½ compared with 1901, while the estimate for the current season is only 96 million lb.

For the twelve months the following on Estate Account passed the hammer in London:—

1902.	1901.	1900.
1,012,100 pkgs.	1,059,800 pkgs.	1,125,100 pkgs.
(Av. 6½d per lb.)	(Av. 7d per lb.)	(Av. 7½d per lb.)

PROSPECTS.

With the steady progress that is being made in all consuming countries the necessity of keeping supply from outstripping consumption appears to be the one thing needful to ensure a continuance of the brighter outlook now before us, and on looking back at the crops under reference it is a good omen to see, that judging from the average quality, there would appear to have been a praiseworthy disposition not to sacrifice the success achieved when our last Annual was issued, and we would venture to refer to the exhaustive remarks then made on this important subject. Formerly a somewhat curious phase of the industry has apparently been that no sooner had a better position been built up than every possible means were taken to demolish it, for instance, a remunerative price for common tea being the general signal for indiscriminate plucking, the obvious result being an eventual slump in values. "Climatic causes" have once again proved to be a trusty friend in disguise, as, to judge from unofficial estimates of the crop put forward in some quarters last spring, had the season been more favourable for flushing, our congratulations today would be more modified. We do not suggest that growers would have again fallen into the fatal and long felt error of 1900, when prudence was cast to the winds, and aided in that instance by the weather, the competition to produce quantity at any cost, resulted in a crop out of all proportion to requirements and upset for a long while the important relations of supply and demand. The danger cannot be said to have altogether passed and we would urge upon those interested in the industry to adopt such a policy that the measure of prosperity now attained may be in no fear of being dissipated. The outlook is undoubtedly one of great promise and the temptation to mar it by a system of coarse plucking is bound to have its attractions. We cannot conclude this subject better than by saying "Remember 1900." In this relation the labour question has become a most important factor when considering the contingency of an unduly large crop, as even given the rare experience of a weather being favourable throughout all the districts to abnormally free growth, it is impossible to take the leaf without a correspondingly increased force of coolies, and this, under existing conditions, is apparently not available. These remarks more especially refer to India, but Ceylon is not exempt from troubles in this direction.

MANUFACTURE.

Instead of any endeavour being made to suit a perhaps momentary feature of the demand, which may have disappeared ere the Tea made to meet it has been shipped, we commend each garden to adopt the system which has been found best suited to its soil and surroundings, and so afford a varied supply, rather than all following a general policy, be it that of coarse, medium, or fine plucking. On the average of seasons this will be found to give the best result. Uniformity in leaf and liquor is to be aimed at, as buyers will always then follow a mark to its advantage.

GREEN TEA.

Production a year ago was in its infancy, but so rapid has been its growth, stimulated by the cess, that Ceylon estimates to displace black tea during the current year to an extent of no less than over 12 million lb. India is also making marked progress in this direction and will add an appreciable quota. These teas are being freely introduced in Canada and the States whilst Home dealers also, in many cases, find them suitable to their requirements. Those "finished" in the new style are particularly liked and owing to their cheapness compared with China kinds are receiving more attention; the producing of this style of Indian and Ceylon Green is, however, practically only in an experimental stage and has great possibilities in the future. Various machines are being tried, one recently brought out in Calcutta being specially well spoken of.

GEO. WHITE & Co., Tea Brokers.

INDIAN TEA.

(CARRITT MORAN & CO.'S INDIAN TEA MARKET
REVIEW, SEASON 1902-1903.)

Calcutta, April 1903.—Season 1902-1903 has closed with an actual crop through Calcutta and Chittagong of 175 millions, of which shipments to the United Kingdom have totalled 145½ millions, the corresponding figures for last year were 174½ and 153 millions, respectively. The quantity sold on the Calcutta market totalled 47½ millions or 27½% of the crop.

QUALITY.

In respect of quality the crop has been barely up to average standard, and taken all round has not been equal to that of last year. Assams have, in some measure, been disappointing, at no period during the season have they stood above ordinary average quality, and like last year the supply of good, autumn teas has been small. Cachars & Sylhets have, as a rule, been good, Terais fair, and Darjeelings, with the usual exceptions, have been attractive. Doonars teas in the early months were plain and somewhat indifferent, but towards the close of the rains they rapidly improved, and this district was fortunate in producing a particularly good autumn crop which commenced early and was consistently desirable until the close.

From Southern India supplies have again found their way to this market in small quantities; the offerings throughout the season have totalled two thousand packages, which have realised an average of about 5½ annas. The teas have been well-received, considering that they are strangers to this market, and also that growers have not yet had time or opportunity to study the particular requirements of the trade here, and produce such types as would secure for them a price that would be really indicative of the full benefit to be derived on this market, where freight and charges are so much lower than they have been accustomed to pay.

MANUFACTURE.

The system of manufacture, in Travancore more especially, seems to be chiefly directed towards cup character, in which a colory liquor is apparently the desideratum, and aimed for consequently at much expense of style and appearance. London having hitherto been the exclusive market, this tendency is explained and the teas are doubtless right for that centre. In Calcutta, however, much importance is attached to make and shape, and generally stylish appearance in teas of the same level of value, and Travancore teas could undoubtedly be made a great deal more attractive than they are with some slight deviation from the present recognised system of withering and rolling and particularly in respect of sorting also, which requires more careful and thorough manipulation. With these improvements there is no doubt that the Eastern market, with its variety of interests, would give a fair return to producers, provided the supply became regular and consistent.

The industry has again been perhaps more fortunate than circumspect in producing a moderate crop; like last year the weather has played an all-important part in levelling down supplies, and although it cannot be said that there has been any positive tendency to increase the supply at the expense of a quality, the impression nevertheless is that the real check is explained by

ADVERSE CLIMATIC CONDITIONS.

The effects of weather as affecting supply have been phenomenal; the cold season set in early, and at the same time so earnestly that a few days sufficed to upset all calculations, and a continued shortage became evident as the season grew older. The local market responded immediately to the altered conditions and prices advanced appreciably and steadily from sale to sale. London, however, was slow to recognise the changed aspect; it eventually broke away from its dead level of value, but only for a time, and in spite of a heavy shortage in supply, not only from here but also from other countries of production, it again set back. The sullen and sensitive tone which existed in the home market for many weeks, difficulty in moving up values, and a non-responsive trade generally must at the time have been a great disappointment to sellers and productive of serious reflection on their part.

THE RELATIONS BETWEEN BUYERS AND SELLERS in London in the latter months have never been so pregnant with suppressed antagonism as indications seemed to portray, and in this was probably seen the inconsistency of the position of the home trade. Sellers, however, have since had the balance all in their favour, they have seen their opportunity to force the market and have taken advantage of a position which though new to them, was assured and justifiable. They have had to carry the stocks but it has paid them to do so, and it has been no burden to them. Buyers have retaliated by holding aloof and relying upon hand to mouth dealings to see them through, but it could not last long enough and they were unable to keep pace with consumption.

At the close of the twelve months therefore the producer finds his position strengthened very considerably, but it should be recognised as the outcome of a short yield and a still further deficient supply, so far as London is concerned, owing to the increased offtake in Calcutta by new markets. These are the factors that have formed the backbone of the sellers' position, enabling them to carefully nurse the home market in a way that has not hitherto been experienced in the trade, and with results so satisfactory to themselves. To producers, the season, though full of encouragement at the close, has again shown disappointing results. The position on their side is undoubtedly stronger and a brighter future is before them, and it is not difficult at present for them to appreciate both, seeing that the recent recovery in prices has imparted financial encouragement to some slight degree. They have, however, been handicapped by climatic influences which have cut down yield and the advance in value has been long delayed.

THE PRODUCERS' POSITION.

That they have done much to improve their position cannot be denied, the improvement though acquired is not yet fully apparent but will certainly take substantial form in the near future. In the meantime the history of Indian Tea for the past two seasons affords much for contemplation on the part of the grower. On a two years' comparison he will recognise that the supply of the United Kingdom has been about right, that market having stood two consecutive short crops without disturbing the average value to any great extent; at the moment demand and supply at home

are running almost abreast and on the same reckoning he will realise how sensitive and easily affected by supply and the handling of it, the value of tea in London is likely to be during the ensuing season. It leaves a very small margin to allow for increased production without disturbing value, and if exports to the United Kingdom show at any time only a moderate increase even, it will probably be immediately reflected in prices.

Although the crop this year has been short of estimates and expectations the supply has been sufficient. The total outturn was actually in excess of last year; had this excess gone to London the position there would have been one of extreme anxiety; outside markets, however, saved the situation, for they not only absorbed the increase through Calcutta but a great deal more, and their worth has never been brought home to the producer so strikingly as during the past season. The quantity diverted from the London Market through these channels has played a much more important part in determining the value of tea than inclement weather or any other factor affecting supply, and although these demands are at last being recognised, they do not receive the full consideration they justly deserve, as the only real and sound means of securing the industry in every way from the evils attending a full or abundant yield and of permanently raising value. The history of the past season's trade with countries other than the United Kingdom is extremely satisfactory; it is indicative of continued perseverance and energy by those engaged in the trade who are to be congratulated on the success achieved.

LOCAL MARKET AND DIRECT SUPPLY ABROAD.

The supply placed on the local market for disposal in 1901-1902, shewed a very marked decrease on previous figures, and consistently, Indian Tea lost much ground in the markets of the world outside London. Last year, however, Calcutta received a somewhat larger proportion of the crop, the increase was small, but it gave these markets the opportunity to recover lost ground and new ones to come in also; they responded at once to a more liberal supply and not only have they now regained their absorbing powers of 1900-1901, but they have gone further, and during the past year their accumulated strength has been the brightest feature of the season's retrospect.

As before remarked, the persistent expansion of these valuable outlets should be recognised as the safety valve and governor of the industry. They have unquestionably prevented a state of stagnation in the home market, and the movement towards a higher level of value this year can only be attributed to their dealings, for without their increased offtake, the crop, though short, would have been quite enough to make it impossible to raise prices.

The progress made in the twelve months necessitates an extension of last year's figures and comparison with those of Ceylon, which will once more substantiate the assertion, that the more reasonably liberal the supply to this market, the more will our fresh outlets expand and afford relief to London.

INDIA.

	Total Crop. millions	Offered in	Shipped to
		Local Market. millions	outside Markets. millions
1902	.. 175	47½	29½
1901	.. 174½	46½	20½
1900	.. 187½	50	25
1899	.. 174½	50	22
1898	.. 153	49	17½
1897	.. 148½	46	13
1896	.. 135½	47½	13

CEYLON.

	Total Crop. millions.	Offered in	Shipped
		Local Market. millions.	to outside Markets. millions.
1902	... 149	51	45½
1901	.. 146½	51	40
1900	.. 148½	48	34½
1899	.. 130	38½	25½
1898	.. 119½	36	23½
1897	.. 116	33½	17
1896	.. 108	32	14½

A careful comparison of the above figures for seven years will show how consistently the offtake of Indians by outside markets has followed and been governed by the irregular offerings in Calcutta, and in the case of Colombo how carefully their corresponding demands have been fed and fostered in the local market from year to year; this will go some way to explain her present figures which are so much better than ours, but her geographical position has much to do with her success.

DISTRIBUTION OF THE CROP.

The following figures show the distribution of the crop from Calcutta and Chittagong compared with recent years:—

	1902- 1903.	1901- 1902.	1900- 1901.	1899- 1900.
	millis.	millis.	millis.	millis.
To United Kingdom	145½	153	161	149½
„ Colonies	5½	8½	10½	8½
„ America	9½	2½	4½	6
„ Other outside markets	14½	10	10	7½

These show excellent progress, except in the Colonies, where there has been much depression in trade generally. In respect of tea, business there has been sadly disorganised by drought and the uncertainty in regard to the settlement of duty, and imports of all tea last year fell off to a very serious extent; latest advices, however, are satisfactory. They report a recovering trade and an improving market, and a very much better state of affairs with a larger offtake may be confidently anticipated during the ensuing season. The figures for America are particularly good, but the most noteworthy increase has taken place in our trade with Russia. This demand is not a new one for Indian tea, but it is new to this market and the transfer from London of a very large portion of these interests is the most welcome and satisfactory feature of our dealings with foreign markets. The quantity she has taken has been very considerable and she has been a more reliable and consistent customer than the Colonies.

In detailing outside market figures it must be noted that a fair quantity of tea is actually destined for these ports in Chittagong shipments; though definite information cannot be ascertained at this end, enquiries on the home side make

it probable that between 1½ and 2 millions have to be thus accounted for which will further improve the foregoing figures. At the same time it is probable that a certain quantity eventually finds its way to London where it has possibly been intercepted on its way elsewhere.

The following figures show the ratio between exports to foreign markets from Calcutta and sales on the local market. The total is 62½ per cent of the offerings compared with 44½ last year.

	1902-1903.	1901-1902.	1900-1901.	1899-1900.
	mills.	mills.	mills.	mills.
of Calcutta sales ..	47½	46½	49½	50
Shipments to Colonies ..	12	18½	21½	16½
Shipments to America ..	19½	4½	9	12
Shipments to other markets	30½	21½	20	15½

GREEN TEAS.

The past year has seen a definite start made in the manufacture of green teas and in respect of value these types have, as a rule, compared favourably with ordinary blacks from the same garden. A fair quantity has been made, totalling about 1½ million pounds, and in the Calcutta market ¾ million pounds have changed hands at an average of 5½ annas per pound. Consistent and regular supplies have been received from the following gardens:

—Manabarric, Moheema, North-Western Cachar, Longview and Kolbong, and occasional invoices have come forward from Holta and East India (Cachar); in addition to these sundry lots of a tentative nature have been seen but they have been of no service for gauging comparative values of greens against blacks, the breaks having been small, in many cases single chests or half-chests only. As a test of style and character they have however been useful, but in regard to price, to obtain a true comparison of probable results of manufacture of each type, it is necessary to conduct the trial on market lines and put fair-sized breaks before the trade.

The class of green tea chiefly produced has been the unfinished type, which has met a ready demand for certain outlets. But in this state other markets that required finished types have not had opportunity to interest themselves, a few small lots only having appeared spontaneously, but these have also been good and have been well spoken of in the terminal market. The process of converting the unfinished into pure finished types has now been introduced and has proved successful; it is simple and effective and the finishing is done at small extra cost. During the ensuing season arrangements will probably be made for finishing teas in Calcutta, which can be availed of either by sellers or buyers.

The duty question has once more formed the subject of an appeal to the Home Government, and the Tea Association have asked the powers on this side to use their influence in support. Twelve months ago the industry was disturbed to some extent in expectation of the possibility of an increased impost, which happily did not occur; this year anticipated legislation has also had some effect on the markets, but in a different direction, dealings for some time past having been controlled by the prospect of a reduction in duty which is generally considered reasonable and fair. The Indian Tea Association are to be congratulated on the success they have achieved in the direction of instituting a compulsory tax on all exports, similar to that which has been in existence in Ceylon since 1893.

There are many ways in which the object of the bill can be attained, all of which, it may be assured, will receive the careful attention of the special Committee to be appointed to deal with the funds; one of the most important, however, is in connection with the manufacture of green tea, and the opportunity afforded to induce freer supplies. Ceylon granted bonuses to producers of green tea last year to the extent of about R2,50,000; the supply increased almost 2½ millions during that period.

That more attention will be given to green tea in India seems probable, but at the same time there is some hesitation in taking up and providing for its manufacture. This is to be understood, as in the present state of the industry producers do not see their way to increase their outlay by the cost of additional and necessary machinery, and to embark on a new enterprise without having some inducement which, as in the case of Ceylon, might take the form of a bonus. It would, of course, be unwise for any garden to allow a return of this nature to have any bearing in estimating possible results of the manufacture of greens, it should be ignored altogether, and a self-supporting basis only considered; what is required is *inducement at the start*, and provision against the possibility of unfavourable results during the experimental stages. A bonus would supply this want. The manufacture of greens in India would not have been started last year had it not been the Association's bonus that originally induced it; the American and Canadian markets can take greens freely, and if India does not make them she cannot hope to push her trade with these centres to any appreciable extent. Ceylon in the meantime is making rapid strides in this direction, and she will capture these outlets to her exclusive advantage unless India; if she wants a share of the trade, is placed on the same footing. In anticipating the ensuing season events during the past year furnish useful indications. Recent incidents are full of significance in respect of the course of the home market which promises to be an extremely sensitive one. The movements of exports from this end, which will be carefully kept in view, and the handling of supplies in London, which will be cautiously followed, will be the chief factors in determining the value of Tea. At the moment the producer's position is strong and his prospects good, better than they have been for some years; home consumption is free, stocks light, (they will probably be abnormally low in July next) and buyers carry no burden in the shape of dear tea and difficulty in moving it. To maintain their position and further improve it, the producers' policy is clearly suggested in keeping the crop within reasonable limits, and in being fully alive to the certainty of a return to starvation prices as a result of the taking of any liberties in the direction of supply. The recent bed rock level of value has in some measure influenced better and less tea, but there is no disguising the fact that weather has been the prime mover. At this juncture it would be extremely unwise if the recent advance in value should be met by converse working, and reflected in a freer system of plucking, the drawbacks of which may be further aggravated by weather favourable to yield. The interests of growers and sellers being identical, the latter will realise from the past year's experience the advantages derived by feeding the market

judiciously, and above all the real cause of the turn of events in their favour which a free and expanding trade in Calcutta with outside markets has brought about; it will encourage them to give these markets every consideration. Much assistance is also at hand in dealing with the ensuing year's outturn; not only has Calcutta a rapidly growing constituency in all parts of the world which is ready to relieve London to an ever-increasing extent, if properly supported, but the manufacture of green tea will sensibly reduce the supply of black; the influence of the Cess also, if it become law, will soon be manifest.

In contemplating the approaching year's crop there is nothing to convey an impression that it will be a heavy one, beyond the assumption that two moderate yielding seasons are likely to be followed by one of abundance, or that growers will be persuaded by the advance in value to aim for quantity. The first named possibility is a distant one, and favourable weather will meet counteracting influences. Lean years and hard times through which the industry has been passing have enforced a continued and rigorous cutting down of expenditure, which has had, and will have, its effect on cultivation and, in turn, on yield to a greater extent than is generally supposed. Short labour forces in past years will affect outturn in a similar manner, and it must be remembered that considerable areas have been abandoned. At the same time extensions coming into bearing are small and the plucking area is probably much about the same as last year. The second named possibility cannot be so definitely answered, but circumstances are in favour of moderation. It is quite recognised by producers that the turning of the corner, over a period of two years, has been brought about by care, as well as by weather and greatly assisted by the expansion of foreign markets, and it is also accepted that the situation can be easily disturbed from its present tendency which is so much in their favour. The position is appreciated, and a reasonable conclusion is that it will be respected. The ensuing season can, therefore, be anticipated with much confidence. Prospects are exceptionally favourable from every point of view, and, with careful working in the districts and judicious handling in the markets, there is every reason to look forward to a prosperous year.

WILL THERE BE TOO MUCH RUBBER?

In view of the amount of rubber planting now in progress the question has been asked—and it is a very natural question—whether there is not danger of a new source of supplies being created, out of all proportion to the world's needs. In other words, whether the result may not be overproduction of rubber to a degree that will render the new planting interest unprofitable.

If the consumption of rubber were a fixed quantity, with a definite limit already reached, caution might be wise in the matter of providing new sources of supply. But this is not the case. The consumption of rubber in the United States alone has doubled within seventeen years, and from whatever standpoint the rubber industry may be viewed, it gives promise of a more rapid rate of expansion to come with the many new uses of rubber, the growth in population and the greater buying capacity of the people. The consumption

has also become much greater in other lands, and there yet remains a large part of the world's population to become users of rubber goods. Within twenty years the production of 'Para' rubber has increased threefold, and meanwhile the present enormous supply from Africa has been developed. Yet such has been the increase in demand that prices have tended constantly upward, and market supplies are smaller today than for years past.

The natural supply of rubber on the other hand, is limited. There is no longer any unexplored country in which rubber trees may be hoped to exist. There are forests known to contain rubber which have not yet been 'worked,' but these virgin fields are lessened in extent every year. The gradual opening of new fields is offset in part by the exhaustion of old ones. It is true that, under the more intelligent supervision now given to them, the existing rubber trees in Brazil and Bolivia, for example, may long be conserved. Still there must come a time when all existing natural supplies will be taxed to their utmost, and then, without new resources, the further growth of the rubber industry will be impossible. No date for this situation can be fixed, of course, but its imminence certainly appears to us to justify the planting of rubber.

Several millions of rubber trees have been planted, thus far, but so recently that only a few thousand have reached a productive age. It is not reasonable to suppose that all the others will reach maturity, for the reason that rubber planting is a new interest, and as such liable to its share of failures. The addition to the world's supply of rubber from the existing plantations will be made gradually, as each year's planting begins to yield, and is likely to be required by the growing consuming demand. The same consideration will apply to such planting as may be done for a good many years to come. It must be remembered that rubber can be cultivated successfully only within very restricted limits. The territory in which rubber might thrive is much wider, but the natural conditions preclude undertakings there by outsiders, and render the collection of wild rubber so difficult as to make the cost of the product sometimes \$2000 or more per ton.

It must be expected that, ultimately, the success of rubber planting will result in lower prices, but not necessarily to the disadvantage of the planters. We have quoted Mexican rubber lately at 68 cents a pound, which means \$1,500, gold, per metrical ton. If rubber planting is going to succeed at all, it is not going to cost \$1,500 or half of it, to prepare and market a ton of products, and at much lower market rates there ought to be a good profit. At the same time every material decrease in the cost of rubber is bound to give a new impetus to consumption. This page would not hold a list of the practical uses for rubber which are held in check today by the high cost of the raw material. But when people once become accustomed to a new use of rubber, in which they are encouraged at first by low cost, they do not give it up latter if obliged to pay more for the article. A reasonable expectation, therefore is that if rubber prices should, in time, be depressed materially from the present level, the effect will be such an increase in consumption as to check the fall and soon create an upward tendency. This sort of fluctuation may be the continual experience of future generations of rubber planters, but it is a consideration too remote for those who are engaging in the business today.

Finally if the rubber planters are alive to their opportunity they will produce an article superior to many rubber grades now marketed, and obtain better prices. Then, if the market should become overstocked the last sorts to feel the depression will be the carefully prepared plantation products, which will be preferred by manufacturers at good prices to badly cured dirt-filled and foul-smelling rubber collected by natives in their primitive way, and now used in the factory through necessity. It might be suggested that people have been cultivating rice and wheat and other crops, and making iron and cloth and leather, for some thousands of years, and that in none of these lines has overproduction ever resulted to such an extent as to render the work unprofitable, taken as a whole, or unprofitable anywhere for a long continued period.—*India Rubber World*, March 1.

DEVELOPMENT OF COTTON-GROWING IN BRITISH POSSESSIONS.

The Committee of the British cotton-growing Association held a meeting yesterday at the offices of the Manchester Chamber of Commerce, Mosley-street. Letters were read from the experts already sent out. Mr. Severs (the Gambia), Mr. Prince (South Nigeria), and Mr. Neely (Sierra Leone) all expressed the opinion that the various places they had visited were suitable for cotton-growing, and that the prospects were encouraging. Mr. Neely sent a sample of cotton just picked, grown from American seed, which was pronounced very good and the kind of cotton required. Letters from Mr. E Nathan and Count Gleichen were read relating to cotton-growing in the Soudan. Mr. Nathan is sanguine as to the prospect. The consideration of the matter was deferred till Mr. Nathan's return. The secretary reported that four bales of cotton sent by the Zambesi Industrial Mission had been sold at 5½d per pound. Had it not been mixed the value of the cotton would have been much higher. A letter was read from Mr. T Morris, of Barbados, and it was decided to send out at once three gins and three presses to the West Indies. A large number of persons are now growing cotton there, and the prospects are good.—*Manchester Guardian*, March 10.

PINEAPPLE CULTIVATION IN MADURA

The cultivation of these and other pines is quite easy, and I think well repays the trouble taken. In August I re-plant all my pines, I make up a compost of 2 baskets red earth, 1 basket sand, 1 basket each well rotted cattle and horse manure. The pots are well drained, as I find the plants like a lot of water and like it to run away quickly. When re-potting I take away all shoots, but the one which I am going to grow for fruit. (It fruits the second year). As soon as the young shoots are well established plants, I cut away the portion that has carried fruit this year. In January of each year, I give each pine that has fruit, a good supply of liquid manure once every week. I find this is a great help to them and the fruit is much larger and heavier. I do not think the country pines are worth growing when you can get the Kew or Ceylon pine, but I have

grown them up to 6 lb (including the head) and the Ceylon pine I have grown to 11½ lb (including the head). I am told they should grow to 18 lb.—W. H. OAKES, Esq.

COTTON CULTIVATION IN CENTRAL ASIA.

In view of the increasingly important part which the production of cotton in Central Asia seems to play in connection with the textile industry of European Russia, the following remarks translated from the "Journal" of the Ministry of Finance by the "Journal de St. Petersburg," concerning the cotton crop and the state of the plantations in 1902 may be of interest. Last year was not favourable to the cultivation of cotton in Central Asia and Turkestan; the yield was 13.1 per cent below that of 1901, which was itself not abundant. The diminution in the yield of cotton from American seed was as much as 32.2 per cent, while on the other hand indigenous cotton showed an increase of 32.5 per cent. It was not so much a question of diminished production as of a restricted area. Another factor has indirectly contributed to the temporary decline in the cultivation of cotton in Central Asia. Owing to the system of protection in vogue, the cultivation of cotton had become so profitable in Turkestan that the natives had abandoned all other branches of agriculture. Moreover in the absence of agricultural banks, they have recourse to a system of advances which weighs very heavily upon them. Under this system the buyer readily makes advances to every grower who guarantees to supply him with a certain quantity of cotton. Being better informed than the producer, the merchant generally knows how to keep for himself the best chances of profit, and if the price of cotton is high at the time when the product is delivered, the grower finds himself deprived, of a part of the profit which he expected to obtain. Another cause for the present decline in the cultivation of cotton is the lack of manure. In the absence of irrigation works, the natives find themselves obliged to cultivate cotton year after year on the same land; hence the need for manure and the abnormal loss of the seed. In Khiva and Bokhara the cultivation of cotton has replaced that of wheat. The average yield of the cotton plantation in Central Asia was greater in 1902 than in the previous year except in the district of Tashkent. Compared with 1901, the total yield of cotton in 1902 showed a decrease of about 1,683,400 pounds, the estimated figures for last year being 4,900,000 pounds, of which 2,700,000 were American cotton.—*Board of Trade of Journal*, Feb 26.

SELANGOR RUBBER.

From Bukit Rajah Estate, Klang, a small quantity of gutta rambong from trees 4½ years old was sold in Singapore at \$190 per picul [or £19 18s per 136 lb—i.e. or 2s 9d per lb.] the cost of collection being \$72 per picul [above 14s 6d per 136 lb.] This rubber was scrap. Subsequent tappings, while no more expensive to collect, show great improvement in quality, and should fetch considerably higher prices.—*Straits Times*, March 25.

TEA PRUNING:
THE LATEST DELIVERANCE BY THE
INDIAN EXPERT AUTHORITIES.

The appearance at this time of the *brochure* by Sir George Watt, and Mr. Harold H. Mann on the "Principles of Tea Pruning"—1903 No. 1 of *The Agricultural Ledger*, published in Calcutta—is opportune. The postponement of the date for receiving the Ceylon Prize Essays on Pruning, will give intending contributors who read this paper the benefit of the latest deliverance of the recognised Indian authorities; and although it is unlikely that they will find in its pages much that is new, yet the re-statement of the old and established principles of scientific tea pruning should be a useful check. The Ceylon students of the "Principles of Tea Pruning" are ever made conscious of the fact that the field of observation from which the conclusions are drawn is the Indian Presidency, and that it is necessary to keep this in mind when applying them to our local industry. It detracts somewhat from the value of the paper that the range of its field is limited; still the general conclusions, which apply here as well as elsewhere, are of high value, are worthy of remembrance, and in practical hands will be found making for utility. In tea pruning, it makes all the difference in the world if the planter has an intelligent knowledge of what the application of the knife aims at, as compared with the uninstructed man who knows the system but not the reason for it.

"Pruning," say the learned authors, "is the most important operation in the tea garden . . . demanding the most skilled, careful, and constant supervision." This note is sounded all through the paper and reaches its climax in these words, "the sooner it is recognised that pruning should be bush by bush, and not plot by plot, the better will it be for the industry at large." As an ideal, the principle here laid down is indisputable, but as a working hypothesis it is simply hopeless. On a moderate-sized estate—300 acres or so—the number of trees run over the million, and when this is stated, the utter impracticability of an individual treatment of each bush is glaringly manifested. This objection to the "bush by bush" system of pruning has had the attention of the gifted authors, having been urged before by Indian tea planters. The authors admit the difficulty, and offer as one way of overcoming it in the following method. "Trained sirdars go through their respective portions of the garden, and fasten a stake bearing a coloured string alongside of each bush that would require to be pruned in a particular way." The Manager examines these sufficiently to satisfy himself that his ideas are understood; then coolies follow, each pruning his own colour. A very ingenious plan, indeed, but—we incline to think—hardly a feasible one. It would be interesting to know what the cost of the "coloured string" system amounts to, and if the financial results as compared with the style which usually obtains—a few

broad principles which the cooly's mind can grasp, with moderate supervision—are in striking contrast. We are not quite sure if the expert authors are not making somewhat of a fetish of their system of pruning. Less elaborate and burdensome styles have been adopted with some success, and the test should be, *results*. Good results are, however, not always admissible evidence in the eyes of the Indian authorities if their principles are departed from, but are said to be "*in spite* of a bad system of pruning." When the good results follow the Watt and Mann methods, to dispute the connection is not allowable! It is possible, we think, to make tea pruning too scientific, and this seems to us a real danger when the guide has no practical experience. Correct pruning is, according to our authorities, a cut which "leaves practically no wood above the bud from which the new shoot is to arise." Again "If the knife be inserted below the base of the bud, and a long slanting section be made, the bud will be starved and thus produce a sickly shoot. If the section be made at a point, say from half-an-inch to two inches above the bud, the protruding portion will be starved and die accordingly." It takes a good deal from the practical value of the above information when we elsewhere read, "It is often impossible to know where the bud will appear in a tea bush!"

The scientific man, who is not also a practical man, is too apt to ignore the necessary commonplaces which lead to success. Expert scientific advice is invaluable, and if it can be linked on to work-a-day methods, there is room for rejoicing; but the effects on the planter must be depressing when he is urged to follow lines which are quite unworkable with the material at his command. Ramasamy hunting for the "often-impossible" to find tea bud, while expected to finish a task of pruning, would be a puzzle-headed thing on any estate, and mostly making for mutiny. We would not, however, be misunderstood in what we have said, as if we lightly valued these authoritative deliverances on the "Principles of Tea Pruning." No planter can make himself master of this *brochure* without benefit to himself and the work he directs, and although he may see in it, but a "counsel of perfection" still it is a sure guide as far as he can follow it. He can never expect to reach the proclaimed ideal; but to have an ideal ever with him is a great gain, and to reach forward to it, even in an imperfect and faltering way, has hope and healthy stimulation in it. The price of this scientific pamphlet of 36 pages is only three annas, which places it within the reach of all.

IRISH RAINBOW TROUT FOR JAPAN.

Covered with damp moss in muslin troughs and hermetically sealed in tin, some 20,000 Irish rainbow trout eggs are on their way from Innishannon, co. Cork, to Tokio, for the Japan Exhibition. —*Daily Mail*, arch 21.

"VIOLETS OF ALL SORTS."

—*Tusser.*

If the early records of the Violet were accepted in a too literal sense, its use as a medicinal agent or as a food would lead to the inference that the early Englishwoman was a too devoted utilitarian to have any room in her constitution for mere sentiment. But it is more pleasing to think that the Violet though estimable in its way as the constituent of a salve, or a remedy for headache or neuralgia, or even as an ingredient in the universal pottage so dearly loved by the old-time Englishman, was at the same time no stranger in the plot of pleasant flowers. One of the marked characteristics of mediæval times was the strong liking for aromatic and sweet smelling flowers, and we may be sure the Violet was not forgotten among these. At the same time, there is no room to doubt that the Violet is indebted to Shakespeare for its position. He it was who published its perfume—

' Sweet thief, whence didst thou steal thy sweet
that smells,

If not from my love's breath? "

Its purity—

" From her fair and unpolluted flesh
May Violet spring,"

Its fragility—

" Forward not permanent; sweet, not lasting;
The perfume and supplience of a minute—
No more."

The Violets Spencer painted were of a less noble type. He needed "Primroses greene" to "emhellish the sweete Violet." Milton calls it the "glowing" Violet," and misses the plant altogether. In the routine of daily life the flowers were used for strewing sometimes the bridal bed—"Lay her in Lilies and in Violets"; sometimes the grave—

" And Violets and every kind
Of flowers, about the grave
They strawe."

In the garden, along with Camomile and other sweet-smelling flowers, Violets were planted on seats and banks; nor is it at all improbable that Shakespeare had an artificial bank of this nature in view, "Where Oxlips and the nodding Violets grow" and certainly so, the bank of Violets in *Twelfth Night*.

In the *Country Farme* and works of a kindred nature, recipes are to be found of method of preserving the flowers of Violets "for salad to serve all the year." Syrups, conserves, and sugar-plates composed of Violet flowers and sugar, were in much request for lung affections, coughs, and agues, and in every case it was essential to gather the flowers early in the morning previous to sunrise, in order that the virtues and sweet smell should be preserved. In ancient vocabularies, Viola is translated Banwyrt, Hofe, Appel-leaf, and a few more names not applicable, as for example, "Clover," which would appear to refer to the cut-leaved form of Viola tricolor; but by the time Turner initiated the recording of English plants and names, it was recognised simply as a Violet. On the other hand, quite a large number of plants other than the Violet bore the name, and some without possessing the slightest resemblance to justify the application. Thus Spanish Violet at one time was popularly applied to *Lupinus luteus*, both Parkinson and Cole mentioning the fact. Several campanulate flowers also acquired the name, but from a Latin source. Thus, *Gentiana pneumonanthe* was widely recognised as the Calathian or autumn Violet, and the spring Gentian the blue Violet. *Viola Mariana* in the same way became Marie or Marian Violet, and Mercurie's Violet, and is *Campanula medium*. The pretty *Campanula hybrida* is the Corn; and the yet prettier *Specularia perfoliata*, the Five cornered Violet. Then of bulbous Violets there is the Snowdrop, also called Narcissus Violet, and the Leucicoms or Snowflakes. One can sympathise with

Turner in his search for appropriate names, when he calls *Cyclamen Europæum* the Rape Violet, at the period of fairly descriptive of the plant, for then and long afterwards Rape was applied to the Turnip, and Violet was not at all inappropriate. It is, indeed, one of the old-fashioned names that we could ill afford to lose, the more so when its botanical equivalent is all we have left. The Dog's Tooth Violet (*Erythronium dens-canis*) has a general appearance to the last-named, though it is the root that is the distinguishing part; just as with *Dentaria bulbifera*, the scaly roots are the medium by which it has acquired the same name. It has also been called merely Toothed Violet. The last-named brings us in touch with the Crucifers, some of which are Violets, but I think in every case from a directly Latin source, just as the *Dentaria* is. Nor was the designation confined to England, for we find it current in forms modified to the speech of the several countries, in all the chief European nations. Lyte explains that, "under the name of Viola in Latine are commonly comprehended all sortes of floures which be anything like violets"—meaning *Viola alba* (*Mat'iola incana*) and *V. lutea* (*Cheiranthus Cheiri*), the former the white Violet and Guernsey Violet, the latter the yellow and tree Violet. Other plants of this group comprise *Hesperis matronalis*, rejoicing in a varied assortment of epithets, e.g., Queen's, Rogue's, Dame's Damask, and sometimes Guernsey Violets. When *Lunaria biennis* was introduced to the notice of botanists it was dubbed the Strange or Foreign Violet but Gerarde, in addition to the name applied to the flowers, supplies a long list of names derived from the white membrane separating the flat seed-vessels. These are "Penny-floure or Money-floure. Silver Plate, Pricke Songwort; in Norfolk, Sattin and White Sattin and among our women it is called Honestie." Honesty is still its common name, but they are mistaken who ascribe its imposition on account of some supposed virtue possessed by the plant of instilling honesty into the minds of its cultivators. The name refers to another kind of honesty, and is indeed merely the popular name of a membrane which the white dividing wall of the depleted seed-vessel of the plant resembles. To Parkinson we are indebted for the knowledge of its tubers having been eaten, though their use seems at no time to have been extensive. *Hottonia palustris*, the Water Violet, derives its common name from the appearance of the flower to the Crucifers. *Pinguicula vulgaris* is the Irish or Marsh Violet; and among other plants, the Lily of the Valley may be mentioned as one that narrowly escaped being a Violet!

Reverting now to the true Viola of botanists, we discover among the numerous names of the Pansy those of Horse Violet, three-leaved and Trinity Violet, Autumn Violet, and the less Violet. Of these the two last are of peculiar interest. The latter is also called Banwert and Mygelwort in *Medical Workes of the XIV. Cent.*, and at first sight *Gentiana pneumonanthe* would appear to be the plant. But it negatively was of so little importance in medicine as to be the thrust among the other *Gentians* for its virtues, and among these the "conglutinating" of bones is not to be found. The plant is really the variety of *Viola tricolor*, distinguished by botanists as "arvensis," and good descriptions of what early French writers call "grosses and menues pensées," are to be found in Liebnald's *La Maison Rustic*, and De Serres' great work on agriculture.

In the *Country Farme*, *Menue Pensée* is translated Autumn Violet, from its flowering late in the year, and its value as a honewort is fully described. As banwyrt, the old form of hone-wort, it occurs in the oldest vocabularies along with common Violet and Wallflower, the latter being called *Viola aurosa*. This and the Pansy have an altogether curious relationship, for not only were they described as Banwyrt but they were both known as Tree-Violets a name that the Wallflower still retains in France.

Moreover the two plants had medicinal properties in common, and in due time, as the Wallflower lost its relationship with the Violets, its old name of Heartsease was transferred to the Pansy. As a garden plant, the Wallflower seems to have an older standing than the Pansy, but neither so extended a one as the Violet. These, I think are the more interesting of our Violets, but it must not be supposed that the list is by any means exhausted. The yellow Violet (*Viola lutea*) of Gerard is interesting as having been confounded with the Wallflower, and of late years as being, with *Viola amena*, the earliest forerunner of our somewhat unhappily named bedding *Violas*—a nowadays strange instance of setting aside a common designation for one more pretentious, and certainly less felicitous.—R.P.B.,—*Gardeners' Chronicle*, March 28.

A NEW TEA MACHINE.

Mr. Perman is again in the field with a new process for tea making which he has protected in India and Ceylon. He claims the following salient features for his invention which is worked in conjunction with a machine called the 'Expressor' (priced at R450, ex Messrs. McLeod and Co.'s godown.) (1) Stronger and better coloured liquors. (2) Process fully retains the characteristic appearance of the finer grades, particularly the golden tips which are not discoloured in any way. In the lower grades the leaf is turned out much brighter and blacker. (3) 'Expressor' extracts 14% of moisture out of the rolled leaf, consequently the work of the Dryers is decreased with a saving in fuel and labour as a result. (4) In wet weather the 'Expressor' enables any Manager to overcome many of the difficulties hitherto met with in the withering operation. (5) For the manufacture of green tea the 'Expressor' will be found of considerable assistance after the leaf comes out of the 'Steamer' when it is necessary to rid the leaf of all the superfluous moisture prior to rolling. The process is no untried thing we are enabled to say, for it has been at work at several Assam gardens last year, besides Mr Perman's own (Deckajulie Tea Estate) where complete success attended the introduction of the press system of manufacture, the teas showing considerable improvement in quality and style with a corresponding increase in price for better value. Mr. Perman by its aid was able to reduce the temperature in the Dryer he used and to dispense with the services of one firing machine throughout the season. It will be seen that the process thus makes for economy and good quality being assured is therefore a step in the much desired direction.—*Indian Planting & Gardening*, April 4th.

PRODUCTION OF WEST INDIAN TOBACCO.

The following table, shewing the average annual production of leaf tobacco, cut tobacco, cigars and cigarettes in each of the undermentioned West Indian islands, is quoted by the *Board of Trade Journal* from a recent report by the Belgian Consul-General for the Antilles. One kilogram, we may add, equals 2 1-5th lb avoirdupois:—

	Leaf Tobacco. Kilogs.	Cut Tobacco. Kilogs.	Cigars. Kilogs.	ettes. Kilogs.
Cuba ...	20,000,000	250,000	1,200,000	10,000
Porto Rico ...	2,800,000	—	—	—
St. Domingo ...	8,000,000	—	—	—
Jamaica ...	20,000	—	14,000	4,000
Total ...	30,820,000	250,000	1,214,000	14,000

DISEASED COCONUT PALMS.

A disease, the cause of which is not stated, is doing some damage to the coconut trees in Jamaica. The following description of the disease is taken from the Jamaica *Gleaner* for January 12, 1903:—The heart leaves drop out and the leaves, which are usually upright, fall down. When a tree in this condition is cut down the heart is found to be one mass of bad-smelling, decaying vegetation, while the root and trunk are in perfect condition. The disease often attacks the flower spikes with the result that many of the coconuts drop off while still young. This is frequently preliminary to the disease getting to the heart leaves, after which nothing can save the tree. In the *Journal of the New York Botanical Garden*, Vol. IV, pages 4-7, Mr F S Earle gives an account of his recent visit to Jamaica. He examined coconut trees suffering from what is apparently the same disease as that described above. Mr Earle attributes the disease to bacterium. He points out the necessity for the prompt cutting and burning of all infected trees, and says that 'it is claimed by some planters that a certain green skinned variety of coconut is less liable to this disease than the reddish and yellowish kinds.' If this is confirmed there is a possibility of raising a resistant race of coconuts. A disease, similar in many symptoms is the subject of a paper in *Bulletin No. 38, New Series Division of Vegetable Pathology and Physiology* of the United States Department of Agriculture. The disease appeared among the coconut palms in the province of Santiago, Cuba. The first indications of trouble was the falling of the young fruit. Shortly after the larger nuts dropped and the leaves assumed a yellowish colour. Within a month all the large lower leaves droop and fall, leaving only the pale, sickly tops which blow over at the first heavy wind. Here also from the root to within a few inches of the top, the trunk was found to be perfectly sound. Perforating the entire upper part of the trunk for 2 to 12 inches downwards was found the mycelium of a fungus, the fruiting bodies of which appeared as small white spots on the underside of the leaves. These might easily be mistaken for the scale insects (*Aspidiotus*) often found there. The fungus was identified as *Pestalozzia palmarum*. On breaking open the lower leaves and cutting the centre of the green growing part open, the heart is found to be one putrid, offensive-smelling mass. It was found that the best way of preventing the spread of the disease was cutting down and burning the diseased palms. It is not necessary to burn the entire trunk, but only the top, with a couple of feet of the upper end of the trunk. In order that this preventive measure may have its greatest effect, it is absolutely necessary that united action should be taken. It would obviously be futile for the proprietors of one estate to eradicate the disease within its limits, if the owners of neighbouring estates omit the precautions and allow the disease to multiply and send its spores abroad to the others. These two diseases are so similar in their symptoms that it would seem not improbable that they are really one and the same. This however, cannot be definitely settled until some thing more is known of the cause of the disease in Jamaica. We trust fuller information will be obtained as the result of the work which we understand Mr F S Earle has in hand at the New York Botanical Garden, and of the field experi-

ments of Mr W Cradwick of the Department of Agriculture, Jamaica.—*Agricultural News*, Feb. 28. —

TEA PRUNING.

(Remarks on *Agricultural Ledger* No. 1 of 1903.)

Why the subject of pruning should have been matter for a number of the *Ledger* is somewhat obscure. Is it supposed that number of persons who have tea to prune are likely to require the help of this oracular pamphlet? Or is it sought to standardise the operation? Finally is it intended to be a fund of information for laymen who are shareholders in tea to throw piecemeal at the heads of practical men who depart from its precepts? It is probably none, or all, of these—a statement of the scientific side of the case, and as such can only have an academic interest to practical men. Put forward by two such men who between them use up half the alphabet on the title page, criticism is half afraid to speak up, and the *Ledger* might have been suffered to pass into the obscurity of dust and cobwebs but for its too evident effort at belittling the mental proportions of the average planter. Like all who dabble in tea affairs, the authors have fixed their minds on pruning as a *most important operation*. Our authors go further, however, and give their opinion in favour of its being “the most important operation in the tea garden.” Here we have the apology for their attention to the subject, and after this deliberate judgment who will say where manufacture or even the planting of the bush itself stand in relative importance? But probably the next *Tea Ledger* on the subject of, say, the weeding of nursery beds, will equally use the time-honoured phrase, and the industry will get a level keel again. The palmy days of the industry were not modelled upon such deliverances, and whatever success our fathers had they achieved without getting lopsided views of the eternal importance of this or that; they went, it may be supposed, for them altogether. Irresponsibility is writ large over this epoch-making *Ledger*. But that is not its worst fault. The amazing assumption that planters are generally not up to their work or inept in carrying it out is what the industry cannot take from even such valuable men. That variety of opinion exists is a healthy sign of coming and existing grace. As to “principles” which this *Ledger* is designed to lay down, what in the ultimate position are they? And can they not be stated without calling in question the competence of those engaged in the actual work? Verily, “Behold, ye are the people and wisdom shall die with you.” Have our very superior friends ever tried to prune a bush on the principles laid down, *i.e.*, 45 degree cuts just over a bud and all useless wood to be carefully removed? It takes 10 to 15 minutes to do it working hard. Now working moderately hard eight hours a day, a man would on this reckoning do 40 to 60 bushes and the cost would be £11 a acre; one man would do an acre in about even weeks, and you would require a man for every acre of your garden, which clearly is impossible. And just in this sort of thing lies the crux of the whole matter, that the planter does as well as he can with the means at his disposal, and must not be called names or have it suggested that he is an amateur at making his bread and butter. Practice is often at variance with the principles or science; and the reasons for

any departure in this particular case are well able to bear examination. All things considered, it seems likely we shall still have to go over the garden and cut it some how into shape, though hereafter we shall not call it “pruning” without visions of Sir George Watt and Mr. Mann and their clever, thoughtful *Ledger*. After all there is more in the management than they have yet dreamt of. O. P.

—*Indian Planting and Gardening*, April 4.

TROUT IN THE NILGIRIS.

FRY TO BE IMPORTED FROM CEYLON
IN CASKS.

I hear that there are several promising trout in Snowdon Pond and no more in the stream near Emerald Valley in the Kundahs. Of the fate of the fry that were floated out of the nursery pond on the Pykara River last year there is no news, but it is very probable that many of them went up stream and these may yet be heard of again. The suggestion of the Nilgiri Game Association that Major Bagnall should make enquiries with a view to procuring a fresh supply of ova when he went to England on leave last year has come to nothing. A scheme which has every promise of success, however, is now being attempted by the Association. It is well known that the Ceylon Association has been very successful in rearing rainbow trout in the streams there, and the District Forest Officer here is now in correspondence with the Association with a view of bringing over fry from Ceylon in casks. If an agreement can be arrived at it is intended to bring over healthy fry, from five to six inches long, and there seems to be a great probability that the Nilgiri Association will be able to acclimatise, at any rate, a fair percentage of them in local waters.—*Ootacamund Cor., Madras Mail*, April 13.

CAMPHOR PRODUCTION IN CHINA.

(*Daily Press*, 21st March.)

One of the great staple products of Formosa during its occupation by the Chinese was camphor, and a considerable proportion of the export was in the hands of foreign firms until after the cession of the island to Japan. Under Chinese administration there was a great deal of waste in the production, and we believe that the Japanese have been attempting the conservation of the camphor forests. The loss of this important export has been felt by China, and it is with no little satisfaction that the Chinese are able to announce that an experiment in the production of the tree in the province of Hunan has been attended with great success. It is stated that the soil of Hunan has now been found to be well suited for the extensive cultivation of the camphor tree, and the inhabitants are enthusiastically planting it wherever they can. A Changsha letter reports that there are now, in consequence of this industrious planting, innumerable camphor trees several feet in diameter in the province, and it is expected that with care it will be possible for Hunan to soon be able to export annually several thousand piculs of the

drug. This is a step in advance, and may perhaps go some distance to reconcile the Chinese Government to the loss of Formosa. The market is at present dependent chiefly upon the supply from Formosa, and in consequence the price is maintained at a high figure. Camphor is not the only product that might be introduced into the eighteen provinces and the Viceroy might profitably institute enquiries as to what new products the soils and climates of their respective provinces are best calculated to reproduce. Now that tea has practically ceased to be an export except on a comparatively small scale, it would be well to endeavour to find out other articles of commerce that could be successfully and profitably raised to take its place as a paying export and to redress the balance of trade, now so largely against China. With the heavy indemnity to be paid to the Foreign Powers, it is a matter of vital import to China to find new articles of export. And unless sustained efforts be put forth in this direction, it is tolerably certain, spite of the foolish optimism of the opponents of a gold standard in China, that the exports of this great Empire will remain stationary, or at any rate barely maintain their present position.

PROTECTED PEPPER.

Pepper from French Indo-China pays lower customs duties on entering France. In other words the import duty on colonial pepper there is fifty per cent. less than on the foreign article. This protection has so largely stimulated pepper-growing in Cochin-China among Europeans and Chinese that the French market is glutted with that spice from the Colony. Growing the article there has become unprofitable. The European planters seek to ward off heavy loss by starting an agitation against Chinese pepper-planters being allowed to share in the preferential tariff rates. This simply means the ruin of the Chinese planters. The prevalent opinion is that the planters should hang together, and should seek to meet the bad times by turning to other markets and by resorting to improved business methods.—*Straits Times*, April 2.

CACAO.

EXPERIMENT PLOTS AT GRENADA.

The following summary is taken from the report of Mr M McNeill, Agricultural Instructor at Grenada, on the cacao experiment plots in that colony. The information given refers to the period from October 1st 1901 to September 30th 1902. The report is published in full in a recent issue of the Grenada *Government Gazette* :—

The following is a comparative statement of the yields for 1900-01 and 1901-02 :—

	1900-01	1901-02
	lb wet cacao.	lb wet cacao.
Vendome (one acre) ...	421	1561
Colombier (do) ...	564	117
Vincennes (half acre) ...	340	379
Nianganfoix (one acre) ...	3935	3939
Bellevue (do) ...	1611	2087

The yield for Vendome and Vincennes is three times greater than last year, about double for Colombier, with a decided improvement for Bellevue and Nianganfoix.

Average cost of working per acre for 1901-02, including cost of manures, cartage, etc., has been £5 17s 0d.

The average cost of production per cwt, allowing for wet cacao to give half its weight in dry, on which, however, there is at present wide differences of opinion has been 12s 9d.

Summary of manurial results :—

	Vendome.	Vincennes.	Colombier.	Nianganfoix	Bellevue.	Totals.
Basic slag and sniph. potash	522	279	340	1109	561	2811 lb wet cacao
Basic slag and sulph. ammo-nia	426	252	252	1202	613	2745 lb wet cacao
Basic slag and nitrate of soda	251	200	307	1021	420	2199 lb wet cacao
Sheep or pen manure	362	148	218	657	493	1878 lb wet cacao

Basic slag and sulphate of potash sections have taken first place in three plots and second place in two.

Basic slag and sulphate of ammonia sections have taken first place in two plots, second in two, and third place in one.

The total yield for the basic slag and nitrate of soda sections has been better than that for the sheep or pen manure sections.—*Agricultural News*, Feb. 28.

INDIAN TEA AND PROSPECTS.

We call attention to the long and instructive Report of the leading Calcutta Tea-broking house for the season 1902-3—see page 759. It will be observed how much importance is given to the restriction of crops by fine plucking, and to the need of supporting the Calcutta market as a check on that of London, and also to the value of encouraging green tea. For the coming season, the tea crop prospects are favourable; but much depends on weather and labour supply; and the expectation on the whole, is of a prosperous year for producers, if due care is taken in the directions pointed out.

ASSAM PLANTERS' PURCHASE IN THE NILGIRIS.

A group of estates near Colacumbay has just been sold to two tea planters from Assam. The properties consist of the Terrania, Pembroke and Carshalton estates, comprising about 600 acres of land, of which about 200 acres are under tea and 100 acres under coffee. It is said that the purchasers intend to open out all the uncultivated land in tea and make a big concern. It is significant that planters long resident in that well-known tea-producing district should leave it to settle on the Nilgiris, and one is inclined to seek the reason. It must be that the labour difficulty in Assam is preventive of any profits being made in these times where large advances have to be made to the coolies, Rs 75 per head and even more, and where Government interference is so irksome. The planters here will no doubt hail the advent of these wellcomers, as they will be sure to carry out economical methods and keep down the rates of pay, which have a tendency to rise of late years, and could undoubtedly run high but for the fall in voices.—*Indian Planters' Gazette*, April 11.

COCONUT CULTIVATION IN CEYLON AND FIJI.

Mr. Edward McCarthy, - an experienced coconut planter now of the Rajakadalawa district, Chilaw, sends us a very instructive and useful letter in reference to the bearing powers of the coconut palm and the foolishness of drawing deductions from the experience of one or two trees, or again of supposing that all small nuts are to come to maturity, - or that, once again, a head of 100 or more small nuts will give more oil or copra than one of 50 to 60 large, fully-matured nuts. All these qualifications indicate the directions in which, alone, sound comparisons can be made. Mr. Tarte of Fiji and any other planter proud of his prolific palms, must not only tell us of the number of nuts per tree and of trees per acre; but also the weight of the nuts, of the resulting copra, or oil, *per acre*. Then indeed shall we be in a position to institute a fair comparison with the best plantations in Ceylon.

MATALE PLANTERS' CASE FOR THE COCOA THEFTS COMMISSION.

(Extracted.)

Cocoa stealing has continued in a greater or less degree ever since Cocoa came generally into bearing some 14 or 17 years ago, the question of degree coinciding with the variation in prices, thus from 1889-1893 prices were at their highest and stealing was rife, so that after considerable agitation a Commission was granted in 1895. But in the meantime in 1894 prices fell until Cocoa was almost unsaleable and thefts also fell away, figures and data had not been collected so that when the Commission sat after a year in which there was little or no theft, there was no proper evidence to place before it, and although men were prepared to swear that they had suffered severely from thefts some 16 months previously, they had to admit that at the present time they were not suffering in that way. Sufficient stress not being laid on the fact that they were not robbed because it was hardly worth anyone's while to rob them. A record of thefts had not been kept and the fact of the absence of specified cases, was held by the Commission of 1895 to prove that a sufficient case had not been established. A Trial of rural police was however recommended and failing that, a Receivers Ordinance was to be tried. The rural police was given a fair trial. The cost of them is small, planters had every reason to adopt this form of protection if it was found efficacious, but it was not so. Such success as was attained was due to the personal influence brought to bear on the headmen by the Government Agent and his assistant. This is of course so far satisfactory, but it is not law and past experience has taught us that individual effort is not the proper thing to rely on in such a case. We may mention that in all reports on rural police, the cost of Estate Watchmen is ignored whereas the cost of them was very considerable; on one Group which came under the system, being about R500 per month.

We have to point out that the Assistant Government Agent of Matale after two years' experience of cocoa stealing, and of the active management of

rural police, pronounces himself at the end of 1901, in the most unqualified way as in favour of special legislation, taking the form of a Receivers Ordinance, plus certain restrictions on cocoa growers. This paragraph was framed into a resolution which was brought before the Planters' Association of Ceylon by the Chairman of the Matale Planters' Association, and carried unanimously: -

SPECIAL LEGISLATION FOR CACAO STEALING.

"We, the undersigned, are of opinion that the law, as it now stands, is not sufficient for the protection of Cacao-proprietors. We would, therefore, respectfully suggest some amendment of the Prædial Products Ordinance, which, while continuing to make the possession of *Green Cacao* without a satisfactory account of such possession an offence, might also provide against the dishonest possession of *Ripe and Cured Cacao*. We should also be grateful for any protection against receivers" which the Government may be disposed to "grant."

This embodies the demands of both European and Native planters. It is well known that natives suffer severely, and often pick their cocoa before it is ripe to save it from theft. Testimony as to a specified case of this can be given by Mr J B Tennant, Mr Lyall, and the Assistant Government Agent of Matale.

There are in Matale 7,000 acres of European Estate cocoa in bearing. As to the acreage of native owned cocoa, there is some uncertainty. It is given by the Assistant Government Agent of Matale as 2,200 acres, there is no Government record of the native acreage in bearing. According to Government figures there would be 1,500 acres of native owned cocoa in bearing, and according to the planters' estimate there would be 1,000. The Matale cocoa is despatched by the Railway, and from figures very kindly given us by the General Manager, C.G.R., we obtain the following results: -

1902-Despatched by Europeans from Matale, Ukuwella and Malvern Stations	cwts 11,465,
to which we add cwt 1,137 sold by Europeans to Natives, making a total of cwt 12,602, giving an average of cwt 1.80 per acre on European Estates,	Cwts. 180
Despatched by natives from the same stations	4,366
Less purchased from Europeans	1,137

3,229

Giving an average on Government figures of 2.15 per acre, and on Planters' figures of cwts 3.1 per acre.

We wish to say that European owned cocoa is easily distinguished by the names of the Estates being marked on the bags and by its being consigned to well-known firms in Colombo. European owned cocoa is not forwarded by any Native Agency at the Stations mentioned. The native gardens taking a liberal estimate, may perhaps have been cwts. 1,500, leaving cwts. 1,729 totally unaccounted for. - And this is a year when the Rural Police system has been worked for all it is worth.

When Cocoa Planters first approached Government on this subject, their case was dismissed by the then Colonial Secretary by the curt remark that cocoa could afford to pay for its own watching. Such an utterance shows ignorance of the subject. Cocoa Planters do not and never have asked Government to relieve them of the duty of watching their Estates, what they do ask is that the law should

NOT ALLOW UNDOUBTED THIEVES TO ESCAPE.

On another occasion one of his watchmen was stabbed, and his gun stolen. Many other instances could be added, Mr Martin has tried Rural Police

and found them worthless, and now has to get men from the Punjab at a very large expense to protect his Estates. It is true that the Cocoa stealing cases in the Matale Court increased in 1900 as compared with the two previous years by 50 per cent but it is not correct to say that they decreased in 1901. The very reverse is the case, the figures of 1901 as compared with 1900 show an increase of some 25 per cent. Mr Dunuwilla is, we believe, a Cocoa planter amongst other things, and he is singularly ill-informed as to that branch of his business if he does not know that the reason that thefts decreased towards the end of the autumn's Crop of 1901-2 was that Cocoa towards the end of that crop become practically unsaleable, the native traders were enormously overstocked and refused to purchase on almost any terms. Therefore when he says that towards the end of crop thieving fell away and gives the headmen and the rural police the full credit of this decrease in theft, he will get few people who know anything of the matter to agree with him; further, he writes as if the rural police system applied to the whole district whereas, it only applied to some 10 or 12 per cent of it. The chief reason of the decrease in theft was the fall in the value of Cocoa. And now we have to deal with the statement made by Mr Dunuwilla against planters that thefts are common because planters employ "Dishonest Watchmen." Twice Mr Dunuwilla has advanced these very general charges against the planters, and each time has only been able to bring forward one case to prove what he says, and neither of these cases as stated by him will, we submit, bear investigation. That planters whose living depends on their crops should deliberately select "dishonest watchers" is at variance with common sense, and with the true facts of the case. Planters select the best men they can get, they do not draw upon any particular nationality. Sinhalese, Tamils, Malays, Moormen, have all been tried, the best men of their class are selected, and good wages are given. If Mr Dunuwilla would tell us where amongst his countrymen or the native races of Ceylon we can find passably honest watchmen, he would do something towards proving his case.

We submit a list of the
AMOUNTS SPENT ON WATCHMEN AND PREVENTION OF THEFTS

by estates in Matale and elsewhere. Taking the yield per acre, the value of same, the expenditure per acre on estates, and the Railway figures showing what was sent away in last year, we are prepared to show that Matale proprietors have to spend 10 per cent of their income in trying to protect the rest. We instance a group of five Estates under the same management where 22 per cent of the profits from the cocoa in bearing have been spent in protective measures. We instance an Estate where about 70 thefts occurred last year. We draw attention to cases instanced by Mr. Garrick and Mr. Wilkinson. We suggest that the following witnesses be examined:—

R W Bolling, Longville; Gilbert James, Katugastota; C M Krickenbeck, Matale North; J A Mao Allister, Pansalatenne; L R Rudd, Marakona; H D Garrick, Ukuwela; W Lyall, Allooohare; J Anderson, Bandarapolla; James R Martin, Yattawatte; J A Burmester, Warriapolla; Harry Storey, Warakamura; the Hon. the Colonial Secretary; C H T Wilkinson, Kondesalle; Dan. Joseph, Matale; A H Don Bastian De Silva, Matale; the late Arachi Pattagedera, Wattagama; Dingeri Banda Lukam, ambawella.

We suggest that the Commission procure from Government the cost of the rural police system to Government, including not only rural police but headmen's wages and rewards, amounts paid Government watchers and every other expense incurred. We finally submit that cocoa cultivation deserves consideration at the hands of Government. Crops are small, prices are bad, and the cost of cultivation has been largely increased by canker.

The Matale Police Court figures for Cocoa stealing are as follows:—

1898	37	14 convictions
1899	37	18
1900	55	37
1901	67	37*

*Four absconded.

Figures collected by the Matale Planters' Association point to 35 per cent only of Cocoa thefts being taken to Court, the uselessness of prosecuting under the existing law being the reason that so many thefts are allowed to go unnoticed.

We wish to point out that the legislation we ask for is nothing new. In Ceylon at one time Cinchona was largely cultivated in the Central Province. It was much stolen and it was found that the most dangerous receivers were the owners of small gardens with a few Cinchona trees growing in them, as stolen bark was then openly sold as the produce of these gardens and to check this the Ordinance No. 9, 1885 was amended as follows in 1886 "Whenever.....the bark whether of the branch, root or stem of the Cinchona tree shall be found in the possession of any person who is unable to give a satisfactory account of his possession thereof, such person shall be deemed and adjudged of an offence and shall on conviction be liable to the punishments.....under section 368 C.P.C." This legislation stopped the theft of Cinchona bark and never was known to injure any honest man—and this is the species of legislation that European and Native Cocoa planters have united in demanding.

We would draw the attention of the commission to the Mauritius Ordinance for the suppression of Vanilla theft which is on the same lines as our Cinchona Ordinance.

Also to the Grenada Ordinance for the suppression of Cocoa and Nutmeg theft and the amendments to the same which bring it exactly into line with the Ceylon Cinchona Ordinance.

Also to the statement in the Administration Report for the Central Province 1901, page C 35, to the effect that, the old Ceylon "Coffee stealing" Ordinance and the Madras Act VIII of 1878 "were found to be inoperative to a great extent." "The reason for this has been stated by the Hon. the Chief Secretary to the Government of Madras. They impose no adequate check upon the dealings of receivers of stolen coffee who own small patches of land planted with coffee in the vicinity of large estates and account for the possession of large quantities of Coffee by the statement that it is grown in their own land." This is precisely the difficulty that meets any purely receiving ordinance in Ceylon. We would suggest to the Commission that the Hon. the Colonial Secretary be asked to state from his West Indian Experiences, what nature of laws exist there, for the suppression of Cocoa theft and what their effect has been. We would also suggest that some influential natives be asked to give their opinion on the proposed legislation to the Commission and would mention Mr Dan. Joseph and Mr Bastian de Silva. We submit this case to the Commission and would be glad to attend in the form of a deputation and go over it carefully and give evidence as to the points raised.

[Correspondence in connection with cocoa thefts Commission and rural police.]

No. 307.

COCOA POLICE.

Police Station, Matale 11th February, 1903.

Sir,—I have the honour to request that you will be good enough to inform me whether you were satisfied with the conduct of the Cocoa Police employed for the protection of your Estates during the past season, and whether you consider that they were of assistance in checking thefts of cocoa.—I am, Sir, your obedient servant,

(Sgd.) E. B. ALEXANDER, A. G. A. (Police.)

D. E. RODRIGO.

The SUPERINTENDENT, Alloowehare Estate.

Alloowehare Estate, Matale, 16th, Feb., 1903.

The ASSISTANT GOVERNMENT AGENT, Matale.

Sir, I am in receipt of yours of the 11th instant, requesting me to give my opinion as to whether I was satisfied with the conduct of the Cocoa Police for the past season, and whether they were of assistance in checking thefts of cocoa.

In reply to this, I have to state . . . that the Police did their work well, and only on two occasions (at the commencement of the Season) did I find them absent from their posts. On all other occasions I found them at work, and I must say the headmen attended to their duties in a very satisfactory manner. I put down the zeal of the headmen, and the constant attention to duty of the Police in a great measure to your very close supervision, and to the co-operation you received from the Ratemehatmeyya and Korale under you,—these latter were closely under your control, and they in their turn kept both Constables and headmen well up to the mark. I would venture to point out that, considering the majority of the before-mentioned headmen were busily engaged guarding my cocoa from 4 to 7 a.m., and again from 4 to 7 p.m., they were unable to do justice to their

other numerous duties in their districts. Under the condition on which the Cocoa Police worked during the past Season, I have no hesitation in saying that they did their work well and prevented thefts of Cocoa.

—Yours faithfully, (Sgd.)

WILLIAM LYALL.

P.S.—The headmen guarding the Cocoa were paid by Government for this work. W. L.

COCOA THEFTS.

Katugastota Estate, 18th March, 1903.

My dear Martin,—In reply to yours, I have pleasure in handing you a few facts which I hope will go to help us in proving that we want something better in the way of protection in cocoa. This place is a scattered one, and lends itself more to robberies perhaps than places more compact, but that does not lessen the fact that we want better protection but proves that the present law is not enough. The villagers will not steal unless they can get rid of the stolen cocoa, and the receivers are the ones to get at. They give one cent per pod to people who bring them, and if they don't agree to those terms they threaten to expose them. I think if we get a stronger law, and the receivers made to account for the cocoa they receive, it would stop a good deal of it. In my opinion it is no good sending a low-caste Sinhalese to prison or fining him much, he is received with open arms when he comes out of jail by his friends, and they do not attach any shame or disgrace to it. The better class and good caste Sinhalese do not steal I think. It is often the case that the same man has been convicted and sent to jail for stealing several times, that goes to prove that he does not fear going to jail.

No. 1.—I should say I had quite 70 thefts last year, but fortunately none of these were big ones owing to good work of my watchmen, which prevented large robberies,

No. 2.—I caught and took to Court 31 cases.

No. 3.—I got 20 convictions and 11 dismissals.

No. 4.—The Watchmen cost the Estate R2,427 and Legal Expenses cost R500.

No. 5.—I consider there were cases dismissed which ought to have been convicted.

Yours Truly,

GILBERT JAMES.

March 22nd, 1903.

My dear Martin,—I will willingly do anything I can possibly do to help you and the cocoa theft Commission. I have sent for a Native Proprietor, a neighbour of mine, who is perhaps as honest as natives are made. He may be able to give you some help by suggestions, can the cocoa commission not send out Forms with leading questions and headings. An example of one theft I detected was, I was losing cocoa from one of my far Fields. We could not detect anything for months. By a big bribe I received information where I might find some of my cocoa drying. I went and there was quite a beaten track towards some Lantana a few chains from my boundary. Into this there was a hole about 18 in. wide by about 18 in. high, through which I had to crawl on my stomach about 10 yards long: arrived inside was a cleared space (a barbecue well stamped) not noticeable from outside as it was surrounded by thick Lantana. Cocoa was drying and there were Sacks and Seals on the spot. We remained in ambush. After a while a Tam I Proprietor and two Moormen crawled in, whom we captured, and handed over to the Arachchi. Pauwila was then my Court. Owing to being ill I had to postpone the case several times and then having Pleuro-pneumonia I had to leave the island. The case was dismissed as the F. M. would not let my Conductor or *Locum Tenens* to go on with the case. My watchers cost me over R1,300 per annum and expenses, battas etc. to witnesses about R400. We have detected about 18 thefts but had only about 4 convictions. I have now a case pending for 5th April. The accused's previous convictions here are (1) 1 year, (2) 6 months, (3) 3 years. The case pending is District Court,

This year's crop is about 2,200 cwt. Average Crop about 1,500 cwt. Expenditure about R35,000. Crop stolen about 10 per cent. If I can give any further help, I will willingly do so and am grateful to the Commissioners.—Yours sincerely,

C. H. T. WILKINSON.

PLANTING NOTES.

AGRICULTURAL PROGRESS IN FORMOSA.—The Japanese are going ahead in this fine island. An Agricultural Experiment Station has just been established at Taipoli and Mr. Y. Fujini, the Director sends an order for the "Tropical Agriculturist" to be forwarded.

ORANGES.—The Florida orange crop for the past season has totalled 800,000 boxes, being 300,000 less than last season, but growers have not suffered through the shortage, owing to better prices obtained. The cause for the small crop was the drought which occurred in the spring just at the bloom of the oranges; and the red spider partially destroyed the crops in some groves; while the very heavy rains that came later did not better matters. This is something like the experience here this season; dry weather in June decreased the quantity and size of the fruits in St Ann and Manchester. Yet market results have been good. The grade of fruit all over has been improvement, better packing, grading and handling generally, with great room for greater care still.—*Journal of the Jamaica Agricultural Society of February.*

THE CEYLON TEA AND COCONUT ESTATES COMPANY—which has, since its inauguration in 1896 been worked at a loss has, we are glad to see, completed this year's working with a profit of R4,377.22. No dividend was declared at the last annual meeting, but the report when compared with last year's statement is decidedly encouraging. This year the tea crop was slightly over that of last year, while the prices obtained were 60 cent better. The coconut trees gave 707,034 nts as against 516,008 in the previous year. Rubber too has now begun to yield a return and 55 lb. have been sold at an average price of R2.50 The Company have 50 acres under rubber, so that considerable revenue will soon be obtained from this source.

COMPANY REPORTS.—The annual reports of a number of Ceylon Tea Companies registered in London appear elsewhere. Mount Vernon, as reported by Wire, has paid a dividend of 8 per cent for the year and in addition has placed to reserve £200 and carried forward a similar amount—on the whole, considering the unsatisfactory season, a very good first result. Yatiyantota Company pays 5 per cent for the year and writes off £1,000 for cost of properties &c. and carries forward £2,029. The Punduloya Tea Company has had one of the best years it has yet experienced in its six years of existence. It pays 5 per cent as against 4 last year, places to reserve for depreciation &c. £2,250 and carries forward a balance of £225 15s. The Augusta Tea Company closed their year with a credit balance of £652 12s. Beside paying Debenture interest and other fixed charges £100 ls written off machinery account, and £41 5s 3d is carried forward. Balmoral Company has had a very successful year and pays 10 per cent. A balance of £706 7s 3d is carried forward.

OLD TREE STUMPS.—To remove old stumps, a correspondent to the *Country Gentleman* gives the following:—'Get a 2-inch iron pipe, 8 feet long; have a steel point welded into one end of it. With a sledge hammer drive this under the stump as far as may be necessary. Drop half a stick of dynamite into the hole thus made, and tramp earth upon it until the hole is filled; then light the fuse. The stump will be lifted entirely out of the ground with no earth adhering to it, so that it may be burned the next day.'—*Hawaiian Planters' Monthly*, February 15.

THE EUCALYPTS.—Mr. J. H. Maiden, Government Botanist of New South Wales and Director of the Botanic Gardens, Sydney has begun a very valuable work in a critical revision of the Genus *Eucalyptus*, part I, (with four plates), has just reached us. It is a quarto in large type clearly printed and covers some 50 pages, the description and four plates being devoted to "*Eucalyptus Pilularis*." The Contents are:—

Synopsis:—Preface—Variation in the Genus; Doubtful Species; Non-Eucalypts described as Eucalypts; and Works Consulted.

1. *Eucalyptus Pilularis*, Smith:—Description, Notes Supplementary to the Description; Synonyms (with descriptions), Notes on the Synonyms; Range, Typical Form and Varieties; Affinities; and Explanation of Plates.

From the preface we quote:—

During the 20 years that have elapsed since the publication of Mueller's '*Eucalyptographia*,' which added valuable information to Bentham's masterly account of the genus *Eucalyptus* in the *Flora Australiensis*, we have obtained a large accession of facts. It seems to me that the time has arrived when these additional facts should be incorporated with the labours of the old workers. I have spared neither time nor expense to obtain access to the types. I have spent many years in field observations on the genus in every State of the Commonwealth (though, of course, particularly in my own State of New South Wales), and thus have endeavoured to secure what is an essential qualification for the study of this protean genus.

A very important departure in a work of this kind is the following:—While expressing my opinions as to affinities, synonyms, etc., I shall in all cases give the original descriptions of the species whether considered to be synonyms or not. In this way my readers will be able to weigh the evidence for themselves, and, if they do not concur in my conclusions, they will at least be placed in possession of the data on which they are based.

The genus *Eucalyptus* is the most important in Australia. The individuals which comprise it are all pervading, while the number of species and varieties is very large. As the work proceeds I will give my views as to the grouping of the species. The present part contains much prefatory matter referring to the genus. Then one species is taken in detail, and the other species will be treated in a like manner, the facts being grouped in the same way. The rapidity with which this work can be issued depends mainly on the plates; I have only the partial services of one artist.

The future number of this valuable work will be eagerly looked for.

TO THE PLANTING WORLD.

Seeds & Plants of Commercial Products.

Hevea Brasiliensis.—Orders being booked for the coming crop August-September delivery 1903, booking necessary before the end of April, quantities of 100,000 and over at special low rates. Plants available all the year round, 100,000 and over at special low rates. A leading Rubber planter in Sumatra, who purchased 50,000 seeds in 1899, and 100,000 in 1900, writes us, under date 15th November, 1900 :—“ I received your letter of 20th October, from which I learn that you added another case of 5,000 seeds to replace the loss, &c. I am satisfied hereby, and even after this adding I am satisfied by the whole delivery of this year.” Special offer, post free on application.

Castilloa Elastica.—True superior variety cultivated in Mexico, seeds from specially reserved old untapped trees. Orders booked for October-November delivery 1903, immediate booking necessary; large quantities on special terms; Plants in Wardian cases.

A foreign firm of Planters writes under date 11th October, 1901 :—“ We beg to enquire whether you would procure us 100,000 Castilloa seeds, in which month we might expect them, and what would be the average price.” Special offer, post free on application.

Manihot Glaziovii.—Seeds and Plants available all the year round, 100,000 and over at special low rates. A Mexican planter in sending an order for this seed wrote on the 22nd August, 1900 :—“ If they arrive fresh and germinate easily I may send you larger orders, as they are for high ground where the Castilloa does not thrive.”

Ficus Elastica.—Seeds available in May-June; booking necessary before the end of March; also plants.

Mimusops Globosa (Balata) wood of the tree is much sought for buildings, fruits sweet like a plum and eaten, oil from seeds, said to yield as much as 45 lbs. of dry rubber per tree per annum, the milk is drunk and when diluted with water used as cow's milk, grow from-sea-level up to 2,000 feet, orders being booked for seeds and plants, price on application.

Cinnamomum Zeylanicum (Cinnamon superior variety).—New crop of seed in April to June; booking necessary before the end of February, also plants.

Coffea Arabica-Liberian Hybrid.—A highly recommended leaf-disease resisting hardy new variety of Coffee (cross between Arabian and Liberian). New crop March-April; immediate booking necessary.

A foreign Agricultural Department writes dated 9th September, 1901 :—“ Please accept our order for 175 lbs. of Tea seed and for 2,000 Coffee beans. In regard to Coffee seed I would say that this will be the first importation made by this department, and we will leave the selection of the varieties to be sent to your judgment.”

OUR DESCRIPTIVE PRICE LISTS.

The following six Descriptive Price Lists are now being forwarded with Circulars and special offer of Seeds and Plants of Rubber and other Economic Products :—

1. Tropical Seeds and Plants of Commercial Products, enlarged edition for 1902-1903.
2. Seeds and Plants of Shade, Timber, Wind-Belts, Fuel and Ornamental Trees, Trees for Road-sides, Parks, Open Spaces, Pasture Lands, Avenues, Hedges, and for planting among crops (Tea, Coffee, Cacao, Cardamoms, &c.)
3. Seeds and Plants of Tropical Fruit Trees including Mango grafts.
4. Bulbs, Tubers and Yams.
5. Orchids—Ceylon and Indian.
6. Seeds and Plants of Palms, Calamus, Pandanus, Cycads, Tree and other Ferns, Crotons, Roses, Dracinas, Shrubs and Creepers.

Special Arrangements made with foreign Governments, Botanical and Agricultural Departments, Planters and others for supplying seeds and plants of Commercial Products in larger quantities.

“ SOUTH AFRICA.”—The great authority on South African affairs of 25th March, 1899, says :—“ An interesting Catalogue reaches us from the East. It is issued by WILLIAM BROTHERS, Tropical Seed Merchants of Henaratgoda, Ceylon, and schedules all the useful and beautiful plants which will thrive in tropical and semi-tropical regions. We fancy Messrs. Williams should do good business, for now that the great Powers have grabbed all the waste places of the earth, they must turn to and prove that they were worth the grabbing. We recommend the great Powers and Concessionaries under them to go to William Brothers.”

Agents in London :—MESSRS. P. W. WOOLLEY & Co., 90, Lower Thames Street.

Agent in Colombo, Ceylon :—E. B. CREASY, Esq.

Agent in British Central Africa :—T. H. LLOYD, Esq., Blantyre.

To the Editor.

THE PINEHURST "TEA" EXPERIMENT.

March 10.

DEAR SIR,—At it again!—but this time from the facile pen of Mr. P. C. Larkin of Toronto! You should naturally expect a *douceur* for the advertisements given Pinehurst. Alas!—I am almost bankrupt, having to pay 5 cts. for each clipping concerning Pinehurst, and so many are they that it keeps a paster at work transferring them to huge invoice-books. And then our generous Government, which would give me everything (except a salary), has been called on by me for this fiscal year to loan me some tea machinery and to give me some foreign tea seed. Aside from that, I have not received any assistance, and it is very questionable whether I shall ask for anything next year. "A huge joke," indeed. (Different countries do not agree on what is witty.) But Mr. Larkin's information on how "to do it" with the American Press may some day prove useful, and—with the rest of the valuable notices emanating from your office—have been duly posted under your impressive motto, *Fiat Justitia*. I have had, a few days since, a most agreeable visit from Mr. Robert Hart of India, and shall be most happy to see you here whenever you will honor me with a visit. Only do, please, not forget to have sent me all the kind notices which your columns contain concerning "Pinehurst." Never mind my feelings; I am old and tough and the laws against duelling in South Carolina are vigorously enforced.—Yours very truly,

CHARLES U. SHEPARD.

COCONUT CULTIVATION IN FIJI AND CEYLON.

Rajakadalawa, March 23.

DEAR SIR,—To those of us who have been connected with the Coconut Industry for the last three or four decades and who have never been able to realise, even with the most modern and approved modes of culture, a higher annual average per tree than 50 to 60 nuts, Mr. Tarte's letter from Fiji, dated 5th February, comes as a startling revelation illustrative of the wonderfully prolific nature of coconut trees in the isles of the South Seas. We cannot do otherwise than give full credence to his statements, but it is strange that we have never heard of this sort of thing before. Coconuts have been cultivated in Fiji these many years, but such stupendous results have never reached our ears till now. He tells us "I can assure you it is a positive fact I have often seen from 1,000 to 1,200 nuts on a tree; but this caps all." I should think so indeed. Where can we produce the like of it or half as good? If we had known before that Fiji was such a wonderful coconut country I warrant there would have been a stampede and a large exodus of capitalists from Ceylon would have testified to the attractions of the new El Dorado. Our coolies and artificers and mechanics would have fled thither pell-mell for higher wages. Enge. Ramasamy?—Peejnpuku odinan. Ko

Haramanis? Peeju ratata pennalla giya. Onde Signior Jokong? Ja fugi per Fiji.

The tree referred to by Mr. Tarte certainly beats the record hollow; but, I think, he is rather too sanguine about the prospective quantity of oil to be had of it.

He draws attention to the unprecedented plethora of tender nuts in three peduncles, but the mere appearance of these thousands, fresh from the embryonic stage, does not guarantee their uninterrupted progress to full maturity. I have seen as many as 30 tender fruit on a single peduncle, but, alas! their number has eventually dwindled down to 8 or 10. Some dry and drop off, affected by changes in the weather or some secret inaptitude for further development, others are nibbled by rats and squirrels and otherwise prove that "brief life is here our portion," so that no one could accurately predicate what his crop is going to be by making the newly opened spathes his data for calculation, any more than he could count his chickens before they are hatched. Mis-carriages occur in every department of life, animal or vegetable, and in their best regulated families and classes—notably in the flower of the coconut tree. As Mrs. Malaprop says "Man proposes and God disposes."

On the banks of the Maha oya I have counted over 250 nuts on a tree at a time, but this number was far short of what the spathes revealed on newly opening. Exceptionally favoured trees—that is to say, those benefited by the alluvial deposits of a river given to inundating its banks, or those growing on excellent loamy soil and well tended, or those highly manured and carefully looked after near dwelling houses, coolie lines, cattle sheds and horse stables—have borne wonderful bunches; but they are few and far between, and cannot come near the Phenomenal Phenomenon of Fiji. In the Keriang Kalliye District, north of Badulu oya, the finest specimens of coconut trees in this Island are to be seen flourishing, spite of hundreds of envious and evil eyes cast on them daily by footpads and passengers in coaches. They are second to none but the Maha oya coconuts; yet all these must hide their diminished heads before the awful tree which is the lawful property of Mr. Tarte. With rare exceptions the ordinary number of spathes produced by a coconut tree is twelve in a year. I know of some trees in Ambepusse which gave fourteen. The nuts on those trees were from 250 to 300; but every rule has its exception and those were exceptional trees.

I have invariably noticed, and so have a good many people, that when there is a multiplicity of "Etties" or tender nuts (as they appear on the opening of the spathe) on a peduncle, the fruit is generally small. On the other hand those hanging in twos and threes are nearly always big coconuts. The Goondara or Maldivian coconuts appear in thicker clusters than the ordinary kinds; but they are exceedingly small—in fact too small to be scraped for culinary purposes with a "hirramaney." The Bhodi Poll is still smaller and more numerous in a bunch than the Goondara. I wonder how large the Fiji nuts in general and Mr. Tarte's nuts in particular, are. It would be interesting to have a specimen of a well-matured nut from Mr. Tarte's tree of trees—a photograph could not give us an idea of the size. It would also be interesting to have another letter from him, when the fulness of time shall have come, telling us how

many of those thousands now on that particular tree actually attained maturity.

Let us hope a change may not come over the spirit of his dream—if the enormous weight of the bunches in the Kurumba stage were to snap the peduncles at the base, which would, indeed, be a base proceeding after so high a promise of a ton of copra! We all know that the biggest bunches often come down with a rush in spite of props to prevent them and it is a heartbreaking sight to see a splendid cluster of 15 to 20 coconuts so suddenly brought low and scattered in every direction ere half matured: If these Fiji trees bear such extraordinary, ponderous bunches and if all the little fruit develop into big ones, the tree, in soot, would be in imminent danger of snapping short off, immediately below the fronds, especially when swayed to and fro violently by those terrific winds so prevalent over the Fiji isles—almost enough to bend the teeth of a carpenter's saw. We know what fine trees come down with an ordinary weight of top hamper when a blustering gale bursts through our coconut tops; what must it be over among the low-lying islands, surrounded by an infinity of sea with the storm, when it does come, howling like a thousand fiends and devastating everything high and low. I think it unwise to be dazzled by the fair pictures drawn by the over-sanguine respecting prospective fortunes in foreign lands, of fortunes too rapidly made, in black and white, but like the *ignis fatuus*, in point of fact ever nigh but never grasped.

Seeing is believing, and if the good friend who sent me the cutting ament this subject could be liberal enough to send me on a reconnoitring expedition, on the extreme quiet, as the spies were sent to the promised land, I might come back from Fiji not with a cluster of grapes, but a bunch of coconuts, a faithful report and a new lease of life. In the meantime, on the principle that a bird in the hand is worth two in the bush, I prefer to cultivate coconuts in good old Ceylon where—if I make not a splendid fortune—I need fear no magnificent bankruptcy. As Pat says: "Betther dale wid a divvle yer know than a divvle yer don't know."

If an anonymous writer had written the account of the now famous Fiji tree we might have been inclined to take it with a grain of salt, but coming as it does we are bound to receive this Tart [E] without a dollop of sugar or a wry face.—I am, dear sir, yours very truly,

EDWD. MCCARTHY,

CEYLON PARA RUBBER.

London, E.C., 27th March, 1903.

DEAR SIR,—The following particulars of Ceylon grown Para Rubber sold in Public Sale here today may interest your readers:—

Mark.	Quality.	Description.	Price @ lb.
Yatipanwa	5 cases	Fine thin bisenits	4s 1½d
Do	1 do	Good scrap	3s 3½d
Arapolakande	6 do	Fine thin pale biscuits	4s 2d
Do	1 do	Good scrap	3s 3d
Do	1 do	Fair scrappy biscuits	3s 2d
Igalkande	1 do	Fine thin bisenits	4s 1½d
Devitrnai	1 do	do	4s 0d
Do	1 bag	Scrap fair	3s 1d
Tudugulla	3 cases	(not ready)	

The market is good.—We are, dear Sir, ours faithfully.

LEWIS & PEAT.

A WARNING TO PLANTERS' SELLING TEA FLUFF.

April 2.

DEAR SIR,—We would like to warn planters against selling any tea fluff, sweepings or other refuse tea to native buyers unless the same have been denaturalised before leaving the estate, for we know for a certainty that such fluff, etc. is carefully picked and the tea obtained in this way either sold in Colombo or shipped. The denaturalising is best done by mixing fluff, sweepings, red leaf, etc. with 5 per cent of slaked lime, which will render them unfit for human consumption, and will not interfere with the extraction of caffeine. We are quite willing to provide planters with the lime free of charge to mix with refuse teas and sweepings they intend sending to us, and if they insist on native buyers doing the same a good turn will be done to the tea trade. We think the matter well worth the attention of the Planters' Association and others interested in the Ceylon Tea Enterprise as the quantity of fluff and refuse teas sent to Colombo is, we think, far greater than people have any idea of.

CHS. A. BOHRINGER.

DROUGHT IN AMBEGAMUWA; AND THE GREEN TEA GRANT.

Ambegamuwa, March 23.

SIR,—What an awful drought, almost everything and everybody scorched out; not sufficient water in our streams to even dilute the "auld crathur." It puts one in mind of 1887 or 1888—I am not very sure which year it was—when the drought lasted from end of November to the 14th of February. With the exception of just 28 in. of rain we have not had a shower for over a month. Patana fires galore!

What about that green tea grant? Surely the "Thirty Committee" do not expect men to be philanthropists when most of them are face to face with ruin. The men around here are averaging 35 cts. and more for their blacks. Can you expect them to go in for green teas which average about the same and which cost nearly 4 cts. more to produce as you can never get the same outturn from green teas as you can from black? No, Sir, the only remedy is for the "Thirty Committee" to go on with the grant. If they have no money—stop the American campaign at once. It has done precious little good and will do no more if continued to the millennium. Keep up encouraging green teas for another 2 years and then it can look after itself. We are still in the primitive state, and every encouragement is absolutely necessary at this juncture to save a rising industry from a lamentable collapse.

G. T.

GREEN TEAS AND BLACK: COMPARISONS OF OUT-TURN.

Calcutta, April 11.

DEAR SIR,—Judging from the enclosed cutting which appears over the signature "G.T." in the last *Observer* of 25th March, (see above) some at least of your Green Tea makers do not

seem to be quite up-to-date. At least the statement that "you can never get the same outturn from green teas as you can from black" does not apply to our North Indian adaptation of Mr. Drummond Deane's process, and the estimate of 4 cents or 8 pies (nearly $\frac{1}{2}$ d!) per lb. extra for manufacture is a sheer waste of money. We get our full weight from green as from black, without any loss of quality—as you may have noticed from certain appreciations of our Indian green teas published by yourself and others in Ceylon. Our new Indian appliances for the purpose are good, and naturally from long knowledge of green tea on the old Indian processes we have a bit of a pull in handling leaf; but there should be nothing beyond the resources of your local talent in reducing cost and getting full weight with a little trouble. If I could not truthfully assure Indian tea concerns that they could make green tea without loss of weight on our Indo-Ceylon system, and without any material increase in expenditure, our business-like men would laugh me out of their offices. But there is little encouragement to the introduction of our North Indian improvements till the question of security from imitators is more settled. If your correspondent's estimate is generally true in Ceylon, Indian tea concerns working on our system are going to make green tea at a cost some 3 cents below yours, and if sales at public auction in London can be relied on (and there is no sentiment, so far as I know, in London) our Indian teas will average some 3 cents more than your correspondent's estimate of value. This, of course, is purely based on your correspondent's statements which, perhaps, are not universally true. I enclose three statements from leading Indian green tea gardens, bearing out the results I claim. I am sorry I am not authorised to publish the names in support of the first two, though I append them for your information, but the third I give, and it is one that is well-known as a successful mark.—Your faithfully,

CHARLES JUDGE.

(Extract from cutting referred to.)

Ambegamuwa, March 25.

Sir,—What about that green tea grant? Surely the "Thirty Committee" do not expect men to be philanthropists when most of them are face to face with ruin. The men around here are averaging 35 cents and more for their blacks. Can you expect them to go in for green teas which average about the same and which cost nearly 4 cents more to produce as you can never get the same outturn from green teas as you can from black? No, Sir, the only remedy is for the "Thirty Committee" to go on with the grant. G. T.

(Reports on three marks of green tea)

Extract from a letter from the Manager of estate to Mr. C. Judge:—"Given adequate machinery the only extra cost would be in the fuel. At with short drying machinery and working night and day when busy I consider $\frac{1}{2}$ d per lb. extra on the 2,500 maunds. I made easily clear all extra expenditure on fuel and labour and also leaves sufficient over to pay the cost of machinery, *Green Tea after manufacture weighs out as well as black.*"

Extract from a letter of the Superintendent of to whom the above letter was submitted for confirmation or criticism. "I see no reason why should not get as much weight from their greens as from their blacks. If there is any loss in the manufacture of greens it is when true greens are panned occasionally and, of course, does not make true greens (i.e. the first estate makes 'uncoloured' and does not "finish.")

A third statement is from the Manager of Kolbong whose teas (after pan-firing in Calcutta by machine) fetched in open auction in London 9 $\frac{1}{2}$ d for Yonng Hyson, 8 $\frac{1}{2}$ d for Hyson and 8d for Hyson 2—who says:—"Greens and blacks here weigh out the same."

GREEN TEA MANUFACTURE AND BLACK.

Ambegamuwa, April 20.

DEAR SIR,—Replying to Mr. Judge's letter and your correspondent *re* green teas and outturn (see page 783), I still maintain that it costs nearly 4c. more than black tea. Carelessness in manufacture or extreme supervision will not give an outturn of over 23 per cent. I will ask Mr Judge or your other correspondent to weigh out, say, 300 lb. of green leaf from the field straight to the steamer. They must be sure it is done under their immediate eye and if they can with a *bona fide* 300 lb. tea leaf turn out more than 68 to 69 lb. I am open to be instructed how it is done. I have carefully weighed out 200 lb. green leaf, *withered it separately*, and when ready, rolled the leaf off and had the lot fired. *24 per cent black tea* was the result. There is weighing and—weighing!—of leaf,!! and results accordingly. All true men know this. Mr. Judge is quite right to get in as much advertisement for his machine as possible. He is no exception to human nature. Apologising for any trouble,—Yours truly,

G. T.

P.S.—If 23 per cent is the result of green tea outturn, add the cost of extra leaf and extra cost of manufacture, it will turn out very close on 4c. above blacks.—G.T.

SOILS OF DOMINICA.—We have received from Mr. D. Morris, C.M.G., copy of a report on the physical and chemical analyses of the Soils of Dominica, 1902, by the Hon. F. Watts, B. Sc., Government Analytical and Agricultural Chemist for the Leeward Islands, issued by the Commissioner of Agriculture for the West Indies. The Report contains a great deal of valuable information; for as Mr D Morris says:—

In countries where the land has been tilled for long periods, much knowledge is gained by experience and the need for thorough chemical and physical analysis may not be urgent. In Dominica the case is entirely different. Much of the land has never been cultivated and there is no fund of experience to guide intending planters. The valuable information contained in this report may well then be the means of preventing costly mistakes in planting crops on lands unsuitable to them. This report is a valuable contribution to our knowledge of West Indian soils and embodies the results of very careful work by Mr Watts, continued over a long period of time, and the thanks of the Government and the Planting Community are due to him for his active and zealous efforts.

THE BATTALGALLA ESTATE COMPANY,
LIMITED.

THIRTEENTH ANNUAL REPORT, 1902.

The Directors are pleased to Report that the year's working shows a better result than in 1901. The crop has been larger, and therefore the cost of production has been much less, and although the average selling price has not reached last year's level, the profit realized is some £700 better. The quantity of tea manufactured has been 254,692 lb against last year 218,531 lb. The average selling price in London has been 8'07d gross, against 9'34d gross in 1901; and in Colombo 34'82 cents gross, against 37'06 cents gross; the total crops averaged a selling price of 7'16d gross, against 7'50d gross in 1901. London sales amounted to 119,853 lb, realizing net £3,471 0s 4d, and Colombo sales 134,755 lb, realizing net R15,544'77. This compares with 63,282 lb, realizing £2,156 16s 4d, and 154,518 lb, realizing R55,638'87, sold in London and Colombo respectively. Exchange for Drafts has averaged 1/4 9-32 against 1/4 19-64 in 1901.

An interim dividend of 3 per cent. was paid in October, the Directors, now propose to pay a further 3 per cent. free of Income Tax, making 6 per cent. for the year, to also write off £512 ls. 8d. from Machinery and Factory Account, and to carry forward £96 7s. 6d. to next Account. The best thanks of the Shareholders are due to the Superintendent, Mr G C R Norman, as well as to the Colombo Agents, Messrs E Benham and Company, for valuable services rendered to the Company during the year. In accordance with the Articles of Association Mr Edward H Hancock retires from the Board and being eligible offers himself for re-election.

50 & 51 Lime Street, London, E.C. 9th March, 1903.

THE GREAT WESTERN TEA COMPANY OF
CEYLON, LIMITED.

REPORT OF THE DIRECTORS.

DIRECTORS :—F W Bois, J Anderson, J C Dunbar.
At a General Meeting held on 21st July, 1902, it was decided that the financial year of the Company should in future run from January to December, and in consequence the Directors have on this occasion to submit Report and Accounts for nine months only to December, 1902. The yield of Tea was 272,147 lb netting 44'34 cents per lb. after estimating the value of 37,961 lb, which sold at a net average of 7'41 pence per lb but of which account sales have not yet been received. The Directors much regret the fall from average of 47'37 cents last season but do not attribute it to any actual falling off in the quality of the tea. The cost per lb. was 32'13 cents including 3'20 cents per lb. for manuring as against 29'05 cents for last season, and the increase may to a great extent be attributed to the shortage of crop which was 12'49 per cent less than that of the same nine months in the preceding year, and partly to the change of the Company's financial year. The amount available for distribution is R35,214'24 out of which the Directors recommend the payment of a dividend of 6 per cent absorbing R 35,040'00 and to carry forward the balance of .. R 174'24

R 35,214'24

The Estimate of Crop for the current season is 430,000 lb to cost R129,355'88 equal to 30'03 cents per lb. including 2'54 cents for manuring and with favourable weather this should be realised. The acreage of the Estate is :—921 acres 2 roots 12 perches Tea; 39 acres 0 roots 0 perches Fuel 38 acres 2 roots 4 perches

Ravines; 17 acres 1 root 12 perches Grass Field; 11 acres 3 roots 13 perches Buildings and Gardens; 30 acres 0 roots 14 perches Cart-road and roads; 23 acres 2 roots 25 perches Railways; Total 1,082 acres 0 roots 0 perches. During the year Mr. G F Walker left the Island, and Mr. F W Bois was appointed a Director in his place. In terms of the Articles of Association F W Bois retires by rotation and being eligible offers himself for re-election. It will be necessary to appoint an Auditor for season 1903.—By order of the Board of Directors, J M Robertson & Co., Agents & Secretaries.

THE LETHENTY TEA ESTATES ASSO-
CIATION, LIMITED.

The report and balance sheet to be presented at the fifth ordinary general meeting, to be held at the Registered Offices of the Company, Liverpool House, Middlesex Street, E.C., at 12 o'clock noon on Tuesday, the 31st March, 1903 :—

The Directors beg to present their Report and Balance Sheet for the season ending December 31st, 1902, showing a net profit of £4,071 16s 10d; to which has to be added balance from last year £7 4s 3d.—Total £4,079 1s 1d; which, after providing for Debenture Interest £2,500, and fees to Trustees for Debenture-holders £50—Total £2,550; leaves a sum available for Dividend of £1,529 1s 1d. Your Directors now recommend a dividend of 3 per cent for the year on the ordinary shares, free of Income Tax, £1,364 14s; with Income Tax payable, £95 2s 6d.—Total £1,459 16s 6d. And that the balance of £69 4s 7d be carried over to next account

ACREAGE, 1902.—Tea in full bearing, 958 acres; tea five years old, 44 acres; tea four years old, 30 acres; tea under four years old, 6 acres; forest, 85 acres; grass land, 18 acres; roads, ravines, and waste lands, 61 acres. Total, 1,202 acres

REPORT.

The total crop for the year 1902 amounted to 482,079 lb. of tea, being 15,261 lb. more than was obtained in the previous season. This, considering that the season was a very unfavourable one for flushing, and that the yields of most estates were below those of last season, must be looked upon as satisfactory pointing as it does to our properties being in good heart and condition.

The whole crop was sold on the Colombo market, and realised a gross average of 39'37 cents, being the equivalent of 7'3d in London, a very satisfactory average in view of the low prices ruling last season, and one that reflects great credit on our estate management.

The profit for the year, including the balance of £7 4s 3d. brought forward from last account, after providing for debenture interest, income tax, and bonus to estate manager in Ceylon, shews a balance of £1,433 18s 7d.

Your Directors recommend a dividend on the ordinary shares at the rate of 3 per cent, free of income tax, carrying forward a balance of £69 4s 11d to next account.

Your Directors take this opportunity of pointing out that the result of closing the retail business has fully come up to their expectations, and net profit made this season fully justifying the action they took in January of last year.

In accordance with our Articles of Association, two of the Directors, Mr. James Skene and Mr. Sholto G D Scriver from office, and, being eligible, offer themselves for re-election.

The Auditors, Messrs. Carter, Son & White, offer themselves for re-election.

THE CEYLON TEA AND COCONUT
ESTATES COMPANY, LIMITED.

DIRECTORS:—Messrs. F Capper, G H Alston, J A Henderson; Estate Inspectors. (Tea.)—Mr. R W Harrison. (Coconuts.)—Mr. W Jardine; Estate Superintendent—Mr. P T L Wetherall.

ACREAGE.

TEA.—In full bearing	Acres.
Coconuts	410 2 2½
Cinnamon	559 3 3
Rubber	21 2 30
Jungle, Patua and Scrub	50 0 0
	365 2 38
Total,	1,407 3 13

The Directors have now to submit to the Shareholders the accounts for the past year. TEA DIVISION.—The crop secured amounted to 159,487 lb., being about 40,513 lb. below the estimate. Unfortunately, this estate with many estates in Ceylon has suffered from the unfavourable weather for growth. A very careful system of plucking has been followed as usual. The cost of laying down the tea in Colombo was 25.58 cents per lb. as compared with 23.31 cents per lb. in 1901, and the nett average price realised was 29.46 cents per lb. against 28.86 cents in 1901. COCONUT DIVISION.—The crop gathered was 707,034 nuts a large proportion of which was made into Copra 557.4. 1. 14 candelas, and sold at a nett average of R53.78 per candy. The coconut crop for the current year was sold as Copra at R55.00 per candy. The estimates for the current year are:—TEA, 200,000 lb. against an expenditure on working account of R52,002.00. The Directors have put in machinery for making Green Tea which has been sold on the Colombo market. COCONUTS, 760,000 nuts against an expenditure of R16,420. RUBBER, is coming on well. 55 lb. have been secured and sold at an average price of R2.50 per lb. It will be noticed that the profit on last year's working is R4,377.22 and it is hoped that the present year will show even more satisfactory results. Messrs. W H Figg & F C Rolea having resigned their seats on the Board, Messrs. G H Alston and F Capper were appointed to fill the vacancies. In terms of the Articles of Association, Mr G H Alston retires from the Board of Directors and is eligible for re-election. The appointment of an Auditor for the current year will rest with the meeting. By order of the Directors, TARRANT, HENDERSON & Co., Agents and Secretaries. Colombo, 7th April, 1903.

THE TALAWAKELLE ESTATES CO., LTD.

DIRECTORS:—Messrs. Arthur Phelps Hoskyns and Charles Murray Robertson; Agents in Colombo—Messrs. George Steuart & Co.; Agents and Secretaries—Messrs. Robertson, Bois & Co.

The Directors have the pleasure to submit the Balance Sheet and Accounts of the Company for the year ending 31st December, 1902, duly audited. The mortgage has been reduced to £14,000, by the payment of the fifth instalment of £1,500 on the 31st December last, which has been charged to Profit and Loss Account. The profit on the year's working is up to the average of the preceding four years, the increased yield compensating for the slight falling off in the price obtained for the tea. The amount expended in new clearings, about £270, has been charged against revenue. In the five years since the formation of the Company, the cost of production has varied but little, the average annual yield has been 528 lb. per acre, and the average price of the tea 10.47d. During the above period, after charging all expenditure on buildings, machinery, and on the conversion of 104 acres forest land into tea, the nett profits have amounted to £37,886 2s 11d, equal to rather more than 12

per cent on the purchase price of the estates. The sum of £7,500 having been paid out of the profits towards redemption of the mortgage, the cost of the estates has been reduced to £54,646 7s 11d, the acreage now being 802 acres tea in full bearing and 104 acres young tea.

STATEMENT SHEWING RESULTS OF WORKING

FOR THE FIVE YEARS ENDING 31ST DEC., 1902.

Season.	Average Plucked.	Total Tea Crop.	Yield per Acre.	Sold in London.	Gross Average per b. Tea sold in London.		Cost of Crop per lb. f. o. b. Colombo.		Average Rate of Exchange per Rupee.

THE VELLIKELLIE TEA COMPANY OF CEYLON, LIMITED.

DIRECTORS.—George Abercrombie Dick, Esq., Percy Lawrence Johnson, Esq. Agents and Secretaries.—Robertson, Bois & Co.

REPORT.

Your Directors beg to submit their Report and Balance Sheet for the year ending 31st December 1902, duly audited. The yield of tea fell short of the estimated quantity by 72,182 lb, the shortfall being attributed to the unfavourable weather during the latter half of the year, and other causes. The total yield was 207,818 lb tea, plucked off 540 acres, being at the rate of 385 lb tea per acre, costing free on board at Colombo 33.86 cents per lb. The gross average price of the 195,350 lb sold in London was 8.19 per lb. Last year the crop amounted to 275,549 lb, costing 26.90 cents per lb. f.o.b., and the average price for the 251,699 lb sold in London was 8.03 per lb. The crop anticipated for the onrrent season is estimated at 250,000 lb tea, a considerable increase on the crop secured last year, which may reasonably be expected in response to the liberal cultivation carried on. The rate at which Drafts were negotiated was 1s 4s.16d per Rupee, the same as last year.

	£	s.	d.	£	s.	d.
The Net Profit for the year amounts to	..	1,134	15	0		
And the Balance from last year to	..	213	9	2		
Making a total of	..	1,348	4	2		

The Directors have already paid out of this, Dividends on the 6 per cent Preference Shares for the year ending 31st Dec. 1902	285	0	0	
Interim Dividend on the Ordinary Shares of 1 per cent free of Income Tax	..	352	10	0
Income Tax	..	113	19	8

And it is proposed:—

To pay a Final Dividend of 1 per cent free of Income Tax on the Ordinary Shares, making 2 per cent for the year	..	352	10	0
And to carry forward the Balance of	..	244	4	6
		1,348	4	2

Mr Edgar Bois resigned his seat on the Board during the year. The Director retiring on this occasion is Mr George Abercrombie Dick, and, being eligible, he offers himself for re-election. The Auditor, Mr J Hamilton Alston, also offers himself for re-election. By Order of the Board, ROBERTSON, BOIS & Co., Agents and Secretaries.

London, 21st March, 1903.

THE LINDOOLA TEA COMPANY, LTD.

DIRECTORS:—Messrs. Edward Dumaresq Thomas, Walter Cross Buchanan, Charles Murray Robertson. AGENTS AND SECRETARIES:—Messrs. Robertson, Bois & Co.

The Directors have the pleasure to submit the Balance Sheet and Accounts of the Company for the year ending 31st December, 1902, duly audited. The total crop was 180,375 lb tea, against 175,000 lb estimated, and 171,311 lb obtained last season. The crop was at the rate of 563 lb per acre, and cost 23.34 cents per lb, free on board at Colombo, and the gross average price of the 168,935 lb sold in London was 7d against 8½d last year. It will be seen that the fall off in profits is entirely attributable to the lower average obtained for the tea. Drafts were negotiated at an average rate of 1s 4½d, the same as last year.

The Net Profit for the year amounts to	..	£1,589	9	8
And the Balance from last year to	..	36	6	9

Making a total of £1,625 16

The Directors have already paid out of this, Dividends on the 6 per cent Preference Shares for the year ending 31st December, 1902	..	£	780	0	0
Income Tax	..	90	1	3	
Amount written off Investment	..	64	6	0	

And it is Proposed:—

To pay a Final Dividend of 2½ per cent free of Income Tax on the Ordinary Shares	650	0	0	
And to carry forward the Balance of	..	41	9	2
		£1,625	16	5

The Director retiring on this occasion is Mr. Charles Murray Robertson, and, being eligible, he offers himself for re-election. The Auditor, Mr. J Hamilton Alston, also offers himself for re-election. By order of the Board, ROBERTSON, BOIS & Co., Agents and Secretaries.

London, 25th March, 1903.

THE TYSPANE TEA CO., LTD.

DIRECTORS.—Messrs. Edward Dumaresq Thomas John Philip Herringham, Walter Cross-Buchanan and Col. E D Newnam-Smith.

AGENTS AND SECRETARIES.—Messrs Robertson, Bois & Co.

The Directors have the pleasure to submit the Balance Sheet and Accounts of the Company for the year ending 31st December, 1902, duly audited. The total yield was 261,878 lb. Tea against 280,000 lb, estimated and 277,773 lb. obtained last year, and in view of the unfavourable weather during the latter part of the year, this may be considered satisfactory. The average price realised per lb. Tea was 5.59d. nett against 5.66d. nett last year. The cost of production, exclusive of expenditure on new clearing, was 25 cents per lb. free on board at Colombo, or about 4½d. The present season's crop is estimated at 280,000 lb. Tea. Exchange averaged 1/4½ per rupee against 1/4½ last year.

The Net Profit for the year, after payment of the Interest on Debentures is .. £1,071 1 11

To which has to be added the balance brought forward from last year 22 9 10

£1,093 11 9

The Directors have already paid out of this an Interim Dividend of 1½ per cent, free of Income Tax .. 270 0 0
 Income Tax 54 5 11
 And it is proposed:—
 To pay a final Dividend of 3½ per cent free of Income Tax making 5 per cent for the year .. 630 0 0
 And to carry forward ... 139 5 10

£1,093 11 9

Mr Walter Cross-Buchanan, the retiring Director, offers himself for re-election. The Auditor, Mr J Hamilton Alston, also offers himself for re-election. By Order of the Board,—ROBERTSON BOIS & Co., Agents and Secretaries. London, March 25.

THE PUNDULOYA TEA COMPANY OF CEYLON, LTD.

REPORT

to be presented at the Sixth Ordinary Annual General Meeting of the Company to be held at the Office of the Company, on Wednesday, the 8th April, 1903, at 12-30 p.m.

1. The Directors now submit their Report for the year ending the 31st December, 1902, together with the balance sheet and accounts of the Company made up to that date, and duly audited.

2. The crop amounted to 749,445 lb., of which the old tea contributed 734,445 lb., being the largest crop it has ever given, and the new clearings 15,000 lb. The net average price obtained was practically the same as in the previous year, but the cost of production per lb. was considerably less as shown in paragraph 4, and the Directors desire to record their appreciation of the successful efforts of the Ceylon management in this direction.

3. Since the end of 1902 the statistical position of the tea market generally has considerably improved, and the outlook for producers is more promising than for some time past.

4. The following statement gives details which may be of interest:—

Season.	Acreage Plucked.	Total Tea Crop.	Yield per Acre.	Cost of Crop per lb. f.o.b. Colombo,	Gross Average price obtained per lb. Tea.	Average rate of Exchange per Rupee.	Dividend on Ordinary Shares free of income tax.
	acres.	lb.	lb.	d.	d. s. d.	s. d.	per ct.
1902	1,800	749,445	416	4.87	8.45 1 4½	5	
1901	1,777	692,579	390	5.29	8.37 1 4.3-16	4	
1900	1,640	697,359	425	4.86	8.68 1 4.17-64	6	
1899	1,640	644,565	393	4.81	9.23 1 4.9-32	6	
1898	1,640	627,886	383	5.29	9.27 1 4.3-16	6	
1897	1,640	623,699	380	5.22	9.52 1 3½	6	

5. The profit for the year amounted to £7,872 6d, to which has to be added interest £98 19s 8d, and the balance from last year of £318 15s—Making a total of £8,289 15s 2d.

The Directors have already paid out of this, interest for the year upon the mortgage, less Income Tax £225 5s, dividend for the year upon the 6 per cent Preference Shares, less Income Tax £1,858 6s 8d, Income Tax £430 8s 10d, And they propose to deal with the balance as follows:—To pay a dividend of 5 per cent free of Income Tax, on the Ordinary Shares, requiring £3,300, to transfer to Reserve for Depreciation and General Purposes (increasing this account to £9,000) £2,250, and to carry forward the balance of £225 15s 1d—Total £8,289 15s 2d.

6. The Director retiring on this occasion is Mr Frederick Henry Christian, who being eligible offers himself for re-election.

7. Messrs. Winney, Smith and Winney, who were appointed Auditors, in the place of Mr John Smith retired, offer themselves for re-election.—By order of the Board, ROBERTSON BOIS & Co., Agents and Secretaries.

THE AUGUSTA TEA ESTATES COMPANY, LIMITED.

DIRECTORS:—Messrs. Charles A Reiss, (Chairman). Edward H Hancock, Hamilton A Hancock, Thomas J Lawrence, Henry Will (Managing Director in Ceylon). Secretary.—Albin B Tomkins.

SIXTH ANNUAL REPORT.

The Directors beg to submit their Report and Audited Accounts for the year ending the 31st December, 1902. The quantity of tea manufactured has been 134,747 lb. which has sold at an average price of 5.95d per lb. gross, the cost of production for the same, works out at 24.90 cents., or equivalent to 4½d per lb in London. The average rate of Exchange has been 1s 4 11-32d. The Profit on Working Account is £589 18s 5d and with the balance of £62 13s 7d from last year brought forward, the amount at credit of Profit and Loss Account is £652 12s 0d.

Debenture Interest, Preference Dividend and all fixed charges have been paid, and the Directors propose to write off £100 from Machinery Account and to carry forward £41 4s 3d to the credit of the new season.

By the Articles of Association, Mr. Hamilton A Hancock retires from the Board, and, being eligible offers himself for re-election. The Auditors, Messrs. Singleton, Fabian & Co., also offer themselves for re-election.

Messrs. Charles A Reiss, Thomas J Lawrence, Directors. Mr. Albin B Tomkins, Secretary. 23rd March 1903.

MOUNT VERNON (CEYLON) TEA COMPANY, LIMITED.

INCORPORATED UNDER THE COMPANIES ACTS,
1862 TO 1900.

DIRECTORS.—John Alexander Melville Stephens, 13, Devonshire Terrace, Hyde Park (Chairman). William James Chrystal, 7, West George Street, Glasgow. John George Chrystal, 8, Royal Exchange Buildings, Glasgow. Robert Francis Barclay, 19, West Regent Street, Glasgow. Alexander Cantlay, Anchagatt, Aberdeen.

SECRETARY AND OFFICE.—James Ferrier Anderson (of Lyall, Anderson & Co.), 16, Philpot Lane, London, E.C.

REPORT OF THE BOARD OF DIRECTORS,

to be presented to the Shareholders at their First Annual Ordinary Meeting, to be held at the Office of the Company, 16, Philpot Lane, London, E.C., on Monday, 30th March, 1903, at 11 a.m.

The Directors have pleasure in submitting to the Shareholders the Report and Accounts of the Company for the year ending 31st December, 1902. The Company was incorporated on 27th December, 1901, and the transfer of the property duly completed on 10th January, 1902, from which latter date the Estate has been worked for account of the Company. As indicated in the private prospectus issued in December, 1901, The Vendors have made over to the Company the whole net profits earned by the Estate from 1st January, 1901, to date of purchase 10th January, 1902. These amounted to £4,702 17s, and were utilised in the payment of dividends of 1½ per cent, in all, absorbing £1,700, leaving a small balance of £2 17s to carry forward. The net profits from 10th January to 31st December, 1902, amount to £3,597 4s 6d, which, with the £2 17s mentioned above, gives a total to be dealt with of £3,600 1s 6d. An Interim Dividend of 4 per cent, free of Income Tax, paid in September, 1902, absorbed £1,600. It is now proposed to pay a final dividend at the same rate (making 8 per cent, for the year) £1,600. To place to Reserve Account as a nucleus of that Fund £200. And to carry forward to next Account £200 1s 6d.—£3,600 1s 6d. The Directors regret that the profits for the past year have fallen considerably short of those realised by the Estate in previous seasons, the reasons for such shrinkage being threefold, namely, exceptionally unfavourable weather in Ceylon, the depressed state of the Tea market, and the loss of profit on the purchase of Belton Leaf—the proprietors of that estate having built a Factory of their own in the early part of the year. The crop secured for the past season was 352,319 lb, or about 466 lb per cultivated acre, and in addition to this, 4959 lb tea was made from Belton leaf in the beginning of the year, giving a total output from the factory of 357,278 lb tea. It will be seen from the accounts that the tea has been sold partly in London and partly in Ceylon, the system adopted being to sell the higher grades in the former and the lower grades in the latter market, and the market continues to maintain a prominent position both in London and Colombo. The management of the estate has changed hands during the year, Mr Cantlay having resigned, and Mr Joseph C Dunbar having been appointed Manager in his place. It is a matter for satisfaction that, as a member of the Board, the Company will continue to have the benefit of Mr Cantlay's long experience and intimate knowledge of the estate, while the Shareholders are also to be congratulated on securing the services of an experienced planter like Mr Dunbar as the Company's Manager and Representative in Ceylon. In accordance with the Articles of Association, Messrs J A Melville Stephens and W J Chrystal retire from the Board, and these gentlemen being eligible offer themselves for re-election.

Messrs Cape and Dalgleish, C.A., also offer themselves for re-election as Auditors.—By Order of the Board,
JAS. F. ANDERSON, Secretary.

THE YATIYANTOTA, CEYLON TEA COMPANY, LIMITED.

DIRECTORS:—Messrs A Thomson, Chairman, Charles Young, J M Skinner.

MANAGING AGENTS:—Messrs Whittall & Co., Colombo.

SECRETARY AND OFFICERS:—T A Williams, 27, Mincing Lane, London, E.C.

REPORT OF THE DIRECTORS

to be submitted at the sixth annual general meeting of Shareholders to be held at the London Commercial Sale Rooms, 30 to 34, Mincing Lane, London, E.C., on Wednesday, the 8th April, 1903, at 12 noon.

The Directors now beg to submit the duly audited accounts of the Company for the year ended 31st December, 1902. The bearing area, of all ages, was 2,982 acres, from which crops amounting to 1,434,496 lb were secured, and, in addition, 7,107 lb were made from purchased leaf. Of the total, 772,011 lb were sold in Colombo, and 669,592 lb were shipped to London, the net average realised for the whole being 4'84d per lb, including purchased leaf, the average cost, f. o. b. (or delivered to buyers in Colombo) was 3'37d per lb. The average rate of exchange for the year was 1s 4 3-16d per rupee.

The following is a comparative statement of the past three years' working:—

Year.	Average plucked Mature and in partial bearing	Crop secured from Company's Estates.	Average yield per acre Plucked.	Average Rate of Exchange per Rupee.	Cost of Crop per lb.	Net Average Sale Price per lb.
1900	2,854	1,470,590 lb	515 lb	1s 4 7-32d	3'40d	4'56d
1901	2,970	1,261,484 „	425 „	1s 4 7-32d	3'83d	5'10d
1902	2,982	1,434,496 „	481 „	1s 4 3-16d	3'37d	4'84d

The outturn for 1902 fell below expectations, owing to unfavourable weather during nearly the whole of the second half of the year. The market was very poor during the earlier months of the year, but since October it has undergone material improvement.

The net profit for the year amounts to £3,157 3 1
To which has to be added balance from

1901 Account	2,072 5 5
Together	10,229 8 6

Dividends have been paid as follows:—

On the Preference Shares at 6 per cent per annum—	
On 1st July, 1902, and	
1st Jan, 1903 ..	2,700 0 0

Leaving now to be dealt with ... £7,529 8 6

This the Directors propose to appropriate as follows:—

(1) In payment of a Dividend on the Ordinary Shares of 5 per cent for the year 1902 ..	£4,500 0 0
(2) In writing off Cost of Properties, including Depreciation of Machinery and Buildings ..	1,000 0 0
(3) In carrying forward to 1903, the balance of	2,029 8 6
Total	£7,529 8 6

The following are details of the acreage of the different properties as on 1st January, 1903:—

ESTATE.	ACREAGE UNDER TEA.				Forest Reserves &c.	Total Acreage.
	Bearing	Partial Bearing	Not Bearing	Total.		
Polatagama ...	791	..	50	841	201	1,042
Weoya and New Polatagama ...	632	95	..	727	345	1,072
Walpoia ...	871	871	145	1,016
Rondura ..	581	20	..	601	629	1,230
	2,875	115	50	3,040	1,320	4,360

The condition of the Company's Estate continues satisfactory, and the Directors desire to record their high appreciation of the management and general working of the properties. In terms of the Articles of Association, Mr. C Young retires from the Board, and being eligible, offers himself for re-election. Messrs. Cape & Dalgleish, C.A., offer themselves for re-election as Auditors of the Company. By order of the Board, T. A. WILLIAMS, Secretary.

27, Mincing Lane, London, E.C., March 30th 1903.

BALMORAL (CEYLON ESTATES) COMPANY, LIMITED.

REPORT.—To be presented at the Fifth Annual General Meeting of the Balmoral (Ceylon) Estates Company, Limited, to be held at the Offices of the Company, 12, Fenchurch Street, E.C., on Thursday, 9th April, at 11-30 a.m.

The Directors have the pleasure to submit the Balance Sheet and Accounts of the Company for the year ending 31st December, 1902, duly audited.

The total yield of tea was 540,057 lb., against 595,197 lb. last year, being at the rate of 581 lb. per acre all round; the cost of production, exclusive of Capital Expenditure, was 26 cents per lb., free on board at Colombo, and the gross average price obtained was 9-22d. per lb. against 8-53d. per lb. last year—Sandringham Teas averaging 8-84d. and Clydesdale 9-61d. per lb. Exchange has averaged throughout the year 1s. 4-7-32d. against 1s. 4-3-16d. last year.

All Capital Expenditure has been charged against Revenue, and in view of this the Directors do not consider it necessary to set aside a specific sum for depreciation.

The Net Profit for the year amounts to £7,451 18s. 4d.; and the balance from last year to £675 10s. 6d., making a total of £8,127 8s. 10d.

The Directors have already paid out of this, Dividends on the 6 per cent Preference Shares for the year ending 31st December, 1902, £1,800.; Interim Dividend on the ordinary Shares of 5 per cent free of Income Tax £2,601 15s.; Income Tax £357 11s 7d.; and it is proposed to pay a Dividend of 5 per cent free of Income Tax on the Ordinary Shares, making 10 per cent for the year £2,601 15s.; and to carry forward the balance of £766 7s. 3d.—Total £8,127 8s. 10d.

The Auditor, Mr. J. Hamilton Alston, offers himself for re-election. By order of the Board, C. G. Bois, Joint Secretary.

London, 31st March, 1903.

THE CRAIGHEAD TEACOMPANY.

REPORT.

The Directors have the pleasure to submit the balance sheet and accounts of the Company for the year ending 31st December, 1902, duly audited.

The mortgage was reduced to £2,700 by the payment of the third instalment of £450 on the 31st December last. This sum is debited to profit and loss account, and is an ample charge for depreciation.

The total yield, excluding some 20,000 lb made from purchased leaf, was 428,091 lb tea which cost 25½ cents, F O B Colombo, and the gross average price obtained in London was 6-66d per lb. The crop of the previous year was 481,265 lb tea, and the gross average was 6-67d. per lb.

The net profit for the year amounted to £2,580 18s. And the balance from the previous year to £670 11s 1d. Total £3,251 9s 1d.

Interest on the mortgage has been paid £157 10s. The fourth instalment of the mortgage (£4,500) has been paid £450. Dividend on the six per cent. preference shares for the year has been paid £481 16s. An interim dividend of 2½ per cent. on the ordinary shares, free of income tax has been paid £572 15s. Income tax £104 9s 2d. It is proposed—To pay a final dividend of 3½ per cent free of income tax, on the ordinary shares, which will require £801 17s. And to carry forward the balance of £683 1s 11d. Total £3,251 9s 1d.

The Directors desire to place on record their appreciation of the efficient management of the estates by Mr. Ernest Hamilton and his staff.

Mr. George Alston, the Director who retires on this occasion, being eligible, offers himself for re-election.

The approximate acreages are as follows as per recent survey:—

Tea.—In bearing ..	834 acres.
" In partial bearing ..	53 "
" Not in bearing ..	9 "
Ravines and Waste ..	62 "
Timber Clearings ..	53 "
Jungle and Patana ..	31 "
	1,042 acres.

CEYLON PLANTERS' RUBBER SYNDICATE.

Authorised Capital R250,000. Called up Capital R140,000.

DIRECTORS:—W P Halliley, A H Dansmure, E Hamilton. Secretary:—J E B Baillie Hamilton.

ACREAGE.

The Acreage of the Syndicate property is as follows:—

Opened Land ..	644 Acres
Reserve ..	249 "
Total ..	884 Acres

At 31st December, 1902, 644 acres were cleared which:—

350 Acres were in Rubber under 2 years.
85 " " " " 1 "
9 " " " " " "
200 " " " " " " Coconuts
Coffee. " " " " " " cleared and 60 planted with

Mr. L T Boustead visited the Syndicates Estate on 11 and 12th March and reports that all the older fields show a good even growth fully up to the average of other Estates and a fair percentage of trees have started to branch out and stems to thicken.

The 60 acres of Coffee planted looks very well, about 4 per cent of vacancies only, and the Superintendent is confident of finishing the remaining 140 acres by the end of April.

A new Director and Auditor will have to be appointed in place of Mr. A H Dansmure and Mr. W H Graham.

C.—*Investors' Guardian*, March 28.

INDIAN 'S, CEYLON GREENS.

RELATIVE COST OF MANUFACTURE AND LONDON PRICES.

A merchant with considerable experience and knowledge of the Ceylon Green Tea trade writes in regard to Mr. Judge's letter published on page 775, as follows:—

With regard to Mr. Charles Judge's letter to you, it will be noted from the weekly sales of greens held in Colombo that the average rates obtained for the teas of various gardens average from 33 cents to 39 cents per lb, depending upon the quality and elevation of the estate. "G.T." 's statement in a letter addressed to the newspapers dated 25th March (which stated that the greens cost 4 cents more to manufacture than blacks) cannot be endorsed by any but careless manufacturers in Ceylon. As stated by one of Mr. Judge's Indian correspondents, the cost of firewood is necessarily slightly in excess of the cost of firewood for black teas, as there is a larger percentage of moisture to expel from the Green Tea. Many estates, however, turn out quite as large a percentage of green as of black tea ; so that India has no advantage over Ceylon in this respect. Where firewood is scarce and dear, the extra cost for fuel is a serious item. As regards Indian Green tea fetching higher prices than those of Ceylon manufacture in London, a glance at Messrs. Gow Wilson and Stanton's Circulars for February and March, to take a convenient period, will show how prices rule. On February 6th no green tea averages were given. On February 13th a break of Ceylon Young Hyson fetched an average of 8½, while the average obtained for a break of 5S packages including Young Hyson, Hyson No. 1, Hyson No. 2, Fannings and Dust got an average of 6¾. In the February 27th circular a break of Indian Greens, including only Hyson and Hyson No. 1, got an average of 7½, while a break of Ceylon Tea including all grades—Young Hyson, Hyson No. 1, Hyson No. 2, and Fannings and Dust also got an average of 7½ notwithstanding that it included two more grades than the Indian break. In the March 6th circular a Ceylon break including four grades is recorded as having obtained a 6d average, while an Indian consignment only gets 5½d, while the break only included two grades. In March 13th's circular a break of Indian Green Tea gets an average of 6d for three grades, while in the March 27th circular a break of Ceylon including two grades got an average of 5½d.

If these prices can be taken as a criterion, Indian Green tea is certainly not getting higher prices than Ceylons.

PLANTING NOTES.

EGGS.—Remember that the hen that is laying needs about twice as much feed as she would need if not laying. Like many other machines, she must be furnished the material from which to manufacture her finished product.—*Agricultural Gazette of New South Wales*, March.

MONTHLY TEA AVERAGES IN LONDON.—The table we publish elsewhere from Messrs. Geo. White & Co.'s annual tea report is always looked forward to with high interest. For 1902 Udapussellawa and kindred districts are first with 8^d average— $\frac{1}{4}$ th below last year, and still $\frac{1}{4}$ ths below 1900. Maskeliya similarly shows a drop of $\frac{1}{4}$ d; but Lower Dikoya, Kellebokka, Matale and Kelani Valley a rise of $\frac{1}{4}$ th. Others are stationary e.g. Hantane, Kurunegala, Rakwana and Kalutara, while falls are seen again in Pussellawa ($\frac{1}{4}$), Udugama ($\frac{1}{4}$), Haputale and Madulsima ($\frac{1}{4}$), and in the general average, 6^d as against 7d—and 7 $\frac{1}{2}$ in 1900. Kurunegala, &c., 5 $\frac{1}{2}$ d, is the lowest average recorded for 1902.

COLLAR-PRUNING FOR CEYLON TEA.—An Indian planting correspondent, Mr. A Cooke, who asked in our columns the other day whether collar-pruning had ever been done twice on Ceylon bushes, has a fairly complete answer in the most useful remarks given elsewhere by a local planter, signing "Still uncollared." The treatment is a drastic one and—like most drastic treatment everywhere—is in Ceylon only applied to the worst cases, teas of bad *jât*. At the same time there may be collar-pruning and collar-pruning!—if Mr. Cooke has confused the two operations of "coppicing" and "stumping" which are carefully distinguished elsewhere. The poorer the *jât*, the more attention the bush requires, to be kept in passable condition; and whether collar-pruning, or other means, will do this, is left to the practical planter to find out.

CAFFEINE COFFEE.—It has long been known that coffee berries usually contain something like one per cent of caffeine, the substance to which coffee owes its stimulating properties. Recently M Bertrand of the Pasteur Institute has analysed nine kinds of coffee with interesting results which are referred to in the *Agricultural News* Barbados. The beans of one species (*Coffea humblotiana*) contained no caffeine, and in another species (*C. mauritiana*) only 0.07 per cent, was present. These two varieties are thus for all practical purposes free from the simulating alkaloid. In Arabian coffee (*C. arabica*), obtained from various sources, the caffeine present varied from 0.83 to 1.60 per cent. Liberian coffee (*C. liberica*) yielded between 1.06 and 1.45 per cent. The new African coffee (*C. stenophylla*) appears very rich in caffeine, 1.52 and 1.70 per cent, being the results of two analyses recorded. *Coffea canephora* gave the highest caffeine content, 1.97 per cent. The paper is printed in *L'Agriculture pratique des pays chauds*, Year II., pp. 211-13.—*Journal of the Society of Arts*, March 27.

GREEN TEA IN AMERICA.—The *American Grocer*, March 18th, states:—"Messrs. Wisner & Co. received advices from Shanghai stating that no further supplies of green teas can be obtained from the country, as the whole of this season's crop has been marketed. The point is of particular interest when the large size of this season's production of green teas is taken into consideration." This will continue until about the first week of June when the first of the new seasons' shipments should begin to arrive from China. Japan, we note in an Eastern paper, has again commenced to make black tea to suit the Russian taste.

POISONS AND PESTS.—Quite recently we have seen a preparation intended for the destruction of ants. This preparation, as we have been informed, contains arsenic in very large quantity, namely, not less than 24 grains to the ounce, two grains being a fatal dose. A pint bottle would thus contain sufficient arsenic to poison one hundred and fifty or more adults. The actual cost of the "mixture" is estimated at about threepence half-penny. What the selling price is we do not know, but in all probability it is one which admits of a very large profit. It is true that to the sample we saw a label with the word "poison" was affixed but the bottle was an ordinary medicine bottle with nothing distinctive about it to prevent carelessness or accident.—*Gardeners' Chronicle*, April 4.

THE PINEHURST TEA EXPERIMENT.—The only fault we have to find with Mr. Shepherd's letter on the tea experiment of which he is in charge is that it does not convey sufficient fresh information to dispel the cloud he seems to feel has been caused by Mr. Larkin's uncomplimentary remarks. We are glad to hear that it is so far progressing that he has asked Government for tea machinery, indicating increased manufacture, and, even if it be of academic interest only, all tea planters will be glad to hear how the Pinehurst experiment is getting on from time to time. Of course it is within the bounds of possibility that this pleasure will be tempered, with those whose interests are against any development of fresh tea-producing countries; but for this we have still a little while to wait.—?

THE MANUFACTURE OF GREEN TEA AND BLACK.—"G. T." who has evidently demonstrated the matter to his own personal satisfaction firmly adheres to his former contention. We referred his letter to our correspondent who wrote on Saturday and he suggests "that it would be interesting if "G. T." were to give particulars of his process, so that some more knowing one may give him the tip how to save loss in weight. It is a pity that he should go on losing 4 per cent weight when Mr. Judge and perhaps a few Ceylon planters also, can give such advice as will save this loss. Unless he expresses 4 per cent solid matter from his leaf, when squeezing out the surplus water, how can there be loss in weight? If he sends this stuff out of his factory drains to manure his fields he may of course get a corresponding return from his bushes at a later period, which may satisfy him." Some other green tea manufactures in Ceylon might also give us the benefit of their experience on this question,

[ESTIMATE for May 1903—8½ to 9 million lb.]

A NEW FODDER PLANT: "PENICILLARIA."
—This new fodder plant seems to be attracting universal attention among our readers, says *American Gardening*, and the crop is truly wonderful, as it yields from three to seven cuttings per year from one sowing and has produced ninety-five tons of green fodder per acre from three cuttings in a carefully weighed test. The seeds are so very small that one pound will plant an acre, and still one plant usually has 25 to 75 stalks, growing seven to fourteen feet in height. When it is figured that one-fourth acre will produce sufficient fodder to support a cow six months, either for summer or winter food, and that the dry hay, as well as the fresh fodder, is highly nourishing, the value of the new plant will be better appreciated,—*Indian Planting and Gardening*, April 11,

THE CHANGING OF THE SEX IN PLANTS.

THE *Journal d' Agriculture Tropicale* avers that the inhabitants of the Southern oases in Algeria claim the ability to change the sex of date palms. Of 100 date palms 80 are male trees, hence it may readily be conceived that it is greatly to man's interest that the cultivator's intervention should be crowned with success. The method consists of tearing off all the leaves from the foot-stalks at two or three years of age, so that the medial nerve is split in two from the centre to the leaf sheaf. The idea of the Arabs is that this tearing process brings on a concentration of the sap movement in the same way as in the case of an annular incision, and results in an accumulation of sap, which is more necessary for the vital functions of the female plant than for those of the male. No objection, says the editor, from a vegetable pathological point of view, can be raised against the above assertion, for the reason that in young plants the organs are not yet different from each other.

In our experience, the topping—or cutting of the terminal bud—of "male" papaw trees (*Carica Papaya*) as soon as the character of the flower is ascertainable, results in altering that character and inducing them to yield good fruit in lieu of the wretched specimens borne by the so-called male tree.

In this case as with the date palms there is no doubt that the drastic treatment adopted results in what is referred to in the *Journal d'Agriculture Tropicale* as a "concentration of the sap."

In the Papaw the weakly nature of the male tree is characteristic, and the sex could almost be anticipated before blossoming. Whether any such distinctive physical character is observable in the date palm we cannot say, but it is more than likely there is. By cutting back, therefore, it is reasonable to suppose that the sudden checking of the upward flow of sap to meet the demands of the new growths in the region of the terminal bud, brings about a turgid condition of the cells and a corresponding concentrated or vigorous condition of the cell-sap, which is thus enabled to develop the fruit-bearing organs of the flower.

In a "male" or staminate flower, we must of course assume that the pistillate part of it is only suppressed and capable of development under extraordinary conditions. Suppression is defined in botanical text-books as the absence of parts in a flower, which, from analogy, we might expect to find. The correctness of this view is proved by the fact that we often find an imperfect or partial development of organs that should be present under ordinary circumstances. To such partial development of the pistil must be attributed the production of imperfect fruit on the so-called male papaw tree. And that the further development of organs, which have a tendency to suppression, is possible by artificial means, is further proved by the fact referred to above, namely, that the cutting back of the plant in the male papaw results in the production of pistillate flowers. It will be found in actual practice that one cutting back does not always bring about the desired result, and that the tree has to be attacked more than once before the tendency to suppression of the female organ is overcome.

The ingenuity of the skilled gardener has produced marvellous results in floriculture, not merely in the development or suppression of organs, but also in the multiplication of the parts of flowers, the increase of the number of one series with the corresponding decrease or suppression of another. With the possibility of such results, the apparent marvel of changing the sex of flowers loses its marvellous character. For change of sex would be nothing more than the development or suppression of the stamens or pistil, resulting in the production of male, female or hermaphrodite flowers. The sexual character of the flower would thus appear to be, to some extent at least, controllable, and dependent on the influence of external forces.

OCCASIONAL NOTES.

Many people complain of the great difficulty in raising vegetables by the sea-side. That such difficulties exist it cannot be denied, but there are crops that will thrive, and thrive well for the greater part of the year, quite near to the sea. What is wanted is experience and that can only be gained by trials of different varieties. It would appear that cucurbits are not unfavourably affected by proximity to the sea, and Luffa grows particularly luxuriantly in such situations.

A contributor to the *Agricultural Gazette* of N. S. W. writing on *Paspalum dilatatum*, which he says "is now so much grown everywhere," refers to its reputation as "hard to germinate," and explains this by stating that it produces very little good seed, the percentage of fertile seed being very low, only $\frac{1}{2}$ to 2 per cent. It is surmised that the seed is greatly affected by external conditions, or perhaps like some other known grasses, only few seeds are produced, and of these only a small percentage fertile. For propagation, therefore, the writer concludes that "without doubt, division of the roots remain the best method." In our own experience propagation by seed is very difficult, but, with root division, there is little difficulty in establishing this grass which may be seen growing in the Government Stock Garden in Colombo.

A very common plant in Dumbara, growing with the grass and sticking close to the ground, with outspread leaves, is the "et-adi" or elephant foot, so called no doubt owing to some remote resemblance to the print of the mammoth foot. In spite of very dry weather it seems well able to hold its own amid the short dry grass, eaten down by cattle and scorched by the sun, but itself apparently untouched. Botanically the plant is *Elephantopus scaber*, belonging to the order Compositae.

The generic name *Elephantopus* is Linnaeus' translation of the native name *et-adi* (Sinhalese) and *Anishovadi* (Tamil), both meaning "elephant's footprint," and, like *melastoma* (black mouth)

embodies an attribute of the plant as noted by the native observer. Trimen says of this plant, "One of the commonest weeds in turf, and owing to its long roots, difficult to eradicate. The leaves are used as an external application."

Enquiry has been made for *Equisetum debile* as a material for making a cooling drink. The plant is described by Watt as "a vascular cryptogam with creeping rhizomes and fluted stems," and is said to be used in India as a cooling medicine and for gonorrhoea. Though found upcountry we doubt if it could be got in sufficient quantity to meet a large demand. We have, however, supplied samples to be sent to Germany from whence the enquiry came.

Mr. A. Despeissis, writing on Tropical Fruit to the *Journal of the Department of Agriculture of Western Australia*, says that the weight of the breadfruit goes up to 30 lb. This is a stupendous weight for the breadfruit and will astonish readers in Ceylon, where the breadfruit grows so well. On the other hand the smooth Cayenne (Giant Kew) pine is said to weigh from 6 to 10 lbs., whereas a weight of 20 lbs. (the record we should say) has been reached in Henaratgoda Gardens, while in Matale (as noted in our last issue) Dr. VanRoyen has succeeded in raising pines weighing 16 lbs. and over.

Mr. G. S. Sykes writing to the *Indian Agriculturist* speaks of "banana meal or flour prepared from the ripe banana fruit." Surely this is a mistake? Banana meal or flour, as we know it and prepare it, is made from the unripe but "hard" fruit.

ALEX. PERERA.

THE DEVELOPMENT OF VILLAGE INDUSTRIES.

No policy for the improvement of the condition of the villager in Ceylon will be complete unless attention is paid to the development of minor industries. Our villager in the majority of cases is a land owner, and he can never be induced to leave his ancestral holdings. But these ancestral lands are gradually being alienated in many places, and in these instances the land is being so sub-divided as to leave barely a sufficient area for a man to support himself by agricultural labour. One result of the reduction of the extent of land held by individuals will be an appreciation of improved methods of cultivation, for when a man finds that by better attention to tillage operations, manuring and selection of seed he is able to take as much out of a small plot as he did with larger areas of land under the old system, necessity compels him to pay some intelligent attention to the new methods which he looked to with suspicion at one time. The School Garden system which was recently introduced in the Island should prove to be of great use at this juncture, and the development of the scheme will in time be welcomed by even the most conservative village *goyiya*.

The second requisite for the development of village industries is the freeing of the *goyiya* from the village money lender, at least in regard to what he actually requires in the cultivation of his lands. It has often been mentioned that a village cultivator has to pay a hundred per cent on the seed grain he obtains, hundred per cent on the manure, and an equally large percentage on any little money he raises to enable him to grow a crop. This is a very large waste, and a saving in this interest will increase his earnings to two or three times of what they are at present.

For example, a *goyiya* who owns in his own right an acre of paddy land, expends personal labour in its cultivation, but has to borrow the seed paddy, say $2\frac{1}{2}$ bushels, for sowing his acre; he also borrows the bone meal say 56 lbs. After he reaps his crop in four or five months' time he has to return five bushels of paddy for the $2\frac{1}{2}$ he borrowed and four bushels for the manure. His full crop may be anything below 20 bushels, and only 11 bushels are left for all his labour, including cattle for ploughing and thrashing. There is no reason why an Agricultural Banking system cannot be introduced in Ceylon, and that too with profit. We have the system now working successfully in such places as Egypt and the Deccan, where the conditions and the surroundings of the cultivator are decidedly more unfavourable for the development of such a system than in Ceylon. An Agricultural Bank will do more than allow the cultivator to obtain his seed and manure at reasonable rates, it will help in the speedy development of the tens of thousands of acres of land which are now being made available for cultivation under the new irrigation scheme. It is only the small landholder that can successfully cultivate irrigable lands. These cultivators with a little encouragement

will take up every available acre of irrigable land. The encouragement they require is not much, and will in no way affect the public funds. They will not ask for bonuses, or free grants, or leases on favourable terms.

If we have an Agricultural Bank, and if a little money is lent out on favourable rates for cultivating the land, nothing more will be required to see all these lands profitably cultivated.

There are districts in Ceylon where a number of minor industries can be successfully started among the villagers, and it is here that some special attention should be given to the subject. The preparation of jams and preserves, the manufacture of various articles out of the different kinds of fibres, leaves and rushes so commonly met with here, reed, rattan and bamboo work; and various forms of ornamental work in wood are industries that will readily appeal to the villager. At present these products are put to use to a very small extent to meet immediate local demands; but to create regular and systematic industries, with a steady demand for the articles turned out, some efforts have to be made to instruct and encourage the producers. There are a large number of wild fruit as well as easily-cultivated vegetable products that can be profitably used in making preserves. The villager will be prepared to give his labour very cheap in preparing preserves, if he only knew what is required, and if he is able to readily dispose of his produce. Woodapple, bael fruit, bilin, lovi-lovi, guava, rambutan, pineapple, Saville oranges and many other fruits now almost run to waste in places far from the chief towns. Fibre leaves and rushes are now put to use in certain localities in the preparation of mats, bags, and a few other articles; but these have only a very limited demand. People must be taught to turn out articles to suit modern requirements. Thousands of kinds of paying articles can be easily made out of these raw products, and the villager who can turn out a mat in complicated patterns, or a tray or a bag with ingenious devices can easily be taught to turn out anything that may be required in the market. The same applies in the case of rattan and bamboo work. The numberless articles prepared in Japan and the Straits in these materials can be turned out here, and can be made a profitable industry among the villagers. The same can be said of ornamental work and wood carving.

These are very simple matters, but if once systematically introduced will have far-reaching effects. There should be some practical training in industrial work in our village schools. The village schools need not be converted into so-called industrial schools where the pupils are taught to be labourers in mere mechanical trades such as smithing, shoemaking, tailoring and printing. Every village school boy should know something of form, colour and the properties of common objects; he should have some training in plaiting, weaving and modelling, in fact in the use of his hands; without this knowledge his learning will not be of much use to him. The art schools in India and Burmah are doing a great deal towards the improvement of minor industries similar to

those noted above. We have no art school, or a school of handicrafts in Ceylon. The Technical College only trains boys in the higher branches of engineering and mechanics which will undoubtedly help large manufacturing industries. But we have no manufacturing industries in Ceylon, neither is it likely that we will ever induce capitalists to open workshops and set up costly machinery for manufacturing, when the raw material required for such purposes is not forthcoming in any appreciable quantities. The Ceylon Technical College should open classes in the vernacular for teaching the properties of raw materials found in the Island, and the methods of utilizing them for making articles that are required in modern markets. It is only at such an institution that a collection of suitable models can be made. The latest methods of food preserving, fruit packing and canning can be scientifically taught at this institution. The preparation and blending of colour, the manufacture of hundreds of varieties of useful articles out of fibre, leaves, rushes, rattan, reed and bamboo can be studied and systematically taught. The scientific staff attached to the institution will be capable of collecting information that will be of great value, they will be able to experiment on, and test local materials and find new raw materials for the use of the village worker, and eventually open up industries that will benefit a large number of people who are ready to work with their own hands.

W. A. D. S.

OCIMUM SP.

Considerable prominence has been given to the value of the different species of *Ocimum* by Mr. Shipley's article in *Nature* (January, 1902) which treats more especially of *O. viride* as a cure for mosquitoes. This particular variety does not occur in Ceylon, but the reputation of the plant as a mosquito-fuge (to coin a new term) at once suggests the close connection between the plant in question and *O. sanctum*, known among the natives as *madurutala* or "the mosquito plant."

The testimony of Capt. Larymore, C.M.G., Resident, Kabba Province (Nigeria?) is certainly very strong, when he avers that by placing 3 or 4 of the plants round his bed at night he was able to sleep unmolested without using a mosquito curtain; and if we may assume that the experience was not a solitary one, and also that there were no other circumstances prevailing to which the absence of mosquitoes could have been attributed, then we must admit that a valuable discovery has been made for British East Africa. For ourselves we are inclined to think that *O. sanctum* would serve us quite as well as *O. viride*, and we would advise all mosquito-ridden ones to take the hint from the native, as Capt. Larymore has done in East Africa, and make use of *madurutala*, the mosquito plant of Ceylon, in the manner suggested.

Regarding *O. sanctum*, Trimen says, "The scent of the bruised leaves is faintly sourly (*sic*) aromatic; they are used in medicine in cases of cough and catarrh," but he does not

add, "also for keeping away mosquitoes—hence the native name."

Other species of *Ocimum* are: *O. canum* (Hintala), the leaves of which are pleasantly aromatic when bruised. *O. basilicum* (suvanda-tala), the "Sweet Basil," with a very sweet aromatic scent when bruised. *O. gratissimum* (gas-tala) and its variety *O. suave*, with faintly aromatic apple-like scent, and used in medicinal fumigations. Lastly *O. adscendens*.

The majority of tropical labiates are characterised by aromatic properties, such as species of *Mentha*, *Colens*, *Plectranthus*, *Pogostemon*, &c. *Anisomeles ovata*, another member of this order, which possesses "a warm Camphoraceous scent" must, however, take the palm for keeping off noxious creatures, for we read that the smoke from this is believed by the natives of Ceylon to drive away not mosquitoes but demons!

SOME PROBLEMS OF THE RURAL SCHOOL.

(Continued from last issue.)

With the better organisation of the rural school will come very much wider opportunities for the enrichment of the courses of study by the introduction of subjects which are directly related to agricultural improvement and the inculcation of the love of country life in the minds of the young. All round the country school is a wealth of material for the most attractive and useful study which has been neglected for lack of knowledge and the absence of a teacher. The secrets of air, soil, plant and animal are coming to be common property, and science no longer mere classifying and naming. In the United States the enthusiastic and successful labours of such men as Professors Bailey and Roberts of Cornell University in formulating plans for nature study in the rural schools have borne much good fruit. Special efforts are now being made to secure the interest of teachers and parents,

The great obstacle to the spread of the movement to introduce nature study into the rural school, aside from the lack of competent teachers, is found in the conservation of the patrons of these schools. Reading, writing and arithmetic they know, but what, forsooth, is this new-fangled nature study? The subject is often so presented to their minds that it seems to them as if the new study must necessarily crowd out some of the old ones, or at least weaken the already too imperfect hold which the average pupil has on such fundamental things as spelling, writing, and arithmetic. But this need not be so. Instruction about plants and animals and insects may easily and naturally be connected with exercises in composition and in numbers, which will bring into practical use from day to day what the child is learning in his lessons about the English language, arithmetic, or geography. Properly taught, nature study will not crowd out any essential branch of learning from the common schools, but, on the other hand, it will stimulate interest in them all as the pupil discovers that they may be directly

related to his daily life and the world about him. Once the child's mind is awakened to the innumerable wonders of nature, and his interest excited in explanations of phenomena with which his farm life makes him familiar, it will be far easier than ever before to stimulate him to continuous endeavour to widen his knowledge through reading, as well as through observation. He will have more thoughts to put on paper, and he will often wish to draw objects he has seen.

The country boy often has a wonderful familiarity with nature—animals, birds and trees—which is of little value till it is broadened and deepened by being connected with facts and principles of which he has no knowledge.

The school is the place where we should learn to connect the practical and other knowledge we already have, with what other men knew who have lived in the past or in other places, or who have studied certain subjects very thoroughly.

What is wanted in our schools is to connect a child's limited knowledge of nature with what science has improved of nature's mysteries, so that life and work in the country may be improved thereby. If we have any such idea as that practice and science must remain apart, we must discard it at once. So far from being "divorced," they are joined as Dr. True forcibly puts it "in indissoluble wedlock." When the needs of the common schools are studied with unprejudiced minds, it will be seen that if they are to be brought into harmony with modern progress in horticulture, agriculture and other industries, they must be developed so as to bring them into direct touch with the land and its productiveness. The nature study movement promises to do this, and for this reason all those who have any concern with the cultivation of land should take an interest in it. True, nature study in the village school is only in its beginning, and much experience will have to be gained before we learn its just limitations and develop its proper service; but this can only be done through its actual working in the schools. Therefore, says Dr. True, open the common schools to instruction in nature, and make that instruction relate directly to the land. Insist also that normal schools and teachers' institutes prepare teachers for this line of work.

PLANTAIN FIBRE.

Hitherto the general impression has been that plantain fibre was only got from a particular species of *musa* which produces the fibre known as "manilla hemp," and hence no serious attempt was made to utilize the stems of the trees so long cultivated only for fruit.

Since of late, however, considerable interest has been aroused by the publication of reports on the value of the fibre to be got from the edible varieties of the plantain. *Musa* fibre, extracted from the outer sheath of the banana or plantain (call it what you will, for there is no real distinction) after the fruits have been cut, is

reputed to be suitable for making "mats, coarse canvas, cords, hats, plaited work, raw fibre cables, rope, twine, fine muslins, and fabrics 'half stuff' and paper of all kinds, lace, fine lace handkerchiefs, and cloth of a close texture and very durable."

In a contribution to the March number of the *Indian Agriculturist*, Mr. G. S. Sykes deals at length on this subject. It is needless for us to give a full summary of the article, but a description of the method of extracting the fibre will no doubt be acceptable to our readers, some of whom have, indeed, been making enquiries as to how this could be best done. According to Mr. Sykes the method of extracting the fibre is simplicity itself. The stem is cut down to the ground and each leaf is sliced off. The operator then sits on the ground with the end of the leaf stalk in his lap, makes an incision under the fibre at the end, and with a smart twitch rends off strips of the outer skin with adhering fibre, up to the whole length of the stalk. In this way ribbons of fibre are got, and in the same way the stem is also stripped into ribbons.

The contrivance for extracting the fibre consists of a small plank, to which is fixed a blunt iron knife that can be weighted, under which the strips are drawn three or four times, separating pulp and juice from the fibre. The exact amount of pressure to be applied must be learnt by practice. The knife must not be too sharp, but also not too blunt. From ordinary stems $1\frac{1}{2}$ to 2 lbs. of fibre should be obtained, but from $2\frac{1}{2}$ to 3 lbs. could be got from large stems when the whole length as well as the petioles are used. It is estimated that one man can produce 50 lbs. of fibre per day. The fibre should be at once thoroughly dried in the sun to preserve colour and quality. Carefully prepared fibre is said to be worth from £25 to £30 per ton in London, while the entire cost of placing it on the market should not exceed £10 per ton.

This is certainly very encouraging to those who are in a position to embark on the new industry.

HOUSEHOLD HINTS.

ARROWROOT BISCUITS.—1 lb. of butter, 1 lb. sugar, 1 lb. arrowroot (or corn flour), 1 lb. flour, two eggs. First beat well together the butter, sugar, and yolks of the eggs till it is like cream, then add the white of the eggs which have been beaten to a stiff froth, then add slowly the flour and arrowroot, mix well, and roll out on a board till the required thickness is got. Then bake.

ARROWROOT CAKE (BERMUDA CAKE).—Take 4 oz. each of butter, arrowroot, and sugar, two eggs, and the rind of half a lemon. First beat the butter to a cream; beat the yolks and white of eggs separately for ten minutes. Next add the sugar and flour rubbed through a sieve and the grated lemon peel. Beat all together for twenty minutes, grease a flat tin, line with butter paper, pour in the above mixture, decorate it with almonds, and bake in a quick oven. Turn on to a sieve to cool, and cut in squares. Sift sugar over and serve.

BANANA COMPOTE.—Pare thinly a lemon and squeeze the juice. Put both into a basin and leave for about an hour. Place a teacupful of cold water in an enamel saucepan, add to it a teacupful of sugar, and boil; when boiling strain into it the lemon juice. Pare 4 or 5 bananas, removing all fibre, and cut in half lengthwise, and then divide each half into three pieces, cook a few at a time in the syrup till transparent. When all are done, let the syrup get cool and then strain over the fruit.

Mildew stains may easily be removed by wetting and soaping the spot, covering it with powdered chalk, and then putting it in the sun to bleach. Damp it from time to time as it dries, and then wash it in the usual manner with soap and water. If necessary, repeat the process.

Alum purifies water in a remarkable degree. Four gallons of water may be purified by stirring into it a teaspoonful of powdered alum. Allow it to settle for a few hours, when all the impurities will be found to have sunk to the bottom of the vessel, leaving the water fresh and clear.

Wash vessels which have contained milk in cold water first, and afterwards scour them with hot water and soda. The use of cold water first insures greater cleanliness, for plunging at once into hot water is apt to set the milk and cause it to hang about the cans and pans to the detriment of the milk which is afterwards placed in it.

Cold water is said to be efficacious in removing a tight stopper. The bottle must be thoroughly immersed in plenty of cold water and allowed to remain in the latter all night. On removal it will be found that the stopper, after being carefully wiped all round, will come out without any difficulty. A small amount of vaseline rubbed on it will prevent any recurrence of the trouble.

To make liquid glue which will last for years put some pieces of glue into a bottle with some whisky. Cork tightly, and set aside till the glue has dissolved. This should be ready for use without heating, but in very cold weather the bottle may be stood in hot water for a few minutes before using the glue.

If you have not a night light, take an ordinary candle and put finely powdered salt round the wick up to the black part. A candle thus treated will burn very slowly, and give the dull light which is so often desirable in a sick room at night.

As a cough mixture for children the following recipe is unsurpassed:—Liquified honey, $\frac{1}{2}$ oz., lemon juice, 1 oz. Another mixture for strengthening the voice, as well as for curing a tickling cough, is:—Glycerine, $\frac{1}{2}$ oz.; fresh lemon juice, 1 oz., whisky, one teaspoonful. A quarter of a teaspoonful taken every fifteen minutes when the cough is troublesome will soon relieve it.

The odour of onions, either on the hands or on pots and pans, is easily removed by washing with ground mustard mixed with a little water. Linseed meal will answer the same purpose.

MARTHA.

PRINCIPLES OF NUTRITION AND NUTRITIVE VALUE OF FOOD.

(Continued.)

It is unnecessary, for the purposes of the ordinary reader, to give a description of the complex apparatus for ascertaining the functions and nutritive value of food, but it is sufficient to know that with such apparatus it is possible to learn what effect different conditions of nourishment will have on the human body. The methods and apparatus are very costly in time and money, but the results are proportionately more valuable than those from simpler experiments.

To summarise what has already been said: Food as purchased consists of an edible part (flesh of meat, yolk and white of egg, flour of wheat, etc.) and refuses (bones, shells, bran, etc.). The edible portion consists of water and nutrients (Protein, fats, carbohydrates and mineral matter). Protein (white of egg, curd of milk, lean of meat, gluten of wheat, etc.) goes to form tissue. Fats (fats of meat, butter, olive oil, etc.) are stored as fat. Carbohydrates (sugar, starch, etc.) are transformed into fat. All these three (Protein, fats, and carbohydrates) serve also as fuel to yield energy in the form of heat and muscular power. Lastly, mineral matter or ash (phosphate of lime, potash, etc.) takes part in the formation of bone, assists in digestion, etc. In view of the above functions, food may be defined as that which, taken into the body, builds tissue or yields energy. The most healthful food is that which is best fitted to the needs of the consumer. The cheapest food is that which yields the most nutriment at the least cost. The best food is that which is most healthful and cheapest.

The value of food for nutriment depends mainly on its composition and digestibility. Composition is determined by chemical analysis. In studying a table showing the composition of foods, one of the first things to be observed is the differences in the proportion of non-nutrients (refuse and water). Meat, fish, fruits, etc., as purchased, contain a good deal of refuse, which necessarily lessens the proportion of nutrients, while such refuse is usually absent in dairy products, cereal stuffs, and foods prepared from the latter (bread, cakes, etc.) In the edible portion the proportion of water present affects nutritive value. Water forms from 40 to 50 % of the ordinary kinds of meat, and is abundant in lean flesh, tending to decrease as fat increases and *vice versa*. In fresh fish water is more abundant than in meats. Fresh vegetables and fruit contain as much as 80 and 90 % or more, while dried seed and flour prepared from them contain roughly from 10 to 12 % only. Many cooked foods, of course, contain more water (added during cooking) than the raw materials. Soups are often little more than coloured and flavoured water, and are hence of extremely low

nutritive value. In some cooked food, on the other hand, notably baked, roasted, and fried meats, little water is present as the proportion has been diminished by the process of cooking.

The most important of the actual nutrients is protein. As stated it is most abundant in meat, fish, eggs, cheese, and dry legumes (beans, peas, etc.) The proportion of protein varies with the kind of meat and fish. In beef, veal and mutton it forms between 14 and 26 % of the edible portion. It is generally less in fish, because the latter is more watery than meat. The fatter the meat, the less is the protein. Lean pork has less than beef and mutton; fat pork almost none. In cheese there is from 18 to 38 %, in dried beans from 18 to 25 %. In cereals there is from 7 to 15 %, being most abundant in oats; wheat flour has about 11 %, and bread about 9 %. Fresh vegetables and fruits contain almost none, seldom if ever over 5 and often only 1 % or less. Fat is derived as a rule from animal foods, but some fat also from vegetable foods. In meat it varies from less than 10 in some cuts of beef and veal to 40 % and over in a side of pork, and over 80 % in fat salt pork. Lean fish like cod contain almost none, but in salmon it goes up to 10 and even 15 %. The chemical composite of salmon is indeed not unlike that of lean meat. Milk contains about 4 % fat; butter is practically pure fat, and full milk cheese may contain from 25 to 40 % according to the richness of the milk or cream.

With the exception of oatmeal, which contains about 7 %, there is little fat in cereals as sold, or in dried legumes, and it is practically wanting in green vegetables and most fruits. Oil seeds (like olive, cotton) are of course rich in fat. Edible nuts also contain a considerable amount.

Carbohydrates are almost entirely absent in animal foods, except milk, but forms the chief nutrient in vegetables. They make up from 70 to 80 %, of cereals, 60 to 70 of dry legumes, and the bulk of the nutrients of fresh vegetables and fruits, as of sugar, honey, etc.

Mineral matters occur in all ordinary foods. Fresh meat and fish contain about 1 %, and milk contains 7 %. In cereals the amount varies from 3 to over 2 %, but in green vegetables and fruits it is usually less than 1 %. Dry legumes contain from 3 to 4 %.

In short, meat, fish, eggs, milk, fresh vegetables and fruits contain most refuse and water. Protein is most abundant in animal foods and legumes, and also in cereals. Fats occur chiefly in animal food. Carbohydrates are found almost exclusively in vegetable products and milk. Mineral matter, in small proportion is found in all foods. The fuel value varies within wide limits, being greatest in these materials which contain the most fat and least water.

(To be continued.)

GENERAL ITEMS.

The United States Consul at Gothenburg, in a recent report to his Government, says that Dr. Ekenberg, of that city, has made a discovery which will be of importance to dairy farming.

He claims to have invented an apparatus by which milk can be brought into the form of powder, like flour in appearance, but possessing all the qualities of milk in concentrated form, moisture excepted. It is said that this milk flour is completely soluble in water, and can be used for all purposes for which common milk is employed. The milk flour does not get sour, does not ferment, and in the dry state is not sensitive to changes in the weather. It can be kept and transported in tin cans, barrels, bags, etc. The cost of production is estimated at about 27 cents per 106 quarts, and flour made from skimmed milk can be sold for about 13 cents per lb. At a recent meeting of the Academy of Agriculture, Dr. Ekenberg exhibited samples of the milk flour which received favourable comments. It is considered that the invention will be of the greatest importance for the utilisation of skimmed milk, which heretofore has largely been wasted, but in the dry form it can be transported without losing any of its original qualities. The product mentioned is considered superior to the casein products "proton" and "proteide," now manufactured from milk by the aid of rennet, acid, or lye.—*Natal Agricultural Journal*.

As an instance of the tenacity of life in timber trees, we quote from the same Journal, the reference to the Kaffir plum (*Odina caffra*) regarding which a correspondent writes:—"The tree was cut in the beginning of March about 4 ft. from the ground. It was at once cleared of all branches, and cut in halves, each piece measuring 15 ft. in length and the diameter 2 ft. with very little tapering, if any. I had it taken outside the boundary of the forest at once. A trader bought it, but left it lying till September, when he dragged it to his house. He roughly squared one side of each piece, cut off 6 ft. from each end, and bored two holes right through for driving in the hinges, as he intended these lengths for gate posts. He eventually put them in 3 ft. deep holes on the 25th September, and hung his gates on them. About three or four months later each of these gate posts had developed fine strong branches all around, even on the squared side. For about 7 months this tree had been exposed to heat and cold, cut in pieces, and yet when only roughly put in holes, stone and earth stamped round, it became a lovely tree or, rather, two lovely trees. Out of the remaining 6 ft. from each piece of timber the trader made the top of a table, and I have never seen any wood take a more beautiful polish; the grain is fine and close." Common local forests give us an instance of a similar character?

The following is a note on Guinea grass (*Panicum Mavimum*) from a report on grass experiments made to the Director of Agriculture, Natal:—"This grew well and attained to a height of over 4 feet between spring and the end of autumn,..... It is an exceedingly coarse grass, and I do not think stock would care for it. It might be useful for hay or ensilage, but I fancy

many of our indigenous "land grasses" are superior to it in every respect." This latter statement may be correct, but all the same Guinea grass has proved to be an excellent fodder grass for stall feeding, and it is highly valued both in India and Ceylon. If not cut at the proper time it will of course be found to be coarse.

Collar rot (*mal digoma*), or gumming in lemon trees, is a disease primarily due to defective drainage and smothering of the root-system with rich manures. The first symptoms are exudations of gum from the stem, then the foliage gradually becomes yellow; finally the leaves drop, and there is a profusion of bloom. In the first stages, the disease can be successfully treated by cutting away with a sharp knife all the diseased bark and sap wood. As a rule, this will be found to extend an inch or two below the surface of the soil. When there is nothing but sound bark and wood left, smear the surface with a mixture of Stockholm tar two parts and carbolic acid one part. If it happens that the disease is so far advanced that the stem is entirely girdled with decayed bark and sap wood, it is better to remove the tree, and carefully dress the ground with a heavy sprinkling of lime. By removing the earth from about the base of the tree, and applying 2 or 3 lb. of slaked lime, the disease can in some measure be arrested. The annual whitewashing of the trunks of lemon-trees is also a good check; but nothing can effectually prevent the disease if the drainage is bad, or the trees are overdosed with manures rich in organic matter.

Lysol is one of the most useful disinfectants we have. A solution of half per cent when used for wounds induces rapid healing and

prevents suppuration. Lysol has also been successfully used for dressing badly-affected hoofs in horses, for destroying animal parasites and grubs attacking cultivated plants, for keeping off flies and insects such as ticks, fleas, and in numerous other ways.

What is nicotine? When pure it is a colourless fluid of somewhat oily consistency and a strong, peculiar, penetrating odour; but it darkens on exposure to the air and light, becoming first yellow and then brown, so that it looks in this darkened condition something like the tarry matter that soils or smother's fingers, or the substance that is deposited in the stem of a pipe. But this tarry deposit has nothing essential in common with nicotine, and contains but traces of this alkaloid when any at all. A part, but only a small part (about $\frac{1}{4}$ in the experiments by Melsur) of the real nicotine of tobacco is volatilized without decomposition, the remainder being burnt and destroyed in the process of smoking. The brown oily substance which is so troublesome to pipe smokers is really the tar produced by the action of heat on the woody fibre of the leaf. So says Prof. Mullett of Virginia University.

Equal parts of white lead and castor oil mixed near the fire into an ointment are highly recommended by a correspondent to the *Queensland Agricultural Journal* as a cure for long standing and itching sores as well as for eczema. Spread the ointment on linen and renew morning and evening. Every day give a good washing with coal tar soap and rub well with a towel.

To induce sweet potato vines to set, twist the vines in a heap on the top, when potatoes will begin to form.

No. 12.

SISAL, THE YUCATAN FIBRE

WRITTEN FOR MODERN MEXICO BY UNITED STATES
CONSUL E. H. THOMPSON, OF PROGRESO.

SISAL grass, sisal hemp, henequen, or simply "sisal," are the various commercial terms apply to a fiber that is neither a grass nor a hemp and is not produced to any great extent in Sisal. The name "sisal" was applied to it because it

originally reached the outer world through the port of that name. Sisal was, up to 1871, the only port of entry in Yucatan. It is 35 miles from Merida, the capital of the State and the great center of the Yucatan fibre market. In 1871 private enterprise, stimulated by the demands of commerce that required a shorter route to the coast, caused a board-gauge railroad to be built to the town of Progreso. The custom house was transferred there, and Sisal as a port of entry ceased to be. Progreso is a busy port. The wharves are lined with shipping and the streets are filled with hemp bales going out and general merchandise coming in. Two railroads connect it with Merida and a third is underway.

The agave is one of the most characteristic plants of Mexico. One of the family, the *Agave americana*, produces the pulque, the intoxicating drink of the country. Great fields are covered with this plant upon the Mexican table-land, and long "pulque trains," like the milk trains of the United States, roll daily into Mexico City. This beverage is practically unknown to the inhabitants of Yucatan, and the agave that produces it is to be seen only as an exotic in the gardens and parks. Its place is taken by another member of the family, whose importance is more far-reaching. The *Agave sisalensis* furnishes a fibre that not only helps to knit firmer the commerce of the whole world, but binds the sheaves of wheat so that the price of bread in every la is made cheaper for its use. To the casual

observer a field of the fiber plant and one of the fiber plant are very similar in appearance. Both show the same peculiar green, the same many-thorned leaves. Investigation, however, soon shows the difference.

There are three known varieties of the species growing wild in the forests of Yucatan—the Chelem, the cahum and the citamci—and I think that I have found a fourth wild variety during my explorations in the interior. There are also two varieties of the cultivated plant—the yaxci, or green fiber, and the sacci, or white fiber. The last-named plant is the most cultivated and the one producing the sisal hemp of commerce. The primeval inhabitants probably did not at a first attempt to extract the fiber from the thick pulp, but took the leaf and wilted it in the fire, then split it and used the splits as thongs. The leaves so treated make thongs of great strength, and as they dry they bind with wonderful force. In the primitive forms of habitation in the region the mud and wattle "nás" are bound together by these saccids or fiber-wilted leaves. They are shapely, water-tight and durable, and the native builder's tool is a heavy, sharp-edged knife. Not a spike or nail or metal of any kind enters into the building. Later the people found that if they cleaned off the thick pulp and the green corrosive juice they could get a firmer hold and so bind tighter. Then they learned to twist the shreds and this idea led to the making of ropes and cords. The wild agave, known as the chelem, is, I believe the progenitor of the cultivated sacci. The fiber is of good quality, but scant in quantity. The fiber of the cahum is long and silky, but even scantier in quantity than that of the chelem, and it is said to be brittle. In ancient times the agave, or henequen, was one of the most important plants of the peninsula. At a time when most of Europe was in the pall of utter darkness, when the "Parisii" lived in caves and the Gauls in "wattled huts," the priests and rulers of Yucatan lived in stone temples and palaces. Up the steep sides of the

myriad pyramids were carried great blocks and sculptured columns. To move these mighty masses of limestone no powerful engines were at hand; but the Batabs of Yucatan, like the rulers of ancient Egypt, had little use for mechanical devices. Human muscle and ropes of agave were all-sufficient. If ten ropes and a hundred slaves were not enough, a hundred ropes and a thousand slaves were not lacking. The ancient artists made use of the fiber in their work. They were not content to make the figure; they made the skeleton, and upon the bones and in the flesh—like the cords and muscles of the body—they placed cords and plaited bands of fiber. Close examination indicates that the fiber used was that of the yaxci plant. Over the imbedded muscles and flesh they placed a thin, hard wash of stucco to represent the skin and surface pigments. The writer has examined many dozen specimens of the broken figures of stucco wherein are plainly shown the casts and the knots and braid—even the very character of the fiber. Ropes and cables for boats were also made of agave fiber, cleaned by the ancient method and twisted by hand into the cordage needed. When there happened to be scarcity of hemp for the cordage of the Royal Spanish Navy, search was made for a new material to eke out the supply from Manila, and the fiber used by the Campeche people came up for discussion. A royal commission was ordered to investigate, and its report, made in 1783, gave unstinted praise to the new fiber. This fixes approximately the time of the first exportation of sisal hemp. For half a century afterward its existence seems to have been forgotten by the outside world. This fact was probably due to several causes, the principal of which was that the buccaneers made the path of Spanish commerce often seem the shortest road to ruin and death. Meanwhile the people of Yucatan grew poorer and poorer. Men looked around to see what could be turned into the money needed for the necessities of life.

Attention was turned toward the fiber concealed in the leaf of the henequen, and in 1839 a kind of association was formed to make the experiment of producing the coarser fiber "sacci" on a commercial basis. It was known that the spiny-edged agave called sacci produced a fiber coarser than that of the yaxci, but much more abundant, and consequently more profitable to cultivate, as the fiber then sold by weight and not by quantity. The fiber was cleaned by native instruments, and, packed in loose bales of about 200 pounds each, was sent to New York. It found a market, but the price was such that there was but scant gain for the seller. The methods of cleaning the fiber were so slow that even with the small wages of the day the cost per pound to the planter was discouraging. The State government, recognizing the great need of a suitable machine to clean the fiber, offered a gratuity of \$10,000 Mexican to the person inventing an apparatus capable of producing a stated output per hour. This finally resulted in the "*raspador*," the device of a Franciscan friar, which was used for many years. To-day half a dozen machines are in the market, some of them marvels of design and potency.

At this point a brief résumé of the fiber-cleaning machines in use may be interesting. Taking them in order of precedence by priority of invention, the list must unquestionably be headed by the *pacché* and the *tonkas*. This is simply a triangular, sharp-edged piece of wood, with rounded ends as handles. The chohul is the material from which it is generally made, as it has a special quality of preserving its edge under constant use. A flat face of a "chacah" wood log is made with a hold and a peg in the upper portion. The leaf is taken, one end firmly fixed into the flat surface by jamming it into the hole and pushing the plug in after it; then the scraper is pushed away from the worker, held somewhat diagonally from the flat surface, and the pulp is

gradually scraped away, leaving the trees of fiber hanging from the uncleaned half of the leaf. The leaf is then reversed, the clean fiber is fixed into the whole and the uncleaned portion presented ready for the action of the clearer. The second prehistoric implement, called the "*tonkas*," is a flattened piece of hard wood about 18 inches long by 5 inches wide. At its upper end it is about an inch thick, and it dwindles until at the end it becomes a thin, sharp edge, curving inward, so as to grip and scrape the pulp from the fiber. The bedboard of the *tonkas* has a curve to correspond with the curve in the edge of the implement. The leaf is placed between the bedpiece and the *tonkas*, and while the *tonkas* is held firmly in one hand the other draws the leaf sharply toward the body, this movement being repeated until one-half of the leaf is clean. The same operation takes place on the second half of the leaf until the clean trees of fiber hang soft and pliant in the grasp of the operator. The *pacche* is the implement most in use today among the natives of the interior of Yucatan. Women use it to clean fiber, but the *tonkas* is used only by the strongest. An able-bodied person can produce with the use of this implement from 6 to 9 pounds of fiber daily. It is unquestionably true that the fiber produced by these ancient implements possesses qualities not to be obtained by the machine-cleaned product. In the hammock-making districts of Yucatan the yaxci is cleaned by these processes, and the makers of the finest hammocks (those worth their weight in silver) will not use a fiber produced by any other method.

The next step in the evolution of the fiber-cleaning machine is the Soils machine, or *raspador*, which, in principle, is a wheel upon which are placed the edges of many *pacche*. The angle of application is exactly the same. The *raspador* marked a new era for the commence of Yucatan. With the aid of this machine two men could clean in one day more than forty could with the *tonkas* and *pacche*. Its use became extended, and henequen farms began to multiply and become prosperous. The merits of the various machines I shall not discuss. The Stephens machines are at work; the Prieto is believed by many to be the most efficient all-round machine; the Villamor follows it a close second, while the Torroella, the Lopez and the Lanau each has its partisans and seems to do good work. These machines are the only ones in evidence to-day in Yucatan. Inasmuch as the inventors of the machines above mentioned have made improvements in their apparatus, I have prepared the following table from data given me by the inventors of their authorized agents:

Hemp-cleaning machines in actual use upon the plantation of Yucatan.

Machine.	Leaves cleaned in 10 hours.	Men ed.	Actual power.	Cost of Machine.	
				Mexican.*	U. S.
	(Number)				
Lanau reformed...	150,000	4	25	\$7,000	\$3,003
Prieto reformed..	150,000	4	16	8,600	3,689
Torroella reformed...	150,000	* 4	16	7,000	3,003
Villamor reformed...	100,000	7	16	5,000	2,145
Stephens...	150,000	3	70	No more being made.	
Solis ...	9,000	3	9	2,000	858

* The average value of the Mexican peso in 1902, according to the United States Mint, was 42.9 cents.

The most important implement of all is perhaps the *corba*, or *machete*, with a hooked end. It weighs about 1½ pounds, and its size and shape can be seen by the annexed cut. With the *corba* the native dexterously cuts the thick leaf, leaving the

stubb as close as is compatible with the safety of the plant, and trims the side and end thorns. Yucatan ingenuity has attached to the corba a device like an apple and potato parer. This cuts off the side spines with only a very small portion of fiber.

A thin, rocky, limestone soil is generally supposed to be the best for the growth of the sacchi plant. Experience indicates that the fiber grown upon this class of soil has a percentage of tensile strength greater than that produced on the richer lands, though the last is more flexible and is longer. The percentage of safety allowed by the cordage-makers is so high that I doubt if the diminished tensile strength of the rich-land hemp would seriously affect the quality of the output. Contrary to the general idea, a poor sandy soil is not congenial to the growth of a large, full-sized fiber plant. Few, if any, good-sized, well-formed plants grow very near the coast line. The best Yucatan fiber plant seems to be produced in a zone or belt following the coast, about 12 miles away from it and 70 miles wide. The plant can be propagated in various ways—by seeds, by cuttings and by scions or suckers. The first-mentioned method is now never undertaken. Very few of the abundant seeds are fertile and the time lost in raising the seedlings is great. The second method—by cuttings—is frequently undertaken; the top of an old, nearly worn-out plant is taken just before the long pole that should bear the flowers shoots up. It is cut off and trimmed of all save the newest leaves and then planted in the ground as though it were a scion. These plants are said to produce earlier than others. The general method, however, of producing a field of the sisal plant is as follows: A field is cut and the refuse burned; then a month or so before the rainy season the "hijos," or scions of sisal, that have sprouted under the shelter of the parent plant are rooted out of the ground, when they get to be 18 or 20 inches high, and thrown in a heap. There they lie for two or three months exposed to the sun and the weather. Just before the rainy season, when they seem to be dried up and decayed, they are carried to the cleared fields and planted in rows. Formerly, they so planted the young plants that they were separated by spaces of barely two yards, but of late years it has been found best to space them so that they will be in lines, each plant separated from the one preceding it by a space of $1\frac{1}{2}$ yards and the lines 4 yards apart (about 1,100 plants to the acre.) Thus long and wide lanes are formed between the rows that facilitate cutting and carriage of the leaves and also lessen the wounding of the leaves by the spines and thorns of their neighbours.

Previous to 1889 but little attempt was made to grade the hemp. Yaxci, sacchi, short staple, long staple all went as "sisal." Now, a fine, white fibre, well cleaned and baled, can command a notably better price than mixed fibre, ill-cleaned and badly baled.

The hope of the future is in the careful selection of hemp plants. Many plantations, more by good fortune than otherwise, are stocked with fibre-producing plants of a high order; others are handicapped by plants producing a meager fibre. The quality of the soil in both cases seems to be the same; the difference is in the class of plants. This phase is a comparatively new one on the plantations of Yucatan fiber and has only recently been taken into serious consideration.

The scion when planted ("anchored" would perhaps be the better word, as it is more often held by heavy stones than by the earth around it), needs no special care or irrigation. Once or twice a season the fields are roughly weeded. The plant thrives, and generally in about five years the earlier leaves commence to extend themselves laterally at right angles to the trunk of the plant. This is nature's signal that the fiber has reached its highest point

of tensile strength, and that the leaves are ready to be cut. The native cutters then throng the field and with their corbas deftly cut the leaves close to the trunk, trim off each line of side thorns at a single stroke, snip off the horny end and bind up the leaves in bundles. Tram cars take these bundles and carry them to the cleaning machine. While experience and dexterity are required the work is not hard or the hours long to the cutter of henequen leaves.

Fire is its greatest enemy. Hot seasons do not affect it. In fact, the heat of the sun, especially when accompanied by dampness, seems to act as a tonic. It is then, if ever, that the plant recovers from its injuries. The greatest heat experienced in Yucatan for the last ten years was July, 1900, when the thermometer reached 119° F. in the half shade of a veranda; 147° F. has been experienced in the sun on the principal street of Merida. Long droughts may delay its development, and by wilting the mature leaves causes them to double and injury the fiber, but it cannot stop the ultimate growth of the healthy plant, once it is well rooted. Rainy seasons do not seriously affect the plants, except those in stagnant water. This weakens the plant, but this condition is not common. Cold seasons of the kind that Yucatan experience do not seriously affect the plant. The coldest known period was in February, 1899, when the thermometer registered 47° F.

But fire conquers it. Let a spark from a locomotive, the lighted end of a cigarette, or the embers of a fire made to heat the bread of the native workers start the flames in an ill-cleaned field, and nothing but a miracle can save the crop from total loss. It is said that some planters in the past have taken advantage of the susceptibility of the plant to artificial heat, and when young plants were desired for export they were doctored before delivery by having their roots heated over embers or dipped into boiling water. The effects of this treatment are not perceptible for a time, and possibly this fact may make clear to some enthusiastic foreign planter why his scions, purchased with so much care and expense, never grew and prospered. Naturally, the Mexicans do not desire to have the plant that is such a valuable product of their country made common.

Next to fire, a large black beetle is the greatest enemy of the cultivated sisal. This large, long-nosed insect, known to the natives as the "max," may also attack the wild varieties, but I have not yet found evidence thereof. This beetle, I am told, is similar to the one that burrows into the trunks of the palm trees in Guatemala and British Honduras. At my request Dr. George F. Gaumer, an American physician, residing in Yucatan, has kindly consented to give in a few brief words the life history of this insect. Dr. Gaumer, whose studies and writings upon the fauna and flora of Yucatan have made his name familiar to naturalists everywhere, writes:

The female insect lays its eggs on the trunk of the henequen plant a few inches above the ground. When hatched the larva burrows into and through the outer bark to the harder fiber of the interior, when it generally takes an upward direction and burrows from 6 to 12 inches during its larval existence. When full grown it works its way to the bark, where it changes to a pupa and so remains for some months, when it hatches into the adult beetle and emerges from the plant, which it leaves injured and weakened, but rarely kills. Three or more larvae in the same plant will surely destroy it, but that number is of very rare occurrence.

The life of the plant can be greatly prolonged. I have seen fields old at ten years and others vigorous and hearty at nineteen years. The plants should be originally healthy scions, the leaves must be cut at just the right time and the long pole must be nipped off before it has grown more than a mere protuberance. Once the pole has grown the plant ages rapidly.

The output of the Yucatan fiber for the ten years ending December 31, 1901, was:

Year.	Bales.*	Year.	Bales.*
	No.		No.
1892	353,525	1898	418,972
1893	355,123	1899	445,978
1894	373,883	1900	499,634
1895	381,504	1901	517,519
1896	397,163		
1897	419,975	Total	4,163,276

* Each bale weighs approximately 400 pounds. A bale of hemp at to-day's prices is worth \$84 Mexican. The Mexican dollar is worth to-day 40½ cents gold.

The output for the fiscal year ended June 30, 1902, was:

Month	Bales.		Value.	
	Number.	Tons.	Mexican.	U. S.
1901—July	64,460	10,319.7	\$1,960,737	\$841,156
August	48,726	7,988.6	1,917,277	822,512
Sept.	44,634	7,271.9	2,337,017	998,290
Oct.	32,455	5,295.7	1,725,912	720,416
Nov.	40,328	6,342.3	2,377,077	1,019,766
Dec.	34,747	5,515.1	2,126,960	912,466
1902—January	45,998	7,355.1	2,726,792	1,169,794
February	38,652	5,889.2	2,334,179	1,001,363
March	60,915	9,712.7	3,496,591	1,500,038
April	61,887	9,769.8	4,469,689	1,917,497
May	50,547	7,956.7	3,433,308	1,472,909
June	41,559	6,588.4	2,662,344	1,142,246

Total. 364,308 90,005.3 31,557,888 13,538,343

There will be a falling off in the supply for the season of 1903. The causes of this diminishing output, despite the high prices that prevail, will be the decreasing acreage of new fields. Labourers are scarce, and the great majority of planters dislike to stop cleaning fiber long enough to plant new fields or replant old ones.—*Modern Mexico.*

CARDAMOM NOMENCLATURE: HOW MISTAKES AROSE.

(To the Editor "Times of Ceylon.")

Sir,—In your issue of 20th instant there appeared extracts from the Report of the Controller of the Government experimental Station at Peradeniya. One of these extracts refers to cardamoms. The writer of the Report refers to the unfortunate reversal of the nomenclature of the two varieties of cardamoms in Ceylon. I was engaged in the cultivation of cardamoms for 6 years in Mysore, and I fully established the fact that what the planters in Ceylon call the *Malabar* is the true and only *Mysore* variety. What the planters in Ceylon call the *Mysore* is the Allepy or Malabar variety. The former—the true *Mysore*—has a layer of silky hairs on the under-surface of the leaves, and a trailing inflorescence or raceme. The latter—the Allepy or Malabar has a glabrous under-surface of the leaves and an erect inflorescence or raceme. The sowing of seeds obtained from an experienced Mysore planter, in order to settle the point; is a belated though sure method of doing so. I obtained seeds of the robust or glabrous variety and raised plants from the same which astonished the Mysore natives considerably. I understand that Travancore has both varieties. Mr. J. A. Hunter can speak of this. The origin of the mistake I believe, was stated by the late Mr. Macartney. The first lot was obtained from Travancore, which was the true *Mysore*, and it was named *Malabar*. Another variety arrived and this was ignorantly named the *Mysore*, thus, as I have said before, entirely reversing the names.—Yours, &c., W. A. TYTLER.

Kotuwagedera, Matale, May 21 st.

P. S.—A good way to distinguish the varieties is to call one the *glabrous* and the other the *pubescent*, but it is too late now to attempt to alter the marks in the London market.—W.A.T.

CARDAMOMS.

The cultivation of cardamoms is being extended in many up-country districts and nearly 10,000 acres of forest are now occupied with this product in Ceylon. Hitherto planters have adopted the "stool" method of cultivation, and effected the curing by means of sunlight and fumes of burning sulphur. There are few products which lend themselves better to experiment both in methods of cultivation, and curing, and the following plots have been arranged with these objects in view. The time of planting and condition of plants when put out was very unsatisfactory, and much replanting will have to be done in these plots.

VARIETIES.

In Ceylon there are two forms in cultivation, distinguished respectively as the Mysore and Malabar varieties. There is much confusion as to the equivalent of these varieties with those in India, and many assert that the names as applied in Ceylon are reversed in India. In order to avoid further confusion it will be necessary to define the characters of the varieties chosen.

The Mysore cardamoms are characterised by a larger habit, glossy leaves, and usually erect inflorescence; the fruits are elongate and rarely cornered.

The Malabars are characterised by a layer of silky hairs on the under surface of the leaves, a trailing inflorescence, and a more globular and shorter fruit than the Mysore.

The most striking difference is in the erect inflorescence of the Mysore, as against the trailing flower system of the Malabar variety.

The other characters form a continuous series of variations, and the two kinds of cardamoms cannot be regarded as anything but varieties of the same species. From examination of the development and form of the fruit it occurred to me that the Mysore variety was probably the more advanced form in cultivation; the stages presented in the development of the fruit of the Malabar variety were observed in the Mysore variety, but the latter proceeded one stage further, giving a fruit more elongate in outline.

In order to determine the relation of the varieties recognised in Ceylon as "Mysore and Malabar," specimens of the true "Mysore" of India were obtained from an experienced Mysore planter. These have been planted in a separate plot.

The wild cardamom (*Elettaria Cardamomum*, Mat.) is said to be common in the wet forests of Ceylon up to 3000 feet. It can be distinguished from the cultivated varieties by its short and sparsely flowered inflorescence, and when opportunity occurs a plot will be established. It may be possible to improve the Ceylon wild form, and efforts will be made in this direction.

Many natives in Ceylon class several species of *Anomum* as "wild cardamoms." In the Matale district *Anomum petrocarpum*, Thw., and *A. floribundum*, Thw., are thus regarded. Up to the present no attempts have been made to cultivate these species, though the seeds of the former are decidedly aromatic. The genera *Elettaria*, Mat., *Anomum*, L., are so closely allied that it would appear reasonable to expect profitable results to follow from the experimental cultivation of the aromatic species of *Anomum*.

CULTIVATION.

The only form of cultivation in vogue in Ceylon is the "stool" system. The bulbs are planted two together or one double bulb per hole, the holes being 7 to 8 feet apart. In 4 to 6 years a clump or stool of plants is produced, measuring 3 to 4 feet in diameter. The stool increases in size from within outwards; the old bulbs occupying the central position gradually die down. Such a method of cultivation has been found to yield profitable results, and has been adopted by most cardamom planters in Ceylon. It is I think accompanied by several disadvantages. In the first case the stools occupy a limited area, and the roots of

the few score of hulbs in each stool have to obtain their nutrition from the immediate neighbourhood. The roots often extend several feet beyond the stool, but the large space between the stools is rarely drawn upon to any great extent. The stools being in lines along hillsides, it is obvious that the rains will successfully carry away the greater part of the soluble materials in the soil between the stools. In order to prevent this an experimental half-acre plot of each variety has been laid out with a view to establishing what we may call the "terrace" system. In this system single hulbs have been planted 4 feet apart, and their growth will only be allowed to continue in the direction of lines running at right angles to the slope of the hill. The lines will be kept at from two to three hulbs wide.

By this means the whole of the materials washed down the hillsides by the rain will become lodged along the lines of cardamoms, and as their root system will extend upwards and downwards there ought to be minimum loss of nutritive materials.

The original number of plants in these plots is the same as in those which are being cultivated on the "stool" system, the only difference being that they are planted singly 4 feet apart instead of in pairs 8 feet apart.

In the second place the stool method lends itself to the establishment of many fungi, myxomycetes, &c.: in consequence of the crowded nature of the plants preventing the access of light on the lower part of the hulbs. In the terrace system the light will have easier access to the hulbs, and may consequently keep fungi in check.—*Times of Ceylon.*

A STUDY IN RUBBER PLANTING.

In No. 7 of the "Bulletin de la Societe d'Etud's Coloniales" Octave Collet gives a long account of rubber planting in the East, and as he appears to think that the two species of rubber tree known respectively as *Ficus elastica* and *Hevea Brasiliensis* offer the best prospect for planting purposes, a review of his publication may be of some interest. This all the more so as the general opinion amongst those best able to judge is at present rather in favour of *Castilloa elastica*. In this relation, however, it should perhaps be pointed out that while there can be no doubt regarding the eminent suitability of the last named species for planting purposes in all parts of Central America, including all the northern districts of South America the results obtained in the East with *Castilloa* are, to say the least of it, not by any means encouraging, whereas *Hevea* seems to offer very good prospects in the Malay Peninsula, Sumatra, and Java. That many rubber planting experiments have been with *Ficus elastica*, particularly in Java, is well known, but as we possess no very clear accounts respecting the results obtained, Collet's paper on this subject is of considerable interest.

Collet describes the following plantations of *Ficus elastica* :—

"The oldest of all existing plantations is the one at Pamanoeakan and Tjassem Landen in Java, consists of 212,000 hectares, 33 of which were planted with *Ficus elastica* in 1864, and which have been tapped since 1881.

"The appearance of this plantation is very unsatisfactory. The trees incline in all directions, have been allowed to grow at random, and to throw out branches at very little height above the soil. In many parts the air shoots sent out by the trees form an almost impenetrable tangle.

"Next in age comes the plantation of Tjkandi Oedik, covering almost the same area, but containing rather fewer trees, as these have been planted at nearly four yards distance from each other.

"Against these plantations laid out by Europeans we have at Poewokerto a plantation made by the natives of that village. The trees, which are now twelve years old, are planted at intervals of 12 yards

and have grown to the considerable height of 16 yards. The best developed trees possess a circumference of two yards, measured one yard above ground.

Mention should also be made of the plantation at the hotanikal gardens at Buitenzorg, which covers over 4,000 square yards, the trees having been planted at a distance of seven yards.

It appears that although these plantations yield satisfactory results from the commercial point of view, the most instructive example as regards the plantation of *Ficus elastica* is afforded by the plantations existing at Deli Moeda, Priok, and Boeloe (Sumatra), which contain about 77,000 trees, about one-half of which consist of *Ficus elastica*, most of them less than five years old. The trees of various ages showed the following measurement:—

	Height, ft. in.	Circumference, in
Ficus in nursery (6 months)	2 4	...
Ficus in plantation (1 year)	8 4	.. 10
" " (2 years)	11 8	.. 14
" " (3 ")	16 8	.. 16
" " (4 ")	21 8	.. 20

These figures represent very low averages, indeed most of the older trees exceed these measurements very considerably. It is, therefore, safe to state that upon suitable land *Ficus elastica* reaches in a very few years, quite an imposing growth if properly treated.

The most interesting matter is, of course, the yield of rubber produced by these trees. It appears that on the average about 2 cwts. of rubber per hectare are obtained annually, which is quite sufficient to render such cultivations highly remunerative. At Pamanoeakan and Tjassen Landan, the oldest plantations of *Ficus* in existence, the trees yield 5 lb. per tree, or the almost incredible quantity of 55 cwts. per hectare. There remains, therefore, only the question to be answered at what age the tree is ready for the first tapping.

Warburg states that the trees begin to yield rubber when five years old, but that the quantity produced then is unremunerative, and only becomes satisfactory when the trees are from eight to ten years old. Collet finds that although satisfactory yields are obtainable from trees not more than four years old, it is in the interest of the development of the trees, nevertheless, desirable not to tap them until they are seven years old. He states the following yields:—

Tree 16 years old	4 lb. 6 oz.
" 7 " "	1 " 10 "
" 6 " "	1 " 2 "

From a 5½ year old tree he obtained 1 lb. 11 oz. of rubber, and Schlechter 3 lb 14 oz., from a ten year old tree. There is, therefore, no doubt that the cultivation of *Ficus elastica* is extremely easy, and at the end of seven or eight years produces most satisfactory results.—*India Rubber and Gutta-Percha Trades Journal.*

BOTTLE-TREES AS FODDER.

The following interesting cutting from *The Pioneer* of the 15th June was sent to the Society for further information on the subject:—"Trees as fodder.—A Brisbane newspaper says: The value of the bottle-tree as fodder for stock during times of drought has been brought under the notice of the Agricultural Department by Mr. E. Bowman, of Bannhiniavale, Taroom. He states that a trial was first made by a neighbour. Mr. Bowman was cutting down a tree for the leaves, when the sheep began to run after the chips, and so the tree was opened up, with the result, he says, that every head of stock "went mad over it." Mr. Bowman, although he has no grass, has brought 900 merino ewes on the strength of the discovery. Lambs eat it as well as the old sheep. An instance is given of a 15 years old pet wether without a tooth, growing fat since eating the tree. Any kind of stock will eat the wood after

a little use of it. Mr. Bowman considers that it will soon be carried on the railway at fodder rates. He stated that cows which were almost dry from want of condition are now not only fat and strong but are giving a good yield of milk. Bottle-trees often contain from 50 to 100 tons of fodder. There are plenty of bottle-trees within easy reach of the railways. Mr. Bowman believes that hundreds of stock can be saved with it. The trees will keep for months in the log with the bark on." The use of fanciful names of plants and trees in reports, etc., is greatly to be deprecated, as it leads to endless confusion and needless waste of valuable time in searching for the plant, or trees, most likely to fit the description. In the present instance several trees were referred to until it was thought that *Sterculia (Delabechea) rupestris (Sterculiaceae)*, a native of north-east Australia, was the one alluded to. "It is allied to the Gouty-stem tree (*Adansonia Gregorii*), being thickened below, tapering upwards, or often swollen in the middle to the extent of 30 or 40 feet in circumference, with an apparently small tree growing out of its apex, so that it has been compared to the neck of a bottle. The gouty stem is soft and porous, and contains much mucilaginous gum, which is readily obtained by pressure, and is used as an article of food by the natives. It is also called Barrel tree.—*Journal of the Agricultural and Horticultural Society of India.*

HINTS AND INFORMATION IN REGARD TO CASSAVA POISONING.

(Issued by Imperial Department of Agriculture for the West Indies.)

In view of the many cases of poisoning by cassava that have recently occurred in the West Indies the following information has been prepared in the hope that it may be possible to warn those likely to fall victims. The hints as to the mode of dealing with persons suffering from cassava poisoning have been prepared by an experienced medical man.

CASSAVA POISONING.

There are two kinds of cassava known in the West Indies. These are the 'bitter' and 'sweet' cassava. Both are largely grown and in some localities the roots afford an important article of food. The roots of the bitter cassava are usually grated and the milky juice is washed out, leaving a coarse flour from which cassava cakes are made. In Brazil and elsewhere cassava flour, known as farine, is eaten cooked or heated on plates and made into tapioca. The roots of sweet cassava are more commonly eaten as a vegetable after they have been boiled or roasted. There are so few differences to be observed between the plants yielding bitter and sweet cassava that children and inexperienced persons may easily take one for the other. Usually the peasants are fully aware of the distinction between them. It is well known that the fresh roots of the bitter cassava are poisonous. If eaten raw or in a half-cooked condition they contain prussic acid, and numerous deaths are recorded, every year, in the West Indies due to this cause. The object of this leaflet is to bring prominently under the notice, especially of the poorer class, not only the poisonous character of bitter cassava, but the fact that some kinds of the sweet or roasting cassava (especially from old plants) have been found to be injurious, if not fully or properly cooked. The record of deaths from cassava poisoning in Barbados has been examined for nearly twenty years. In one year, viz: 1884, twelve inquests were held on persons who had died from cassava poisoning. In subsequent years the number of deaths have been slightly less, but recently, several deaths have been returned due to cassava poisoning. In two cases the ages of the victims (men) were 57 and 45 years respectively. In a latter case the victim was a boy of

9 years. Usually, those that die from cassava poisoning are ill-fed and neglected children. This is a class most difficult to reach unless a special effort is made with that view.

HOW TO PREVENT CASSAVA POISONING.

Although the sweet or roasting cassava is not so poisonous as the bitter cassava, it would be safer to let it be widely known that *no kind of cassava should be eaten without being carefully and thoroughly cooked*. In preparing cassava for table, it is important to bear in mind that what poison is present lies mostly near the outside of the root. It is desirable, first of all, to scrape off the skin and the outer portion of the root so as to remove the greater part of this poison. In the second place the roots should be *carefully cooked right through* so as to drive off any remaining portion of the poison. Further, it would be advisable not to eat cold cassava or cassava that has been allowed to stand for some time after being cooked. The rules to be followed in preparing cassava, of any kind, for table would be as follows:—

1 Scrape the roots and remove the outside parts.
2 Cook the cassava well and be sure it is heated throughout.

3. Eat cassava only after it has been freshly cooked.

WHAT TO DO FOR CASSAVA POISONING.

If a person after eating cassava feels or looks ill, medical aid should be obtained at once without any delay. That is to say, *the doctor should be called*, or the patient should be taken to the doctor, or to the nearest hospital, dispensary, or almshouse, where medical aid can be obtained *as soon as possible*. A few minutes may make all the difference, and no time should be lost. The doctor can inject some medicine under the skin of the arm which may save the patient's life. *Therefore lose no time*. While waiting for the doctor to come, or for the cart or trap to take the patient to the doctor, there are several important things to be done which anyone can do. The following things should be done:—

1. Place the patient in the open air, or near the open door of the house. 2. Make the patient vomit by tickling the back of the throat with a finger, a feather or a piece of grass, and, if he can swallow, make him drink water at intervals after each vomit so that the stomach is washed out thoroughly. If he does not vomit freely, get someone to mix a tablespoonful of 'ground' mustard in a tumbler ('half-pint glass') of warm water—(for a child, a teaspoonful of mustard in half a tumbler of water) *and make him drink it off*.

3. If the patient begins to get insensible or 'lifeless': Take the clothes from the upper part of the body and pour a large stream of water out of a jug or bucket from a height of three or four feet on to the back of the head, the spine and chest. *This should never be left undone*.

4. Afterwards dry the body with a rough towel or any coarse garment, and put on some dry clothes and blankets, shawls, or anything to keep him warm. Continue to rub the arms and legs *briskly* to keep up the circulation. If he gets cold, put some bottles filled with hot water round about him.

5. All this time hold 'smelling salts' to his nostrils every now and then.

6. As soon as the stomach is empty and nothing but water comes up when he vomits, give a strong dose of rum, whisky, or brandy diluted with twice as much water; and if it comes back at once, repeat the dose.

7. If anyone near by knows how to carry out what is called 'artificial respiration,' it should be done if the patient gets very bad and stops breathing.

Those in charge of persons suffering from cassava poisoning should not despair. Some of the worst cases have recovered after energetic treatment. Remember that the patient's life is at stake, and there is no time to consider whether 'wetting him will give him a cold or any idea of that kind. What is recommended above should be done without fail.

HOW TO RAISE VANILLA.

A VERA CRUZ PLANTER GIVES MODERN MEXICO'S READERS THE RESULTS OF HIS EXPERIENCE.

So many inquiries about vanilla have been made recently that it occurred to me that a general reply regarding its planting and production would be of interest to many of Modern Mexico's readers. There are six different varieties of vanilla, namely, Manza, Mestiza, Simarona, Ponpona, Tabalina and Tarro. These are all Mexican names. The first, Manza, is the only variety cultivated in this Republic. The Mestiza and Simarona are used only to make Picadra.

There are two methods of planting vanilla. Some planters clean up the underbrush and cut out the larger trees, leaving the smaller trees standing, on which they tie up the vines. The other method, which I consider the best, is to clear the ground entirely and then burn off all underbrush. The land is then planted with Higuera trees, 500 or 600 to the acre. Two or three crops of corn may be raised on the land while the trees are attaining a sufficient size to bear the vines. When the trees are five or six feet tall, or when about two years old, the cutting, or vanilla vine, should be planted. It should be about a meter long, one-third of it covered with rotten leaves or grass or with two inches of soil at the base of the tree. The rest of the vine is trained up the trunk of the tree and tied in its erect position, a bit of bark from the tonote tree being used to hold it. Two vines should be planted to each tree and affixed to the northern side to avoid exposure to the noonday sun. The season for planting is from February to November, excepting one or two dry months. The cultivation of vanilla consists in simply cutting weeds and grass about a foot high two or three times a year, and in pruning the trees in order that plenty of sun and air may reach the vines. Another operation, that of fructification, is necessary when the vanilla vine is in bloom. It is simple, and can be learned by any intelligent man in ten minutes.

The total cost (all sums in Mexican money) of cutting and fructifying vanilla vines is about \$40 per hectare (nearly $2\frac{1}{2}$ acres). The price of cuttings for planting around Cazes is about \$10 per 1,000; at the Colonia de San Rafael, about \$25 per 1,000. When three years old each vine will bear from 10 to 50 beans (or vanilla), which ripen from November to January. The price ranges this year from \$95 to \$105 per 1,000 beans. Five years ago the price went as high as \$140 per 1,000. The vanilla buyers generally arrive on the scene about a month before the crop is ready to be gathered and contract for the number desired. The best climate and soil for vanilla are found in the State of Vera Cruz, from Tuxpam to the mountains of Jalapa. Papantla and Zamora are the centers for curing vanilla beans. The vanilla cured at Papantla has the reputation of being the very best in the world and its price is generally from 15 to 30 per cent. above all others in the market. A. PETIN.

Jicaltepec, V. C. January 10
—*Modern Mexico*.

firmed his result. The disease has recently again been causing great damage to the cacao trees in Surinam, although it is not actually killing many trees. It is accompanied by hardening of the pods so that many estates are losing the greater part of their produce. In the absence of any more definite knowledge of the fungus and of the method by which the disease spreads, the only remedy that can be suggested is the cutting out of the tufted bunches of twigs and of the diseased pods as soon as they are observed and burning them. In the meantime it is of the utmost importance that the witch broom disease should be kept out of the West Indies; for this purpose the importation of all cacao pods, seeds and plants from the continent of South America should be strictly prohibited. Proclamations to this effect have already been issued at Jamaica, Trinidad and Tobago, St. Vincent, Grenada, St. Lucia and Dominica (see *Agricultural News*, Vol. I, pp. 14, 38 and 100.) For a fuller account of the disease, Volume II, pp. 205-6 and 289-91 of the *West Indian Bulletin* should be consulted.—*Agricultural News*.

A SUBSTITUTE FOR DISHORNING.

It is well known that polled or dishorned cattle can be managed and fattened with greater facility than horned animals, and that they can be conveyed by land or sea with less risk of injury. The process of dishorning cattle is one that inflicts great pain on the animals and may even be the cause of death. In a recent leaflet issued by the British Board of Agriculture, a description is given of a method whereby the growth of horns may be prevented. The operation is said to be comparatively painless and is carried out as follows:—'Clip the hair from the top of the horn when the calf is from two to five days old. Slightly moisten the end of a stick of caustic potash and rub the tip of each horn firmly with the potash for about a quarter of a minute, or until a slight impression has been made on the centre of the horn. The horns should be treated in this way from two to four times at intervals of five minutes. If during the interval of five minutes after one or more applications, a little blood appears in the centre of the horn, it will then only be necessary to give another very slight rubbing with the potash.' Caustic potash is poisonous and must therefore be kept in a safe place. It should also be kept in a well stoppered bottle, as it soon deteriorates if left in contact with air. The operation is best performed when the calf is under five days old, and should not be attempted after the ninth day. It is better for one man to hold the calf while another uses the caustic. To avoid injury to the operator's fingers the potash stick should be rolled in a piece of brown paper or tinfoil. The stick should not be moistened too much or the caustic may spread to the skin around the horn and destroy the flesh; for the same reason the calf should be kept from getting wet for some days after the operation; also the operator must be careful to rub on the centre of the horn and not round the side of it.—*Agricultural News*.

WITCH BROOM DISEASE OF CACAO.

This disease of cacao trees was first noted from Surinam in 1898. It receives its name of 'Witch broom' from the enrious broom-like appearance of the bunches of mal-formed twigs (Fig 8) which are its most conspicuous symptom. An examination of the diseased tissue shows the presence of abundant fungus hyphae but at present it is still uncertain what the fungus is or how it spreads from tree to tree. Professor Ritzema Bos of Amsterdam, to whom specimens were first sent, concluded that the fungus was an *Exoascus*, a close relation of the fungi that cause witch broom formation on birches, cherries, alders, etc., in Europe, but no one has as yet con-

COCONUT OIL INDUSTRY IN SULU LAND.

Mindanao, P. I.

One of the strangest conditions under which our correspondent discovered oils in process of manufacture was on the Sulu Archipelago in the Southern Pacific. Here the natives handle the products of the vast coconut groves of the country in a way that promises rich returns for oils, copra, etc., in the future. The resulting oils are not only utilized in the making of illuminating and lubricating stuffs but are exported to Spain, Japan, and even America,

for manufacture into candle stuffs, soaps, waxes for matches, etc. These materials are likewise manufactured in the Philippines. In addition to the oils secured from the coconut growths by the inhabitants of the Sulu Archipelago, there are a few oil wells in operation from which a limited quantity of illuminating oil is secured annually. If this oil product of the soil were properly developed there is no doubt that in a short while the wells should be as productive as the wells in Cebu. The Cebu wells promise success with improved apparatus. The Sulu wells are worked entirely by the crude hand devices of the natives, and considerable time and energy are expected in obtaining a little of the oil. There are one or two oil springs in working order in the hills, from which the natives secure a little oil at times, but lack of proper refining devices prevents the general introduction of the industry. The natives do not understand either the art of correct refining or how to put up the oils for the markets. They run it into coconut shells and it evaporates quickly. Then these natives get fats, waxes, etc., from the various saps of trees, and by crushing in mortars or rolls some singular formations of minerals and herbs which are unknown, I believe, to the world of science. I showed samples of the mineral stuffs and sections of the sap-producing trees, also specimens of certain oil-producing leaves and herbs, to experts here, who make a business of assaying for the miners, and who have studied oils and chemicals, and these assayists have informed me that these barks, minerals containing oils, herbs and kindred products of the soil are new to them.

All through Jolo, Zamboanago, Cottobatto, Parang, Cebu and other commercial and industrial centers in these portions of the new possessions of American in the Southern Pacific, I found evidences of progress along the lines of oils as procured from the coconut, tree saps, juices crushed from plant-life and the like.

Wherever one visits in the sections of the Sulu group he finds evidences of the manufacture and sale of oils from the coconut and other tropical growths. The supplies of coconuts, barks, herbs, minerals and kindred products from which the natives get oils of some sort are brought into the central stations on the heads of men, women and children on pack animals, and sometimes on the crude carts of the natives. First, the native train from the interior has to pass through the garrisoned portion of the town, where the required passes are shown to the sentries of the United States military, and the natives then pass on to the market in the town or to the manufactories. In the working up of the coconut into marketable form the fruit is first assorted by native women, as this is light work. The women crack each shell of the nut until it opens, exposing the white fruit within. Then the half shell is grasped in the hands and the interior ruit scraped by working the fruit over and over on the edge of a sharp stone, piece of wood or metal, properly set for this operation. The granulated white scrapings may be seen falling to the mat below. Then this prepared fruit is spread for drying in the sun on mats and copra results. Sometimes the stock is sweetened with native sugar. If oil is required the stuff is pressed between rolls or in presses or pounded in hollowed stones or wood pieces, until the oil is gotten out. After the oil is removed the remaining stock is used for copra as well as when the oil is left in.

The oil and copra markets in this part of the world are curious affairs. There are no sides to the building. There is a big nipa roof set up on poles, and under this roof squat the vendors in oils and the products of the coconut. Likewise the makers of oils from the coconut and the herbs and barks of the country may be seen here operating their crude contrivances. There are native police stationed

about the market place to preserve order, and these fellows carry knives, spears or shotguns.

There is not much money in the Sulu oil industry for the natives the way that the native manages things, as may be judged by the character of the houses occupied by these people. Their homes are mere shacks with one room, and the entire family lives here. The devices for making the oils is often in the same room. There are pigs and chickens about. Here the father and mother and grown children work several hours per day, turning out an oil or copra product that brings in only a few cents to them, but which is of considerable value in the foreign markets or even at Manila or Iloilo. The natives know only the local price. The men engaged in buying this oil, copra and fatty mixtures from the natives are the ones who turn the money. They buy very cheaply, and often by exchanging very inferior Spanish cloths, lamps, tinware, trinkets and the like for the products. I have seen 10-cent articles buy several dollars worth of good oil or copra from the natives.

Oil of all descriptions is carried back and forth here in the Sulu land very much as it is conveyed in the islands further north. Bamboo tubes and tins of all kinds are used. Kerosene oil cans imported here, with Russian illuminating oils, are popular for native oil conveying, these cans being balanced one at each end of a pole placed upon the shoulder of a native. The native water craft carries oil and copra from the point of production up north to the stations, where the riddlemen buy it for exporting to other countries. The prices on the oil begin to jump at this stage. In all of these towns and hamlets one may see natives trotting in and about the shacks with the inevitable bundle of coconuts attached to poles thrown on the shoulder or tied up, bunch fashion, and carried on the head.

Some of the oils and fats obtained from the coconut or the gums of native trees or minerals are procured in very odd ways. I saw native men, women and boys with blowpipes blowing drafts of air into masses of flame in process of burning under pans or flat stones, on which fats were being treated for the purpose of obtaining the oils. There are certain herbs which the natives get in the jungle which are pressed for the juices, and these juices have to be fried, as it were, before the oily substances are in proper order for extraction. Because of these very strange customs of getting oils from products the oil industry of Sulu is interesting and amusing. Millions of ants and kindred pests infest the oil devices, the oils and the surroundings, and whether the oils are for burning, illuminating, eating or what not, the ants that get in the way are crushed in with the material and become part of the oil. Oil cakes for purposes of eating are known to contain much insect matter, but this does not affect the sale of the greasy stuff.

A few Americans (usually discharged soldiers), some British and quite a number of Chinese are undertaking to engage in the oil business here. These parties go at it on a better scale than that of the natives.

At one place the men had erected a substantial saw-lumber building, and fitted it up with a few crude devices for crushing and refining purposes. Some tanks were used. Acids were in use for purifying purposes, but nearly all of the work is done by native help. I happened to arrive at one of these places on a pay day. The natives were receiving from one to two dollars gold each person for the week's work. This money they immediately proceeded to gamble with until they lost practically, all. I am inclined to believe that some day there will be oil mills of modern design in this part of the new United States territory, and that these will be run by Americans, who will find an exceedingly rich growth of never ending products, of coconuts, herbs, tree gums, etc, from which to make oil with very inexpensive native labour. This oil can be exported at profitable prices.—*Oil, Paint and Drug Reporter.*

THE TEA FACTORY OF THE FUTURE.

BY CLAUDE A. LOWE.

The general idea of this article is to present, in an orderly and more or less comprehensive form, the probable future development of the modern tea estate and factory, showing, in some detail and parallel, the various difficulties and inconveniences of present day practice, and the methods likely to be evolved in the near future to override and abolish them.

It has already been pointed out in the editorial and correspondence columns of this journal, that such nostrums as a comprehensive reduction of output—even if all concerned were agreeable to join in the movement—would merely result finally in throwing wide the door to the gleeful competition of foreign teas from China, Java and elsewhere; and even the more obviously practical endeavour to devote a large capital to opening out new markets while meeting with opposition from some planters of exceptional experience and ability, gives no substantial guarantee to the planter that the price of his commodity will permanently rise to the old scale of high profits. Looking at the subject from the consumer's point of view, it will require no great imagination to suppose that the members of the great army of working classes in Great Britain who have got accustomed to obtaining their weekly pound of tea for one price, will refuse to submit to a rise in the same; rather it will probably be found that the grocer who caters for them will be willing, as has happened before with other products, to sell the same quality of tea at the former price without profit for a time, in order to retain or increase their custom for general groceries.

Even from the planter's point of view, the position under existing circumstances would be no firmer in the long run, as, given an increased demand who is to prevent companies or individuals who own undeveloped land, from extending their gardens? Certainly not the Tea Association, and it is not probable that Government will step in with a veto on the subject, and lay themselves open to the charge of fostering the China trade at our expense.

We thus come by a process of exhaustion to the old question of reduction of working costs, but even here, under existing conditions, a dead-lock must soon be reached, as it cannot be doubted that many concerns which continue to pay good dividends, are accomplishing the same as the result of stringent economies, many of which they will be unable to maintain without ultimately bringing about either directly or indirectly a deterioration in the asset value of their estates.

That stress of circumstances has brought about a series of permanent and practical economies is undeniable, and that these same economies have been most immediately beneficial where practised on large concerns combining several estates under one supreme local authority, is equally evident to the seeing observer; it is therefore highly probable that the greater the concentration on a central local office under a really capable Superintendent, the higher will be the economic efficiency attained.

From this point to the Tea Trust or Combine is but a step, and now that we are hearing and reading so much about Trusts and Combines in every branch of commerce, it can hardly be doubted that, sooner or later, the eyes of the monied world, roaming around in search of new outlets for idle capital in bulk, will alight on the confusion of conflicting interests and antiquated farming procedure of the vast tea districts, struggling or sleeping under the protecting arm of the British Raj.

That really serious opposition could be maintained in the face of a movement to acquire whole provinces* in the tea districts is questionable, when we look at the backing off and wrangling that takes place every time the Association calls for combined action on any subject; indeed the mere attempt to fight a really formidable corporation would in itself be suicidal, as one of the first logical effects of consolidation under enormous capital would be the local abolition of the Planters' Association as at present constituted, and therefore any isolated estate would be entirely at the mercy of a conscienceless and invisible power.

Even without this huge and wholesale combination the near future must show a modification of the principle in self-defence, and combine at least whole districts under their own respective centres, in order to produce a certain uniformity of method, and reduce the number of individual units to a comprehensive whole.

Let us enquire now why even on adjoining gardens under one ownership, one so frequently finds factories set up within a couple of miles of one another. It appears when all the *pros* and *cons* are sifted, that the real difficulty resolves itself into a question of locomotion. Because leaf packed into large baskets and carted in a slow bullock gharry or on coolies backs, heats and turns red on arrival or soon after, therefore another factory must be built and a special staff and plant of machinery must be maintained. There are as secondary reasons, the difficulty of managing the withering, and the size of the plant required to deal with what is considered to be an unwieldy quantity of leaf, both of which may be summed up under the head of want of courage and enterprise on the part of those concerned.

We will now, however, proceed to consider these objections in detail, and find how they can be overcome in a combination of estates under one ownership working towards a central factory from a radius of eight or ten miles in every direction.

The question of the actual working of the land is not likely to change very considerably. It is possible that machinery may to a modified extent be used for cultivation, but actual plucking must for obvious reasons be always carried out by hand, the only likely change is that the estates will be re-divided into lots of about five hundred acres, and each placed in charge of one European who will be responsible under the Chief Superintendent for cultivation and quality of leaf alone, having nothing whatever to do with the sale or manufacture. We will therefore take the factory of the future and consider, as first in order, the question of transport.

TRANSPORT.

The two methods of rapid transit available for use on tea lands at present, are the narrow gauge railway, and the wire rope tramway; but seeing that in the majority of cases the ground in the vicinity of tea estates is cut up by nullahs and jhoras, and in some districts is actually mountainous, the railway system would be not only cumbersome, but prohibitive in first cost. There remains, however, the wire rope tramway, which is able to make a beeline for any desired point, irrespective of the contour of the land over which it has to pass. This latter is worked on various systems at the present day, chief among which are (1st) that in which the carrying rope is also itself a traveller; (2nd) the carrying rope is a fixture, and the trolleys hanging therefrom on running wheels are hauled by a lighter endless rope passing round a pulley at the end station and so back to the winding engine, and (3rd) that in which the trucks

* It is probable that no attempt at consolidation which did not aim at acquiring at least the whole of such a province as Cachar, Sylhet, Darjeeling or the Doonars would be effective, as it would be a *sine quâ non* that the means of communication should be under the Company's control.—C. A. L.]

carry their own electric motor, or are hauled as trailers by a single motor, collecting its current from a fixed wire or pair of wires as it travels along. The second system, known as the "Bleichert" system has at present the greatest vogue, and there are hundreds of miles in working order in various parts of the world to-day, but I am inclined to think that where power is cheap, the third system of electric traction will be the system of the near future.

The motive power for this and all the other factory machinery will be generated on one or two of the rivers or large streams which, more often than not, are running to waste near every tea district, for want of sufficient profitable work to justify the expenditure of the necessary capital to exploit them.

Having got our wire rope tramway laid to the centre of each sub-garden, or a convenient point therein, the signal will be given from the factory as convenient to call in the labour; the leaf being weighed will be emptied into a travelling belt, which will convey it into a small chamber, where it will be chilled to just a low enough temperature to prevent any possibility of heating within the next twenty minutes or so. In the same chamber, it will be fed into tipping cages, divided horizontally into compartments not deeper than six inches each, so that when the trolley is turned upright, the leaf at the bottom cannot be crushed by that above. All the trolleys being thus filled with cool leaf the train will be pushed out into the open way, and set going at a high speed direct to the factory. Here it will be received, not as often now, on a muddy floor, but into the topmost loft direct, and the carriages detached from their motor, will be run off here and there by the attendant boys and tipped down the various shutes in obedience to the requirements and orders of the European Superintendent in charge of the automatic leaf spreaders. Having thus got our leaf into the centre of the web, let us before going into further details of its treatment, consider the general construction of the factory itself.

The factory of the future will of necessity be a very different concern to the present day two or three storey affair, with, so often as not, wide spreading closed verandahs, especially designed to catch the sunshine on their iron roofs, and heat up the very rooms which it is most desirable to keep cool; small withering lofts which render extra outside withering houses absolutely necessary, and from which latter in wet and cold weather, the leaf has to be gathered up, doubly handled, and brought into the factory loft under the influence of the fans to get it withered at all.

The new factory will make allowance for the maximum of leaf within its own compass, or at any rate arrange for storing it harmlessly till there is room for it on the withering machines; it will scarcely be less than sixty to sixty-five feet high to the eaves, allowing in each bay for 15 ft. for the ground floor, and two withering lofts or rooms of at least twenty feet high each, and a receiving loft, though this latter may easily be accommodated in the depth of the roof.

The factory *in toto* will consist of four, five or more bays, converging radially into a central house, in which will be situated the fans and air shaft in use for the whole of the withering apparatus, and for general punkah work and ventilation. The building itself, from floor to ridge, will be constructed of iron and steel throughout, the withering loft, floors and walls being further lined with some non-conducting and combustible material, such as *papier mache*, manufactured by the Company in India from local timber, and intermixed with grain mica recovered from the local river beds, or with crude asbestos fibre: the whole being coated with some one of the so-called "Asbestos" paints, even now coming to the front as fire-protectors.

The several bays will probably not exceed sixty to sixty five feet in width, and will each contain, as aforesaid, two withering rooms twenty feet in height

running their entire length, and fitted with the necessary withering apparatus, hereafter to be described with its feeding, discharging and ventilating gear complete.

The lower floors will in all cases be devoted to the manufacture of tea, and the various accessories of the trade, store rooms and other heavy work. The rolling and drying departments would probably occupy a whole floor each, fermenting another, and box making in all its branches a fourth. Space would also be found in the building for a repair shop fitted with all the necessary machine tools, and also wood working machinery, and paper-moulders and presses to reduce the cost of outside building operations in those parts where at present expensive Chinamen are employed.

Such being the general outlines of this building, we will turn our attention in another chapter to a tentative forecast of the machinery likely to be employed therein.—*Indian Planters' Gazette.*

(To be continued.)

PEPPER VINE DISEASE IN THE WYNAAD.

MR. BARBER'S REPORT.

The following is from interim Report to the Wynaad Planters' Association of Mr. C. A. Barber, the Government Botanist, on his investigations into the pepper vine disease in the Wynaad:—

"I visited the following places:—Neddikarna, Moopenaad (briefly), Nedimballi and Poothacoolie, Cotternaad (briefly), Anda Tode, Moovatie. The bulk of my work was done at Anda Tode and Nedimballi, where vines were carefully dissected out for a couple of days in each place. Since leaving Moovatie, I had the opportunity of visiting about a dozen gardens on my way to Calicut so as to get a glimpse of the mode of cultivation in the plains.

I have come to the conclusion that whatever the trouble be, it is situated in the mound of earth surrounding the root stock. The two factors which seem to point in this direction are—(1) that the canker, which sets in all diseased plants is situated in the mound of earth surrounding the root stock, and (2) that in diseased plants there is an almost total absence of the fine net work of surface-feeding roots which I have always observed in healthy plants. My statement that the canker seems to originate at the collar is based upon the fact that, however, completely that part of the plant may have gone, it is possible within a reasonable period after death to trace the cankerous spots both upwards and downwards into what appears to be perfectly healthy tissues. I take it also from my examination that there are two systems of roots in the pepper vine—one deep rooting and one superficial. The first eight plants which I dug up were diseased, and in these there were hardly any surface roots. I was thus led to the false (as I believe) idea that the pepper vine is a deeper feeder than generally supposed. By the kindness of Mr. Winterbotham, I was able, however, to dig up a fine healthy plant. Then I at once saw that the great mass of roots was superficial and indeed largely confined to the heap of earth which seems to be always piled up around the base of the standard. If these two points are held in view, it will be seen that it is of the utmost importance to examine into the question as to whether the current heaping up of earth round the standard is a proper operation. I may say at once that I saw nothing in the low-country cultivation which would justify it.

Briefly, I do not think it is done in an altogether reasonable manner. Let the question be asked of practical planters, "Given that the pepper vine is a surface feeder and that the bulk of its feeding roots are developed near the main root stock, ought not the mound of earth to be made suitable to delicate feeding rootlets?" I have frequently found this mound of earth so hard that it was with difficulty penetrated

with a knife. I think it ought to be kept in a friable condition, and also that it should be protected as much as possible from the direct heating and desiccating influence of the sun during the hot weather, as well as the heavy drip of the monsoon. I would therefore suggest for immediate experiment, the scattering of lime over the surface of the mound, as has been done in certain cases at Auda Tode, and its protection from sun and "wash" by a mulch of some sort. As to the forking up of the mound, I leave it to the experience of practical planters. But I would most strongly insist on the great danger to delicate rootlets of any disturbance of the cake-like crust which I have so often met with. When it is made friable there may be advantage in a little forking, but I am not at all sure that this would be necessary.

I do not feel at liberty to make any definite statement concerning the cause of the disease at present. That will come better after I have had the opportunity of making a microscopic examination of the large series of specimens collected in spirits. But I would point out that in my short inspection of the plantations in the plains I have come across a definite and serious disease of the rootlets of the collar. I would, therefore, strongly urge that the idea of obtaining fresh "seed" from this source be abandoned until a clean bill of health may be given. Meantime would it be too much to ask that all who are interested in this matter should, when convenient, make a cursory examination of the rootlets of the mound? They will then be able to justify or criticise my opinion that here are the chief feeders of the plant, and also they will be able to determine whether the disease of the plains is of common occurrence in the hills. The diseased rootlets in the plains show very distinct nodules or swellings in their course. They are frequently twisted or swollen at their ends and on being cut open, show little round dots in both transverse and longitudinal sections. The uncovering of patch of mound roots in friable soil should not be injurious and if the disease is present, it should be visible all over the mound, but in hard crust, the individual rootlets will, with difficulty, be seen and smashed to pieces.

I would also suggest that for the present fresh cuttings should not be taken from the mound, but from the tops of healthy vines, if these are found to strike as well.—*Madras Mail*

PRODUCTS IN UGANDA.

We take the following extracts from an official report of Mr. J. Mahon, relating to the plantations made in the Botanic Gardens at Entebbe:—

CACAO.

The two cases of Cacao (*Theobroma Cacao*) sent out from Kew in August, 1901, have thriven exceptionally well. They arrived during the drought already referred to and as there could be no thought of planting them out I had them all put in pots, and to shade them, had recourse to converting my tent into a greenhouse, and it suited the purpose admirably. Whilst there they were attacked by rats, which gnawed the stems of many quite close to the soil. Trapping several frightened the others away eventually. It was not possible to plant out the Cacao till December, 1901.

Their progress in nine months permanently plauted out has been, and continues to be most satisfactory. I am not aware of any country where Cacao is grown commercially at 4,000 ft. altitude. If we prove it can be done here, the experiment will be valuable.

COFFEE.

As an excellent Coffee is frequently found in this country in a wild state, it is perhaps only to be expected that introduced sorts should do well. The London Market Report, recently to hand, on a sample of Nyasa plantation Coffee, grown and prepared here proves that the country can produce Coffee of first rate quality. Some of the books dealing with this country call the indigenous Coffee a form of *Coffea arabica*. It is nothing of the kind. It is probably a distinct

species, and certainly allied to the well-marked large leaved West Coast types. It responds most readily to cultivation, and grows rapidly after the seedling stage is passed. A Congo species (*Coffea robusta*) bears a striking similarity to it. This latter grows splendidly here. Our plants are from seedlings given by Kew. One plant has just flowered. I believe *Coffea robusta* has a considerable market in parts of Europe.

Maragogipe Coffee, a south American hybrid, and a splendid cropper, is growing freely. I have a number of seedlings of Sierra Leone highland Coffee (*Coffea stenophylla*), raised from Singapore seed.

TEA.

grows with but moderate rapidity just here. Our rain fall is not great enough. When we have a period of rains it flourishes nicely. If its cultivation were carried on here even on a moderate scale to meet some of the local demands, it would be necessary, I feel certain, to call in the aid of irrigation. Mr. Scott Elliot, the naturalist and traveller, seemed satisfied from his explorations in the Ruwenzori country that large areas there offered a fine field for cultivating Tea on a large scale.

Vanilla is growing moderately well. Our forest belt on the lake shore suggests a climate where it ought to thrive apace, but doubtless our elevation accounts to a great extent for its tardiness.

The fruits mentioned in the accompanying lists are practically all well-known tropical sorts. We are pushing on their culture as fast as possible, for fruit is one of our scarcest commodities. Our plants are doing excellently, but the majority are not old enough to have reached the fruiting age yet. A number of Pine apple suckers I brought from Kew are now bearing their first crop of fruits; they are choice dessert sorts grown in British gardens. Already a quantity of shoots from these have been distributed to local residents and to some out-stations. This distribution will continue to be carried out whenever opportunities occur.

TIMBER TREES.

A great deal of attention is given to the introduction of timber trees. The fine Manji Cedar of Nyasaland makes most satisfactory progress here. Specimens about three years old are now over 15 feet high. A large quantity of seeds of this tree was recently obtained from the Botanical and Forestry Department, Zomba, and distributed widely in Uganda. There is a considerable number of trees planted in the gardens here and about the station. Establishing the useful and ornamental *Eucalypti* is practically impossible, owing to the depredations of 'white ants' (termites). One avenue alone has been planted no fewer than four times by myself. Fine young trees from 15 to 20 feet high are ringbarked in a short time just below the surface and quickly die. A wide selection of species have been tried; but all seem equally vulnerable to the attacks of this insidious pest. We have tried all methods of fighting it, but with little or no result. It is rather interesting to know that in one of the worst portions of the gardens for 'white ants' the common *Gnava* thrives and is never attacked by the creatures.

West Indian Mahogany, various *Coniferae*, palms, and several timber trees of the Straits Settlements, &c., are amongst recent introductions. Mahogany will be extensively planted and distributed. A barrel of seeds (through Kew) from the Commissioner of Agriculture, (Barbados), is due to arrive presently. Some seedlings, of a few months old plauted out lately are thriving well.

A large selection of a species of Australian *Acaciae* useful and ornamental, in addition to other trees from that country, have recently been sown.

FIBRES.

There is already some local enterprise in the matter of exporting native fibres, *Sauviera* (Bowstring Hemp) is abundant and there appear to be three or four species. A favourable report was received from London on specimens we sent, and one was valued at £25 per ton. *Raphia* fibre from the magnificent

Palm so common on the lake-side is, like Sansevieria, extremely abundant. Both of these items could be propagated to any extent by planters here at a trifling cost. We have some common Ramie, or 'China grass' growing very favourably. I consider that many parts of this country are peculiarly well suited to Ramie growing. I am not aware if the difficulty of finding a really suitable and practicable machine to prepare this splendid fibre on the field has yet been overcome.

The indigenous cotton is a very fair sample, and imported sorts which we have experimented with on a small scale do very well; the fibre was favourably reported on in Manchester. The only drawback is a tendency on the part of some varieties of known perennial habit to become annual, dying off as soon as the crop is matured."

[The Mianji Cedar, *Widdringtonia Whytei*, was first described by Dr. Rendell in the *Transactions of the Linnean Society*. Our illustration (fig. 69), which we owe to the courtesy of the director of the Royal Botanic Gardens, Kew, shows a young plant growing in the gardens at Entebbe. In our number for June 16, 1894, p. 746, we extracted from the *Kew Bulletin* of 1892, some interesting particulars relating to the tree. Ed.]—*Gardeners' Chronicle*,

MANURES FOR PASSION VINES.

The description of the soils is as follows:—

Mr. Arnold's.—Chocolate loose loam.

Mr. Dale's.—Shaley loamy clay.

Mr. King's.—Black soil and a loamy soil.

Mr. Taylor's.—A very loose sandy and gravelly loam.

The commercial manures used were hased by the Chemist Mr. F. B. Guthrie, on the assumption that the bearing passion-vine removes from the soil (in a year) about

6½ oz. nitrogen,
1½ oz. phosphoric acid,
4 oz. potash,

as determined by analysis, and costing between 4d. and 5d. per vine.

Complete manures in every instance showed themselves far more preferable than single manures, and the following were the best used:—

- "No. 21.—52 oz. dried blood,
9 oz. superphosphate,
6½ oz. potassium chloride.
- "No. 23.—40 oz., nippo.
24 oz. Sugar Co.'s 'A' manure.
16 oz. Australian potash.
- "No. 22.—43 oz. nitrate of soda.
9 oz. superphosphate.
6½ oz. potassium chloride.
- "No. 39.—32 oz. sulphate of ammonia.
18 oz. superphosphate.
8 oz. sulphate of potash.

"This last mixture answers well for the very dry season we have experienced, and is the best for summer dressing. These manures are the best so far used, and side by side with the single manures the comparison is very marked; and as regards the rows left between, and which received no manure, they look half starved and in a hang-fire condition when compared with the vigorous growth of the well-fed vine carrying a crop of well-developed fruit,—clearly proving that commercial manures will pay when we can arrive at the exact requirements of the various soils. It was strikingly apparent in these tests that the results in no two cases were exactly alike, the manure in each class of soil producing difference in growth, &c., more or less slight, but nevertheless noticeable."

To this report, the Fruit Expert, Mr. Allen, adds: "So far as the experiments go, it is clear that on the soils on which they are being conducted it is absolutely necessary to manure if anything like good returns are to be expected. The manured vines are

so far ahead of those untreated that, generally speaking, there is no comparison between them, and while the manured vines are in good condition after carrying their last year's crop of fruit, and promise well for the coming season, the unmanured vines appear to have become exhausted and look as if they had little vitality left for the approaching season. In my opinion, passion-vine growers cannot afford to allow a season to pass without assisting the vines by the application of some manure, and, so far as the present experiments enable me to judge, the complete manures undoubtedly give the best results."

The Chemist, Mr. F. B. Guthrie, reports: "I visited the orchards in which the experiments are being carried out, with Mr. Allen, in November. The results were striking and the differences between the manured and unmanured vines very marked. The experiment is being watched keenly by the orchardists in the district, and provides an invaluable object lesson as to the efficacy of manuring. I arranged with Mr. Allen for a further set of experiments for this season, to test particularly those mixtures which are giving the best results. These are so arranged that the crop for each row can be picked and packed separately, so that the actual money-return from the use of the different manures can be ascertained."

Messrs. Taylor, Dale, and King will keep a record of the quantity of fruit taken from each of their plots of sixty vines to which the manures were applied, so that there will be available reliable figures for future guidance. Mr. Taylor will also keep a record of the quantity of fruit taken from six of his best plots of nine vines, which will be determined by independent inspections.—*Agricultural Gazette of N.S.W.*

GREEN TEA FOR AMERICA.

[By T. GOSSEUP in *Times of Ceylon*.]

NEW YORK, February 20th, 1903.

There has been of late a much larger trade doing it Ceylon green teas, owing to the fact that between February and May, there is generally a shortage of Japan teas and this year has been no exception. The new Japans arrive in this country in fair quantities about June, and between June and December the bulk of the crop is sold (a quantity to arrive in the early part of the following year); but it is a fact that each year there has been a shortage of Japan teas, the quantity shipped from that country being less than the requirements of the United States.

It has, therefore, been a very good opportunity during the last month to introduce Ceylon green teas, but I regret to say that the majority of the uncoloured Ceylons (called basket-fired here) are coloured and packed in Japan half-chests and faced with paper facings, outside the packages, and matted to represent Japan teas. I have written before pointing out the necessity to most of the Ceylon planters to wake up to the fact that if they wish to get hold of the United States green tea trade, they must conform to the wants of this country by shipping pan-fired or sun-dried (both coloured teas) in Japan half-chests, to nett 80lb., the packages faced with paper bearing the following inscription:—

VIA SUEZ CANAL.

Chop Mark: letter as

H V

— or a Liou, etc.

T

EXTRA CHOICEST FIRST PICKINGS.

GENUINE CEYLON-JAPAN TEAS.

Pan-fired, nett 80lb.

"I have seen recently some very good Indian green coloured teas made by the Deane-Judge pan-firing machine, and these teas are the best that I have

seen since I have been in this country—that is to say, that they are the class of Japan and China greens that are sold here.”

I am sending to you, by this mail, samples of Japan teas which, if the planters of Ceylon will only follow carefully, they will find already sale for here, because the cost of production in Ceylon is so much less than that of Japan and, therefore, the Ceylon teas can be sold at more favourable prices to the buyer than Japanese, which, in this era of keen competition, is as important here as elsewhere. It is quite possible that, if Ceylon produces the right kind of tea for this market, that they will seriously cut into the Japan exports, and there will be a time when it will not pay many of the Japan planters to ship teas to this country on a favourable basis, and that Ceylon will gradually oust Japan teas altogether.

It must be borne in mind that the ignorance of the grocer in the States is appalling as regards tea. Many a man who has been a tramway conductor will start as a grocer, and, as you can imagine, taking fares on a tramway is not the best apprenticeship to serve before handling or knowing anything about teas. On the other hand, a lot of the wholesale grocers here finance the retail grocers; and, therefore, the retailers have to buy all their produce through the wholesale houses, and it is the wholesale merchants that we have to cater for first. They make the retailer the distributor, and can practically give him what they like, and take advantage of giving them Ceylon greens if they can make more money out of this class of tea than they can out of Japan.

Of the houses in this country who are doing most for Ceylon green teas Lipton leads, having pioneered Ceylon greens into many parts of the country where it was never taken before, selling teas in bulk to many of the large merchants all over the country. Larkin does a certain amount through his packet business, but he does not get at the wholesale as Lipton does, selling invoices of Ceylon greens to merchants who have innumerable channels to distribute the teas through. Finally—Muir is doing a regular business in this country in Ceylon greens, and their method of colouring and shipping has been the greatest help in getting the teas tried by the merchants, and repeat orders are generally the result.—*Indian Planting and Gardening.*

VARIETIES OF CASSAVA.

In your issue of October 25 last, Mr. W. G. Freeman, scientific assistant of the Imperial Department of Agriculture for the West Indies, directs attention to the poisonous properties of sweet cassava. His statement with regard to the West Indian sweet Cassava is correct, and recently that Department has noted the fact that from time to time people are poisoned by eating sweet Cassava in the West Indies. Bitter Cassava is much more poisonous. In view of the great possibilities of this cultivation in the Tropics, I herewith enclose the result of the analyses by the Government chemist here of the tubers of seventeen varieties of Cassava which I have recently introduced to Jamaica from Colombia. It is important to note that these new varieties are non-poisonous, so that their culture may be turned to account as a leading article of food throughout tropical regions.

In your issue of August 9, 1902, p. 99, you commented upon a report of mine on Cassava as a great prospective industry, i.e., for the production of starch and glucose, for both of which it surpasses all other plants in the quantity producible per acre and at a minimum cost. Thus, 10 tons of Cassava tubers per acre is a moderate estimate; from the common naturalised West Indian varieties, which yield only about 20 per cent. of starch, 2 tons. But my best varieties recently introduced, will be seen in the Government chemist's report, as yield from 30

to 36.50 per cent. of starch. The variety yielding the last-named percentage I have named "Governor Hemming," in compliment to our Governor.

Potatoes in Europe yield an average of about 6 tons per acre, from which the starch obtained amounts to only 16 per cent.

In America, Maize yields an average of about 30 bushels per acre—less than half a ton of starch.

During the last few years, Florida has established Cassava cultivation on a commercial scale, and of splendid quality. Florida, however, can hardly compete with purely tropical regions. At the same time, the Florida farmers have demonstrated to the world the importance of cassava, not only for the making of starch and glucose on a commercial scale, but also as stock-feed from the tubers and by-products.—ROBERT THOMSON, Half Way Tree, Jamaica, March 19, 1903.—*Gardeners' Chronicle.*

THE CHICLE INDUSTRY OF MINDANAO.*

I am writing to you from the locality of Zamboango, one of the largest towns on the island of Mindanao. This narrative will concern the production of the substance known as Chicle and the manufacture of the same into form for the commercial centers of the country. South American Chicle and the gum resulting from the treating and preparing of the same has had a place in the markets of the world for many years. Gums of this nature from this portion of the world are not so well known. It is only very recently that the country has been opened to the extent of permitting Americans and others to investigate into these natural growths of a commercial product.

The Moros for years have secured the milky, white saps from the gum-producing trees of the country by creating wounds in the barks. Oftentimes the blows of knives or pricks with spears form the only means by which crevices and fractures are effected in the rough bark, to the extent of developing a flow or an oozing of the valuable gummy substances. There is a cut made in Fig. 1, showing one of the systems employed by the natives for securing the flowing saps. When the gummy liquids pass from the tree to the tube of bamboo *a*, these liquids are very similar in consistency and appearance to milk. The bamboo tube is usually suspended horizontally by means of the crosspieces, *b*.

Shortly after the mass of liquids is exposed to the air, it begins to harden and in a short while can be cut or broken into cakes. The cakes are often shipped to the coast from the interior in this form or as is the case in some places, the cakes of gum are reworked into desirable order and forms for transportation to other countries or to centers where there are agents who handle the gums of the country. At present writing there is one agent of a foreign commercial concern here who is buying gums at market values in large quantities for shipment.

Another mode of securing this white sap is from the unripe fruitage of the tree, which is very similar to the *sapota* growths of Yncatan.

The natives of Mindanao use some crude devices in the Chicle gum industry. In Fig. 2 is the awkward yet effective, manner in which the masses of gum-like sap can be exposed to the action of the atmosphere without undue wastage due to specks and foreign matters falling in. A series of bamboo tubes are adjusted side by side, as shown, and these are joined with bamboo strips underneath and fastened to crosspieces. The latter are arranged so as to support the whole affair about three feet from the level of the ground. There are openings cut out from each of the tubes at intervals, as shown, and the air can

* From *The Paint, Oil, and Drug Reporter*, New York, September 29, 1902.

impregnate, and with the heat and drying influence of the sun the desired results are secured. After the mass begins to form in the tubes it is forced out before it hardens and cooking follows.

Your correspondent sketched two or three different designs of cook ovens of native make, and shows one of the most practical kinds in Fig. 3. This is erected by first excavating the earth to a depth of about four feet, and three feet square for the fireplace, as represented. Then stones are put in position for the forming of the archlike structure immediately over the fire on which rests the pot of iron containing some of the lumps of Chiclé in readiness for dissolving and cooking. This iron vessel is designated *c*. Above this vessel is still another arch of stone, describing a more definite circle. Several native workers are required to keep the fire going and the vessels properly filled. These ovens last indefinitely when properly built, as those I saw were very old indeed. The cooking operation involves several others, such as the sweetening and flavouring. The natives use the common brown sugar product for sweetening purposes. The natives discolor the substance by employing stains squeezed from leaves, herbs, barks, etc. Some of the coloring barks are those from which the dye-substance-collectors of the country obtain stains. Reds, yellows, and blues in coloured gums are prominent.

After the gummy stuffs are properly sweetened and flavored they are usually rolled out into sheet like order, so that slabs of the substance can be secured, as in Fig. 4.

After a time the substance is in readiness to shape into loaves, and this is done by the natives in several ways the best I saw being the rolling of the gum into thin sheets, the weight desired, and then cutting through with knives made for the purpose. A white powder substance is scattered over the surfaces of the gum while this is going on, so that the natives can handle the stock without danger of the fingers adhering to and soiling the matter.

They have a process of kneading, which is used in connection with the finer grades of gums, and this device for accomplishing the work is shown in Fig. 5. It is a crude bit of work, as shown involving the use of a tree stump or section, which is chipped out in the middle to form the oval depression in which the round-nosed instrument of hard wood can be turned by manual labor. The particles of the Chiclé are granulated in this trough beneath the weight and frictional surface contact of the rounded device.

In Fig. 6 is shown one of the strange devices employed by the Moro Chiclé workers for mixing and working the material. This contrivance is made with stone, heavily erected so as to make the walls firm, and the interior is coated with a cementlike surfacing, which results in the smoothing and rounding off of the tub. Inside this tub sets the upright post, *c*, in which there are projecting arms of wood as shown. This affair is revolved by a belt passing from wheel *a* to wheel *b*, on the shaft. Manual or water power is usually employed to give the necessary turning movement to the gearing, *a*. I saw several devices like this, but in most cases they were out of order and unfit for service. The gums here, when finished, lack the flavors employed by American makers. The only flavors utilised are such as can be procured readily.

Costly wintergreen, for example, is not known here. Malt, mint, etc., however, are used. The natives chew the gum to quench thirst. They use it much as they use the tooth staining beetle nut.

As to packing for transportation, you can see that the packages are put up in the form like Fig. 7, as a rule. The substance is rolled up in mats, into various packages, and three or four of these packages are tied up together, as in the view. The writer is inclined to believe that there is money in the Chiclé industry of Mindanao for capitalists. The gum materials can be purchased from the natives

very cheaply, and at the seaports, where the stocks can be properly packed for export.—*India Rubber World*.

COFFEE-GROWING ON THE CLARENCE.

From accounts to hand, it would appear that coffee-growing on the Clarence River has passed the experimental stage, and that the industry is on a fair road to commercial success. Mr. John Bale some eight or ten years ago secured certain rights from the Government to found an experimental station at Wolbin Island. There he planted out several acres of young trees, which are now in full bearing. Already he has harvested 30,000 lb. of berries, and has still another 10,000 to gather. This means that each tree's yield is from 50 lb. to 60 lb., or fifteen 1 lb. tins of the prepared article. Retailled at 1s. per tin, the revenue represents a handsome income, as the trees are planted in rows about 20 feet apart. At this rate, and providing that a market can be secured for the product, the industry, on the same basis of success, ought to give returns much more handsome than any of the sub-tropical crops raised on the North Coast. The drawback to farmers used to returns ranging from monthly to yearly, is that there is no yield from the coffee trees till they are 4 years old, and then they are not in full bearing.

Mr. Bale has for many years devoted much of his time to crop experimenting. He has demonstrated that many crops, other than those now raised, can be profitably cultivated on the fertile Clarence as commercial ventures.

Besides raising the coffee in its raw state, he has also roasting appliances and modern grinding machinery, and turns out the coffee in labelled tins ready for the market.

In the latter end of 1896, Mr. Bale submitted samples of his locally-grown coffee to the Department of Agriculture. The samples were brought under the notice of Mr. C. Skelton, who had been engaged for seventeen years as a coffee-planter in Ceylon. He was greatly impressed with the quality of the berries, and some months afterwards, under arrangement, visited the Clarence and other Northern River districts, with the object of reporting on the suitability of the soil and conditions generally for extension of the industry which was proving so successful in the admirably-adapted site elected by Mr. Bale.

In the *Agricultural Gazette* for October, 1897, page 744, Mr. Skelton published his opinions concerning the capabilities of the districts mentioned. As many present traders of the *Agricultural Gazette* have, perhaps, not seen the report, some extracts from it are now reproduced:—

"In all three districts—Clarence, Richmond, and Tweed—I saw large tracts of land, cleared and un-cleared, well suited for coffee-culture; soil and climate are all that could be wished for. I saw growing in the different districts, strong, healthy, well-grown trees, in many instances laden with fruit. With the wonderful fertility of the soil, and the general suitability of those parts of the Colony for the purpose, it is surprising that the industry has not progressed beyond the experimental stage.

"The conditions for planting here being somewhat different from India, and Ceylon, where cheap coolie labour is obtainable, I believe it would be an advantage to set the coffee trees about 7 feet apart, or even more, so as to permit of the employment of a light one-horse scarifier to keep down the weeds, and also to allow of the passage of some sort of vehicle between the trees in gathering the crop. With the exception of planting and pruning, which latter commences after the second crop has been gathered, nearly the whole of the work can be carried out by ordinary labour. The picking of the berries is essentially women's work. A good picking woman can gather twice as much as almost any man, her fingers being so much more nimble."

The chief risk to be avoided in coffee-growing is that of frosts, but Mr. Skelton observed very many sites on well-sheltered hillsides where there would be little risk of injury from such a cause.—*Agricultural Gazette of N.S.W.*

CULTIVATION OF FRUIT IN FLORIDA.

With a view to promoting the cultivation, on a large scale, of pineapples, oranges, etc., in Jamaica, Mr. Robert Thomson, late Superintendent of the Government Botanic Gardens of Jamaica, has recently investigated the methods employed in the fruit plantations of Florida. His report to the Jamaica Board of Agriculture discloses many interesting features in the cultivation of tropical fruit. For pineapples, which are grown to many districts, a system of shed culture has proved successful. Until about twelve years ago this fruit was grown in the open, but one or two severe frosts destroyed nearly the whole of the plants, and it was found necessary to afford them protection, both against frost and the tropical sunshine. The sheds are made of close boarding 7 to 8 feet high and partially covered with thin laths, opening being provided to admit the requisite light and air to the plants; during the frosty nights canvas sheets are placed over the sheds as an extra protection. The plants flourish very well under these conditions, and 80 to 95 per cent. of them bear fruit; about 200 acres of land are under cultivation, and average pinery consisting of five to twelve acres. The cost of erecting sheds, which last about 7 years, average \$300 per acre, the canvas costing about the same; the suckers, which are planted to the extent of 9,000 per acre, cost \$900 and the fertilizers about \$100 per acre annually. The first crop, which is taken within twenty months of planting, is calculated to pay all expenses; the price obtained per crate of twelve to sixteen fruits is about \$3 for the best varieties, and less for smaller fruit, a little difference in size making a considerable difference in the price. Some of the growers replant after each crop, some after two crops, very rarely at longer intervals.

Jensen, on the Indian river, one of the southern districts, contains several thousand acres of pineapple plantations; only a small proportion are under sheds, the growers relying, as a protection from frost which is much less prevalent, on the very close planting of the suckers (12,000 per acre), and on the greater hardihood of the varieties they cultivate. From this district 200,000 crates, containing about 6 million fruits, are shipped to the northern cities annually; the yield of fruit per acre is about 8,000 to 9,000, and on occasions up to 15,000; the replanting is usually done every eight to ten years, but in Mr. Thomson's opinion half that interval only should elapse. The food for the plants is furnished by fertilizers. In all the districts visited, the soil was found to consist of 96 to 98 per cent. of sand or silica, one analysis showing 99.4 per cent. of insoluble residue; the fertilizers are mixed by the grower to suit his own conditions of cultivation, they contain ammonia and potash and are thrown between the rows of plants and raked in to the top surface of soil. The average annual rainfall is from 50 to 60 inches. Jamaica at present exports annually about 65,000 fruits, the yield per acre being very low and capable of great improvement; the soil is not sufficiently sandy and is too rich, but there are many parts of the island highly suitable and which are not under the slightest cultivation.

Prior to 1895 the cultivation of oranges was the greatest industry in northern parts of Florida, but in that year a severe frost killed every tree and ruined several thousand growers, but at the present time many plantations are being cultivated further south; before 1895 the annual export was about five million crates, but after the frost referred to it was 100,000 crates, rising 150,000 last year. Great care

is given to the packing of the oranges, an important point to which insufficient attention appears to be paid in parts of Jamaica, which has now a much larger export of oranges than Florida.

A growing industry in Orlando is the cultivation of cassava; its plant appears to grow well on the sandy soil, the annual yield per acre being about 9 tons. From the cassava tubers the production of starch and the manufacture of tapioca and dextrine is to be taken up. The cultivation will probably be successful, since there will be a considerable local demand for cassava as a cattle food, and it will furnish starch to the great cotton factories further north, and owing to its high content of starch (17 to 20 per cent.), and sugar (3 per cent.) and low fibre value (1.63 per cent.), it appears a more suitable material than corn from which to manufacture glucose. As a food for cattle cassava is stated to be better and cheaper than either cotton seed or corn, and it will grow under conditions unfavourable to other food-stuffs. In view of this Mr. Thomson recommends the extensive cultivation of cassava in Jamaica; it is very profitable, no fertilizers being needed, although a small quantity is required for its growth in Florida.—*Imperial Institute Journal.*

ORANGE CULTIVATION IN JAFFNA.

The efforts now being made to establish the cultivation of oranges on a large scale in several British Colonies, and especially in the West Indies, renders it opportune to draw attention to an interesting article on the above subject in the current number of the German journal *Der Tropenpflanzer* (No. 7, 1902, 341), contributed by Messrs. Aaronohn & Soskin, in which a full account of the trade in, and cultivation of, Jaffna oranges is given. It appears that, altogether even varieties of citrus are cultivated in that district, the following being their names and characteristics:

Citrus aurantium (Portuguese orange). This is the Jaffna orange proper, and is the one so largely imported into England. It is probably a native of Portugal, but is now cultivated in two varieties which have little in common with the original stock. The popular in England is known locally as *Schamuli* and differs from the second and less common kind, *Beledi*, in being larger and having a thicker skin and, no seeds.

Citrus Bigaradia (Seville orange).—This variety is only grown as a stock for grafting purposes, as it has been found that an orange tree raised on this species bears fruit for a longer period than when grown in any other way.

Citrus medica (citron).—The two kinds of fruit raised from this species never come to England, but are exported to the countries bordering on the Mediterranean, and to some extent also, they find a market among the Jews.

Citrus limonum (lemon).—This plant is never grown in Jaffna for the sake of its fruit, but, like the bitter orange, is used as a stock on which to graft the sweet orange. It is stated that the best and oldest orange trees of Jaffna were entirely raised on lemon stocks, but the experience of the present planting community is that trees so raised only bear fruit for six or seven years, and are, therefore, less profitable than those propagated from the bitter orange.

Citrus limonum var. dulcis (sweet lemon).—This species is also employed only as a grafting stock where orange trees are to be grown on the light sandy soil characteristic of some parts of this district. The trees so raised have the advantage of bearing in a short time. The sweet lemon itself is popular with the Arabs, and is, to some extent grown at Akki.

Citrus Nobilis (Mandarin orange).—This tree has been grown in Palestine only for a short time, but has spread rapidly. The fruit bears carriage well, and is therefore suitable for exportation, whilst the tree is small, and fruits readily.

Citrus decumana (grape fruit).—This species is rarely seen, and is nowhere cultivated as a crop in the country.

The production of oranges in the neighbourhood of Jaffna is carried on both by Arabs and by Europeans but the methods adopted by the two classes are identical, with the exception that the European planters have, as a rule, adopted machinery where possible. One of the chief factors in successful orange culture is efficient irrigation, and every garden is provided with a well, from which water can be pumped either by the primitive Arab methods or by the use of oil engines, to all parts by means of stone canals. The ground is dug either by direct manual labour, as the Arabs prefer, or by a plough cutting to a depth of from 19 to 38 inches. In this prepared soil seeds of the bitter orange or cuttings of the sweet lemon are placed, and the young plants produced from these receive no further attention beyond regular watering. After two years' growth, they are taken up and planted out in the orange groves. This transplantation takes place all the year round, without distinction of seasons. The young trees are planted very thickly, often not more than four or five square yards being allotted to each. After a further two years' growth in the orange garden proper, preparations are made for grafting the true Jaffna in the young stocks usually towards the end of the summer season, although there is considerable risk at this time of the graft being killed by the cold weather which is apt to come on suddenly. The trees begin to yield well four or five years after the ingrafting has taken place; they receive comparatively little attention, but are watered about once a week and the ground is turned over three or four times a year, in order to facilitate the passage of water to the roots. The chief enemies the orange-planter has to contend with are a group of insects resembling wood-lice, which infest all parts of the orange trees and various vegetable parasites, which attack both old and young plants, and rapidly destroy them. The Arabs take no precautions to prevent the spread of these fungi, and even plant fresh young trees in the neighbourhood of old dead trunks covered with vegetable parasites of old kinds, so that an Arab orange garden often presents a pitiable spectacle to the eye of a modern cultivator. As regards the future of orange cultivation in Jaffna, the authors are of opinion that the present careless methods of the Arabs will, if persisted in, lead to a great falling off in production, as has already occurred in other orange-growing districts, such as Majorca, Sardinia, and St. Mignel; whilst, if a rational culture under European supervision could be secured, a considerable extension of the industry might be made, since, in face of the decreasing output of the other orange-growing districts over-production is scarcely possible.—*Imperial Institute Journal*.

BAMBOOS.

With reference to the flowering of the Bamboos and their alleged death in consequence of the production of seed, we append an extract from an official report drawn up by Major-Gen. C. B. Lucie-Smith, when Deputy Commissioner of the Chauda district, in the Central Provinces of India, a tract of country some 10,000 square miles in extent, over more than half of which in 1869 the forest rolled league upon league, one mighty wave of trees and Bamboos. Gen. Lucie-Smith was for some years in the West Indies and South America, but he never heard that the Bamboos growing in those countries died after flowering.

"The uses of the Bamboo," he wrote, "are almost infinite, and it could probably be the least spared by the people of all the products of the forest. It is of two kinds—the common, and the Kutung

Bamboo. The first grows in all light soils, and in each clump there will be one or two canes which shoot up above the others, with only a small hollow at the core, being the "male Bamboo," so prized for the shafts of hog-spears. The Kutung is much larger than the common species, attaining a height of sixty feet, with a corresponding thickness of stem, and grows chiefly on the banks of streams. In the Khalsa country it is found principally in the dense Mohurlee forest, but the Zemindars have it in great abundance.

"During the rains the young cane shoots from ground, and being then tender, though of considerable thickness, is boiled and eaten by the Gonds. It seeds at irregular intervals, and the produce is carefully collected for food. With the effort the Kutung dies, and people of all classes believe that seeding only takes place during years of scarcity. My own experience is that in each year since 1854 various clumps of Kutung have seeded in succession."—*Gardeners' Chronicle*.

FRUIT CULTIVATION IN CEYLON.

The importation of fruit plants into Ceylon by Mr. A. J. Pearson has been again satisfactory especially in regard to the various species of the citrus tribe which flourishes all over the island, and the imported varieties can be easily propagated by either one or the other process of grafting, budding, layering, inarching, etc., etc., with the useless bitter orange and wild lime which grow in nearly every up-country and low-country garden. This is the most reliable way of propagating the species, as seedlings in the case of oranges and lemons seldom turn out true to seed. Lemons are doing as well as oranges, and up-country baskets of excellent and large fruit from four-year old trees have been seen in Colombo. The imported varieties also grow very well in Colombo, and oranges, lemons and olives have been grown in pots and transferred later on into tubs. These plants have put on remarkable growth and, being root-bound, the trees show a tendency to run into fruit early. Olive (*olea*), which has been cultivated in the East from remote times, is another tree that grows almost all over the island, and the different imported varieties, the eatable and the oil-yielding kinds can no doubt be propagated by grafting with the wild olive (*Elcocarpus serratus*; Sinhalese *veratu*). The pears, plums, peaches, nectarines and apricots naturally require a temperate climate, and the imported varieties are doing very well up-country. In this direction too the stock can be improved by grafting, and the old peach trees which are to be found in the region of Bandarawella and Badulla can by a simple process be converted into modern fruit bearers. Nectarines can be treated with peaches by budding and grafting, and it is not an uncommon thing for peaches and nectarines to be found growing on the same branch. The fig, which is another excellent fruit can also be grown in different parts of the island. Several varieties have been imported by Mr. Pearson and it will be interesting to know if the cultivated kinds can be grafted with some of the wild species growing in Ceylon.

OLD BOOTS IN VINE BORDERS.—I was asked to examine some old Vines recently, and found in the border many old boots and shoes. They had apparently been buried under the idea that they were of manorial value. Most of us have heard of the folly of burying carcasses of animals in Vine borders, but I was not previously aware that their hides had been used for the purpose after being tanned and made into boots.—T. COOMBER, Hendre Gardens, Monmouth.—*Gardeners' Chronicle*.

**CLOSE OF THE PEARL FISHERY.
ANOTHER FISHERY NEXT YEAR.**

Official secrecy as to the date of the closing of the Pearl Fishery has been very well preserved and few can have been prepared—unless it were by the “burst” of the little monsoon in Colombo on April 15th,—for the announcement made by our correspondent in his telegram the next morning. The total yield of the Pearl Fishery, owing to the fact that the last day's oysters (90,650) have been reserved for experiment purposes—whether at Galle or elsewhere our correspondent does not say—is just above what we recorded yesterday, £815,569.75, or £81,557 calculated at R10 to the £ sterling, the official estimate being put at R825,000 or £82,500 a figure which has only once been beaten in the history of Ceylon Pearl Fisheries since 1838 as recorded in the *Ceylon Handbook and Directory*. That occasion was in 1891 (the last) when £96,374 18s. was collected from the fishery which lasted 43 days. The present fishery can only be said to have lasted 38 days and has yielded an average of £2,265 *per diem*; as against £2,241 6s in 1891. The result is one on which the authorities deserve the fullest congratulation and the “Ridgeway” Pearl Fishery will be remembered as amongst the richest events of an almost unbroken prosperous administration.

**TOTAL GROSS RECEIPTS R825,000—THE
SIXTH LARGEST RETURN ON RECORD
IN BRITISH TIMES.**

We find we did not, in the above article, take account of some of the phenomenally rich Pearl Fisheries which occurred in the early days of British rule. The result of our further examination of the old records (which will be found reproduced at page 523 of our “Handbook” for 1898-9) is seen in the following comparison:—

Pearl Fisheries in British Times giving largest Returns:—

Year.	Gross Receipts. R.	Expenditure.	Days Fishing.
1797...	1,100,000	1,918 pagodas	No record.
1798...	1,400,000	12,729 "	"
1808...	842,574	19,636 rupees	"
1814...	1,051,876	36,343 "	"
1883...	804,247	80,000 "	42 days
1891...	963,749	100,000 "	43 "
1903...	825,000	(?)	38(?) "

It will be seen, therefore, that only on five previous occasions—out of a total of forty-one Pearl Fisheries in the British era—have the gross receipts been in excess of those accruing for the present year. Sir West Ridgeway in the last year of his prosperous rule will receive a larger amount than did any of his predecessors, back to Sir Robert Brownrigg, in any one year, with the sole exception of Sir Arthur Havelock from his one fishery in 1891. At the same time, if all accounts be true, the expenditure this year,—especially if the cost of Professor Herdman's Mission

and Mr. Hornell's experiments be added in,—will be heavier than the 100,000 rupees approximately spent twelve years ago—although that was the largest outlay ever incurred in any one year up to that date by the British Government. Nevertheless, there ought to be a handsome net amount to credit for disposal by the Governor with the advice and consent of his Executive and Legislative Councils. St. Louis Exposition is certain of a full vote for its Ceylon Court, and we suppose the long-promised extension of the Museum buildings will be no longer delayed. Such objects have always been regarded as having a peculiar claim on Pearl Fishery receipts, and, therefore, we may further fairly anticipate that the claim of Colombo to a really worthy and satisfactory Observatory for astronomical and marine as well as meteorological purposes, will not be overlooked. Not only has our present Governor to be heartily congratulated on the result of the Fishery just closed; but it would appear that there is every reason to anticipate that his successor will have no less good fortune in the same direction during his first year of office,—with, we would fain trust, a continuance of Fisheries for two or three years to follow, even if the returns be not so large. Pearl Oyster Fisheries in the past have generally come in successive groups of three or four years. Thus Sir Henry Ward got four fisheries from 1857 to 1860; Sir James Longden got three fisheries from 1879 to 1881; Sir Arthur Gordon four from 1887 to 1890, followed by that of 1891. On the other hand the years 1863, 1874, 1877 and 1884 gave detached fisheries with NONE in the preceding or succeeding years. There is every reason to expect that the fishery just closed is to be the first of “a group” which, we trust will, on the whole, be as prosperous as any in the Ceylon record. So note it be. And further may we not hope that before this spell of good fortune expires, the experiments of Messrs. Herdman and Hornell may be so crowned with success as to show us how to secure a permanent annual return from Pearl Oyster culture on, or near to, the coast of Ceylon.

**RUBBER TAPPING IN THE MYSORE
GOVERNMENT GARDENS.**

ANGALORE, April 8th.

CENTRAL AMERICAN RUBBER.—(*Castilloa elastica*.)—Three trees seeded during the months of April and May, bearing collectively about 3,000 seeds. Of this same number a thousand seeds were sold to the Conservator of Forests in Travancore, at R5 per 100. This tree will succeed well on coffee estates throughout the Province, and it is recommended that abandoned estates may be planted up with it. In the matter of supplying rubber hereafter, it should do for the mainland what the *Ceara* rubber tree is expected to do for the maidan.

CEARA RUBBER.—(*Manihot glaziovii*.)—Tapping experiments made on this tree have continued to prove instructive not only in gauging the approximate yield of caoutchouc from a given tree, but also in recording the best season, time, and manner of tapping. It has also been noted very clearly that some trees yield

much more copiously than others. This result may in some cases be due to the position of the trees as regards shade, soil and moisture. But irrespective of these important factors there can be no doubt but that certain trees are physically more productive than others under any condition of growth.

Tapping experiments were made on a tree of the latter class, only 10 years old, with fairly good results, and the tree has not diminished in vigour, nor would it have done so had 5 lb caoutchouc been extracted instead of 2½ lb. The flow of milk sap from the trunk of the tree was best during the months of October, November and December, very heavy rain having fallen in the latter part of September. Only five tappings of the root limbs were made in this experiment, which is an insufficient test. Root tappings are most productive during the first half of the calendar year, when the tree is deciduous and the ground dry. During the remainder of the year the trunk should be more productive than the root. The results of tapping a number of trees at different periods and in different ways, throughout the year, are given, and show how irregular the flow of sap is when tapped at the wrong season and in the wrong place. They also show that 14 root-tappings produced 17 ounces of caoutchouc against 12 ounces in the same number of trunk tappings. In making these experiments, the collector had to work with primitive materials and unskilled labour, so that the percentage of waste was considerable.—*N. Times*.

CACAO PLANTING; SAMOA.

In his report for the year 1902, the Acting British Vice-Consul at Apia states that the mainstay of Samoa is cacao. There is, he says, little reason to doubt that 20 acres of cacao in full bearing yield a substantial income. On the other hand there are drawbacks, e.g., the possibility of hurricanes which will throw the plantations back three years, and the danger from disease.

Persons should not go to Samoa to plant cacao unless they have at least a capital of 1,000l. In five years' time, from the date of planting, the trees should be in full bearing, provided they are well attended to during that period. Some people say they will bear sooner, but as an average statement the above is correct.

Samoa cacao was recently quoted at 95 pf. per lb. in Hamburg, equivalent to 5l. per cwt. The trees have, in most existing small plantations, produced at least sufficient to pay expenses in the fourth year, and when in full bearing from the fifth year onward, have so far exceeded the average output of other countries. Hitherto no disease has manifested itself, and as a safeguard the Government has wisely prohibited the importation of seed from other countries. No doubt continues the Vice Consul, there is a great future in Samoa for plantation companies, assuming that the price of cacao does not fall with increased production. There should be with proper management, very heavy dividends. Some particulars of a plantation company now at work are contained in the report.

The Vice-Consul adds that various enquiries from Englishmen reach his Consulate respecting Samoa. For their information it may be said that that country offers no inducement to needy immigrants of any nationality. Knowledge of the German language by persons seeking employment in Apia is necessary. Trading and storekeeping are completely exhausted.—*Board of Trade Journal*, March 26.

WHITE-GROWN SUGAR.

QUEENSLAND'S INCREASE IN GROWERS.

Melbourne, April 19.—Prior to leaving for Sydney on Friday last, Sir George Turner inquired from the Sydney and Brisbane authorities as to whether, as anticipated in a recent publication issued by the Mossman Central Mill Company, there would be only a few new applications this season for a rebate on white-grown sugar. He received a reply from Brisbane to the effect that, while 1,511 farmers registered in Queensland last year as growers of sugar by white labour, the number this year was 1,398.—*West Australian*, April 20.

A TRIP TO THE ANNAMALAIS, A GREAT FUTURE AS A COFFEE COUNTRY.

Mr. D Edwards, well-known in Colombo commercial circles and in Ceylon generally, has last month paid an interesting ten days' visit to the Annamalais. In conversation with an *Observer* representative on his return, Mr. Edwards gave some interesting information especially regarding the journey to the Annamalais which he suggested might be noted.

FOR THE BENEFIT OF PROBABLE PROSPECTORS.

"Leaving Colombo by the ss. 'Africa' on 9th April," he said, "and Tuticorin by rail next morning I reached Podanur on the 11th at 7 a.m. On the 12th I travelled by tonga to Pollachi, 25 miles, slept the night at the travellers' bungalow and "tonga-ed" on to the foot of the Ghaut the following day, a further 13 miles. Now for the climb 16 miles by short cuts to my destination, the biggest piece of real hard work I have ever done. I should mention there is

A CART ROAD ALL THE WAY TO THE

ANNAMALAIS,

but the heavy rains last November played havoc with the culverts on the face of the Ghaut, and wheel traffic has not yet been resumed. At the present moment, however, some hundreds of coolies are employed on the work, and it is expected, that in two months some carts will be going through the whole way. The Annamalais greatly resemble Haputale in lay of land, soil, climate, &c., and I shall be surprised if this district is not better known before long. The climate is perfection.

THE RAINFALL AVERAGES ABOUT 133 INCHES. This may be considered heavy for coffee, but it is not so in this district, where the soil is very porous with deep loam. There is not the slightest indication of wash. The dry months are December to April—just what coffee requires. Even at present low prices, coffee at four years old is leaving a fair margin of profit. The crop now setting is very fine indeed and stripping will again be necessary to save the trees from over-bearing. Coolies are plentiful and the average of

THE CHECK-ROLL IS ABOUT 28 CENTS, AGAINST OUR 34.

I made a point of seeing cooly rice and

thought very highly of the samples shown me. It was native milled, clean and wholesome food. On my return journey I covered 54 miles across the plains from the Annamalais to Podanur, riding, walking and "tonga-ing" which is my record for the tropics.

While at the Annamalais Mr Edwards stayed at Parlei estate, of which Mr Marsh is manager, with two European assistants, Messrs. Congreve and Vincent. About 19,000 acres of land are opened up and about 3,000 acres are planted with Coffee, Cardamoms, Cinchona and Tea, while some Rubber is being tried. The cardamom crop, Mr Edwards thought, phenomenally good. On one estate, Valpari, there were 900 acres of cardamoms and 300 of coffee.

TEA IS STILL IN ITS INITIAL STAGES.

Monaco estate, with 200 acres and a finely equipped factory, and Lord Stanmore estate with 125 acres under cultivation, being the ones growing it. Regarding labour, Mr Edwards noticed a general air of prosperity in the cool districts which he certainly thinks

NOT CONDUCIVE TO IMMIGRATION

at present, especially as Government is now carrying on extensive irrigation works. Large and extensive tracts of land and fields are being irrigated, and the people are industriously cultivating paddy in the fields, and tobacco and chillies on dry land.

Mr Edwards, although for about 30 years resident in the East, had never previously visited India and is loud in his praises of his visit which he thoroughly enjoyed. Mr Edwards leaves for home by the "China" in a fortnight's time.

TEA CULTIVATION IN THE ANDAMANS.

The areas under cultivation aggregated 518½ acres. Navy Bay 301½ acres, Goplakabang 187 acres, and Kalatang 30 acres. No extensions were made nor abandoned plots resumed. The Navy Bay and Kalatang Gardens were hoed four times and the Goplakabang Garden thrice. The Navy Bay Garden was also forked three times; this means of cultivation could not, for want of labour, be carried out at the other gardens. All three estates were manured, where necessary, with castor cake and cowdung; 900 lb. of the former were used on the Navy Bay Garden, 600 lb. on the Goplakabang, and 500 lb. on the Kalatang Gardens, respectively. The pruning was satisfactorily performed. At Navy Bay 45 acres were low pruned and 44½ acres of the previous year's low pruning had 6 inches of good wood left on them. At Goplakabang 3½ lb. of the acreage were cut three fingers over 1st year's pruning, and the bushes of the remainder cut back two prunings. At Kalatang a little more than half the garden was cut back 2 feet 4 inches below the pruning of 1894; the remainder of the garden, as also the abandoned extensions, were cut three fingers above last year's cutting. Nine thousand two hundred and forty-four seedlings were planted to supply vacancies in the Navy Bay Garden. The seedlings were carefully weeded, manured and forked and protected from the heat. They appeared healthy and strong at the close of the year.

NURSERIES.—Four maunds of Manipuri tea seed from the Mokum Tea Estate were planted out.

The seedlings raised from this seed will be used in filling vacancies during the ensuing rains. The two old nurseries at Goplakabang and Kalatang were not plucked from May. The plants were pruned to allow growth of good pruning wood this year. This was achieved and 6 inches over the previous year's cutting were taken off. The plants will be forked and cleaned. No watering was needed as rain fell in February. No seedlings were raised, nor could vacancies in the Goplakabang and Kalatang Gardens be supplied for want of labour, on which account also no drainage work could be undertaken.

DISEASE.—The thread blight at Goplakabang was as destructive as ever, but the bushes in the Kalatang Garden were not as badly attacked as those at Goplakabang, nor was the attack so severe as in the previous year. The bushes were frequently examined, and the parasite, where found, cut away.

OUTPUT.—The tea manufactured amounted to 169,287 lb. against 166,064 lb. in 1900-01. This shows an increase of 3,223 lb. over last year. Of this quantity the Navy Bay Garden contributed 83,500 lb., the Goplakabang Garden 46,439 lb. and the Kalatang Garden 37,348 lb. The only decrease was in the Goplakabang Garden, due, it is said, to want of cultivation owing to paucity of labour.

INCOME AND EXPENDITURE.—The cost of the manufacture of tea per pound was Rs. 05 9 7/11 against Rs. 05 2 6/3 last year, shewing an increase of Rs. 00 7 3/11. The increase is due to Rs. 6 2/3, cost of new machinery, being included in the cost of manufacture. The income of the gardens was Rs. 50,320 and the expenditure Rs. 61,465 against Rs. 42,544 and Rs. 54,167, respectively, last year. There has, therefore, been a loss of Rs. 11,145 this year against a loss of Rs. 11,623 last year. There would have been no loss but a profit had (1) 37,515 lb. tea (value Rs. 11,528) not been retained for shipment early in April 1902, towards the supply of Commissariat Department contracts for Madras and Burma, and (2) 18,180 lb of broken tea in Burma been sold before the close of the year and the value credited in the accounts. The stock in hand at the close of the year was 33,895 lb.—at close of last year was 6,506 lb.

SALES.—The contracts entered into with the Madras and Burma Supply and Transport Departments were for the supply of 106,864 lb and 31,136 lb of tea respectively, or a total of 143,000 lb. Of this quantity the Navy Bay Garden contributed 71,236 lb, the Goplakabang Garden 36,250 lb, and the Kalatang Garden 37,514 lb. The contract rate during the year was Re. 05 0 against Rs. 06 0 per lb in the preceding year. Contracts for the supply of tea to these Departments have again been secured for the ensuing year to the extent of 107,250 lb for Madras and 51,050 for Burma but at a further reduced rate. Two thousand eight hundred pounds of tea were supplied to the local Commissariat Department at Re. 08 0 per lb and 2,630 lb will again be needed by this Department next year. Sales to local residents took place from the three gardens. Twenty-eight thousand four hundred and thirty-five lb. of broken tea in bulk of 55 and 60 lb. chests were shipped during the year to Rangoon for sale. Of this quantity account sales were received for 10,955 lb. before close of year: the gross price realised was Re. 04 0 per lb.

MACHINERY.—The two factories of Navy Bay and Goplakabang which manufacture all the tea turned

out contain the following machinery. Two 10 H P horizontal engines, two 12 H P locomotive boilers, three Jackson's rapid tea rollers, two 20 tray up-draft and two large down-draft Davidson's Sirocco dryers, two Davidson's small tea sorters, two Jonas' Taxidianometers, two Reid's tea cutters, two Davidson's Sirocco suction fans and one Potters 48' Disc fan. Of the above machinery one of the rapid tea rollers was recovered in July and one of the Sirocco dryers in September from the Secretary of State for India. All the machines were in good working order at the close of the year.

PROSPECTS.—Mr King estimates the next output of tea at a lakh, sixty-five thousand five hundred pounds, *viz.*, 85,500 lb. from the Navy Bay Garder, 45,000 lb. from the Goplakabang Garden, and 35,000 lb. from the Kalatang extension.—*Indian Planting and Gardening*, April 18.

PARS FOR PLANTERS.

(By One of Them.)

1.—IN THE GARDEN.

Don't do your heavy pruning with a hoe:—it is bad for the hoe.

Don't cut yourself with your knife when pruning:—the sharp points on the bushes are there for the purpose.

Don't sit on a newly-pruned bush:—you will have to walk your pony home.

Don't pluck leaf with a sickle:—you might cut yourself.

Don't rest your foot on the scale when weighing in:—especially if you wear "Small Policeman's."

Don't swear when the hail starts cutting off a fine second flush:—it will go on cutting just the same.

Don't run your drains uphill:—if absolutely necessary, a steam pump is cheaper.

Don't report to your Agents that the bushes are covered with webs spun by redspiders:—they may reply by return of post.

Don't arrange your garden and make a programme for the Agent's travelling Superintendent:—he will certainly take the other road.

Don't bluster when your coolies go out on strike:—it does not haste matters; take the opportunity for a big shikar.

Don't wipe the floor with the biggest Sirdar on the garden in the presence of his coolies:—they may return the compliment.

Don't, when newly out from home, call things by their vernacular names in the *Burra Mem-Sahib's* bungalow if you have learnt the words on the *Mela*:—better verify the information.

Don't keep your Assistant out the whole day on one work, with just bare time for meals, for weeks on end:—he lasts longer with a rest and change occasionally.

Don't instruct your Manager on planting matters:—he has probably been as many years in Tea as you have months.—*Indian Planters Gazette*, April 18.

MICA DEPOSITS IN INDIA.

Mr. T H Holland contributes an interesting and important article on "The Mica Deposits of India" to the *Memoirs of the Geological Survey*. He discusses the mineralogical and chemical characters, the geological occurrence and distribution, the uses of mica, and the mining practice. Crystals or 'books' of muscovite-mica have been obtained in Nellore District, measuring 10 feet across the basal planes, but usually they are much smaller. This mica occurs in granite-pegmatite, and being the most delicate mineral in the rock, it is the first to show

the effects of crushing earth-movements, so that large quantities of valuable mineral have been destroyed; but the author observes it is on account of the remarkable stability of the Indian Peninsula, the geologically long and perfect quiescence it has enjoyed, that India is able to boast of the nest mica deposits in the world.—*Pioneer*, April 18.

THE FUTURE OF INDIAN GREEN TEA.

In Indian tea-growing circles a good deal of attention is being paid to green tea, and the way in which the manufacture is being taken up, despite the rise in the price of black common qualities, shows that our leaders are taking a sound view of the future prospects of tea generally. Permanently inflated prices for common teas are not—on the face of things—likely to be brought about nor are they even greatly desirable unless they can be secured without prejudicing the sales of the better qualities, a result which has never hitherto been attained. Even now the price of well-made green tea from common producing gardens compares favorably with blacks, and when the inevitable reaction comes and 'teas for price' come back to more normal levels of value, green teas will show up even better than they do now. In the circumstances our Indian business men are wise in not relaxing their efforts to put a really first-class article in green tea upon the markets of the world, and so far, it must be admitted, great success has attended their efforts. Of course, there are better things to come and we understand that arrangements are well forward for

A CENTRAL FACTORY OR HONG AT CALCUTTA where the most approved and recent systems of pan-firing green teas for finish will be carried out under the management of an expert. Teas finished in this manner in Calcutta have already been accorded a high place in the estimation of American and London tea men, and Messrs. George White & Co, in their Annual Report to hand, make special mention of the Calcutta process. Pan-firing needs very special knowledge and application owing to the delicate gradations obtainable by the modifications possible in the process, but whereas the trouble is greater than that necessary for merely polishing green teas cold, the extra trouble is amply repaid by the superior results to be obtained. It is highly desirable that measures should be taken for ensuring some sort of uniformity in the green teas India is now in a position to put forth in fair quantities. In this connection we may quote a valued London correspondent whose intimate acquaintance with the tea world entitles him to speak to the point. "A desideratum," he says in writing to us, under date 27th March, "is a

UNIFORM NOMENCLATURE FOR OUR GREEN TEA.

We have now 'coloured and uncoloured with the several variants of 'finished and unfinished,' 'true green' and 'faced' tea, all more or less inexact and confusing. It is a matter' continues our correspondent, 'that could be settled by your Calcutta Association in conference with the heads of the trade in New York and Canada. An official pronouncement on the subject of green tea is what is wanted.' Now, of course, we know that the confusion has been largely introduced from Ceylon, where green tea was an unfamiliar article when the manufacture was taken up, and perpetuated by those districts in India where the manufacture had been forgotten by long disuse, so that the article became new to them. In our North-Western districts there has never been any confusion, except on the point whether green tea could be made by methods hitherto unknown to those parts. Still, as our correspondent remarks, it is unfortunate that so many misconceptions and misdescriptions should have arisen. With regard to the China type teas made in the North-West no confusion is possible. All China type teas are pan-fired and so possess the distinctive colour in the dry leaf. To men accustomed to this process the uncoloured

TEAS ORIGINALLY PUT FORWARD IN CEYLON AND BENGAL DID NOT APPEAR AS GREEN

TEAS AT ALL

and a great deal of talk was wasted in endeavouring to stamp them as 'Oolong' and 'Namouna'—quite different articles. But with Japan teas the case is different and both coloured and uncoloured green teas are produced in that country; the technical description being 'basket-fired' and 'pan-fired.' Basket-firing answers to our hot air drying on mesh trays and produces a tea olive or brown-black in the dry leaf. Pan-firing describes itself and produces the green grey colour which the Japanese heighten with artificial colouring matter to the prejudice of the tea. Here then we have the necessary nomenclature if we require to describe our teas; 'basket fired' and 'pan fired' will describe our teas as well as the Japanese article, that is for all these grades that are intended to reproduce Japan. For China type hyson, gunpowders, etc., no such description appears necessary for the trade.

THE TERM "FACING"

or "faced," we are informed by a reliable New York authority, does not apply to the teas but to the packages, which in the case of Japan and China are generally "faced" with paper. The Calcutta Hong or factory now to be established will probably be able to put these matters on a good footing, and as a leading Calcutta firm are interesting themselves in the establishment, it is probable that Indian green tea will be organised on recognized lines before long.—*Indian Planting and Gardening*, April 18.

DR. WEBER ON RUBBERS.

In the literature bearing upon india-rubber we very frequently find the statement that even the most carefully prepared and purified rubber on exposure to the light and atmosphere soon loses its white colour, and turns dark brown owing to oxidation. I am in a position to declare this statement entirely erroneous. I possess samples of *Castilloa* rubber prepared by myself on the large scale, and which for over eight months have been exposed to air and light, without the slightest change in their colour having taken place. The fact that these samples are entirely free from every trace of albumen goes a long way to prove that the well-known discoloration of india-rubber is really due to the albumen it contains.

Even washed and dried rubber may be very far from being a pure product. Cases are by no means exceptional of even the better qualities of African rubbers in the washed and dried state containing not more than 85 per cent or even less of actual pure rubber. This is a point which certainly fully deserves the attention of the rubber manufacturer. By way of an example, I quote the analysis of a washed sample of black Kassai, which, on receipt at the factory, was not considered altogether satisfactory, but was, in spite of this, taken into work, with the result that no end of trouble arose about the goods manufactured from it. These were the results of the analysis (of the washed and dried rubber be it noted):—

Resins	5.3 per cent.
Albumen	7.4 do
Oxygen	5.3 do
Ash	2.3 do
			20.3 per cent.

From these figures it will be seen that this washed and dried rubber which the manufacturer assumed "to be practically pure" rubber, contained not more than 80 per cent as actual rubber, the rest consisting of rather considerable percentages of impurities.—*India Rubber Journal*, March 30.

TEA PLANTING IN THE KANGRA VALLEY.

The class of Tea Planters who seem to fare best in the Kangra Valley are, from what I hear from the Kangra *chowdri* here, the native planters, who, as a rule, have only small gardens, but are grain growers as well, they make nothing but green tea. The price of tea estates has, I fancy, come down with the fall in tea, writes the Kulu correspondent of the *C. and M. Gazette*. I know one of the oldest plantations, the owner of which told me that he had paid £4,500 sterling for it, in 1863. At his death in 1879, though it had been greatly improved, as well as enlarged in the outturn, it only fetched Rs25,000 less than one half, even at the then rate of exchange. The most remarkable price for tea that ever I heard of, was the yield of a garden down Assam way, owned by a company of Bengali babus, their entire season's crop sold in the open market at *nine pias* per lb. It must have made a curious brew! Cinchona planting was also tried to some extent in the Kangra Valley but the experiment seems to have been soon abandoned, the winter climate being found unsuitable to the trees, if I remember rightly.—*Indian Daily News*, April 20.

THE GENTILE ISLE OF PALMS.

brings a stronger sun, a more generous warmth Two or three days out from Liverpool winter resolves into the sweetness of spring. The grey seas change to brilliant blue It is a gentle, lovely welcoming into the choicest pleasure that Nature can offer in all the range of all the seasons. The traveller is made free of the delights of summer without the long weary waiting for those seasons in the land that has bred the men who have done and are doing the work of the world, Assuredly Las Palmas in Grand Canary that gentle Isle of Palms, not a place for the workers of the world, except as a resting place from the struggle—a temporary refuge from the turbulence of modern existence. Long living here would turn the Briton to kinship with the laughing, laudorous, pleasure-loving children of the sun. A month will send him back to his northern home, a giant refreshed with the best of Nature's wine, Las Palmas is perfect. It is far enough south for the northerner to catch his first glimpse of the Southern Cross. It is far enough north for the men who march on the outposts of Empire along the African coast to come here for recuperation. At this time of the year it is a favourite rendezvous of the English. The Elder-Dempster tourist tickets give a first-class return, with a fortnight's board at the Hotel Métropole for £15. Las Palmas is becoming more and more every year a resort which can compare in popularity with Nice, Mentone, or any pampered city of the Riviera. Grand Canary is 900 miles nearer the equator than any place in the south of France,

TROPICAL SURF.

The surf thunders on its shores as it does in all tropical climes. The microbe is unknown; ozone of the sea is fatal to the bacillus with murderous intent. Mosquitoes are not numerous, and they are of a harmless kind. Moreover they are only out by night, and every bed is furnished with nets through which the inquisitive insects cannot pass to their human prey. The person who occasionally happens to lie awake for a few moments in this somniferous air at night may hear their sharp ping-pong cry and know that they are assailing his net in vain. In spite of its s...

tropical position, Grand Canary is not unpleasantly hot. The climate is dry, bracing and warm. There is no cold in winter, and no extreme heat in summer. The average winter temperature is 63deg. or 10deg. higher than at Mentone. Just now it is 65 in the daytime and 55 at night. Rain falls mostly during the night—the best time for all concerned. There are no sunset chills, no heavy dew in the evening, no frosts and no hot winds such as those which sweep across Morocco and Algeria. I do not think it is possible to convey a better impression of the climate than to say that people are bathing every day from the hotel, and that they do this all the year round. This is always done in the clear sunshine and under cloudless skies. The palm from which the town takes its name are scattered everywhere within the zone of the sea level. Date palms grow and produce their fruit amid the white houses that climb the slowly-rising hill on the sides of which Las Palmas is built.

AVENUES OF EUCALYPTUS.

Avenues of eucalyptus trees line the dusty roads that wind in and out in endless circles from the town to the highlands of the interior. The pepper tree mixes with them in a catholic spirit. Sharp, fierce aloes lurks everywhere, keen reminders that we are on the threshold of the tropics. Tropical vegetation is strangely cruel and ferocious. Orange groves nestle in protected valleys, sugar canes grow on sunny uplands, vineyards cover the long slopes of the hills. Maize fields are cultivated by the peasants, the corn being threshed in the open on earthen threshing floors by patient oxen. The banana, however, is the plant most in evidence. The whole island moves on a banana pivot. The moment we land from the liner out in the roadstead the banana confronts us. Long, raking carts, loaded to a perilous height with cases of the fruit, are grouped on the quays. The mules which draw them are feeding as they stand. Some, loose, are waiting for the least justification to kick at something. All along the road these mules and these carts, moving in slow, tranquil procession, are met. They descend laden in the morning from the interior. They unload on the quay during the day. At evening they climb the hills, slowly sauntering homewards in the same impervious way. Life is very quiet in the Isle of Palms. For exercise there are golf, lawn tennis, and cricket. For diversion there are fishing and excursions innumerable. Mountain climbing on muleback is followed by the adventurous. The lovely wild scenery and the vagaries of the mule afford all that a reasonable biped can conscientiously demand. Mules are hired for half a crown a day. Donkeys which will carry any weight up to 16 stone cost the same.

CARRIAGE EXCURSION.

The usual manner of making an excursion is by carriage. We feel two genially happy to walk much. The cabby always asks three times what he wants in the expectation of being bid down one-third, and so getting twice his legal fare. Three horses running abreast make the usual team. They will cover thirty or forty miles a day without discomfort, and then cheerfully take their stand on the ranks outside the hotels to wait for chance customers. The cabman is very independent, and pulls up regularly at houses of call to quench his thirst. We wait his convenience, and then resume our journey. On Sundays the correct evening occupation is to join the church parade in the

Alameda de Coton, the fashionable square or plaza. Here all the beauty and the chivalry of Las Palmas congregate after vespers. This church parade under the stars is a typical Spanish custom and remains whatever Spaniards have mingled their blood and their traditions as a result of conquest or colonisation. The native (not the aboriginal) element is seen to advantage at such a time. Half a score of cafes do a flourishing trade. Tartanas a sort of inverted Irish car, are hired by the hundred. Cavaliers ride in on horses or mules. Visitors from alien climes throng to the Alameda in light evening dress. The girls of Las Palmas come in mantillas which become them wondrously well, and which, unhappily they are disposed to abandon for European headgear. Above all there is the band. It is a typical scene in a land of pleasure. On other evenings we sit out on the verandah as in England—we might on a warm July evening. Twinkling lights in the bay show where the great liners have anchored for a brief pause on their way home from the African coast, the Cape, or still more distant shores.—*Home paper*.

NEW ZEALAND APPOINTMENT FOR DR MORRIS'S ASSISTANT AT DOMINICA.

The appointment of Superintendent of the Botanic Gardens and City Reserves at Dunedin, New Zealand, has been accepted by Mr. David Tannock, Officer in Charge of the Agricultural School in Dominica, West Indies, which is under the Imperial Department of Agriculture administered by Dr. Morris, C.M.G. Mr. Tannock will leave the West Indies for England next month, prior to taking up his new appointment.—*Morning Post*, March 20.

HUNAN AND THE CAMPHOR TRADE.

Since the loss of Formosa, the camphor trade has been lost to China. The Chinese endeavoured to make good this loss by trying to grow the tree in China itself. News has now come that the trial has proved to be successful in the province of Hunan. There are now countless camphor trees several feet in diameter in the province, and it is expected that with care it will be possible for Hunan soon to be able to export annually several thousand piculs of the drug. The market is at present dependent chiefly upon the supply from Formosa and Sumatra, and in consequence the price keeps high.—*Bangkok Times*, April 8.

MORE ABOUT THE EUCALYPTUS.

Mr. Benjamin Judkins of San Diego, in speaking of the descriptive "write up" of the eucalyptus tree which appeared in the February issue of THE RURAL CALIFORNIAN, among other things, says: "Few people in California know the real value of the three species of that tree, viz: The blue gum, red gum and white. There are over one hundred and thirty-four varieties. The sugar gum is the favorite which the Australian governments plant along their highways and round some of their buildings. It grows a straight grain stem if well cared for, and will stand most dry weather. These three varieties are said to contain the best medicinal properties for health of all the others. If there is one thing more valuable than another in

these trees, it is the eucalyptus extract which will be found in future to have more uses than is now known. In Melbourne the extract commands twenty-five cents per quart, and is used for various purposes. The wood while burning in the stove has a wonderful effect on health. The leaves when young and soft are often picked, and mattresses and pillows made of them, even when green, and in this way lives have been prolonged."—*Rural Californian* for March.

A COLLECTION OF MOSQUITOES.

Mr. E. H. Aitken, at the monthly meeting of the Bombay Natural History Society on Thursday, the 16th instant, said that it was proposed to make as complete a collection as possible of the mosquitoes of India, and the Committee hoped that memos would help by sending them specimens of the kinds which paid them attention. The importance of a knowledge of the different species of mosquitoes could scarcely be exaggerated in the light of recent discoveries; but of the many medical men in India whom it concerned to know them, few had the opportunity or time to make large collection, and without a reference collection, identification was very difficult if not impossible. To make and keep such a collection would be altogether in line with the honourable career of usefulness which had distinguished the Society in the past, and there could be no question that it ought to be commenced at once. Mr. Aitken then showed how mosquitoes were killed, pinned and preserved, and said if members were not disposed to take the trouble of performing the operation themselves they might send live mosquitoes to the Secretary in small bottles or glass tubes. A vote of thanks was passed to Mr. Aitken, and the meeting then terminated.—*Times of India*, April 20.

TROUT-FISHING ON DERWENTWATER.

A meeting convened by Mr. Tindall Harris was held at Keswick yesterday afternoon, at which the riparian owners of Derwentwater and other were present. Canon Rawnsley, who was in the chair, explained the object of the meeting, which was to restock Derwentwater with lake trout and to take such steps as were necessary in killing off pike and perch and in watching the spawning beds. He quoted Frank Buckland's *dictum* after his visit in 1878, that this district was the most magnificent fish farm in Her Majesty's dominions, and went on to show that, with a splendid bottom feed, a rise of the green drake, and water undisturbed by boating for three quarters of the year, there was a fair chance of making Derwentwater as good a stretch of trouting water as Lake Vyrnwy or Loch Leven, while the lake was so situated in relation to Lancashire and the North as to be of great concern to the fisherman who had neither time nor money to go as far afield as Scotland or Ireland. An executive committee was elected, and an appeal for funds decided on.—*London Times*, April 1.

THE BAMBOO PARTRIDGE.

(TO THE EDITOR OF THE "INDIAN FIELD.")

Sir,—Is the so dubbed bamboo partridge a distinct species or only a freak of nature? Is it ever seen in the plains? or like the Spur Fowl of the Nilgiris only found in the hills. An acquaintance asserts the bird is not a partridge at all, but a quail.

AVIS.

[These very handsome birds (*Bambusicola Fytchii*) are probably a connecting link between the pheasants and partridges. They form a small group of game birds in the Burmese-Chinese country and occur in the Khasi and Garo Hills, the North Cachar and Naga Hills and in Manipur. They approach the pheasants in the shape of the wing and are rather closely allied to the Spur Fowl.—Ed.]
—*Indian Field*, April 23.

"ORANGE" PEKOE IN CHINA

AND HOW IT IS MADE.

Scarcely less fragrant than the flower fields of France are the tea orchards of China and Japan, that are ready for the first picking of leaves. The leaves have a delightful fragrance, and, too, in Southern China orange trees are often grown in the same plantations, for the tender tip leaves of tea that are to be cured as Orange Pekoe, are cured on screens above trays of orange petals. In drying, the tea actually takes up a perceptible perfume from the orange blossoms. This tea commands a fabulous price in the market, and most of it is kept in China for the court and provincial mandarins. It would seem as if April were specially favoured with fragrant crops. The coffee season has begun on the plantations of Brazil, to continue for several months. There is thyme, sage and mint in France, and pepper in the East Indies.—*Little Chronicle*, March 28.

THE CAMPAIGN AGAINST MALARIA.

A NEW DEPARTURE.

In a communication made by him to the April number of the *Indian Medical Gazette*, in the shape of gleanings from the *Atte della Società per gli Studi della Malaria* (Proceedings of the Society for the Investigation of Malaria), Lieutenant-Colonel Giles, I. M. S. (Retired), gives an interesting account of certain observations which if verified, are not unlikely to lead to a new departure of great importance in the campaign against malarial disease. It is an established fact, says the *Sta smán*, that the physical conditions known to favour the development of malaria, even when combined with the presence of swarms of anophels of the susceptible species, may exist without giving rise to the disease. Hitherto this fact has been attributed to the absence of infected human beings, and in many instances it may be unnecessary to look further for an explanation of it. But it has been ascertained that in a multitude of cases not only does such immunity co-exist with the proximity of active foci of the disease of great virulence, but the introduction of infected persons into the immune areas is unattended by the development of malaria. The inference is thus suggested that the mosquitoes of the immune areas are for some reason insusceptible of infection. No explanation of such an immunity is, however, in many cases to be found in change of local conditions, where the areas in which it occurs had been violently

malarious in comparatively recent times; and it thus becomes evident that some hitherto unknown factor is at work.—*M. Mail*, April 27. [Regarding that unknown factor we may have something to say shortly.—ED. C.O.]

SENSATIONAL ADVANCE IN THE PRICE OF PEARL SHELL.

At the recent London public sales of mother-of-pearl shell from Queensland an advance in price of £1 to £4 per cwt was registered. This article, which is in much request at the present time, has been steadily rising for years, and since January last, an advance of over £100 per ton has taken place in the superior grades. The particular cause of the late heavy rise in market value is the fashion prevailing in the United States for pearl buttons for ladies blouses. It will be *à la mode* in the coming summer for blouses to have three large pearl buttons in front, and to be fastened at the neck and wrists with smaller buttons and links of the same material. So fashion decrees in New York and the brokers, hastening to obey, cabled over to their agents at the London sales "Buy white shell at any price."—*Daily Chronicle*, April 10.

MR. KINGSTON AND THE KANAKA QUESTION.

"YELLOW AGONY" AND "BLACK CURSE."

Brisbane, April 17.—At a luncheon, which was tendered to the Minister for Customs (Mr C C Kingston) in Cairns, yesterday, Mr Draper severely criticised the Federal Government with regard to white labour. Mr Kingston, in replying said that he had never had and never would have any sympathy with the Kanaka. A white man could do all that a Kanaka could do, and if there were an industry that must have the "yellow agony" or "the black curse" to keep it alive—a proposition which he did not admit—then that industry must be swept off the face of Australia which was a white man's land.—*W. Australian*.

PLANTING NOTES.

TROPICAL QUEENSLAND—we have always maintained—should be made into a "Crown Colony" but the majority of the white Colonists will not hear of this and they are now engaged in the bold experiment of acclimatising the European race and excluding Kanakas who are capital labourers for sugar and other plantations and are ready to come over very freely. But neither they, nor Chinese, nor pedlars, nor coolies from India, are to be allowed to gain a footing on this soil. We are not hopeful of the experiment succeeding—in spite of the increase of white sugar farmers and the vehement support of men like Mr. Kingston, the latest of whose violent language on the subject appears elsewhere.

TEA IN AMERICA IN 1902.—Elsewhere we quote the latest information from the *American Grocer*. The same paper gives some interesting figures as to America's total Drink Bill. The cost at retail of all bever-

ages, consumed in 1902 alcoholic and non-alcoholic stimulants was \$1,369,098,276, as follows: Alcoholic drinks \$1,172,565,235; Non-alcoholic stimulants—Coffee \$149,891,030; Tea \$39,612,011; Cocoa \$7,000,000. The quantities of the four leading beverages consumed for the year ending June 30th, 1902, were as follows: Coffee 1,498,910,304 gallons; Beer 1,381,875,437 gallons; Tea 396,420,115; Spirits and wines 157,206,554 gallons.

THE LABOUR COMMISSIONERS' REPORT—is in Ceylon ahead of the Labour Commissioners themselves. Mr. Kingsford sends it to us today, pointing out that the Commissioners recommend that the Planters' Association should station an agent in South India for recruiting and that he should be sent early next month as that is the month in which coolies usually think of emigrating and rival recruiting agents are already at work. We trust therefore that Estates willing to support the agency will respond to Mr. Kingsford's appeal with the utmost despatch. Another departure recommended is that Telugu districts should be tapped first in order to work up their connection with Ceylon; further that a Labour Bureau in Kandy, specially appointed, should collect all important information bearing on labour in the Madras Presidency and publish it at intervals; and thirdly that a strong Sub-Committee should study not only the regulations affecting South Indian Labour emigration but also the conditions involved in rival agencies being at work and in the coolies' innate dislike to exile. Messrs. Hill and Turner have evidently done their work thoroughly and have fully appreciated the necessity for speedy steps being taken.

THE VITALITY OF POLLEN—is a matter of high practical interest to all cultivators who are engaged in the fascinating work of establishing new varieties of useful plants by means of the process of cross-fertilisation. At the recent international conference on plant breeding held in New York, in the course of a discussion upon the subject, it was mentioned that the pollen of the tomato blossom will retain its vitality for fully six months. That this is so receives confirmation from the practice of collecting pollen during the late summer and autumn months from plants grown out of doors for the purpose of fertilising tomatoes grown under glass in the winter. It was also stated that the pollen of the grape retains its vitality for at least two months, and that of the date palm for a year or more. The pollen of the carnation, again, may be kept alive in closely stoppered tubes for several weeks, and thus sent from one part of the country to another. In the preparation of pollen for keeping it is recommended to dry the material thoroughly, and then to put it in well stoppered bottles. In the case of plants grown in moist climates the drying of the pollen should take place in the shade, but for those growing in arid regions the drying may be more quickly effected in the sun. The pollen of certain plants is said to be commonly distributed through the West Indies on dry blotting paper enclosed in pasteboard boxes, and in this way retains the vitality for upwards of three weeks.—*London Times* March 30.

THE STANDARD TEA COMPANY OF CEYLON, LIMITED.

TWELFTH REPORT OF THE DIRECTORS TO THE SHAREHOLDERS

to be submitted at the General Meeting, to be held on Wednesday, 22nd April, 1903, at noon, at the Offices of the Company.

The Directors submit Statement of Accounts to 31st December, 1902. The Profit and Loss Account shows a profit on the working of the Estates in Ceylon of £12,443 13s 8d, which with the amount brought forward from last year, less interest and home charges, shows a sum of £11,634 2s 51 available for division. In August, 1902, the Directors, under the powers entrusted to them, distributed an interim dividend for the six months ending 30th June, 1902, of 5 per cent (10 per cent per annum), absorbing £3,975. They now recommend a Dividend at the rate of 10 per cent. (making 15 per cent. for the year) absorbing £5,950, the placing £500 against reserve and £1,000 against depreciation; and the carrying forward to the next year £1,209 2s 51. The Coffee crop was 61 cwt.; it realised about £70. The Tea crop was 1,183,972 lb, against 1,105,995 lb. in 1901.

The Export Tax, called "Tea Cess," cost the Company R3,000, or £200, calculated on the first half of the crop at 20 cents per 100 lb, and on the latter half at 30 cents, to which it was raised in June. The average Exchange for the Company as drawers in Colombo was 1s 4 3-16th d, against 1s 4 5-32nds d. in 1901, and 1s 4 7-32nds d in 1900. Price for Ceylon Teas were generally about the same as last season. Of the Company's Teas produced during 1902: those from the St. Leonard's factory sold at about 1/3d per lb. lower price than 1901 Teas; those from Gordon, 1/4d per lb higher; those from Gouravilla, at about 1/3d per lb higher. The Uda Pusselawa Railway passing through Eskdale and Liddesdale, the Company received during the year £399 13s 9d for land taken. The amount has been credited in reduction of the cost of the estates. The Company's Properties at the close of 1902 were 3,466 acres, with 2,183 acres of Tea considered in full bearing, viz. :-

in Uda Pusselawa—St Leonards			
Coneygar	902 acres.	530 acres Tea bearing	
Liddesdale	814 "	200 "	"
Eskdale	240 "	227 "	"
Gordon	386 "	304 "	"
Tulloes	419 "	275 "	"
in Up. Maskeliya—Gouravilla			
and Up. Cruden	705 "	652 "	"

There are also 296 acres Tea in partial bearing, and some 25 acres in addition planted with Tea. Mr. William Rollo, the Director who retires by rotation, being eligible, offers himself for re-election. By Order,

A. TRAFFORD BROOKE, Secretary.

25, Fenchurch Street, London, 8 April, 1903.

BANDARAPOLA CEYLON COMPANY, LIMITED.

Report of the Board of Directors to be presented to the Shareholders at their Tenth Annual Ordinary Meeting, to be held at the Office of the Company, 16, Philpot Lane, London, E.C., on Tuesday, 28th April, 1903, at 12 o'clock, noon.

The Directors have pleasure in submitting to the Shareholders the Balance Sheet, Estate Working Account, and Profit and Loss Account for the year to 31st December, 1902, duly certified by the Auditor. After providing for Interest on Debentures and all other charges, there remains a net profit of £2,046 12s 11d, to which has to be added £345 6s 11d brought forward from last accounts, giving a total of £2,391 19s 10d, and this the Directors propose to deal with in the following manner:—To pay a Dividend for the year of 6 per cent (free of Income Tax) £1,260, to write off estate account £500, to

write off building and machinery account—10 per cent on £1,739—£173 18s. to carry forward to next accounts £153 1s 10d.—Total £2,391 19s 10d.

The crops secured for the year amounted to 509,185 lb. Tea (including 19,161 lb. from purchased leaf), and 372 cwt 2 qrs 24 lb. cocoa, against 468,901 lb Tea, 303 cwt 0 qrs 15 lb cocoa, during the previous season; the average yield of Tea per acre being 626 lb, as compared with 575 lb in 1901. The average prices realised for the Company's Tea show a slight falling off as compared with the previous year, being 6d per lb in London, and about 2 3/4 cents in Colombo, against 6 1/4 and 3 3/4 cents respectively; but an increased income has been derived from Cocoa, of which the crop exceeded the Manager's estimate by over 72 cwt. The rate of exchange for the year averaged 1/4 19-64ths per rupee. At the request of the Board, the Manager has recently gone very carefully through all the Company's Title Deeds, &c., and he reports that the Company's holdings now amount to a total of 1,760 acres, of which 1,654 are Freehold, and 106 Leasehold. The following statement gives particulars of the acreage as fully and accurately as possible:—Tea in full bearing 782 acres, tea in partial bearing 6 acres, cocoa in bearing 224 acres, cultivated area 1,012 acres, grass, ravines, &c. 12 acres, reserve, jungle, &c. 736 acres.—Total Acreage 1,760 acres.

The Reports from the Visiting Agent, Mr. Joseph Fraser, continue to be of a very satisfactory character. In his last Report he writes as follows:—"The Tea in all three divisions looks vigorous and healthy. There is a remarkable absence of insect and fungoid pests; in fact, I may safely say I have never seen the Tea, on this estate, all over, looking better or more promising than it does at present." The Board consider this reflects great credit on Mr. Anderson's management of the property. Of the Debenture issue, £2,500 matured for payment on 1st January, 1903, and this amount was renewed for three years at the former rate of interest—five per cent per annum. In accordance with the Articles of Association Mr. George G. Anderson retires from the Board at this time, and, being eligible, offers himself for re-election. Mr. John Dalgleish, C.A., also offers himself for re-election as Auditor. G. W. PAINE, Chairman. 16, Philpot Lane, London, E.C., 8th April.

HIGHLAND TEA CO., OF CEYLON, LTD.

REPORT OF THE BOARD OF DIRECTORS, to be presented to the Shareholders at their Seventh Annual Ordinary Meeting, to be held at the Office of the Company, 16, Philpot Lane, London, E.C., on Monday, 27th April, 1903, at 2-30 p.m.

The Directors have pleasure in submitting to the Shareholders the Balance-sheet, Estates Working Account, and Profit and Loss Account for the year to 31st December, 1902, duly certified by the Auditors. The net profit for the year amounts to £1,893 5s 4d, to which has to be added £74 13s 9d brought forward from last accounts, giving a total of £1,972 15s 1d, and this the Directors propose to deal with as follows:—An Interim Dividend paid on 30th September, 1902, at 2 per cent (free of Income Tax), amounted to £640, it is now proposed to pay a Final Dividend of 3 per cent (free of Income Tax) making 5 per cent for the year £960; to write off Estates Account £250, and to carry forward to next Accounts £122 15s 1d—Total £1,972 15s 1d.

The above profits show an increase of £398 17s 10d over the figures for 1901, and, but for the unfavourable weather experienced in Ceylon during the closing months of the year, the expansion would probably have been considerably more. The crops secured from the Company's properties amounted to 241,913 lb, or 413 lb per acre of Tea in bearing, against 211,481 lb for the previous season, and the prices realised averaged 7 1/4d per lb for the Tea sold in London and 42 cents per lb for the sales in Colombo against 7 1/4d per lb and 45 cents per lb respectively for the 1901 crop. The reports from both Chrysler's Farm and

Glenorchy Estates continue to be of a satisfactory nature, and the prospects for the current season are encouraging. In accordance with the Articles of Association, Mr. R. C. Bowie retires from the Board at this time, and, being eligible, offers himself for re-election. Messrs. Cape & Dalgleish, C.A., also offer themselves for re-election as Auditors. By order of the Board, LYALL ANDERSON & Co., Agents and Secretaries, 16, Philpot Lane, London, E.C., 7th April, 1903.

EDERAPOLLA TEA CO., OF CEYLON, LTD.

REPORT OF THE BOARD OF DIRECTORS—to be presented to the Shareholders at their Seventh Ordinary General Meeting, to be held at the Office of the Co., 16, Philpot Lane, London, E.C., on Tuesday, the 21st April, 1903 at 11.30 a.m.

The Directors beg to submit to the Shareholders the Report and Accounts of the Company, duly audited, for the year ending 31st December, 1902.

The total outturn of Tea from the three Factories, inclusive of 17,040 lb made from bought leaf, amounted to 533,049 lb, shewing an increase, compared with last season, of 24,991 lb a result which must be deemed satisfactory considering the very unfavourable weather experienced during the last four months of the year.

The average price realised for the whole crop was 5'873d. against 6'186d per lb secured for the previous year, and the average rate of Exchange was 1/4 23/64ths, against 1/4 3/8ths for 1901.

The net profit on the year's working amounts to £1,356 14s, which, with £183 4s 8d brought forward from last accounts, gives £1,539 18s 8d to be now dealt with, and this it is proposed to apportion as follows:—Amount as above £1,539 18s 8d; To Dividend of 5 per cent (free of Income Tax) £1,275—To carry forward to next account £264 18s 8d.

Your Directors have had under consideration for some past time the desirability of manufacturing Green Tea and have now decided, on the recommendation of their Ceylon advisers, to make it at St. Helen's Factory and to continue the ordinary Black Tea manufacture, at Ederapolla and Ardross. During the absence of Mr Arthur Watt on furlough from May last until February of this year, Mr H E Watt acted as General Manager in Ceylon, and the Board desire to place on record their high appreciation of the manner in which he conducted the management of the Estates.

The Debentures amounting to £3,500 which matured on 1st January, 1903, have been renewed at 5 per cent interest per annum, as follows:—£450 for 3 years; £3,050 for 5 years. In accordance with the Articles of Association, Mr R Porter retires from the Board at this time, and, being eligible, offers himself for re-election. Messrs Cape and Dalgleish, C.A., also offer themselves for re-election as Auditors.

G. W. PAINE, Chairman.

15, Philpot Lane, London, E.C., 7th April.

RAGALLA TEA ESTATES, LIMITED,

Report of the Directors to be submitted to the Shareholders at the Eighth Annual Ordinary General Meeting to be held at 30, Mincing Lane, E.C., on Monday, 20th April, 1903, at 12 o'clock noon.

The Directors beg to submit their Report, and also Statement of Accounts duly audited, for the period of 12 months ending 31st December last—Showing a net profit for that period, after making liberal provision for depreciation of £3,804 12s 11d and the balance of last account £126 7s 8d.—Total £3,931 0s 7d.

Out of which the following dividends have been paid:—1902, 1st July—Preference Shares £1,050; 1903, 1st January Preference Shares £1,050—£2,100.—Total £1,831 0s 7d.

From which the Directors recommend a dividend of 4½ per cent, free of Income Tax, on the ordinary shares £1,755 leaving a balance to carry forward of £79 0s 7d.

The tea crop for the season amounted to 713,045 lb showing a shortage of 31,955 lb on the estimate, and the net average price obtained was 6'90d per lb, against 6'97d per lb realised last season. The average rate of exchange was 1s 4'20d per rupee. The Directors have written off for depreciation a sum of £1,300 which covers the whole of the capital expenditure of the year amounting to £994 0s 8d.

The crop for the present season is estimated at 793,000 lb. It is fully expected that the Government Railway extension to the Company's Ragalla property mentioned in the last report will be completed before the end of the present year. The Company has received from Government for the sale of land acquired for the extension the sum of £340 12s 6d, which, with the approval of the Trustees for the debenture holders, is being used for adding to and improving the bazaar buildings on the property.

The following are the acreages of the Company's estates:—

Name	Tea.	Coffee & Cinchona	Timber	Patna &c.	Total
Ragalla and Halgrán Oya	913	15	174	288	1390
Kelburne	709	9	208	64	981
	1613	24	382	352	2371

It is with very great regret the Directors record the death of their colleague, the late Mr M P Evans. His place on the Board has been filled by the appointment of Mr William Dunn.

Under Clause 97 of the Articles of Association Mr Hannen retires from the Board, and being eligible offers himself for re-election.

The appointment of Auditors rests with the Shareholders, and Messrs. Fuller, Wise and Fisher offer themselves for re-election.

C E STRACHAN & C HANNEN, Directors; P E HARVEY, Secretary.

London, 9th April, 1903.

THE EASTERN PRODUCE & ESTATES COMPANY, LIMITED.

REPORT.—To be presented at the Sixteenth Ordinary general meeting, to be held at Winchester House, Old Broad Street, at 12 o'clock noon, on the 22nd April 1903.

The Directors submit Report and Balance Sheet for the year ending 31st December, 1902.

The profit for the year is £19,540 15s 8d, which, added to £7,221 12s 11d, balance from last account, amounts to £26,762 8s 7d.

From this has to be deducted:—Interest on Debentures £3,262 10s; Debentures for £7,500 drawn and paid off, with bonus of 5 per cent. on 31st December 1902, £7,875; Interim and Final Dividends of 2½ per cent. on the Preference share capital £56 9s 6d. Interim Dividend of 1½ per cent. on the Ordinary Share Capital paid 4th November, 1902 £3,728 2s 6d Total £14,922 2s 0d leaving a balance of £11,840 6s 7d., which it is proposed to apportion as follows:—Final Dividend on the Ordinary Shares of 1½ per cent., making 3 per cent. for the year £5,219 7s 6d. Balance to be carried forward as provision for retirement of Debentures in the current year £6,620 19s 1d. Total £11,840 6s 7d.

The Debenture debt has been reduced by the usual annual payment of £7,500 out of profits, and now stands at £65,000.

In furtherance of the policy recommended and approved at the Extraordinary General Meeting of the Company held in April last with regard to the conversion of the balance of the Debenture issue into Capital of a permanent form the Directors have, as a first step, called up the £4 per Share unpaid Capital on the 753 issued Preference Shares of the Company; and as a more convenient arrangement the final

dividend on these Shares for 1902 was paid on 31st December last; future dividends on the Preference Shares being payable half-yearly on 30th June and 31st December. The Directors also decided to offer to the Debenture-holders, whose Bonds were drawn for payment on 31st December, 1902, the opportunity of re-investing the amounts in Preference Shares of the Company, which resulted in the placing of 359 fully-paid £5 Shares issued at par as from 1st January, 1903. The Preference Share Capital of the Company now issued is therefore represented by 1,112 fully paid Shares, of which 753 only appear in the Balance Sheet, the remainder having been issued subsequently to 31st December, 1902.

As shown in the schedule below, the Company, on 31st December last, had 11,007 acres under Tea cultivation, of which 10,857 were over four years old. The yield of Tea in 1902 was 4,004,319 lb, the average gross sale price being 6'39d as compared with 6'61d in 1901, the recent improvement in market value not having been sufficient to compensate for the very low prices which ruled previously. The average rate of exchange was 1s 4 5-16d as compared with 1s 4 11-32d in 1901. Looking to the future, it is satisfactory to observe from the statistical position of British grown Tea, that there is substantial reason for anticipating a more remunerative condition of affairs than has prevailed during the last three years. In accordance with the Articles of Association, two of the Directors, Mr C B Smith and Mr Edward Wahab, retire from office, and, being eligible, offer themselves for re-election. The retiring Auditors, Messrs. Walton, Jones & Co., offer themselves for re-election. RALPH A. CAMERON, Chairman and Managing Director. 41, Eastcheap, E.C., 6th April, 1903.

SCHEDULE OF THE COMPANY'S ESTATES AT 31ST DECEMBER, 1902.

Arapolakande, Asgeria & Bulatwatte, Colonna, Congedalla, Doombagastalawa, Dromoland, Hope, Ingurugalla & Berrewella, Kirrimittia, Kumaradola, Kumbukkan, Labookellie, Meddecoombara, Norwood Rothschild, Sogama, Vellai Oya & Dandukelawa, Weyekellie.	
Under Tea	11,007 acres.
Do Cocoa	593 do.
Do Cardamoms, Rubber & Sundries	363 do.
Do Forest, Grass & uncultivated Land	4,628 do.
Total	16,591 acres.

POONAGALLA VALLEY CEYLON COMPANY, LIMITED.

REPORT OF THE BOARD OF DIRECTORS to be presented to the Shareholders at their Seventh Annual Ordinary Meeting, to be held at the Office of the Company, 16, Philpot Lane, London, E.C., on Tuesday, the 28th April, 1903, at 2'30 p.m. The Directors have pleasure in submitting to the Shareholders the Balance Sheet, Estates Working Account, and Profit and Loss Account, for the year to 31st December, 1902, duly certified by the Auditors. The Net Profit for the year, after payment of Debenture Interest and all other charges, amounts to £1,650 4s 5d, and, after deducting therefrom the debit balance shewn in last Balance Sheet, there remains £632 7s 2d, which the Directors propose to carry forward to next accounts. The following figures furnish a comparison between the season now closed and the previous year:—

	1902.	1901.
Total Tea Crop secured ..	417,376 lb	396,593 lb
Total Coffee Crop secured..	217 bushels	140½ bushels
Average Price realised for Tea—		
Sold in London	7½d per lb	7d per lb
Sold in Ceylon	45½ cents	36 cents
Equivalent to	about 8½d in London.	Equivalent to about 7d in London.
Total Rainfall	116.23 in.	89.64 in.

The estimate of Tea Crop for the year was 450,000 lb, and there seemed every prospect of this being secured, until the last quarter of the year when persistently wet cold weather set in and upset all calculations; of the 116.23 inches of rain for the year, the last three months were responsible for 52.77 inches, and flushing was consequently greatly retarded. As indicated in last Report a further area of 20 acres Jungle has been cleared, and planted up with Cardamoms, making a total of about 45 acres under that product. The Visiting Agent, Mr R Morison, reports that the appearance of the Tea throughout the group generally is very satisfactory, for which credit is due to the Manager, Mr R G Coombe, and to Mr W S Coombe, who has proved a very efficient Acting Manager during the absence of the former on furlough. In accordance with the Articles of Association, Sir George A. Pilkington retires from the Board at this time, and, being eligible, offers himself for re-election. Messrs Cape and Dalgleish, C.A., also offer themselves for re-election as Auditors.—By Order of the Board, LYALL, ANDERSON & Co., Agents and Secretaries. 16, Philpot Lane, London, E.C. 8th April, 1903.

BURNSIDE TEA COMPANY OF CEYLON, LIMITED.

REPORT OF THE BOARD OF DIRECTORS,

to be presented to the Shareholders at their Seventh annual ordinary meeting, to be held at the office of the Company, 16, Philpot Lane London, E.C., on Wednesday, 29th April, 1903, at 12 o'clock noon. The Directors beg to submit to the shareholders the report and accounts of the Company, duly audited, for the year ending 31st December, 1902. The total crop of tea from the four estates was 426,062 lb., the Burnside Group contributing 347,775 lb. and Midlothian 78,287 lb., the former shewing an increase compared with last year of 67,940 lb. and the latter 4,838 lb. The average price obtained in London for the Burnside Group tea was 6'25d per lb., against 6'047d for the previous year, and in Ceylon 29 cents, against 32½ cents, while the corresponding averages for Midlothian were 8'36d per lb. and 38 cents, against 7'108d and 37½ cents. The average rate of Exchange was 1/4 3/16ths per rupee. Included in the crop figures are 4'215 lb. Green Tea made towards the close of December as an experiment by Mr Tait, the Manager of the Burnside Group, who deserves great credit for having at a very trifling cost constructed appliances on the estate capable of turning out a considerable quantity of Green Tea per day. The quantity in question and some 4,000 lb. more made subsequently were sold in Colombo at fair prices, but it has been deemed advisable, for the sake of still further efficiency, to purchase at a moderate cost a special steamer, and it is intended, as long as it proves remunerative, to make a portion of the leaf gathered into Green Tea. Mr Porter proceeded to Ceylon in September last and since November has taken the personal management of Midlothian estate, and his Co-Directors are deeply sensible of the benefits which have been derived from their colleague's temporary presence in the island. After payment of debenture interest and other charges the result of the year's working is a profit of £183 15s 5d, by which amount the debit standing at profit and loss account is reduced, and now appears as £883 10s 5d. The estates are all in good heart and present prospects, excepting the labour question, are more favourable than they have been for some time past. In accordance with the articles of Association, Sir George A. Pilkington retired from the Board, and, being eligible, offers himself for re-election, Messrs. Cape and Dalgleish, C.A., also offer themselves for re-election as Auditors.—By order of the Board, LYALL, ANDERSON & Co., Agents and Secretaries. 16, Philpot Lane, London, E.C., 9th April, 1903.

THE SOUTH WANARAJAH TEA ESTATE.

REPORT OF THE DIRECTORS.

The Directors have pleasure in submitting their report, also statement of accounts duly audited for the year 1902.

	£ s. d.
The profit for the season, after writing off £150 for depreciation, is ..	150 16 7
Add balance of last account ..	8 2 7
	1,508 19 2

Out of which a dividend at the rate of six per cent. on the preference shares has been paid .. 471 16 11

Leaving a sum of .. 1,037 2 3
From this the Directors recommend the payment of a dividend at the rate of five per cent., free of income tax on £20,000 ordinary shares .. 1,000 0 0

Leaving a balance to carry forward 37 2 3

The tea crop for the season, including that made from bought leaf, amounted to 581,440 lb., and the net average price realised was 5·1d per lb. It will be noticed that the cost of production of the entire crop is only 3½d per lb., a rate which shows that every economy is practised on the estates.

The average rate of exchange was 1s 4·18d per rupee. Owing to the low range of prices ruling during the greater part of the year, the results are not so good as they were for the previous season, but the Directors recommend, after providing £150 for depreciation that a dividend of five per cent., free of income tax be paid on the ordinary shares.

The Directors are pleased to state that they have recently acquired, on behalf of the Company the Poyston estate, in the Bogawantalawa district at a cost of £13,000, of which there remains on mortgage to the vendors a sum of £7000 at six per cent. per annum interest, the balance £6000 having been paid in cash in January. The estate is of high elevation and the recent rise in the price of tea adds considerably to the value of the purchase. The cash in hand on 31st December, including a deposit of £6,000 part of the purchase money of the Poyston properties, since paid away.

The buildings are in good order and the estates in a satisfactory state of cultivation and the Directors desire to give expression to their appreciation of the efficient and careful management on the estates by Mr W R Tatham and his staff.

The acreage of the Company's estates is as follows:—

	Tea.	Grass, etc.	Total.
South Wanarajah ..	230	25	255
Dairy Group ..	636	44	680
Poyston ..	302	18	318
	1166	87	1253 acres

It is with very great regret the Directors record the death of their Chairman the late Mr M P Evans. His place on the Board has been filled by the appointment of Mr W Dunn.

Under Article 97 Mr Oswald C Magniac retires from the Board, and, being eligible, offers himself for re-election.

The Auditors, Messrs Fuller Wise and Fisher also offer themselves for re-election.

THE NUWARA ELIYA TEA ESTATES COMPANY, LTD.

Report of the Directors to be presented to the Seventh Annual General Meeting of Shareholders, to be held on Monday, the 27th day of April, 1903, at Winchester House, Old Broad Street, London, E.C., at twelve o'clock noon.

The directors beg to submit the accounts of the

Company for the year ended 1st December, 1902, together with the Auditors' Report thereon. The crop account shows a profit from the working of the estates of £19,341 8s 9d. The profit and loss account including £1,791 1s 6d brought forward from 1901, and the payment of debenture interest, income tax, &c., shows a credit of £17,592 1s 1d, from which £2,000 has been written off for depreciation, leaving available for distribution £15,592 1s 1d; an interim dividend of 3 per cent free of Income Tax, was paid on 23rd October, 1902, absorbing £6,000; it is now proposed to pay a final dividend of 3 per cent, free of income tax, making 6 per cent for the year, which will absorb a further £6,000—£12,000; and to carry forward the balance of £3,592 1s 1d. The weather during the past season was not generally favourable, and the crops from the Company's estates, although in excess of those of 1901, fell below expectations. The average rate of exchange for the year was 1s 1½ per rupee, and the cost of the crop, free on board steamer or delivered to buyers in Colombo was 4·79d per lb. The average nett price realised was 8·28d per lb, equal to about 9·33d per lb gross on the London market. The following Table shows the results of the working of the individual Estates for the past year:—

Estate.	Acreage in bearing in 1902.		Tea yield per acre.	Average bearing per bearing acre.	Profit per bearing acre.
	Full.	Partial.			
			lb.	lb.	£ s. d.
Park ..	242	22	159,145	602	9 11 9
Portswood ..	322	30	186,373	529	8 3 7
Naseby ..	176	20	84,574	431	4 19 2
Pedro ..	391	109	283,693	567	8 2 6
Concordia ..	333	149	223,725	464	8 3 8
Court Lodge.	366	—	165,914	453	6 18 6
Hethersett ..	400	20	196,902	468	5 15 0
	2,230	350	1,300,326	504	£7 9 11

The yield from Tea in full bearing was 522 lb per acre, and that from Tea in partial bearing 386 lb per acre, as compared with 532 lb and 262 lb respectively in the previous year. As on 1st January, 1903, the acreages of the Company's properties stand as under:—

Tea in full bearing 2,156 acres; Tea in full bearing leased lands 98 acres; Tea in partial bearing 321 acres; Tea not yet in bearing 22 acres—Total land under cultivation with Tea 2,597 acres. Timber trees in clearings and belts 51 acres; Forest 124 acres; Patna, scrub, building sites, and waste 265 acres—3,037 acres. The estates are reported on as being in good heart and condition, and if the improvement which has taken place in the general tea position should bring about a higher range of values for teas such as those produced by the Company, its future returns will be on a more satisfactory scale. The retiring Directors are Mr Wharham Megginson and Mr Alexander Thomson, who, being eligible, offer themselves for re-election. Messrs. Cooper Brothers & Co., Chartered Accountants, offer themselves for re-election as Auditors of the Company.—By order of the Directors, FRITH, SANDS & Co. Secretaries.

London, 17th April, 1903.

PRODUCE AND PLANTING.

Mr George Seton, in sending to us some interesting particulars respecting the value of Indian and Ceylon

TEA SHARES

during the past month, chronicles a further

improvement. It will be seen that the market value of the share of the forty-five representative companies chosen by him for particular observation has again advanced during the past month; also that the improvement has extended nearly "all along the line":—

	£
Face value 45 companies' shares	9,500,000
Market value July 1, 1897 (highest point)	12,000,000
Do Jan. 1, 1902 ..	7,000,000
Do April 1, 1902 ..	6,745,000
Do Sept. 1, 1902 (lowest point) ..	6,050,000
Do Jan. 1, 1903 ..	6,600,000
Do Feb. 1, 1903 (corrected) ..	6,750,000
Do March 1, 1903 ..	7,000,000
Do April 1, 1903 ..	7,175,000

As the grand total of the share and debenture capital together of the 170 (or thereabouts) tea companies registered with sterling capital in the United Kingdom amounts to about £19,000,000. The fluctuations of the entire volume, based on these figures, may thus be roughly estimated:—

	£
Face value of (about) 170 companies	19,000,000
Highest market value, July 1, 1897	24,000,000
Lowest market value, Sept. 1, 1902	12,100,000
Present market value, April 1, 1903	14,350,000

Taking 100 as representing the top value, the lowest level would be represented by just above 50 and the present value by nearly 60. There are indications, Mr Seton further observes, that there will now be some pause in the advance until it can be clearly seen how the profits for the past year's working will pan out. Most of the Ceylon companies, whose financial year synchronises with the calendar year, either have already disclosed, or will this month, disclose their results, while the greater number of the Indian companies will issue their reports before the month of May is out, so that onlookers will not now have very long to wait for the information desired.

The following from a correspondent who sighs for the old-fashioned

PROFITS ON TEAS

appears in the *Grocer*:—"The great idea with retailers nowadays is to obtain every article in packet form, so as to save the payment of larger salaries than are due to those who have not learnt, but merely obtained a smattering of the grocery trade. Some thirty to forty years since the profits on small goods were 40 per cent. to 50 per cent. on returns, and the grocer who blended teas on his own premises to suit his customers, could easily obtain from 2d to 3d more than his non-blending competitor, though both of them obtained from 40 to 50 per cent profit on returns. Hence it is no surprise to me that failures in the grocery trade are frequent and disastrous, because many young men set up for themselves who have never learnt the difference between putting on 50 per cent. to the cost price and realising 50 per cent. out of the selling price. They and older members seem only to desire a great run of custom, and by keen competition and the hateful policy of the 'nimble ninepence,' seek to cut out each his neighbour, overlooking the fact that to sell teas from 12½ per cent. to 25 per cent. profit is but to exchange cream for skim milk. The secret of the tea trade does not lie giving one's legitimate profits to the general public indiscriminately by listening to the dictation of merchants and manufacturers as to the profits

they should be open to sell for, as much of their success depends upon annual returns. By dictating to the retailer the merchant makes a rod for his own back when he finds that failure results from insufficient profits, especially on tea."

ADULTERATION OF TEA.

Dr Alfred Hill, medical officer of health for the City of Birmingham, has resigned his position after a period of forty years' service. Interviewed by a local newspaper reporter, Dr Hill said the methods of the food adulterator are daily becoming more scientific and his devices more subtle. At one time pepper was extensively adulterated, but now it is rare to find a case where the quality has been wilfully reduced for commercial purposes. Tea which was formerly treated with minerals rolled up in the leaves and heavily coloured with Prussia blue and French chalk, as equally pure. Cocoa is still capable of being largely adulterated, sugar and starch in some instances being freely introduced. Under the specious plea of rendering the article soluble it was often robbed of much of its virtue.—*H & C Mail*, April 10.

TEA IN AMERICA IN 1902.

During 1902 the agitation of the removal of the duty on tea caused dealers to allow stocks out of licensed warehouses to run down to the lowest possible point and the result was that deliveries during the year were lighter than usual. Deliveries are accepted as representing consumption, but cannot be regarded as actually defining its extent. The imports were light and the per capita consumption smaller than for several years. The net import in 1902 was 74,275,153 pounds, with an average import cost plus the duty of \$16,669,704. The net imports, assumed to represent consumption, have for ten years past been as follows:—

	Net imports.	Average import cost	Consumption
	Pounds.	per pound.	per capital.
		Cents.	Pounds.
1893 ..	88,131,088	16.0	1.33
1894 ..	91,801,565	15.1	1.36
1895 ...	96,437,042	13.5	1.40
1896 ...	93,340,248	13.5	1.33
1897 ...	112,907,548	13.1	1.53
1898 ...	67,697,295	14.2	.93
1899 ...	72,834,816	12.3	.93
1900 ...	83,303,177	12.4	1.09
1901 ...	88,502,554	12.3	1.14
1902 ...	74,275,153	12.4	.94

The following tables show the net imports and yearly consumption:

Tea in warehouse, June 30, 1900	29,425,381	pounds.
Net imports, June 30 1901	83,502,554	
Net imports, June 30 1902	74,275,153	
Total supply, two years	192,203,088	
Less in warehouse June 30, 1902	33,635,042	
Net supply, two years	158,568,046	
Average yearly consumption	79,284,023	

It is conservative to estimate the average retail cost per pound in 1902 at 50 cents, and that one pound of tea as ordinary brewed will make five gallons of beverage, on which basis the consumption in 1902 was 596,420,115 gallons, at a cost of \$39,642,011, or 10 cents per gallon—with the duty of 10 cents removed we may look for increased use.—*American Grocer*.

AN AMERICAN SCHOOL GARDEN.

AN OBJECT LESSON FOR CEYLON.

Whether School Gardens may be succeeding in Ceylon, or whether the new cult is to have here only a flare-up, and then die out, accounts from the United States show that in that great Republic, where most social experiments are tried, tested, and "sized up;" the School Garden, as an educational agency, has come to stay, and a literature has been born of it. In all new countries the cultivation of the beautiful is apt to be postponed indefinitely; comfort and convenience being the chief things looked to, and the hideousness of many of the domestic surroundings of the well-to-do classes in their young rising towns and villages, have only to be seen, to be properly appraised and appreciated. As a rule when a country or town is just beginning its career, there is too much to do, which *must* be done, to allow in the affairs of common life any approach whatever to the æsthetic in taste. Even when circumstances have changed—to more money and ease—and there is both the capacity and field for a display of natural ornament and beauty, these are apt to be long of appearing, unless forced on by some power from without. In the domestic environs, everybody has the same uncovered ugliness, and is content with them; but it only wants a start to be made, an example to be set, and an object lesson to be displayed, to awaken the slumbering sense of the beautiful and the fit, and change the whole appearance and features of a place. It is claimed for the School Garden in America that it has an influence which extends far beyond its own boundaries, an elevating and humanising effect on the every-day life of the parents and guardians of the children who attend, which is reflected in the desire to grow plants for ornament as well as for use; a discontent with the untidy and the slovenly, and a willingness to spend both time and money in efforts to efface all evidence of the squalid and unseemly. Fences are no longer allowed to remain in a tumble-down condition; sheds and out-houses are mantled with the clinging creeper; the pathways are kept weeded and neat; and the whole plot presents a marked contrast—in beauty—with the sordid and mean aspect of the place owned by a family that is untouched by the influence of the School Garden. The illustrated papers have, from time to time, special articles on the theme, and picture what it is possible to do in most unpromising circumstances. Some schools have as yet made but a small beginning—a ledge or corner devoted to flowers; yet to have begun is the main thing. "The making of a definite garden," says a sympathetic American writer, "is an epoch in the life of each school; it makes the progress of the school in pedagogical ideals." The Hampton Institute of Virginia—founded for the higher education of the Negro and Indian youth—has the largest School Garden in the United States, covering two acres in extent. This is divided into some two hundred plots, and to each plot there are assigned two scholars who share

in the work and the produce. The Institute has a Director of the Agricultural Department who supervises and instructs in the work of the garden. To prevent the work degenerating into either play or drudgery, and to give it dignity and interest, supplementary lessons are given in the classroom with experiments on the growth; how best to disperse seed, the comparative value of soils, and the nature of the work which insects—beneficial and injurious—accomplish for the agriculturist. A study is made of the decorative value of flowers, leaves and berries, and the principles laid down are worked out in the pleasing form of bouquets for the table. An extensive and interesting curriculum—which shows that when our American cousins take up an idea, they make the most of it. It will be long before any school in Ceylon, approaches—even at a great distance—such thorough working of the School Garden as is seen at the Hampton Institute of Virginia; and yet the advantages a tropical climate has in the matter of plant-growth over the temperate of semi-tropical are great, indeed. Ceylon is a paradise for the botanist, and ought to be an ideal spot for the School Garden. There is, of course, the question of manual labour which in Ceylon is too often regarded as undignified and unbecoming; but to educate the people into a healthier view of this subject, would be one of the many good results of a successful carrying out of a general system of School Gardens. Enthusiasm is needed both on the part of the Educational Department and the school teachers to make the scheme a success, and harvest for the colony the benefits it has conferred in other lands. The old days when the "three R's" were deemed a liberal education for the common people have passed for ever; and amid the incoming of new methods, and themes of study for the instruction and equipment of the rising race, the advent of the School Garden as an educational agency takes a prominent place, with its numberless potentialities for good, and its atmosphere of sweet graciousness.

Since writing the above, we are glad to recall that the School Garden has in Ceylon begun to have its literature, thanks to the industry of Messrs. J. C. Willis, E. E. Green and C. Drieberg, Superintendent of School Gardens. Already three pamphlets have been issued from the press, with Sinhalese translations, entitled: "How to lay out a Market Garden," by Mr. Drieberg; "Silkworms and Silk," by Mr. Green; and—one which forms the Royal Botanic Gardens Circular No. 22—"School Bungalow and Resthouse Gardens," by the Director. America, however, has still a good deal to teach us both in theory and practice.

 PROGRESS IN BRITISH CENTRAL AFRICA.

Mlanji, Feb. 20.

The British Central African Co., Ltd., has issued a circular to planters and others inviting them to cut sleepers, and

sleeper logs for our railway and intimating that the Company will be ready to take delivery in April or May next, at prices ranging from 2/6 to 5/ per sleeper, sleeper log, or pair of either. So you will see business is meant at last.

The first shipment of material for the line is on the way out, and operations are to be started in earnest on the trace in April. So we will get our railway, although it may be too late to be of any service to the coffee industry; for it is fast becoming an enterprise of the past.

Whole districts have been let out of cultivation with the exception of a few estates that have money or minor products to depend upon for making ends meet.

TOBACCO, CHILLIES AND COTTON ARE GETTING

A FAIR TRIAL

on a big scale for the home market by the large Companies and private individuals in a small way. Rubber is also being grown: *Ficus Elastica* and *Ceara* are the only varieties of rubber producing trees that have been introduced. We have, of course, some indigenous trees, and the vines *Landolphia*, but the yield from them is small, although the rubber is of good quality.

Mlanji can grow tea well; a few acres, three years old, here simply surprise everybody who has seen them. The growth is equal to five and six year old tea in most districts in Ceylon, due probably to the magnificent virgin soil we have got. Messrs. Willisford and Ferrier, of the Blantyre and East Africa Co., Ltd., who were here lately, were agreeably surprised at our tea prospects in Mlanji and wondered why planters did not go in for it extensively long ago. One remarked: "There is a fortune in tea here with your cheap labour." I have managed to get planted now over 100 acres of tea, and Mr. Lauderdale has also got a few acres and is extending like myself. So we will prove in the course of a few years what can be done with the cup that cheers.

Ceylon need not be afraid of a rival in British Central Africa tea, for although we have a huge country to work on, the rainfall is too small—from 20 to 45 in. per annum—over the whole country and that rainfall only on from three to four months in the year. During the other eight or nine months there is hardly an inch falls. It is different with us, however, as proved by the following table kept here for the past ten years:—

Days.	Inches.	Days.	Inches.
1892 ...110	90.08	1897 ... 97	64.67
1893 ...132	89.78	1898 ...118	118.62
1894 ...138	82.89	1899 .. 129	88.69
1895 ...125	106.01	1900 ..101	82.07
1896 ... 96	95.40	1901 ...112	84.31

The bulk of our rain falls from December to April, but hardly a month passes here without a few inches. Our superior rainfall to the other parts of British Central Africa, is due to our situation on the S.E. slopes of Mlanji mountain, which runs up to an elevation of nearly 10,000 feet. So I put our heavy rainfall down to the moisture-laden clouds coming in contact with the

cool atmosphere of the mountain. On the other side of Mlanji they get a drizzle, when we get heavy rain. The division is much the SAME AS YOUR CENTRAL AND UVA PROVINCE, and the same remark might be applied to Mlanji S.E. and N.W. as used to be made in coming up from the Uva side. "Change coats for Nuwara Eliya."

The African Lakes Co. have brought out an expert for cigar tobacco, Mr. L. Van Lemhoff who had many years' experience in Sumatra and recently finished an engagement of three years as Government expert for Natal. Mr. Lemhoff decided on Mlanji for his experiments and has set to work to give the tobacco, cigar leaf, a fair trial. No expense or trouble is being spared on some 40 to 50 acres of a clearing which the writer saw last month. A train of oxen, six in number, were at work ploughing, turning up the soil to the depth of some 15 inches. This has been done over the whole clearing three or four times, as well as harrowing, so that one can push a stick into the soil as if it were a bag of flour. Some four large sheds about 80 feet by 30 and 15 feet high, regular Sumatra style of buildings, are in course of erection to house the tobacco. Sticks and telegraph wire have been procured for hanging the leaves upon.

Nurseries are certainly a marvel of neatness and style, beds laid out 10 feet by 4, with good paths between and all covered with a frame of sawn timber 8 in wide, covered with calico to shade the seedlings. This frame also keeps off insects, and is only removed to water the plants.

If Sumatra seed-leaf tobacco, for cigar wrappers, does not succeed under the most careful management, and the fair trial it is getting from Mr. Van Lemhoff and his assistant, it is doubtful if this valuable leaf will do anywhere in B.C.A. A very fine pipe tobacco is grown as well as a leaf quite good enough for fillers, if not for wrappers, from Havana seed-leaf. No Sumatra seed-leaf tobacco, however, has been tried before.

MR. LEMHOFF'S EXPERIMENTS

will be watched with much interest because, if success crowns his efforts, there will be a fortune in cigar wrapper tobacco-growing in this protectorate. The Blantyre and East African Co., Limited, have got two American tobacco men out, to cure yellow leaf for the London, and other markets, and this Company has got a considerable acreage ready for planting up on their different estates at Zomba, Blantyre, Cholo and Mlanji. We hear of clearings even up to 100 acres in extent on some estates, which is rather a big undertaking at first go off and will tax their uttermost ingenuity to provide house, room handle and cure with our unskilled labour. May their efforts be crowned with the success they really deserve.

COTTON

of the Egyptian variety is being planted up with this rainy season, by Industrial Missions and some private planters to test this product in a practical way. A sample sent home by us some three years ago was

valued at 4½ to 5 per lb. With our heavy freights it is a question whether cotton will pay to grow in B C A. The number of pounds per acre, and the cost of landing this product in London including the cost of cultivation, when carefully worked out, by experiment, will prove whether cotton will be worth cultivating in B C A. The Manchester Chamber of Commerce has offered to spend £50,000 in West or East Africa on cotton, if we can prove that it will grow to pay. This is a pretty canny offer from a wealthy Chamber. They might give the money to our poor Government to experiment with.

Something must be done for this country by Government, for it is going back sadly. Imports and Exports have dropped to about one-third of what they were five years ago; so the future of the country is not at all bright. It remains to be seen what our new products are to do, for coffee is practically a failure as a permanent industry owing to insect pests, and unfavourable climate. The exports of coffee will probably not exceed 200 tons this year. Five or six years ago it was up to 11,000 tons. We want Lord Stanmore and Mr. J Ferguson here to bring B C A. into a state of prosperity—for it is at present just as Ceylon was about '85-'86 through the failure of coffee, owing to leaf disease—and, I may add, a number of independent Ceylon planters, who now know what failure is or to be beaten at any undertaking.

Efforts are being made by

OUR COMMISSIONER, MR. SHARP, to get our agricultural products into the Transvaal and Orange River Colony, at a reduction of duties, if a free exchange of produce cannot be secured. Should we get preferential duties for our tobacco and tea, there is an unlimited market in South Africa, and it will pay well.

Mr H Storey, a well-known Matate and Madukelle proprietary planter, with his cousin, came to B C A in September on a shooting trip on their way home; and made an excellent bag of all kinds of game during their couple of months in the country. They were surprised to find that elephants could be shot a few miles off coffee plantations here. A planter, the Superintendent of Eldorado Estate, shot two small elephants in December, out of a decent sized herd, only about 2 miles as the crow flies from Mount Zion Estate. It would seem that elephants are likely to come back to this country (and be seen in herds of hundreds as in days of yore), now that their persecution has been stopped.

H.B.

THE S. I. TEA EXPLOITATION FUND.

THE SALE OF TEA.

The South India Tea Exploitation Fund, which has been organised by the Travancore tea planters, is doing excellent work in the way of creating a taste for tea and popularising its consumption among the masses of this Presidency. An interesting and practical scheme has been set on foot, principally at the initiative of Mr H M Knight, of the Kanan Devan Planters' Association, to push

the sale of tea in the Presidency so as to bring it within the reach of the poorer classes of the community.

The scheme is based on the lines laid down by the Indian Tea Markets Expansion Commission of Calcutta, which is managed for the Indian Tea Association by Messrs. Andrew Yule & Co. The object was to introduce the consumption of tea among the native population of India by the sale of both packet and brewed teas, and to achieve this end a certain number of planters contributed quantities of tea to be utilised by the South India Tea Exploitation Fund. In January last, Messrs. Parry & Co., as the Agents of the Fund, started the sale of brewed tea in the principal towns, of Southern India. They made arrangements for the establishment of stalls in various towns where tea is brewed and taken round by hawkers for sale in the streets. The scheme has been working in Madras and the mofussil for the last four months with considerable success. In this city brewed tea is being taken round to the Government offices and the principal mercantile firms from stalls which have been established in all the principal thorough fares. The sale is managed entirely by Brahminders under the supervision of Messrs. Parry & Co. Brewed tea is sold in cups at the popular price of 3 pies per cup, which ought to make it available even to the poorest of the population. The sales have been steadily increasing month by month since January and promise to show a remarkable development in the near future. Through the energy and enterprise of Messrs. Parry & Co. packet tea and brewed tea are available at extremely moderate prices in all the important towns of the Presidency, from Cochin to Tuticorin. Messrs. Parry & Co. have taken the initiative in this matter, and they hope that, now that they have demonstrated the success of the scheme, the sale of tea will be taken up by petty dealers all over the Presidency, and the sale of tea and a liking for the beverage extended far and wide among those who have not hitherto been accustomed to drink it.—*M Mail*, May 5.

PREPARATION OF GUTTA-PERCHA AT SINGAPORE.

Thus *the Sourabaya Courant*: The Netherlands Gutta-Percha Company at Singapore, a venture set up in Holland, goes on preparing at Passir Panjang as much gutta as possible from leaves. At first it had much trouble in getting a sufficient stock of leaves. This is now no longer the case, and, as a rule, it can count upon a supply large enough to allow of a continuous and adequate output of gutta.—*Straits Times*, April 27.

INSECT PESTS IN INDIA.

THE NEW ENTOMOLOGIST.

Calcutta, May 3.—Mr Maxwell Lefroy, Entomologist appointed by the Agricultural Department of the Government of India, arrived in Calcutta last week. Mr Lefroy's experience has been largely gained in the West Indies, and though insect pests, which trouble agriculturists in India, differ considerably from those in that quarter of the globe, training in a tropical country will give him immense advantage.—*Times of India*, May 4.

THE COLOMBO TEA SALES AND ESTATE

AVERAGES FOR 1902.

ADVANCE IN QUANTITY AND SOME RECOVERY IN PRICE.

Recently we gave the total quantity of tea sold in the weekly auctions in Colombo during 1902 on account of estates which support the local market. Below will be found the details; and this time another advance in number of marks and quantity is recorded. The names dealt with number 505. We began these yearly averages in 1894 when 90 estates only had to be dealt with. High Forest stood first for 1900 and Naseby for 1901, both with 59 cents; but for 1902 there is no stand-out figure like that. The following is the formidable list; and, as a sign of the times, and of the growing importance of the Colombo market as a distributing centre for the whole world, it may be mentioned that a rumour exists that a large London firm of brokers is shortly opening a Colombo branch:—

ST. LOUIS EXHIBITION.

MR. W. H. FIGG'S REPORT ON HIS VISIT TO
ST. LOUIS.

In pursuance of a request from Mr. Kingsford, Chairman of the Planters' Association, I consented to visit St. Louis and investigate conditions, and if satisfied with them to make preliminary arrangements for the Colony's representation.

INTRODUCTIONS.—After accepting the mission I cabled to Ceylon asking for Letters of Introduction from the Ceylon Government to assist me with the authorities in America. I have to thank His Excellency the Governor for his great kindness in sending me personally written letters to H M Ambassador at Washington, (Sir Michael Herbert) and to the Commissioners of the St. Louis Exhibition. After presenting my letter at the Embassy at Washington, I proceeded at once to St. Louis and lost no time in meeting the heads of the various departments.

INSTRUCTIONS.—From the perusal of my instructions received through Mr Kingsford it will be seen the following were the points dealt with:

(A) The question of the erection of a building to contain all Ceylon's exhibits, or whether Ceylon's products should be displayed in their various departments in the main buildings.

(B) In the event of a separate building being necessary: (1) the site, (2) the style of architecture, (3) the probable cost.

(C) The conditions under which Ceylon Tea could be sold in the cup and in packets.

(D). The appointment of a representative in St. Louis, to act pending the arrival of the Commissioner.

EXHIBITS.—Immediately after meeting the Secretary, Mr Stevens, I was introduced to Mr F J V Skiff, the Chairman of the Committee of Exhibits, who invited me to meet his Committee, who were then sitting. This Committee, consisting, as it does, of the Directors of the various Departments, into which the Exhibition is divided, is virtually the Executive. It was, therefore, of great assistance to me to meet at the outset of my investigations these gentlemen. At the invitation of the Chairman, I briefly addressed the meeting, setting forth the object of my visit. After some general discussion I found there was a very strong feeling against Ceylon's exhibits competing, unless the products were displayed in their various classes in the main buildings. It was clear to me that although this condition was not made absolutely a *sine qua non*, it was to the interests of the Colony to fall in with the views of the Committee, particularly as three-fourths of the Ceylon Exhibits would come under the head of Agriculture. The balance would be divided between Forestry and Mines and Metallurgy. Taking the above into consideration I came to the conclusion that Ceylon ought to show in the main buildings and have a Court and garden of its own in a good position.

AGRICULTURE.—This important building is an enormous structure covering 1,600 by 500 feet and is said to be the largest in the world. I have provisionally secured a space of 2,400 square feet marked on the accompanying blue print and append copy of letter from Mr F W Taylor, the chief of this Department, which gives all necessary particulars. We are particularly indebted to Mr Taylor for the friendly consideration and assistance he

tendered us and I gladly accepted his very courteous offer. I commend to the attention of the Committee his suggestion in regard to the forwarding of suitable plants for decoration of the house and grounds, and hope that the Director of the Botanical Gardens will see his way to exhibit, on behalf of the Colony, and also to assist with a collection of suitable plants.

FORESTRY.—Next in importance to Ceylon, after Agriculture, is the Department of Forestry. I have provisionally secured space, 50 x 60 feet, in a suitable position to be fixed hereafter on completion of plans now being prepared by the Director of Works. Dr. Tarleton H Bean, the Acting Chief of the Department of Forestry, is most anxious for Ceylon to make an exhibit similar to the one made at Paris. His letter covers all the ground necessary and is appended together with a circular referred to therein.

MINES AND METALLURGY.—In this Department I felt a little doubtful in arranging for space, but Mr, Holmes, the Chief of the Department, is very desirous that we should send exhibits. I enclose a letter received from him, and as plumbago is such an important article of export to the United States, his suggestions are worthy of careful consideration. Should it be decided to make a display in this department, I recommend that early steps be taken and such space as will be necessary applied for without delay.

SITE FOR BUILDING.—After going over the ground carefully I decided that the space marked on the accompanying plan was the best for our purpose: (1st) Because it appears to be in the opinion of those best able to judge—a point where most of the visitors to the Exhibition are likely to pass. (2nd) Because the gardens laid out by the Director of Horticulture will abut on our allotment and greatly enhance its attractiveness. Here I may mention that Mr Taylor, the Director of Agriculture, has kindly consented to undertake the laying out of our grounds, continuously with those of the Horticultural Department, using palms and other tropical plants. (3) The position is conveniently close to the Agricultural and Forestry Main Buildings, thus facilitating supervision by our Commissioner.

SPACE FOR BUILDING.—The space at our disposal is 125* x 250 feet, closely approximating the original application from Ceylon for 4,000 square feet. I enclose letter from Mr Isaac Taylor, Director of Works, with site marked on the plan. I informed Mr Taylor that the building would probably follow a Kandyan style of architecture and that plans and specifications would be submitted to him for approval. It is important that there should be no delay in moving in this matter and plans should be sent to our agent. I would recommend a light, airy building, as the climate of St. Louis during summer is very hot.

COST OF BUILDING.—I had an interview with the Chief Architect of the Exhibition who very kindly went into the matter with me, and so far as he could make a rough estimate on the data I could give, thought that we might figure on 7½ to 8 cents American per cubic foot. As I consider it certain that the general products will be exhibited in the main buildings, the size and design of the Ceylon

* Supposed to be a mistake for 150 ft.—ED. T. A.

structure can be regulated accordingly, care being taken to provide room for the kitchen, scullery, and private offices for the Commissioner. In view of the climate of St. Louis, ample wide verandah space should be provided. On receipt of plans and specifications, our agent will call for tenders and submit same before closing contract. Arrangements should be made to permit of cabling consent to proceed.

CONCESSIONS:—The permission to sell Tea in the cup and in packets is one of the most important and difficult matters I had to deal with. Although I impressed upon the authorities that in obtaining their sanction we had no idea of making profit from the sale of these articles, yet the rights of the Restaurateurs, for which they had paid between \$1,500,000 to \$2,000,000, had to be protected. The Director of this Department, at the commencement of our negotiations, laid it down as a condition that 25 per cent of the takings must be paid to the Exhibition. This I could not agree to, but finally arranged to obtain full privilege for the sale of tea from our building in cup and packets and right to issue and display suitable advertising matter on terms set forth in the accompanying letters from Mr Norris B Gregg, Director of Concessions and Admissions and Mr J V F Skiff, Director of Exhibits.

ACTING AGENT.—In terms of Mr Kingsford's request to appoint a representative to act for us, pending the arrival of our Commissioner, I have, with the sanction of Mr. Stevens, appointed Mr. Russell Stanhope, the Secretary to the Committee on Foreign Relations, on a remuneration to be decided by our Commissioner. I enclose letter from Mr. Stanhope accepting the appointment and from Mr. Stevens conveying his sanction. I have deposited \$300, receipt enclosed, with Mr. Stanhope, to meet sundry expenses, and have instructed him to communicate with you direct as occasion may require. A most important matter is the execution of the contract between the Ceylon authorities and those of the Exhibition. Mr. Stanhope is having this drawn up in the terms of the correspondence accompanying this Report.

GENERAL.—In conversation with those who have had experience over here in former Exhibitions, I feel it right to tell you that it is decidedly advisable that native servants should be sent over from Ceylon to serve the tea in the Ceylon grounds. Mr. Larkin, of Toronto, is most anxious to obtain some tea plants for exhibition purposes and I have promised to write asking you to take steps to get some germinated tea seed packed in Wardian cases and sent to him as soon as possible. He is in a position to take full care of them when they arrive in Toronto, if we can only get them there alive. As regards small packets of tea for distribution free in the Exhibition, Mr. Larkin strongly recommends that these packets should be made of lead and not tin. The reason for this is to let people have as nearly as possible a facsimile of the packet which they would buy hereafter in the various stores of the United States of America. My visit to St. Louis has impressed me with the magnitude of the undertaking. It would make this report too lengthy to enter into details here, but I have requested Mr. Stanhope to send you full information from time to time, more especially as to the progress made with the buildings and the probability of the Exhibition being opened in time.

THE "TEA" TORTRIX: THE GREATEST EXISTING TEA ENEMY.

The item on the agenda of the Dimbula Planters' Association at their meeting of the 28th April of most general importance to the tea industry was the discussion on the "shot-hole borer." Mr. Bosanquet, whose opinion carries weight wished for legislation, but —while Mr. Welldon took the view that there should be none without the consent of the district—the meeting voted for Lieut. Colonel Farquharson's amendment in favour of cooperation "with Government, but against" Government interference. This is certainly the most satisfactory view to take. But the shot-hole borer is a comparatively small matter compared with the threatening aspect which the spread of the "tea tortrix" is beginning to wear; and so we are of opinion that by far the most valuable contribution to yesterday's meeting was Mr. Welldon's on this subject, although not one down on the printed agenda list. Dimbula is ever prompt to make measures against approaching danger and the present one that threatens is far greater than the "shot-hole borer" which prevails most in Gampola and Pussellawa and appears to confine itself to medium and low elevations. The "tortrix" on the other hand, as Mr. Welldon shows has been doing much damage in Maskeliya and the latest reports from that district are anything but reassuring. Indeed we hear of its being responsible for reduction of crop on one estate by about one-twelfth or one-fifteenth, at least. Egg-masses in another case—are being collected at the rate of 20,000 to the acre; and one day's collection even totalled as much as 243,000 egg-masses. These figures give some idea of the pest Maskeliya has to fight with—when we state that according to the Government Entomologist, each egg-mass contains on an average 250 eggs. The remedy which has been put in hand is to lop up the grevilleas [as high as possible—these handsome trees, it is thought, being responsible for a great deal of the damage. The moths deposit their eggs very freely on the leaves of this tree, the "silky oak," and when the leaves drop off on to the tea, the result may well be imagined, It becomes, therefore, necessary to take in hand both grevilleas and tea at the same time. It should also be mentioned that it is suicidal to prune tea when the pest is in the moth and egg stage—the reason being that the caterpillar stage is then reached about the time that the young flush is coming on and the flush is at once eaten down and lost. The moth and egg stage is now, we believe, prevailing in Maskeliya and the caterpillar stage should be attained in three weeks' time. This information should be of interest to the strong committee for Dimbula appointed yesterday; and superintendents should at once examine their fields very thoroughly and closely to see if they can find traces of the pest, and report to the Committee, whose secretary Mr. Welldon has kindly undertaken to be. As this gentleman said, it is generally found in small patches first, but once it spreads it is

very hard to cope with. Mr. Green's circular on the *Tea tortrix* gives all the information that is required; and he mentions that the loss from the pest has been estimated in Maskeliya at R10 per acre. The pale yellow eggs appear on the upper surface of the older leaves, turning to white when the green caterpillars (paler green as they get older) emerge; the caterpillars make their shelters by joining leaves together. The chrysalis, half an inch long, is deep red; and the moths, of a pale reddish brown. These are the elementary points for identification. In conclusion—as we warn all planters at high elevations to give the matter immediate (even if renewed) attention—we may add that the tortrix attacks not only grevilles and tea, but also acacias, albizzias and even the eucalyptus. It was first noticed by Mr. Green in 1889, in Dimbula: but it has never been more worthy of careful and systematic eradication than now.

CHINA TEA IN 1902.

(From the Returns of Trade for 1902.)

Although the quality showed some improvement as compared with that of 1901, there seems a consensus of opinion amongst experts that the Teas from all districts, except Ichang, have fallen off deplorably in quality and style during the last 20 years. The Chinese will take no advice and refuse to listen to any suggestions regarding change in cultivation and manufacture while their great rivals in India and Ceylon pay the closest attention to all details and are ever on the lookout for improvements. Strong representations made in the spring induced the Chinese Government to reduce the Export Duty to one-half, but it still remains too high, being at least 12½ per cent on common teas; and, as *lekin* and other internal taxes were not interfered with, although in some districts they almost equalled the Export Duty, it is to be feared that this half-hearted step towards putting China teas on a level with untaxed competitors will not be of much benefit to the trade. The transport of some three millions of pounds by the Siberian Railway was a new departure which will be watched with great interest, and one which might lead to important developments if the Chinese could be induced to pay more attention to quality. Some reduction in the heavy Import Duty charged in Russia would be of great assistance to the trade, especially as Russia is now the principal purchaser of black Teas. The total export of all kinds of Tea was about 31 per cent higher than in 1901; but the shipments to Great Britain showed no improvement although the deliveries from bond in London from June to December were better by 3 millions of pounds. The United States took 168,501 piculs of Black Tea, as against 96,820 piculs in the previous year, and 126,196 piculs of Green Tea, as against 86,747 piculs. This is explained by the fact that the War Tax of 20 gold cents per pound was to be removed on the 1st January, 1903, and stocks had been reduced to a minimum to escape the expense of bounding. Moreover, it is anticipated that lower prices in consequence of the removal of the Duty will increase the demand. Black Tea via Kiakhta rose from 17,745 to 66,464 piculs presumably because the route

was safe again after the late disturbances. The export of Brick Tea showed a considerable advance, Black Brick having improved from 244,565 to 493,103 piculs, and Green Brick from 43,957 to 29,932 piculs. Congou Tea consumed east of Irkutsk was formerly free from Duty, which has now been imposed; the consequence has been that its place is being taken by Brick Tea, of which a finer quality is now demanded. Ceylon Dust, which is blacker in colour than China Dust, is imported to improve the quality and appearance of the Bricks. It may be mentioned that the export of Green Tea from Ceylon to the United States, which was till lately the monopoly of China, rose from 797,796 pounds in 1901 to 1,963,456 pounds in 1902. It is to be regretted that the Chinese Government and the Tea guilds do not take more energetic measures to assist this valuable but moribund trade.—*Hongkong Daily Press*, April 11.

MANUFACTURE AND RELATIVE OUTTURN OF GREEN AND BLACK TEA. EXPERIENCE OF CEYLON MANUFACTURERS.

Considerable interest has been evinced among green tea manufacturers in Ceylon by the statements made by "G. T." in the columns "you can never get the same outturn from green teas as you can get from black" and from the mild insinuation by Mr. Judge, that if that is so in Ceylon we are not quite up-to-date in manufacture. In addition to the emphatic opinion we published on April 18th, which stated that only careless manufacturers in Ceylon could endorse the statement that green tea cost more than black, we have applied for and received the opinions of two green tea manufacturers which we have pleasure in giving below:—

Mr. J. A. Hunter, of Sunnycroft, Veyangoda, writing on 24th April, says:—

DEAR SIR,—In reply to your enquiry as to respective outturn of black and green teas, I am pleased to state, in the interests of this new industry, that I find the outturn of greens the same as that of blacks. The short outturn so much complained of in greens is entirely brought about by the wasteful system of manufacture adopted. To save cost of firing, the general idea is, to squash as much moisture as possible out of the freshly steamed leaf, by rolling it 40, or 45 minutes, and then putting on pressure. This juice is then allowed to find its way to the nearest stream, carrying with it a considerable amount of the essential oil of the tea leaf, leaving the finished article all that the poorer, and the outturn so much the shorter.

P.S.—If all moisture in green leaf is got rid of by evaporation the outturn of greens is bound to be the same as black is. There are cheaper ways of evaporating the excess of moisture than by hot air from a dryer.

J. A. H.

Another manufacturer, at a higher elevation, writes under the same date as follows:—

DEAR SIR,—In reply to yours of the 22nd instant, I have only made green tea for a little over 2 months and have scarcely had time to

tell whether I can get as good an outturn from making green tea as from blacks. My opinion is that there is very little difference, and my figures go to prove it so far. In February I turned out 23.60 per cent of made tea and in March 24.72 per cent, that is on the gross weight of green leaf brought to the factory, no deductions having been made for wet leaf. I don't think I could have turned out more of black tea.

ROYAL BOTANIC GARDENS:

ADMINISTRATION REPORTS.

The greatest interest in regard to the Peradeniya Department, during the past year must undoubtedly attach to the work done at the Experimental Station (Gangaruwa) under the supervision of Mr. Herbert Wright. But in the Reports which have just appeared there is not much recorded on this topic and it is understood that a separate Report is to appear. Meantime it has fallen to the Acting Director, Mr. Carruthers, to furnish the main or introductory Report on the Botanic Gardens and Scientific Department, and this is supplemented by statements, generally very concise, from each member of the Staff. First of all the functions of the Departmental officers are defined as follows:—

The botanical survey of the Island.

The study of various physiological and pathological botanical questions in relation to the economic plants of the Island.

Experimental agriculture.

Experimental horticulture.

The demonstration and encouragement of horticulture at various elevations.

The distribution of seeds and plants that are not to be obtained from local seedsmen.

The giving of advice and information on botanical, agricultural and horticultural matter.

The care of the health of the crops of the Island.

The introduction and trial of new plants suitable for economic cultivation.

As usual, we give elsewhere in full all we are told under the heading of "Economic Plants," and it is of special interest to learn how very thoroughly fungoid disease—affecting 98 per cent of the cacao trees on Gangaruwa, when taken over,—has been subdued and an entirely new face put on this cultivation on the Experimental Station. What we are told respecting Para and *Castilloa* rubber and camphor (see page six) is of special interest; and coconut planters will be interested in the reference to their industry and to the value of mimosa as a nitrogenous manure. It seems hopeless to expect any revival of much importance in respect of cinchona-growing, in view of the experience of careful planters in our leading districts, namely, that cinchona will not grow in their teafields as amongst coffee (tea has probably more and wide spreading roots). The only chance for it is in a virgin forest clearing by itself or among young tea and both forest reserves and young clearings are few and far between. A good deal more might be made of pepper and vanilla in many directions, especially at a low elevation. Cacao planters are warned to fight their

enemies more continuously; but has enough been done by the Mycologist himself?—is a question we have heard asked. Cardamoms promise well. The Entomologist is indefatigable, and his comparatively full Report, as well as contributions to "Indian Museum Notes" and to other publications, indicate Mr. Green's devotion to his work. We reserve remarks on the Reports of the Curator and Scientific Assistant and on the Hakgalla and Minor Gardens' Reports for another time.—One feature of the whole Reports which we must not omit to mention is the finely finished illustrations—quite an innovation in Government Administration reviews—for which Messrs. Kerr & Co. are responsible. Other such publications, which come under the head of Scientific and Miscellaneous, might well be brightened by imitations of this example from Peradeniya.

PHILIPPINE GUTTA AND RUBBER.

Instructions, says the *Manila Times*, have been received from Washington by the Custom authorities of the Philippines to keep a vigilant look out for Chinese merchants engaged in smuggling rubber and gutta percha out of that archipelago. Detailed search on the part of forest rangers of the Government employ has brought to light some very curious facts in regard to the traffic, seriously involving Chinese exporters. Not only has the expedition confirmed the belief that the forests of Mindanao, the Sulu Islands, and parts of other islands abound in gutta percha trees and rubber vines, but the Government laboratory in Manila has demonstrated from samples brought in that these Philippine products are equal to the best Sumatra and Borneo gutta percha, and perhaps not inferior to the highest grades of Para rubber.

BIG SECRET TRADE.

It was evident that gutta percha and rubber were finding their way out of the islands through unlawful channels. It has been discovered by the United States scientific explorers that large Chinese firms in Singapore and Borneo are conducting an immense secret trade with the Philippines in the matter of gutta percha and rubber, thousands of pounds being smuggled out of the archipelago to Sandakan, Borneo, and there skilfully adulterated with colouring matter and sold as Borneo and Sumatra products. In many parts of the Philippine Islands whole tribes of natives are engaged in gathering rubber and gutta percha for these Chinese smugglers. The system is thoroughly organised. The worst thing about this industry is not that the customs houses are cheated out of the export revenue that should be levied, but that the wild tribes of southern Mindanao and other sections are destroying these valuable forests. With no thought for the future they cut down trees and vines to get the sap, or milk, as it is called. In some of the smuggling villages some of the native agents admitted that they made their living by gathering rubber, but would not admit that they had traded also in gutta percha. In some of the coast towns it was discovered that these Filipinos had rubber and gutta percha secreted under the floors of their cottages. It was tied to strings and kept floating in the sea water. This not only kept it effectually out of sight, but served also to make

the products harder and prevent loss of weight until it could be disposed of to the Chinese smugglers.

VALUABLE PRODUCTS.

From various districts samples of gutta percha and rubber were brought to the government laboratory at Manila, where it was subjected to a careful scientific analysis. These tests disclosed the important economic fact that the Philippine gutta percha will doubtless become as valuable for cable insulation and other purposes as the best gutta percha obtainable, while the rubber, with proper coagulation and drying, it is thought, will be equal to the best commercial rubber now on the market. While some of the gutta-percha trees found were new and hitherto unknown varieties, many of them belong to the general species, *dichopsis gutta*, the tree which has furnished the gutta-percha for most of the submarine cables of the world. Samples of these Philippine products were submitted to the chief electrician and to the cable engineer of the U S cables ship "Burnside," who pronounced the gutta percha to be of very superior quality, and inasmuch as many cables will ultimately be laid between the Philippines and Japan and Asia the presence of insulating material in the archipelago is of extreme importance. That the government at Washington may be made fully aware of the necessity for taking some action in controlling these priceless forests, samples of guttapercha are now on the way to the United States where they will be subjected to most careful tests by eminent scientists. In the meantime forest rangers have been detailed to patrol the mountains where the gutta-percha trees grow in greatest abundance, while customs officers will keep a sharp look-out on the coasts where Chinese craft are engaged in the smuggling trade. Secretary Root is being urged to take the entire traffic of gutta percha of the Philippines and put it in the charge of government scientists. The plan is to reserve these forests as State property and the rubber and gutta percha to be collected by the officials of the forestry bureau, or to permit private enterprise under strict conditions over specified areas.

COMPETITION IN THE SALE OF TEA IN INDIA.

Messrs. Brooke Bond and Co., Ltd., are now actively competing for the trade in India. Quite recently a Director of the Company interviewed the Commissioners, who assured him that they cordially welcomed the addition of his Company to the exploiting power of the Indian Market. The well-known Lipton is also pushing Indian Tea in India more vigorously than ever, and other European distributing agencies are showing increased activity. Several European owned estates are also supplying tea in packets or boxes direct from the garden and generally a tide of co-operation is setting, which cannot but be regarded with the greatest satisfaction. The Commission, however, has not only stimulated European trading in Tea, but has aroused the interest of the Indian shop-keeper. This community is beginning to get the idea that it will pay to handle tea. The Commissioners are doing their utmost to foster the trade in this direction, by giving every possible facility to those who make the venture. They are pleased to report that during the past three months a large number

have followed the lead given by the Commission and are now vending brewed and leaf tea on their own account.—From Messrs. Andrew Yu and Co.'s report for the period ending January 1st 1903.

AN ENTERTAINING MELBOURNE TEA HOUSE BY "CYNTHIA."

A few months back saw the transformation of a dingy set of offices in Elizabeth-street to a something which compels the attention of any passer by. A broad shop window, behind which is displayed a series of suggestive little scenes, with a bank of tea plants for a background, was the first thing that got the public in the habit of pausing in front of Griffiths Bros.' new tea house. 'That firm has got hold of a smart window-dresser' was the almost invariable comment of the casual observer, and a dissertation on the subject of up-to-date advertising was safe to ensue. The quaint, carved figures were grouped so fantastically that it was speedily recognised that only an artist could have had the arranging of them. 'It's not tea, I want,' complained one woman gazing through the glass, 'it's one of those little brown men or that ridiculous china pot.' She who hesitates is proverbially lost.

PAUSE TO ADMIRE A CINGALESE GOD
and the first thing you know you are ordering tea at 1/9 a pound. As happened to the woman in question, happens to the majority of appreciative folk who take their walks abroad with their eyes open. The firm confesses that one branch of its trade has almost doubled since it withdrew from the stately seclusion of Flinders lane. And if the firm has gained, so has the city. An attractive shop window is something to be sincerely commended, and though this one, as it so turns out, owes absolutely nothing to a professional window dresser, it can hold its own with any in Melbourne. Small folk are beginning to insist in going round by Elizabeth-street to 'See the elephants,' while children of a larger growth take the same course ostensibly to see the tea plants. Elephants, be it stated, are a prominent feature in the window. A large painting of three Cingalese carriers at present occupies the window. One of them has quite an important history of his own, and is intimately associated with

THE AFFAIRS OF A CERTAIN TEA PLANTATION in Ceylon. One loses nothing by passing on from the window to the sale room. If shop proprietors would only recognise how profits may be increased by picturesque surroundings, how much pleasanter a thing shopping would become! In the sale room in question a judicious arrangement of mirrors and pot plants makes the sale of tea appear a mere incident. In two alcoves and several other nooks and corners tiny tea tables are arranged. At these tables present and prospective customers are served with tea. Smart 'buttons' execute all orders for refreshment and you cannot pay a bill or even lodge a complaint without being offered a perfectly made cup of tea. Electric fans keep the place delightfully cool and comfortable, while the civility with which this firm has always been associated makes dealing with it a pleasure.

A CHAT WITH ONE OF THE POWERS THAT BE in the firm elicits the fact that the increase in business has rendered it expedient for Griffiths Bros. to bespeak the whole output of one of the

best tea planters in Ceylon. As a matter of fact, their arrangement means something more than this, since the plantation is being worked more or less under their direction. The plantation in question has a yield one is diffident about putting down in plain figures. History relates that Australians, next to Russians, consume more tea per capita than any other people. Even then figures connected with the tea trade are staggering, even when the said figures are merely those of an individual firm from one single source. The tea from this lately acquired plantation is of a character that can hardly fail to maintain the reputation of the firm dealing with it. It is no cheaper than any other good tea. The fact has been long since recognised by every level-headed housewife that cheap tea is very poor economy. Other housewives have yet to learn that a tea at one and ninepence a pound goes twice as far as tea at a shilling, beside being infinitely more wholesome into the bargain. You may buy tea from this firm at as low a figure as prices go in the tea trade, but you will do it against the better judgment of any educated individual who sells it to you.

CEYLON IS BY NO MEANS THE ONLY MARKET from which Griffiths Bros. get their teas. China and India furnish their quota, tea from the latter place having been practically introduced to Australia by this firm. No one tea is universally popular, a blend of Chinese and Indian tea commanding a better sale than the unmixed tea from either country. Beside tea, the firm deals largely with coffees and cocoas at its warehouse in Flinders Street. Regarding this warehouse, more anon. It contains the elements of much interest, and is deserving of more attention than can be given it in the terminal paragraph of a dissertation on a tea house.

TEA-GROWING IN VICTORIA.

As a last word on the tea question, I may tell you that the tea plant may be induced to grow without any difficulty in Victoria. It is doing well in Mr Griffith's garden at Bayswater, and it makes an exceedingly pretty ornamental shrub. Economic conditions are against it being grown for commercial purposes, as the land can probably be turned to greater profit by other means. At the same time, it is an interesting item to add to your garden, the flower as well as the foliage having much to recommend it.—*Melbourne Leader*, April 11.

PLANTING JOTTINGS.

Mid Dimbula, May 1st.—The landscape is looking green again and tea bushes are budding. The 45 days' drought up to date has made

SHORTAGE OF FLUSH

for this month universal. Rainfall for the month is 6.70 in., making 13.02 to date, against 21.43 last year.

"The secrets of nature have been opened out to us on a thousand lines." Width has been given to our intellectual horizon. "Those who share the same pursuits are drawn in spite of themselves into sympathy and goodwill. The acrimony of controversy has almost disappeared." So said Froude! Having read with great interest "Agricultural Ledger No. 1 of 1903" on "Tea Pruning" I read with the greater astonishment your quotation from *Indian Gardening and Planting*. "O. P.'s" remarks on same, and his tirade against its worthy authors:—"Too evident effort at

BELITTLING THE MENTAL PROPORTIONS OF THE AVERAGE PLANTER!"

"The amazing assumption that planters are generally not up to their work"! "The planter must not be called names or have it suggested that he is an amateur at making his bread and butter"! I had read the "Agricultural Ledger" referred to without discovering any "evident effort to belittle the planter", and I have re-read the ledger and absolutely fail to discover any reason for offence. The idea of an Agricultural Ledger is a great one. The amount of good resulting from such a ledger must be immense. Sir George Watt is deserving of the planter "sympathy and goodwill" more than that of anyone else. That the Ceylon planter is not of the type to assign Agricultural Ledgers to the "obscurity of dust and cobwebs" is evidenced in the present keen interest taken in

MESSRS. GEORGE STEUART & CO.'S COMPETITIVE PRUNING ESSAY.

The scientific side of the case is not *only* of "academic interest to practical men", but has in Ceylon and elsewhere been made the basis of much practical experiment. I am sure that Sir George Watt in his Agricultural Ledger work has the "sympathy and goodwill" of at least every Ceylon planter.

One thing given emphasis to in the *Observer*, as if emanating from Sir George Watt, was the principle of pruning just above a bud. This very point was emphasised by Mr Kelway Bamber ten years ago in his book of 1893, where he remarks upon the difficulty of working out such a principle with the type of labourer at the planters' disposal.

There is a most interesting article on "EXPERIMENTAL MANURING"

in the last issue of "Amateur Gardening" which says the analyses of the ash of plants are not an infallible guide. For instance, the ash of the turnip contains 50 per cent potash and 16 per cent phosphoric acid, which would naturally lead one to suppose that a heavy dressing of potash manure would make an immense difference to the growth—whereas experiment shews that phosphates have a far greater effect than potash. Fourteen years' experience teaches the writer that "analyses may be helpful, but carefully conducted experiment is by far the truest guide to success." Ceylon tea manuring is very largely based on analyses; and what is not based on analyses is merely the adoption of some current prescription. Mr. W Lennon, in his paper on tea soil cultivation read before the "Luxepore Valley Society of Planters," quoted in *Indian Gardening & Planting* of 10th January, stigmatises the sheep-like tendency of planters in thinking that what is good for the goose is good for the gander, and emphasises that a variety of soil requires a variety of treatment. Perhaps it is not so much a sheep-like tendency, as that most planters have not a free hand to "experiment" with the tea under their charge. There ought to be special tea laid aside for no other purpose than that of "carefully conducted experiment."

GENERAL CEYLON TEA ESTATES, LTD.

DIRECTORS.—James Sinclair, Chairman; Keith F Arbuthnot, T J Lawrence, and T C Owen.

The Directors beg to submit herewith the accounts of the Company and their report for the year ending December 31st, 1902, showing a profit of £9,553, 8s 9d.

After allowance for debenture interests and other charges, there remains a sum of £1,214 2s 2d at the credit of profit and loss, to which has been added a balance of £2,210 19s 10d brought forward from the previous year, making a total of £3,425 2s, out of which the directors have written off a sum of £2,000 on account of depreciation of plant and machinery, and propose to carry forward the balance of £1,425 2s.

The crops from the Company's estates amounted to 2,318,881 lb tea, exclusive of bought leaf (116,011 lb), 2,314 bushels of coffee, and 262 cwt. of cocoa: against estimates of 2,581,190 lb tea, 2,530 bushels of coffee, 250 cwt. of cocoa.

The tea cost, sold in London, 521d, and realized 605d per lb. The exchange for the year averaged 1s 4 17-64th d.

The yield per acre was 430 lb. over the fields in full bearing, after allowing 200 lb. per acre for the partial bearing fields.

The present cultivated area is as follows:—

	Acres.
Tea in bearing ..	5,298
Tea in partial bearing ..	179
Not in bearing ..	167
Cocoa ..	149
Coffee ..	68

Total cultivated area 5,861

The past year was one of very severe depression in prices, which during the summer, touched the lowest point ever experienced. The estimated tea crop, owing to labour difficulties and very unseasonable weather during the last three months, fell short of the estimate by 262,309 lb. Since January last, however, a marked change for the better has come over the tea market, owing to the favourable statistical position of the article, and there seems every reason to believe that the industry has again entered upon a period of prosperity.

A new factory had to be erected upon Hemingford estate, at a cost of £2,115 7s 5d, to replace the old building, which was reported as dangerous. This and other expenditure has been charged against revenue, and makes the cost of production appear high. Eliminating these charges, the cost of the Company's teas sold in London was 498d.

Mr. Keith F Arbuthnot, the Director, retiring by rotation, being eligible, offers himself for re-election.

CEYLON TEA PLANTATIONS COMPANY, LIMITED.

REPORT OF THE DIRECTORS

to be submitted at the Sixteenth Annual Ordinary General Meeting of Shareholders, to be held at the Office of the Company, on Monday 27th April, 1903.

The Directors have the pleasure to submit the General Balance Sheet and Profit and Loss Account for the year ending 31st December, 1902, duly audited.

The net amount at credit of Profit and Loss Account, including Balance brought forward at 31st December, 1901, and after providing for General Expenses, Directors' Fees, Income Tax, &c., is

£ 46,554 16 9
 Dividends the on 7 per cent Preference Shares were paid for 1902 (less Income Tax) amounting to £5,320 1s 2d; an Interim Dividend of 7 per cent on the Ordinary Shares was paid 29th October, 1902, amounting to £11,716 12s; it is proposed to pay a final Dividend of 8 per cent on the Ordinary Shares making 15 per cent in all, free of Income Tax, which will absorb £13,390 8s; to write off for Depreciation £10,000;

and to carry forward to next year a Balance of £6,126 19s 7d—Total £46,554 16s 9d.

It is with pleasure the Directors are in a position to report that the year's working enables them for the sixteenth year again to recommend the usual dividend of 15 per cent., free of income tax, to the Ordinary Shareholders.

During the past year the average price of British grown tea showed no improvement on that of 1901, but owing to diminished supplies and a steadily increasing consumption, prices have now materially improved. The excessive rainfall and sunless weather, which prevailed during the last six months of the year, effected the yield of tea on the Company's estates, which was 71,514 lb. short of the previous year's output. The following shows the quantity of tea accounted for in the profit and loss statement:—

Estate tea lb. 3,885,821. Bought leaf tea lb. 369,683. Tea manufactured for others lb. 304,477. Total lb. 4,559,981. The average gross price for the tea sold in London and elsewhere, including bought leaf, was 7-24d., compared with 7-41d the previous year, and the rate of exchange 1/4 15-64d, the same as last year. During the year the Company manufactured 513,489 lb. of green tea for the American and Canadian markets, as compared with 73,278 lb. in 1901.

The coconut crop was a favourable one, and amounted to 1,740,968 nuts, or 339,200 nnts in excess of the previous year. The Company has become interested in a patent process for treating the kernel of the coconut, and the necessary machinery is now being installed on one of their estates. From this new mode of manufacture the Directors have good reason to hope for remunerative results.

Progress has been made in the further planting out of Para Rubber, which will be continued during the current year on any of the Company's land considered suitable for this product.

The Board has again to acknowledge the good services rendered by the Ceylon Manager and his Staff during the past year. Under Clause No. 69 of the Articles of Association, Mr David Reid retires on this occasion from the Board, and being eligible offers himself for re-election. The Auditors, Messrs Harper Brothers, Chartered Accountants, also retire from office, and offer themselves for re-election.—By Order of the Board, Wm. JOHNSTON, Secretary. London, April 18.

KELANI VALLEY TEA ASSOCIATION, LD.
REPORT OF THE DIRECTORS.

To be presented to the shareholders at their seventeenth ordinary general meeting, to be held at the Office of the Company, on Wednesday 29th April 1903, at 2.30 p.m.

The Directors beg to submit to the Shareholders the Report and Accounts of the Company, duly audited, for the year ending 31st December 1902, and they regret that the results is so unsatisfactory.

The crop obtained from the four Estates amounted to 570,163 lb against 549,906 lb in the previous years the average price realised for the Tea sold in London was 5-813d against 6-206d in 1901, and the average price for the Tea sold in Colombo was 28 cents.

The average rate of Exchange was 1/4 11-32nds compared with 1/4 3-8ths in the previous year. As will be seen, the average price obtained for the year under review is considerably less than that for 1901: this is due to the very low prices ruling for the greater part of the year, and mainly accounts for the reduced profits shown. After paying Debenture Interest and other charges the balance at credit of Profit and Loss Account, including the amount brought forward from the previous years is £432 0s. 9d., which your Directors propose shall be carried forward to the current season's accounts.

The Board considered it advisable to make a chan in the Superintendence of Weregalla and Paruse Estates, and they therefore dispensed with the service of the Manager of those Estates, and appointed his place Mr M J Paine, who took over charge in Ju last. On the strong recommendation of the Manag i Director, who is at present in Ceylon, and Mr Mitchel the Board have sanctioned the making of Green Tea at Weregalla Factory.

In accordance with the Articles of Association, Mr J W Stocks retires from the Board, and being eligible, offers himself for re-election.

Mr J B Laurie, c.a. also offers himself for re-election as Auditor.

G W PAINE, -Chairman.
16, Philpot Lane, London, E C, 17th April 1903.

THE PANAWAL TEA COMPANY.
REPORT OF THE DIRECTORS.

The Directors beg to submit the general balance sheet and profit and loss account for the year ending 31st December, 1902, duly audited:—

The net amount at credit of profit and loss account, including balance brought forward at 31st December 1901, after providing for general expenses, Directors, Auditors' fees and income tax.—£1,576 9s. 2d.

Dividends on the 7 per cent cumulative preference shares were paid for 1902, in full, amounting to—£371 0s.0d.

It is proposed to pay a dividend of 7 per cent on the ordinary shares for the year ending 31st December 1902, which will absorb £1,190 0s. 0d.

Less income tax at 1s. 3d. in £74 7s. 6d.—£1,115 12s. 6d.

To add to reserve, fund bringing it up to £1,800,—£80 0s. 0d.

Leaving a balance to be carried forward to next season of £9 16s. 8d.—£1,576 9s. 2d.

The Directors recommend the distribution of a dividend at the rate of 7 per cent. (less income tax at 1s. 3d. in the £) on the ordinary shares of the Company for the year ending 31st December, 1902.

The Directors have to report that the condition of tea growing industry appears to be gradually improving.

During the past year further progress has been made with the planting of para rubber in the ravines and in suitable land in the jungle. The acreage of the Company's properties stood on 31st December last at—Tea in full bearing 590; Jungle partially planted with para rubber 341½, Total 931½ acres.

The crop realised for 1902 was 275,563 lb. The visiting agent (Mr F J Clements) in his last report on the properties mentions that there was a lack of sunshine during the past season, but that the cultivation of the estate and the condition of the machinery, &c., are generally satisfactory.

Mr John Holgate Batten, the Director, retiring by rotation being eligible, offers himself for re-election.

THE MADULSIMA COFFEE AND
CINCHONA COMPANY, LTD.

REPORT

to be presented to the twenty-third ordinary general meeting of the Company, to be held within the Office of the Company, 4A St. Andrew Square, Edinburgh, on the twenty-first day of April 1903, at 12-30 o'clock afternoon.

There is submitted herewith the Crop Account for season 1901-1902, together with a Statement of Profit and Loss Account, and the Balance Sheet showing the financial position of the Company at 31st December 1902. It will be seen that the Crop Account shows a surplus of £4998 13s 8d. After crediting Profit and Loss Account with this sum, providing for Interest and Home Charges for 1902, and applying the sum £1000 in reduction of the value at which the Company's Estates appear in the Balance Sheet, there remains at the credit of Profit and Loss Account the

sum of £4301 6s 4d. Out of this sum the Directors recommend payment of the Preference Dividend for the year at the rate of eight per cent, subject to deduction of income-tax. This Dividend will absorb £2296, leaving £2005 6s 4d to be carried forward. After payment of this Dividend there will remain seventeen per cent of arrears of Dividend on the Preference Shares. The Tea Crop amounted to about 632,000 lb, averaging 6 15-16d per lb gross, as compared with 476,000 lb, averaging 7 31-32d for the preceding year. For the current season it is estimated that the crop will amount to 590,000 lb. The average rate of exchange was 1s 4 3-32d per rupee, as compared with 1s 4 1/2 for 1901 and 1s 4 3-16d for 1900. The Company has now 1470 acres of Tea in bearing, and 45 acres of young tea, making a total of 1515 acres under Tea. The Directors having ascertained that Mr. W. G. Lang is willing to join the Board (to fill the vacancy which occurred in 1900), his election will be proposed at the Meeting at which this Report falls to be presented. Mr. Pitman, in order of rotation, retires from the Board at this Meeting, and is eligible for re-election. An Auditor for the current year falls to be appointed. Mr. Findlay B. Anderson, the present Auditor, offers himself for re-election. By Order, E. A. DAVIDSON, Secretary.

THE HAPUTALE COMPANY, LIMITED.

REPORT

to be presented to the fifteenth ordinary general meeting of the Company, to be held within the registered Office of the Company, 4A St. Andrew Square, Edinburgh, on the twenty-first day of April, 1903, at 12:45 o'clock afternoon.

There is submitted herewith the crop account for season ending 30th June, 1902, together with a Statement of profit and loss account, and the balance-sheet showing the financial position of the Company at 31st December, 1902. It will be seen that the crop account shows a surplus of £3,809 1s 1d. After crediting profit and loss account with this sum, and with rents, &c., &c., received, and after applying the sum of £700 in reduction of the value at which the estates appear in the balance-sheet, there remains at the credit of profit and loss account the sum of £3 993, 5s. Out of this sum the Directors recommend the payment of a Dividend on the Preference Shares at the rate of four per cent, subject to deduction of Income-tax. This Dividend will absorb £2,308, 10s 10d., leaving £1,689 14s 2d. to be carried forward. After payment of this Dividend, the arrears of Dividend on the Preference Shares will amount to thirteen per cent as at 31st December, 1902.

The Tea crop amounted to 350,000 lb averaging 8 9 3/32d per lb gross, as compared with 89-10d for 1901 and 9 23-32d for 1900. For the current season the estimate is about 350,000 lb. The average rate of Exchange was 1s 4 5-64d per rupee, as compared with 1s 4 3-32d for 1901 and 1s 4 3-16d for 1900. The Company has now about 1394 acres under Tea, of which 1019 acres are in bearing. The Directors having ascertained that Mr W G Lang is willing to join the Board (to fill the vacancy which occurred in 1900), his election will be proposed at the Meeting at which this Report falls to be presented. Mr Pitman, in order of rotation, retires from the Board at this Meeting, and is eligible for re-election. An Auditor for the current year falls to be appointed. Mr Findlay B Anderson, the present Auditor, offers himself for re-election.—By Order, E A DAVIDSON, Secretary.

RUBBER TAPPING AT THE STRAITS.

During the past few weeks, a number of high Government officials, planters from the Native States, and other persons interested in the development of the Peninsula, have been making a regular morning *rendezvous* of the Economical

Gardens at Cluny Road. The cause of this has been the remarkably interesting demonstrations of the result of experiments lasting many months, in the matter of extracting the *latex*, or sap from the Para rubber trees that have been planted there for experimental purpose. In view of the fact that within the next few years, Para rubber is expected to rank next to tin as the staple product of the Straits, anything affecting its cultivation of harvesting becomes a matter of prime public importance. The main item of interest about the demonstrations rests in the fact that Mr. A D Machado, who has carried out the experiments, and now cheerfully demonstrates the results thereof every morning, has found it possible to "milk" a tree every second day for six months in every year without in the least hurting it or impairing its growth, and at the same time he can secure the greatest possible amount of the valuable *latex* from which the rubber is subsequently formed. Heretofore the system in vogue has been to make large gashes in the bark of the tree and catch the *latex*, or white sap, as it flowed therefrom, in tin cups or other receptacles. In the more advanced plantations, the plan followed has been to make a so called "herringbone" gash, with contributory smaller gashes leading into it, looking like the bones of a fish as shown in the cut below. The spine, or main gash in this system would measure from eight to about fifteen inches long, by from a quarter of an inch to three-quarters-of-an-inch wide, according to the size of the tree, and the side gashes would be proportionately larger or smaller. Mr Machado, however, has discovered that the best results are obtainable from a series of little incisions—mere nicks—measuring 2 inches long by only 1/8 inch wide, four of which only equal one narrow incision of 8 inches by 1/8 inch in the bark of the tree. Such a series of tiny wounds is utterly harmless, and it produces a supply of *latex* as ample as does the great "herring-bone" cut which was often capable of seriously injuring, and even of killing a tree. The proof of the pudding being in the eating, it is as well to state at once that from 100 trees, averaging from 12 to 15 years of age, and planted much too closely together to admit of their being properly developed Mr Machado draws an average of about 3 lb. of dried rubber daily, and he expects the supply to be maintained for six months—working half the trees each day during that period. Then the trees will be given a rest for six months, while another 100 will be tapped, and then the original 100 will be tapped again.

In response to queries on the subject Mr Machado has furnished the following data as regards his experiments and the results thereof:—Tapping operations were begun on the 4th March, but it was not till the 20th March that 100 trees were regularly tapped with 4 incisions to each tree. Each incision is 1 1/2 inches long by 1/8 of an inch wide. Four incisions would mean in length 6 inches of a cut to each tree, barely more than a scratch one may say. One noticeable feature is that some trees yield much more copiously than others, and this may be due to the position of the trees as regards shade, soil and moisture. Irrespective, however, of these important factors, there can be no doubt that some trees are physically more productive than others, for much the same reason that one man is stronger than another and so on. The 100 trees operated upon occupy a triangle 176 feet by 220

feet by 250 feet, or barely more than $\frac{1}{4}$ acre, from which it will be observed that they are much too close—a condition by no means favourable for the production of latex. Still, results go to show that the present output, as obtained by means of small cuts, is all that can be desired. The flow of latex is more copious on the morning of a day following a heavy shower of rain than on a dry day: in fact, in very dry weather it would be almost advisable to cease tapping altogether.

ROUGH SKETCH, SHOWING THE OLD AND NEW SYSTEMS OF "MILKING" RUBBER TREES.

The above sketch represents the trunk of a Para rubber tree, nine inches in diameter, and shows the relative sizes of the incisions made according to the plan commended by Mr A D Machado, and the old "herring-bone" system, as depicted lower down near the root of the tree. The incisions made under the new regime are only one-and-a-half inch long, by one-eighth of an inch in width. The cups shown under the incisions are roughly soldered tin affairs, made out of old oil cans. They are simply thrust into the bark of the tree immediately under the incisions, and the latex flows into them. Prior to being affixed to the tree, a little water is poured into each cup, so that the latex or sap, may not dry too soon and stick to the bottom. After about half an hour, the cups are taken away and emptied into a big enamelled-ware dish, where the latex is quickly coagulated by the addition of about a tablespoonful of acetic acid to the product of 50 trees. The emptied cups are rinsed out in another dish, and the latex therefrom is also coagulated. The mere rinsings of these cups from the 50 trees give about half a pound of rubber. The way the latex is extracted and prepared is simple in the extreme. As soon as a cut is made, either with a small axe or a chisel, a tin cup,

enlarged at the apex and tapering towards the bottom—called in the Amazons a *tijellina*—is inserted beneath the wound, and into it the latex flows. At six o'clock tapping begins, and by 6-30 a.m., tapping is over. At 7 a.m. the cups are gathered in, the latex passed through a sieve to ensure cleanliness, a little acetic acid is poured in to hasten coagulation, and the latex is then poured into enamelled soup plates and in about half an hour's time coagulation is complete. The latex, which at this point resembles stiff blanch-mange, is then put into a press and whatever water remains is pressed out. It is then placed over a kitchen fire (wood fire) to dry, after which, if the sheets are thin it assumes a dark yellow colour and is transparent. Drying in the sun will not do, as this causes the rubber to turn sticky. Taking the average for the last 12 tappings, the average daily output of pressed rubber has been 87 oz or lb 5'44. There will be a loss in weight of 40 per cent. when the rubber is thoroughly dry after smoking—leaving, say, 3 lb of dry rubber for each day's tapping. At the present rate of tapping, these trees will stand tapping for 90 days, tapping them preferably every alternate day, or say 6 months in all. This means 3 lb a day for 90 days, 270 lb at 4s a pound, the price at which this rubber is valued in London, and the result is a return of £54 per 100 trees per annum. At half this figure the profit still remains stupendous. Self-coagulated rubber is said to be better in quality than rubber prepared with acetic acid, but the time taken for rubber to coagulate by itself is from 16 to 20 hours, whereas, with acetic acid, from the time the incisions are made to the time the rubber is pressed and ready to be smoked, occupies just two hours, a matter of some importance where time is of some object. The system of tapping now carried on—oblique incisions—is the one in vogue, in the Amazons. The "herring-bone" system has been described by M. Bonnechaux, a gentleman who for some years was a rubber collector in the Amazons, as little short of barbarous and it is said that it speaks volumes for the vitality of these trees in that they have survived the ordeals thereby entailed. In the Amazons these trees would have succumbed to the torture. That it is harmful is proved by the fact that one of the 100 trees now being operated upon had a herring-bone incision made on it, and is now producing next to no milk. It is well to reiterate the fact that the trees now being tapped are planted much too near each other, and are growing under excessively unfavourable conditions generally. In spite of this, they yield an average of 3 per lb. tree per annum. The average circumference of the trees is 2 feet 10 inches, the largest being 5 feet 1 inch, and the smallest 1 feet 3 inches. —*Straits Times*, April 16.

CAMPHOR SUBSTITUTES IN THE CELLULOID INDUSTRY.

The important part played by camphor in the celluloid industry is a matter of common knowledge. Indeed, it may be said that without camphor there would have been no celluloid in the past. Its use, however, is not without several drawbacks. In the first instance, camphor is a rather expensive product, and one, moreover, the price of which is subject to very considerable fluctuations. Many attempts have therefore been made to find a satisfactory substitute for this product, but until comparatively recently these attempts did not achieve any particular measure of success.

In the last few years the importance of finding a satisfactory camphor substitute has been increasingly realised, and the efforts of a large number of chemists have been directed towards this end. The most obvious product to employ for this purpose is, of course, the product known as artificial camphor, a terpene hydrochloride. This substance appeared to work entirely satisfactorily, but it was soon observed that celluloid articles manufactured with this substitute after a short time lost their transparency and the delicacy of their colouring. Eventually, they became altogether brittle, and therefore useless. Although it was discovered that these effects were due to the presence in the artificial camphor of certain impurities, the cost of effecting the necessary purification was found to be excessive. It appears that this difficulty has now been entirely overcome by the discovery of an extremely cheap process for the refining of the artificial camphor, and it is stated that the pure product yielded by this process is greatly superior to real camphor in the manufacture of celluloid articles. In the meantime, however, a very large number of compounds have been patented, all of which are claimed to be satisfactory substitutes for part or the whole of the camphor used in the manufacture of celluloid. No doubt a considerable proportion of these alleged substitutes will never pass beyond the experimental stage in the manufacture of celluloid, but there is no doubt, on the other hand, that quite a number of them answer their purpose in a very satisfactory manner, and will prove a most useful addition to the resources of the celluloid industry.—*India-Rubber Journal*, April 13.

PRESERVING BOOKS IN THE TROPICS.

The books should be lightly painted over by means of a camel's-hair brush, both outside and inside the covers (and especially along the margins and backs where paste has been used), with a mixture as follows:—

- 1 oz. Corrosive sublimate,
- 1 oz. Carbolic acid.
- 2 pints methylated or white rum spirit.

This solution (if carefully applied) will effectually preserve books with either paper, cloth or leather covers from cockroaches and other insects. No harm will be done to the books, and after the mixture has dried they may be handled with perfect safety.

Every new book received should be at once treated in this manner. The result will be that they will keep in as good order in the tropics as in temperate climates.

Bookbinders in the tropics are recommended to use a paste poisoned by adding half an ounce of copper sulphate (or blue stone) to every pound of paste.—*Agricultural News* Jamaica.

CITRONELLA OIL.

(To the Editor, "Chemist and Druggist.")

SIR,—Our experiences as exporters of citronella oil from Ceylon may possibly prove of interest in view of the discussions and articles appearing in your journal on the adulteration of this export.

The prevention of excessive or, in fact, any adulteration rests mainly in the hands of the home importers, who would obtain a very fair oil if they would pay a fair price, but who, availing themselves of the cutting competition which was started a few years ago, so reduced the price of the oil that it has been an open secret for some time past that the distillers were unable to produce it at a profit to themselves unless they resorted to adulteration. This policy of cut-throat competition will exist as long as home buyers are content

with Schimmel's test, which, according to our experience, admits of an adulteration of about 15 per cent. of petroleum. His Excellency Sir West Ridgway, in his recent speech at the opening of the present sitting of the Legislative Council, referred to the subject of the increasing adulteration of this Ceylon export and the consequent discredit which was coming over the trade. We immediately inquired of the Director of the Botanical Gardens as to the steps Government contemplated taking, and were informed that they proposed to plant up an acreage with the grass in order to demonstrate to the distillers that a better oil could be produced. We suggested that Government should rather cause every shipment exported to be analysed by the Government analyst; buyers could then obtain an analysis of the shipment before accepting it, and it would ultimately result in exporters being compelled to send such certificates with each shipment. Winter's oil, which, we notice, has formed the subject of one of the experiments mentioned, has always been exported by us as their agents. It is obtained from a grass imported years ago into the island by Mr Winter, and is not identical with that cultivated by the natives; in fact, it is only grown on his estates, and its distillation is supervised by a European manager, so that there is no question about its purity.

Our experience having shown us that Schimmel's test was unreliable, we worked out and adopted a test of our own, which gives, in our opinion, very satisfactory results, and for the disclosure of which we have had at least one offer. We have for many years in consequence been compelled to pay a higher rate for oil satisfying our test than we should have had to pay had we adopted the milder standard of purity, and, being adverse to shipping oil which would not pass our standard, we lost ground in the trade in proportion as the adulteration and the consequent difficulty in obtaining pure oil increased. In truth, the quality had fallen off to such an extent that during the past three years we have exported but a quarter of the quantity yearly than we had done during the previous six years.

The test we employ is distinctly a practical one, and we have always obtained good results from it, though we would by no means claim that it is better or surpasses a thorough quantitative and qualitative analysis at the hands of an expert analyst. Contrary to the opinion of Messrs. Parry and Bennett, and with all due deference to these gentlemen, we do not think that any resin-spirit as a distinct article is the medium of adulteration. We have an intimate acquaintance with the districts where the oil is distilled, and are not aware of any other oil or resin-spirit being made which could be used as an adulterant; but, in our opinion, the adulterant is the same as it has been for the last ten or fifteen years—namely, petroleum or, as it is more commonly called here, kerosene. The only change that may possibly give rise to the suggestion and presence of resin-spirit is that change in kerosene which has taken place within the past few years, for the Russian bulk petroleum installations have almost altogether ousted the former American qualities, and, being carted from door to door as it is, a cheap, handy, and well-known adulterant is at hand to every native wishing to increase the quantity of his distillate. The differences between the two petroleum mentioned are very marked, and if

Messrs. Parry and Bennett were to experiment with a pure oil and Russian kero-sene we think it very probable that they would arrive at the same results as they have done in the adulterated samples they have examined.—Yours faithfully,
 CHAS. P. HAYLEY & CO.

VALUE OF THE TREE TOMATO.

Mrs. T B Shepherd, an eminent florist and who resides in Ventura, says that when the value of the tree tomato as a fruit is once fully appreciated acres of it will be planted. It bears from seed the second season, and a young plant set out in the spring grows six feet and comes into bearing by Christmas. The foliage is large and handsome, the branches spreading. The fruit is pendant in clusters below the foliage, is the size of a large egg and of a beautiful orange, salmon colour when ripe. It has a decided sub-acid taste, slightly resembling the tomato. It is delicious raw, served with sugar and cream or cooked as sauce, and for jelly or jam is very fine. It will keep for weeks, as it does not bruise on account of its very tough skin and the solid nature of the fruit covering the seeds which are like those of the tomato. It is a showy plant for house and conservatory, and a most beautiful plant in the garden. It is a native of South America, and is known as the poor man's fruit.—*Rural Californian*, for March.

PLANTING NOTES.

PROFITABLE POULTRY.—Nearly 8s per hen profit was made for the year ending 1st November by I B Koons, of Lehigh county, Pennsylvania, U S A, who started the year with thirty-eighth Plymouth Rocks. They laid 4,118 eggs, which at an average of 11d per dozen brought a little over £15. Chickens sold and dozen brought £4 15s, and the increase in the flock of forty-two head was valued at £4, making a total income of £23 15s. The expenses for feed were £10, leaving a net profit of £13 15s 5d. During the year four fowls were lost through disease. This shows that fowls—well cared for—are profitable live stock.—*Agricultural Journal*.

THE "TEA TORTRIX."—Our remarks on the "tea tortrix" on page 832, in view of the notice drawn to it at the previous day's meeting in Dimbula, were none too strong and—in higher districts especially—if work for the pluckers is short, a careful round should be made, of search for tortrix egg-masses, and coolies paid according to the quantity brought in. This is what Mr E E Green has to say on the pest in his Administration Report—to which we alluded yesterday:—

(*Capua coffearia*, Neitner).—This pest, which has attracted attention on and off for the last six years, has given considerable trouble in parts of the Maskeliya and Dikoya districts during 1902. Two separate visits were made to Maskeliya to study the insect, resulting in a more accurate knowledge of its life-history which has enabled me to suggest remedial measures that should be sufficient to keep the pest in check. The eggs of the insect have been determined, and it has been found possible to collect and destroy them in very large numbers at a very small cost. A circular on the subject was prepared in December, accompanied by a plate showing the insect in all its different stages. Through the courtesy of the Acting Surveyor General this plate was executed by the lithographers of that Department.

THE RESHIPMENT OF TEA FROM AMERICA TO LONDON.—*Appropos* the letters of a firm of merchants which have appeared in recent issues of the *Observer* on this subject we note the following in the *American Grocer*, April 1st:—"Further large quantities of Congou teas have been sold for export to London. There was talk among brokers that several large English firms have standing bids here, which, however, are 3/8c. per pound below sellers' views here. At the bid prices, the above English firms, it is said, are ready to clean up all supplies of Congou teas in this market." The same paper also states that the new crop Japan it is expected will arrive there in the early part of May. Formosa and Congou will arrive about the same time, while new crop Ping Suey will not come in until June.

INTELLIGENCE v. PESTS.—We commend the following from an American journal to the attention of our cacao planters, each of whom ought to do his duty in fighting any fungus or canker, for his own as well as the general benefit, without compelling legislation:—

When the cultivation of oranges for profit in Southern California began, the orchardists were met in the outset by the ravages of scales which threatened to destroy their young orchards. No known means of combating the pest was available, but such means were soon discovered and the powers of the legislature were invoked to compel all orchardists to unite in destroying the pests. The same is true in the islands. Difficulties will be encountered at first, but the intelligent farmers will win in the end.

CONSUMPTION AND EUCALYPTUS.—Dr. Gandevia and others in Ceylon interested in consumptive patients should see a fair trial given to the following remedy as reported by the Berlin correspondent of a London daily paper:—

"An important discovery has been made by a German savant which, if it does not exterminate tuberculosis altogether, is expected by its advocates to go further to reduce the ravages of this dread disease than any other curative agency known. Under the supervision of Professor Sommerfeld, a physician of great reputation, the new method was tried at several hospitals for about six months, at the end of which time the most gratifying results were recorded. Of 100 cases of tuberculosis, including all stages of the disease, sixty were pronounced entirely cured. The process is as follows: Oil of eucalyptus is mixed with sulphur and charcoal, and this mixture is then evaporated over specially-constructed alcohol lamps. The vapours inhaled by the patients killed the tuberculosis bacilli. In some cases the patients were kept day and night in the atmosphere thus impregnated until they showed signs of relief. I have interviewed Professor Sommerfeld, who is anything but a notoriety seeker. He said he did not wish to encourage any over-sanguine hopes, but he was sure that "sanosin," as the new curative agent is called, constituted an enormous advance towards the extermination of tuberculosis."

CASTILLOA RUBBER.

We cannot well understand what Mr. G. C. Pearson writing in *Modern Mexico* as quoted below means, when he condemns Ceylon as unfit to grow *Castilloa* rubber, profitably. We cannot see that the figures quoted for yield by him in respect of Mexico and Central America are so much more favourable than those of the late Dr. Trimen on which the condemnation is apparently based. Mr. Weber got 2 oz. rubber from 6-year old trees and reckoned he could have doubled this per annum or 4 oz. Dr. Trimen reported over 7 oz. hard rubber from his trees of same age. From 12-year old, Mr. Weber got 3.6 oz.; Dr. Trimen from 11-year old 25.7 ounces—so that how Mr. Pearson can say the Ceylon figures are unfavourable, is very puzzling. But there is some confusion; elsewhere, we are told Mr. Weber's result equalled 11½ oz. rubber from a 6-year old tree, and Mr. Pearson himself reports 3½ oz. from a tree 4½-year old, and rather more from other trees of same age. That the yield depends on climate and soil as Mr. Pearson tells us, is fairly well-known, but it depends also on the methods of tapping, the most suitable varying according to climate. It is thought by those best able to judge that a series of "V" cuts, made spirally round the tree, will be the best suited to the trees grown in the Ceylon climate.

Referring again to the subject of figures, the more businesslike are those given in a report in the *India Rubber World* of the experimental tapping on a regular plantation. The details will be found on page 844, and the result is 112 lb. rubber per acre of 200 trees, 7 years' yield; 174 lb. at 8 years; 249 lb. at 9 years; and 314 lb. at 12 years—or 1 lb. 9.12 oz. per tree, against 1 lb. 9.7 oz. got by Dr. Trimen from 11-year old trees. So that Ceylon again scores.

The great fact, remains, namely, that there is a ready, profitable market for all the rubber likely to be available for a long time to come.

THE YIELD OF THE CASTILLOA TREE

(Written for "*Modern Mexico*" by George Cullen Pearson.)

Well may an English writer in a recent article say that 'the question of the amount of rubber yielded by the *castilloa* is characterised by a degree of discrepancy perfectly appalling.' To instance this: According to Cross, the well-known Kew botanist, a *castilloa* of from 18 to 24 inches in diameter produces 13 pounds of rubber annually, and that exceptionally large trees may give as much as 100 pounds!

Collins observed 'that a 6 year old *castilloa* possessing a diameter of 19 inches' (where can such a development be found?) 'on being tapped in April in the dry season, furnished 20 gallons of latex from which 49 pounds of rubber were obtained,' and he further declares that this is the average yield of all trees, the trunk of which before branching out reaches a height of from 18 to 27 feet above the soil.

Dr. Morris, one of the foremost botanists, now, I believe, director of the Botanical Department in the West Indies, states that a *castilloa* when first

tapped should yield 16 pounds of rubber. If my memory is not at fault, Dr. Morris has stated that the first tapping should take place at 6 years.

In Nicaragua it is found (in consular reports) that a *castilloa* tree yields from four to six pounds of rubber annually. In the U. S. Consular report for October, 1896, I find that 'if the trees have matured properly' in the sixth or seventh year from eight to twelve pounds of rubber can be taken from each tree biennially!

The Bureau de Informations Agricoles de Mexico is more conservative, giving the yield of *castilloa* trees when 4 to 5 years old at 2 pounds 6 ounces of rubber.

Certainly the range is wide enough according to these statements, selected from many similar, showing that the yield of rubber, even of trees not exceeding 6 years' growth, may be anything from 2 pounds 6 ounces to 49 pounds annually.

Now, I am not in a position to prove that these statements, coming as they do from official and authoritative sources, are not correct. I can only say that having given considerable attention to all points connected with rubber culture, my own experience does not bear them out. And I prefer, in common with all who have seriously taken up the cultivation of rubber, to base my calculations of the probable returns on facts as ascertained by actual experiment. The following are the results as obtained myself of the yield of the *castilloa*:—The greatest amount of rubber I have secured from one tree was 12¾ pounds, which I obtained from 30 lb. of milk—about 46 per cent of solid rubber. This was the result of tapping a tree growing on my property which measured two meters nine inches in circumference—87 inches—at six inches from the ground. I may here state that an old *hulero* (native rubber collector) who has worked much with me and in whose statements I have learned to place exceptional belief, a man of long experience, who has collected rubber in all parts of the Republic, told me that the most he ever found a tree to yield was 20 pounds of solid rubber, which he obtained from an exceptionally large tree measuring three meters in circumference—117 inches—growing in a wild part of the State of Oaxaca. He believed the tree to be from 40 to 50 years old. On November 24th last I tapped six trees, averaging 40¾ inches in girth with a net result of 7 pounds 15½ ounces of rubber. These trees were comparatively lightly tapped. If they had been operated on in the wholesale fashion of the native collector at least half as much again would have been obtained. On November 30th I tapped two trees of the respective circumference of 63 and 60 inches, obtaining therefrom 6 pounds 2½ ounces of rubber. As to the age of these trees I can say nothing, as they are wild trees growing on the property. On December 3rd I tapped a rubber tree planted by myself, age 4 years 4 months, girth 26 inches, height 27 feet, the result being 2½ ounces of rubber. Eight days after ward I again tapped the tree and obtained ¾ of an ounce of rubber, making total product 3¼ ounces. A few days later I tapped ten trees, age 4 years and 4 months, average girth 23 inches, obtaining therefrom 22 ounces of rubber. These trees could all have been bled again, the second operation in no way affecting the tree, as I proved by the first-named experiment. In both cases the quality of the rubber after preparation was excellent. On December 7th I tapped a tree of the age of 3 years and 4 months; result ¾ ounce of rubber of poor quality, sticky and little life in it. It need hardly be re-

marked that these experiments were made not for marketable purposes, but in order to see what the increase in yield might be in each successive year.

In order to compare these figures with other, I will quote those obtained by the writer of the article previously referred to. Mr. Weber gives the following as the results of his experiments made at the plantation of Las Cascadas on the Isthmus of Panama:—

	Per tree.
Five-year old trees, mean yield of 77 trees.	2.3 oz.
Six-year old trees do. do. 61 „	2.0 „
Eight-year old trees do. do. 61 „	1.8 „
Twelve-year old trees do. do. 61 „	1.3 „

Mr. Weber states, and in this I quite agree, that 'the trees can with perfect safety be tapped twice yearly; thus the annual rubber yield may be taken at double that in the last column of the table.' He further observes that he considers his figures as rather below than above the mark. It will be remembered that Mr. Weber gives the amount of rubber contained in the latex at from 26 to 31 per cent. This is far lower than I have ever obtained. According to Dr. Ure and Professor Faraday, the percentage of pure rubber in the latex is 45 per cent. I have never found the milk of the castilloa give less than 39 per cent, and in one case, with unusually thin milk from an old and much-tapped tree, I obtained as high as 49 per cent. If, then, we take the yield of a 6-year old tree at 1 lb. 13 ounces, as given by Mr. Weber, the result would be at 40 per cent, say 1½ ounces of rubber, which is, I think, a perfectly safe and conservative estimate. I have no doubt, as Mr. Weber states, that trees can with perfect safety be tapped twice a year, and though the yield may not be doubled, a very material increase of production will result.

My experiments have shown me that trees that have been already bled yield their latex much more freely than those bled for the first time. This was most noticeable in operating on a number of trees on my own land when I found that the milk flowed more readily and copiously from those that had been apparently maltreated for years than from splendid trunks which did not bear a scar. It is also evident that the yield of the castilloa depends much more on soil and climate than has been hitherto supposed.

Dr. Trimen, the superintendent of the Botanical Gardens in Ceylon, gives the following results from trees grown in that island:—

Age of Tree.	Yield of latex, lb. oz.	Per cent of rubber in latex.	Hard rubber, lb. oz.
Six years ...	1 13	26	0 7.5
Seven years ...	2 5	26	0 9.6
Eight years ...	3 1	29	0 14.2
Elven years ...	5 3	31	1 9.7

These results bear out the statements so often made by those acquainted with Ceylon that the castilloa cannot be profitably grown there, owing to shallowness of the soil and the underlying rock bed. It may be that the climatic conditions are also unfavourable, so that planting of the castilloa has in many cases been abandoned.*

Another cause which undoubtedly greatly affects the yield, or at least the free flowing of the latex, is the amount of rainfall in the season preceding the tapping. The fall of rain during the wet season of 1902 was up to the beginning of November not over 50 per cent of the rainfall in normal years. It is stated on reliable authority that so small a rain-

fall has not been known for the past 20 years. I am speaking of the central parts of Vera Cruz and the adjoining State of Oaxaca, though I believe the same paucity of rain was remarked in other parts. Clearly owing to this deficiency of rain, many large trees on the property which in former years yielded abundantly gave not more than half the former amount obtained, the milk running sluggishly and coagulating rapidly. The principal yield was thus furnished by the *grenia* (the rubber which dries in the cuts on the trees). As an instance of this from 13 trees, averaging in circumference 33 inches, I obtained only 126 ounces of milk, which gave me 3 pounds 3 ounces of rubber, or 42 per cent, while the *grenia* collected from the trees amounted to 5 pounds 12 ounces; total, 8 pounds 15 ounces. It was my intention to tap all these trees a second time, but the bad weather of December, when the heaviest rains in the year fell, and subsequently other occupations prevented me from making the desired experiment. But I am firmly convinced that a triennial tapping can, with perfect safety, be carried out, the trees in no way suffering if sufficient time be allowed to lapse between the two operations.—Oaxaca, March 10.
—*Modern Mexico* for April.

RUBBER PLANTING AND EXPLOITATION, RESULTS OF RUBBER TAPPING AT SAN MIGUEL.

An exact record was kept of the results of some recent tapping of rubber trees (*Castilloa elastica*) on the 'San Miguel' plantation, owned by the Tabasco Plantation Co. (Minneapolis), Minnesota, located on the Macuspaná river, in the state of Tabasco, Mexico, which are summarised below. There are on this estate about 400 large rubber trees, which were planted in the shade of cacao and coffee. These trees were not only grown in cacao and coffee, but under the shade of 'mother' trees (not rubber) planted for shading the coffee while the rubber was getting a start. The secretary of the Company, Mr. James O'Field, in communicating these results to *The India Rubber World*, writes:—"A fact well-known to the rubber planters is that trees planted in the shade require a much longer time to attain their maturity and full size than those planted in the sun. In fact, the most casual observer could not fail to notice the astonishing difference in size between the trees grown in the sun and those in the shade. It is believed that the size of a rubber tree has more to do with the amount of rubber which it will produce than its age." In the table which follows is given the age of the trees, except that the age of those placed at 10 and 12 years is not accurately known; the circumference of the trees three feet from the ground; the weight in ounces of the latex secured; and the average yield per tree of dry rubber (including a small amount of scrap pulled from the trunk of the tree after tapping). The details follow:—

Age.	No. of Trees.	Average Girth.	Ounces Latex.	Ounces Rubber
7 years ...	257	33.80"	11.80	9.30
8 years ...	14	37.75"	20.70	14.25
9 years ...	7	40.14"	21.28	18
10 years ...	4	43.25"	26.75	17.50
12 years ...	21	50.50"	40.50	28.90

Based upon the above figures, the rubber product from an acre of land containing 200 trees seven years old would be 112 pounds; at eight years old, 174 pounds; at nine years old, 240 pounds; and at twelve years old, 314 pounds.

* Quite a mistake so far as recent years are concerned.—Ed. T. A.

The following account of the rubber tapping at San Miguel was prepared by Mr. Boyer, the plantation manager:—"We were very fortunate in securing for the plantation a native rubber tapper, who has been raised in the rubber district, and for many years has successfully tapped both wild and cultivated rubber trees in the states of Chiapas and Tabasco. With this experience he was able to obtain the best results without injury to the trees. The first step in tapping a rubber tree is to clean a small place around the tree, a small gash then being made in the bark with the point of a *machete* and a leaf inserted therein, which serves as a spout to run the milk into pails. This leaf is placed about fifteen inches from the ground. From this point the cuts are made upwards at an angle of 45 degrees and extending in each direction a sufficient distance to include three-fourths of the circumference of the tree. Directly above this, a distance of one meter, another cut is made exactly like the first, the milk flowing down the side of the tree into the first cut and on into the pail. These cuts are repeated on the entire body of the tree, or until the branches are encountered. You will at once see that all the milk has not been secured, but a sufficient amount left to maintain the tree in good condition for another year. The next tapping, which will be made in a year from now, will be made on the same side of the tree, three inches above the cut made this year, and the following year three inches above that, so that it will be possible to make thirteen tapings on one side, or twenty-six on both sides; or in other words, a tree can be tapped twenty-six years without re-tapping the old cuts. The instrument used by the natives is a *machete*, or long knife. The bark of a ten-year old rubber tree is about three-fourths of an inch thick. The rubber trees on San Miguel are of the variety known throughout Mexico and Central America as *Castilloa elastica*. This variety is divided into two classes, the first of which is known as the yellow rubber tree, or 'hule amarillo,' this being the male. The milk from these trees flows very freely, having a rich yellowish colour. It flows so freely that there is scarcely any left in the cuts after tapping. The other variety is known as the white rubber tree or 'hule blanco,' this being the female. The cuts made in these trees are not made at a 45 degree angle, but horizontally, a sufficient distance to include three-fourths of the circumference of the tree. The milk from this tree oozes into and fills the cuts, flowing down the tree several inches. The milk is very thick, requiring several days for it to dry so that it can be gathered. Of the two varieties the yellow is regarded as superior. The milk, gathered in pails, is taken to the rubber drying house where it may be converted into rubber through either of the following processes, both of which we have used: First, it is spread on a cement floor to a depth of three-fourths of an inch, this floor being so situated that the milk is constantly in contact with the sun's rays, thus drying very rapidly. After it is dry the sheets are rolled up into convenient sizes for shipment. The second process is through coagulation with a native vine known as 'bejuco de necta.' During the coagulation the rubber is left porous, and as it contains more or less water it is necessary to remove the same by using a press. It requires more time to prepare rubber by the first process. The average shrinkage in converting milk into solid rubber is 2.3, or in other words, 2.3 pounds of rubber milk will produce one pound of rubber. I

have personally attended to the tapping and the figures herein given are absolutely correct."

'CEARA RUBBER' IN EAST AFRICA.

The last *India Rubber World* contained a reference to the interest in rubber of the Deutsch Ostafrikanische Plantagengesellschaft on their plantation at Lewa, in German East Africa. A letter from Berlin offices of that company informs us that the species planted is *Manihot Glaziovii*—the rubber of Ceara—of which they now have 250,000 trees standing. Recently 4,000 5-year old trees were tapped, yielding about $\frac{1}{2}$ pound of latex each, of which they estimated that 30 per cent in weight was lost in drying. This would give a yield of 700 pounds of dry rubber for the 4,000 trees, which, considering the age of the trees, and the good quality of the product, is considered very encouraging.—*The India Rubber World*, April 1.

THE MALARIAL CAMPAIGN:
SIR WILLIAM MACGREGOR'S
AMSTERDAM VISIT.

The report, by Sir William Macgregor-Governor of Lagos, of his visit to Amsterdam, in connection with the water-supply there, as applicable to the Capital City of the West Coast of Africa, which reached us some days ago, is a comprehensive, clear and exhaustive document. It reflects its author on every page, and shows in the keen intelligence, patient research and thorough mastery of detail, those high qualities which have built up the imperial reputation of the West Coast Governor, and have earned for him a stand-out character among the men of gubernatorial rank. Lagos, like all our settlements on the African West Coast, has long suffered from a bad reputation. It has been regarded as a kind of penal settlement, where white men found an early grave, or, if fortunate enough to return home, arrived hopelessly undermined in health. It was a surprise when Sir Wm. Macgregor was appointed its Governor, for the splendid work he had achieved during his time in New Guinea certainly entitled him to a healthier and higher post. If the call came as a disappointment to Sir William, he has successfully hidden away his chagrin and allowed it in no way to affect his public work. Indeed, if anything, it has made him more strenuous, and when he is called on to resign the reins of office, his personality will be visible, and remain visible for good, far into the future years. As a fully qualified medical man, the health conditions of Lagos have had more than usual interest to him as Governor; and, while it would have been excusable in the enervating and depressing atmosphere of its deadly climate to have followed the *laissez faire* policy of his predecessors, Sir Wm. Macgregor, has made improved conditions of his province, his objective, and has spared neither trouble nor pains to effect the removal of causes telling against the health of this Capital. It was in connection with a better water-supply for Lagos, that this high official made in November last, such an exhaustive study of the system which obtains at Amsterdam, for the topo-

graphical and physical conditions of the Dutch City are in many respects nearly similar to those of the African town. Amsterdam has three different sources to furnish it with water for domestic and general purposes—well-water, river-water and water from the sand dunes. It is from latter that the principal supply of potable water is obtained, and it was the hope that the sand dunes of the Lagos coast might be similarly utilised for the requirements of Lagos that brought Sir Wm. Macgregor to Holland. The visit is likely to be very fruitful in good, and to improve much the hygienic conditions of the West Coast Capital. Fever is the scourge which is most dreaded on the West African Coast, and the Lagos Governor has thrown himself heart and soul into the Malarial Campaign. One does not require to read between the lines of his report, to notice how earnest he is that while the *anopheles* mosquito may be reduced if not exterminated, nothing that can otherwise be done for the improved sanitary conditions of his province should be omitted or overlooked. In Holland since the introduction of the "dune" water, the mortality from typhoid has been reduced from 1.910 per 1,000 inhabitants of 40 years ago, to 0.215 of 1880 to 1889, the latest statistics quoted; while Malaria all but disappeared through the destruction of the larvæ of the mosquito by the introduction of sea water into the canals for flushing purposes. Temperature, as well as the salinity of the water, has much to do with the increase of mosquitoes; and as the heat at Lagos has a very much higher range than it obtains at Amsterdam, the results noted there will hardly be a safe guide for the African tropical town. The destructive action of salt-water on the mosquito larvæ is a more hopeful subject; but the minimum degree of salinity sufficient to arrest the development of the mosquito larvæ, has yet to be determined. And in this connection its determination has its own importance for Colombo—if the "fly" nuisance of our own inland sheet of water is only to be remedied by turning the latter into a semi-saltwater lake. Appended to Sir Wm. Macgregor's report is an interesting paper on "Malaria in Holland," by Dr. H. J. M. Schoo of Krommnie. Dr. Schoo's experience in some respects runs counter to the opinion of other experts—for while he traces malaria to the puncture of the *anopheles*, he denies the protecting quality of quinine, which other authorities recommend to be taken when in feverish localities. He had for many years kept his district free of malaria by the long and liberal use of the drug, but the fever had re-appeared in an epidemic form, and he had not found that his people were less affected than in other places where but little quinine was used, and only for short periods. "I cannot, therefore, believe," he says "in the prophylactic influence that Koch attributes to quinine." It is, however, a comfort to know that although quinine may not prevent malaria it can cure it, and acts like a poison on the blood parasites

which appear with the malady, especially on the gametes of which the blood is full. Dr. Schoo says "a single dose of sulphate of quinine, arrests completely the development of the gametes." The cause of the Dutch malarial epidemic, which broke out after some twenty years of immunity is a puzzle to explain, and Dr. Schoo is inclined to find one of the latent centres in the soldiers and others who had returned to Holland from the over-sea colonies with malaria in their systems. This is, apparently, the "unknown factor" in the communication of malaria referred to in our columns but a day or two ago. The centre of the Malarial Campaign is in Lagos, and although Sir Wm. Macgregor may not be the head of it, he is certainly the heart and soul of the enterprise, and displays all the energy and skill of a successful and sympathetic leader. All over the world where the dread fever has its haunts, the Lagos influence is felt, and if the African West Coast Governor had done nothing else to deserve grateful recognition, the impulse he has given to this branch of scientific research entitles him to the honour of having secured one of those famous victories of Peace, which are no less renowned than those of war.

STUMP ROT IN TEA AND COFFEE. INDIAN CRYPTOGRAMIST'S LETTER.

The following is the letter by Dr. E. J. Butler, Cryptogamic Botanist to the Government of India, on "Stump Rot and its Treatment," which was read after Mr. Graham Anderson's memo. on the same subject at the recent meeting of the South Mysore Planters' Association:—

This history of the ordinary cases of stump rot as I have seen it on one Coffee estate in Coorg and on numerous Tea gardens in Assam and Dehra (there being little doubt from what I have seen that the Tea and Coffee diseases are for all practical purposes identical) is as follows:—

A shade tree is cut down or more commonly "ringed" and the stump left to rot in the ground. Some time afterwards, it may be in a few weeks or perhaps not for 18 months or more, the tea or coffee bushes next adjacent to the site of the stump begin to wither and die off. Then a circle further out dies, and year by year the circle grows. On exposing the roots, the old stump is seen to have undergone a peculiar rot which results in a condition by which the outer layers become converted into a soft mass of earth and bark in which whitish cobweb-like patches can be seen here and there. This rot, which usually begins at the base of the tree stump, extends out along the main roots to where these adjoin the roots of a tea or coffee bush. These latter take the rot, and if they are dug out before quite dead, it will be noticed that a knife can be driven in quite easily for an inch or so into the bark of the "collar," with which earth and white patches are found intermingled just as on the tree stump. Having once attacked the coffee roots the rot can pass from root to root even across a few inches of earth and can apparently extend indefinitely. The cause of the disease is a fungus which has been identified at Kew as *Rosellinia radiciperda* (Massee). Though

it is possible that this may commence its destructive action by directly attacking a living coffee root no such case has yet been proved, so far as I know and certainly the usual thing is that the fungus, requires to start on a dead root of some shade tree until having acquired a certain vigour by living on the dead roots, it can then pass on to attack living ones. What you refer to as "mealy bug" may be instances of direct attack without any intervention of a rotting stump, since from your description it closely resembles the condition produced by *Rosellinia radiciperda* in some cases which I have seen.

The evil appears to be on the increase, and in stances have been reported from Assam of the stumps left on clearing the jungle in opening out new gardens, taking the rot and killing off much of the tea two or three years after the clearing was effected.

In dealing with the matter the first thing to be borne in mind is that certain trees only serve to originate the rot. In the tea districts these trees are gradually getting known, and there is a tendency to avoid them as much as possible. Two which have been found very commonly to start the disease are the silver oak (*Grevillea*) and the Bor (*Ficus elastica*). It would be of great value to obtain a list of such trees for the coffee districts by circularising the planters whose estates are known to be affected. Where the tree is not known specimens of leaves, flowers and fruit, pressed between blotting paper and sent to me, will serve for identification. Unfortunately the *Grevillea* is of value on account of its copious leaf production. Still if, as I suspect, it be found as dangerous in South India as in Assam, it will have to be abandoned, and I cannot but think taking into account the great richness of the forest flora of India, its replacement by an equally good shade tree will not be a difficult matter. The Dalbergias should be avoided, for even if they do not affect coffee, the Sheisham (*Dalbergia latifolia*, Kaurarese *Biti*, Tamil *Ili*) itself suffers from a root fungus very similar to (*Rosellinia radiciperda*) which kills many trees in Behar, and which I saw destroying trees in a Coorg coffee estate.

I do not think you could fail to have opinions of great value from planters whose estates are badly diseased for some years as to what trees may be recommended as insusceptible to rot, and I am clear that the question of what shade to employ is one of very great importance not alone as regards stump rot, which I repeat is increasing, but also from the influence certain trees exert on the coffee growing under them.

When the disease has appeared the treatment is to run a trench two feet deep and one foot wide around the infected area remembering, since the rot commences some time before the bush shows signs of it above ground, to include one row of healthy bushes within the trench. If this measure be taken immediately the disease is detected, a loss of not more than half-a-dozen bushes may be secured. Where large lateral roots from the stump are encountered on running the trench it should be carried further out, but small roots of an inch or two in diameter are not likely to start the disease if the trench be early made, and when divided by the trench may safely be left to rot beyond its limits.

The longer the disease be left to progress the greater the danger of the fungus getting established

from the centre along the smaller roots of the stump and the greater the need to carry the trench far enough out to include these roots. The trench should be drained, as it appears probable that the fungus can pass across it if allowed to remain full of water.

Once the trench is made and the bushes within it have ceased to bear they should be pulled out and the ground well turned over to a depth of at least two feet, several times, and lime mixed with it. If lime cannot be used (it appears to be harmful to tea and may be so to coffee) a little sulphur or a solution of iron sulphate which is cheap and may be used in 5 per cent solution (1 oz. to the pint) can be relied on to destroy the fungus. Then after a year the diseased area may safely be replanted.—*Madras Mail*, April 29.

PROFIT IN PLANTAINS.

The wealth which exists in plantains grown for their fruit and fibre has on several occasions been referred to in our columns, and Mr V T Venotraman Iyer, of Valavanur, S Arcot, who has made experiments in this direction, and even gone to the length of having the fibre which he has manufactured valued in London, has also favoured us with the results of his interesting experience. Today we publish an account of the experiments made under the superintendence of Mr K Narayana Iyer in the Government School of Arts at Trevandrum. Mr Narayana Iyer hopes that from his facts and the figures it will be evident to all that great advantages are likely to accrue to the public, both commercially and artistically, "in continuing further trials with plantain fibre for textile purposes, and in designing and making all possible improvements with the help of qualified maistries in the looms and other weaving processes, as well as in utilising all other materials obtainable in the country; at comparatively cheaper rates, in introducing other weaving industries."

These Travancore experiments were made at first "on a very small scale, and a few square inches were woven and different fast colours were tried successfully." The extraction of the fibre was found to be a simple process, and inasmuch as the edible and valuable portion of the tree was not affected, the fibre being extracted from the sheaths which are at present wasted, it would appear likely to be a lucrative one. Afterwards, more elaborate experiments were made, and Mr Narayana Iyer sums up the results of these under 10 headings, and gives details of the advantages of a new pattern hand loom which has been devised at the School. Of 29 varieties of plantains tried, 12 were found to yield fibre silky in colour and gloss and sufficiently strong for weft thread suitable for weaving cloths of fine texture. The remaining varieties were fit only for coarse weaving and cordage. The fibre was also found to possess peculiar advantages over other known varieties of fibres used for textile purposes, possessing "almost an exact resemblance to silk in the polish of the thread which it is found to retain even after it is dyed with any colour or boiled or washed." It needs, moreover, no spinning operations, but is ready for the loom soon after its extraction. Mr Narayana Iyer also found the fibre to be very light—a great advantage in this country—being one third the weight of cotton thread, and it is especially recommended for native turbans. Thick plantain fibre could, he suggests, be used for thick garments, curtains, carpets, etc., and a small carpet made of it was sent to the Delhi Art Exhibition. As regards cost, plantain fibre compares favourably with cotton, 1 oz. of plantain fibre, costing 1½ anna, going as far as 3 ozs. of cotton which cost 4½ as. With the assistance of a new and improved machine, which we are told is now being made and by means of which a longer fibre will be obtained, there should be a bright future for plantain fibre.—*M. Mail*, May 15.

THE STEAM TRAWLING INDUSTRY.

IN THE NORTH OF SCOTLAND AND IN CEYLON.

[It is an unhappy coincidence that the following very interesting, instructive and encouraging account of fishing by steam trawlers off the North of Scotland, should reach us just after the Colombo experiment has been closed, with a heavy loss to the spirited promoter, though we see it stated now that the total debit does not nearly reach the 1½ lakh mentioned to us by one who ought to be an authority. Before, however, the writer of the following account condemns the stoppage of trawling off Ceylon, he must explain the failure of a trial on an even larger scale by a Scotch Firm in Bombay which brought out and started a fully-equipped trawler, and gave it an ample trial, we believe; but without results to warrant a continuance of the enterprise. Surely, it must be that fish are not so plentiful in the Indian Ocean and that the local markets are also not sufficient to take off any increased quantity at a profitable rate?—ED. T.A.]

(Communicated.)

It cannot be said that Colombo is rash in entering upon new enterprises, or in adopting up-to-date methods of prosecuting existing industries. It has for years been a marvel to many, who have witnessed the great success of trawl-fishing elsewhere, why Ceylon should still lag behind and remain content with a meagre supply of the fish which abound round her coasts, food so much more wholesome and suitable for the tropics than the tough beef produced in the country. In every new enterprise, however, there are always difficulties to contend with. Sentimental croakers will arise to plead for the poor fishermen, who, from time immemorial, have earned a scanty and precarious living by the old methods.

I am old enough to remember the populous villages in Scotland, the inhabitants of which earned their bread by hand-weaving, and recollect the howls of execration with which the introduction of machinery was met. I recollect too, in Ceylon, when the railway to Kandy was proposed, the poor cartmen and the village providers of fodder, formed the theme of many pleading letters. Coming nearer home the introduction of the Linotype is causing many wails from young compositors, who begin to wonder if it is worth while serving seven years to learn typesetting. Old methods must pass away, and time be economised in this busy age. The catching of fish by baited hook and line is only for men whose time is of little value.

Trawling, by the way, is no new innovation. In all probability it was practised in the Sea of Galilee 1900 years ago. Certainly the fish then were caught with a net, and not by the miserable make-shift of a line and hook. Moreover, there are many of the best fishes that won't take the hook, and since the introduction of trawling to Aberdeen, there has been added to the supply many excellent fishes never before heard of, or seen in our markets, chiefly flat fish

equal to the English sole and also turbot, which do not readily take the hook, are now plentiful here.

Very likely, the same would happen in Colombo where some change from the everlasting searfish, good as it is, would be welcomed. But, it is argued, "the sea would soon be emptied and the greedy trawlers when the market was likely to be over-stocked would throw the good food overboard, in order to keep up prices." As a matter of fact we have never seen the market over-stocked, and the more fish that is taken out of the sea, the more rapidly seems the supply to increase, "*practically inexhaustible*," says Professor Mackintosh, of St. Andrew's, the best authority we have on the subject.

Fifteen years ago we landed	cwt
of all kinds	... 176,103
Last year we totalled	... 1,547,21

And the strange thing is that instead of being in excess of the demand, the prices realised are quite 100 per cent over what they were 15 years ago, so many more have learned to appreciate this excellent food, who, owing to the lack of facilities for carriage could not before procure it.

We are glad to see Colombo has made a start in the right direction, and that its one trawler has found a few good, and some rare fish. It is to be hoped the enterprising owner will not be too easily discouraged by the early struggles incidental to all such undertakings. It is in the hope that it may be useful to those interested that I am led to offer a brief history of the Steam Trawling Industry in Aberdeen. The inception of Steam Trawling in Scotland ought, perhaps, to be credited to Mr. R. W. Duff, late Governor of New South Wales who in 1881—as then M.P. for Banffshire—seeing the loss of life by the ordinary frail fishing craft, wrote a letter to the newspapers pointing out that in his opinion, the time had come for the introduction of steam-boats in the catching of fish, and to evidence his interest in the matter, he promoted a Company at Granton, called The General Steam Company, Ltd. This Company, is still in existence. It had its ups and downs, but is now a thriving industry. Twenty-one years ago, two shrewd Aberdonians put their hard heads together, and thought out the prospect of introducing trawling to the Granite City. They quietly went south, and, taking a consulting Engineer with them, proceeded to Dublin of all places, and there invested in an old tub of a tug boat, called "The Toiler," which under her own steam soon paddled her way to Aberdeen. "The Toiler," cost £1,500, was quickly put in ship-shape for her new work, and went to sea on 22nd March, 1882, the crew consisting of her owners and two friends. Only one drag was made; the haul was not a big one, but sufficient to allow of a distribution amongst the party, and this was the first trawled fish ever caught by an Aberdeen boat. Next day "The Toiler" began her regular business, returning with 3 boxes of haddock

which formed the first auction sale of fish in Aberdeen, and realised 37%. The first month's fishing realised £207. At the end of six months a balance was struck, showing a gross revenue of £1,772 1s; the expenditure came to £1,002, 17s, leaving a balance of £769 4s. Out of which a dividend of 100 per cent per annum was paid. A grand beginning, certainly! But somehow this rate of dividend was never repeated. For several reasons the returns began to wane. *Not, indeed,* for want of fish, the enormous resources having only just been tapped, but the old wooden clinker boat, herself, began to show symptoms of decay, and finally through bursting of a pipe, she sank to rest in the waters of the Moray Firth. She had, however, done her work; proved the feasibility of profitable steam trawling, and was soon followed by a fleet of fine screw steamers—fit to face any storm, even in the North Sea. The local fishermen of Torry, Fittie, Finnan and adjacent villages, were all this time by no means disinterested observers. At first, they jeered at the attempts of the land-lubbers, and laughed at the mishaps, but as big hauls began to arrive—tons to their basketfuls—they could not repress their annoyance; which gradually grew into fear and horror, as they saw visions of the sea being emptied of fish, and nothing but starvation left for themselves and families. In this state of mind they approached the Powers—that were, by sending a large deputation to interview and lay their grievance before the Lord Provost. The gentleman, who occupied the civic chair at that date, was the late Mr. P Esslemont, afterwards M. P. for E. Aberdeenshire. The deputation was ably led by a gentleman who, by the irony of fate, is now one of the largest steam trawl-owners in Aberdeen! His views underwent a remarkable change and probably the interview of that afternoon had much to do with his conversion; for Mr Esslemont was a long-headed man and did not mince matters. His advice in effect was "Go and do likewise." This advice was not appreciated by the bulk of the fishermen who returned to the street to swear at large. But their leader did not join with them in this frame of mind. Like a sensible man he resolved to move with the times, and having resolved, spoke to his brethren as follows:—"No doubt, my friends, the sea may soon be emptied of fish but before this happens, I am determined to have a shot myself by the new process." This is 15 years ago and to this day Mr W is busy at the shot; albeit, one of the wealthiest men in Aberdeen. And the fish are not all caught yet! On the contrary, they seem more abundant than ever. Government appointed one of its Royal Commissions to thoroughly enquire into the grievances of the old line fishermen, and to ascertain if there was any ground for their fears. Lord Dalhousie was Chairman, and amongst the other members were Lord Tweedmouth, Professor Huxley, W S Caine, &c.

One of the fishermen was subjected to rather a warm cross-examination by Huxley, in reference to his statement that *the trawlers damaged the spawn at the bottom of the sea.*

"Are you aware, sir," asked the great scientist, "that neither your cod, haddock nor whiting spawn ever goes to the bottom at all?"—The witness's reply was that his evidence was not sufficient to say positively. —The Professor tersely observed that "all this about spawning grounds at the bottom of the sea had no very strong foundation."

The number of steam trawlers now engaged in fishing at Aberdeen is fully 200 and weekly being added to. A boat costs £3,000. As much as £7,000 has been earned by one boat in a year; a gross average of £4,000 will, however, if the expenses are fairly moderate, be sufficient to allow a dividend of 15 per cent. The grand total value of fish landed in Aberdeen last year was £811,976; and if we make allowance for additional value imported by curing, and profits of merchants, the industry is worth at least £1,000,000 yearly to the City. Colombo has a population almost equal to Aberdeen and a fishing ground perhaps not inferior. How would she like to have "£1,000,000 stg." added to her income?

Don't say there is not sufficient market; for like the Canadians you can eat what you can, and 'can' what you can't!

The following is a table showing the quantities of the various kinds of fish landed in the market here during 1902:—

	cwt.		cwt.
Cod	172,338	Dabs	2,035
Codling	6,371	a Whitches	24,409
Ling	76,699	a Megrims	11,860
Tusk	7,019	a Squid	2,114
Saithe	30,953	Conger Eels	1,241
Haddock	610,000	Hake	23,824
Whiting	99,370	Skate	51,181
a Turbot	3,384	Other Kinds	17,435
Hallibut	23,877	(The other kinds include	
a Brill	438	many enemies of the	
a Lemon Soles	15,694	more useful fishes, dog	
a Plaice	26,243	fish, shark, &c.)	

a These are new to the Aberdeen Market as never seen here before the introduction of trawling.

This is exclusive of herring and salmon, both of which have greatly increased in quantity, owing, it is supposed, to the destruction of so many of their enemies by trawlers.

Over 200 tons are frequently landed in one morning; but by noon, all are cleared away and the hose turned on, when the acres of cement smell as sweet as the polished floor of a spacious ball-room. £311,100 has been spent on the erection of this building. There are few more interesting object-lessons now in Scotland than to see the boats arrive and deposit their varied cargoes, and summer tourists ought not to miss this scene:

"The sun is up, and, bathed in golden beams,
The plain Fish-market like a palace gleams,
Scotland than it can furnish not, I ween;
In all her broad domains a busier scene;
Vessels discharge, not singly, but by scores,
Carts, drags, and lorries, crowd in open doors,
Hundreds each day traverse its long extent;
On pleasure some, but most on business bent,"

The briefest history of trawl-fishing would be very incomplete without a description of the "Otter" which has now been generally adopted in place of the "Beam." Few people, perhaps, know anything about the working of trawling gear, or how the fish are caught. The beam trawl might be described as a triangular purse-shaped net, with a mouth kept open by a horizontal wooden beam, usually about 50 feet in length, raised from the bottom of the sea 3 or 4 feet, by pieces of iron, shaped like a sleigh, so as to slip over the bottom as easily as possible. To the beam is fastened the net about 120 feet in length contrived with pockets so that the fish cannot escape when once they enter.

This clumsy contrivance has now been altogether abandoned in Aberdeen for the "Otter," which, it is safe to say, has revolutionised the industry—increasing the catching-power by 100 per cent, especially as regards round fishes, such as cod, haddock, etc., which swim a little distance from the bottom of the sea. After the introduction of the "Otter" the prosperity of the Aberdeen fishing went up by bounds.

The principle of the thing and *modus operandi* are simplicity itself.

Two boards $4\frac{1}{2}$ feet square are fixed at the mouth of a net, which on being dragged through the water are forced apart, thereby opening the trawl. Not only are more fish netted, but the apparatus being less unwieldy, the work of the fishermen is greatly lightened. Professor McIntosh, of St. Andrew's, in his very interesting work "The Resources of the Sea," says:—The trawl is usually down for five hours on the Great Fisher Bank, though trawlers working nearer home regulate the time by the nature of the bottom, the trawling period on hard ground being three hours, on soft ground five hours, the rate of speed while trawling is about $2\frac{1}{2}$ knots an hour, though on muddy ground a higher rate of speed may be maintained."

The Moray Firth, as is well-known, is closed against Scottish trawlers; but absurdly enough, open to foreigners who are constantly at work there:—"Slowly," he says, "the conclusion has been reached that the closure of regions of the open sea in a country like Britain presents few advantages worthy of the constant strain and irritation of class against class, or of the considerable annual expenditure. The closure is powerless to prevent the capture of small fish and so far as history and observations go, there is no ground for alarm in regard to the permanence of the food fishes."

Aberdeen is, of course, the chief centre of trawl-fishing in Scotland and it is not without some pang of regret that one sees the ancient fishing villages along the coast being abandoned. The older fishermen will never take to trawling, much less to life in a large city; but the younger generation takes kindly to both and knowing the fishing grounds so well, their services are valuable. The trawling-fisher is altogether a different type from the sturdy old salt we were won't to see in blue jersey and sou'-wester.

The modern trawler, while ashore, affects the dandy, struts in high-heeled shoes, with bowler hat cocked jauntily to one side, gold ring on his fingers and a good cigar in his mouth; while his speech indicates that he is none of Scotia's sons, his aspirates betray the fact that he was bred in the far South. An attempt was lately made to transport and settle a small fleet and crew at a northern township called "The Broch," but our Anglo-trawler positively refused to remain there. "Why! there is no 'all' there," said one to me, meaning that there was no Music Hall to furnish them with amusement when they came ashore, and no doubt their life is a rather monotonous one. The Englishman is not so fond of reading as the average Scot, who can always while away an hour with a book. I have already indicated that the industry yields handsome profits, but I ought to add, that these profits do not always reach the

pockets of the shareholders. Like some Syndicates more intimately connected with Ceylon, the office expenses, mismanaging directors, &c., often absorb every farthing of the ample profits. There is, perhaps, less difficulty in tracing the leakage of trawling profits than that of Tea Companies. The fishing grounds are free to all, and, as a rule, all come in pretty equally fished. Yet, while some pay from 15 to 35 per cent yearly. Others, for years, have not paid a penny to the poor shareholders who found the bulk of the capital. A strict enquiry might reveal the fact, that while one director supplies the gearing, another the coals, the Manager may supply the ice and in addition draw his 5 per cent on sales—which, in a small fleet would amount to over £1,000 per annum. The unsuspecting investor rarely thinks of guarding against such extortion. It seems probable, however, that many such directorates will be placed under a legislative ban, when a little enquiry will show that there is not a Trawling Company in Aberdeen; not a Tea Company in Ceylon; but should give a decent return to the shareholder, if fairly and squarely managed.

P.S.—I find I rather under-estimated the daily deliveries at about 200 tons—300 may be nearer the mark. Indeed yesterday (8th April) the figures were 373 tons.

FISHING AND TRAWLING.

We find there is more in the argument put forward by Dr. Gandevia against indiscriminate "trawling" than we had supposed. We have been enlightened by an interesting and important paper which has just come into our hands, entitled,—

The Possibilities of Fishery Improvement in Jersey, with Notes on the Present State of Marine Pisciculture and Fishery Regulation, by James Hornell (Director of the Jersey Marine Biological Station).—Reprinted from 'The Journal of Marine Zoology and Microscopy.*

* Mr. Hornell, we need scarcely say, is the scientist who has been called to his assistance by Professor Herdman, F.R.S., and who has taken charge of experimental pearl-oyster culture (a Marine Laboratory) in Galle Harbour. He is the author of several other learned papers in home scientific journals, for instance:—Report on the Schizopoda, Cumacea, Isopoda and Amphipoda of the Channel Islands, by Alfred O. Walker, F.L.S., and James Hornell (Reprinted from 'Journal of Marine Zoology and Microscopy,' Vol. II. No. 7; Sept., 1896).—Notes on the Marine Worms of the Channel Islands, by Mr. James Hornell (Reprinted from the Transactions of the 'Guernsey Society of Natural Science' for 1895).—The Use of Formalin as a Preservative Medium for Marine Animals, by James Hornell (Reprinted from 'Natural Science,' Vol. II, No. 46, Dec. 1895.) But of greater importance is a volume of 'Microscopical Studies in Marine Zoology' with twenty full-page plates of original illustrations, being a reprint of articles from the 'Journal of Marine Zoology' and which was published in book form in 1901.—All these show that Mr. Hornell takes high rank as a Marine Zoologist and authority on Fisheries.

The substance of this essay was first delivered as a lecture under the auspices of the Jersey Natural Science Association and its scope may be judged from the following synopsis:—

1 The continuous decay of inshore fisheries, here and abroad; the chief causes locally.

2 Remedial measures pursued elsewhere.

3 Scope and Programme of the investigations and experiments requisite locally.

4. Summary of the Fishery Laws having force in Jersey; their inadequacy to meet present requirements.

5 Forecast of the probable outcome of an adequate local fishery investigation.

Here then are the opening sentences of Mr Hornell's lecture essay:—

During recent years, in well-nigh every fishing hamlet in Great Britain the plaint of lessened catches in the places where fish formerly abounded has been practically unanimous. The total catches landed on the quays have, however, not decreased; on the contrary, by the employment of powerful steam trawlers able to fish far from home, by the longer journeys made by sail-trawlers and by the larger liners, and by the invention of improved methods and appliances, the fish supply of Great Britain has materially increased, but an increase entirely obtained from extra-territorial waters. The inshore fishermen, such as we have in Jersey, the men who fish in small undecked boats, have no share in this prosperity; these men find their own particular grounds rapidly becoming depopulated, and unable to seek the more distant fishing-grounds, are compelled either to seek new occupations or to languish on earnings that are miserably insufficient. Along the French coast a similar evil state of matters exists; thus, my esteemed friend Dr. Cann, Director of the Station Aquicole at Boulogne, and the foremost authority on pisciculture in France, writes:—"In the Eastern portion of the English Channel, the majority of the banks formerly frequented on account of the number and the quality of their fish, have long since witnessed the loss of their reputation; they are even partially abandoned." And again:—"The diminution of fish catches on the banks which line our Channel coast can no longer be disputed." . . . "The decrease of our small Northern fishing ports is more eloquent than any statistics upon this point."

And among the causes of such decrease, Mr Hornell indicates,—

Trawling within the three-mile limit is considered by liners as highly prejudicial on account of the wholesale destruction it effects. In Scotland trawling is now prohibited, both within the three-mile limit and also in certain of the great bays or Firths, and many authorities are extremely anxious to have the range of prohibition extended further, so that the territorial waters shall form a zone of, say, seven or even thirteen miles in width, wherein trawling shall be rigorously suppressed.

In dealing with remedial measures Mr Hornell refers to "protective laws" in the past, to the good done by Fisheries Exhibitions, which have promoted Fisheries Committees among which that of Lancashire, directed by Professor Herdman, takes the lead. Protective bye-laws have been passed; but more important is the inception (first in America) of "marine fish hatchery" which in Norway and Scotland especially has

become an important institution. The Fishery Board of Scotland instituted a Hatchery at Dunbar which in 1895 had an output of fry as follows:—

The output of fry from this hatchery in 1895 was:—Plaice, 38,615,000; cod, 2,750,000; turbot, 3,800,000; miscellaneous, 1,050,000; a grand total of 46,225,000. and we read,—

It is worthy of note that the authorities consider the services rendered by the Fishery Board for Scotland fully justify the indefinite continuance of the grant of £23,000 per annum.

In the case of Jersey, Mr Hornell recommended a thorough investigation, followed by a series of Experiments, together with the establishment of an Education and Information Bureau, more especially for the benefit of the fishermen. The total cost he estimated so moderately as £150 to £200 a year and yet he was confident of very notable results in a few years. We do not know whether the suggested experiments were taken up; but it is well to know that the Ceylon Government has at hand in Mr Hornell so experienced and excellent an authority on any questions arising or connected with our Fisheries. May his experiments in Pearl Oyster culture prove an unqualified success.

CULTIVATION OF RAMIE.

[TO THE EDITOR OF THE "DAILY CHRONICLE."]

SIR,—I am very pleased to see that at last the value of the Rhea, or Bohmeria fibre, is recognised, according to Dr. Edwards-Radelyffe. It requires no more cultivation than the ordinary garden nettle; in fact, three decades since every effort was made to exterminate it in sub-tropical regions. The fibre is splendid in texture, lightness, and tensile strength when freshly woven, but "shorts" by continuous bending or folding. This is due to the presence of formic acid, which cannot be eliminated entirely by the process of decortication. There is a process termed the "Sochon" process, the invention, I believe, of W E Sochon, which, if still extant, seemed to provide an inexhaustible market for the rough fibre. Briefly, it consisted in the formation of a vegetable leather, synthetically, which could not be done with any fibre not containing free formic acid. This leather I have tried for aeroplanes and model balloons, and it is impervious to hydrogen, comparatively, with dressed silk, and resembles goldbeaters'-skin, the weight per square foot being less by eighteen per cent. And in this state it allows of folding and creasing; and if the process no longer exists I should think it would be due to the lack of material, and it may be resuscitated in some form if the market for raw material is rendered open according to your correspondent's account. In these days of air-ships, war-kites, and racing yachts I do not think a really good product of nature should be left "out in the cold."—Yours faithfully,

FREDK. WALKER, C.E.

Oxford, April 15.

[TO THE EDITOR OF THE "DAILY CHRONICLE."]

SIR,—As sole importers of ramie prepared by the new French method, we should be glad if you would allow us to confirm the statements of your various correspondents with regard to the benefits that would arise from the growing and cultivation

of ramie grass in the British Colonies. At the present time our manufacturer has to obtain his supplies from China, where, largely, the grass grows wild in abundance. Nevertheless, great difficulty is found in securing immediate requirements at reasonable prices. British manufacturers have long recognised the possibilities of ramie, but the methods hitherto used in preparing the grass have been defective. These troubles have at last been overcome, and, in consequence, the demand for ramie is daily increasing. With a plentiful regular supply of the raw grass, cotton "rings" or "combs" need, therefore, trouble the public no longer. The British Colonies cannot be too strongly urged to cultivate this ramie grass. The cost of production and shipment should not be great or prohibitive, and we may add that we should of course prefer the British to a Foreign grown grass. This might be an encouragement to those interested, and we trust that you will accordingly find space to publish this letter.—Yours faithfully,

(For Van Geelkerken and Co., Ltd.)

H E A COOPER, Director.

—Daily Chronicle, April 17.

THE HULETT TEA PLANTATION IN NATAL

is the largest of its kind in South Africa, in fact, in all Africa, for tea is not grown in any other part of the Continent. 'I believe,' says a writer in the 'Magazine of Commerce,' 'its greatest output for one day is 10,370 lb. of tea and the estimate for a recent season is 1,000,000 lb. Its acreage is extensive, and beside a large factory and quite a village of huts for the Indian employees. It also has a railway of its own—a 2 ft. gauge line—being the first light railway laid in Natal, and costing £20,000 to lay. The native labour mainly consists of coolies, of whom there are about 1,000.—*Grocers Journal*, May 2.

"PLANTING ROADSIDES WITH SHADE TREES"—is an item in P. W. D. estimates now-a-days; but why not select really useful trees? At one time it was proposed to plant palmyra palms all along the North road for 100 or 150 miles. In France and Belgium, the country roads are, more and more every year, lined with fruit bearing trees.

GREVILLEAS—do not seem to be responsible for the spread of "tea tortrix" alone, but—as will be seen by the paper (see page 846) read to the Mysore Planters from the Indian Cryptogamic Botanist—it is found to start the disease of "stump rot" in tea bushes. At least this is the experience in Assam. We wonder if it has been noticed generally in many districts in Ceylon. What do our planting correspondents say?

AN "ENTERTAINING MELBOURNE TEA HOUSE."—The phenomenal success of Ceylon tea in Australia does not appear to have yet reached its zenith by any means. On page 835 under the above heading we quote an interesting article, showing Messrs. Griffiths Bros. (whose representative, Mr Shelley, was lately in Ceylon) have by the erection of an elegant tea house been popularising our staple. We trust the venture may be a complete success and profitable to the merchants as well as the producer.

TO THE PLANTING WORLD.

Seeds & Plants of Commercial Products.

Hevea Brasiliensis.—Orders being booked for the coming crop August-September delivery 1903, booking necessary before the end of April, quantities of 100,000 and over at special low rates. Plants available all the year round, 100,000 and over at special low rates. A leading Rubber planter in Sumatra, who purchased 50,000 seeds in 1899, and 100,000 in 1900, writes us, under date 15th November, 1900:—"I received your letter of 20th October, from which I learn that you added another case of 5,000 seeds to replace the loss, &c. I am satisfied hereby, and even after this adding I am satisfied by the whole delivery of this year." Special offer, post free on application.

Castilloa Elastica.—True superior variety cultivated in Mexico, seeds from specially reserved old untapped trees. Orders booked for October-November delivery 1903, immediate booking necessary; large quantities on special terms; Plants in Wardian cases.

A foreign firm of Planters writes under date 11th October, 1901:—"We beg to enquire whether you would procure us 100,000 Castilloa seeds, in which month we might expect them, and what would be the average price." Special offer, post free on application.

Manihot Glaziovii.—Seeds and Plants available all the year round, 100,000 and over at special low rates. A Mexican planter in sending an order for this seed wrote on the 22nd August, 1900:—"If they arrive fresh and germinate easily I may send you larger orders, as they are for high ground where the Castilloa does not thrive."

Ficus Elastica.—Seeds available in May-June; booking necessary before the end of March; also plants.

Mimusops Globosa (Balata) wood of the tree is much sought for buildings, fruits sweet like a plum and eaten, oil from seeds, said to yield as much as 45 lbs. of dry rubber per tree per annum, the milk is drunk and when diluted with water used as cow's milk, grow from-sea-level up to 2,000 feet, orders being booked for seeds and plants, price on application.

Cinnamomum Zeylanicum (Cinnamon superior variety).—New crop of seed in April to June; booking necessary before the end of February, also plants.

Coffee Arabica-Liberian Hybrid.—A highly recommended leaf-disease resisting hardy new variety of Coffee (cross between Arabian and Liberian). New crop March-April; immediate booking necessary.

A foreign Agricultural Department writes dated 9th September, 1901:—"Please accept our order for 175 lbs. of Tea seed and for 2,000 Coffee beans. In regard to Coffee seed I would say that this will be the first importation made by this department, and we will leave the selection of the varieties to be sent to your judgment."

OUR DESCRIPTIVE PRICE LISTS.

The following six Descriptive Price Lists are now being forwarded with Circulars and special offer of Seeds and Plants of Rubber and other Economic Products:—

1. Tropical Seeds and Plants of Commercial Products, enlarged edition for 1902-1903.
2. Seeds and Plants of Shade, Timber, Wind-Belts, Fuel and Ornamental Trees, Trees for Road-sides, Parks, Open Spaces, Pasture Lands, Avenues, Hedges, and for planting among crops (Tea, Coffee, Cacao, Cardamoms, &c.)
3. Seeds and Plants of Tropical Fruit Trees including Mango grafts.
4. Bulbs, Tubers and Yams.
5. Orchids—Ceylon and Indian.
6. Seeds and Plants of Palms, Calamus, Pandanus, Cycads, Tree and other Ferns, Crotons, Roses, Draecinas, Shrubs and Creepers.

Special Arrangements made with foreign Governments, Botanical and Agricultural Departments, Planters and others for supplying seeds and plants of Commercial Products in larger quantities.

"SOUTH AFRICA."—The great authority on South African affairs of 25th March, 1899, says:—"An interesting Catalogue reaches us from the East. It is issued by WILLIAM BROTHERS, Tropical Seed Merchants of Henaratgoda, Ceylon, and schedules all the useful and beautiful plants which will thrive in tropical and semi-tropical regions. We fancy Messrs. Williams should do good business, for now that the great Powers have grabbed all the waste places of the earth, they must turn to and prove that they were worth the grabbing. We recommend the great Powers and Concessionaries under them to go to William Brothers."

Agents in London:—MESSRS. P. W. WOOLLEY & Co., 90, Lower Thames Street.

Agent in Colombo, Ceylon:—E. B. CREASY, Esq.

Agent in British Central Africa:—T. H. LLOYD, Esq., Blantyre.

Telegraphic Address:

J. P. WILLIAM & BROTHERS.

Correspondence.

To the Editor.

INSECT FOR DESTROYING LANTANA.

Cavite, Philippines, April 28.

DEAR SIR,—I think that the Ceylon Government should get the Mexican insect which is destructive to Lantana (see annexed cutting). Insects and eggs might be obtained from the Government Entomologist, Hawaii.—Yours truly,

T. H. STEPHENS, Dentist.

(Extract.)

San Francisco, March 17.—Professor Koebele, Government Entomologist of Hawaii, has discovered an insect that is destructive to lantana. Koebele has been spending some months in Mexico in search of such an insect and has since been ill in Oakland, suffering with Mexican fever.—*Manila Times*.

[But does lantana deserve to be destroyed? It has done much towards renovating abandoned land in Ceylon.—ED. T.A.]

DEAD FISH IN THE COLOMBO LAKE.

April 20.

DEAR SIR,—Many years ago, at the time the late General O'Brien was Acting Governor, there was a severe drought in Colombo. The dry season commenced about the end of January and lasted for months before the rains set in; and the fish in the lake were seen dead, floating on the water, and the margin of the lake was getting dry and exposed to the fierce rays of the sun, the public in Colombo was greatly alarmed at this and expected an epidemic of some kind. The cry was so great that the Acting Governor had to pay occasional visits to the exposed banks of the lake to satisfy himself, that all that needed to be done was properly carried out. The crows, our scavengers, had a good time and the dead fish was soon removed. No epidemic of any sort occurred. The probable cause of the fish in the lake dying may be attributed to the rapid sinking of the water in the lake and the water becoming saturated with sewage. It may also be partly due to the rise in the temperature of the water from the fierce rays of the sun during the day, and to more sea water being admitted into the lake from the lock-gate as the river must be trackish in the dry season. This is only a supposition and it is left for science to settle the question.—Yours truly, X.

RHEA FIBRE FOR THE WEST INDIES

Bulls, Rangitikei, New Zealand, March 15.

DEAR SIR,—Some months ago I was in one of your issues a short para, relating to the growth of Rhea fibre, and as I have not been able to obtain any information regarding the plant out here I am going to trouble you in the matter.

The points upon which I am seeking information are:—

- (1.) Can the fibre be grown in the climate of the Bahama Islands?
- (2.) What is the period between planting and maturity?
- (3.) What plant is necessary for milling the fibre and who are the best people to supply the same?

I am aware that it is not the editorial custom to reply personally to enquiries like the foregoing, but my excuse must be the inaccessibility of this place to any centres of reference.—I am, dear Sir, Yours faithfully, RICHARD H. DALHOUSIE. [Seeing that the Rhea Fibre plant grows in Ceylon (its profitable cultivation here has yet to be effected) from sea level up to Nuwara Eliya, 6,300 feet above the sea, we have no doubt it will grow on ordinary soil in the Bahama islands; but sisal fibre is the great product already cultivated there, although, we fear, not very profitably. To the second question, we should say from 1 to 2 years according to soil from seed to maturity, "Death and Ellwoods" patent machinery has been most spoken of, though there are rivals; an enquiry through any large Machine and Iron Firm would bring the needful information.—ED. T.A.]

Since writing the above, we have come across the following in the *Indian Planters' Gazette* of April 11th:—

"RHEA is undoubtedly one of the coming crops which Behar planters look forward to as a saviour of the situation, and as many of our constituents are purchasing and planting out roots, the following hints for cultivating it, given by those clever pioneers of the industry, Messrs. Jules Karpeles and Co., will doubtless be welcome.—Light Sandy land free of water-logging. Plants should be planted for permanent cultivation 4' x 4' apart. In purchasing roots buy them in lumps and place them in the ground as received 2' x 2' and after one year's growth divide them into pieces of about 8" long and transplant them as described above 4' x 4' by burying them 2 to 3 inches below ground with about 1 inch of root above ground. Planting should be done in the months of July and August. After two years the plants should be ready for decortication. Keep the cultivation clean of weeds by hoeing and ploughing between the bushes, and every two or three years prune away below ground the old roots which accumulate at the side and top of the roots, to induce the growth of stems from the fresh roots below the surface. The stems when ready to be cut should be about 6 feet high and the bark should appear brown at the base to 15 inches from the ground. Plant the roots in well-manured land and keep giving back to the soil what is taken from it either in the shape of the refuse from decortication or the addition of other manures."

THE LABOUR QUESTION.

PRELIMINARY REPORT OF THE CEYLON LABOUR COMMISSIONERS.

Rookwood, Hewaheta, April 22.

SIR,—I enclose for publication the preliminary report of our Labour Commissioners, Messrs. Turner and Hill. Additional information will be available at the Planters' Association Committee and general meetings, on the 1st and 2nd proximo.

The Commissioners recommend that we should station an agent in South India for recruiting purposes, and that he should be sent early in May, if possible. I shall be glad if estates who are willing to support a recruiting agency will send in their names to Mr Philip, stating also the number of coolies required. A registration fee of 10 cents per cultivated acre per annum would probably meet the expenses of the agency, and in addition the coolies would cost from R15 to R20 per head, according to the distance they would have to travel in India and Ceylon. It should be to the advantage of all estates to maintain such an agency, as estates now well supplied with labour are equally interested in the establishment, if possible, of a new form of recruiting. If the cost of bringing over the coolies is borne by the estate, a saving in head-money should be effected, and as this amounts on an average to over R12 per annum, the cost of recruiting would, in eighteen months, be recovered. I wish to ascertain at an early date, what support would be given to a recruiting agency; but promises now made will not be considered binding until a more detailed scheme can be submitted.—I am, Sir, yours faithfully,
A. C. KINGSFORD,

Chairman, Planters' Association of Ceylon.

(The report referred to.)

In accordance with the resolution passed at the general meeting of the Planters' Association held at Kandy on February 17th, 1903, Your Commissioners have visited Southern India and beg to submit the following preliminary report.

Your Commissioners left Ceylon on the 16th of March, and proceeded straight to Madras to present their credentials. They found that G. O. 244 (*vide* appendix) had been sent out to all Collectors and District Officers in the Madras Presidency, and, having got all the information they could from the officials in Madras, they left for Chingleput, and proceeded through North Arcot, S. Arcot, Tanjore, Trichinopoly, Madura, Tinnevely, Coimbatore and Kistna.

The Indian officials gave them all the information at their disposal and helped them in every way and they personally have to thank them for their kind hospitality throughout the trip.

Your Commissioners having travelled through the Presidency for six weeks have come to the following conclusions: That the scarcity of labour is due to the following causes:

1. The 9,000 crops of all grain during 1902 and 1903 and the increased acreage under ground nut in the Trichinopoly, S. Arcot, Tanjore and other districts—a ground nut has been imported from Mauritius which is said to give three crops a year and thus affords employment practically throughout the year.

2. The want of organisation with regard to recruiting.

3. The greater inducements held out to labourers to emigrate elsewhere. Your Commissioners were asked to report on the whole question of labour and actual recruiting did not come within their province unless it could be effected without interfering with the more important

part of their mission. They found it impossible to recruit unless they devoted practically their whole time to it as recruiting necessitates either staying in one central place while sub-agents are out in the villages possibly for a month or being at the beck and call of a telegram from a sub-agent which might take one 200 miles in order to verify a statement as to number of coolies and amount required for advances. Your Commissioners came across two cases where coolies had been borrowed "for this occasion only" and when it came to putting them into the train, it was found that they were employed in a neighbouring mill or some other work.

The district of Coimbatore should be a good ground but the poorer the people the more conservative they are and they prefer to earn a living wage of 2 annas at home, rather than exile and 5 or 6 annas a day.

The Telugu districts north of Madras, are also favourable for emigration, if the difficulty of the language can be overcome, and the extra expense of trainage allowed for.

Your Commissioners beg to offer the following suggestions which they think are necessary with a view to establishing the immigration of labour to Ceylon on a sound basis.

1. That a reliable Agent should be appointed whose duty it would be to have a thorough knowledge of every taluk in the Presidency, and his first work should be in the Telug Districts in order to work up a connection with Ceylon from that part of the country.

2. That a labour bureau should be started by the P A in Kandy, whose duty would be to collect and publish all available information as to crops, weather, and health of each taluk (division) of each district in the Madras Presidency.

3. That a strong sub-Committee with legal help should study the New Madras Labour Act. The Straits Settlements Labour laws, and the Emigration Act of India, to see whether any similar ordinance in Ceylon would benefit the Planting Community or failing any new ordinance, what inducements should be offered to immigrants in order to make Ceylon more favourable in the cooly's eyes than other countries.

Your Commissioners would only add that action should be taken at once, as May appears to be the opening month for coolies generally to think of emigrating and your rivals are already in the field.

Your Commissioners have collected a lot of figures and interesting matter, which they will lay before the Committee on their return to Ceylon, all bearing on the conclusions and suggestions mentioned in this report.

Your Commissioners visited Tataparai (Tuticorin) Pamban, Ammapatam and Tondi, the four ports from which all the immigrants to Ceylon book; and think that until the railway from Negapatam to Pamban or wherever the Indian Government decide to think up is finished, it would be very bad policy to close the parts of Ammapatam and Tondi as they consider the country inland most favourable for coolies, if properly worked.

(Signed) EDGAR TURNER. JOHN HILL.

Madura, S India, April 17th, 1903.

[Some further matter may be added later together with the appendices referred to.]

CEYLON TEA IN SOUTH AFRICA.

P. O. Box No. 263, Gerniston, Transvaal, April 9.

SIR,—I address you on a subject that affects Ceylon tea in South Africa, and must ask you to submit copy to the English Press in Colombo. During the month that has just passed, a Conference has been held at Bloemfontein, under the presidency of the High Commissioner, Viscount Milner, whereat delegates from Cape Colony, Natal, Orange River Colony, Transvaal and Rhodesia, met to discuss mutual affairs, and they resolved on certain changes in the Customs Tariff, though they are not to be made public till 1st July, this year. I learn that it is intended to make the duty on tea on a par with the Natal and Cape duties, that is, 6d a lb.—whereas at present 20 per cent has to be added to invoice price: and in this value is to be included all packing which is being sold with the articles, and on that value $7\frac{1}{2}$ per cent, together with a special duty of 5s in the 100 lb. is charged. As it is, packing, duty, and charges, on my last invoice came to 5'380d per lb. of tea, and on the previous shipment 5'366d; this is quite enough for the tea to have to carry. If we take 42 cents of the rupee as cost, at an average rate of exchange it works out at 6'982d per lb. Is it fair to an English Crown Colony to tax that tea 6d a lb. as duty? This is to protect Natal-grown stuff. One of the largest Natal tea and sugar growers is now leader of the Natal Opposition, and the parties are pretty even in numbers. This gentleman was, I believe, one of the members of the Conference, and here you have the key to the position. As a part result of this Conference, last week's "Gazette" repealed the duty on produce grown in British South Africa, except in as far as spirits were concerned; while all along the produce of Natal has been carried over its railways at a specially reduced rate. If the Chamber of Commerce, the Planters' Association, and the "Thirty Committee" pull together on this point as they should, there is time for a strong remonstrance to be lodged with the High Commissioner before such duty is imposed.

Once imposed, Sir, you will have far less prospect of being heard to effect.

As far as the tea trade here is concerned, I may state that large quantities of groceries, including tea, are being sold by auction on account of the Field Force Canteens, and also the Army Supply Department. So far the "Field Force," since the war, have sold, according to figures given by the Colonial Secretary the other day, goods to the value of £88,000—and £78,000 worth still remains to be sold—on an average goods being 30 to 50 per cent below what they can be landed at in the Transvaal.—Yours, &c.,

ARTHUR H. GREEN.

COLLAR-PRUNING FOR TEA.

Lower Dimbula, April 26.

DEAR SIR,—In reply to Mr. A. Cooke I know of no one in Ceylon who has "collar-pruned" the same tea-bushes twice, for the simple reason that there has not been time to try it. Up till 5 years ago, if my

memory serve me, this operation was a mere name in Ceylon, known to us from Indian tea literature. Your Nagpur correspondent may confuse two operations on the same stem under this name. First:—A "copping" or "stumping," leaving a stem of 6 in. or more projecting above the surface of the ground from which would spring a candelabra growth of suckers—if it (the stump) was not killed back by drought in the meantime. Second:—The real operation—cutting off at the junction of the stem with the roots. This results in a growth of straight suckers, from the junction and along the roots for a few inches. These are allowed to run up for 12 or 15 months till they are 2 ft. 6 in. to 3 ft. high when they may be plucked with the rest of the field with the object of making them bush out, more than that of getting leaf. At the usual pruning—(every two years) they are levelled over with the knife at, say, 20 in height above ground, never less, and fall into plucking with the rest of the field in due course, whippy growths having been cut out. At the end of two years more they would be cut to a lower level, say 16 in. and more thinning out of stems done and side growth encouraged. Again for two years they would be plucked like the rest of the field and (6 years from collaring) then pruned a step higher and thinned of superfluous stems, leaving, say, a 5 or 6 stemmed bush, which, so far as I can predict ought to go on for 10 years more or less—till these stems in their time become effete, I refer, of course, to medium and high jât, tea—not to bad hybrids, which no man knows how to treat—except, perhaps with an axe and mamoty!

Except in cases of cutting down seed-bearers and fire-damaged bushes to produce bushes of many stems, I think collar-pruning in Ceylon has been confined to bad jâts; and the results cannot be said to be on the whole satisfactory. They just flush for half the time of good jâts and show their ugly Ethiopian integuments again which neither knife nor saw can change—ay! nor guid manure either! In the Indian tea districts I take it that the successful collar-pruning, has been done in the case of *originally* good jât bushes, which have become hollow-stemmed, hide-bound, sapless an effete, from age, from many prunings and from the ravages of white ants, etc. on the decayed core, resulting from heavy pruning and the collection of rain water in the hollows so caused.—Yours faithfully,

STILL UNCOLLARED.

TEA COMPANIES—AND TEA COMPANIES?

The Watie, April 30th.

DEAR SIR,—Why is it that some Tea Companies, or rather their Directors, give such full information about their properties (as well as crops) in their Annual Reports; while others are absolutely silent as to acreage of tea, young and old, and other products? What are shareholders about, that they do not insist on a schedule wit

full particulars for each estate, the same as the C. T. P. Company, the Eastern Produce, Nuwara Eliya, Ceylon Land and Produce, and other such large Companies invariably give? Some of the smaller Companies* are the worst sinners and give the most meagre Reports.—Yours, &c.,

DIOGENES.

[* "Directors" of course are to blame and the only cure in the cases complained of is for them to be "heckled" at the annual meeting; but we understand "Diogenes" refers more to sterling, home, rather than to Rupee, local Companies' Reports as the ones deficient in information.—Ed. T.A.]

CHINA AND JAVA TEAS IN GREAT REQUEST IN LONDON.

May 2.

SIR,—While once again lowcountry and cheap teas generally are in great request in the Colombo market and are fetching much above intrinsic value compared with price for high-grown, what will become of fine plucking and green-tea making? We shall see. But meantime there is authentic news of large quantities of China teas from New York and of Java teas from Holland, being imported to London to make up for the absence of common Indian and Ceylon teas. Surely there is in this something to make us planters, (in the lowcountry)

STOP AND THINK?

INDIA AND GREEN TEA.

Calcutta, May 4.

DEAR SIR,—Judging from the discussion excited I seem to have served a useful purpose in challenging "G T"'s statement with regard to alleged deficiency of percentage of weight in green tea compared to leaf against percentage of black. I note the useful remarks of a Ceylon merchant in your issue of 18th April as well as the record of Mr. Hunter of Sunnycroft and your other correspondent in issue of 27th April and am glad to see that our Indian experience of careful green tea manufacture is confirmed in the island. The comparison I made upon Indian and Ceylon green tea was, as you know, purely suppositions, being based upon "G T"'s figures, and I am glad to see that the writer's experience is not general in Ceylon. There is no reason as I took the liberty to point out why it should be even partial, except that your assured bonny enables producers working even on such faulty lines to keep afloat, of which more below. The "note of admiration" I inserted was intended to convey that I considered the comparison called forth by "G T" too good (from an Indian grower's point of view) to be true, and I thought that a hint that there were better standard to work to would be useful to "G T" and others (if any) in a like predicament. In reply to his second communication in yours of 22nd April, the matter is really beyond such experiments as he proposes. The results I gave you were based on an amount of crop exceeding half-a-million pounds, and it is confirmed by Ceylon experience as shown by your

other correspondents. The matter is not of small importance. I suppose all tea men are interested in their various ways quite as much as myself in the success of the green tea industry, and damaging statements based on faulty working are likely to check a desirable development which also works in the interests of black tea producers. A manufacture at such a disadvantage in point of cost of production as stated by "G T" can only be kept going by the compensating bonus, and even in Ceylon the bonus cannot be continued for ever. The green tea industry must get on its own leg, or die. In India our tea agency firms have put the bonus out of their calculations so far as compensation for cost of manufacture or deficiency in price of the article compared with black is concerned. We are working without any definite promise of a bonus, the London I T A Committee's proposals on the subject being quite *ultra vires* considering that the decision of the matter rests entirely with the new "Twenty Committee" to administer the Cess, unconnected with the Association. If the bonus is given at all, it will only be a small one. This is understood by those who are going in for the manufacture and they would leave it alone if they did not hope to make it pay for itself, thankfully receiving anything that may be given them towards cost of initial installations of machinery, not towards equalising prices or making up for increased cost of production or loss in manufacture. It seems to me that this view of the question is sound. Compensation for extra initial expenditure, more or less in the interests of the whole industry, is sound in principle. An attempt to supply inherent defects in results, on the other hand, cannot succeed in the long run. We, in India, have got to make green tea pay by itself in the near future, or we have got to drop it and this necessity makes our Indian men who take up the process especially keen and critical. There would be no chance of their continuing the attempt with such a handicap as 4 cents extra in cost of manufacture as per "G. T." If your long-continued bonus system encourages such lame ducks to play with green tea for a time, only to throw it up as soon as the bonus is withdrawn, as they must do it seems to me that you are spending a certain proportion of your Cess funds to no permanent good. The matter needs looking into. Only such green tea makers as can show results giving a reasonable hope of establishing the new industry as a paying branch of tea manufacture deserve support. In India this result will be obtained by the restricted support which I am, at present, informed will only be accorded, and I am in a position to know more of the difficulties than the facilities of the matter. As a typical instance of the manner in which our men are working, I may say that one of our very prominent tea agents, who is a power on every Committee, while putting one or two of his gardens into green tea, is totally opposed to any bonus being given. He was deterred at first from taking up the process at all by just such uninformed statements as those of your correspondent's with regard to weight of output in green till I showed him the testimony of the managers who calculated on the half-million pounds of crop as above mentioned.—Yours faithfully,

CHARLES JUDGE.

DESICCATED BANANA: A NEW INDUSTRY.

May 5.

DEAR SIR,—As I know you are interested in all industries connected with Ceylon, I am sending you a sample of semi-desiccated banana, or plantain, sent me from home, which the sender informs me is usually supplied from the West Indies, and which is used in large quantities by bakers for fancy cakes instead of, or along with, orange-peel.

As there appears to me to be an opening for business with home in this stuff, I write to ask you if you know of any house out here that deal in it, or if it has ever been tried.—Yours sincerely,
ENQUIRER.

[This letter should have appeared before. Can any one tell us if a local experiment has been made? Respecting plantain "flour" we have had a good deal of discussion; but the "desiccated plantain" is new. Why should the local mills not desiccate plantains as well as coconuts? But is the supply of fruit sufficient? At present the Colombo fruit market, we suspect, requires all the plantains that can be sent to it; and the West Indian islands with their much richer soil and proximity to England and the United States can supply the fruit both natural and desiccated at a rate, probably, to beat Ceylon? Still there should be no harm in trying an experiment at one or other of the local Desiccating Mills.—ED. T.A.]

DESICCATED PLANTAINS AND FRUIT CANNING.

May 15th.

DEAR SIR,—I am glad to see the Old Rag taking up, as is its wont, the questions of new products and new industries. There is awful waste of fruits in the Island. Partly, owing to the temperature which is fatal to the keeping of ripe fruit for more than two or three days, and partly owing to the rush with which crops like mangoes, jambus and country pines come on, scarcely more than one-half of the low-country fruit is consumed. If canning fruit is set up, it should pay. Fancy our getting canned pine-apples from the Straits! But plantains are always in season, and their cultivation and production can be indefinitely increased if desiccating be started on a large scale. Vavasseur's and the Orient Company have facilities at hand for the enterprise; but Lipton and the Australian Stores may be first in the field. I have sun-dried ripe plantains sliced in two, and they both keep well, and are as tasty as figs, or they may be stewed.—Yours truly,
LOWCOUNTRY.

DESICCATED BANANAS.

May 15.

SIR,—With reference to "Inquirer's" letter re desiccated bananas and your note on same, I wish to point out that the supply of plantains would be unlimited in Ceylon if a fair price could be offered. They will grow luxuriantly in dry country with irrigation and

give freight to the new Railway Line. At present the producer can only get an average of R30 per 100 bunches, when in the West Indies, according to Mr Fawcett of the Public Gardens, Jamaica, the average of the contracts are £3. 15. 0. per 100, or R131. Half of this would be very remunerative in Ceylon and allow for cultivation, where at present the banana is generally grown as a by-product. That enormous difference in price would justify "Inquirer" to think that there is a very profitable industry to create.—Yours truly,

A. VAN DER POORTEN.

[The sooner an experiment is made in desiccating, and shipping, an appreciable sample, to try in London, the better. Could Mr. Vanderpoorten himself not prepare such a sample and test the market? We fear the voyage is too long from Colombo to Europe to be able to send bunches of green plantains.—ED. T.A.]

PLANTING IN B. C. AFRICA: COFFEE, TEA, TOBACCO.

AN ADVERSE REPORT.

May 16.

SIR,—With your permission I will make a few remarks on an article in *Tropical Agriculturist*, 1st May, on "Planting in British Central Africa" referring to a "fortune" to be made in Tobacco—and Tea, written by a bit of "young enthusiasm" from Ceylon. I was right through the Blantyre District in June-July, last year, from "Katunga's" to Zomba via Blantyre, and again in November from Zomba to Blantyre and from Blantyre via Cholo to Chiromo, so that I passed through a considerable portion of the planting district. As your correspondent says, coffee is almost a thing of the past. Whatever induced any man to plant coffee there, is more than I can understand. The lay of land is excellent, soil is very good, elevation good, but—the average yearly drought may be reckoned at seven months. Rainfall is, I believe, about 60 in. in Blantyre, badly distributed. Where our old friend, Mr Henry Brown, is, on the magnificent M'lanje mountain, the rainfall is a little more, and there by care and unceasing attention a man may scrape along. A few men have made money in coffee by having the luck to get a rather better rainfall than usual at first or second crop season and then selling their estates. The life of the coffee seems to be about 4 years from a planter's point of view. The young stuff seems to come on in spite of the drought, but as soon as it has borne one or two crops it simply snuffs out. As to Tea and a "fortune" in local consumption, at 3s per lb., the whole of British Central Africa cannot contain, I fancy, more than 300 white people, so where does the consumption come in? As to exporting it—well, wait for the railway, if it ever comes, and even then cost of transport will kill it. As for Tobacco, a coarse kind can be grown and at present there is a somewhat precarious market for it in S. Africa as "Boer" tobacco. The foregoing is the real state of things, according to my enquiries and observations. As to labour, it is cheap but not permanent. Each male native has to work a month in each year or pay double hut tax (6s) instead of (3s). They are sent to Blantyre in thousands each

year by the outstation Collectors or Assistants. Hence the force is not permanent and men are always *new*. Cost of transport of goods *via* the 'Shire' and Zombesi steamers is pretty heavy, plus the cost of overland carriage after that. British Central Africa, is a great transport highway for Central Africa, the lakes and surrounding territories—that is about all.—Yours faithfully,
H. STOREY.

DESICCATED PLANTAINS AS A LOCAL INDUSTRY. A STEP ONWARD.

May 17.

DEAR SIR,—I am much obliged for the interest you have taken, and the information you have given me, regarding desiccated plantains.

I am going to write home by this mail, and ask for a large sample of, and prices given for, desiccated plantains. On receipt of this I will be glad to communicate with Mr. Van Der Poorten, or any other low-country planter, interested in the product. It is a pity that there should be any waste out here in the better-flavoured plantains when a demand is ready at home.—Yours truly,
ENQUIRER.

PLANTING NOTES.

AGE OF TREES.—The best authorities on trees state that the English oak may live to the age of 1,500 years, only cedars, sequoia, and baobab having a still longer life. Poplars reach only 50, elms 335, maples 516, birches 576, oranges 420, cypresses, walnuts, and olives 800, planes 1,000, and limes 1,100 years.—*Agricultural Journal*.

THE EARTH-NUT—or pea-nut (*Arachis hypogæa*)—has come to be considered one of the best foods for poultry, whether laying hens or growing chickens, excelling maize, wheat, or oats. Unlike the first two it does not over-fatten, and keeps the birds in good health. They are thrown with tops and all, and keeps hens busy all day.—*Agricultural Journal*.

"DESICCATED BANANAS": A NEW INDUSTRY FOR CEYLON.—We trust a trial will be given by some one or other of our coconut desiccating mills to the drying and preparing of Ceylon plantains as suggested by our correspondent "Enquirer" in another column. We omitted to quote one important paragraph from Sir John Grinlinton's letter. It is after he speaks of the large shipments from the islands:—"The bananas in the Canary islands and Teneriffe are not nearly so good as those produced in Ceylon." Since writing the above we have been favoured with the following information from Sir Wm. Mitchell:—"Referring to the enclosed ("Enquirer"'s letter) Mr. Chas. Stonter (who went to Paris with the Commissioner) got a gold medal for his exhibit of plantain flour. I had it analysed for him in Paris, and it was thought a great deal of, for its anti-septic properties amongst other things. Shipments were recommended, but I fear the cost of laying it down in Europe was too great to be covered by the price obtainable. The desiccated plantains might well become a new industry, only I fear the cost will stand in the way."

TEA IN SOUTH AFRICA.

It is a pity that Mr. Arthur Green's important letter, which we publish on page 856, did not come some weeks earlier, so that it might have been considered at the Planters' Association meeting and at that of the Chamber of Commerce—both of these meetings having had very much of their interest taken from them at the eleventh hour. Although no resolution could be come to, the matter might still be noticed, as a subject to be taken up at the very next opportunity. It is against all but a very narrow reason, that a heavy—though not, of course, prohibitive—duty should be placed on the East Indian grown teas in the interest of a comparatively small acreage under tea in Natal. As Mr. Green shows, with all expenses and charges paid before he can sell tea in the Transvaal, the article costs a pretty considerable figure; and if tea is to be popularised in South Africa it must be by cheapening it to the utmost possible limit. The climate is not so far different from that of Australia that the new colonies would be unlikely to follow its excellent example as the leader of the tea-drinking world. In order to attain this, however, heavy taxes must be lightened. The "Thirty Committee" and Chamber of Commerce, we have no doubt, will do their part promptly. But that part will be neither so effective as would be a message to His Majesty's Government from Sir West Ridgeway, pointing out that the principles of inter-colonial free-trade are being interfered with, in favour of a very small section in Natal; whilst the prospects of development of trade in the new colonies for a large industry in India and Ceylon will be hampered by a 6d South African duty on tea. Sir West Ridgeway's prompt protest against any proposed increase in the home tea duty on a previous occasion is well and gratefully remembered, and speedy action in the present case might lead to results of which Ceylon would become increasingly conscious and full of recognition, when the present Governor is ruling—not so very many months hence—over the fortunes of those rich new colonies to which we have referred.

COFFEE PLANTING IN BRITISH NEW GUINEA: THE LEAF FUNGUS AT WORK: EFFECT OF DROUGHT ON THE BEANS.

THE FUTURE OF B. N. GUINEA.

Mr. Donald Mackay sends us the following interesting "notes" from Singapore:—

When at Port Moresby I was shown
COFFEE LEAVES,
showing *Hemiteia Vastatrix* fully developed. These were from a plantation some 40 miles inland belonging to Messrs. Burns Philp & Co. of Sydney and many other places in Australia and the Islands. I took the liberty of recommending the Manager to send you the diseased leaves with the view of your obtaining expert opinion on the fungus growth and receiving suggestions as to the remedial measures that might be adopted. I felt that in the interests of a pioneering industry in a new country you would be only too glad to help the infant colony to whatever the dearly bought experience of Ceylon could give, in an effort to extirpate the disease while in its first stages and before it had over-spread and gone beyond remedies. I felt the more impelled to suggest an appeal to your well-known

experience on account of what I took to be a sort of hopelessness which saw nothing better than abandonment of the enterprise altogether. There are only two

COFFEE PLANTATIONS

at or near Port Moresby, one about 50 acres owned by Messrs. Burns Philp & Co., and the other about 100 acres owned by someone whose name I forget. They were too far for me to visit during our stay in port even if there had been roads worthy of the name to enable a journey to be quickly done.

I understood that the disease had not spread over the whole area, but was confined to the outlying corners where it had broken out. Possibly this may mean that the disease of fungus came out of the forest. Nothing had been done in the way of remedial measures and they seemed quite at a loss what to do. I told them that the vapour of carbolic acid and the fumes of sulphur had been tried in Ceylon without any better result than a temporary stoppage in the progress of the disease and a temporary recovery in the output of foliage. Even if hot lime applications would be of avail there is no lime anywhere near and, wanting roads for carts, flogging up the trees with manure is out of the question as a matter of reasonable expense. The age of the coffee in Messrs. Burns Philp & Co.'s plantation runs up, I fancy, to 6 years. I did not find out for a certainty, where the seed came from, but I am inclined to think from East Java, where I saw leaf disease in 1897. I have advised them to seek the co-operation of Government in sending some competent man to Java to see how things are there with regard to coffee and the conditions under which it is grown as regards shading, pruning and cultivation generally. It may be that shade would mitigate if it did not prevent the attacks of the fungus. Dutchmen do not believe in growing coffee without shade and their experience goes a long way back in their own island and climate. The climatic conditions in New Guinea must be pretty much skins to those existing in Java though the soils may be different, the latter being volcanic, and the former now more or less volcanic. There is immense scope for coffee growing in the numerous valleys of the uplands, where the rainfall is more abundant and its failure a matter of unfrequent occurrence. Coffee is grown here and there on the mainland of Australia, but New Guinea by its situation and conformation should be the coffee-growing country of the Commonwealth. As an example of the

RESULT OF DROUGHT

it might interest you to see

COFFEE BERRIES

of this year's picking after drought from Burns Philp's estate as compared with the berries from last year's picking from the same estate before the drought took effect in New Guinea. The small shrunken beans tell their own tale of the severity of the drought in a land of high, forest-covered mountains that is supposed to be always attracting and distributing moisture. It only shows how, though in a modified degree, Australian droughts react on New Guinea though separated by considerable seas.

The future of

BRITISH NEW GUINEA

is what the Commonwealth, who are now taking it over, may choose to make it. If the Central Government go in for spending money in opening up

the country, great results will follow in enterprise, in establishment of plantations of all tropical products, especially coconuts in which there has been next to nothing done on any large scale. If Government continue the starvation policy hitherto followed, then private enterprise will leave New Guinea alone and go to the other islands of the Southern Seas for a field of investment.

The coffee leaves referred to, have not yet reached us; but the experience of Ceylon is not encouraging to any one trying to fight *hemileia vastatrix*. At the same time, a better fight could be made over small isolated plantations in New Guinea than on our extensive planted districts. The first and most potent means of getting rid of the fungus should be to gather and burn all affected leaves, if possible as soon as the yellow pin spot appears. If in addition sulphur and lime can be applied, all the better; but burning the affected leaves should in any case be done.—The contrast between the properly grown sample of parchment beans sent us and the small pealike beans matured in the drought, is very striking. No doubt a good cup of coffee can be got from the tiny beans; but it would take a big lot of such beans to fill a bushel or weigh a cwt.

THE SHRINKAGE OF TIMBER.

Some little known facts as to the shrinkage of timber are disclosed in the latest Report on the Punjab Forests. It is calculated that during the last ten years there has been a loss in the timber launched on the river from the Pangri forests amounting to 157,000 cubic feet of deodar in the log and 94,000 cubic feet in scantlings. Similarly, from the Bashahr forests in twenty years there has been a loss of 834,000 and 196,000 cubic feet, respectively. This is by no means all due to theft or accident, for observations taken at Chamba show that between forests and sale depots identified logs lose 13 per cent in volume from shrinkage. It is calculated by the Divisional Officer of Bashahr that for every 100 cubic feet of logs cut in the forests not more than 72 cubic feet are received in the depots, 19 per cent of the loss being due to shrinkage, while only 48.5 per cent of the scantling despatched reaches the sale depots. It is to be observed that the Punjab Government is already looking forward to the time when "all the chief fuel preserves of the Forest Department in the Punjab plains will have been surrendered for colonisation," and we are told that to retain any large area of these *rakhs* under natural jungle growth would be prejudicial to the success of irrigation schemes now maturing as well as bad economy. In the zeal for irrigation it is to be hoped that the importance of trees as affecting climate will not be forgotten. Only a few days ago we called attention to a report from the Punjab, in which reference was made to the ruthless denudation of the Punjab forests for fuel, and the opinion was expressed that already this denudation had had an appreciable effect on the climate and rainfall. There is some talk of an extension of irrigated plantations; but so far as we can gather from the Report, these are to be regarded only from the financial point of view: if they do not pay a substantial profit they will not be extended.—*Pioneer*, May 15.

[No. 12.

IMPROVED MACHINERY.

THE question of the introduction of improved machinery for agricultural operations in Ceylon deserves careful attention, and it is time that some systematic experiments were conducted with a view to test the efficacy of implements which are so largely used in foreign countries. In doing this it is essential that those carrying out the experiments should study the conditions of village labour and village resources. In the first place, it has to be borne in mind that the Ceylon *goiya* carries on his work without any capital so to speak, and is not in a position to raise capital to any advantage, for the scarcity of money will hardly admit of his employing borrowed capital. As the *goiya* is never able to borrow money unless he is prepared to pay a very large percentage of interest on it, it makes it absolutely necessary that he should have implements of the cheapest description. In fact, any implements that are to be introduced should be capable of being made locally without the use of costly materials. There is a possibility of a great deal of work being done in this way, both as regards implements used in tillage operations and those used in the gathering of crops. We will take for example the cultivation of rice, and the main operations employed by the *goiya* in the preparation of a field for sowing. Three methods are in vogue: first, ploughing with the wooden native plough; second, digging up and turning the soil with the mamoty, then puddling the soil by using buffaloes to trample the wet soil. The plough used can be drawn by any ordinary pair of country

cattle. Can it be improved without increasing the draught power required for its working? Light Swedish ploughs were tried at one time. They cost about ten times the value of a country plough, they had to be imported, and they required heavier draught, and in some places the work they did was not what was required by the cultivator. The cultivator requires an implement that will stir up the soil and not turn it up. The native plough does this, but cannot the native plough be improved in the light of present knowledge, and in such a way as to do the same work that has to be done now, in a cheaper and more efficient manner, and cannot the improved implement be built by the village carpenter or blacksmith with materials obtainable in the neighbourhood? Is there any possibility of improving the mamoty now in use? Can anything be introduced that will do the work of puddling the mud more expeditiously than is now done by buffaloes? Can a contrivance be devised that will make it possible for a labourer to get the work done by some hand implement instead of animals, or can some implement be attached to the buffaloes, that will expedite the work?

Next we come to the operation of reaping. At present a small sickle is used in reaping the crop. Can this be improved on, or can something be introduced that will enable the reaper to do more work than he gets through at present? There is much room to effect improvements in thrashing and winnowing. These take up a great deal of labour, and wooden thrashing machinery is said to be successfully used in Italy and other places. Cheap winnowing machinery is easily made. These are then the lines on which some investigations and

experiments should be conducted. A single improvement will well repay the labour of experts even if they were to take years to discover it. As a preliminary step it will be of great importance to make a collection of agricultural implements which are in use in other countries. Such a collection will be a very interesting one, and will give some ideas as to improvements that can be effected in Ceylon.

OCCASIONAL NOTES.

We regret the error that has crept into our April number which gives the botanical name of the flowering tree commonly called "Madre-de-cacao," and a familiar sight about Colombo, as *Millettia atropurpurea*. Through some mistake the label bearing the name was attached to a specimen in the Peradeniya Gardens, from where the information given was derived, and hence the confusion that has arisen. The name "Madre-de-cacao" came with the seeds from Central America, but this term, also applied to *Erythrina umbrosa* (another introduced tree in Ceylon), is no doubt a general term for cocoa shade trees. The name *Millettia* was given to the tree in question on high authority, but it would now appear that it belongs to the genus *Lanchoarpus*. Our attention was called to the error by Mr. Ridley of the Singapore Botanic Gardens.

Three of the eight Queensland bananas growing in the Government Stock Garden, Colombo, are now in fruit, namely the varieties labelled Borego, Ladies' Fingers and Cavendish. The only one, which has so far ripened, is the first named. The fruit

of this variety is of moderate size with a thin skin and a yellowish mealy pulp of good flavour. Plants of all eight varieties (which have thrown up suckers freely) have been sent out to School Gardens in various parts of the Island.

A fresh nursery of fruit trees has been established in the Stock Garden. A highly-recommended variety of papaw (seeds procured from Bangalore), sapodilla, *Acras sapota* (seeds kindly supplied by Dr. Passe of Colombo), and a variety of other fruits (seeds obtained from the Peradeniya Gardens) are to be found in it.

Can any of our readers give us the botanical name of the plant known as "massoy" or "muswe" found in Singapore, and the roots of which are used medicinally? A correspondent will be greatly obliged for the information. We believe the latter name is Malayam. Another Malay plant, the rhizome of which resembles ginger, and is used as an ingredient of a special curry preparation, is locally known as "Lankwas" (spelt as pronounced). The root resembles that of the great galangal, *Alpinia galanga* (Sinhalese kaluwala).

Experiments made by a well-known planter with Arsenite of Soda (recommended by us) go to show that the poison is ineffective on "illuk," *Imperata arundinacea*, but is very effective in eradicating the sensitive plant known in Sinhalese as "Nida-kumba," *Mimosa pudica*, and "Kalanduru," *Cyperus rotundus*.

That the seeds of the citrus fruit will produce different varieties has been proved over and over again. We have been informed by a reliable authority that among the older generation of Sinhalese there are men, to whom the knowledge is said to come down from the Dutch, who are able to classify the seeds taken from a single fruit, distinguishing different kinds really as certain to produce oranges, shaddocks, &c., the distinction being based upon differences in the shape, size, weight, and general external structure of the seeds.

There has been some correspondence in the local press over the plant known by the native name of "Et-tora" (not to be confounded with Etor, *Panicum repens*, the Ceylon "couch grass") which one authority considers identical with "Uru-tora" *Cassia sophora*. According to Trimen "Et-tora" is *Atylosia Candollei*, described as an ornamental shrub, occurring like broom or furze gregariously on open patanas. The young leaves, according to a correspondent in the local "Times," are used for wounds in cattle.

The plant known as "Rampoh" is botanically a screw-pine, belonging to the order Pandanaceæ, and is named *Pandanus latifolia*. It is a graceful shrub possessing a peculiar odour imparted to rice when boiled with it, the leaves being also invariably used as an ingredient in the preparation of curries. A single loaf can be sold for a cent, but much more is asked in the markets.

Rampah affects a damp situation and is rarely seen in flower. The common name is derived from the Malay.

We reproduce an interesting paper on Diseases of Poultry in the present number, and have no doubt that the useful information it contains will be welcome to local poultry-keepers, among whom there have been evidences of great activity of late.

SORGHUM POISONING.

Sorghum vulgare or the Great Millet, known in North India as Jowari, and among the Tamils as Cholum, is largely grown in India both as a grain and fodder crop, and to some extent also in Ceylon.

The following report by Dr. Maxwell on the poisonous properties of Sorghum under certain conditions is of interest to all who are growing the crop. Hydrocyanic acid, we may mention for the benefit of those who are not aware of the fact, is the same as Prussic Acid, well known as a deadly poison:—

"I have the honour to make a preliminary statement upon given investigations that are being conducted with certain green crops in order to determine the presence, or non-presence, of given poisonous bodies. The results of the investigations, so far conducted, make it advisable that a brief statement should be made at once to our farmers and others using such green crops for feed. Examinations at different stages of growth of sorghum show that the plant in its early history contains distinctly fatal amounts of hydrocyanic acid. The object of the examinations is to determine at what age sorghum and similar plants, containing these poisonous bodies, can be safely used. So far the samples cut, reaching up to an age of seven weeks, still contain highly dangerous, in fact fatal, amounts, if fed in liberal quantities. The chemist, Mr. Brunnich, who has exclusive charge of the laboratory work, is still engaged on the matter, and I hope, before very long, to make a full statement. In the meantime, however, it is strictly advisable to notify the farmers of the almost certain danger, as many have discovered, of feeding young sorghum to cattle. It is indicated that it will not be safe to give cattle free access to sorghum—that is, to eat as much as they like—until it has reached the seeding stage. This question, however, it is hoped to have settled within a few weeks. The Laboratory is also engaged upon other plants, including maize, Kafir corn, &c., with a view to determine their safeness, during their early growth, for feed.

The investigations also promise to prove beyond question a statement previously made by me that the amount of the poisonous body (hydrocyanic acid) present in the plants is very largely controlled by the nature of the soil, or, in other words, by the amount of nitrogen that the soil contains. This fact will make it also clear that sorghum, for example, which is grown upon rich soil, is likely to be much more dangerous

during its early stages of development than the same plant grown upon poor soils. These matters, however, will be made clear in a fuller statement as soon as the investigations are completed.

I beg to urge the immediate distribution of this information through the public Press, since this is the particular time when these green crops are being fed to cattle."

DISEASES OF POULTRY.

By F. H. ROBERTSON.

Poultry, like all live stock, are liable to be affected with sickness or disease, especially if not kept in accordance with "Nature's Laws." It is, therefore, necessary that all poultry-keepers should have some knowledge of the ailments of fowls and how to treat them. Not that I am in favour of wholesale doctoring—far from it; rather should the poultry man or woman use every endeavour to keep the fowls in good health by paying strict attention to their many little requirements. At the same time it frequently happens that the spreading of some contagious disease is stamped out by the speedy withdrawal of the bird affected before it has had time to contaminate the rest of the flock. In such cases it is generally advisable to destroy the sick fowl. In any case, it is absolutely necessary to be always on the alert for the slightest appearance of sickness. Do not delay, but at once catch the ailing one, ascertain what is wrong, apply the proper remedies, and keep the invalid in the hospital, with which every yard should be provided. This sick pen should, if possible, be right away from the regular fowl runs; and as fowls, even when in good health, chafe under close confinement, it does not do to keep sick ones entirely closed up in a box or basket, so a small run must be provided to allow the birds to move about in when the weather is fine. An enclosure of, say, 12 ft. square is sufficient, situated in a sheltered locality quite away from the ordinary runs; let the sides be covered in all round to a height of about 2½ ft., and to complete the isolation it should be wired in overhead, to prevent healthy fowls gaining access; also to keep the inmates of the hospital in their own pen. A small water-tight house, provided with a perch in the pen, which is wired in front so that the sick birds can be kept indoors if the weather is cold or wet. This system is the simplest mode of coping with sick fowls, as, owing to the smallness of the run, they are easily caught, and a dozen fowls can be quickly handled and doctored in a few minutes.

Apoplexy is not at all uncommon in this State, but it is very sudden in its attacks. The fowl is generally dead before treatment can be administered. Hens found dead on the nest is frequently due to this disease, owing to excessive straining or intense heat. Highly-fed and over-fat fowls, if subjected to undue excitement from chasing or fighting, are liable to go off suddenly. If a fowl is noticed staggering about and going round in a circle, letting cold water run from the top on to the bird's head will generally bring it round;

failing that, try bleeding by cutting the large vein under the wing.

Bronchitis.—Fowls affected with this complaint give a short, dry cough, generally noticeable at night, when on the perch. If unaccompanied by any other symptoms such as swollen eyes, discharge from the nostrils, or growths in the mouth, it is simply a form of cold, which is generally cured in two or three days by keeping the fowl in a warm coop, fed on soft food only, and add a few drops of aconite to the drinking water. This complaint must not be confounded with roup, which is described later on.

Bumble Foot.—This starts with a corn on the sole of the foot, caused by hard or stony fowl runs, or by birds having to jump from high perches on to a hard floor. If noticed when only the thickness of the skin, it can be cured by paring and removing bird to a soft or sandy run. But if neglected for some time the corn increases, eventually going right through the foot and swelling up considerably on the upper part of the foot, causing great pain and impediment in moving about, besides being very unsightly. When it has reached this stage it is very difficult to cure; but it is cruel to allow a fowl to go hobbling about with this distressing complaint. Great relief may be given by penning the bird up in a coop, thickly covered with straw and poulticing the foot until the parts become quite soft, when the yellow, cheesy matter can be squeezed out; but as this is tedious work, it is much better to take the small blade of a sharp penknife, insert it right through the bad part and cut outwards, completely severing the web in two; it will bleed freely, but if the operation is done under a running water-tap blood will soon cease to flow. All the yellow secretions can then be removed, and when all are taken away thoroughly wash out with strong phenyle and water, apply crude phenyle to the wounds, and carefully bind up the foot with linen bands, tying each one separately, so that the fowl cannot peck them off; the bird then should only be allowed to run on sand or straw until the wound is healed.

Chicken Pox.—This complaint is very common in this State; chickens and young birds under 12 months old are very subject to it, old ones being seldom affected. It comes in the form of warts on the comb, face, and wattles. Fortunately this nasty complaint is very easily cured; an unfailing remedy is to paint the warts with crude phenyle, one or two applications being sufficient.

Cholera is another frequent complaint in this warm climate; sometimes only individual birds are affected, and at other times large numbers. The symptoms are dullness of eye, ruffled plumage, staggering gait, general weakness, intense thirst, complete loss of appetite, droppings of a slimy greenish colour at first, then turning white or creamy. This disease comes on suddenly, and frequently kills off birds very quickly. The first intimation of its presence is the finding of several dead fowls, and others lying about in a helpless condition. All affected fowls should be immediately caught and kept in a warm coop. An effective remedy is chlorodyne; pour a few

drops on a dry crumb of bread, and give every three or four hours; give little or no water; but as fowls are generally very weak and will not feed, it is necessary to keep up their strength, and for this purpose nothing is better than beaten-up egg, which can be administered by means of a tea-spoon or small syringe. Sunburnt or dirty water, putrid meat, want of shade, and filthy surroundings are the chief causes of this disease.

Cold or Catarrh.—This complaint is one of the commonest, and is very frequent among young stock; although not serious if taken early, it is a great nuisance, and retards growth. Late-hatched chickens are more subject to it than the early and more hardy stock. It generally goes through the majority of the young birds, and is very catching, but if the first bird affected can be spotted and killed at once the complaint is nipped in the bud. The symptoms are a slight watery discharge from the nostrils, which if neglected becomes thicker, and in course of time develops into roup; the eyes are often inclined to be watery and puffy.

All affected birds should be removed to the hospital pen, and there fed chiefly on good nourishing soft food, but little grain, and plenty of greenstuff; add to the drinking water aconite, sulphate of iron, or any of the well-known advertised poultry tonics. Each bird should be handled daily, and the nostrils washed out with some anti-septic, such as permanganate of potash (Condy's Crystals) or phenyle and water, always taking care to thoroughly dry off all moisture. Under this treatment birds improve rapidly, but with some it is impossible to quickly get rid of the affection; a thin, watery fluid continues to exude from the nostrils. Such birds, if they eat well and are of good constitution, may be turned out of the sick pen after about 10 days' treatment, and it will generally be found that they shake off the complaint in a few weeks, especially if the weather is in their favour. The birds that get worse and develop roup, if not valuable, might as well be killed off.

Canker.—There are two forms of this complaint; the first is on the comb. The large-combed varieties such as Leghorns, Minorcas, and Australusians are most subject to it, especially the cocks. Hens pecking at the comb cause a sore, which frequently turns into canker; it starts with a small yellow scab, which soon spreads and eats into the comb, leaving a hole and causing the comb to hang over. The other form of canker is a yellow growth round and sometimes down the windpipe. To get rid of this disease, when in the throat, remove the growth with a pointed stick or pair of tweezers, and paint with the following mixture:—

1 drachm carbolic acid
3 drachms sulphurous acid
 $\frac{1}{2}$ oz. tincture perchloride of iron
 $\frac{1}{2}$ oz. glycerine.

Chlorinated soda is also a good remedy, especially when the comb is affected.

Crop Bound is due to a hungry fowl being allowed to indulge too freely on hard grain. It

is generally easily cured by pouring small quantities of warm water down the bird's throat, at the same time work with the hand the moisture among the grain. Affected birds should, of course, be couped up and given no feed until the crop has emptied itself. Should the crop fail to empty by this means, an operation is necessary, by cutting the crop open at the upper end and removing every particle of food. A surgeon's needle is required for this work, but the necessary curve can be got on any ordinary needle by heating red hot, and then bending as wanted.

Crop Soft.—In this case the crop is swollen up, but is soft to the touch. To empty it, hold the bird by the legs and squeeze out as much of the liquid as possible, but care must be taken not to hold the bird long in this condition, owing to liability of choking. Then place a small quantity of effervescent powder, such as Eno's Fruit Salt, in the bird's mouth and immediately wash it down with warm water; give doses until the crop is fairly full; coop the fowl up for a day or so without feed or drinking water, and a cure will be very soon effected. But do not let the bird have immediate access to feed or water in large quantities.

Egg Bound.—This complaint, generally caused by the bird being too fat, is noticeable by a fullness and constant visiting of the nest in attempts to pass an egg. A good deal of trouble and patience is required in treatment, also great care must be exercised to prevent the breakage of the egg whilst being passed out. The usual treatment is to soften the posterior portions of the fowl by holding it over boiling hot water, and thus thoroughly steaming for a quarter of an hour at a time; also inject salad oil into the vent.

Egg Eating.—Many fowl-yards are troubled with this vice, and some birds are very determined and hard to break off the habit; but it will be found that a mixture of kerosene and mustard made up in an empty egg-shell, and kept continually before the offenders for a few days, will soon cause them to cease breaking good eggs for the purpose of eating their contents.

Feather Eating.—This is a vice prevalent among poultry kept in small runs, over-fed, generally badly kept, and in want of exercise. Lice on the plumage generally starts the habit. Fowls picking at the vermin, a feather or two are drawn out, and thus the taste is acquired. As a remedy, dig over the whole of the run, dust each bird with insect powder, particularly around the vent, at the same time pluck out all lice nits which are found, principally round the vent, damp the plumage with some unpleasant mixture such as Jeye's Fluid, feed rather sparingly, chiefly on grain, which should be partially buried to give scratching exercise. To the soft food add sulphur and salt; give plenty of green stuff; cabbages hung up give good jumping exercise. Moulting cooks in well-kept yards are sometimes attacked by hens, the new tail feathers being the attraction. In this case at once remove the cock to a pen by himself until the feathers are well grown. Frequently the hens turn their attention to the cock's comb, which they pick, making a large,

raw sore. This sometimes happens in the breeding season, when the cock cannot be taken out of the pen. The best plan is to every day smear the comb with carbolated vaseline.

Leg Weakness.—This is not a disease, but a complaint, principally confined to cockerels of the long-legged breeds, such as Langshans, the weight of their bodies being too much for their long shanks. Prevention is decidedly better than cure, therefore if breeders of lanky chickens would always mix a little dry bone-meal in the soft food there would be but little leg weakness. It is often the biggest "youngster" in the flock that gets badly infected with the tired feeling, and has to squat on his hocks to feed. If he is not valuable, use him for the table; but if a good pure-bred bird, keep him in a roomy coop or small pen, well covered with sand or straw; give good, sound, nourishing food, plenty of green-stuff, bone dust, and tonic in the drinking water.

Roup is the greatest scourge of the poultry yard in this State, and the want of knowledge how to treat it has led to the loss of large numbers of poultry, and been the means of damping the ardour of many poultry breeders. At the offset, I might say, before going into details about the disease, that it is well worthy of a good deal of consideration being given to the best means of taking all precautions to prevent the disease breaking out. One of the chief causes is in allowing diseased fowls to come into contact with the healthy ones, either by association with the flock of a neighbour's birds or from stock purchased from a diseased yard. Contagion is very easily spread, and although an apparently healthy bird may be bought, yet it will carry the diseased germs with it. Therefore the greatest care must be exercised in introducing strange birds to an already healthy yard. Carefully examine all new arrivals, squeeze the nostrils to see if there is any discharge, examine the throat and windpipe for any appearance of yellow spots, and if there is the slightest doubt about the health, quarantine the new arrival for a week or ten days.

Roup generally starts with a slight cold, the symptoms of which are already described. Should the poultry-keeper be so indifferent or careless as to allow birds to remain running about with colds, roup is likely to develop, and will have got such a hold on the stock that the death of some, and the distressing symptoms shown by others, will at last have had the effect of drawing their owner's attention to the fact that his fowls are seriously ill, and that something will have to be done to prevent further loss or the total extinction of his flock. The symptoms by this time will be well developed—swollen eyes, filled with a thick cheesy matter, nostrils also discharging or clogged up, and mouth much ulcerated, loss of appetite, difficulty in breathing, and great weakness. Of cures there are hundreds, but whatever remedy is adopted, regular handling once or twice a day is necessary, which, besides being disagreeable work, also requires a fair amount of skill in carrying out; and even if a cure is effected it is not wise to use a bird that has been badly infected in the

breeding pen. It may be necessary to use the knife to remove the cheesy matter by making a cut below the eye, extract as much offensive matter from the mouth as possible, wash out all the parts with a mixture of phenyle and water, apply crude phenyle to the bad parts in the mouth, and as a medicine, if none of the advertised "roup cures" are available, add sulphate of iron to the drinking water, or Parrish's chemical food. Feed only on soft food, seasoned with a little salt, ginger, and cayenne pepper. The following prescription is recommended by Lewis Wright:—

Balsam copaiba, 1oz.
Liquorice in powder, 4 drachms.
Pepperine.

Add sufficient magnesia to make a mass, into 60 pills, giving one morning and evening.

Roup, in a diphtheric form, occasionally affects a single bird in an otherwise healthy yard; in which case immediately isolate the infected bird. The symptoms are a sudden and general depression and loss of appetite, accompanied by a swelling in the eye and a growth in the throat. Keep up the bird's strength by feeding on beaten-up egg. Extract the cheesy matter from the eye, and touch the spot where it was extracted from with a minute speck of pure phenyle; also apply some to the mouth. Other prescriptions for the same complaint are to paint the diseased mouth or throat with sulphate of zinc or the following:—

1 drachm carbolic acid
3 drachms sulphurous acid
 $\frac{3}{4}$ oz. tincture perchloride of iron
 $\frac{1}{2}$ oz. glycerine.

Scaly Leg is an unsightly affection of the shanks, consisting of a growth of scales and lumps, which are a source of considerable irritation to the fowl. A minute insect, invisible to the naked eye, is the cause of this disease, which by some authorities is said to be infectious, but such has not been my experience. It is fortunately easily cured by first removing as much of the growth as possible by means of soap and water applied by a nail brush. Then, with a small bit of wood, remove all growth from under the scales without bringing blood. Then thoroughly rub in a mixture of sulphur and lard. One or two applications generally affect a cure.—*West Australian Journal of Agriculture.*

HOUSEHOLD HINTS.

The banana is one of the most nourishing of fruits. The amount of nutrient material contained in a pound of bananas is almost equal in sustaining value to that found in a pound of beefsteak. The amount of nitrogenous or albuminous substance found in banana is about 5 per cent. In the dried banana the proportion is about 20 per cent, or one-fifth. A gruel made of dried banana flour is not only highly nutritious but in the highest degree wholesome, and is often tolerated when ordinary farinaceous preparation and milk are promptly rejected.

Cut flowers will keep fresh much longer if a small quantity of alum is added to the water in

which they are placed. A solution should be made by dissolving the alum in hot water, allowing it to cool and then adding fresh water in about the proportion of a pint to a table-spoonful.

The leather coverings of chairs and writing tables may be renovated by being well-brushed and dusted, then rubbed lightly over with a soft brush dipped in white of egg beaten to a froth. The leather when dry will appear quite fresh again.

GINGER PUMPKIN.—Peel and slice $3\frac{1}{2}$ lbs. of pumpkin, place in a preserving pan with $2\frac{1}{2}$ lbs. of sugar and let it stand over night. In the morning drain off the juice and add to it two lemons sliced and 2 oz. of ginger-root. Boil until the syrup is thick, then drop in the pumpkin and boil until cooked through.

LEMON OR ORANGE CHIPS.—Cut the fruit lengthways and take out all the pulp and soak the rinds in salted water for three days. Cut into chips and boil in plenty of water until very tender, then place on a sieve to drain, make a syrup with a pound of sugar to every one of rind, and a pint of water, and boil the chips in it until the syrup candies on the chips and round the sides of the pan. Then take them out and sprinkle freely with pulverised loaf sugar, arrange them on a hair sieve, place in a cool room, and let the sugar harden. When dry and firm pack in layers in boxes with rather thick paper between.

ORANGE SNOW.—Soak one ounce of gelatine in a gill of cold water till very soft, then a gill of boiling water and two ounces of castor sugar. Pass three oranges through a sieve and add to the gelatine and sugar. Stir all together over the fire till just on boiling point, then remove from the fire, and when cold and nearly stiff whisk to a stiff froth, whipping in the whites of three eggs. When all is stiff and very white, pile in the centre of a glass dish and edge with sponge fingers. If this is not sufficiently flavoured with orange for your taste simmer a piece of the peel with the gelatine, and take it out before adding the whites of eggs.

TOMATO SAUCE.—Boil 40 lb. of tomatoes to a pulp without adding water, strain to take out seeds and skins; add 2 quarts vinegar, 3 lb. sugar, $\frac{1}{2}$ lb. salt, 2 oz. garlic, 2 oz. allspice, $1\frac{1}{2}$ oz. cloves, $1\frac{1}{2}$ oz. black pepper corns; 1 oz. cayenne; simmer gently for five hours till thick as cream, bottle and cork when cold. Strain through a piece of strong mosquito net. Tie the spices and garlic in a net, which saves straining a second time and does not waste the sauce.—

TOMATO SAVOURY.—Scald three ripe tomatoes, peel them, and remove the seeds, bake until tender, and mash through a sieve. Add 1 oz. of fine breadcrumbs, 1 oz. of grated cheese, two well-beaten eggs, salt and pepper to taste. Have ready some croutons of fried bread. Stir the tomato and egg mixture together in a

enamelled saucepan over a clear fire till set. Pile on the croutons, scatter a little chopped parsley on each, and serve at once.

PRINCIPLES OF NUTRITION AND NUTRITIVE VALUE OF FOOD.

(Continued.)

"We live not upon what we eat, but upon what we digest." Food as we buy it in the market, or even as we eat it, is not usually in condition to be made into body structure or used as body fuel. It must first go through a series of chemical changes by what is called digestion, which prepare it to be absorbed, taken into the blood and lymph, and carried to the parts of the body where it is needed. Digestion takes place in the alimentary canal, partly in the stomach, but more in the intestine. As the result, the useless portions are separated and rejected, while the parts which can serve for nutriment are changed into forms in which they can be absorbed, taken into the circulation, and utilized.

The alterations which the food undergoes in digestion are brought about by substances called ferments, which are secreted by the digestive organs. The saliva in the mouth has the power of changing insoluble starches into soluble sugar, but as the food stays in the mouth only a short time, there is generally little chance for such action. The saliva, however, helps to fit the food to be more easily worked on by the stomach. The gastric juice secreted in the stomach acts upon the protein, fats, and carbohydrates. The action of all the ferments is aided by the fine division of the food by chewing and by the muscular contractions, the so-called peristaltic action, of the stomach and intestine. These latter motions help to mix the digestive juices and their ferments with the food.

The parts of the food which the digestive juices cannot dissolve, and which therefore escape digestion, are periodically given off by the intestine. Such solid excreta or feces, include not only the particles of undigested food, but also the so-called metabolic products, *i.e.*, residues of the digestive juices; bits of the lining of the alimentary canal, etc.

The digested food finds its way through the walls of the alimentary canal, and in this passage undergoes remarkable chemical changes, as is seen when we compare the contents of the alimentary canal before they are absorbed and taken into the circulation, with the blood which has been made from the digested material. When finally the blood, supplied with the nutrients of the digested food and freighted with oxygen from the lungs, is pumped from the heart all over the body it is ready to furnish the organs and tissues with the materials and energy which they need for their peculiar functions; at the same time it carries away the waste which the exercise of these functions has produced. It is a characteristic of living body tissue that it can choose the necessary materials from the blood and build them into its own structure. How it does this is one of the mysteries of physiology.

The body, as we have learned, has also the power of consuming not only the materials of the food but also parts of its own structure for the production of muscular work, or heat, or to protect more important parts from consumption. How it does this is another mystery, still to be explained.

After the material has been thus assimilated and utilized the resulting waste products must be removed from the body. The chemical elements which this waste contains are of course the same as those making up the structure of the body and the food—carbon, oxygen, hydrogen, nitrogen, calcium, phosphorus, sulphur, etc. Most of the carbon and part of the oxygen are given off from the lungs as carbon dioxid. Hydrogen unites with more oxygen to form water, which is passed off in vapour from the lungs, in perspiration from the skin, and in urine from the kidneys. Almost all the nitrogen is excreted in the urine. Waste mineral matters are given off to some extent in the perspiration, but mainly through the kidneys and intestines.

The real nutritive value of a food, then, depends not simply on the proportions of nutrients which it contains, but also on the amount of those nutrients which can be made available to the body by digestion for building material and for fuel. Part of the food eaten escapes digestion and is given off from the body in the feces. If we subtract the amount of this undigested residue from the total food the remainder will be the amount actually digested in the stomach and intestines, absorbed through their walls and taken into the circulation. This difference between the amounts eaten and those undigested represents the actual digestibility of food. A part of the food taken into the circulation, however, is later returned again to the alimentary canal mainly in the digestive juices that are needed for digesting the food. The material thus removed from circulation and returned to the elementary canal, which consists of so-called metabolic products, is excreted with the undigested residue in the feces. The remainder of the food taken into the circulation represents the amount retained by the body for building material and for fuel. The difference between the food which is absorbed and that which the body secures, therefore, is represented by the metabolic products. By the present methods of experimenting, however, the portion of the feces that consists of metabolic products cannot be satisfactorily distinguished from the undigested residue. It is very difficult, therefore, to determine the actual digestibility, but comparatively easy to estimate the apparent digestibility of food.*

* It would be more exact to use different terms to denote the apparent digestibility of food as distinguished from its actual digestibility. It has therefore been proposed to limit the use of the term digestibility to actual digestibility and only use the term availability when apparent digestibility, as ordinarily determined in nutrition investigations, is meant. (See Connecticut State Station Report 1899, p. 69.)

† William Beaumont, *The Physiology of Digestion, with Experiments on the Gastric Juice*, 2d ed. Burlington, Vt., 1847.

Suppose, for instance, that 15 per cent of the protein in a specimen of bread is excreted, then 85 per cent remains for the use of the body. If the bread has 8.4 per cent of protein, 100 pounds will have 8.4 pounds, of which 85 per cent or 7.1 pounds will be utilized by the body.

The terms digestible, indigestible, etc., as here used refer simply to the food which is or is not available for the general nourishment of the body after the process of digestion is completed. In common parlance, however, they are used more loosely as referring to the ease and quickness of digestion, and to the general healthfulness of food. One kind of food, bread, for instance, is spoken of as "simple" and "digestible," and another, like fruit cake, as "rich" and "indigestible." There is often much practical truth behind such statements, though little is definitely known concerning the time or labour required to digest different kinds of food.

Among the earliest and most famous experiments concerning the time required for digestion in the stomach are those made by Dr. William Beaumont, U. S. A., between 1825 and 1833. His subject was a French-Canadian trapper, a man quite normal except for an aperture through the abdomen into the stomach made by a gunshot wound, and closed only by a valve which had developed over it. By pressing the valve inward the contents of the stomach could be observed or removed at will, thus affording excellent opportunity to study the action of the gastric juice. Dr. Beaumont fed the man on various diets, and noted the different conditions accompanying each. The book in which he describes his experiments † contains a table of the average time required for the stomach to digest various articles of diet, from which many of the statements still current concerning the relative digestibility of different foods are taken.

One of Dr. Beaumont's general deductions was that most of the common foods required from 2 to 4 hours. He says further:

"The time required for the digestion of food is various, depending upon the quantity and quality of the food, state of the stomach, etc., but the time ordinarily required for the disposal of a moderate meal of the fibrous parts of meat, with bread, etc., is from 3 to 3½ hours."

Valuable and interesting as Dr. Beaumont's book undoubtedly is, its conclusions cannot be taken as final, because he does not state the amounts of food consumed. The science of nutrition in its development has also shown many errors in the reasoning. It should in justice be said that Dr. Beaumont recognized the fact that his experiments had to do only with digestion in the stomach, or "chymification," as he terms it. Furthermore, his experiments have been often misquoted and given a different interpretation from that which he intended.

Food does not ordinarily pass from the stomach into the intestine until it has been reduced to a liquid or semi-liquid condition. The length of time required for different foods to leave the

stomach has been recently studied by Penzoldt with healthy men. He used a stomach tube for removing the stomach contents for examination. He found that the amount and consistency of food have a marked influence on the rate of digestion in the stomach. Fluids leave the stomach more rapidly than other materials. From 6 to 7 ounces of water or other common beverages leave the stomach in 1½ hours. Seven ounces of boiled milk leave the stomach in about 2 hours. Hot drinks do not leave the stomach more quickly than cold ones, nor does the quantity have much effect. Solid matter in solution or suspension delayed the passage of fluid from the stomach somewhat. The consistency of solid foods thus seems to have more effect upon digestibility than the amount consumed. The quantity eaten increases the length of time the material remains in the stomach, but not proportionally.

To select a few examples of the time required for foods to leave the stomach: Two eggs (raw, poached, or in the form of an omelet), 7 ounces sweetbreads, 10 moderate sized oysters, 7 ounces white-fish or 3½ ounces of white bread, cauliflower, or cherries, each left the stomach in 2 to 3 hours. Eight and one-fourth ounces of chicken, 9 ounces of lean beef, 6 ounces boiled ham, 3½ ounces roast veal or beefsteak, 5½ ounces of coarse bread, boiled rice, carrots, spinach, radish, or apple, left the stomach in 3 to 4 hours. Nine ounces of smoked tongue, 3½ ounces smoked beef, 9 ounces roast goose, 5½ ounces string beans, or 7 ounces peas porridge, left the stomach in 4 to 5 hours.

Generally speaking, the most readily digested animal foods were materials of soft consistency. White meats—for example, chicken—leave the stomach more quickly than red meats or dark meat—for instance, duck. The method of cooking also exerts a very marked influence on stomach digestion. Fresh fish was found to be more readily digested than meats.

As regards vegetable foods in general, the consistency and the amounts of solid material were again the principal factors affecting the time required for digestion in the stomach. Mealy potatoes, for instance, were more easily digested than waxy potatoes, and mashed potato more readily than potato cut up in pieces. Fine bread was more quickly digested than coarse bread. There was not much difference in the time required for bread crust, bread crumbs, toast, new bread, and stale bread to digest in the stomach, provided all were equally well chewed.

It must be remembered that digestion continues in the intestine, and that the total time required for the digestion and absorption of the nutrients in any given food material is not shown by such experiments. They find their chief application in prescribing a diet for invalids, as in such cases it is often desirable to require of the stomach only a limited amount of work.

Digestibility is often confused with another very different thing, namely, the agreeing or disagreeing of food with the person who eats it. During the process of digestion and assimilation the food, as we have seen, undergoes many

chemical changes, some of them in the intestines, some in the liver, muscles, and other organs. In these changes chemical compounds may be formed which are in one way or another unpleasant and injurious, especially if they are not broken down (as normally they are) before they have opportunity thus to act. Some of the compounds produced from the food in the body may be actually poisonous.

Different persons are differently constituted with respect to the chemical changes which their food undergoes and the effect produced, so that it may be literally true that "one man's meat is another man's poison." Milk is for most people a very wholesome, digestible, and nutritious food, but there are persons who are made ill by drinking it, and they should avoid milk. The writer knows a boy who is made seriously ill by eating eggs. A small piece of sweet cake in which eggs have been used will cause him serious trouble. The sickness is nature's evidence that eggs are for him an unfit article of food. Some persons have to avoid strawberries. Indeed, cases in which the most wholesome kinds of foods are hurtful to individual persons are, unfortunately, numerous. Every man must learn from his own experience what food agrees with him and what does not.

How much harm is done by the injurious compounds sometimes formed from ordinary wholesome food is seldom realized. Physiological chemistry is revealing the fact that these compounds may affect even the brain and nerves, and that some forms of insanity are caused by products formed by the abnormal transformations of food and body material.

(To be continued.)

GENERAL ITEMS.

A practical gardener of considerable experience attributes much of his success in fruit cultivation to what he terms his "own methods." In the case of Oranges, Mangoes and other hard-stemmed trees he periodically slits the bark from top to bottom, on two sides, and removes "weedy" and "uncalled for" branches. In the case of the plantain he digs out the entire underground stock of the tree that has borne its fruit, for the reason that the young plants are hampered by a sodden rotting mass that keeps their roots from developing on the side of the old plant.

Balsamodendrum caudatum is the botanical name of a tree known in Tamil as "Kilivai," and largely used as a lipe fence stick in the North. It belongs to the order Burseraceae to which "Kekuna," *Canarium zeylanicum* and "Pehimbiya" *Filicium decipiens* (two well-known Ceylon trees of large size) also belong.

An old subscriber writing to us from a station in Queensland under date 13th April, says: "Since last writing prospects have slightly improved, but under the most favourable circumstances we cannot hope for more than a half crop, and that

will not pay expenses, irrespective of wear and tear, interest and such items. I append a memo of our rainfall here for the last ten years, which may be of interest to you. This is a comparatively new district, and our records do not go further back. You will observe they are taken for our season September to August, and not as the official returns (which are entirely misleading) from January to December. I have no records for temperature, but they were very high, with unusually high hot winds for the past three or four years." We only give the return for the last season which is as follows:—September to December, 1901 = 4'27, January to April = 5'45, May to August = '91, or a total of 10'63 for the season. This is a poor record indeed, and our correspondent's note as to crop "oil" is not to be wondered at.

For nearly a century past Germauy has been alive to the supreme importance of training the children of agricultural districts in the intelligent cultivation of the land, and has been advancing year by year towards the attainment of this end. Opportunities are offered at well-equipped horticultural centres to landowners who can attend within easy distance of their homes courses of instruction in forestry, vine culture and fruit-growing, landscape gardening and horticulture, no less than to elementary teachers, farmers, and professional gardeners, the latter classes being assisted by Government grants for expenses and fees when they are unable themselves to defray the cost of such practical education. A large proportion of elementary village schools are provided with garden ground, where the elder children are trained in the grafting and management of fruit trees, of vegetables, and of flowers as are best suited to the conditions of the particular district. Even town schools, it would seem, are not left out of the general scheme, and have their allotted garden plots.—

For the information of a correspondent who is apparently studying, or at least much interested in Ceylon ferns, we supply the following botanical names corresponding to the common names sent to us:—

Kekilla, *Gleichenia linearis*.

Maideuhair, *Adiantum capillus-venaris*.

Bracken, *Pteris aquilina*.

Silver fern, *Gymnogramme leptophylla*.

Wel-henduru, (Epiphyte), *Stenochtaena palustre*.

Pamba, *Lygodium* sp.

N.B.—"Badalwauassa" is not a fern but a lycopod, and is botanically known as *Lycopodium cernuum*.

We are informed by a reliable authority that though Patipola appears in official rainfall returns as the wettest station in Ceylon, with a fall of over 200 inches per annum, nearly 400 inches of rain falls per annum not far from the Peak. Query: Why is no record kept of the rainfall of this extraordinarily wet region?

LITERARY REGISTER SUPPLEMENT:

AND CEYLON

"NOTES AND QUERIES"

[Under this heading, in future, we mean to give a small "Supplement" with our *Tropical Agriculturist*, from quarter to quarter, according as there is matter of sufficient value so to be preserved.]

DECEMBER, 1902.

DUTCH ARCHITECTURE IN CEYLON.

PART I,

(From *Architectural Review* for Sept. 1902.)

In a work published in 1900,* Mrs Trotter gives a number of sketches and engravings, from photographs of the "Old Colonial Houses of the Cape of Good Hope," with brief descriptions of them, and the subject has been treated from a more technical point of view in an article published in *The Architectural Review*, by Mr Arthur H Reid (Vol. viii., pp. 147-152 and 220, 225) which is also illustrated. The article is a fitting supplement to the book, and the illustrations in both serve to show what interesting and picturesque old buildings still remain in the Cape Colony as relics of the Dutch occupation, which ended in the first decade of last century.

The present writer has been much struck with the similarity in the appearance and details of these buildings to what he has been accustomed to see in the maritime towns of Ceylon. The same gables, doorways, windows, stoeps, garden walls, outside staircases, the same fort gateways, churches, belfries, are to be found in Ceylon as those that we find depicted in these illustrations. The explanation is that the Dutch East India Company that ruled at the Cape for a century and a half, also occupied the maritime ports of Ceylon for almost exactly the same period, leaving the island only a few years before its rule ceased at the Cape. So it comes about that even the cover of Mrs Trotter's book is suggestive of Ceylon, for on it we find the same monogram that confronts us from the gateways of the old Ceylon forts, and on the copper coins that are still to be met with in the bazaars—not now, however, fulfilling their original function, but for sale as old metal. It is the monogram of the company, and in this same shape cut in stone or wood, cast in metal, on cannon, swords and bayonets and coins, graved on

glass or painted on Delft, it went wherever the company went.*

The Dutch buildings extant in Ceylon are of course not so elaborate nor in such good preservation as those in the Cape Colony, and the inferiority on the part of Ceylon is sufficiently explained by its tropical climate, with the twofold result of a much smaller colonisation by the Dutch and a more rapid decay of the buildings, perhaps also by the use of inferior materials of construction.

There remain, however, several interesting old Dutch buildings, especially the churches, in regard to which Ceylon would appear, if anything, to have the advantage over the more important colony; and it seems a pity that some attempt should not be made to do for Ceylon what the writers referred to above have done for the Cape, before modern changes sweep away these relics of Dutch rule. The present writer has, during a residence of more than twenty years in the island, taken pains to leave no considerable Dutch building unvisited, as well as to provide himself with sketches or photographs of most of them, and though not an architect, has, in the present paper, essayed a task which might otherwise be unattempted.

The last century saw the removal or modernization of many old Dutch buildings, both by Europeans and natives, especially in the Colombo Fort and Pettah. In the former, the necessities of European trade have removed not merely the fort itself, but also nearly every building within it that had a distinctly Dutch appearance, and to find one now in its streets requires some search. The streets of the Dutch quarter of a Ceylon town† usually had on each side of

* By resolution of 28th February, 1603, it was decided that the monogram should be of the shape depicted in Illustration I., p. 108, and that the letters should be blue on a silver field.

† This was either within the walls of the fort, as at Colombo, Galle and Matara, or just outside it—"The Pettah"—as at Jaffna, Negombo, Kalutara, etc.

* London. B. T. Batsford, publisher, 91, High Holborn.

them a long row of one-storied houses with low pitched roofs and deep verandahs or steps, the latter supported by tall and slender wooden pillars, while along the outer edge of the verandah of each house was a wooden railing separating it from the street, which was a few feet below it; so that the perspective showed two long rows of these pillars diminishing in the distance. What variety there was, arose from the different shapes of the end gables of each house, the different colours of the woodwork—the Dutch have always been fond of bright colours—and on closer inspection, from the variety of ornamental fanlights and doorway lintels. Nowadays these wooden pillars have in many cases given way to pillars built of brick and plaster, not perhaps to the advantage of the picturesque, and the line of the street is often broken by the substitution for the overhanging eaves of an old house of a new two-storey house with a pretentious plaster façade, embodying the native conception of European architecture—whitewashed and spick-and-span to start with, but in a year or two weather-stained into shabbiness.

I have referred to the forts that were built by the Dutch at every station of importance held by them on the coast or inland as far as their territories extended. A detailed description of these is not necessary, as there is nothing distinctively Dutch about them except in their gateways.* The gateways are usually surmounted by the coat-of-arms of the state or the monogram of the company and the date of the erection of the fort. There was generally a belfry on one of the walls. The Colombo Fort was demolished thirty or forty years ago, when two or three fine gateways were destroyed. That at Jaffna, in the north of the island, owing to the drier climate and the materials of which the fort is built, viz, coral, is in excellent preservation, though it has suffered in the past from vandalism.

At Galle the preservation of the fort, which, like the Colombo Fort, included within it a great part of the Dutch settlement, gives the place the appearance of a walled town. Its demolition was threatened some years ago, but for the present it is safe. There are smaller forts at Batticaloa, Matara and Tangalla, and a few remains at Negombo, Kalutara, and at some places a few miles inland from the coastline.

Next we come to the churches. One at Colombo and one at Galle had been demolished before the British occupation. There are, however, churches in good preserva-

tion at Colombo, Jaffna, Galle and Matara, which belong or belonged to the Dutch Reformed Church. There are others in the Jaffna Peninsula, some in ruins, some rebuilt out of all likeness to their original design. Some have disappeared altogether, as at Negombo and Batticaloa, as well as the two referred to as having been demolished at Colombo and Galle. While on this subject, I must take leave to dissent, at any rate as regards Ceylon, from an opinion expressed by no less an authority than Mr. James Fergusson in his "History of the Modern Styles of Architecture" (p. 463), that "the Dutch have done very little in their settlements. Their churches, which are few and far between, are of the worst class of meeting-house architecture." On the contrary, wherever they had a station of any importance, the Dutch in Ceylon erected a church,* and the church was the best building in the station. It was always substantially built; and one is rather surprised to find that the Dutch, though Calvinists, have departed so far as they have done from the meeting-house type in their ecclesiastical buildings. The churches at Colombo (Wolvendahl) and at Jaffna are large cruciform buildings (Figs 6 and 7) with a central tower on lantern; large doorways and windows with arched lintels; pulpit, not in the centre of the walls as in the meeting-house, but at the intersection of the transept and what we should call the chancel or choir, with carved sounding-boards over them, and large pews or stalls for the civil and military officials and for the elders and deacons. At Jaffna the "Commandeur's" pew occupies the angle of the chancel and transepts opposite the pulpit, and stalls on each side of the chancel remind one of the mediæval arrangements (Figs. 9, 10). At Wolvendahl the pulpit occupies one corner of the intersection and a large pew or stall each of the other three corners. On the wall are memorial tablets of stone or wood, with armorial bearings blazoned in colours, supplemented by insignia such as batons, swords, and spurs. Though these buildings are of course designed in the quasi classical or Renaissance style of the period, they are instinct with the mediæval spirit, and their interiors with their massive walls and deeply recessed and heavily mullioned and many-paned windows, are solemn and church-like, with little of the meeting-house about them.

* In the populous Jaffna Peninsula alone they had a church in each of the thirty-two parishes into which the district had been divided, and "the substantial walls of many of them were standing" when the American missionaries entered into possession of them twenty years after the Dutch had left the Island. The Batticotta church, even though one-third of it at the "east end" has been partitioned off as a dwelling-house, can accommodate 2,000 people (Report of the American Ceylon Mission, 1896). I think myself, however, that the division of the Peninsula into parishes, as well as many of the church buildings, including Batticotta, were a legacy from the Portuguese, though the Dutch kept up the former and preserved or rebuilt the latter.

* The gateway of one of the two forts at Matara, in the Southern Province—"The Star Fort," as it is now called from its shape, though its official name was the "Redoute Van Eck"—has over it the arms and initials of Governor Van Eck, carved in wood with a wooden tympanum, on which is carved the monogram of the company, surrounded by a floriated design (see Fig. 3). This woodwork is still in excellent preservation, though it was done in 1763.

Both the masonry and the woodwork are solid and substantial, and altogether these two buildings and the church at Galle contrasts favourably with churches erected in the Island at a later period for the use of the Anglican Church.*

The writer has not visited Batavia, but Heydt,† who visited India, Ceylon, and Batavia about 1736, and made sketches of the principal Dutch forts and other buildings in those countries, gives a drawing and plan of the Dutch Church at Batavia which show a large classical building of a design which I should consider creditable for the place at and period in which the church was erected, with a central dome of good proportions. Possibly this church is not now in existence, but in any case I should say the opinion quoted has been formed on insufficient data.

The Jaffna church is situated within the walls of the fort. Its quaint gables, belfry, central tower, large two-light windows, with a circular opening above the lights under a general arch, giving it a touch of Romanesque, make it very picturesque, especially when seen over the fort wall and moat. The central tower of the Wolvendahl church seems at one time to have partially collapsed, and is now like that of the Jaffna church, rather squat. It is topped with a slated roof of modern construction. Judging from Heydt's picture, the tiled roof of the Jaffna church was in his time more spire-like than it is at present, and the apex was surmounted by the conventional cock, which remained, in fact until well on in the last century.

The Colombo and Galle Churches are still in regular use by congregations of the Dutch Reformed Church, though the Dutch language has been forgotten. The Jaffna Church belongs to the Government, which preserves it for its antiquarian interest. The church at Batticotta is of a different type altogether from these churches. It consists of a long nave with side aisles all under one roof, the aisles divided internally from the nave by massive pillars of masonry, eight or ten on each side and over a yard in diameter. A

* The pulpits are of the usual hexagonal or octagonal shape, those at Wolvendahl and Galle being attached to one of the walls, and that at Jaffna springing out of a central column. (The photograph, Fig. 12, does not show this, as the column is hidden by the preacher's or clerk's desk in front of it; but this two-decker arrangement may be an addition made in Anglican times, as are the altar rails. Wolvendahl has a quaint crown-shaped sounding-board. The organ galleries at Galle and Jaffna have a very Dutch look about them. That at Galle is at the "west" end and is a regular gallery (Fig. 11). That at Jaffna (Fig. 10) is a platform supported by heavy turned legs, and having a panelled front with a carved wooden valance. The centre panel is a representation of King David harping; this is painted in different colours.

† "Alterneuster Geographisch und Topographischer Schatz-Platz von Africa und Ost-Indien." Von Johann Wolfgang Heydt, Wiltbergsdorf 1744.

Dutch inscription over the doorway gives the date as 1678; but this is probably the date of the repair or rebuilding by the Dutch of the church. I am inclined to think from the plan, that this is one of the old Portuguese churches of the Jaffna Peninsula. The inscription runs: ("Doen maken door den Heer Commandeur Laurens Pyl, Anno 1678.") This may refer to the rebuilding only. The façade is apparently Dutch.

This departure of the Dutch from the meeting-house model in their churches* is no doubt due to the fact that in their beloved Netherlands they were accustomed to worship in large mediæval churches, shorn, it is true, of most of their ornamental details, such as tracery, carved work, and painting, and adapted to the Reformed worship, but still in the main preserving their most characteristic features—nave, choir transepts, and tower, elaborate pulpit and sounding-boards, stalls, organ, and organ gallery. When their merchants and officials in the East had to provide themselves with churches, they made them as like as possible in form to the churches of their native land, preserving at least the main features and plan, if not the details, of mediæval architecture. In an age which was incapable anywhere in Europe of building in true Gothic, it could hardly be expected that the Dutch in the East could have done more than they did. The churches at Colombo, Jaffna and Batavia compare favourably with many churches of the same size erected in England at the same period† and they had, if anything, less of the meeting-house type about them.

The most characteristically Dutch church in Ceylon, perhaps, is the church at Galle. It is of quasi-cruciform shape, with very shallow transepts, but it is the gables that give it its distinctively Dutch appearance. They are the best examples of the Dutch gable to be found in Ceylon. The gables of the Jaffna church are not of so markedly a Dutch shape, while those of the Wolvendahl church are more of the ordinary Renaissance or Italian character.

This introduces me to the subject of the Dutch gable, by which I mean the gable with a wavy outline which one has come to associate with Dutch domestic architecture. The work to which I have referred at the beginning of this article contains a chapter by Mr Herbert Baker, A.R.I.B.A., the archi-

* Whether the Batticotta Church is Portuguese or Dutch in plan, it, as well as the other three churches mentioned, is certainly a departure from this model, which regards a church merely as a preaching room. The American Mission report complains of the Batticotta Church that, "The massive pillars which make so brave a show hide the speaker from a considerable part of the room (*sic*), and are about as much a hindrance as a help." Accordingly, it has been made as much like a meeting-house as possible.

† The Church at Jaffna bears the date 1706, that at Wolvendahl, 1749. The Galle Church was probably built about 1755.

tect of Groote Schuur, the late Cecil Rhodes' house in the Cape Colony, on "The Origin of the Old Cape Architecture," in which he traces the development of the Dutch gable, and illustrates this, its most distinctive feature, from the Cape examples, and shows their similarity to examples in Holland and Belgium, in which he thinks this form of gable had its origin.

Though, however, I call this the Dutch gable, I do not think there was anything peculiarly Dutch about it in its origin. The same gable is to be found in use in most European countries soon after the birth of the architecture of the Renaissance. In England it is a feature of what we call the Elizabethan style, and there is a good example of it, for instance, at Mettingham, near Bungay, in Suffolk. The drawing of "A Kentish Homestead," by G C Haité, in *The Architectural Review*, vol. iii., p. 32, exhibits another.* The church at Gsteig, near Interlaken, has a saddle-back tower with gables in the same style, the date being 1650; and no doubt many other examples might be mentioned both in England and on the Continent. But the Dutch, once having made the discovery of this form of gable, seem to have taken a special fancy to it, and to have reproduced it, both at home and abroad, over and over again, with every possible variation in detail, and to have stuck to it when other countries had abandoned it for more classical forms, or for no form at all, as in our street architecture of the latter part of the eighteenth and first half of the nineteenth century. Streets and houses in Holland built at the same time would have been diversified by gables of every possible combination of curve and scroll-work and moulding. This gable has accordingly come to be regarded as distinctively Dutch. As Mr Reid puts it, it is "dear to the heart of all true Dutchmen, and in the treatment of it they excelled," and they carried it with them to their colonies. Mr Baker finds three main types of it at the Cape, and we have probably as many in Ceylon.

He describes what he thinks is an Amsterdam type, "two vertical bordering lines, with spreading scrolls at the sides." We have an example of this in the gables of the Wolvendahl Church, though the influence of the classicism then prevalent (1749) is seen in the substitution of a pediment for the wavy outline of an earlier period, the flat pilasters supporting it, and the breaking up of the surface of the wall by horizontal lines so as to suggest that it is constructed of blocks of stone. A variety of this gable is to be seen in a house in the Fort of Colombo. The date is probably 1684.

Mr Baker distinguishes another type of Cape gable by "its peculiar characteristic, the scroll running in graceful lines over the surface of the wall," and considers it admirably suited to plaster. He thinks this type "an undoubtedly original form," and

states that nothing exactly like it is to be found in Holland or Belgium, that "a similar type of gable existed formerly in Amsterdam, but none exist at the present day." It is, however, not peculiar to the Cape, for it is to be found in Ceylon, where, as at the Cape, all these gables are plastered over. A good example of it is to be seen in the gable of the Galle Church. Its origin, says Mr Baker, is to be found in Belgium, also "the same peculiar feature of the scrolls running over the walls can be observed in the monster fronts of the rich guild houses in Antwerp and in the simple plaster gables of the Cape farmhouse—the rude attempt of a colonial craftsman to copy what he remembered of the buildings of his native town." These features will be noticed also in the Galle example. In Ceylon at the present day we have no Dutch farms or country houses. If there were at any time in Ceylon houses of the Cape style showing one or more gables in the front elevation—and it seems probable that there were, as some of the Dutch officials had country houses standing in extensive grounds—they have disappeared, or have been modernised, and Dutch domestic architecture in Ceylon is the architecture of the street only. For the most part, except in the churches, the craftsman had to confine himself to the end gables of the houses of a street. The front elevation, consisting merely of a roof carried over a verandah supported by wooden pillars, afforded no scope for more elaborate work. The commoner form of gable in Ceylon was, therefore, of a similar type. Each slope is formed of scroll-work, something in the shape of the ordinary "bracket" used in writing moulded in plaster. There is a vase, or a leaf, or a ball, on a pedestal at each end, and another similarly mounted caps the apex.*

Another feature of the Cape gables which struck Mr. Baker was "an unusual double scroll," as seen also in an Antwerp house. The same feature is found in the gable of the Galle church, and I think from this circumstance that its origin must be looked for not in Belgium but in Holland, the home of the Reformed Church.

Simpler forms than any of the foregoing are to be seen in the end gable of what is now a large European store in the Colombo Fort, and in the gables of the church at Matara. In the latter, the *tout ensemble* strikes one at once as very Dutch. The date over the doorway is 1767, but this may be the date of its repair, as in the case of Batticotta, for the church certainly existed in Heydt's time. A still simpler form of gable, which, in my opinion, is of very early date, is to be seen in the façades of the Batticotta and Kalpitiya Churches,† and in the

* Mr. Baker notes that in the Cape gables "a vase is sometimes added where the scroll broadens out."

† The front porch or verandah of the Kalpitiya Church, which has a flat roof and is supported by Corinthian pillars seems to be an addition made early last century.

* See also some "Kentish Gables" at Ramsgate and Broadstairs of 1615-1678, in *The Architect*, Vol. XXVI. (1881), p. 107.

gateway of the fort at the latter place. The small pyramidal-shaped pinnacles may be compared with those on the tower of the church at Gsteig. They appear also, but more squat in shape, on the gateway of the Mannar Fort.

It may be laid down as an axiom that whenever the Dutch built a gable, how ever simple, they endeavoured to ornament it in some way with plaster mouldings and finials. Reduced to its most primitive form, the gable sometimes consisted of a triangle on the top of a rectangular wall. But there was a moulding of some kind along the sides, and the three angles were surmounted by pedestals with their ornaments. One can always, in Ceylon, detect a Dutch gable by this peculiarity, as well as by the substantial character of the work.

DONDRA.

From an archaeological point of view Dewinuwara, or Deundara, or Dondra, as we call it nowadays can claim some importance. It is, as we know, the Southernmost point of the Island; but few are aware that it has much to tell about the past.

Tradition assigns it to Dápuluséa, probably the Dapula I. or Dáthapabhuti who was enjoined by his father Silakúla to guard the sea-coast. He ruled the Ruhnna, as the country South of the Kaluganga was then called. After a period of three years he succeeded his father A.D. 539, and after the very short reign at Anuradhapura of only six months he is said to have committed suicide rather than suffer defeat from his brother Moggalana, who was the rightful heir to the crown.

Pattayame Lekama, a poet of some celebrity in the 18th century, in his "Kowminikoudala," the Buddhist Jayaddita Jatakā, records:—

DEVINUWAREHI PORANA
DEVOLKARAWU NARANA
DAPULUSEN NARANA
SARANA SEVENKHI WEDUNU PURANA.

In view of its geographical position its sacred associations and its being the haven of trading vessels from Arabia, Persia, and China, Dapulusen made it his capital. It is just a little hill projecting into the sea, with a Light-house at the present day. It is in the Wellaboda Pattu of the Matara District, four miles from the Railway and on the Tangalle Road, which almost bisects it from West to East. It comprises the three villages of Dewundara, Kapugama and Wauwa, with a population as computed by the last census of 6,733 souls. The inhabitants fish in the sea except a few northwards who follow some agriculture.

Eighteen pokunas or reservoirs and a like number of streets, tollokkuwas or lanes are said to have adorned the city, which must have extended to Gandara, "door of the city." The Devale is sacred to the Votaries of Vishnu who call it Thénamale, "Honey Hill." Though it is the exclusive property of the Buddhists, both creeds meet here to worship in peace and amity.

Ship-wrecks on the coast must have been of common occurrence as more than one legend seem to suggest. The following is one of them:—

A fine log of timber which was afterwards identified as Kihiri (Tennent calls it Sandal-wood) floated on the little bay by the side of the present

Light-house, whence the name Kihiriwella, corrupted into Kiralawella. It recoiled into the sea with every attempt to board it.

"Let us ask some prophet, priest or prove"
"Some dream-interpret (for dreams are often sent from jove.)"

In accordance with auguries, the sanctified people of the Devale approached it in fitting procession, and conveyed it from another little bay, Magaltotawala to the Devale. Next the sculptors are baffled. Their chisels refuse to carve the idol. In this predicament the old man whom you will at once recognise comes to the rescue:—

"Slow tottering from the novel where he hid,
Crept forth a wretch in rag, haggard and foul,
An old, old man, whose shrivelled skin sun-tamed,

Clung like a beast's hide to his fleshless bones.
Bent was his back with load of many days,
His eyes pits red with rust of ancient tears.
His dim orbs blear with rheum, his toothless
jaws,

Wagging with palsy, and the fright to see
To many and such joy. One skinny hand
Clutched a worn staff to prop his quivering
limbs,

And one was pressed upon the ridge and ribs."

The workmen had retired for their rural, and the solitary lad forbids entrance. Says he "there are the tools. Durst thou, an outcast, sacrilege besides?" Replies the spurious old man, "Tools want not I. Lo! one of my legs is already in the grave. Prithee, but for once let my eyes feast on the blessed one." He entered uttering these few words, but only not to be seen again. The workmen returned to find their work done to perfection. The idol lay carved as only the divine could carve it. The Kapuwo soon placed the idol in the sanctum. By a coincidence, however, the figure looked right into the sea with the disastrous consequence that every vessel crossing in a line with it must be wrecked. It reminds us of another old friend, Sinbad, the sailor. To make the idol look down was the ingenuity of two of the Kapuwo, whose descendants are known to this day as Devéndra and Dáva Suréndra.

The prosperity of the city was thus assured and the invaders succeeded in its overthrow only by first carrying off this precious idol, nobody knows where, perhaps, over the seas.

That the Devala was everything goes without saying. There is a solitary stone slab, probably the 'sannas' still remaining, but it is undecipherable. Stone pillars are scattered over the ground from the sea-beach and around the Devale. There are signs of a wall enclosing the Maluwa or Court-yard; but what is left of the Devale proper, is only a huge stone door frame. Pillars, evidently forming the carved way north, east and south, run as far as the Widiya. The Southern was perhaps, the principal entrance as one may judge from the base of a flight of steps. The present Devale and the Vihara are modern structures, the ancient buildings having been destroyed by the Portuguese, who also confiscated the endowments which are said to have been considerable. Not far from the Devale is an unpretentious artificial rock cave said to have been the abode of Galgane, whose cabalistic feats were unequalled. It is said that he had so much power over the unseen that all his servants were demons and

incarnate. Altogether Dewundara should prove a rich field for research. The belief of the people throughout the island in the power of the presiding deity has lasted for 13 centuries and it still lasts.

There is an annual Perahera and a fair a description of which should form another paper.

The "Kovulsandésa," an epistle conveyed by a cuckoo, invoking a blessing on the prince Sapumal, son of Prakrama Bahu VII, and praying that the war in Jaffna, in which the Prince was then interested, might terminate favourably was addressed to the god Devundara by Irigal Parivénadhapati, incumbent of the Muliigala A.D. 1410.

"Paravisandésa," a similar message conveyed by a pigeon, supplicating Vishnu to protect the king Prakrama Bahu and his son, and to grant a suitable consort to the king's daughter Chandróvasi was written by Sri Ropula of Totagamawa about the same period.

There lies at Sinhasanawella, the anchor of a vessel said to have been wrecked off Dewundra in the year 1812. Is it possible to ascertain to whom she belonged, or what was the fate of her unfortunate crew? The people were then famine-stricken and the wreck of the vessel was a god-send. They must have looted the vessel and it is a well-known fact that relics in the shape of plates, &c. are still found in the possession of old families. I have myself come across a piece of plate which I shall be happy to shew any gentleman who would care to see it. The finding of it prompted me to write these lines.

SECTION OF THE TROPICAL DISEASE.

AT BRITISH ASSOCIATION.

SIR WILLIAM R. KYNSEY, C.M.G., F.R.C.P.I.,
PRESIDENT.

PRESIDENT'S ADDRESS.

It affords me great pleasure to preside over this Section, and the honour conferred upon me by the British Medical Association in appointing me your President is one I highly appreciate. I accepted the position, I may assure you, as a compliment to the Colonial Medical Service, in which I spent many years of my life. * *

In the words of Lord Salisbury on a memorable occasion, "We live in a small bright oasis of knowledge surrounded on all sides by a vast unexplored region of impenetrable mystery. From age to age the strenuous labour of successive generations wins a small strip from the desert and pushes forwards the boundaries of knowledge"; or, as that great philosopher, Professor Huxley, well puts the same idea, "The known is finite, the unknown infinite: intellectually we stand on an islet in the midst of an illimitable ocean of inexplicability; our business in every generation is to reclaim a little more land, to add something to the extent and solidity of our possessions."

Marvellously minute observation is perhaps the most notable feature of scientific research in the last quarter of the nineteenth and the opening years of the twentieth centuries, combined with a severe spirit of criticism, and that now, as has always been the case, science, like religion, meets out its rewards only to those who diligently seek

it. In medicine one of the most surprising discoveries has been the relationship which has been proved to exist between insects and grave disease—the direct outcome of the modern spirit of research.

I have no intention of occupying your time with an account of the successive malarial discoveries made by observers of different nations which can now be found in the textbooks, and are known even to the man in the street, nor with the unworthy questions too often raised by discussions about priority. But it cannot be too often repeated that in the whole story of medical science there has been recorded nothing more wonderful than the prophylactic measures which have followed on the discovery of the malarial organism by the illustrious Frenchman, Laveran, and by the investigations into its life-history by Italian, German, and American observers, and by our own countrymen, Manson and Ross, according to the experimental method advocated by Bacon and Harvey. If these investigators have no other reward they will have the highest satisfaction men of science can enjoy—that of extending our knowledge of disease and of doing good to humanity. I consider the discovery of the malaria parasite—and that man is its temporary and the mosquito its definitive host and transmitter, that it completes its asexual life and prepares its sexual forms in human blood, while it completes the sexual cycle of life, that by which the life of the parasite external to man is assured in a particular species of mosquito, and that man becomes infected only through the bite of the *Anopheles*—one of the most epoch-making events of the age in which we live. It may be truly said that scientific research has gone hand in hand with practical and preventive medicine. The physician can give quinine with a full knowledge of how his remedy acts; and the sanitarian can try, and in many cases succeed in preventing the occurrence of malarial diseases by methods devised on scientific principles. The treatment and the modern prophylaxis of malaria exemplifying the idea of Socrates and Plato that "right knowledge involves right action."

Another most gratifying result of the study of the causation of malaria, and directly traceable to it, is the increased interest taken in the investigation of all tropical diseases by the establishment of schools of instruction and the formation of scientific expeditions and travelling scholarships. In the schools of Tropical Medicine of London and Liverpool, and from the lectures on diseases of the tropics in many of our colleges, the medical man intending to practise abroad can acquire an acquaintance with the diseases he will be called upon to treat, special advantages long enjoyed by the army, Indian, and naval services in the great schools of Netley and Haslar. I have the most grateful recollection of the instruction I received at Netley, where diseases from all parts of the world could be seen and studied. No one who had the privilege of their acquaintance can forget the gifted and amiable Parkes, the father of hygiene, that accomplished gentleman, speaker and writer Maclean, whose lectures may still be read with profit, and Aitken, the first pathologist of his day, whose work is a store-house of facts relating to tropical medicine. It is pleasant for an old Netley man to feel that the instruction in that great school has not deteriorated, and that it continues to send forth highly trained-officers ever

ready to fight disease in any part of the world. If the rumour is true that the army school is to be soon moved to London, I am sure you will all join me in wishing it a brilliant future.

In the history of the past year there is no great discovery to be recorded ; it may be looked back upon as one of steady progress in elucidating some of the many problems of tropical medicine, the greatest and most beneficent being in the scientific prevention of disease. In the case of yellow fever the mosquito—a *Culex*, not *Anopheles*—has been tried and found guilty of being the sole agent in the spread of that disease. In Havana yellow fever was endemic for a century and a-half ; during the past year it has been freed from the scourge by killing the mosquitos in the neighbourhood of each focus of disease as discovered, and by carefully disinfecting every house that had lodged a yellow fever patient in order to destroy the mosquitos that had bitten a sick person. This great sanitary triumph must ever redound to the honour of American medicine.

No excuse is necessary in this Section for dwelling a little on the important subject of the prophylaxis of malaria. An epidemic of any kind is among the most costly in life and money that can befall a town or district. An epidemic of malaria differs from other outbreaks of disease in this important fact that its effects are not limited to the deaths it causes, but that it often leads to years of suffering, poverty, and depopulation.

I have high authority for stating that, taking one year with another, malaria destroys twice as many people in India has cholera, small-pox, and all other epidemic diseases put together. It is a matter of history that the same cause almost annihilated the soldiers of the Walcheren expedition, and the army under Wellington in Spain was so assailed by malaria that according to Ferguson the enemy and all Europe believed the British forces were exterminated. Malaria stopped the great Panama scheme of de Lesseps. I have known districts in Ceylon almost depopulated. Almost disastrous outbreak occurred some years ago at Galle a town previously malaria free—attended with great loss of life in consequence of the construction of a railway the embankments of which were made by excavating pits at the sides that soon were filled with rain water. In those days the origin of the fever was, of course, attributed to disturbance of soil. We now know the pits provided breeding places for the *Anopheles*, and the Sinhalese and Tamil labourers from malaria districts supplied the organisms.

Although we were ignorant of the true conditions which caused the outbreak, we advised the filling up of the pits on the disturbance of soil theory with satisfactory results, proving that much can be done in the prevention of disease before full knowledge of causation is reached.

I will only occupy a few minutes of your time while I describe two experiments—one made by the Colonial Office on Dr Manson's advice, and the other by the Japanese Government, which clearly show it is both possible and practicable to prevent malarial infection.

In the experiment conducted by Drs. Sambon and Low in the Roman Campagna and in London in order to prove the truth or error of the mosquito malarial theory, and also how far protection against malaria might be consistent with the ordinary avocations of life, two experiments were necessary, one that healthy persons in London should be bitten by infected

mosquitos from a malarious region, and the second that men should live in an undoubtedly malarious place during the fever season, being protected only from the bites of mosquitos. Those bitten in London contracted ague. Drs. Sambon and Low and two others lived in a mosquito-proof hut in a most intensely malarious place in Italy, where all the inhabitants suffered from malaria. The four inhabitants of the hut remained perfectly healthy all the time, and, I believe, are so still.

The experiments by the Japanese Government were carried out on the Island of Formosa, and they furnish a most conclusive demonstration of the relations between mosquitos and malaria. A battalion of soldiers who were completely protected from mosquitos for 161 days during the malaria season escaped the disease entirely ; whereas there were 259 cases of malaria in another battalion in the same place and during the same length of time not protected from mosquitos.

I am sure you will agree with the conclusions of Drs Sambon and Low that their experiments prove that mosquitos only are capable of transmitting malarial fever ; that protection from their bite implies absolute immunity ; and that protection can be easily obtained. If further proof is considered necessary for large bodies of men, it is furnished by the Japanese experiment.

By a study of the life-history and surroundings of the *Anopheles*, and by varied and long-continued experiment, Ross has determined the best means of preventing malarial infection. He advised the extermination of the *Anopheles*, and although this is difficult it is not so difficult as at first sight it appears. These mosquitos breed in small pools of a certain kind easily recognized and easily dealt with, always close to human habitations, as the females must pass frequently between the pools where they lay their eggs and the houses where they obtain their food. If the *Anopheles* are found in a house the breeding puddles are close by. The great practical points derived from Ross's work are two :

1. That the life of the *Anopheles* is in direct and intimate relation with the annual epidemics of malaria fever.
2. That it is only necessary to drain the *Anopheles* puddles and not the whole of a malarious district.

I believe the discovery of the malarial parasite, and the investigations into the life-history of the mosquito which conveys it to man have placed us in the position to suggest measures which if carried out would have the effect in an unhealthy district of largely reducing the amount of malarial fever and eventually of exterminating it.

1. Malarial fevers should be included and notified among infectious diseases, so that precautions could be taken to prevent their spread.

2. Persons, especially children, suffering from malaria, primary infections or recurrences, should be isolated and treated with quinine to prevent as far as possible the infection of mosquitos.

3. Persons infected with malaria should be prevented coming to a healthy place to infect mosquitos.

4. The puddles in which the *Anopheles* breed should be drained and lilled up or treated with kerosene to destroy the larvae.

5. Doors and windows of houses, gaols and hospitals in malarious districts should be screened with wire gauze, and beds should be provided with netting to prevent mosquitos entering and biting the occupants.

I am painfully aware how far this address falls short of what might have been accomplished by a more skilful hand-writing upon the all-important subject of malarial prevention, but my remarks will not be thrown away if they induce those not acquainted with recent work to take an interest in and to appreciate the wonderful results in tropical medicine which have followed on the discovery of the malarial parasite.

Let knowledge grow from more to more
But more of reverence in us dwell ;
That mind and soul according well,
May make one music as before ;
But vaster.

(IN MEMORIAM.)

British Medical Journal, Sept. 20.

THE NEW BIOLOGICAL STATION AT PORT ERIN.

VISIT OF THE ISLE OF MAN NATURAL HISTORY ANTIQUARIAN SOCIETY.—DR. HERDMAN ON THE STUDY OF MARINE BIOLOGY.—PRESENTATION OF A BURST THE LATE PROFESSOR FORBES.

On Sept. 27th, the members of the Isle of Man Natural History and Antiquarian Society paid a visit to the newly erected laboratory and museum at Port Erin, by invitation of the Liverpool Marine Biology Committee. The latter body was represented by Prof. Herdman, D Sc., F.R.S., etc., and Mrs Herdman, Mr Isaac Thompson, F.L.S., and Mr H C Chadwick, the curator. The visiting party included the Rev. C H Leece, President of the Isle of Man Society, and Mrs Leece; Mr P M C Kermedc, Hon. Sec., Sir James Gell, Deemster and Mrs Moore, the Rev. Canon Kewley, Mr F Saunderson, Mr W R Teare and Miss Teare; Mr G Patterson, Mr P G Raffe, Mr W C Cubbon and Miss Cubbon, Mr Henry Kelly, Mr Egbert Rydings and others. The visitors spent a short time in making a preliminary examination of the new and commodious building, and in admiring the live specimens of Manx fish in the tanks of the Aquarium. The whole party then seated themselves, and the following proceedings took place.

PROF. HERDMAN said: Ladies and gentlemen, on behalf of the Liverpool Marine Biological Committee, I have the honour and pleasure to welcome you to their biological station. This visit of the Isle of Man Natural History and Antiquarian Society to the Port Erin Biological Station is now really assuming the character of what botanists call a hardy annual, and I am finding it increasingly difficult as occasions go on to find anything new to say to you which you might care to hear. But, on the present occasion, there seem to be two points that one might say a few words about—two points obvious to us, because they are present. In the first place there is the new building in which we are assembled, and, in the second place, there is your Society, which has come here. In regard to the building, the first point I must make clear is that I am only speaking on behalf of what we call the L M B C. Although the building is, in

great part, a Manx institution, the Isle of Man Sea Fish Hatchery, on the present occasion I have nothing to say in regard to it from that point of view—all that will come later, I hope, at the opening of the institution as a fish hatchery by the Committee—the Government Committee I think one calls it—which has charge of the fish hatchery. On the present occasion we welcome you here on behalf of the other side of the building to a scientific institution—the Marine Biological station. The building is composed of three parts. There is the central part, in which we are now meeting, and two extensive wings. The west wing is the sea fish hatchery, on both floors, and the east wing is the scientific laboratory, on both floors. We shall afterwards go through the various rooms and see the various purposes to which the different parts are put. This room in which we are assembled, as is obvious, is the aquarium, and above is what is going to be a museum; but that will come later. These three different parts have three different purposes, and yet they all help one another. The sea-fish hatchery, as the name suggests, is for dealing with the eggs and the young fish in the larval state, which are of importance to men—the economical, the marketable fish—and we all hope the result of the operations in the sea-fish hatchery will be

STOCKING OF YOUR BAYS

round the various parts of your Island with valuable flat fish—(hear, hear)—and the supplying to your rocky cliffs and sea weedy regions of additional lobster population. I look upon the flat fish and the lobster as two of the most important things in the sea with which one can deal economically in this particular building. It may be that other kinds of marine animals useful to man will be dealt with in the future, such as oysters, and possibly others; but my own impression is that we shall find that our work will best be devoted to flat fish and lobsters. I am speaking for myself now as a scientific man, and not for the sea-fish hatchery at the present moment. This is the scientific part of the building, that is, of course, for the work of the naturalists of the Liverpool Committee, several of whom are present today, and others of whom who would have been glad to have been present if they could have managed it. We have had several letters regretting the inability of members to come over on this occasion. Why should naturalists want to have marine laboratories? The genesis of modern laboratories is rather an interesting question in the history of science. Not so very long ago, in the first half of the last century, naturalists were what we generally call field naturalists. They had not, therefore, to do with laboratories or aquaria, or any such accessories; they went into the open and made observations with their eyes, and that is very good practice; and I have very much admiration for the old-fashioned field naturalist—I wish we had more of them at the present day (Applause.) A considerable change took place in the study of natural history about the sixties or the early seventies—in the day when Huxley was at the height of his fame and the thick of his important work. He introduced

THE LABORATORY METHOD;

he went more deeply than had been done before except by certain medical anatomists, into the structure of all animals, and saw how important it was that the biological student should not only work in the open, but in the laboratory

with instruments of precision—with the microscope and with the microtome, used for cutting thin slices of animals so that you can study the most internal parts with highly magnifying powers. That plan was then taken up with such energy that it led for a time, one may almost say, to neglect of field work, and reached its climax, perhaps, in the great school of natural history at Cambridge, under the late Professor Balfour and his pupils, in his school of research, in the eighties. And then it began to be felt that the pendulum had swung too far in that direction; that it was time to turn again to Nature, and that is what gave rise to the biological station. It was felt that we were beginning to examine animals so minutely that we were likely to forget what animals were like, and so the combination was effected of the field naturalists and the laboratory anatomists. That combination led to the establishment of biological stations. A biological station is only a laboratory placed close to the edge of the sea, so that you can go from the laboratory very easily to the sea shore or bring the sea into tanks in your laboratory, and, by that means, have the animals living in your laboratory and bring your instruments of precision to bear upon the living animal and its habits. This is merely the seaside workshop of the naturalists, and once that rather obvious point had been observed, biological stations became important, and sprung up in all directions. Thirty years ago or so there were none; now there are some forty or fifty, perhaps, scattered round the shores of the civilised world, extending as far as California in one direction and Japan in the other at that very notable biological station at Misaki, on the shores of the inland sea of Japan. There is also one in Australia, and one on the northern coast of Russia, within the Arctic Circle. The most notable of all, and one of the earliest, is the great biological station at Naples, and the aquarium, which many of you have, perhaps, seen—it is one of the sights to visitors to Naples. But the best one in this country is at Plymouth—it does not belong to Plymouth, but is there because Plymouth is the best place to have it. It belongs to a London Society, or rather to the naturalists of the United Kingdom, the chief officials of which are the London biologists. Well, as you know, the Liverpool biologists, some 15 or 16 years ago, came to the conclusion that they must have a marine laboratory in order to conduct their work properly. They established the first institution on Puffin Island, on the coast of Anglesey, and then we removed to this very much

BETTER CENTRE AT PORT IRIN,
in 1893, I think, when Governor Walpole opened for us our little pair of cottages on the other side of the bay, where we have worked for the last 10 years nearly. And now we are in these much more favourable, almost palatial, quarters, which will certainly give us greater facilities for work—you will see for yourselves what these facilities are. There are nice little work-rooms placed at the disposal of members of our Committee and students from the universities. Mr. Chadwick, our excellent resident curator—(applause)—has already had three or four university students working during the long vacation which has just finished, and we shall hope to have a great many more next year. Then, there is this central part of the building, about which I must say a word or two. This is the part that is going to be opened to the public, and our view is that it has an educational value. You

all know how, in high educational circles, of late years, great stress has been laid upon what has come to be called Nature study. You know how the Board of Education—the Education Department—in London, has taken the matter up; how schedules and schemes of Nature study have been authorised, and examinations held on the subject. Classes have been opened in public schools, and, in fact, the subject is a growing and important one. Nature study cannot be advanced better than by such buildings and such arrangements as tanks and museums, added to walks in the fields, and the study of the actual animals on the sea shore and the moors. And, in addition to these, which cannot be undertaken at all times, and in all weathers, a great deal of Nature study can be advanced by means of aquaria and well-arranged museums. That is coming to be understood in all the large towns, and I hope that this part—this central part—of this institution here may be made use of in this Island for Nature study classes. While talking, as I did a minute ago, of the facilities which the scientific part of this institution—a modern laboratory in a modern biological station—can afford to the university student, I should just like to add

A WORD OF WARNING

—a word in the other direction—and that is, it is not altogether good to provide too many facilities; we must not let the worker or the student think that the facilities are everything; and that brings to one's mind two little stories I happen to have heard of two great men, one of whom was Huxley's, and the other a man of whom we are going to hear more about from Mr Kermode—your great Manx naturalist, Professor Edward Forbes. The stories are these: Huxley, on one occasion, when he was shown a very finely equipped modern laboratory, said to the young students who were working there, "You fellows, you little know the difficulties we had to contend with in my young days, when one had to make observations with one's microscope lashed to the mast"—of course, "that lashed to the mast"—was a mere figure of speech. Huxley did not mean that he had to lash his microscope to the mast, but it indicates forcibly the difficulties that the pioneers in the early days had to encounter. I believe Edward Forbes, on one occasion, said, when he found some of his students discussing the powers of their microscopes and criticising adversely some of the glasses what are called the objectives at the lower end of the microscope, that do the more important part of the work "Gentlemen, bear in mind that the glass—at the lower end of the microscope is not so important as the eye at the other end of the microscope." And it is not even the eye that he meant, but the brain that was behind the eye, because the eye is only a part of the optical apparatus. We also see the thing, probably, very much alike, but it is the brain behind the eye that makes the difference in the observation. Well, of course, Edward Forbes naturally brings one to your Society which has met here today, and I should like to conclude by saying a word or two specially directed at your Society, if I may take the privilege of an old friend—

Mr Kermode: And member. (Applause)

Professor Herdman: Yes, and as a member of speaking plain words to my fellow-members, I have had the pleasure of meeting you on various occasions, and I have almost always met the same members. It is exceedingly pleasant to meet old

friends, but it would also be pleasant to meet young friends—some additional members. I don't know why you don't have more

Young Recruits—

why you don't have more fresh blood coming into your Society. I want you to carefully consider this point, you who are the officials of this Society, and see if you cannot do more to enlist the active membership and the active work of young people in the Isle of Man. This is a criticism and a statement one might make against many natural history societies throughout the country, and not this particularly. I do not know whether it is so, but I have got the distinct impression that there are not so many young people devoting themselves to the study of natural history as amateurs nowadays as there were in former times—as there were, perhaps, 20 or 30 years ago. Natural history societies and societies of a like nature—geological and antiquarian societies—I think flourished more in former years than they do now, and that ought not to be the case, for there is far more education now. Of course, there are far more diversions for young people—I don't know whether it is cycling, tennis, golf, and so on. (Laughter) Of course, these are very excellent things in their way, and one would not say a word against them—one indulges in them oneself; but I hope they are not having, and will not have, the effect of driving out of the lives of young people such exceedingly pleasant intellectual recreations, even if one regards them merely as recreations, as the study of natural history. Then I hope the member of our Society will continue their membership, and not only so, but that we shall have more members, and that the members there are will try and do a little actual serious work as contributors to science. As you all know, probably, Professor Edward Forbes had as his intention, when he was a young man in the Isle of Man, the compilation of a complete Natural History of the Isle of Man. He alludes to it more than once in his letters and his writings; he did something towards it by issuing a small edition—*Malacologia Monensis*—which dealt with the molluscs and the shell fish of the Island, but we wish to deal with all the other groups of animal and plant life, so as to complete the Natural History of the Island, but he did not do so. He died a comparatively young man, and it has never been done. No one else has done it, and it would be an admirable piece of work for the Society to take up. We, who come to visit this part of the Island, and to work in this institution, will help you. This institution could do a great deal, but we only lay ourselves out to deal with marine life; but there is a great deal of other work—land plants and animals to be dealt with. A great deal of valuable work has been done by members of your Society in the past, and I only wish that you should continue and that your present members should devote themselves as much as they can to taking up special little groups, however small, of plants, animals, rocks, and fossils, so as to complete in the end our knowledge of the natural history, in the widest sense, of this Island. We cannot all, of course, be Huxleys or Darwins, or Edward Forbes; we cannot all be great architects of science, but we can all do useful work in small ways; we can, each of us, bring a brick or a handful of mortar to help in completing the fair fabric of natural history. (Loud applause.)

The Rev. C H LEECE said: As President of the Isle of Man Natural History and Antiquarian

Society, I would desire to express to Dr. Herdman and the other members of the Liverpool Marine Biology Committee, our deep appreciation of the reception we have received here today, and particularly for the very interesting address which we have just listened to from Professor Herdman. I am sure it is a great pleasure for us to be here, and to be allowed to inspect, under Professor Herdman's direction, the wonders of this new biological station. I represent a Society, which, in a small way, as amateurs, takes a deep interest in, and we are endeavouring to further, the work which scientific men like Professor Herdman are so ably carrying out in the world. As President of the Society, I am sure I can speak for all its members when I say we are very proud indeed to think that the little Manx Nation has had such an institution as this established upon its shores. A few years ago I would not have dreamt that such a thing would take place in my day. When I came down here and saw these fish sailing round in the tanks, and was introduced to them in this very personal way—(laughter)—it really opens up to my mind enormous possibilities, from an educational point of view for the people of this, my beloved native island. I know that many people in the island have said: "What is the good of it?" We ask that about every new thing, and it is a very natural question to ask. Well, Professor Herdman, I think, has impressed on all our minds the enormous advantages which a work of this character has for the people of the district in which it is carried on. I think we shall all go away with a different and more enthusiastic idea about the work which this biological station may carry out, not only here but in other places. You have heard that this institution was meant to fulfil three different phases of usefulness. It has an educational use, even to be here and see these creatures in the tanks, though they are not all full yet, when you think of it, not only for those who dwell in this place but for the visitors. What a great pleasure it is to go round and say: "That is a dog-fish, commonly called a gobag," and so on; and to be introduced to the various animals, and your interest in them is excited in a way it would not otherwise be. It performs, I think, three phases of work in this way—from an educational point of view, a scientific point of view, and, I hope and trust, from an industrial point of view—if they are going to hatch lobsters, crabs and so on—they do not wander far away from our shores, and the fear that many people have that the fish we hatch will be caught by other people won't apply to lobsters and crabs. They will be deposited near our shores, and, when they grow big, our men will catch them and sell them at a good profit. It is not for one to go on any further, but I think it is right, at this stage, that I should give expression to our gratitude to Professor Herdman and his co-workers for the pleasure we have had in coming here today, and also appreciation of our Manx Government in having the enterprise to make a grant to build this beautiful station. I think it says something for our Government that it is sufficiently go-ahead to make a grant to build this beautiful place. Now I have to introduce to you our very energetic and valuable secretary, and I may say, with regard to Professor Herdman's remarks about our numbers, that I grant we might have more enthusiasm and more work might be done; I hope your remarks may tend to achieve that result, but, nevertheless, much quiet work is

being done. If it was only known what wonderful thoughts pass through our minds, and the wonderful work we do at home, I am sure the world would be surprised—(laughter)—and I am sure you would express appreciation and pleasure at these Manx workers, who are living in comparative obscurity and are working hard, perhaps, for a time when their work will be appreciated more at large. On behalf of Mr Kermode, a more untiring faithful secretary we could not find, and I am sure he will redouble his efforts on behalf of the Society. I have now to ask Mr Kermode to unveil the bust which he is so generously presenting to this institution.

Mr P M C Kermode, spoke in presenting the bust. He said the particular reason for making this presentation of the bust of their great naturalist was that Edward Forbes was their one great Manx naturalist—(applause)—great not only as a local man, but recognised throughout the world for his scientific knowledge and skill.

Mr I Thompson:—I believe it is because I happen to be treasurer of the L M B C, and custodian of its valuable assets, that I have been asked to receive this beautiful bust on their behalf.

Sir James Gell said they in the Isle of Man were very proud they had an institution like this. He trusted that the young people of the island now would take up this subject as a matter of study and education. He thought it was very important that they should do so. He was very glad that an institution of this kind was now established. He trusted that the people of his own country would avail themselves of the grand opportunities for the study of natural history and for doing good in their day and generation. (Applause.)

The vote of thanks to Professor Herdman was carried with enthusiasm.

Professor Herdman, in response thanked the Manx visitors present for the welcome they had accorded the Liverpool naturalists, not only on that occasion but on every occasion they had come amongst them. They all felt as if the Isle of Man were their adopted country, and he could assure them they had the interest of the Isle of Man quite as much at heart as if they were really Manxmen. (Applause.)—*Isle of Man Times and General Advertiser*, Oct 4.

TRINCOMALEE :

“ INSCRIPTIONS FOUND ON MONUMENTS IN THE CEMETERY, TRINCOMALEE.”

This is a very curious collection of inscriptions of all kinds, dating from 1804—each being printed on a single page—and we suppose the little volume before us belonging to a lady in Trincomalee, is the only one in existence. The very first is worthy of reproduction here:—

Sacred to the memory of Capt. George Napper of His Majesty's 51st Regt., Late Town Major of this Garrison, who departed this life Dec. 21st,

1804, Forty-four years; Twenty-two of which were devoted to the service of his King and country:
Should chance thy footsteps hither bend
Turn not in haste away.

A braver soldier, warmer friend
Death never made his prey.

It is striking how many young officers were struck down between 20 and 30 years of age. Here are two examples:—

Beneath are deposited the remains of Lient. Samuel Molfett, eldest son of the Rev. James Molfett, Magistrate for the county of Longford in Ireland, who departed this life on the 18th of March, 1812. Aged 25 years.

Sacred to the memory of William Taylor, Esq., His Majesty's Naval Storekeeper, who departed this life on the 4th day of May, 1814. Aged 24 years. A gentleman of the strictest honour, and integrity, whose conduct as a Public Officer had gained the esteem and approbation of his superiors, and whose private virtues will ever endear his memory to his afflicted relatives and friends. As a token of respect and to commemorate departed worth this tomb is erected by his faithful and affectionate friend, J. W. Dale, of Madras.

The representatives of names still familiar in our midst, arrest attention:—

Sacred to the memory of William John Lushington, Esq., of H.M. Civil Service, Collector of Trincomalee, who died 6th September, 1831. Aged 25.

To the memory of Mrs. Maria M. Tranchell, widow of the late J. Tranchell, Esq., of H.M. Civil Service, Ceylon, who died on the 14th of May, 1818. Aged 49 years. Her amiable qualities endeared her to her family and friends and she quitted the world with the just, regretted of all who knew her worth, that which language cannot attempt to describe, but memory will often retrace.

Sacred to the memory of Robert Atherton, Esq., acting Government Agent of the Eastern Province and late of Her Majesty's Royal Navy. Died 23rd of June, 1855. Aged 54 years. “The memory of the just is blessed.”

To the memory of Lt.-Colonel C. A. Tranchell, late Ceylon Rifle Regiment, who died on the 31st March, 1866. Aged 79 years. “Blessed are the dead which die in the Lord.”

To the memory of Mr. William Twynam, purser, late of H.M.S. “Liverpool,” who died June 2nd, 1821. Aged 46 years. He was faithful and upright in his public capacity and his excellent private qualities have obtained this record of affection and regard.

Two very melancholy monuments and inscriptions are the following:—

Sacred to the memory of 56 non-Commissioned Officers, and Privates, two women and one child of 78th Highlanders who were carried off by epidemic cholera, between 12th October and 7th November, 1832, and whose remains lie in, or near this spot. This fatal and most malignant disease, first showed itself on 12th October, but on the 23rd had attained a degree of extreme virulence. On that day 14 men died, on the 24th, 11. The names of the sufferers are inscribed on the other side of the monument which is erected by their brother officers.

Sacred to the memory of Men of her Majesty's 37th Regiment of foot who departed this life at Trincomalee during the years 1847, 48, 49, 50, 54, 55, their names are inscribed on the other side of this monument, which is erected by their

officers and comrades, as a tribute of esteem and regard to departed worth and in token of the respect, and affection in which their memory is held. "Be thou faithful unto death and I will give thee, a crown of Life"

FLIGHT SHOOTING IN CEYLON.

Lifeless and dreary was the scene, yet fascinating beyond description. We were on one of the burning sandbanks which separate the great lagoons of Ceylon from the sea, the narrow boundary between the feeding and sleeping grounds of innumerable wildfowl. For many a weary mile, as far as the eye could reach, lay a shimmering line of sand; on one side the still lagoon, glassy and grey, steamed patiently under the sinking sun; on the other, the limitless Indian Ocean stretched on and on to where the blue dome of the sky seemed to mingle with it and melt away into space. Long green waves rolled slowly in, and, passing the coral reef, crumbled into white-topped breakers, which boomed and thundered unceasingly upon the dazzling beach.

We had discovered the route taken by the passing fowl to their favourite haunts, and lay hidden in the tussocks of coarse herbage waiting for the flight. The sun, setting in its glory of coloured light, seemed to set the world aflame, and turned to gold the distant inland mountain peaks which soared above the low-lying line of coconut palms that fringed the mainland shore. As if answering to its farewell blaze, a flock of whistling teal rose afar off, and with sibilant cries commenced their evening gyrations, preliminary to departing to their feeding grounds inland. Rising one after another from their reedy sanctuaries, the flocks wheeled round in wide circles, uttering the while their hissing calls. Nearer and nearer they came, till suddenly the sound became shrill, as one flock unsuspectingly approached our ambush. Bang! and a quick swerve, but too late; a rapid succession of reports, followed by the sound of bodies thumping on the soft sand, greeted our anxious ears.

With the exception of a few blue coots, which trailing their legs awkwardly behind them, sought refuge with a splash among the reeds of an adjacent islet, our shots caused little disturbance, and again the 'swish, swish' of a closely packed flock of teal was distinctly audible as they swung round

overhead. Four barrels were emptied in their midst and some half-dozen left the ranks and fell with splash or thud, the rest being soon out of shot. Higher and farther circled the startled flocks, till at last they were mere specks in the deepening red of the western sky.

Already the west mist was beginning to gather round the red-beds which lay scattered over the grey water, their graceful lines reflected to perfection on its still surface. For some time the occasional croak of a frog, or 'korok' of a hidden coot, were the only sounds besides the eternal booming of the surf behind us. Suddenly the cry of a curlew sounded clearly in the evening air, and one's thought went back to the shingle banks and marshes of England, where, with a biting wind driving in from a grey sea, one had so often heard the familiar note. It sounded strangely out of place on that lagoon; but there was little time for wandering steamy thoughts, as an answering call came back, and soon a small flock passed just out of shot, making for the flat beach upon which the tide was falling. They were the forerunners of the numerous birds that followed. Soon we descried a string of elegant flamingos heading straight for us, their long legs streaming out behind them. A moment of doubt, and then they were over-head. Picking out our birds we fired, and two of the graceful creatures crumpled up and fell with a crash into the reeds hard by. The sky was seared with lines of fowl, each winging its way to some favourite ground, and ever and anon the guns spoke out, till the short-lived light of the afterglow faded and made way for the approaching night. Then suddenly darkness came, and with it the myriad fire-flies, which danced and circled aimlessly among the dank and sweating reeds—and another day was dead.

As in the gathering gloom our canoe glides over the silent water, we can see the torches of the native fishermen burning luridly on the distant shore. Fainter and fainter grows the sound of the pounding breakers, till only a murmuring roar reaches us through the still night air. A heavy white mist gathers and obscures all from us but the glittering firmament above. There is a caw-sound as our canoe grates on the mainland shore, and, stepping out, we gladly leave the great grey waters to whisper their secrets to the night. Our bag is heavy and our hearts are light.

—*Field*. Sept. 17.

AND CEYLON

“NOTES AND QUERIES”

[Under this heading, in future, we mean to give a small “Supplement” with our *Tropical Agriculturist*, from quarter to quarter, according as there is matter of sufficient value so to be preserved.]

FEBRUARY, 1903.

A DUTCH NATURALIST ON CEYLON: SPEECH BY PROF. DR. M. TREUB.

The Society for the promotion of natural science, medicine and surgery held its annual general meeting on 29th October in the hall of the University at Amsterdam, when Prof. M. Treub of Buitenzorg at the invitation of the general council gave a chat on a journey made by him two years ago to the island of Ceylon. From this address we take the following, (the translation being made for the *Ceylon Observer* from the *Indische Mercur* of 4th Nov. 1902:—

“In Ceylon it can often blow fiercely, and it is probably due to this circumstance that in the higher mountain districts the plant growth of the island makes no luxuriant impression. In our Java one meets with high trees on mountains 5,000 feet above sea level: Ceylon has on the mountains only underwood.* These mountains, which are found in the south-western and southern portion of the island dominate the whole nature of the island. Indeed, they as good as confine the rainfall to their domain. As far as the mountains reach, therefore, Ceylon is moist and fertile. To the north and east of the mountains, which pass very suddenly into low, hilly land, the soil is arid, infertile. One speaks, therefore, of ‘wet’ and ‘dry’ Ceylon. And the transition is so striking, that within a quarter-of-an-hour, travelling by railway through the mountains, one can pass from dripping rain and cold mist into scorching heat. Here and there the Hollander finds in Ceylon the traces of the sojourn of his forefathers. For nearly two centuries the Hollanders carried on trade in Ceylon, and for 150 years the island was to be considered as entirely ruled by the E. I. Company. In 1796, however, England was so good as to take possession of it temporarily for us; and since then it has also in this respect demonstrated the fact that ‘one must know how to give and to take,’ in particular to understand and cultivate the last mentioned. [What about Britain handing over Java, the richest island in the World to Holland?—ED. L.R.]

“A peculiar factor in Ceylon society is the crow. Compared with the crows of Colombo the Netherlands’ crow is a paragon of modesty. The Colombo crow compels you either to keep every window closed, or to keep all movable property under lock

and key. If one does not observe this precaution, every portable article will soon disappear from the traveller’s luggage. The cunning and boldness of the crows have led the inhabitants to entertain a certain superstition regarding them. Thus it is known, that once a crow carried off in succession the complete apparatus of a spectacle-maker. The collection was found again later; the different shining objects were bound together with straws, intended for the adornment of the nest, in which a new progeny of crows was to be born. The crows are too slim for the Ceylon dogs—which moreover fill a very similar role to those of Constantinople. If one is sitting with a dainty morsel in front of him, a crow appears before his nose, at first only to keep watch until a comrade comes. The latter approaches the dog from behind and at a convenient opportunity pecks him in a sensitive portion of the body under the tail. The dog turns round angrily, and crow number one whips off with the bone, which he consumes with his mate in the gutter of a roof, whilst the cheated dog may search in vain for it. The crows are protected by the Buddhist teaching, which forbids the killing of animals. In the time of the East India Company the killing of these birds was forbidden, because it was known that the crows helped in distributing the seeds of the cinnamon.

“The chief street of Colombo swarms with gem merchants who in their little shops carry on a trade with which even a Chinese has not been able to contend. These shopkeepers, of mixed Arab and Indian blood, are probably the sharpest dealers in the world. Their presence has only this advantage, that Ceylon is freed from the Chinese. There was once a Chinese merchant. But, as the man could not succeed, he hastened to become a Buddhist priest.

“Although the Buddhist teaching prescribes, that one must kill no animal, it does not therefore appear to prevent the animal’s life from being sometimes a torture. One knows that the Sinhalese, when he brings his turtle to market, turns the living animal over, so that it lies on its shell and then in succession cuts off and sells the portions that appear most attractive to the buyers. The miniature oxen also, that serve as draft beasts for little carts must also pay tribute with great pain to the artistic sense of the Sinhalese: on the hide of this little beast the owner tattoos his name arabesques whole pictures.

* This is surely going too far—at 5,000, and even 6,000 feet, the forests are very far from being all undergrowth.—ED. L.R.

“The town of Colombo displays in its type of houses its Netherlands’ origin. The Dutch church both inside and outside has the

appearance of our village churches. There are stone-hewn coats of arms, tombs, &c. There are also many inhabitants with Dutch names. They are called "Burghers," but are descendants of mixed blood, and thus colored. Gradually all coloured persons have in Ceylon come to be known under the name of "Burghers." And, although often these colored persons have studied at English high schools, they are treated by the English in Ceylon as veritable pariahs. No Englishman would "degrade" himself to have the slightest intercourse with them* The cultivation of rice does not appear to have brought to any high degree of development, and Ceylon is poor in bamboos, suitable for use as building material. The people also are far from cleanly. One may say that the inhabitants to put it mildly, smell badly.† The men are of fairly handsome build, though somewhat effeminate; they wear a comb in their hair. The women are small in stature and ugly. They look as if they had little pleasure in their lives, and this is perhaps the result of the polyandry practised in Ceylon; most of the women have seven or eight lawful husbands as their portion.‡

The little town of Kandy, regarding which the English make so much, in fact somewhat disappointed Prof. Treub. Kandy owes its fame for the Buddhist to the circumstance, that in a Buddhist monastery there, a tooth of Buddha himself is preserved. If one asks after this tooth, one obtains for money and good words only a sight of a complicated collection of caskets, in which Buddha's tooth is supposed to be enclosed. No one, however, has ever yet had this relic of Buddha's tooth under his eyes. Even the King of Siam, who is also the acknowledged head of the Buddhist religion, was denied by the monks the sight of the tooth, to the King's manifest annoyance.§

AFTER JUNGLE-FOWL IN CEYLON:

"Some large patches of millu are ripe in my neighbourhood, and jungle-fowl consequently plentiful." The letter ended in an invitation and I leapt from the depths of my teak chair to answer it at once.

The "millu" (*strombilanthes*), grows in the hill-forests of Ceylon, and flowers but once in seven years. When the berries, which succeed the blossoms, are ripe, they attract jungle-fowl and pigeons in such numbers that the sport to be had amongst them is excellent. My luck with jungle-fowl had hitherto been poor, and as it has never been my wont to knowingly miss a good thing, I duly presented myself at MacL's hospitable bungalow armed with a gun, a boy, and a bag. What Mac was pleased to describe as his neighbourhood, however, turned out to be a lonely spot

* This is too bad of Dr. Treub when he should have known of Judges of the Supreme Court and high Civil Servants being of the class he refers to, with whom their brethren in the Service are generally on most friendly terms; and also that many Burghers are pure or nearly pure Dutch descendants.—ED. *L.R.*

† A gross libel.—ED. *L.R.*

‡ Another big libel; polyandry never prevailed among the lowcountry Sinhalese, and only to a limited extent among the Kandyans and it is now dying out.—ED. *L.R.*

§ Another great error: we have seen the tooth twice—once in 1875, when King Edward VII (then Prince of Wales) saw the tooth and every jewel in the temple.—ED. *L.R.*

miles away from anywhere, with neither food nor shelter obtainable, I had therefore to send my boy, Gregories back for provisions and camp necessaries, and on the following day we sallied forth on foot, taking some estate coolies to carry our loads, build our huts, and act as beaters when the time came. Having arrived and selected our site, we left the rest to our men, and strolled off to view our surroundings. And then dusk was upon us.

Far up on the mountain side, where the sun beats fiercely by day, but coolness comes with the evening, we stood and watched the quivering plains gradually grown dim in the failing light. A mist had already gathered in the valley, and the stars suddenly flaming out, shed their pale light over endless billows of white fog which crept over the steaming low-country far beneath us. Our camp was pitched by the edge of a precipice, and, near by, a torrent rushed and jostled, bending back the luxurious tropical growth which sought to choke its path. Stopping on the verge, as if to gather strength, the water leapt over the last rock and fell with a dull roar into the pool two hundred feet below; and no other sound broke the stillness of the mountain jungle. But in camp all was merry enough. The coolies, having built our huts, were laughing and jabbering, glad of a change in their weary routine; and the crackle of dry wood, and hiss of green, as the fires leapt into flame, all lent a cheerful tone to the scene. Two fowls were soon spluttering over the bright flames, and the seltzer hissing soothingly in our glasses, the mere knowledge of its scarcity rendering it the more appreciated. And by nine we were asleep. I may be forgiven for this long preamble, but, to my mind, sport is made sport by the colour of its surroundings. If it were not so, we would enjoy fishing in a cistern, or shooting the pigeons in Charing Cross Yard.

It was scarcely dawn when I awoke to the crow of a jungle-cock. Closing my eyes for a moment, I revelled in anticipation. Then there was another crow, and yet another—but not from jungle-cock. Our poultry were awake, and no rest is left for man when the domestic cock begins to challenge his wild congener of the forest. There is something fascinating being awakened by the jungle-fowl, but the startling song of underfed "natives," delighting as they do in a ditty with an oft-repeated chorus, is another thing. I arose, and after barking my shin against our only case of seltzer, emptied a chatty of water over the wakeful birds, in hopes of damping their musical ardour. But sleep had gone and nature was astir. The utter loneliness which pervades the mountain forests is less impressive in the early dawn than at any other time. The gaudy jungle-cock crows his loudest, the grey monkeys squabble in guttural voices, while the forests resound with the melancholy cooling of pigeons. I went over to Mac's hammock to find him fast asleep under his mosquito curtain. His face was aggressively red, and reminded me of a steak in a meat-safe. A playful tap with the empty chatty where the contours of the hammock looked most pronounced, knocked all the sleep out of him, and in a few minutes we were splashing in the pool by the precipice edge. Then, as we sipped our tea, we watched the magic splendour of a sunrise in the Ceylon mountains, and while the valley was yet one deep cobalt shadow of eddying mist we set out for our shooting ground. The air was quite

ebilly, and we were glad to walk at a brisk pace; the betel-chewing gang following excitedly behind.

As we approached the *hillu*, pigeons became more and more numerous. Every step sent squirrels scampering up the straight stems, and rats scurrying into safe cover; for where the *hillu* berries are ripe, there will these animals teem. But our attention was directed to the clustering leaves above. There were pigeons of all kinds, and in any number, and after each report the air was full of the clapping of their wings. But such plenty could not last for long, and they soon sheered off, or circled out of shot, and arriving at an open glade we sent the coolies round to beat the patch in front of us. The first birds that came over were pigeons flushed from a distance, and they offered very easy shots, just skimming the underwood and making across the sunlit opening. They soon found us out, however, and flew in any direction but ours. The jungle-fowl, which had been running before the beaters, now began to make their appearance. There was a sudden metallic outcry, and a cock and two hens dashed out of the jungle in front of me. I had both barrels at the cock, but he went away serenely, followed by his dowdy little wives. I looked at Mac for sympathy, but got none: he was busily engaged with two birds, which came down to a good right and left. A moment later and the cock flew out on my side, and I duly missed him. Mac was smiling audibly, and remembering my luck had always been bad with these birds, I snatched my flask from Gregoris and toasted success to myself, and the next instant had the satisfaction of crumpling up a cock, which fell with a thud in his glory of black and gold. Nothing succeeds like success, and as the beaters' din grew louder, and the birds flew out faster, I got more and more on the spot. Many a wily old cock ran to the edge of the jungle, and, catching sight of us, disappeared again and broke back. But many another dashed out as straight as an arrow, and few of these got away. The beat came to an end, and some eight to ten couple of jungle-fowl were picked up, besides several pigeons.

The next beat was less productive in numbers, but made up for that by the sporting shots it gave. We stood in a small ravine, and the driven birds flew high overhead from one jungle to the other. The majority were out of shot, and those within gave no time for hesitation. It was at the finish of this beat that Mac nearly bagged a coolie who was much in advance of the line. He received one pellet in the hand, and, giving himself up for dead, could only be persuaded to get up by the offer of some brandy. He then bound his head up, and seemed to forget the incident. It is curious how a native will always bind up his head if ill or hurt, irrespective of the locality of his ailment, and appears to derive comfort therefrom. The heat was becoming unbearable, and as perspiration running copiously into one's eyes does not improve one's shooting we returned to camp, well satisfied with the morning's sport. The afternoon beats found us in fair fettle, but we were in sore need of another gun. It was heart-rending to see birds in plenty, flying beautifully on either side, and nobody there to shoot them.

That evening we dispensed with the services of home-bred fowls, and fed heavily on their *hillu*-fattened confreres. A slight gun-headache that had bothered me wore off with my appetite, and

then, stretched in our hammocks, we discussed the details of the day, till the cheroot-ends burnt our fingers, and we stared at one another through the bottoms of our empty glasses. Then once more in the solemn hush of the mountain forest, a steady roar rose from the pool below, and the world seemed left to the creatures of the night.

TOM-TIT.

—*Land and Water*, Nov. 29.

THE OCCUPANTS OF THE SEE OF CALCUTTA: THEIR NAMES IN CHRONOLOGICAL ORDER.

Stewart Place, Dec. 17.

SIR,—1—The first Bishop of Calcutta was Dr Thomas Fanshawe Middleton, and was consecrated on May 8th, 1814, by Archbishop Charles M Sutton and assisted by Bi-hop William Howley, (of London); George Tomline (of Lincoln); and John Fisher (of Salisbury). 2—Reginald Heber, consecrated on June 1st, 1823. 3—John Thomas James, consecrated on June 4th, 1827. 4—John Mathias Turner, consecrated on May 17th, 1829. 5—David Wilson, consecrated on April 29th, 1832. 6—George Edward Lynch Cotton, consecrated in 1833. 7—Robert Milman, consecrated on February 2nd, 1867. 8—Edward Ralph Johnson, consecrated in 1876. 9—J E C Welton, consecrated in 1898. 10—Reginald Stephen Copleston, translated in 1902, and consecrated in 1875.

The ruling Viceroy of India, Lord Curzon, takes his title from Kettle-ton in Derbyshire which was the birth-place of the first Bishop of Calcutta. He was the only son of Rev. Thomas Middleton and was born in January, 1769. When he was offered the See of Calcutta, he had to resign the office of Archdeacon of Huntington, and the Vicarage of St. Pancras, Middlesex. His reputation as a scholar, was very considerable; but it was not until the year 1803, that he more fully established that reputation by the publication of a "Treatise on the doctrine of the Greek Article applied to the Criticism and Illustration of the New Testament"; a work of great importance to the Biblical student, and which brought Dr. Middleton more prominently before the public.

The great object of the Bishop, soon after his arrival in India, was the erection of a College, where the means of some scriptural education might be afforded, and where the rising generations for the time to come might derive instruction, with more special reference to the Propagation of the Gospel. He saw that without the assistance of native teachers, and the translation of the Scriptures into the languages of the country, little real good would be effected, and, therefore, in reply to a letter from the Society for the Propagation of the Gospel, he strongly pressed the necessity of establishing a Mission College near Calcutta. Towards the accomplishment of an object so desirable in every point of view, the Bi-hop directed all the powers of his active and comprehensive mind, and after some years' of patient labour, and no small anxiety, he had the happiness of laying the foundation stone of the Calcutta Mission College on the 15th of December, 1820. Last Monday, then, the 15th instant, saw the 32nd anniversary of this important undertaking. The building was designed in a manner well worthy of the important object in view. It stands on the right bank of the Hooghly (nearly opposite Garden Reach) on a piece of

ground granted by Government, about three miles from Calcutta. The Botanical Gardens are about half-a-mile farther down the river.

This College supplied some agents for work in Ceylon. Those who laboured well, steadily and faithfully in their day and generation and whose "task is o'er" were :-

1—Rev S Dias, Colonial Chaplain, All Saints'.
2—Rev S Ondaatje, Colonial Chaplain, St Thomas. 3—Rev E LaBrooy, Colonial Chaplain, Jaffna. 4—Rev S Nicholas, Colonial Chaplain, St Paul's, Pettah. Mr H F Muttukistna, Barrister-at-Law, Crown Counsel, Jaffna. Mr W Morgan, Advocate and Crown Counsel, Kandy. Mr Henricus de Saram, District Judge, Kegalle. Mr P Muttukistna, Private Advocate, Batticaloa. Mr Henricus de Livera, Proctor, Colombo.

The two now living are the Rev A Dias, ex-Chaplain of All Saints', and the writer of these lines; we are both on the verge of our graves. Bishop Middleton died of "a stroke of the sun," on the 8th July, 1822. A monument in all respects worthy of his exalted character and station has been erected to his memory in St Paul's Cathedral, London.—Yours truly,

CUCULUS ECCLESIASTICUS.

CRICKET IN DIMBULA AND DIKOYA :

OVER THIRTY YEARS AGO.

THE FIRST CLUB AND MATCHES.

(See Photograph reproduced with this Supplement.)

Writing on 17th December from Monmouthshire, Mr. Humphrey Humphreys, one of Dimbula's pioneers, and, perhaps, the first amateur photographer who appeared in Ceylon, sends us the following interesting notes :-

"Some time ago I received a *Ceylon Observer* with the account of the Dimbula and Dikoya matches. I noticed that the first match that was played in Dikoya, at Darrawella, was not put in. J. Paterson was Captain and F. Byrde, who is still in Ceylon, was Secretary, and C. Fetherstonhaugh, Captain, and L. Kelly, Secretary for Dikoya.—I enclose you a small enlargement of one of the two pictures that I took of the two teams and the Pavilion. Our ground was made the same year 1870. Lechmere Thomas, Græme Elphinstone and I finding coolies, and a Tamil man, who afterwards looked after the ground, that I had taught to use a spade, dug some turf. We found in a ravine in Radella and I laid it in the centre of the ground for the wickets to be pitched on, and it was standing well still, when I played on it the last time in 1884. The second match was played in 1871, R D Elphinstone, Captain; and that also was now by Dimbula, the chief score being got by W Saunders.—I was very much interested in your letters from India."

The accompanying photograph is full of interest, and we have had a half-tone block made by Mr. Chas. H. Kerr to enable us to print a *Supplement* which, we feel sure, will be appreciated by many upcountry and Colombo residents, and by old Ceylon colonists in Europe and elsewhere. It gives a very clear likeness of some 22 planters, we can scarcely say cricketers; for, we expect some at least, had scarcely ever

handled the willow, before they were called on to make up "an eleven" for Dimbula or Dikoya. The Pavilion (of coir matting ?!) comes out well and the front row is flanked, right and left, by Mr. Humphrey Humphreys and the Secretary, Mr. Frank Byrde (still with us), both "bearded as the pard." Next to Byrde is seen the manly form of Lechmere Thomas; next, cultured and scientific but asthmatic Heelis, jovial Vanderspar with his round face and fringe of beard, "spider" CH Skrine, with L H Kelly alongside of the "Captain," Fetherstonhaugh, both looking very "fit" in their youthful manly vigour. Then came T C Anderson (not much with the willow" but manly enough), J C Roberts (still to the fore at home), "backbone" Skene and J G Palmer, afterwards killed through his horse slipping in crossing near Blackpool, Nuwara Eliya. Then in the back row, we find Giles Walker leaning on his bat, looking very spare, alert and juvenile; great Pillsworth (a six-footer); laughing Jock Paterson (the Dimbula "Captain.") "Daddie" Howard of Manikwatte, don-looker John Stronach, handsome Marshall of Blair Athol, curly-headed "Bees" Knight; John Tilly, bearded and head and shoulders above his fellows; and finally J Penny, a clever all-round athlete as well as a good swimmer and billiard player. There is only one face out of the twenty-two we cannot identify (even with the aid of such veterans as Messrs. Frank Byrde and W Somerville) or rather the name cannot be recalled, although the face is familiar enough. Mr. Humphreys includes "E. Edis" among some 12 names he gives; but we do not recall this name among our early planters? The photograph was, as Mr. Humphreys states, taken at Darrawella. One misses "Logie," but he seldom got caught in a group or in a cricket match, although his twin-brother "Bob"—the Baronet before him—captained the Dimbula team in 1871 and led it to victory.—As regards "Logie"'s athletic powers, R C Grant, still with us, will recall one year when—though he had gone into "training"—Logie, coming forward at the last moment, beat him in the long foot race?! Alas! how few remain of the men of thirty years ago,—the young planters who literally "rashed" the hills and valleys of Dimbula and Dikoya, with the brightest anticipations of fortunes from "coffee," and at any rate with the fullest enjoyment of life in "the merrie greenwood," in watching the new clearings, living first in impromptu, and later on in "pucka" bungalows. Of the 22 before us, we know that at least ten—Thomas, Heelis, Vanderspar, Kelly, Palmer, Anderson, Patterson, Stronach, Knight and Penny—have passed that bourne from which no traveller returns; while we fear some more have to be added to the number? We are thankful that in Ceylon, F Byrde is still with us—the only one who continues an active planter—while at home, though still interested in Ceylon, are Fetherstonhaugh, Walker, Tilly, Humphreys, Skene, beside Roberts and C H Skrine leaving Pillsworth, Howard, Marshall and the un-named one (? Edis) doubtful?

Cricket Match—Dimbula *vs.* Dikoya at Darrawella in 1870.

(From a Photograph by Mr. Humphrey Humphreys—Half-tone Block by Mr. Chas. H. Kerr.)

AND CEYLON

“NOTES AND QUERIES”

[Under this heading, in future, we mean to give a small “Supplement” with our *Tropical Agriculturist* from quarter to quarter, according as there is matter of sufficient value so to be preserved.]

MARCH, 1903.

ST. PAUL'S CHURCH, KANDY.

Steuart Place, Colombo, Jan. 19.

SIR,—I see that the Jubilee of the Consecration of this Church is to be celebrated on Sunday next, the festival of the conversion of St. Paul.

Towards the erection of this church the S.P.C.K. contributed liberally; and at a meeting of the Society, held at 67 Lincoln's Inn Fields, April, 1853, the following letter by Bishop Chapman giving a brief history of the church was read to the Board. The letter was written at Nuwara Eliya, February, 1853:—

The history of the erection and consecration is as follows:—“On my way to this hill station of the Society for the Propagation of the Gospel, for a short sojourn in its invigorating and bracing climate, at an elevation of 6,000 feet above the sea-level, I passed a week as the guest of His Excellency the Governor, at Kandy, for the purpose of consecrating its church. It was the first work aided by the generosity of the Committee since the capital of the Kandyan Kings became subject to British rule, and before the island of Ceylon was created into a separate See. It shared again, on my arrival, in the bounteous aid afforded me by the Committee in their hearty “godspeed” on my departure from England. It was one of the earliest works I visited, when in progress under the energetic and most effective superintendence of Lieut.-Colonel Philpotts, R.E., brother of the Bishop of Exeter. It is gratifying to me to acknowledge this publicly to the Committee my sense of obligation to one who has long since left our island. Without his valued aid and most persevering efforts, amid unlooked for difficulties and obstructions, I doubt whether the church would have been so successfully completed. Before he left us for China he finished the external fabric and tower; and provided the interior fittings in all becoming order, sufficiently to enable me to license it for use in divine service, where it was so urgently needed. The exertions of its late most earnest and lamented pastor, the Rev. F. Von Dadelszen, originally a missionary of the Society for the Propagation of the Gospel, from King's College, London, while in England on sick leave, enabled him to furnish the windows, communion-table, and rails, timber for the roofing, and a rich East window. Little, therefore, remained to complete it for consecration; and his last act almost was to obtain from the Government with the kind assistance of Sir George Anderson, a loan

of £150 for this purpose. But he was not permitted in the mysterious dealings of God's providence, to which we bow submissively, to witness the fulfilment of his heart's most earnest wish. He was seized in August last with brain fever and dysentery; and after a few weeks, sank under it; to the great sorrow not of his own people only, but I may say of the whole church in the island. The consecration, therefore, was an occasion full of saddened interest. All the clergy in the Central Province assisted in it. Surrounded as it is on almost every side by Buddhist temples, two of which adjoin its enclosure, I fixed the Conversion of St Paul, the chief Apostle of the Gentiles, for the solemnity to give both the dedication and name to the church. The building is large and massive, and, though not, perhaps, architecturally in very correct taste, has a good elevation, being in the form of a cross, and having a good tower. The interior, being without aisles or pillars, affords an ample area of, I believe, 120 feet by 80 feet, with a chancel and transepts. The soldiers of the 37th Regiment formed the choir on the occasion as on every Sunday with their band. I preached to a full congregation; and having many memorials before and around me of him who had been its first exemplary and devoted chaplain, and had laboured so earnestly to build up the spiritual as well as the material fabric of which he had the charge, I could not be unmoved. The very pulpit in which I stood was a tribute of affectionate regard to him from the non-commissioned officers and soldiers of the 15th Regiment who had felt the blessing of his faithful and fearless ministrations among them when stricken with that scourge of the East, the cholera, a few years ago. The desk from which the prayers were read was the gift of an intelligent native, a Sinhalese of high Kandyan family, who had been converted to Christianity and had attached himself to the English congregation, having an entire command of our language to speak and write, as well as understand it. Indeed, I might correctly have applied the tribute to his memory as far beyond one of ‘dull cold marble’: ‘Si queris monumentum, circumspice.’ I shall ever look upon the church itself as his monument (knowing that in many hearts he will so live as best the Christian pastor should live)—though dead, yet speaking to them by his warning voice now that he is gone from us, as by his example while among us. On the following Sunday, as the first after its consecration at an early service, the holy rite of

Confirmation was administered to about forty, and at 11 o'clock the Holy Communion: in the afternoon at 3 o'clock, confirmation was again administered in Sinhalese in the Mission Chapel to twelve candidates, most of whom had been baptised as adult converts by the Rev W Oakley. Their reverential deportment and earnest expression of intelligence was very pleasing. May an abundant in-gathering in God's own good time, be prepared for 'His blessed harvest'!—Yours faithfully,
CHARLES A. KOCH.

(Some notes by an Old Resident.)

I first visited Kandy in 1849, about 54 years ago. St. Paul's Church had then been erected, and services were being held therein. It appears that a public meeting was held in 1841, presided over by Governor Stewart Mackenzie, and it was then resolved to take steps for the erection of a Church for the use of the members of the Church of England. A large and influential Committee was appointed by the subscribers in January, 1841, and a marble tablet let into the Western wall of the Edifice gives us all the needful information. The inscription is as follows:—"In grateful remembrance of the efforts which preceded the erection of this Church and to record the names of the gentlemen composing the Committee with the deep sense entertained by the subscribers of their unwearied activity and zeal, this monument was raised, A.D. 1843.

Lient. H Bird	Capt. R. Jefferson
Mr. L G M Bird	Mr. J L Kier
Mr. L Butler	Mr. J Lambert, F.G.S.
Mr. H de Alwis	Capt. W T Layard
Mr. C Delegal	Mr. J Layard
Mr. P W de Waas	Mr. D B Lindsay
Rev. N Garstin, L.L.D.	Mr. J N Mooyaart
Mr. D C Jayatilleke	Capt. R Mylius
Mr. H Stuart	Rev. W Oakley
Mr. W A Staples	Mr. C Webster
Mr. J Swan	

Lieutenant H. Bird was the father of Lieutenant-Colonel H Byrde (now Secretary, K.M.C.) and L G M Byrde was, I believe, his uncle, the Pioneer of Coffee Planting in Ceylon. The others were: Planters, Merchants, Civil Servants and Military Officers. The Rev. N Garstin, L.L.D. was then the Colonial Chaplain of Kandy. J L Keir was the head of the well-known firm of Keir Dundas and Company. J N Mooyaart was the Government Agent of the Central Province and C Webster, I think, was his Assistant and Fiscal. Rev. W Oakley was in charge of the Church Mission here, P W de Waas was the Secretary and D C Jayatilleke, the Interpreter Mudaliyar of the District Court and a man of much influence at the time; David Baird Lindsay was one of the parties, as will be remembered, to the famous Rajawella case and W A Staples was a leading and popular Advocate at the time. This Committee appears to have been dissolved in December, 1842, when the special Church Ordinance came into operation. The stair-case and gallery were, I believe, the gift of Lady Torrington.

The Building Contractor was, I understand, Mr T Afflick who started the Bogambra Mills, afterwards taken over by Mr John Walker of Rose-nearth; and during the progress of the Building, Lt. Colonel Philpotts, R.E. had the supervision of it. The high Tower had been completed and was without a clock for some time. It, somehow, leaked out that there was a very good clock, lying unused in one of the vaults of the

Colonial Secretary's Office. Some interest and influence were brought to bear—the clock was fished up and forwarded to Kandy and placed in position on the Tower. This is the famous Town-Clock now in charge of the Kandy Municipality.

In 1849 Rev F Von Dadelzen was the Incumbent, and his zeal earnestness and devotion to his work were greatly appreciated by his large congregation. He died in August 1852, a few months before the consecration of the Edifice, and a very beautiful Tablet made of plaster of Paris was erected to his memory and placed above the door leading to the Organ Chamber.

The tablet looks quite fresh and new as if it had been placed there only a short time ago. The next Incumbent was, I think, Dr Symons, and about this time it was quite a Garrison Church, as some European Regiments were stationed here from time to time, viz., the 37th and 15th Regiments; the town people who attended were apparently small in number, I remember the Bandsmen of the 37th Regiment, forming the Choir and the Band playing all the Church music. Dr Symons was succeeded by Archdeacon Wise, who was the founder of the present thriving Industrial School; and he was succeeded by Archdeacon Schrader who was known as the "Great Preacher." He was immensely popular and his eloquent sermons drew large congregations. On his promotion to Galle he was succeeded by Archdeacon Mooyaart, on whose retirement Rev S O Glenie became Incumbent. On his going on pension, Rev John Bamforth (an Oxonian) was appointed Colonial Chaplain, until his removal to Galle when Rev Walter G Matthew became the Incumbent. It was during his time the Chancel was enlarged and a surpliced Choir introduced. The old East Window representing the Prophets and the Apostles was removed and a new Window (the one now in use) substituted. This window was placed in position and the tracery manipulated by Rev Richard Collins of the Church Mission and the Principal of "Trinity College."

The Church was consecrated in 1853 by Bishop Chapman, the corner stone having been laid by Bishop Spencer in March 16, 1843, and we are now celebrating the Jubilee of the Consecration. When Archdeacon Matthew went down to Colombo to take charge of Polwatte, the Revs Henley and Burrows acted for him with much acceptance, assisted by Revs Becket, Riddelsdell, Jacob Mendis, Jayasekera and Barnabas until the appointment of the present Incumbent Rev E A Copleston—the brother of the Rev Metropolitan of India, and during his temporary absence in England, on two occasions, his place was worthily filled by Revs L E Cox and F Lorenz Beven.

The Jubilee Celebration-Services were very successful, and it goes without saying that they drew large congregations including the Governor, Planters from neighbouring estates and town-residents from all classes and denominations of the Christian community.

OLD FRIENDS AND OLD DAYS.

(By a Planter.)

John O Fraser, must be, I think, J C G O Fraser who was on Inguragalle under William Rollo in 1869 and on Berrewella under Keith Rollo in 1870. After that he went to Manikawatte, from thence to Balangoda, where I lost sight of him.

Alexander Fraser I don't remember; but Tom and Robert, if I remember rightly, went on to the Straits.

[Our correspondent is quite right about J. C. G. O. Fraser; but Alexander Fraser who was the oldest brother, was a well-known, bright and active manager for Messrs Keir, Dundas and Coy., in the early "sixties" in the Knuckles district. When his brother Tom came to Ceylon Alex., who had saved money, bought a block of land in the Kegalle district, and put Tom after a time to open it for him. The great Kandy firm "K. D. and Coy." had a rule that none of their superintendents must own land on their own account and so A. Fraser got notice to sell or quit. He chose the latter and very soon got a much better post as manager for Mr. George Christian of his Pundaluoya estates. There Giles Walker learned under him as his first place in planting. But there again Fraser came to grief with his superiors, this time through thinking his dignity had been offended by remarks made by his Visiting Agent during his absence from the property. The fact was that Alex. Fraser like a great many more able men, had an overweening conceit of himself. Nevertheless for the third time he was lucky. Arthur Sinclair ("Old Colonist") was on the point of going on leave and Fraser got the post of acting for him as Visiting Agent for Lee, Hedges & Co., who were at that time one of the largest Estate Agency Houses in Colombo. He did his work so well that when Sinclair returned John Hedges, as head of the firm, said "We must do something for Fraser," and Sinclair at once proposed the work should be ent in two and Fraser allotted the southern portion—Morowakorale, Rakwana and Haputale, with a corresponding salary and he doing the rest from Primrose Hill. Hedges fixed on a very handsome amount for Fraser, but because it was rather less than he had been drawing for the full work Fraser demurred and in so cheeky a way that "J R H" said "Your agreement closes as originally arranged" and poor Fraser had nothing to fall back on except his old worn-out property of Gongalla, in Rakwana, where we found him in low spirits in passing through in March 1872. He never again held up his head in Ceylon, and breaking down in health eventually went home. Tom went to the Straits, we believe; but did not make a success either. J C G O we knew least of,—ED. L.L.]

with which he opened the Bar of England to all the Eastern subjects of the Empress of India. This great act deserved a public recognition, and even he would not have done it, but for the assistance of Lord Brougham, which he was fortunate enough to secure. I remember when he was very ill in this house, he desired me, if he died, to send his ashes to his mother and there is something very pathetic in the pious pilgrimage of that venerable lady [to Benares with his ashes in 1879] I will ask you to offer her my respectful condolence and to believe me, yours very truly,

HUGHTON."

The illness is thus referred to in Sir T Wemyss Reid's "Life, Letters and Friendships of Richard Monckton Milnes, First Lord Houghton." Vol. II, page 37, et. seq. :—

"Mr. Coomaraswamy was an honoured guest at Fryston. Milnes's son [now Earl Crewe] and daughters still retain the pleasantest recollections of the accomplished Hindoo who was their father's guest in their early days. It happened that during his first visit to Yorkshire, Mr. Coomaraswamy suffered from a very severe illness, which at one time threatened his life, and through which he was assiduously nursed by the family at Fryston. A lively recollection is still retained of the anxiety which Milnes showed at the time when Mr Coomaraswamy was at the worst. He had given his guest a promise that if the illness from which he was suffering ended fatally he should not be buried in the English fashion, but should be cremated. Those who knew Lord Houghton will understand how, having given that promise, he was eager to prepare for its fulfilment, should the necessity unhappily arise, and a legend is still extant of the way in which he wandered about the broad domains and the umbrageous woods at Fryston, until he had at last fixed upon a spot which was, in his opinion, entirely suited to what would have been the first cremation on English soil in modern times. Fortunately for the object of these delicate attentions the good nursing at Fryston proved effectual, saving him from the fate to which he had been dedicated. No one, it need hardly be said, rejoiced more heartily than Milnes at the recovery of his interesting friend, but mingled with his rejoicing was a droll sense of disappointment at the thought of the distinction which had been lost to Fryston for ever."—I am, sir, yours truly,
P. ARUNACHALAM.

LORD HOUGHTON ON SIR COOMARASWAMY AND THE ENGLISH BAR.

Colombo, Jan. 28.

DEAR SIR,—Among some old papers I have come across the following letter from the late Lord Houghton, which will be of interest to the public in Ceylon and India as showing how the late Sir Coomaraswamy, among his many distinguished services, was instrumental in "opening the Bar of England to all the Eastern subjects of the Empress of India."

"Fryston Hall, Ferrybridge, Yorkshire, July 3rd, 1879.

"DEAR SIR,—I thank you much for your kind note respecting my excellent and able friend Coomaraswamy. I held him in great esteem and he has never received due credit for the energy

TAE LATE SIR M COOMARASWAMY AND THE ENGLISH BAR.

Jan. 30.

DEAR SIR,—I am afraid it is not correct to say that the late Sir M. Coomaraswamy "rendered the important service of opening the English Bar to natives of India and Ceylon—indeed to all British subjects in the East." Sir Muttu was called, I believe, in 1861. I haven't the exact date with me. The late Sir Harry Dias was called to the English Bar on the 7th of May 1847 (Middle Temple). Lorenz was called on the 6th of June 1855 (Lincoln's Inn) and the late Sir R F Morgan in December 1858. Henry Muttukisna, who married Miss Pole at Jaffna, was called later, I believe. He visited England when Coomara-

swamy was being lionised by English society, which provoked a well-known parody by Lorenz, commencing :—

O kiss me quick and go, Henry,
Kiss me quick and go.
Old London streets can't hold us both,
So kiss me quick and go.

Coomaraswamy was however the first *Hindoo* barrister. The fact was noted in the London papers, and the London *Times* drew attention to it in a leader.—Yours truly,
J. R. WEINMAN.

SIR COOMARA SWAMY AND THE ABOLITION OF RELIGIOUS DISABILITY AT THE ENGLISH BAR.

Colombo, Feb. 4.

DEAR SIR,—The authority for my statement that “Sir George Jessel was, for many years after being called to the Bar, so situated that any one might have driven him from it, because, being a Jew, he was not qualified to be a member of the Bar,” is the *Encyclopædia Britannica*, edition 1902, vol. 29, p. 745 (Article, “Jessel”). When this was the case with the Jews, already an influential part of the English community, no wonder the obstacle seemed insurmountable by other non-Christians.

We who live in these happier times can hardly realise the severity of the religious disabilities which prevailed in England till recently. The principle that none but persons professing the established religion was eligible for public employment was adopted by the Legislatures of both England and Scotland soon after the Reformation. Political necessity or religious bigotry continued to enforce the direst penalties against recusants, whether Roman Catholic or Non-Conformist Christians or non-Christians. Only in 1871 were the last traces of these disqualifications removed by Mr. Gladstone's University Tests Act, which abolished in the Universities of Oxford, Cambridge and Durham, subscriptions to the Articles of the Church of England and all declarations and oaths respecting religious belief (except in the case of degrees in divinity and of divinity and Hebrew professorships), and all compulsory attendance at public worship.

It was because Lord Houghton knew the great religious obstacle which Sir Coomara Swamy had to surmount in getting called to the Bar—an obstacle which involved him in labours and anxieties that undermined his health and even threatened his life—that Lord Houghton said that Sir Coomara Swamy “never received due credit for the energy with which he opened the Bar of England to all the Eastern subjects of the Empress of India” and that “this act deserved a public recognition, and even he would not have done it but for the assistance of Lord Brougham which he was fortunate enough to secure.”

My object in publishing Lord Houghton's letter was to make known a leaf from the past, an interesting addition to local biographical history, and to awaken in the present apathetic generation somewhat of the indomitable courage and energy with which their predecessors attacked difficulties and overthrew abuses and won the esteem of the world.

May young Ceylon emulate the example of those great men, of Wall and Lorenz, Coomara Swamy, Dias and Alwis, and, rejecting “the barren optimistic sophistries of comfortable moles,” strive unhesitating, unresting, for the public weal!
—Yours truly,
P. ARUNACHALAM.

THE “OBSERVER”'S CHRISTMAS SOUVENIR AND “DAYS OF OLD” : INTERESTING REMINISCENCES FROM “W. M. L.” AS AN OLD KANDY RESIDENT.

Yesterday's mail brought us the following interesting notes from the veteran Secretary to the “Ceylon Association in London” who was, for many years, a leader in planting, mercantile and political matters in our Central Capital. Mr. Leake, writing under date, London, 9th January, says :—

“Many thanks for your ‘X'mas Souvenir.’ It stirs memories of times long past and of almost forgotten controversies wherein many a hard knock was cheerfully given and received. Well do I remember the publication of Sir Hercules' despatch that you quote and the storm aroused not only by the matter, but also the manner, of the publication. As to the latter I had some share: William Rose had been up in Nuwara Eliya, where the Governor and the Queen's Advocate (Sir R. Morgan) then were, and to him was entrusted a copy of the famous despatch to be delivered to me in Kandy with instructions to deal with it as seemed fit to me. I lost no time in handing it to the ‘Kandy Herald,’ in whose sheets the text first saw the light.

“The episode of the rise and fall of the one Kandy journal was for me a curious experience—amidst much therein that was comic to a degree there was also an element of woeful tragedy. I had nothing to do with the starting of the paper, nor had I any personal interest in it except in so far as I was a resident in Kandy. But I knew the enterprising proprietors, Dr. Baylis and Charles Tottenham, very well; and on the eve of the appearance of the first number, I found myself called on to write the opening editorial on the ground that the Editor, Mr. Arthur Jones, brother of Keppel of the ‘Times,’ just arrived from home, knew nought of the burning local questions of the day. From that time I gave my friends any reasonable help; and I believe that the poor paper might have flourished, had it not been for the sad fate of the Editor, for whom colonial politics proved altogether too exhausting. He came to me one morning, in the most serious manner begging me to protect him from Dr. Baylis, who he said had insisted on bringing a band of music into his bedroom and would not go away. Poor fellow! he went quite out of his wits and very shortly died. The paper, falling then under the direct management of Dr. Baylis, who cared for nothing but spiritualism, came likewise to a speedy end.

“All interested being dead, I feel that I can do no harm in gratifying any curiosity you may feel as to these details of old and stirring times.

“February 17th, 1903, will be the 40th anniversary of my first election by the P. A. as Secretary! What changes since that day!—W. M. L.”

LITERARY REGISTER SUPPLEMENT:

AND CEYLON

"NOTES AND QUERIES."

[Under this heading, in future, we mean to give a small "Supplement" with our *Tropical Agriculturist* from quarter to quarter, according as there is matter of sufficient value so to be preserved.]

APRIL, 1903.

OLD AGE IN CEYLON.

(From Census Report.)

As many as 145 persons, of whom 71 were males and 74 females, returned ages of 100 years or more. Exaggeration of their ages is one of the ways in which the vanity of old people finds expression, and no credence should be given to stories of abnormal longevity, unless supported by more trustworthy evidence than uncertain tradition or the memories of the old people themselves. Mr. William J Thomas, in his work on "The Longevity of Man," instances thirty cases of reported centenarianism investigated by him. In only four of them was he satisfied beyond doubt that the ages claimed had been attained; four he regarded as doubtful, the evidence in support of their claims being "not clear and continuous;" and the remaining twenty-two were either absolutely disproved or shown to be unsupported by any proof. The limit of life is of course not absolute at hundred years, and there probably have been, and are in Ceylon at this day, persons entitled to centenarian honours. But, as Mr. Thomas observes, "the tendency to set the clock of their age too fast" is so common to old people of all classes alike, that all statements of exceptional longevity should be received with extreme caution.

In every case, therefore, where the age of a person was stated to be a hundred years or more, I caused a special inquiry to be made as to whether any and what evidence existed of the accuracy of the age recorded, and whether the alleged centenarian remembered any of the incidents connected with the capture and deportation, which took place in 1815, of the last king of Kandy, Sri Wickrama Raja Sinha, or other similar notable event.

In most cases the only proof was that furnished by the recollections of the old people themselves. In some cases their horoscopes were found to confirm their statements; and in one case an extract from an ancient baptismal record was produced in evidence. As many as forty-one persons say that they well remember the capture and deportation of the last Kandyan king and other contemporaneous events. One man, a Kandyan Sinhalese, who is said to be 107 years of age, declares that he was employed in the royal household and witnessed the cruel execution, which occurred in 1814, of the children of the ex-Prime Minister Ehelapola, who had taken refuge with the English in Colombo. Another man (a Moor) who claims to have completed hundred years, says that he re-

members the execution, and further that he "followed the men who were in pursuit of the last Kandyan king towards Urugala." A Moor woman (age 100) states that she remembers having gone (when about eight years of age) with her mother to see a person whose hands had been lopped off by the order of the king. Whether these are *bond fide* recollections of these people, or whether they believe that they saw with their own eyes what they only heard talked of in their infancy by others, it is impossible to say. A Tamil of Jaffna District, aged 102, professes to have been born in the year when Jaffna was taken by the British, (1795) and his horoscope confirms his age.

The highest age returned is 120 years. The age distribution of the alleged centenarians was as follows:—

Years.	Males.	Females	Years	Males.	Females.
100	43	52	108	2	1
101	1	2	109	1	1
102	3	3	110	5	1
103	—	1	112	2	—
104	3	1	113	—	1
105	4	6	114	2	—
106	3	2	115	—	2
107	2	—	120	—	1

THE LATE MR. C. H. CAMERON, THE CEYLON COMMISSIONER OF 1829-30.

Wilhelm's Ruhe, Turret Road, Feb. 8.

DEAR SIR,—I have had Sir M. E. Grant-Duff's "Diary" in the house, but, being a somewhat busy man, I had not done more than glance through it and had not noticed the reference to my father until I saw it mentioned in your issue of last night.

It may interest you to know that the correct text of the Epigram on Bacon is:—

Nature's deep secrets to explore thou loved'st
over-much

But loved'st Honour not enough; Oh! from
corruption's touch

How earnestly we Britons wish, with shame
and sorrow stricken,

Thou had'st preserved The Chancellor, and not
preserved the chicken. C. H. C.

Then again the lines written on suddenly coming upon the colossal statue of Buddha in the then almost unexplored jungles of

Anuradhapura were :—

Saxeus ipse sedet, placido spectabilis ore
Vix quoque subridens, et mollia crura reflectens,
Gautama. C. H. C.

It is so incorrect to refer to the great sage as a "god" as has been done in the translation published by you, that I have ventured myself to attempt an English rendering of the lines :—

See Gautama in stone ! his lithe limbs bent
In everlasting rest, whilst on his quiet lips,
The smile two thousand years have not effaced,
Proclaim him still, as then, ineffably content.

H. H. C.

—I am, yours truly,

HARDINGE HAY CAMERON.

[We are much obliged to Mr. H. H. Cameron for the trouble he has taken to bring these interesting mementoes of his illustrious father before us in a correct form.
—ED L.R.]

THE LATE MR. C. H. CAMERON.—We have come across another reference to the late Mr. C. H. Cameron, father of the Hon. H. H. Cameron, in Sir M. E. Grant-Duff's *Diary*. It is in connection with a picture of the Treasurer's aunt, Lady Somers, by Mr. G. F. Watts. On this Mr. C. H. Cameron wrote a Greek couplet which (in English letters) we may give as follows :—

Kalleos ouranian Theos, Eikona deiknue tautēn
Aideisthai men edei, Zōgraphie, mēde graphhein.

In humble prose the lines may be translated thus

This image of heavenly beauty was sent to us by God Himself ; it is for you, O Painter, to worship it, but not to dare to reproduce it on canvas.

Mr. Watts, it may be added, used to live with and have his studios at the house of Mr. H. T. Prinsep, Mr. H. H. Cameron's uncle ; the last-named was the father of Val Prinsep, the artist, and Mrs. H. T. Prinsep was a sister of Lady Somers, the subject of the portrait.

HINDU BARRISTER AND ASIATIC F. R. C. S'S.

Jaffna, Feb. 5.

DEAR SIR,—Sir M Coomaraswamy opened the bar of England not only to all the Eastern subjects of the Empress of India but also to all Asiatics, be they Buddhists, Shintovists, Confucianists or Mohammedans. Natives of such independent States as Afghanistan and Japan have availed themselves of the privilege Sir Coomaraswamy secured for all religionists. In Ceylon there are only three Hindu Barristers, namely, Messrs Arunachalam, Ramanathan and Tyagaraja. In the *conservative* Southern Presidency there is, I believe, not more than one Hindu Barrister. The paucity is due partly to the circumstance that the Madras pleader enjoys certain special advantages. The Vakil there may, like a Barrister, be instructed by a Solicitor. Unlike a Barrister, he may appear without a Solicitor. Like a Solicitor, he may instruct a Barrister, and there is no obstacle to his being elevated to the High Court Bench. In the medical profession, the highest distinction in surgery was first secured by the Tamils of Ceylon in 1890 when Drs Santiago and Sinnatamby were admitted to stand the examination for the

fellowship of the Royal College of Surgeons of Edinburgh. Cardinal Mauning helped Dr Santiago whilst Dr Sinnatamby was assisted by some friends of Sir G H Dalrymple Elphinstone, Bt. The two Tamils headed the list of successful candidates. This created some consternation at the time. They were the first pure Asiatics, who obtained that coveted diploma. Dr S Paul is the first Ceylonese that secured a London fellowship. It thus appears that the Scots of the East have been the pioneers that paved the way of distinction for other Asiatics (in the sense that they are not of European descent, nor those that profess Christianity or Judaism) in the fields of Law and edicine.—Yours faithfully,

M. TISAINAYAGAM.

THE DIMBULA-DIKOYA CRICKET TEAMS IN 1870:

PIONEERING IN DAYS OF OLD.

A recent mail has brought us several acknowledgments from old Colonists of their delight at receiving a reproduction of Mr Humphrey Humphreys' photograph of the double team of 33 years ago. One well-known Bogawantalawa proprietor, we must quote, rather fully as his remarks are of general interest, and indeed are typical of what all the pioneers of the two districts, still to the fore, feel on the subject. Writing from Devonshire under date 4th February, he says :—

"Your last *Observer* with the *Supplement* in the shape of the reproduced picture of the Dimbula and Dikoya teams in 1870 takes me back in one leap the 53 years : I remember as clearly as if it was last week, Humphrey Humphreys arranging the group ; then focussing us all through his camera, and when all was ready, he himself sliding into the position, leaving a friend to do the mechanical part of the performance, which in those days meant removing the "cap," counting "so many" and popping the "cap" on again ; no "trigger" kind of business as the instantaneous photography of the present day. The names as given in your letter-press are not quite correct. I can put some right, but not all ; and in this I will send you my idea of the names of the group. Was not he you put down as Penny, one called Gibson, who was S D to T C Anderson on Batalgalla?" Marshall is between Jock Paterson and Stronach ; then comes "Daddy Howard" on Stronachs' left hand. Skene I am not sure about, but as I shall probably see him next week I will ask if he remembers the match. In the Darrowella Pavilion or Club, there is, however, a copy of the same photo framed ; and, if I recollect rightly, has the names written underneath : so this would settle any doubt about the people who took part in that match. The old "coir" matting, and jungle poles made a grand "Pavilion" and no mistake, but it answered the purpose, and screened, when necessary, 22 light-hearted young fellows who were as happy under it, as any who seat themselves in the splendid building at Lord's to watch the Varsity or Eton and Harrow matches.

* James Gibson ? Scarcely, as he is still in Colombo and has not claimed the prototype (—Ed. L.R.

"DAYS OF OLD"

On the 4th of next month—April, it will be exactly 40 years since I left Southampton in the P. & O. ss. "Ripon*": the last of the paddle steamers belonging to that Company. I was the only passenger for Ceylon and I can remember well my feelings, when, after "doing" Galle with my fellow-passengers, accompanying them back to the steamer, and having to return ashore alone, having seen the last of my English friends; and so far as I knew there was not a soul in Ceylon that I had ever set eyes on. Of course, I had had letters of introduction, and that night dined with old Sonnenkalb,—I won't answer for the spelling!—slept at "Ephraums Hotel," and next morning had my first experience of the Galle-Colombo coach. To skip a bit, July of that year, 1863, found me on Summerville in Dikoya, where good old W R Daff sent me to see new clearing work done under John Smith, then of Oonoogaloya, Kotmale. On arrival we found the "Bungalow" 2 rooms 10 x 10 had not even been thatched, or covered in any way; the door frames so narrow, that we had to break back the legs of our couches, which were to answer the purpose of beds and chairs. It was whilst living on Summerville—60 acres opening—that a special cooly arrived one day with a letter offering me my first billet of £100 a year, and which, of course, I accepted. It does one good to go back to one's teens sometimes, but the gaps left by those who are "gone before," shade over the otherwise pleasant picture. Once start me on the memories of by-gone days, and I would weary a Saint, and drive an ordinary mortal mad,† so we had better stop. I must thank you, however, Mr Editor, for having given me the chance of this pleasant chat, as by the photo of the cricket teams you transported me to the happiest days of my life, which is on the eve of "three : score years."

From Mr Humphrey Humphreys himself we have an appreciative letter under date 5th February, from which we take a few sentences :—

It was a first rate idea of your getting them printed and sent round with your paper, and I am very glad to know who all the men are save the one whom none of you can make out I should not wonder if some Ceylon man who was in Ceylon in 1870 will be able to fill that one gap in the two teams. I have another group I took when Sir James Elphinstone was over in Ceylon, that I took after a meeting we had at McLeod's, and more of those men have passed away than in the two cricket teams. This group was taken in December, 1870.‡ I heard from a Ceylon friend this week, and he very much appreciates the picture and your remarks upon it.

* Ours was the *Pera*—also paddle—in October, 1861.—Ed. L.R.

† Not at all, we feel sure; nothing could be more interesting, or useful in teaching the "creepers" and S. D.'s of the present day to be thankful for their comforts as compared with the "roughing" of early pioneers.—Ed. L.R.

‡ This group we reproduced some years ago for our *Tropical Agriculturist*: we must send a copy soon to Mr. Humphreys to show him how it was done.—Ed. L.R.

ROYAL ASIATIC SOCIETY :

CEYLON BRANCH.

ANNUAL MEETING: TWO PAPERS READ.

THE HON. THE MENT. GOVERNOR ON OYSTER

WASHINGTON.

The annual general meeting of the Ceylon Branch of the Royal Asiatic Society was held in the Library of the Colombo Museum at 9 p.m. on the 9th Mar. 1903. The Hon. Everard in Thurn, C.B., C.M.G., President, presided and there were also present:—The Hon. Mr John Ferguson, Vice-President, Dr. and Mrs S C K Rutnam, Mr Adv. Perera, Messrs D B Jayatilaka, B.A., F C Rules, M K Bamber, Dr. A J Chalmers, Dr. W A de Silva Dr Savarananattu, Hon. Mr S C Obeyesekere, Messrs P E Morgappab, G H Sahren, Mr Advocate Batuwantudawa, Messrs B Vanderstraeten, W E Byles, W F Gunawardana, Mudaliyar, F D Jayasinha, J Harward, Gerard A Joseph, (Honorary Secretaries) and others.

The minutes of the previous meeting were read and duly confirmed.

THE ANNUAL REPORT.

Mr G A JOSEPH then read the annual report of the Society, as follows:—

The Council of the Ceylon Branch of the Royal Asiatic Society have the honour to submit the following Report for the year, 1902.

MEETINGS AND PAPERS.—The only general meeting held during the year was, the annual general meeting, held on Feb. 26, 1902, when the introduction to the paper entitled "A descriptive catalogue of the more useful trees and flowering plants of the Western and Sabaragamuwa Provinces of Ceylon" by Mr Fredrick Lewis, F.L.S., was read. Besides the above paper a paper entitled "Resolutions and sentences of the Council of the Town of Galle, 1640-4 edited by Mr R G Anthonisz (not read at a meeting) has been printed in the Society's Journal for 1902; and the following papers have been accepted for publication in the Journal for 1903, viz:—I. "Two Ola Grants of the 17th Century" by Mr T B Pohath Kehelpannala. II. "Temporal and Spiritual History of Ceylon compiled by Rev Fernao de Queiroz, s.j., of the Province of Goa," translated from the Portuguese by Mr F H de Vos.

MEMBERS.—During the past year 19 new members were elected:—The Hon. Mr Everard in Thurn, C.B., C.M.G., (elected as a member of R A S, Great Britain and Ireland, under Rule 45) Messrs J R Tosh, V J Tambi Pillai, J S Collett, F J de Mel, Dr Tha Do Oung, Sir W W Mitchell, Messrs R A Rama Pillai, C Batuwantudawa, Dr A J Chalmers, Messrs G B Leechman, D Montagu, GE Weerakoon, Dr Arthur Willey, F.R.S., Messrs W F Gunawardana, W Jayawickrama, P C MacMahon; N Bonaparte-Wyse and T P Ponnambalam Pillai. Three members resigned, viz:—Mr H T Gardiner, Dr P M Muttuomaru and Mr H O Barnard.

Mr. W H G Duncan has become a non-resident life member. The Society now has on its roll 197 members including 24 life-members and 10 hon. members. The Council record with regret the death of the following members of the Society, viz:—Messrs J B Cull, M.A., Oliver Collett, J.P., F.R.S., T B Pauabokke, J.P., and Dr J S Mac Palle. Mr Panabokke joined the Society in 1884. He contributed to the Society's proceedings for 1882, the following paper:—"A Agenda to Professor Rhy's David's Translation of the Jataka 1-40, to supply certain omissions."

Mr Collett joined the Society in 1893. He contributed the following papers to the Society's Journal, viz:—1. (I) Contributions to Ceylon Malacology Vol XV No 48. 2. (II) Contributions to Ceylon Mala-

ology:—Description of a New Helicoid Land shell from the Southern Province Vol. XV:No 49. 3. (III) Contributions to Ceylon Malacology Vol. XVI No 51.

At a meeting held on 5th February, 1902, the following resolution was passed and communicated to Mrs. Collett. Resolved:—"That the Council of the Ceylon Branch of the Royal Asiatic Society wish to record their regret at the death of Mr. Oliver Collett, a member of the Society, who has particularly identified himself with biological research and contributed some valuable papers to the Society."

LIBRARY.—The additions to the Library during the year including parts of periodicals numbered 317. The Library is indebted for donations to the following:—The Secretary of State for India; the Government of India; Archaeological Survey of India; Professor A. Bastian, the Postmaster-General; Gerard A. Joseph; the Colonial Secretary; India Office Library; Mr. A. W. Fernando; Dr. Tha Do Ouug; Cape of Good Hope Geological Commission; Oberlin College Library; Rev. P. D. Wajiranana; Messrs. H. C. P. Bell; J. F. W. Gore; Dr. A. Carol, and Mr. A. K. Coomaraswamy. For valuable exchanges received during the year the Society is indebted to the following:—The American Oriental Society; the Royal Society of Victoria; the Academy of Natural Sciences, Philadelphia; the Smithsonian Institute; Bombay Branch of the Royal Asiatic Society, U. S. Department of Agriculture, Wagner Institute of Sciences, Philadelphia; Geological Survey of U. S. of America; Field Columbian Museum; (the State Archives); the Bureau of Education; (the Societe Zoologique, Paris); (Anthropologische Gesellschaft, Koenig-gruelzer-strasse Berlin); (Deutsche Morgenlandische Gesellschaft, Leipzig); Royal Society of New South Wales; California Academy of Sciences; (Societe Imperiale des Naturalistes de Moscow); China Branch of the R. A. S.; Asiatic Society of Japan; Royal Asiatic Society of Great Britain and Ireland; the Indian Museum; Asiatic Society of Bengal; John Hopkins University; Geological Society of London; the Anthropological Institute of Great Britain and Ireland. The Geological and Natural History Survey of Canada; the Royal Colonial Institute; Straits Branch of the R. A. S. the Royal Geographical Society of Australasia; and Korea Branch of the Royal Asiatic Society.

ACCOMMODATION.—The Council in 1898 directed the attention of Government to the congested state of the Library and referred to the subject touched upon in the Annual Reports from 1888. His Excellency the Governor in reply then stated that he "shares the regret of the Council that other more urgent claims on public moneys have prevented the provision of funds for the extension of the Museum." The Council hope that we are now within reasonable distance of the time when provision will be made for carrying out the long-contemplated extension.

JOURNALS.—One number of the Journal has been published during the year (Vol. XVII. No. 52-1901). It contains in addition to the proceedings of the Council and the Annual General Meeting, the following paper:—"Supplementary paper on the Monumental Remains of the Dutch East India Company in Ceylon," by F. H. de Vos.

ARCHAEOLOGICAL.

ARCHAEOLOGICAL SURVEY, 1902.—The Archaeological Survey continued operations in 1902, at Anuradhapura, Sigiriya and Polonnaruwa. From January 1st Mr. J. Still was appointed to succeed Mr. C. E. Dashwood as Assistant to the Archaeological Commissioner, concurrent field work was thus again rendered practicable at two centres during much of the year.

ANURADHAPURA—Ruwanveli Area.—South of the Ruwanveli Dagoba are still to be found a few scattered sites, marked by pillar stumps, which have not yet been excavated. These isolated ruins are dotted about the Residency grounds, the premises of Government clerks and the open spaces adjoining the Sacred Road.

MAHA PALI ALMS HALL.—One of these detached ruins, an extensive site, roughly pillared, was exploited in the past year, and has fortunately yielded one of the most interesting discoveries hitherto made at Anuradhapura. An excavation spread the plan of an exceedingly spacious quadrangle, with central court-yard, or shallow tank, was gradually disclosed. This four-square ruin measures 135 feet more or less each side. All round ran a range of rooms, or a corridor, once roofed in; and 30 feet in width. The hypethral court-yard, or tank some 75 feet square enclosed within the building, is stone-flagged and at a lower level than the quadrangular rooms. In the west corridor was unearthed a large "stone canoe," perfectly preserved 44 ft. 6 in. long, by 3 ft. 6 in. broad, making the fourth so far found at Anuradhapura. The ruins to the East of Abhayagiriya Dagoba, excavated in 1893, contain a ruin much the same in plan with a similar "kenda oruwa," or "kanji boat" (as these strange "stone canoes" are popularly termed) but greatly damaged, situated in a central group of monasteries. These special buildings were doubtless those "Alms Halls" (Dansala) mentioned not infrequently in the "Mahawanso." The spaciousness and general finish of the present ruin laid bare in the Resthouse premises, seem to justify its probable identification with the "Maha Pali," that chiefest of "Alms Halls" greatly favoured of royalty from the 6th to the 10th century. The excavation of this extensive ruin, deeply buried and tree-covered, occupied the Anuradhapura gang for the better part of 1902. **Mirisavetiya Area.**—During the last three months of the year, work was resumed in the Mirisavetiya Area and will be pushed to completion in 1903. The ruins around the Mirisavetiya Dagoba are probably, all told, not more than half a hundred in number, and would appear to offer no special difficulty in unearthing. The style is severely simple and the grouping easily distinguished. **Clearing.**—The annual allotment of the vote for clearing ruins and jungle at Anuradhapura was very profitably expended owing to the drought during the first nine months of last year. Nearly six hundred (600) acres were cleared and weeded and some rooting out done.

SIGIRIYA.—A gang is engaged at Sigiriya during the early part of every year in the tedious, but essential, work of weeding the citadel on the summit and the several terraces and excavated sites below the rock. Some re-clearing of undergrowth had to be done within the area of the ancient city. Steady progress was made in connection with the continued restoration of the "gallery." The work done in 1902 comprised the completion of the iron bridge spanning the gap between the lengths of the gallery along the west face of the rock, and of that hugging its north scarp; and the building of a substantial abutment in stone to prevent downward slip of the long and steep staircase which culminates at the *Maluva* below the iron ladders to the summit.

By the end of next season it is hoped that the gallery will be restored from its broken entrance near the head of the North and South Staircase approaches from the city below, as far onwards as the *Maluva*. The serious, and unavoidable, hindrances in getting bricks, lime, and sand to Sigiriya, and up into the "gallery" cannot but much delay this most desirable restoration.

With great difficulty, and no little risk, preliminary borings were made into the floor of the largest fresco "pockets," and jungle-stick scaffolding erected ready for next season.

The object, as stated last year, is to effectually afford permanent protection to the unique frescoes of Sigiriya against the ravages of birds and flying insects. Suitable wire-netting when fixed in position, whilst wading off these destructive pests, will not mar the view of the paintings. Belated agitation for similar protection to the better-known paintings of the Ajanta Caves in India has only recently begun.

POLONNARUWA.—Operations were resumed at Polonnaruwa for the third season in May last. Weeding the area already excavated in 1900 and 1901, mainly the ruins (Audience Hall, &c.) situated within the promontory—occupied a fortnight or three weeks. Subsequently attention was given to continuing excavations around the Siva Devale near the 25th mile-post on the road from Minneriya. This Devale was exposed last year. Forest trees and scrub jungle are so thick at Polonnaruwa that much felling and clearing was necessary, and proved slow work. By the end of September, however, the entire group of ruins had been excavated and opened out to view from the high road. This group consists of:—(a) *Siva Devale* (b) A *Vishnu Devale*. (c) A *Kovil* sacred to the goddess *Kali*. In plan and architectural details these shrines display little to differentiate the one from the other. All alike have a vestibule and *sanctum*: the Siva Devale alone possesses an intermediate room. They were brick-built, with stone pillars to support the roof where required. Stone figures of *Vishnu*, *Kali*, and the bull *Nandi* were found near their respective shrines. Beside these three fanes, this Hindu Temple claimed at least three other buildings:—(d) A plain, narrow, structure crowning the summit of the rock hummock, on the west slope of which occurs the long inscription of King Nissanka Malla. (e) A pillared building, oblong, within its own enclosed premises. (f) A bold, terraced, building, on massive pillars, immediately adjoining the bund of the old Topavewa tank. This building was probably the principal residence of the ecclesiastics—first Buddhist monks, subsequently alien priests, after the conversion of the monastery into an extensive temple devoted to Hinduism. At the foot of the entrance stairs were exhumed two handsomely carved moonstones adorned with *hanas* and other ornamentation. As in 1901, a large number of moor villagers from the Marakkala Pattuwa of Tamankaduwa, were engaged for a week in continuing to free the ancient city of the jungle in which it lies buried. The area dealt with in the past year extends for a width of 200 to 300 yards from the Rankot Vehera as far northwards as the Kiri Vehera.

COUNCIL.—Two members of the Council of 1901 viz:—Mr A Haly and the Hon Mr H H Cameron, have been deemed to have retired in accordance with Rule 16; the vacancies in the Council were filled by the appointments of Mr J C Willis and Mr H White, Mr M K Bamber was elected in place of Mr J Ferguson who was appointed as Vice-President.

FINANCES.—The income for the year exclusive of the commencing balance, was R1,562 25; but there has been exceptional expenditure, especially in the latter half of the year, due chiefly to the issue of a number of the journal double the usual size. The re-binding of volumes in the Library, too has been exceptional and continuous throughout the year. In April the Treasurer placed R1,500 on fixed deposit for a year to secure 4 per cent interest; but the printing and binding expenditure being more than twice as large as in 1901, the current account was overdrawn at the end of the year by R359 42. The interest on the fixed deposit will accrue in April next and there will be a net gain to the Society of nearly R50; but the balance sheet below discloses that the commencing balance of R2,200 10 was reduced during the year to R1,140 58.

Mr M KELWAY BAMBER, M R A C, M R A S, ENG., F C S, moved the adoption of the report.

Mr C BATUWANTUDAWA seconded and it was carried unanimously.

ELECTION OF OFFICE-BEARERS.

Mr PAUL PEIRIS—moved that the following be elected office-bearers for the year, Dr CHALMERS seconded and it was agreed, viz:—

President.—The Hon. Everard im Thurn, C B, C M A.

Vice-Presidents.—Mr F M Mackwood, J P, F E S, the Hon. Mr J Ferguson, F R C I.

Council.—Dr. W G VanDort, M D, Messrs. W P Ranasinha, S M Burrows, M A, C C S, C Driberg, B A, F H A S, the Hon. Mr S C Obeyesekera, Messrs. H White, C C S, J C Willis, M A, F L S, M Kelway Bamber, F C S, C M Fernando, B A, L L B, P Freudenberg, Dr. A Willey, M A, D S C (London) F R S., Mudaliyar A M Gunasekera.

Hony Treasurer.—Mr F Crosbie Roles.

Hony Secretaries.—Messrs H C P Bell, C C S, J Harward, M A, and Gerard A Joseph.

OLA GRANTS OF THE 17TH CENTURY.

Mr HARWARD in the absence of Mr T B Pohath-Keheppanala, read his paper entitled "Two Ola Grants of the Seventeenth Century with text, translation and notes."

MUDALIYAR GOONAWARDANA—on been called upon to speak—said he had not much to say on the paper now read. He, unfortunately, had not had the opportunity of seeing a copy of the original until that day, and then only for a short time through the kindness of Mr Harward at his office. The first of these *sannas* bore the date as they would see of 1553. The translation date was "the seventh day on the waning moon of the month of Wesak." He believed there was a misprint there and that it should be, the 13th day; for he found in the original, a word which meant "thirteenth day." He looked into Sir Charles Cunningham's table of dates and according to that the "13th day" of the waning moon of the month of Wesak in the year of Saka 1553 fell not on a Sunday as given there, but on a Wednesday, so that they would see there was a discrepancy between the date of the month and the day of the week. The writing too, of which he saw a facsimile copy in the hands of Mr. Harward, did not appear to him to be the writing of the Sinhalese of the seventeenth century. He did not, therefore, think that this could be genuine. Perhaps, if he saw the original, he might have reason to change his opinion. But so far as he had seen the document he certainly did not think it was genuine. As to the second, he thought there was a good deal to say on the side of the genuineness of that document. In the first place the writing did look like the writing of the seventeenth century of the Christian era. In the second place the document seems to be not of a kind to be forged for any purpose because the deed seemed to grant certain exemptions to one Suruttan Kuttiya and he believed these privileges did not descend on his successors and, therefore, it was difficult to see why at any subsequent date any person should have forged that document. There was thus a good deal to say on the side of the genuineness of this document, but there was still the same difficulty as with the last, with regard to dates. He verified these dates according to Sir Alexander Cunningham's table of dates and he found that "the seventh day of the waxing moon of the month Esala, in the year of Saka 1567" fell not as stated in the document on a Thursday but on a Sunday. That he thought was very fatal to the genuineness of the document having been written on the day it bore on the face of it. It was a fact well-known that the Sinhalese had their calendar of dates very carefully prepared and were always guided by that Calendar in all the documents that passed under their hands. So far, therefore, as that went the presumption was against the admission of the genuineness of the first document. With regard

to the second document he did not know whether it was possible for them to come hastily to a decision. There was a sense of genuineness about it, and, therefore, he thought if the question of genuineness was to be decided it would be better to give all the members of the Society time to go into the matter before coming here to discuss it. (Hear, hear)

MR J FERGUSON—said he could not follow the previous speaker into his learnedly technical and probably useful criticism. He was most attracted by the historical notes; by the reference to the murderous priest-king who caused both his rival to the hand of the queen, and the young princely heir, to be put to death. The time was a critical one for the Sinhalese monarchy, just when it was welcoming the Hollanders as protectors from the Portuguese—a case very much of “out of the frying-pan into the fire,” as they soon proved. The incident as to the grant of land within the circuit of the bangle had its parallel in the case of the founder of the Hay (Erroll) family in Scottish history, and no doubt in other countries. He was interested in what was mentioned in regard to the origin of certain mosques, and would suggest that an interesting paper might be compiled out of the history of the leading Mahomedan mosques in the island.

MR D B JAYATILAKA—said that, leaving aside the question as to whether the documents placed before them were genuine or not, they were very interesting and the author deserved their best thanks. The notes were full of interesting facts. They brought before them a very interesting fact with regard to the medical history of Ceylon. They saw that these grants had been made for past services rendered by two medical men. He believed the descendants of these men were still living in a district in Ceylon. These men were known by the name of Muhandiram of the Royal Medical Service and if he was not mistaken their descendants still passed by that name. It was difficult for anyone to pass an opinion on the genuineness of documents except those who had studied their chronology.

The CHAIRMAN—thought that it might be well that the remarks of Mudaliyar Goonawardana be indicated to the author who was not present.

This view was accepted by those present.

The CHAIRMAN—said it seemed they were agreed that the paper in itself was an interesting one and the notes especially appeared to be very interesting. With a safeguarding note on its genuineness by Mr Bell and with Mr Goonawardana's remarks which, no doubt, would be recorded they would accept the paper for what it was worth and give the thanks of the meeting to the author.

KING KIRTI SRI'S EMBASSY TO SIAM.

MR. PAUL E PEIRIS, M.A. Barrister-at-Law, CCS,—then read his paper entitled “An account of King Kirti Sri's Embassy to Siam in 1672 Saka (1750 A.D.)” The paper was translated from the Sinhalese by Mr Peiris and is a very interesting account of the Embassy's experiences. It is full of incident, and wealthy description and gives a splendid account of the Sinhalese and Siamese customs of the period with which the paper deals.

MR. F C ROLES—on discussion being invited, said he should like to ask Mr Peiris whether the phrase on page 13 “a considerable portion...has been omitted to avoid the risk of appearing to

relate the incredible” was a phrase commonly used at that time. Now-a-days they were not confined and there was no hesitation in giving them the incredible whether it was from Savage Landor or the *goyia* in the witness box. He should like to know if it was a mere formal phrase, or whether it indicated that they had lost, perhaps, the most interesting part of the description?

MR. PAUL PEIRIS—said he could only say he translated what the writer said.

The PRESIDENT :—I do not think it is unusual for writers in books of travel to say that words fail to express what they saw.

MR. HARWARD—said they must remember it was characteristic of Oriental literature to give catalogues of splendid fittings. Such catalogues formed a part of the poetical and prose descriptions in oriental literature, and although, no doubt, the paper gave an interesting description of Siam as it was in the 18th century—there was no doubt a great deal of prosperity and splendour there—he did not think they were bound to accept quite the full picture presented to them in that paper; because he thought it would come quite natural to a Sinhalese narrator at the time to give numerical symmetry to the various details he was describing.

MR. PAUL PEIRIS—said that the writer from whom he had translated was a very careful writer, and he saw no reason whatever for disbelieving him. When he talked about emeralds the size of oranges he might be mistaken, but possibly he referred to the green stone. As further proof of the enormous expenditure of the Siamese Kings on their religion, he had the good fortune to have given him a note which he did not think was yet published; and there was reference there to a certain temple, where there was an image of the Buddha larger than life-size of solid gold. He mentioned also that while in England he saw a bell that was captured at the sacking of a town in that quarter. It weighed 3 cwt., and 2 cwt. was solid silver.

MR. D B JAYATILAKA—said he did not think there was any difficulty in believing these accounts for the simple reason there were accounts by the other envoys to Siam. He might mention the interesting fact that that Embassy was the fourth one. There had been three before it to Siam and it was interesting to note that the first Ambassador to Siam sent by the Sinhalese King to enquire into religion there was a Dutch Officer. He had seen a letter from him to the Kandyan King describing the Siamese Court which was similar in description to the paper now read. He did not believe that the Dutch people exaggerated and if they could believe the Dutchman's description, he did not think, they need cast any doubt on the paper now before them.

Dr. W A DE SILVA—said he had recently been to Siam and had seen most of the things referred to in the paper. He had seen the green stones a little larger than an orange. He had also seen the gold image of Buddha life-size. As regards the processions, and elephants' houses and trappings &c., it seemed to him most of these things still remained. If any of them were to go to Siam and watch some of the religious festivals, most of the descriptions given in that paper would be seen to be quite correct. So far as he had observed, they were.

VOTES OF THANKS.

The Hon. Mr S C OBEYESEKERA—said he had much pleasure in moving a hearty vote of thanks both to Mr Pohath-Kehelpinnala and Mr Paul Peiris for their valuable papers. Mr Pohath-Kehelpinnala might probably be open to the criticisms made by Mr Goonawardana, but nevertheless, they took his will for the deed meanwhile. He devoted a great deal of time to the matter and, as Mr Ferguson observed, he thought he deserved credit for the very full notes which abounded with interest. (Hear, hear.)

Advocate Mr E W PERERA—seconded the motion. In doing so he desired to offer a few remarks. As regards the first paper the remarks made by Mudaliyar Goonawardana did not prove that the documents were forgeries. In fact he based his attacks on the genuineness of the grants on two points. The first point was that the dates were incorrect and he based his argument on a calculation from the computation of Sir Alexander Cunningham. There were several computations among the Sinhalese and he thought in dealing with the matter they should have an entirely independent computation. But apart from that he should very much like to know in what respect the Sinhalese characters of the 17th century differed from those of the 19th or 20th centuries. Only the sannas of the 15th century and 16th century differed very slightly from the sannas of the present day. In regard to the second paper Mr Peiris would greatly oblige the Society with a copy of the original manuscript from which he had made that translation. He believed there was not a copy in the Museum Library. In that connection he said there was in Kandy the original of a letter which accompanied a grant sent by the King of Siam along with an Embassy and that would give them valuable information and supplement Mr Peiris' paper. In regard to what was said about the correctness of the paper he should say the information was correct. The question asked by Mr Roles would have been unnecessary if Sir Charles Mandeville had written the paper. Of course, he would not have drawn the line at the incredible. These Ambassadors, however, while describing the ceremonies seem to have drawn the line. Human nature was, of course, the same all the world over. He had very great pleasure in seconding the votes of thanks.

Mudaliyar GOONAWARDANA,—in supporting the motion, said he would like to say a word of explanation. In criticising the genuineness of the paper sent in by Mr Pohath Kehelpinnala he did not mean, in the slightest degree, to cast discredit on his work. He knew he was a very industrious young man and he, certainly, admired the industry with which he had collected a large amount of information with regard to the history of Ceylon, and all he wanted to say was that, in his view, the document did not appear genuine because there was a discrepancy in the dates.

The PRESIDENT—thought that this was just repeating what Mr Goonawardana had already said. The hour was getting late.

MUDALIYAR GOONAWARDANA—proceeding said he would not go further into that point. With regard to the question raised by one gentleman as to what was the difference between the caligraphy of the 17th Century and the present day, he himself admitted there was a little difference between the caligraphy of the 16th century and the present

day. If that was so why could there not be a little difference between the caligraphy of the 17th century and the present day.

The PRESIDENT—declared the vote of thanks carried.

Mr. J FERGUSON—said the pleasant duty had been allotted to him of proposing a cordial vote of thanks to their President for his services to the Society and at that late hour he would be very brief in doing so. He regretted that during this first year of their President, the Society should have been so barren of papers; but, Irish-like, their gratitude took the form of a lively anticipation of favours to come. The presidential influence, he trusted, would mean for them very soon, some useful papers from members of the Scientific Corps in the Public Service up and down country. The gentlemen for instance, who had been so successfully flashing their maiden swords as lecturers elsewhere, might now come to the aid of this good old Society in its Ceylon Branch, and he was glad to know that at least one of them had a paper on the stocks. Meantime they were fortunate as to their President and tendered him hearty thanks. (Applause).

INTERESTING REMARKS BY THE PRESIDENT.

The PRESIDENT—in thanking the members for the vote of thanks, said the fully appreciated the force of the Hon Mr Ferguson's remarks. He had been able to do very little for them, but coming fresh into a new world as it practically was to him there was naturally a good many things to do and not much time to spare. But he did cordially agree with Mr Ferguson on the subject of papers. They ought to get many of as kind they had not got lately at any rate—his experience did not go very far back—scientific papers. And he hoped one of the earliest papers they would have would be one on The Oyster. It ought to be written by one who could write it no more—he meant Mr Oliver Collett. That was a particularly appropriate subject. There was a meeting before his time at which the Governor—he referred to H.E. Sir West Ridgeway—took the chair and at which a great deal of useful information on the subject of Oysters was put forward by Mr Collett. Sir West Ridgeway and he himself had been during the week at the Pearl Fishery—the first, he thought, held in Ceylon for 11 years. It was, of course, new to them and they had been marvellously astounded at the manner in which that gigantic fishery was worked. There, where three weeks ago, there were hardly any inhabitants and for years no more than three or four huts with about 20 or 30 inhabitants, had suddenly collected 23,000 or 24,000 people, all working hard and bringing in these oysters which were divided between Government and the divers in a most elaborate system and the speed and accuracy of working the whole business was most astounding. By a very curious coincidence on his way to the Pearl Fishery he had received a scientific magazine and in that he came across a very interesting account of a fishery which was held—not where the present fishery was taking place, but opposite Chilaw. What that writer wrote then was just practically what he (the speaker) might have written now if he was to sit down and write what he saw last week. What he intended to say was, however this, that the system has no doubt grown up during centuries

and has no doubt grown very perfect. Still there were certain things which he thought required very much to be corrected and he hoped that by another year or by next fishing at any rate they should be able to do a great deal to reform the present system. For that purpose they had Mr Hornell working out the life history of the oyster and investigating as to the enemies of the oysters and the pearls also and Mr Hornell ought before long to supply them with some information for their Journal. They had also an experiment in which he had taken a very personal interest himself. He had it in his mind for many months and he was glad to say it was working out very well indeed. It was a system of washing out oysters in the same way as he used to see gold washed out in other parts of the world. The other day when he tried the eight oysters—as an experiment, merely—the first produced 10 pearls, not counting the seed pearls. They did it in a few minutes and they might have done 800 in the same time. He thought the experiment promised very well. He thought the old system of washing by merchants would probably survive for a long time and he would be sorry to see it disappear, but it was very good that Government should have a system for washing oysters when occasion arose. (Applause). This terminated the business.

DAYS OF OLD.

REMINISCENCES OF EARLY PHOTOGRAPHY.

(By a Ceylon Man.)

In one of the recent issues of the *Overland Observer* I notice it mentioned that Mr. Hum-

phrey Humphreys was the first amateur photographer in the island. If I am not very much mistaken, I think that honour must be conceded

MR. BARTON.

He took lessons from Mr. Parting between 57-59. Mr. Parting was the first photographer to start in the business in a little place in Baillie Street—next door, I think, to Findlay who was the first European tailor. Mr. Parting sold his business to Messrs. Slinn & Co. and retired, whilst Findlay, by the way, disposed of his business to Bolam and established a general store in Kandy and it was whilst supervising some structural alterations to the building that it collapsed, burying him in the ruins from which he was taken out dead. Some of Mr. Barton's photos of Dondra Head are engraved in your Directory for 1863. This gentleman is living in Bangalore. But there is yet another amateur in

MR. R. W. T. MORRIS,

better known in his younger days, as "Bob" Morris, to distinguish him, I suppose, from his late father who was at that time Government Agent Trincomalee.

In 1862-63 "Bob" Morris was Assistant Agent at Nuwarakalavia and it was at Anuradhapura that I saw his photographs taken under great difficulties. The water he had to distil himself. He rigged up a very crude but at the same time most effective apparatus for the purpose and surmounted all obstacles. Some of his photos of the ruins of Anuradhapura and Mihintale I have in my album, wonderfully well preserved, seeing that they are 40 years old.

LITERARY REGISTER SUPPLEMENT:

AND CEYLON

"NOTES AND QUERIES."

[Under this heading, in future, we mean to give a small "Supplement" with our *Tropical Agriculturist* from quarter to quarter, according as there is matter of sufficient value so to be preserved.]

JUNE, 1903.

THE "BRAHAN SEER" IN THE SEAFORTH FAMILY.

March 13.

DEAR SIR,—I have been much interested in all you have told us about Lady Ashburton and the Stewart-Mackenzie family. Can you add to the favour by saying when the "Brahan Seer" lived,—what he prophesied,—and how it was fulfilled? and oblige—Yours truly,

CURIOUS.

[Kenneth Mackenzie, better-known as Coinneach Odhar, the Brahan Seer, was born about the beginning of the 17th century. He was burnt to death under atrocious circumstances by order of a Countess of Seaforth, about the middle of the century, because he had divined and told her of the unfaithfulness of her husband, the Earl, who was absent in Paris. By killing the Seer, the Countess hoped to make the people believe his report publicly made, was a slander. We read:—

"When Coinneach found that no mercy was to be expected either from the vindictive lady or her subservient vassals, he resigned himself to his fate. He drew forth his white stone, so long the instrument of his supernatural intelligence, and once more applying it to his eye, said—'I see into the far future, and I read the doom of the race of my oppressor. The long-descended line of Seaforth will, ere many generations have passed, end in extinction and in sorrow. I see a chief, the last of his house, both deaf and dumb. He will be the father of four fair sons, all of whom he will follow to the tomb. He will live careworn and die mourning, knowing that the honours of his line are to be extinguished for ever, and that no future chief of the Mackenzies shall bear rule at Brahan or in Kintail. After lamenting over the last and most promising of his sons, he himself shall sink into the grave, and the remnant of his possessions shall be inherited by a white-coifed (or white-hooded) lassie from the East, and she is to kill her sister. And as a sign by which it may be known that these things are coming to pass, there shall be four great lairds in the days of the last deaf and dumb Seaforth—Gairloch, Chisholm, Grant and Ramsay—of whom one shall be back-toothed, another hair-lipped, another half-witted, and the fourth a stammerer. Chiefs distinguished by these personal marks shall

be the allies and neighbours of the last Seaforth; and when he looks around him and sees them, he may know that his sons are doomed to death, that his broad lands shall pass away to the stranger, and that his race shall come to an end.' We believe Sir Hector Mackenzie of Gairloch was the back-toothed laird (an Tighearna Stòrach); the Chisholm, the hare-lipped; Grant, the half-witted; and Ramsay, the stammerer, all of whom were contemporaries of the last Lord Seaforth." Then of the last Earl, born nearly 100 years after this prophecy, we are told:—

Francis Humberston Mackenzie was a very remarkable man. He was born in full possession of all his faculties, and only became deaf from the effects of a severe attack of scarlet fever, while a boy in school. He continued to speak a little, and it was only towards the close of his life, and particularly during the last two years, that he was unable to articulate—or perhaps, unwilling to make the attempt, on finding himself the last male of his line. He may be said to have, prior to this, fairly recovered the use of speech, for he was able to converse pretty distinctly; but he was so totally deaf, that all communications were made to him by signs or in writing. Yet he raised a regiment (the 78th), at the beginning of the great European war; he was created a British peer in 1797, as Baron Seaforth of Kintail; in 1800 he went out to Barbados as Governor, and afterwards to Demerara and Berbice; and in 1808 he was made a Lieutenant-General. These were singular incidents in the life of a deaf and dumb man. He married a very amiable and excellent woman, Mary Proby, the daughter of a dignitary of the Church and niece of the first Carysfort, by whom he had a fine family of four sons and six daughters. One after another his three promising sons (the fourth died young) were cut off by death. The last, who was the most distinguished of them all, for the finest qualities both of head and heart, was stricken by a sore and lingering disease, and had gone, with a part of the family for his health, to the South of England. Lord Seaforth remained in the north at Brahan Castle. A daily bulletin was sent to him from the sick chamber of his beloved son. A few posts later, brought to Seaforth the tidings of the death of the last of his four sons. At length, on the 11th January, 1815, Lord Seaforth died, the last of his race. His modern title became extinct. The chiefdom of the Mackenzies, divested of its rank and honour, passed away to a very remote collateral who succeeded to no portion of the property, and

the great Seaforth estates were inherited by a white-hooded lassie from the East. Lord Seaforth's eldest surviving daughter, the Honourable Mary Frederica Elizabeth Mackenzie, had married, in 1804, Admiral Sir Samuel Hood, Bart., K.B., who was Admiral of the West India station, while Seaforth himself was Governor in those islands. Sir Samuel afterwards had the chief command in the Indian seas, whither his lady accompanied him, and spent several years with him in different parts of the East Indies. He died while holding that high command, very nearly at the same time as Lord Seaforth, so that his youthful wife was a recent widow at the time, and returned home from India in her widow's weeds, to take possession of her paternal inheritance. She was thus literally a white-coifed or white-hooded lassie (that is a young woman in widow's weeds, and a Hood by name) from the East. After some years of widowhood, Lady Hood Mackenzie married a second time, Mr. Stewart, a grandson of the sixth Earl of Galloway, who assumed the name of Mackenzie, and established himself on his lady's extensive estates in the North. Thus, the possessions of Seaforth may be truly said to have passed from the male line of the ancient house of Mackenzie. And still more strikingly was this fulfilled, as regarded a large portion of these estates, when Mr. and Mrs. Stewart Mackenzie sold the great Island of Lewes to Sir James Matheson. After many years of happiness and prosperity, a frightful accident threw the family into mourning. Mrs. Stewart Mackenzie was one day driving her younger sister, the Hon. Caroline Mackenzie, in a pony carriage, among the woods in the vicinity of Brahan Castle. Suddenly, the ponies took fright, and started off at a furious pace. Mrs. Stewart Mackenzie was quite unable to check them, and both she and her sister were thrown out of the carriage much bruised and hurt. She happily soon recovered from the accident, but the injury which her sister sustained proved fatal, and, after lingering for some time in a hopeless state, she died, to the inexpressible grief of all the members of her family. As Mrs. Stewart Mackenzie was driving the carriage at the time of the accident, she may be said to have been the innocent cause of her sister's death, and thus to have fulfilled the last portion of Coineach's prophecy which has yet been accomplished. Mr. Stewart Mackenzie, the accomplished husband of the heiress of Seaforth, after being for many years a distinguished member of the House of Commons and a Privy Councillor, held several high appointments in the Colonial Dominions of the British Crown. He was successively Governor of Ceylon and Lord High Commissioner of the Ionian Islands, and died, universally beloved and lamented, in the year 1843. Lockhart in his life of Scott, in reference to the Seaforth prediction, says:—"Mr. Morritt can testify thus far—that he heard the prophecy quoted in the Highlands at a time when Lord Seaforth had two sons alive, and in good health, and that it certainly was not made after the event"; and he goes on to tell us that Scott and Sir Humphrey Davy were most certainly convinced of its truth, as also many others who had watched the latter days of Seaforth in the light of those wonderful predictions. "Our friend, Lady Hood," wrote Sir Walter Scott to Mr. Morritt, "will now be 'Oabarfeidh' herself. She has the spirit of a chieftainess in every drop of her blood." The writer concludes thus:—"Scott's ap-

prehensions proved only to be well founded. One section after another of the estates had to be sold. The remaining portion of Kintail, the sunny braes of Roes, the Church lands of Chanonry, the barony of Plinscarden and the Islands of Lewes—a principality itself—were disposed of one after the other, till now nothing remains of the vast estates of this illustrious house except Brahan Castle, and a mere remnant of their ancient patrimony (and that in the hands of trustees), which the non-resident, nominal owner has just been prevented from alienating. *Sic transit.*"

Leaving these extraordinary prophecies with the reader, to believe, disbelieve, or explain away on any principle or theory which may satisfy his reason, his credulity, or scepticism, we conclude with the following:—

LAMENT FOR "THE LAST OF THE SEAFORTHS."

BY SIR WALTER SCOTT.

In vain the bright course of thy talents to wrong
Fate deaden'd thine ear and imprison'd thy tongue,
For brighter o'er all her obstructions arose
The glow of the genius they could not oppose;
And who, in the land of the Saxon, or Gael,
Might match with Mackenzie, High Chief of Kintail?
Thy sons rose around thee in light and in love,
All a father could hope, all a friend could approve;
What 'vails it the tale of thy sorrows to tell?
In the spring time of youth and of promise they fell!
Of the line of MacKeaneth remains not a male,
To bear the proud name of the Chief of Kintail.

And thou, gentle Dame, who must bear, to thy grief,
For thy clan and thy country the cares of a Chief,
Whom brief rolling moons in six changes have left
Of thy husband and father and brethren bereft;
To thine ear of affection, how sad is the hail
That salutes thee—the heir of the line of Kintail!

The story as relating to a past Governor of Ceylon and his family, is of special local interest, and so we may be pardoned for quoting so much.—ED. L.R.]

THE LORENZ LECTURE AND OLD TIMES.

March 10.

DEAR SIR,—The Lecturer last Thursday regretted your absence, as he read out what you had said of his hero on his death; and well he might! I don't think there were many who were able to follow the local hits contained in the extract he read from the Christmas Debates of 1864. All, all, are gone! In that delightful parody of Enoch Arden—Not Enough Hardened—fathered on Tenny-father (the showy, but not too brilliant, Auditor-General of the day being Penny-father)—how many understood the reference to the "half-seen rock" alluring "the steamer 'Pearl,' until she madly strikes against it"? But you, Mr. Editor, knew the Government steamer of that name, which always grazed its bottom or its side against some rock, until she became known as the Pearl of great price, for what she cost in repairs. And was not old Varian her Captain?

DAYS OF OLD.

Anuradhapura, Feb. 28.

Then, the reference to the Heliotropes in the garden at the back of the Council Chamber, "a recent gift of William Ferguson," the genial, popular Botanist of the day; and to "Gibson, the honourable friend of times gone by—stout, hearty, with huge rolls of double chin"! I see the portly old man before me, but not particularly hearty in after years, as he would withdraw his gouty foot from the stool under the table, and rise wearily to answer some question of Coomaraswamy's, and to sit on him! Then, Richard Morgan, "a shorter, but a more developed corporation," with his length of ribbon rosy-red, wherewith they bound the Colony"! Morgan had advised "the General sitting in the chair"—O'Brien, whose son Terence was tried by Court Martial for his part in the Sikh Cooly affair afterwards, and defended by Lorenz—that, as the Unofficials had been appointed by the Crown, the Council was fully constituted without them until their resignations had been accepted by Her Majesty! And the Colonel, who welcomed the ex-Unofficials for the Christmas sitting, with his song *The rebels are coming: hooray, hooray!* was Sir; while, I suppose, the Collector of Customs, who was fast asleep when roused by Lorenz's cries of No, No, was poor old Stephens, the somnolent. It is a pity the lecture was not illustrated by lantern slides.—Yours truly,

SENEX.

[It was our fortune to be alone at the helm of the *Observer* at the time of the death of two of Ceylon's greatest sons:—Sir Richard Morgan and Mr. C. A. Lorenz, and we tried hard, at very short notice, to do justice to both, so far as a newspaper "in memoriam" notice could do so. Our long article on Sir Richard was afterwards taken over in full for his "Life" by Mr. Digby; and in the case of "Lorenz," a sense of deep sympathy entered into our writing; for, it was truly sad that so brilliant a man and earnest a worker should be cut off at so early an age. We can recall one long and most pleasant interview with the then Burgher M.L.C. Left in 1863 to conduct our bi-weekly paper—the three papers, "Observer," "Times" and "Examiner" made a daily issue between them in those good old days—we had also to bring out the Directory for that year, and it was certainly about the neatest and most attractive book with its illustrations, up to that date published in Ceylon. So said Mr. Lorenz very heartily when he called for a copy one Saturday afternoon in Baillie Street and gave us half-an-hour of his lively entertaining conversation. Seven years after in St. James's Hall, London, we had the opportunity of watching Charles Dickens giving what proved to be his final public reading; and again and again were we reminded by the large, bright observant eyes of the brilliant Ceylonese. Lorenz was indeed the Charles Dickens as well as the Washington Irving of Ceylon; but alas! as "Senex" shews, how few there are to catch up the points of witticism so entirely applicable and patent to all in our island world during the "Sixties."—ED. L.R.]

DEAR SIR.—The letters "*Cuculus Ecclesiasticus*" is favouring the public which are most interesting, and the information supplied is such as few besides the only state-paid Clergyman in our Colonial list can supply. I see in his letter enumerating the Ceylonese *alumni* of the old Bishop's College, Calcutta, he has omitted one name, that of Mr J L Flanderka, Assistant Government Agent and District Judge, Nuwarakalawiya (February 1854-1860, and again from March 1863-August 1869). He is the only Burgher A.G.A. in our annals, which of itself marks him out for distinction. In this connection the following extract from a letter of "good Dr. Loos," as your London correspondent styled him recently,—will be read with interest. "Another fact with regard to Anuradhapura is that Flanderka was Assistant Agent there. He was in the Academy with me and a class-fellow. He became a student in Bishop's College in Calcutta, and was there while I was in the Medical College. On his return to Ceylon, he was fortunate enough to obtain an appointment in the Civil Service and became a *protégé* of the Rajah of Jaffna (Mr Dyke). I never met him after his return to Ceylon, and my last meeting with him was on board the vessel in Calcutta in which I was about to return to Ceylon. He made me a present of the Book of Common Prayer which I used for some years." Mr Flanderka probably was a Divinity Student when at Calcutta. Dyke's good opinion of him was fully endorsed by the Governor (Sir Henry Ward). This is what Mr Levers quotes from His Excellency's memorandum of his second tour through Tamankadwa and Nuwarakalawiya in 1856 [? 1858 or 1859.]

"At Habbrenne (Habarana) we were met by the Assistant Agent of Nuwarakalawiya. Mr Flanderka, an active and intelligent public officer in charge of a very extensive district, which, from its isolated position and the strictly agricultural pursuits of the inhabitants, has had little share hitherto in the improvements that are taking place around it. Mr Flanderka is now endeavouring to introduce the Irrigation Ordinance, which is peculiarly adapted to the wants of the population; and though there was some misapprehension in the framing of the rules first sent in, I have no doubt that the next attempt will be more successful." [But *re* this Ordinance in p. 141 of Levers we read "Sir Henry Ward's Irrigation Ordinance was a dead letter so far as the Northern Province (which included Nuwarakalawiya up to 1873) was concerned, it was not suited to the circumstances of the tank country."]

In Levers p 43 we read "In 1859 judgment was given in District Court No. 156 by Mr Flanderka, Assistant Government Agent and District Judge. This was a case between the two branches of the Suriyakumara family, commonly known as "Bulan-klam" and "Nuwarawewa," from the two tanks near which the Walawas are built. By this judgment the estate was divided between these two branches of the family, and the rights as to the Bo-tree, shrine and election of Anunayaka, with other rights as chief of Nuwarakalawiya, were decreed to belong to the plaintiff, Suriyakumara Wannasinha Banda of Enlankulam, son of the Mudiyanse, who died in 1836." Messrs. Advocates Vanderwall and Dunnwilla from Kandy appeared for the respective parties on very handsome retainers. The defendants it seems, were a little too previons for they conveyed their advocate Mr Dunnwilla into the town, with great pomp in a procession of elephants &c. The judgment went however for the plaintiff, and it was Mr Vanderwall's good fortune to be carried back to Kandy with equal demonstrations after the case had been won!

W. H. S.

PANWILA PAST AND PRESENT.

(From a correspondent.)

I first knew the Panwila District in the latter half of the 'sixties. Almost all the way from Wategama—I may say, all the way from Kandy—the hills were then

COVERED WITH THE UBIQUITOUS COFFEE; and although the sight of the green bushes, spreading far and wide, up hill and down dale, was a little monotonous, yet it was from time to time relieved by the snow-white, fragrant blossoms that spangled the vast expanse, and the bright-red berries that, clustering along the heavy-laden branches, gladdened the planter's heart. *Mais nous avons changé tout cela.* "The old order has changed, giving place to the new." And if the new order is getting a permanent footing now, and the dark days of failure have to some extent, been retrieved—all this is due to the pluck and grit of the brave hearts that had to weather the storm, and, as bright hopes began to dawn, buckled themselves up for fresh ventures, and avenged themselves on their enemy by, in humorous punning mood, laughing him to scorn as "*Him a-liar-vast at-tricks.*" Yes! TEA is King now; and though his Majesty is subject to such fluctuations that his subjects who are loud in his praises today, may be down in the mouth tomorrow, their loyalty to him is nevertheless unimpaired, and they would one and all stand up for their liege lord and raise the cry "O King! live for ever!"

PANWILA TODAY

is pretty much the same as it was in the days gone by; for it has nothing of any local public interest that can claim the attention or the sympathy of strangers who live beyond its village-bound. Not even its propinquity to Wategama, through which the Kandy-Matale Railway runs, has lent it any importance nor added anything to its time-honored claim to the possession of a Police Court, a Rest House, a Police Station and a Tavern. These are the institutions that would perhaps justify its pretensions to the dignity of a town. The old Rest House was a very unpretentious structure with a high verandah and two flights of steps leading up to it, kept by one Philippoo Aratchi, who retained as Rest House-keeper the titular honorific which was his as a servant in the employ of a former Judge of the Supreme Court. The present halting place for tea-sellers is a commodious bungalow, built—in 1873, it is said—by the good old veteran, Joseph Holloway, the laird of Wategama. It was built at the instance of Government, and is under the control of the District Road Committee.

THE OLD POLICE COURT

was a long hall,—built with wattle and mud, and thatched with mana. It can still be seen, beyond an open space, on the other side of the road, opposite the present Rest-house; and in this primitive-looking concern, sat for the Administration of Justice in the olden days, no less a person than Mr Justice Withers—who only recently vacated his seat on the bench of the Supreme Court. He was then a rising young Civilian in the service of the Crown, and wisely gave up that service and proceeded to England to qualify himself as a Barrister-at-law; and his career since he returned in that capacity to Ceylon, has ustified

the wisdom of the course he adopted. Another young Civilian of that day, who severed his connection with the Ceylon Civil Service, was Walter Wragg,—a cultured Oxford "*University Scholar,*" who rose to be a Puisne Judge in the South African Colony,—and later on became a Chief Justice, I think, and obtained the honor of Knighthood. He, too, was at one time Police Magistrate of Panwila. Then

TWO OF THE CLEVEREST JUDICIAL SERVANTS

of the Crown, who gained distinction as professional lawyers, began their official life here. Let us hope that the clever young Oxonian, who put his foot on the first rung of the Colonial Service ladder and stepped down again to leave our shores for the wider sphere of Journalistic Literature in England, and has been entertaining his countrymen there with his clever sketches of Cadet-life in Ceylon, may live to make a name for himself in the "fresh fields and pastures new," he has chosen for himself in the old country. Among the men who held the Panwila Magistracy in former days, and were in residence there, one recalls the names of Temple, Knowles, Willisford, Ashmore, Pennycuik, R. O. S. Morgan and Hamilton.

THE PRESENT POLICE COURT

was built in 1858,—and here at the present time, a Weekly Sessions of two days in every week, is held by Mr. Wm. Dunuwille, the popular Police Magistrate of Matale—except on the 1st Friday and Saturday of every month, when the Court sits at Urugala. The Police Station now stands within a few hundred yards of the Police Court, and is in charge of a Police Sergeant. In the olden days, it was kept in a building which is now part of Raxawa estate, in which Mr Parrinton, the Superintendent of Raxawa, lived, before the present bungalow,—nestling in a forest of grevilleas, on the crest of a hill, was erected, Mr Edwin Beven commenced his professional career in Panwila, and then moved on to the Kandyan Metropolis, where he holds a leading position as a Proctor. Arnold Joseph, Fernando, Bartholomeusz and Elders were also proctors practising in Panwila; but these have long ago joined the majority.

OF THE PLANTERS

of a former day living in the Judicial district of Panwila one recalls such names as Forbes Laurie (a very pronounced Darwinian), W B Jackson, Tom Smith, Rollo, Karlake, Hastings Clarke, &c. At the head of them all stood, and stands still, the veteran and highly-respected planter of Kellebokke District, Mr Thomas, late of Oonoogalla, with whom all Ceylon sympathises over the loss sustained by him, in the death of his heroic son, one of the brightest, cheeriest and happiest young men I ever knew, who laid down his life for the honor of his country in the late bloody war against the perfidious Boer.

THE APPROACH TO PANWILA

from the foot of Galphele Estate, (the property now of Mr T Y Wright, but which at first I think belonged to Mr Holloway and then to a Chetty, and then to Mr Fred Van Langenberg, and then to Mr Donald) lies through an avenue of stately grevilleas, and from this avenue, branches off another which is continued, right on to the summit of the hill, and to the bungalow which lies concealed in a forest of trees. This feature in the scenery rises to its highest point of pictures.

(Communicated.)

queness in the roadway leading to Raxawa factory and beyond it. I have seen nothing so pretty anywhere as the groves of grevilleas that spread in all directions on either side of the high road here as far as the eye can reach. I went up among the tea to the highest attainable point on the northern slopes of Raxawa, and the sight of the groves of grevilleas spreading down to the ravines below, reminded me of the forest of tall poplars which made the Villa Borghese at the foot of Monte Pincio in Rome so charmingly beautiful. What a wonderful difference

THIS QUICK-GROWING AUSTRALIAN TREE

(*C. Robusta*) has made in the aspect of the country which has become its naturalised home. Almost every tea estate in the Kandyan province has been beautified by these trees, which stand in stately file like an army of sentinels watching over the dwarf green bushes beneath, protecting them alike from fierce winds and scorching heat. Speaking of the exceptionally hot weather we have had, a planter from the Kellebokke District said to me a week ago: "We are pretty well burned up." If this be so in the higher altitudes where he lives, what must it be in the low-lying districts. The drought however though severe, has not been very protracted. But the welcome rains have set in, and the condition of things around us will soon alter for the better.

KANDY'S HAIL-STORM AND AN HISTORIC TREE.

(Communicated.)

On Good Friday afternoon Kandy was visited by a hail-storm. The wind blew from nearly all points of the compass with much violence; and we had a perfect hail-storm of some duration, accompanied with vivid lightning and loud thunder peals. Trees fell in several parts of the town and amongst other things, the furious blowing brought down a very huge *Nuga* tree, or the largest portion of it, which was a sort of land-mark and was to be seen as a prominent object in the Royal Engineers' yard, right opposite to the old Post Office—only separated from it by the high road from Katukelle to the town. This tree, which was probably over an hundred years old, is said to mark the spot where the foreign Ambassadors to the Kandyan Court halted until they had permission from the Emperor of Ceylon—the brother of the Sun and Moon—to proceed to the Old Palace for an audience with the King. The Ambassadors, amongst whom were those old Hollanders and Britishers Mynheers, Takel and Francois Albertus Prins and Messrs. Phibus and Hugh Boyd, came to Kandy by a very circuitous route from the low-country. After many days of hard travelling, they reached Gan-oruwé, and from thence they advanced through Katookelle until they halted under the shadow of this great *Nuga* tree. At this spot there was a *Mura-pola*—a guard-house—and a gate-way which was barricaded with thorny shrubs and trunks of trees to render it impassable: hence the name *Katookelle*!

It is seventeen years since that treasury of curious lore regarding things connected with the East, "*Hobson-Jobson*," or "*A Glossary of Anglo-Indian Colloquial Words and Phrases*," by Col. Henry Yule and Dr. A. C. Burnell, was published; and it had become so scarce that when a copy appeared for sale in the market it fetched a price double the original. Students as well as the public at large, therefore, owe a debt of gratitude to Mr. John Murray for issuing a new and revised edition* under the competent editorship of Mr. William Crooke, B.A., of the Indian Civil Service, author of several works on Indian folk-lore, &c.

The work as now issued contains a glossary of 986 pages, against 870 in the first edition; while it has been rendered far more useful by the addition of an index covering 35 pages (four columns to the page). The supplement of the original edition (which occupied 119 pages) has, to the great relief of the consultant, been embodied in the work; and almost every word or phrase receives further explanation and additional illustration. In this additional matter Mr. Crooke has received valuable help from various scholars, especially from Mr. R. S. Whiteway for Portuguese writers and Mr. W. W. Skeat for Malay words. All additions to this re-issue are distinguished by being printed within square brackets. In his Preface Mr. Crooke says: "No attempt has been made to extend the vocabulary, the new articles being either such as were accidentally omitted in the first edition, or a few relating to words which seemed to correspond with the general scope of the work." In concluding my notice of the first edition (see *Ceylon Literary Register*, vol. I, pp 230-232, 238-240) I expressed the hope that Col. Yule might "live to issue a new edition, in which the errors that have slipped into this one will be corrected, and which will contain the history of such words: (Ceylon and other) as are not recorded here." The first part of this hope was (alas!) not fulfilled; the second part has here received partial fulfilment; while as regards the last part I have to confess disappointment. I quite sympathise with the reluctance that anyone would feel at tampering with the work of such a magnificent scholar as Sir Henry Yule; but, as in this new edition so much additional matter has been included, I certainly think the vocabulary might have been extended, and I believe the lamented author would have approved of this. Of course this would have increased the bulk of the book; but something might have been saved by omitting a quotation here and there (some of the

* *Hobson-Jobson*: A Glossary of Colloquial Anglo-Indian Words and Phrases, and of Kindred Terms. Etymological, Historical, Geographical and Discursive. By Col. Henry Yule, R.E., C.F., and A. C. Burnell, Ph. D., C.I.E. New edition edited by William Crooke, B.A., London: John Murray, Albemarle Street, 1903. [Price 28s. net.]

words being rather *over* illustrated). Among words in current use in Ceylon, but not recorded here, I may mention (beside many others), *moottoo* (housekeeper) *barbacue* (coffee drying ground), *creeper* (planting-tyro), *totum* (estate), *sick* (in the estate sense), *podian* (boy), *perrily* (dangerous or frisky), *sheemy* (country), *cheddy* (jungle undergrowth) *nilloo*, *patna*, *maduwa*, *pinkama Diss uve*, *dissava*, is here duly recorded, but not *ratemahatmaya*; *modelliar*, *modliar*, and *vidra*, but neither *aratchy* nor *mohandiram*; *mamooty*, *mamoty*, *momatty*, but not *catty* (in the sense of a bill-hook), nor *alavanga*; *conicopoty*, but not *cannick* (account); *coprah*, but not *checko* (coconut-oil-mill); *batta*, but not *samblam* (pay); *boy*, but not *appos* (butler); *catanaram*, but not *padda-boat*; *hopper*, but not *rotee*; *dagoba* and *wihara*, *wihare*, but not *pansala*.

Another fault in this new edition, as in the old, is the smallness of the margin, especially on the inner side. Of course this also is a question of expense; but another inch of margin would have been a great boon for those who, like myself, are accustomed to annotate freely.

In reviewing the first edition of *Hobson Jobson* I pointed out various errors in connection with words relating to Ceylon. Some of these mistakes have been rectified in this new edition; but others still remain, I am sorry to say, to mislead the innocent and unwary reader.

Under "Anaconda" the editor gives the gist of my communication to *Notes and Queries*, and characterises my derivation of the word as "a more plausible explanation." That it is the correct one, I am absolutely certain; though how the name of the graceful whip-snake (*honakandayā*) came to be erroneously transferred to the monstrous python (*pimburā*) I have failed to discover, though I strongly suspect a mixing of the labels on the specimens at Leyden. (In this connection I may draw attention to the fact mentioned by Mr. Lawrie in his *Gazetteer of the Central Provinces*, p. 2191, that one the Kandyan queens was named Henakānda Bisō Bandāra, so called, doubtless, from her graceful and slender figure.) The Malagasy *anakandify* (not *anakandify*, as printed) is a mere coincidence.

At the end of the article on "Bamboo" Col. Yule remarked:—"E. Hæckel, in his *Visit to Ceylon* (1832), speaks of bamboo-stems at Peradenia, 'each from a foot to two feet thick.' We can obtain no corroboration of anything approaching two feet." In quoting these words in my notice of the first edition I added:—"This is a question that can be easily settled: perhaps Dr. Trimen will furnish the maximum diameter." The question remained unanswered, however, for more than a year. Meanwhile Mr. Albert Gray, in a note to the first volume of his translation of Poyard for the Hakluyt Society, had once more drawn attention to Hæckel's statement. Having to review this volume in the *Ceylon Literary Register*, I wrote to Dr. Trimen on the point in question, and he replied:—" . . . I thought it not unlikely that the mistake was the translator's. But I see that Hæckel

really does say '1-2 Fuss dicke.' Of course this is vastly beyond the mark. I have never seen one of our Giant Bamboos over 9½ inches in diameter. But Hæckel's reminiscences of Ceylon are often inaccurate. He never would take a note of any sort but trusted entirely to memory with the usual result" (*C. Lit. Rev.*, ii. p. 272). In the new edition a reference to Mr. Gray's note is added; but it is unfortunate that the editor did not know of Dr. Trimen's correction.

Under "Bo tree" the Sinhalese name is still given erroneously as *bo-gās* instead of *bō-gaha*. The fact should have been noted, that several Portuguese and Dutch writers call it the "devil-tree."

Under "Cabook" Col. Yule's surmise that the word came from Portuguese *cavouco* (quarry) is shown to be correct. (Daalmans calls it *kaphok*, and not *kaphok*, as here printed).

The mis-spellings and erroneous surmises given under "Calamander Wood" remain uncorrected, and have, I am sorry to say, been copied into the *New English Dictionary*. As I pointed out in my notice of the first edition, the origin of the name is perfectly simple. *Calamander* is a corruption of the Sinhalese *kalumediriya*, which word easily resolves itself into its component parts—*kalu* (black) *medi* (middle), *ri-iri* (lines, striae), *ya* (nominal termination). The description of the wood by Thunberg, in the first quotation given by Yule, completely bears out this derivation; though the learned German naturalist states that "in the Cingalese language *Caluminder* is said to signify a black flaming tree." Evidently the philological wiseacre who foisted this erroneous information on Thunberg thought that *minder* was from Sinhalese *mini-dediri*, which means "open, expanded, blown as a flower" (Clough), or else connected it with Sinh. *min*, one of the meanings of which is "light, effulgence." I cannot claim originality in setting forth the above simple derivation, for it was given years ago in the *Library of Useful Knowledge* (see Mendis's *Timber Trees of Ceylon*, by W. Ferguson, p. 7). By the way, *calamander* is surely not a "rose-wood," as Col. Yule calls it?

I come now to "Candy"—for so the name of the mountain capital of Ceylon is entered, not a hint being given that this spelling has long been superseded by "Kandy." What Col. Yule wrote of this place remains unaltered, as follows:—"A town in the hill country of Ceylon, which became the deposit of the sacred tooth of Buddha at the beginning of the 14th century, and was adopted as the native capital about 1592. Chitty says the name is unknown to the natives, who call the place *Maha nuvera*, 'great city.' The name seems to have arisen out of some misapprehension by the Portuguese, which may be illustrated by the quotation from Valentijn." As I showed, when reviewing the first edition, Valentijn simply borrows from Kuox, whose words are quoted by Yule immediately above those of the Dutch writer. It is unfortunate that the learned compiler should have taken his information from Casie Chitty (who is nearly everywhere

referred to as *Chitty*, as though he were an Englishman!), for it is very erroneous. (And yet Ceylon writers, who ought to know better, go on repeating the same old blunders). According to the *Mahāvamsa*, the first Sinhalese king to make Kandy his capital was Vira Vikrama, who began to reign in 1542; and it is noteworthy that the earliest mention of the Kandyan kingdom by the Portuguese occurs in connection with this king. The passage is quoted by Yule, but he dates it "c.1530," which is much too early: 1545-46 is the probable date when the events described by Couto occurred, viz., the mission of the first Franciscan fathers to Kandy, and their attempt to convert the king, who is called "Javira Bandar" (Jayavira Bandāra). But, strangely enough, Yule has overlooked the earliest Portuguese reference to the town of Kandy. This also occurs in Couto's narrative (Dec. VI, lib. IV, cap. viii), where we read of Antonio Moniz Barreto's marching from Batticaloa to "the city of Candea." The date of this was apparently May 1547. The first mention of Kandy (Senkadagala nuvara) in the *Rājavalīya* is also in connection with this king, whom the writer calls Jayavira. (Gunasekara in many places lays traps for the unwary reader by translating *kanda uda* or *udarata* by "Kandy.") The journal that records the first visit of the Dutch to Ceylon in 1602 spells the name "Candy," "Candi" and "Kandi" and it is from the Dutch that we inherited our spelling of the name.

Under "Ceylon," after the statement that "It has been suggested by Mr. Van der Tuuk, that the name *Sailan* or *Silan* was really of Javanese origin, as *sela* (from Skt. *silā*, 'a rock, a stone') in Javanese (and in Malay), means 'a precious stone,' hence *Pulo Selan* would be 'Isle of Gems,'" is inserted in brackets "This," writes Mr. Skeat, "is possible, but it remains to be proved that the gem was not named after the island (*i.e.* 'Ceylon stone'). The full phrase in standard Malay is *batu Selan*, where *batu* means 'stone.' Klinkert merely marks *Sailan* (Ceylon) as Persian." Mr. Skeat's comment is, I think, very pertinent, and disposes of this pseudo-Javanese origin of *Ceylon*. Three new quotations are given, from English writers of the seventeenth century, in which the forms *Celand*, *Silon* and *Zeilon* occur.

At the end of the article on "Chittagong" I still find the extraordinary statement, "*Chaturgrāma* is still the name of a town in Ceylon, lat. 6°, long. 81°." As I pointed out in my review of the first edition, the "town" referred to is Kataragama, the name of which has no connection with *katara* (four), but is said to be from the god of war Kārtikēya; though Clough derives it from *katara*, desert.

Of "Choya, Chaya, Chey," Col. Yule wrote that "It is exported from S. India, and was so also at one time from Ceylon." As far as I know, the export of choy-root from Ceylon has never ceased.

Under "Coffee" are given some new quotations, in which the fragrant beverage

figures as *coho*, *coffao*, *cohu*, *caveah* and *cave*.

The derivation of "Colombo" is still left in doubt; and the printers have now turned Yule's "*Kalani-ganga*" into "*Kalani-gangi*!" It is strange how little we know of the early history of the place that is now one of the leading ports of the world.

In reviewing the first edition of this book I expressed a decided opinion that "Comboy" and "Cabaya" were identical, the former being a corruption of the latter; and in writing to me Col. Yule said he thought I was right. But I now feel doubtful of my correctness, and am inclined to think that Yule's explanation of "Cambay cloth" is the right one.

I am glad to see that under "Galle, Point de," Mr. Crooke inserts a note by the late Prof. Childers to *Notes and Queries* showing that the name can have no connection with *gala* (rock).

Under "Jafna, Jafnapatam," the editor adds an extract from the *Madras Glossary* giving the origin of the name.

Under "Putlam" Yule's indefinite "Mr. Ferguson" (really Mr. William Ferguson, as I showed in my former review) has now become "Mr. Fergusson."

Under "Tea" the editor inserts some further interesting facts regarding the pronunciation of the word in English, and the two forms *cha* and *té*; and under the names of the various kinds of tea there are a number of additions.

I have thus cursorily touched upon a few of the words dealt with in this fascinating work, which will always remain invaluable to the student, and will never fail to yield the casual reader entertainment as well as information. Every public library, especially in the East, ought to possess a copy.

D. F.

LAYARD AND MITFORD.

INTERESTING REMINISCENCES.

Our KuruNEGALA correspondent writes:—"The extracts from the home papers and the correspondence published by you with reference to these eminent travellers have been read by me with absorbing interest. A brief holiday to the hills has prevented me sending you earlier some notes *apropos* the subject, and which, I hope, some day will see the light as part of a biographical introduction to a volume of legal reports prepared by me with the assistance of a brother member of the Bar.

Edward Ledwich Mitford was Government Agent of the North-Western Province in 1836. He retired, after three and twenty years' service, at the age of 56, in December of that year on a pension of £505 9s 4d per annum, E. N. Atherton succeeding him. Mitford was a distinguished traveller. Layard in his *Popular Account of the Discoveries at Nineveh* (1851) pp 1-2 thus refers to Mitford:—"During the autumn of 1839 and the winter of 1840, I had been wandering through Asia Minor and Syria, scarcely leaving untrod, one spot hallowed by tradition, or unvisited one ruin consecrated by history. I was accompanied by one, no less curious and enthusiastic than myself—my travelling com-

panion during a long journey from England to Hamadan was Edward Ledwich Mitford Esq., now of His Majesty's Civil Service in the island of Ceylon. We were both equally careless of comfort and unmindful of danger. We rode alone; our arms were our only protection; a valise behind our saddles was our ward robe, and we tended our horses, except when relieved from the duty by the hospitable inhabitants of a Turcoman village, or an Arab tent. Thus, unembarrassed by needless luxuries, and uninfluenced by the opinions and prejudices of others, we mixed amongst the people, acquired, without effort, their manners, and enjoyed, without alloy, their emotions, which scenes so novel and spots so rich in varied association cannot fail to produce. I look back, with feelings of grateful delight, to those happy days, when, free and unheeded, we left at dawn the humble cottage or cheerful tent, and lingering as we listed, unconscious of distance and of the hour, found ourselves, as the sun went down, under some hoary ruin, tenanted by the wandering Arab, or in some crumbling village, still bearing a well-known name. No experienced dragoman measured our distances, and appointed our stations. We were honoured with no conversations by Pashas, nor did we seek any civilities from, Governors. We neither drew tears, nor curses from villagers, by seizing their horses or searching their houses for provision; their welcome was sincere; their scanty fare was placed before us; we ate, and came and went in peace."

Mitford was the first Englishman who came out to Ceylon overland, and the experiences of his travels are embodied in an enchanting work entitled: "A land march from England to Ceylon, forty years ago, through Dalmatia, Montenegro, Turkey, Asia Minor, Syria, Palestine, Assyria, Persia, Afghanistan, Scinde, and India, of 7,000 miles on horse-back. Illustrated with original sketches by Edward Ledwich Mitford. F. R. G. S. 2 vols. London. Allen and Company 1881." The following extract explanatory of the author's migration to Ceylon will be read with interest:—

"In 1839, after five years' residence and travelling in Morocco, I found myself in the unenviable position of being without occupation, when my attention was directed to the probability of employment in the Colony of Ceylon, either in the Government service, or in the newly-opened enterprise of coffee-planting, and thither I resolved to proceed. To reach Ceylon, I must either take the long sea-voyage round the Cape or the shorter

and inconvenient one by the Mediterranean and Red Seas, with the caravan across the Isthmus of Suez. But moved by a love of travel, after consulting the map, I resolved to undertake the journey entirely by land. * * * At this time, a friend introduced to me a relation of his, who, he thought, would accompany me. I was somewhat taken aback of his youthful appearance, he being nearly a decade younger than myself. However, he accompanied me as far as Hamadau in Persia, when to my great regret he parted company, he returning home by Bushire and Bagdad, and I continuing the other half of the journey alone."

There were the remains of a half finished house, below the Powder Magazine, on the right of the road leading to the Kacheheri and Maligawa at Kurunegala, which (as well as the ground on which it stood) belonged to Mitford. It is amusing to know how he became the owner. Mitford, when Assistant to the Government Agent at Kurunegala, for want of a house, built the structure in question, at his own cost and on his own responsibility, fancying that there would be no difficulty in obtaining the necessary official sanction for such an urgent want, on completion of the work. Accordingly, the building progressed: the walls were raised, the wood-work of the roof completed, and only the tiles had to be put on, to make the house habitable. But, alas!

"THE BEST LAID PLANS OF MICE AND MEN
GANG AFT AGLY."

The Government, through its officers, condemned the building, and refused to sanction the expenses incurred in its construction. All this fell rather heavily on Mitford, who was forced, under the circumstances, to purchase the ground and tenement as it then stood. Foolishly no steps were taken to complete the building, and there it was everyday adding to its dilapidation—a monument of official determination and private obstinacy or worse! Mitford continued to pay the assessment taxes on this property through his local agents for many years after his retirement from the service and departure from the island. In the "eighties," Government, after previous refusals, deigned to accept an offer for the purchase of the land and bought it up. The tottering building, latterly only the stones were to be seen—was razed to the ground, and the bricks purchased by the contractor who utilised them for the building of the Town Hall at Kurunegala.

A cross-street in the town of Kurunegala, is called "Mitford Street" owing to the residence of that official having been there during his employment in the service."

THE PEARL FISHERIES OF CEYLON.

No. 1.

Mr. W. A. HERDMAN, D.Sc., F.R.S., to His Excellency the LIEUTENANT-GOVERNOR of Ceylon.

July 1, 1902.

SIR,—I ARRIVED in Ceylon with Mr. James Hornell on 20th January, 1902, and left on 7th April. Mr. Hornell remains in the Island for a year longer in order to carry out the experiments I have arranged and complete our work. We shall then, in consultation, draw up our final and detailed report; but I think it well to submit to you a brief account of our observations and opinions even at this early stage.

The investigations which I was able to make during the seventy-eight days spent in Ceylon deal with the following somewhat independent matters:—

- (1) The inspection of the pearl oyster banks.
- (2) The investigation of the conditions under which the pearl oyster lives in the Gulf of Mauuar.
- (3) The investigation of the marine zoology of other parts of the sea around Ceylon, especially in the interests of trawling and other fishing industries.
- (4) The selection of the best locality for a marine laboratory.

These are all dealt with briefly in the paragraphs that follow. Fuller reports upon all will be given when our material has been worked up.

I wish to record here my entire satisfaction with the work done by Mr. Hornell. He assisted me throughout in a most able and indefatigable manner, and I felt assured on leaving Ceylon that he was entirely competent to carry on this work and any other marine biological work of a similar nature on his own responsibility in the future. It would have been quite impossible for me to have got through the work I did in the limited time had it not been for Mr. Hornell's skilled assistance.

It is a pleasure also to record my indebtedness to Captain J. Donnan, C.M.G., the retiring Master Attendant at Colombo, and to Mr. Legge, his successor, who, during the time that I spent with them on the pearl oyster banks, spared no trouble in trying to let me see as thoroughly and satisfactorily as possible the various banks and beds, the different kinds and ages of oysters, and the conditions under which these and their enemies exist.

My arrival in Ceylon was so timed as to leave a few weeks free before the period in February at which Captain Donnan had previously intimated that he would be able to commence his annual inspection of the banks. This interval I had thought desirable, if not essential, in order that I might make myself acquainted with the biological conditions in the Gulf of Mannar, and with any special features in which that region differs from the other seas around Ceylon. For the purpose of this preliminary biological survey the ss. "Lady Havelock" was placed at my disposal, in the first instance, for a period not to exceed three weeks. We joined the ship* for this cruise on the evening of Thursday, 30th January, and arrived back in Colombo on the evening of Wednesday, 19th February, having used the steamer for twenty days.

The few days' interval between our arrival in Colombo and the date when the steamer was available for the first cruise was spent by Mr. Hornell in unpacking our apparatus and stores, and by myself in seeing every one I could hear of on the Island who had worked or written on the pearl oyster, or was supposed to have information or opinions on the subject. I was fortunate in being able to meet and discuss the subject with the following, amongst others:—Dr. A. J. Chalmers of Colombo, Mr. J. C. Willis of Peradeniya, the late Mr. Oliver Collett of Roselle, Dr. Fritz and Dr. Paul Sarasin (who had worked at the zoology of Trincomalee harbour, where the pearl oysters were said to have been established by Dr. Kelaart nearly fifty years ago), and Professor Alexander Agassiz, who had recently been investigating the sea to the south and west of the Gulf of Mannar. Later on I met Sir William Twynam, who has had a long-extended experience of the fisheries, and for weeks on the banks I had the advantage of constant association with Captain Donnan, whose knowledge of the topography and condition of the oyster beds is unrivalled.

In the first cruise of the "Lady Havelock" (31st January to 19th February) my objects were:—

- (1) To investigate the general biology of the seas around Ceylon, and especially of those places where pearl oysters were said to exist.
- (2) To examine more carefully any localities that seemed to be likely spots for pearl oyster banks.
- (3) To investigate the fauna, the bottom deposits, and the characters of the water in the Gulf of Mannar for comparison with the conditions at Trincomalee, Galle, and other parts of the coast.
- (4) To make experimental hauls of the fish and the "shrimp" trawl round the coast so as to obtain information as to the prospects of fish-trawling as an industry in Ceylon waters.
- (5) To look into any other departments of marine biology which might be prosecuted as useful industries.

* I ought to state that on the whole the "Lady Havelock" proved a very suitable vessel for the purpose, and I desire to record also my sincere thanks to Captain Campbell and the officers and others on board for the pains they took to carry out my wishes.

On leaving Colombo on 31st January we went northwards first towards the Gulf of Mannar, and started dredging and trawling off Negombo, where a new bed of young pearl oysters was discovered, and then off Chilaw, where there are several well-known banks. A description of each day's work is unnecessary in this preliminary report, but I may note here that during this and the following cruise of the "Lady Havelock" a large number of hauls of the dredge and trawl, amounting to over 250 in all, were made, and nearly all of these were successful. The localities, conditions, and results of every haul were carefully entered each day in our journal, and these notes when fully worked up, compared, and analyzed will afford an important body of information in regard to the marine-zoology of the Ceylon seas. I propose to give all this information in full detail in my final report.

During this first cruise we were able to make ourselves acquainted with the conditions under which the pearl oysters live on the chief banks, such as the East and West Cheval Paars, the Periya Paar, Muttuvaratu Paar, &c., and we also took some series of dredgings across the intervening spaces between the banks, and especially close around the banks, in order to ascertain clearly what conditions determine an oyster "Paar."

We also made a careful examination of the ground in several places outside the oyster banks, to the westward, on the chance of finding beds of adult oysters, from which possibly the spat deposited on the known banks might be derived. No such beds outside the known "Paars" were found either on this or the following cruise.

The water in the Gulf of Mannar generally was found to be of medium density, the specific gravity averaging about 1.023 for a temperature of 80° F. The bottom deposit is mainly a coarse sand, with occasional hard ridges and patches usually formed of coral and nullipores. The sand, however, differs much in its nature, composition, and origin in the different places; and the harder bottoms can be divided into at least two classes, the one of which is evidently suitable for oyster growth, while the other is not. The characters of all these deposits will be fully detailed in our final report.

The water outside the pearl oyster banks deepens rapidly. About a mile to the west of the Periya Paar (mostly 8 to 10 fathoms) a depth of 20 fathoms may be found. Five miles to the west there is a sounding of 134 fathoms; and out in the centre of the southern part of the Gulf of Mannar, to the west of the pearl oyster banks off Chilaw, depths of between one and two thousand fathoms are reached. The bottom deposits in these great depths are Globigerina ooze and "green mud," which are entirely different in nature and origin from the terrigenous sand round about the pearl oyster banks. The very steep slope from 10 or 20 fathoms down to about 100 fathoms or more, all along this coast, seems in most places to have a hard bottom covered with Alcyonaria, sponges, deep-sea corals, and other large encrusting and detritic organisms. Neither on this slope nor in the deep water beyond the cliff did we find any ground suitable for oysters to live upon.

Although we found young oysters in many localities, and the microscopic spat or youngest attached stage of the oyster in several, we came upon no marked accumulation of old breeding oysters which could be regarded as the parent stock from which the successive younger broods were derived. And as in all we spent about six weeks in examining the locality, and took over 160 hauls of the dredge and trawl in the Gulf of Mannar, in addition to many diversings, and examined with care all likely spots that occurred to us without result, we are inclined to think that there is no such assemblage of old oysters outside the banks as has by some been supposed to exist. During this cruise the largest oysters we found upon the banks were about 9 cm. in greatest length, and were probably three years or a little over three years old; but 7 to 8 cm. (about three inches) was a commoner size. There were very large numbers of these found in several localities and the animals seemed to be in a thoroughly healthy condition. Samples of all the oysters obtained by us were examined for parasites and for any diseases or abnormal conditions, and although a considerable number of minute parasites, both Protozoan and Vermean, were found, still that is by no means unusual amongst molluscs, and we do not consider that we saw anything which gave evidence of any epidemic disease or widespread and injurious prevalence of parasites.

In some localities, such as the Cheval bank off Aripu, we were struck by the great abundance and the healthy condition of the larger oysters, which ought to be full-grown and ready for fishing in another year or two.

In addition to these larger oysters, we also found at many localities numbers of much smaller oysters, evidently in their first year, measuring from 1.5 to 3 cm. in length, and of different ages, between three and nine months. The majority of these were probably about four or five months old, and are therefore oysters which were set free and then deposited as spat some time last autumn, up to about October, 1901. The total number of these young oysters on the ground is enormous. We estimated that there were probably over a hundred thousand million (100,000,000,000) of them (of rather small size) on the Periya Paar alone. It was obvious to us, however, that these young oysters cannot be expected to attain maturity in their present position. They are too closely crowded. There is not enough food for them on and above the ground. Unless they are transplanted to a more favourable locality further inshore, the probability is that they will die off before becoming much larger. Fortunately there ought to be no great difficulty in the transplanting, even on a large scale. They seem at present in a healthy condition, although probably rather undersized for their age because of scarcity of food; they adhere together in clumps easily dredged up without tearing the byssus or adhering threads, and there is apparently suitable unoccupied ground where they could be planted out on and about the Cheval Paar a few miles inshore.

These observations made on the first cruise in February were confirmed and extended by our work on the second cruise in March, and when taking part with Captain Donnan in his inspection of the banks.

On leaving the Gulf of Mannar we passed through the Paumben Strait and trawled in Palk Bay. We found that wide shallow area to have an even soft bottom very suitable for fish trawling, and it is apparently inhabited by an abundant and valuable flat fish fauna.

The next locality that we desired to investigate was Trincomalee, to which our attention had been directed both by the work of Dr. Kelaart in 1856-59, and by certain letters in the Ceylon

newspapers, especially one from Mr. J. B. Colomb at Trincomalee, stating that he had found true pearl oysters between tide-marks in the inner bay, and that some of these oysters had contained pearls.

It is known that Dr. Kelaart nearly fifty years ago either found or introduced (probably both) pearl oysters at Trincomalee, and that he had them under observation at some half dozen localities, of which several were inside the inner bay or harbour and two or three outside. At Trincomalee we saw Mr. Colomb and made inquiries from all those we could hear of as having any knowledge or records of the occurrence of pearl oysters. Then we spent four days in dredging and otherwise examining the various bays and creeks in the harbour from the ship's boats and native canoes. We found plenty of pearl oysters at low tide mark or in shallow water near York Island, but although we took six successful hauls of the dredge outside the harbour, off the Sami Rock, in exactly the locality and at the depths mentioned by Mr. Colomb (who was with us in the boat) and by the native fisherman, we were unable to obtain any oysters, and did not even find any dead valves or fragments. In fact the bottom in that locality did not seem to us at all suitable for oysters.

It is evident, however, that the pearl oyster does occur at Trincomalee, and can live and grow in shallow water in the inner harbour. It is also plain from our observations that there is nothing in the physical characters of the sea water at Trincomalee sufficiently different from that of the Gulf of Mannar to lead one to believe that the oysters would not grow large and produce pearls here just as they do on the west coast. And, finally, from the specimens we were shown there is no doubt that the oysters of Trincomalee harbour do, at least occasionally, produce good pearls. It is perhaps well to state that in all the above remarks we refer to the true pearl oyster (*Avicula fucata*, Gould = *Margaritifera vulgaris*, Schumacher), such as is found on the "Paars" in the Gulf of Mannar, and not to the "window" oyster (*Placuna placenta*), which was formerly fished in Tamblegam lake to the south of Trincomalee. We spent a day investigating that land-locked bay from the ship's boat, and are inclined to think that the industry might be revived, and that pearl oysters might also be introduced into Tamblegam with advantage.

In regard to the general suitability of Trincomalee harbour for pearl oyster cultivation on a large scale, and as the site of a Marine Biological Laboratory, our opinion is on the whole unfavourable. Trincomalee possesses certain obvious advantages for continuous biological work, such as shelter from both monsoons, and a great range in depth within a limited area, all parts of which are easily accessible. But a very large proportion of the bottom of the various creeks is occupied by soft mud, and we are inclined to think from the evidence before us that at certain seasons a good deal of fresh water enters the harbour from the land and washes so much fine clay into the sea as to render most parts of the area unsuitable for the necessary work. However, it must be remembered that we have as yet only investigated the locality at one time of year, and that we shall have fuller information as to these and other points at other seasons before drawing up the final report.

After leaving Trincomalee we went to the south end of the Island to examine Beligam Bay and Galle from both points of view—pearl oyster cultivation and fish-trawling.

Beligam was found to be quite unsuitable for laying down pearl oysters. It is entirely open and exposed to the south-west monsoon, and the bottom is sand, with, so far as our observations went, no hard ground suitable for the attachment of oysters.

Galle, on the other hand, seemed to us, after careful investigation lasting over five days, to be without doubt the most suitable point on the coast of Ceylon for the establishment of a Marine Laboratory and the prosecution of observations and experiments on living oysters. Galle has a fringing coral reef round its western shore inside which is in places a shallow lagoon with a hard bottom, formed partly of living animals and partly of dead coral fragments, making a deposit very like that on some of the "Paars" at Mannar. At the opposite or south-eastern part of the bay, inside Watering Point, there is also some hard ground formed in part of coral, and at this spot we actually found the pearl oyster living.

Later on the practicability and the possible advantages of working a Marine Laboratory at Mount Lavinia, at Colombo (Galle Face), Mutwal, Mannar, Arippu, and other places on the north-western coast were carefully considered, but our opinion is that Galle has natural advantages which render it the best site on the coast of Ceylon.

We also took some hauls of the trawl round the southern end of the Island, and found good fish-trawling ground between Callehogalle bank and Watering Point, where at a depth of 20 to 30 fathoms we obtained in one haul of the net over 1,500 fish, many of them small, but mostly edible.

This first cruise concluded with a few days' work up the south-western coast from Galle to Colombo, which showed us, off Panadure, some hard ground made up largely of nullipores, which might possibly be worth planting with young pearl oysters from the Gulf of Mannar.

On returning to Colombo for the purpose of joining Captain Donnan in his inspection of the pearl oyster banks, I saw for the first time the native barque "Raugasameeporawes" and the steam launch "Serendib," and on examining them critically it was obvious, both to myself and to the ship's officers who were with me, that neither vessel would be able, without considerable changes, which could not be effected in time, to carry on the work which I still had to do. On pointing this out to Captain Donnan he agreed with me, and when we waited upon the Lieutenant-Governor and represented the matter to him, he promptly authorized us to arrange for the engagement of the "Lady Havelock" for a further period of three or four weeks, as might be necessary, from 24th February. Thus it resulted that the "Lady Havelock" accompanied the two native barques "Raugasameeporawee" and "Sultan Secandra" and the ss. "Serendib" to the Gulf of Mannar, where, in addition to carrying on my special work, she was on occasions of service in towing Captain Donnan's barque and so saving some valuable time. The second cruise of the "Lady Havelock" lasted from 24th February to 20th March, inclusive, three weeks and four days. During the greater part of that time our steamer kept near to Captain Donnan's barque, and we accompanied him in his inspection of the banks. Not only had we thus the full advantage of the various vessels and their crews by means of which to obtain information, but Mr. Hornell and I were also able to talk over

the work daily with Captain Donnan and Mr. Legge. Later on we were joined by Sir William Twynam from Jaffna. That gave a unique opportunity of hearing from these two veteran inspectors and investigators about the former condition of the various banks and of the past history of the pearl fisheries.

During this cruise the early morning and forenoon were usually occupied in following the operations of the divers, and in examining and recording the material brought up from different parts of the various "Paars." About midday, when the divers ceased work, we started off in the "Lady Havelock" to dredge the neighbouring grounds between the oyster banks, or on parts of the Paar in regard to which we wanted further information. In this way, beginning in the north of the district of Arippu, we examined the large and important East and West Cheval banks and the Periya Paar and several smaller banks lying some to the north and some to the south.

We also, when in that neighbourhood, landed at various parts of the coast in the endeavour to find a suitable spot for a small Marine Laboratory, from which oyster culture and experiments could be conducted. We tried Mannar, Arippu, Chilavaturai, Kodramallai, and later on the shores of Portugal and Dutch Bays, but without success. We could find no spot on the shores of the Gulf of Mannar that seemed suitable for the purpose, and none certainly with the natural advantages of Galle.

On several occasions we, in the "Lady Havelock," left Capt. Donnan and the barques for a couple of days in order to run lines of dredgings across some of the deeper or more remote parts of the region, especially to the north and west.

We then moved south to the Paars off Kodramallai Point, and left Captain Donnan on 19th March, as it was desirable that Mr. Hornell and I should now proceed to Galle to make the necessary arrangements as to establishing a laboratory there. On the way south we examined again the beds off Chilaw and off Negombo, and arrived at Colombo on the evening of Thursday, 20th March.

The general result of this second cruise, and of the inspection of the banks with Captain Donnan, was to confirm our former work and show that there is really an abundance of oysters on the banks, although probably the greater number are upon ground where they cannot grow to maturity. We were able to demonstrate these points and others, such as the microscopic food and eggs of the oysters, to our companions Sir W. Twynam, Captain Donnan, and Mr. Legge, and to discuss them fully and exchange views. All these served to reinforce and establish our former opinion that the chief remedial measure which ought to be adopted in the interests of the fisheries is the regular transplantation of young oysters from grounds such as the Periya Paar, where they are deposited as spat, but where, if left, they seem to be doomed for the most part to perish, to suitable hard bottoms about the Chevals and the Paars further south.

A number of experiments* that we made in our wooden tanks on board both the barque and the "Lady Havelock," and also in the sea water baths of the steamer, showed us that there ought to be no great difficulty in carrying out the transplantation without any serious mortality of oysters.

There are some points which are evidently of considerable practical importance to determine in connection with the matter, such as the best size of oyster to transplant, and the right season of the year (October or March) for the operation. Also whether only young oysters that are attached to movable objects can be used, or whether byssus that has been cut or torn can be replaced without weakening the animal. Upon these and several allied questions Mr. Hornell will continue to experiment, and will report progress to me from time to time.

It was now necessary to make definite arrangements about Mr. Hornell's laboratory, and Galle having been decided on as the most suitable spot, and preliminaries having been arranged with the Lieutenant-Governor by correspondence, it seemed desirable that I should see for myself the various quarters that had been proposed, and advise Mr. Hornell as to any necessary alterations and fittings. We took with us some samples of living oysters, both large (three years old) and small (6 months), which were conveyed safely in large "chatties" of sea water by steamer and train from Mannar to Galle, a journey occupying with our necessary stoppages four complete days. We were, however, able to deposit most of these oysters in a living condition in the sea at Galle on the evening of 22nd March. They soon recovered activity, and were found next day climbing about the chatties and netting in which they were confined.

The next three days were spent at Galle in examining offices and bungalows in the Fort, in the native bazaar, and near Bayley's Villa on Glossenberg. In the end certain conclusions were arrived at, which have already been reported to the Lieutenant-Governor, and have I believe been acted upon, the result being that Mr. Hornell is now established in Galle, carrying on the work which I left in his hands. I shall hear from him at frequent intervals, and shall send him fresh instructions from time to time as may be necessary. The results of Mr. Hornell's work will be given in our next report.

After having settled matters at Galle so far as was then possible, Mr. Hornell and I returned to Colombo and then took coach to Chilaw, and from there by boat we reached the more southerly pearl banks off Karaitivu, where we rejoined Captain Donnan on the barque. Mr. Hornell remained till the end of the inspection, and I was there from 28th March till 4th April, when I had to return to Colombo in the "Serendib" in order to leave for England on the 7th.

During that final week on the pearl banks I took part in Captain Donnan's inspection of the banks off Dutch Bay, and also carried on experimental laboratory work with Mr. Hornell. I also took the opportunity of talking over the practical details of the transplantation of young oysters with Mr. Legge, and I am convinced that he and Mr. Hornell, or Mr. Hornell acting for Mr. Legge in the matter, would have no difficulty in laying out some millions of young oysters from the Periyar Paar upon the Cheval Paars, or other suitable ground, at the next visit to the banks.

There are many detailed points bearing upon the life and health of the pearl oyster and upon the ravages made by its enemies, which I have not mentioned in this preliminary report, but which

* The particulars of these and other experiments will be given in our final report.

will be dealt with in full in the final report. I have also thought it well to defer, until our specimens are fully worked up, my remarks upon the marine biology in general and upon the trawl fisheries and other marine industries upon which biology has a bearing.

The leading points in the conclusions I have come to in regard to the pearl oysters of the Gulf of Mannar may be summarized as follows :—

- (1) The oysters we met with seemed on the whole to be very healthy.
- (2) There is no evidence of any epidemic or of much disease of any kind.
- (3) A considerable number of parasites, both external and internal, both Protozoon and Vermean, were met with, but that is not unusual in molluscs, and we do not regard it as affecting seriously the oyster population.
- (4) Many of the larger oysters were reproducing actively.
- (5) We found large quantities of minute "spat" in several places.
- (6) We also found enormous quantities of young oysters a few months old on many of the Paars. On the Periya Paar the number of these probably amounts to over a hundred thousand million.
- (7) A very large number of these young oysters never arrive at maturity. There are several causes for this :—
 - (8) They have many natural enemies, some of which we have determined.
 - (9) Some are smothered in sand.
 - (10) Some grounds are much more suitable than others for feeding the young oysters, and so conducing to life and growth.
 - (11) Probably the majority are killed by overcrowding.
 - (12) They should therefore be thinned out and transplanted.
 - (13) This can be easily and speedily done, on a large scale, by dredging from a steamer, at the proper time of year, when the young oysters are at the best age for transplanting.
 - (14) Finally, there is no reason for any despondency in regard to the future of the pearl oyster fisheries, if they are treated scientifically. The adult oysters are plentiful on some of the Paars and seem for the most part healthy and vigorous; while young oysters in their first year, and masses of minute spat just deposited, are very abundant in many places.

To the biologist two dangers are, however, evident, and, paradoxical as it may seem, these are *overcrowding and overfishing*. But the superabundance and the risk of depletion are at the opposite ends of the life-cycle, and therefore both are possible at once on the same ground,—and either is sufficient to cause locally and temporarily a failure of the pearl oyster fishery. What is required to obviate these two dangers ahead and ensure more constancy in the fisheries is careful supervision of the banks by some one who has had sufficient biological training to understand the life-problems of the animal, and who will therefore know when to carry out simple measures of farming, such as thinning and transplanting, and when to advise as to the regulation of the fisheries.

I have, &c.,
W. A. HERDMAN.

No. 2.

Sir W. C. TWYNAM, K.C.M.G., to Hon. Mr. R. W. IEVERS, C.M.G.

Alfred Villa,
Jaffna, June 30, 1902.

DEAR MR. IEVERS,—YOUR letter regarding the pearl oysters on the Cheval bank. Captain Donnan has, I presume, told you all that can be said at present regarding them in his report of the last inspection. The oldest oysters on the bank were about $3\frac{1}{2}$ years old. They ranged from 2, 3, to $3\frac{1}{2}$ in March last. I was with Captain Donnan when he picked up the samples for Professor Herdman in October last. I joined him in March last only after the inspection of the Cheval and Moderagam had been made, and therefore the only opinion I can form of them is from what Captain Donnan told me and from the samples he had on board. Of course there was nothing like an inspection of the banks in October, Captain Donnan having only gone to them to pick up samples from sections of the banks for Professor Herdman. We were on the banks only three working days, and anchored on five different spots some distance from each other, viz. :—

Four on Cheval bank : southern part of East Cheval ; centre West Cheval ; north of West Cheval ; north of East Cheval.

One on Moderagam bank, viz., centre of North Moderagam.

From all the patches we anchored on the diver brought up oysters from eighteen months to three years old lying, according to his report, thick on the banks. He brought up 20, 40, 80 at a dive, and in two dives on the North-West Cheval he brought up 100.

Except at our anchorage on the north of East Cheval, the diver reported the ground and the old oysters thickly covered with young oysters from minute spat to four months old. They were lying, according to his report, in myriads on the bank. Numbers of them were brought up adhering thickly to the old oysters. On one oyster there were as many as 65.

The old oysters (those from eighteen months to three years) looked healthy, and we judged that if they or the greater part remained on the bank and came to maturity they would afford good fisheries for perhaps three seasons (certainly for two) from the Cheval alone. There was one matter, however, that we believed had to be considered, and that was "What effect would so large a number of young oysters lying so thick on the old oysters have on the old oysters, if they (the young oysters) remained on the bank? Would they have the effect of smothering the old ones out?"

We had never seen young oysters so thick on the bank before.

Captain Donnan informed me that the older oysters were looking well in March, and a large number of young oysters were still on the bank.

At the close of the inspection it was estimated that there were oysters sufficient on the Cheval, Moderagam, and the Muttuvaratu banks to afford good fisheries for at least five years in succession.

Captain Donnan had some of the oysters picked up from the Cheval opened on board the ship; the pearls found were small and few in number, showing that the oysters were immature. The pearls were given to Professor Herdman to experiment on. Of course the opening of a few oysters in this way does not afford anything like sufficient information on which to judge of the condition of the oysters on a large bank.

The fact is, you are now very much in the position in which Mr. Vane found himself in 1862, and in which Captain Donnan and I were in 1880 and 1881, and Captain Donnan in regard to the Muttuvaratu bank in 1889. In 1862, at the inspection of March, Mr. Vane found the Cheval and Moderagamabanks thickly covered with oysters nearly of the same age. He estimated that there were oysters sufficient to afford fisheries for five years beginning with 1863. It was suggested to him to fish in 1862. He considered the oysters too young, and decided not to fish. In 1863 they were dying off. What were to have been fished in 1864 were destroyed, and all the oysters on the Moderagam were cleared off, so that there was after all only one fishery, that of 1863, instead of four or five in succession.

In November, 1879, the Cheval bank was thickly stocked with oysters of the same age. The oysters were immature. They required another year. The valuation of the sample was low, only Rs. 9 per 1,000. The sample of February, 1880, was only valued at Rs. 12 the 1,000. Captain Donnan wrote to me asking my opinion in regard to a fishery in 1880. I replied that the oysters were too young. He agreed, but pointed out that with the number on the bank it would be impossible to fish all in 1881, and the balance would not probably hold out till 1882, and advised a fishery in 1880. I agreed, and a fishery was held in 1880, and it was a good thing for Government that it was.

In 1889 Captain Donnan recommended a fishery of the Muttuvaratu bank, though the oysters were young, as they were dying out. This bank, however, as I have before remarked, completely upset all our calculations, and it yielded three lucrative fisheries in 1889, 1890, and 1891.

Captain Donnan and I talked over the matter of a fishery in 1903 (next year). We believed the oysters to be too young, and that they should under ordinary circumstances be allowed to remain another year till 1904, when they would be 4 and 4½, 5 and 5½ years old, close on their prime. We thought, however, in reference to the enormous number of oysters upon the bank of nearly the same age, and the impossibility of fishing them up in time, if they or the bulk of them remained on the bank if fishing were postponed until 1904, that it would be advisable to have a fishery in 1903, provided that the valuation of a fair sample lifted in October or November justified the advertising of a fishery.

An inspection of the banks should be made at any cost in October or November and the state of the banks ascertained. A large and fair sample of the oysters should be lifted, washed, and valued. If the condition of the banks is found to be such as to still hold out prospects of three or more large fisheries in succession, and the sample be valued at Rs. 10 or even as low as Rs. 7.50 the thousand, I would be inclined to recommend a fishery in 1903 in order to gather in as much as possible. Oysters which would yield a sample valued at Rs. 7.50 a thousand in November would very probably yield a sample likely to be valued at Rs. 10 or 12 the thousand in the following March.

Whether a fishery should take place or not in March, 1903, must depend on the result of an inspection in October or November next, and on the valuation of the sample lifted then.

Yours very truly,
W. C. TWYNAM.

P.S.—The Inspector should be instructed to carefully examine the oysters brought up in October and November, and ascertain from the reports of the divers and coxswains if the oysters are showing any signs of dying out. He should also carefully note the proportion of dead shells to living oysters.

W. C. TWYNAM.

No. 3.

THE MASTER ATTENDANT to the Hon. the COLONIAL SECRETARY.

No. 38.

Master Attendant's Office,
Colombo, April 10, 1902.

SIR,—I HAVE the honour to report my return to Colombo on the 9th instant from the pearl banks, where I have been employed since the 26th February, during which time I have inspected the following pearl banks :—

2. *Cff Arippu and Mannar*.—Cheval Paar, Moderagam Paars North and South, Kallatidel Paar, Kondatchi Paar, Jaggerboom Paar, Arippu Paar, Periya Paar, Periya Paar Karrai, Outer Vankali Paar, Inner Vankali Paar, Anaivilundan Paar, and Nadakkuda Paar.

3. *Off Karaitivu and Kalpitiya*.—Dutch Moderagam, Karaitivu Paar, Alantura Paar, Steuart's Paar, Hamilton's Paar, Muttuvaratu Paar, Modicoolie Paar, Talavilly Paars, and Navakadua Paar.

4. *Off Chilaw*.—Jokenpidi Paar, Karukupany Paar, and Chilaw Paar.

5. *Off Marawila*.—Ooloo Wittti Paar.

6. *Off Negombo*.—Negombo Paar and a new rocky bank discovered last year.

7. Pearl oysters were found only on the following banks :—Cheval Paar, Moderagam Paar, Periya Paar Karrai, Periya Paar, Outer Vankali Paar, Kondatchi Paar, Dutch Moderagam Paar, Karaitivu Paar, Alantura Paar, Muttuvaratu Paar, Jokenpidi Paar, Chilaw Paar, Ooloo Wittti Paar, Negombo Paar, and on the new rocky bank discovered last year.

8. On the east side of Cheval Paar three separate beds of oysters of about three years old were found, and also two beds of young oysters from three to six months old. The most northern bed of old oysters was found to be very small in area, and therefore of no importance ; but the bed on the centre part of the bank and the bed on the south part of it were found to be in the aggregate about 11,804,676 square yards in area, containing oysters averaging from 19 to 27 oysters to a dive, and I estimated the number of oysters on the two beds to be about 74,413,000. One of the beds of young oysters was connected with the southern bed of old oysters on its west side, and extended about $\frac{3}{4}$ of a mile to the westward of it and covering space between the east and west sides of the Cheval, but the young oysters extended more or less all over the area of old oysters. The other bed of young oysters on east side of Cheval lies to the westward of the centre bed of old oysters, and extends some distance into the space between east and west sides of the Cheval. A few old oysters were also found amongst the young oysters.

9. On the west side of Cheval Paar five separate beds of old oysters of about three years old were found, but one of them is very small in area and therefore of no importance. The other four beds extended from the southern limit of West Cheval to the northern limit with comparatively small intervening spaces of no oysters. The area of the four beds of old oysters amounts in the aggregate to about 10,500,050 square yards, on which the oysters average from 27 to 40 at a dive, and I estimate the total number of oysters on them all to be about 123,357,000. On all of these four beds the old oysters were covered with young ones three to six months old.

10. The North Moderagam was found to be nearly all covered with young oysters of about three to six months old, and the South Moderagam had one small bed of oysters of a similar age with some old oysters of three years amongst them on the north-east quadrant and two very small beds of young oysters only on the south quadrant.

11. On the Periya Paar Karrai two beds of oysters of about three years old were found. The area of both beds was found to be about 1,232,250 square yards, over which the oysters average from 30 to 43 to a dive, and I have estimated the total number of oysters on both beds at about 21,477,000. A large proportion of these oysters are, I believe, likely to come to maturity.

12. On the southern portion of the Periya Paar, which was fished in 1879, there were three small patches of oysters from 2 to $2\frac{1}{2}$ years old, but the whole of the portion of the bank as well as a large extent of ground adjoining it was found to be covered with young oysters two to three months old. Indeed, there is reason to believe that the whole extent of the Periya Paar is now covered with young oysters, as during a run made down the centre of it in the launch "Serendib" for a distance of 6 miles, frequently stopping and sending down divers, young oysters in great abundance were found at every dive.

13. On the Outer Vankalai Paar two small beds of oysters of about $2\frac{1}{2}$ years old were found, one at the centre of the bank and one at the eastern margin, which latter is, however, of very small extent. The centre bed is of about 345,000 square yards in area, on which the oysters average 24 to a dive, and I estimated the number of oysters on it at 3,450,000. There is, however, a probability of none of these oysters being found on this bank next year, as they have largely diminished since last year.

14. On the Kondatchi Paar a small bed of oysters of about three years old was found. The area of the land was found to be about 444,375 square yards, on which the oysters averaged 31 to a dive, and I estimated the number of oysters on the bed at about 5,739,000, a large proportion of which, I believe, will remain on the bank and arrive at maturity.

15. On the Dutch Moderagam Paar a small bed of oysters from 2 to $2\frac{1}{2}$ years old was found. The area of the bed is about 387,500 square yards, over which the oysters were estimated to yield 22 to a dive covering a space of $2\frac{1}{2}$ square yards, and I estimate the number of oysters on the bed at about 3,552,000 ; but I am doubtful of any of these oysters being found next year.

16. On the Karaitivu Paar a considerable bed of oysters from eighteen months to two years old was found. The area of the bed was found to be about 1,570,850 square yards, over which area the oysters were estimated by the divers to average 43 to a dive, and I estimated the number of oysters on it at about 25,330,000, and I am confident of a large proportion of these oysters arriving at maturity.

17. On the Alantura Paar a small bed of oysters from eighteen months to two years old was found. The area of the bed is about 1,606,000 square yards, over which space the divers estimated that 30 oysters could be obtained to a dive on the average, and I estimate the total number of oysters on the bed to be about 11,925,000, of which a large proportion are likely to remain and arrive at maturity.

18. On the Muttuvaratu Paar a very large bank of oysters was found varying from about to $2\frac{1}{2}$ years old. The area of the bank in square yards is about 10,206,725. On the north portion of the bank, which is the largest, the oysters were estimated by the divers to be in sufficient numbers to yield 64 to a dive on the average, and on the south portion 52 oysters to a dive. I estimate the number of oysters now on this bank to be about 277 million. Since last year a large number of young oysters have come upon the bank, thus accounting for the estimated number on it being 99 million more than last year. This bank is at present in a very promising condition.

19. On the Chilaw Paar a bed of young oysters from six to nine months old was found. The area of the bed is about 1,120,000 square yards.

20. On the Ooloowitti Paar a small bed of young oysters from six to nine months old, and on the Negombo Paar also a small bed of young oysters from six to nine months old was found. On the new rocky bed which I discovered last year a few scattered patches of young oysters about six months old were found.

21. In regard to the prospects of future pearl fisheries the present condition of the Cheval and Muttuvaratu Paars is very favourable, and these two banks are likely to yield two fisheries each during the next four years. On the east side of the Cheval the oysters are more advanced than those on the west side, and although they will not be fully ripe for fishing in March next year, yet in view of the west side of the Cheval being likely to yield a large fishery in March, 1904, and the Muttuvaratu Paar a fishery in March, 1905 and 1906, the fishing of the East Cheval next year seems to be unavoidable. I would, however, recommend a sample of 20,000 oysters be lifted from it in the early part of next November, say, 10,000 from the south part of East Cheval and 10,000 from the north part, and the valuation of the pearls of that sample would determine whether it would be possible to fish the bank next year or not.

22. During this inspection I had the pleasure of the company of my successor Mr. Legge, who has made himself thoroughly acquainted with my method of inspecting the pearl banks and of the landmarks to which compass bearings are taken in finding the various banks.

23. I annex for facility of reference a tabulated statement of the pearl banks on which beds of oysters have been found, and of the area of the beds of oysters and the estimated number of oysters upon them.

I am, &c.,

J. DONNAN,
Inspector of Pearl Banks.

Tabular Statement showing the Names of the Banks on which Pearl Oysters were found during the Inspection of March, 1902, the Area of the Beds of Oysters, and the Number of Oysters estimated to be on them.

Name of Bank.	Area of Bed of Oysters in Square Yards.	Estimated Number of Oysters on the Bank.	Age of Oysters.	Remarks as to future Prospects.
Cheval Paar (east side)	11,804,676	74,413,000	3 years	Very good
Cheval Paar (west side)	10,500,050	123,357,592	3 years	Very good
Moderagam Paar (north and south)	—	—	—	Young oysters
Periya Paar Karrai	1,232,250	21,477,000	3 years	Very good
Periya Paar	Very large	—	—	Young oysters
Outer Vankali Paar	345,000	3,450,000	—	Not reliable
Karaitivu Paar	1,570,850	25,330,000	—	Very good
Kondatchi Paar	444,375	5,739,000	—	Very good

1902-1903.

The Planters' Association of Ceylon. KANDY. FORTY-NINTH ANNUAL REPORT, FOR THE YEAR ENDING 17TH FEBRUARY, 1903.

Your Committee now herein submits the Forty-Ninth Annual Report of the Planters' Association of Ceylon for the year ending 17th February, 1903, and in doing so would congratulate the Members on progress maintained with vigorous prosecution of the business that has been presented for consideration and disposal during the period under review.

CORONATION CELEBRATION: ADDRESS TO HIS MAJESTY.

One of the happiest events of the year, following almost immediately after the Declaration of peace in South Africa, was the Coronation of King Edward the VII. But for the King's most distressing illness this would have taken place on the 26th June and preparations were made on a most magnificent scale in the Metropolis to celebrate the occasion.

PLANTING PRODUCTS.

The past season has been on the whole unfavourable for yield. A drought in the early part and an excessive rainfall during the last three months of the year, account for the crop falling considerably short of the estimate, but total shipments of tea were notwithstanding the largest recorded.

The most encouraging feature at the present moment is the rapidly increasing manufacture and demand for Ceylon green tea. Commencing slowly in 1898, the manufacture rose to 500,000 lbs. in 1900, 1,500,000 lbs. in 1901, and 4,000,000 lbs. last season.

As usual your Committee with due acknowledgment extracts from the remarks of London Brokers for perusal, reference and comparison the following:—Messrs. Wilson, Smithett & Co., observe that the BOARD OF TRADE RETURNS for the year just closed fully justify the more optimistic views lately entertained as to the future of the tea market.

From 1st January to 31st Dec. 1902... 1,144,600 packages, average 6½d. per lb. 1901... 1,188,600 " " " 7d. 1900... 1,263,200 " " " 7½d.

Table with columns: Pekoe, Pekoe and Orange Pekoe, Broken Pekoe, etc. and rows: com. to medium from, fine to finest, etc.

Table with columns: Months, 1902, 1901, 1898, 1899. Rows: U.K., U.S.A., Germany, Holland, France.

Messrs. Thomas, Camberlege & Moss, London, write:—The present year opens with a more encouraging outlook for producers than for some years past.

The large increase in 1900 was due no doubt to the railway extensions commenced in that year. A great deal of this labour should shortly be set free, on the completion of the Kelani Valley and Uda Pusselawa railways.

The cultivation of this product continues to attract the attention of European and Native Cultivators and has lately been added to the Experimental products in the Government Experiment Station at Peradeniya.

COCONUTS.

The year 1902 has been another good year for owners of Coconut property. The Chamber of Commerce returns of Exports of Produce for 1902 show that the Export of Coconut Oil wts. 512,498; of Desiccated Coconut 16,227,565 lbs., of Poonac cwt. 247,696; and Coir Rope cwt. 15,681 have been the largest within the last ten years.

TEA BLIGHTS.

Table with columns: United Kingdom, Russia, Other countries in Europe, America. Rows: Black 1902, Green 1902, Blk. 1901, Grn. 1901.

The following show an increase over 1901: Africa, America, Austria, Belgium, China, Germany, Italy, Malta, Mauritius, Russia, Singapore, Spain, Sweden and Turkey; while Australia, France, Holland, India and the United Kingdom show a decrease.

LABOUR SUPPLY.

Your Committee as usual invites attention to Appendix A. hereto annexed for official statements of Exports from Ceylon during 1902, for which your thanks are due to the Hon'ble Mr. H. L. Crawford.

LABOUR SUPPLY.

Table with columns: Months, 1900, 1901, 1902. Rows: January, February, March.

CA CAO.

The crop shipped for the year was cwt. 61,476 against cwt. 47,471 in 1901, and is the largest crop yet shipped from Ceylon. It would have been considerably larger but for the very unfavourable weather of the last three months of the year.

few lots of really pure red which are now put on the Market command exceptional prices. The stocks in London are smaller than they have been for several years.

According to Messrs. C. M. and C. Woodhouse's annual report, the nine chief consuming countries, as far as the latest figures procurable show, consumed 229,459,200 lbs. of cocoa, against 209,771,000 lbs. last year, and 168,625,800 lbs. in 1898, showing an increase of 86 per cent in the five years.

Table with columns: Months, 1902, 1901, 1900, 1899. Rows: U.K., U.S.A., Germany, Holland, France.

Table with columns: Months, 1902, 1901, 1900, 1899. Rows: Consumption in the U.K. in 12 months, Stock 31st Dec.

CARDAMOMS.

The cultivation of this product continues to attract the attention of European and Native Cultivators and has lately been added to the Experimental products in the Government Experiment Station at Peradeniya.

COCONUTS.

The year 1902 has been another good year for owners of Coconut property. The Chamber of Commerce returns of Exports of Produce for 1902 show that the Export of Coconut Oil wts. 512,498; of Desiccated Coconut 16,227,565 lbs., of Poonac cwt. 247,696; and Coir Rope cwt. 15,681 have been the largest within the last ten years.

RUBBER.

This product continues to receive increasing attention, particularly in the low-country, where it is being planted in all Estate swamps and ravines. It has not yet been determined what is the highest elevation at which it can be grown to pay.

TOTAL EXPORTS FROM CEYLON DURING THE YEAR 1901.

Your Committee as usual invites attention to Appendix A. hereto annexed for official statements of Exports from Ceylon during 1902, for which your thanks are due to the Hon'ble Mr. H. L. Crawford.

LABOUR SUPPLY.

Table with columns: Months, 1900, 1901, 1902. Rows: January, February, March.

TEA TRADE IN JAPAN.

Through the good Offices of the Ceylon Chamber of Commerce interesting Reports by the British Consul at Yokohama upon the Japanese Tea Industry and by the British Consul at Amoy on the Formosa Tea Industry were obtained and circulated for the information of Members and your thanks are herein recorded to the writers and to the Chamber for valuable information and co-operation in the matter.

Table with columns: Months, 1901, 1902. Rows: January, February, March, April, May, June, July, August, September, October, November, December.

TEA TRADE IN JAPAN.

Table with columns: Months, 1900, 1901, 1902. Rows: January, February, March, April, May, June, July, August, September, October, November, December.

The large increase in 1900 was due no doubt to the railway extensions commenced in that year. A great deal of this labour should shortly be set free, on the completion of the Kelani Valley and Uda Pusselawa railways.

The labour question, in one form or another, comes up annually, and during the busy months a clamour is raised, but Superintendents must be prepared to work under difficulties and at somewhat high pressure during these months.

The Tin ticket system appears to be working well and in time no doubt will be in more general use. It is a system which could be extended to Southern Indian railway stations.

The revised regulations will be found in appendix D. There have been two meetings of the Committee of the Labour Federation of Ceylon during the year.

SUPERINTENDENT OF IMMIGRATION.

By the death of Mr. C. H. Wilkinson late Superintendent of Immigration your Association was deprived of the services of an experienced and competent Officer and your Committee accorded a vote of condolence to Mrs. Wilkinson.

RUSSIAN TEA TRADE—BRITISH EXHIBITION ST. PETERSBURG.

In connection with the important Russian Tea Trade your Committee learned with regret during the year that the British Exhibition at St. Petersburg would not take place.

CUSTOMS DUTIES ON TEA AND OTHER PRODUCTS ENTERING FRANCE FROM COUNTRIES WHICH DO NOT ENJOY MOST FAVOURED NATION TREATMENT.

The question of increased Customs Duties on Tea and Other Products entering France from Countries which do not enjoy Most Favoured Nation Treatment has continued to occupy the attention of your Committee.

The subject of Freight to Australia and the Southern Colonies has been brought under the notice of your Committee and it would appear that the rate of Freight to the Australian Colonies is in excess of what it should reasonably be.

FREIGHT TO AUSTRALIA.

The subject of Freight to Australia and the Southern Colonies has been brought under the notice of your Committee and it would appear that the rate of Freight to the Australian Colonies is in excess of what it should reasonably be.

The subject of Freight to Australia and the Southern Colonies has been brought under the notice of your Committee and it would appear that the rate of Freight to the Australian Colonies is in excess of what it should reasonably be.

The subject of Freight to Australia and the Southern Colonies has been brought under the notice of your Committee and it would appear that the rate of Freight to the Australian Colonies is in excess of what it should reasonably be.

The subject of Freight to Australia and the Southern Colonies has been brought under the notice of your Committee and it would appear that the rate of Freight to the Australian Colonies is in excess of what it should reasonably be.

The subject of Freight to Australia and the Southern Colonies has been brought under the notice of your Committee and it would appear that the rate of Freight to the Australian Colonies is in excess of what it should reasonably be.

The subject of Freight to Australia and the Southern Colonies has been brought under the notice of your Committee and it would appear that the rate of Freight to the Australian Colonies is in excess of what it should reasonably be.

OFFICIAL ESTIMATE OF TEA CROP FOR 1903.

Your Committee estimates the Tea Crop for Export during the year 1903 at 154,000,000 lbs. The Returns received are believed to be more full and accurate than in any previous occasion...

Table with 2 columns: Region and Quantity. Rows include Asia, Europe, India, Australia, Africa, America, United Kingdom, Far East.

INCIDENCE OF TAXATION.

During the year the Commission appointed by His Excellency the Governor to enquire into the Incidence of taxation commenced its work, it will however be towards the end of 1903 before any definite recommendation is forthcoming.

RAILWAY EXTENSION.

The Kelani Valley Railway Extension it will be remembered, was first prominently brought before your Association at the Annual General Meeting on the 17th February, 1895, when a Member of the Kelani Valley District Association in an able speech proposed the following Resolution:—"That it be urged on Government the necessity for carrying out without delay Railway Extension to Kelani Valley..."

CEYLON GOVERNMENT RAILWAY.

During the year an amending Ordinance relating to the Ceylon Railways entitled "The Ceylon Railways Ordinance 1902" was passed having been watched in the interests of your Association by the then Planting member in Council Hon. Mr. J. N. Campbell...

PUBLIC WORKS.

The exceptionally heavy and constant rain during the last quarter of the year rendered repairs difficult and in at least one case a main road became almost impassable. It is of vital importance to an outlying District like the Morawa Korle, dependent entirely on one trunk road, that that road should be maintained in the highest degree of efficiency.

CONSTRUCTION, UP-KEEP AND REPAIR OF ESTATE ROADS.

(PROVINCIAL AND DISTRICT ROAD COMMITTEE.) In reference to the construction, upkeep and repair of estate roads an Ordinance was passed during last year after being watched on behalf of your Association by the then Planting Member in Council, Hon. Mr. J. N. Campbell, entitled "the Estate Roads Ordinance 1902."

REDUCTION OF BRITISH TEA DUTY.

It will be remembered that in January, 1901, both by despatch and telegram, His Excellency supported the prayer of the Planters' Association in forwarding the following Resolution to the Secretary of State:—"That this Association would urge on His Majesty's Government a reduction, at as early a date as is compatible with the financial needs of the Empire, of the Import Duty on Tea in Great Britain, which is now equal to nearly 100 per cent. ad valorem, whereby consumption is checked and the stability of the tea planting enterprise in this Colony is seriously threatened."

representing an invested capital of £15,000,000 sterling. That Tea is very highly taxed in proportion to its value is officially admitted as a matter which any Chancellor of the Exchequer would be bound to consider, and the Planters' Association therefore confidently relies on early favourable consideration and a reduction of the Tea Duty at an early date by His Majesty's Government...

SPECIAL LEGISLATION RE CACAO STEALING.

The important question of Special Legislation for Cacao Stealing has occupied the consideration of your Committee and also your Association in General Meeting when the following Resolution was passed and forwarded to Government:—"That the Planters' Association is of opinion that the law, as it now stands, is not sufficient for the protection of Cacao proprietors..."

SPECIAL LEGISLATION RE PLANT SANITATION.

The question of what measures in the nature of Legislation if any should be recommended to Government with a view to preventive steps being taken for the safety of the Tea Industry in reference to the spread of "shot-hole borer" and other insect pests and of the Cacao grower in respect of Cacao disease has received consideration and in the ensuing year the matter will have further attention.

SPECIAL LEGISLATION FOR THE PROTECTION OF RUBBER.

During the year the question of the theft of Para Rubber was brought under the notice of your Committee as in the opinion of the Kalutara Association special protection will shortly be required to prevent theft of the products. The matter is one that will not be lost sight of, meantime it is recommended that evidence should be collected showing in what way Rubber is liable to deprecations by thieves.

ORDINANCE No. 13 OF 1902 ENTITLED AN ORDINANCE TO PROVIDE FOR THE INCREASE OF THE EXPORT DUTY ON TEA.

The above mentioned Ordinance came into operation as from and after the 1st day of June, 1902. It provides for the levy upon all Ceylon tea exported a duty not exceeding 10 cents per 100 lbs. in addition to the levy imposed under the provisions of Ordinance No. 4 of 1894. The proceeds of the levy so enacted shall be applied towards the increase of the consumption of Ceylon tea in Foreign lands, in such manner as may from time to time be desired and determined by the joint Committee appointed for the purpose by the Planters' Association of Ceylon on the 17th day of February, 1902, and by the Ceylon Chamber of Commerce the 7th day of March, 1902...

FERTILISERS ORDINANCE No. 12 OF 1901 FOR REGULATING THE SALE OF MANURES.

In connection with the above mentioned Ordinance your Committee reports that His Excellency the Governor was pleased to appoint Mr. M. Kelway Bamber to be Agricultural Analyst for the Island under Section 5 of the Ordinance and to sanction the scale of fee suggested for the approval of Government by your Association.

MINES AND MACHINERY ORDINANCE, 1898, RULES MADE BY THE GOVERNOR.

Early in the year Government forwarded the Rules under the Mines and Machinery Protecting Ordinance made by the Governor with the advice of the Executive Council in terms of Section 4 of Ordinance No. 2 of 1896, and invited any suggestions from your Association regarding same. In reply your Committee stated that the Planters' Association had no new suggestions to offer. The Rules as passed were published in the Government Gazette, July 4th, 1902.

FIRE INSURANCE. CIRCULAR SAWS IN TEA FACTORIES.

A notification regarding Circular Saws in Tea Factories having been considered by your Committee the Ceylon Fire Insurance Association was asked if any reason could be given for the additional charge, it being pointed out that in view of the recent agitation to reduce the rate of premiums the present step appeared to be uncalled for. The reply received was unsatisfactory. It was stated that the regulation in question emanated from the Fire Office Committee (Foreign) London, who in view of the danger believed to exist in the use of Circular Saws, notwithstanding the representation and recommendation for the use of these saws on certain conditions without extra rate by the Ceylon Committee the London Committee were unable to agree to its withdrawal. The next step taken was to refer the correspondence to the Ceylon Association in London inviting support as far as was known no fire has occurred in Ceylon owing to the use of Circular Saws in a tea factory. A copy of the notification on the subject as issued in Ceylon was not forwarded at the time and it is a matter of surprise and regret to learn that though the Ceylon Association in London applied to the Fire Office Committee (Foreign) for a copy thereof the Secretary absolutely refused to give any information, thus entailing unnecessary delay and a further reference to Ceylon for the desired data. Your Committee has since learned with regret that your representation on the subject has been refused by the Fire Office Committee (Foreign).

CEYLON IMPORT DUTY ON INDIAN TEAS.

Early in the year Government forwarded a letter from the Government of India with the accompanying copy of a letter from the Secretary Indian Tea Association, Calcutta, relative to the Duty levied on tea imported into Ceylon and invited an expression of the views of your Association thereon. The proposal which the Indian Committee ventured to advance was first that an attempt should be made to induce the Ceylon Government to exempt Indian Tea from the payment of Duty and second that if necessary Ceylon Tea should be exempt from the payment of Duty in India, but that the existing duty should be maintained in the case of non-British Teas. Your Committee in reply stated that the question had received very full consideration by your Association so far back as 1894 when the following Resolution was passed in August, 1895:—"That in reply, it be stated that in the opinion of the Committee it would be highly detrimental to the interests of Ceylon Tea that the prayer of the petition from the United Planters' Association of Southern India be granted. That Ceylon has for many years worked hard to introduce her teas into foreign countries and to raise their credit for purity, and now that some success has been achieved, it seems unwise to admit other countries on equal terms to the jeopardy of Ceylon's interests. That, regarding the question of blending, the Committee desires again to draw the attention of Government to the resolution on the subject transmitted to Government with the Secretary's letter of the 28th January, 1894, which resolution and connected statement the Committee again fully endorses."

Your Committee added that since 1894 growers of Ceylon Tea had expended about 2,000,000 rupees in making known their produce in the markets of the World and that your Association feels that it is more important than ever that no possible mistake or confusion should arise from Teas other than Ceylon being shipped from Colombo with an implication of Ceylon growth. Your Association is further of opinion that no hardship exists in the matter of Indian Teas being sold in Colombo, as at present except possibly in the case of small invoices and that it would appear therefore as if the object of the request to remove the duty was to facilitate the blending of Indian Teas with Ceylon Teas as such. Your Association fears that with such blending establishments in existence there must be unless stringent precautions are taken, a risk of certain teas other than those grown in the island being shipped as Ceylon Teas. From recent proceedings published it appears that the Ceylon Government was averse to the Indian Committee's proposal and that the Government of India was also in Agreement with Ceylon hence the Indian Committee in view of the definite and final nature of the reply decided it would be useless to proceed further.

THE TEA INDUSTRY AND OVERPRODUCTION.

During the year considerable criticism and discussion have been in evidence as regards the most effective means of combating overproduction of your staple Tea, and of maintaining prices on remunerative terms. A general reduction of the Import Duties on Tea in all principal Countries is greatly to be desired not alone as a certain means of relief in the interest of Tea Growers generally, but as unquestionably of far reaching benefit to the masses of population which are at present prevented from enjoying a remarkably refreshing and wholesome beverage by the highly enhanced price necessary owing to the rate of Import Duty levied when added to the value per lb. of Tea at the point of Landing. The matter is one which is worthy of consideration by the responsible Statesmen of all Countries for the good of the subject peoples throughout the World.

CEYLON ASSOCIATION IN LONDON.

In connection with the important question of the British Import Duty on Tea, Warehouse Charges in London, Fire Insurance Premiums, Freight to Australia and other matters the Ceylon Association in London has lent its services while in respect of several other matters there has been consultation and reference with a view to safeguarding the producers interests.

PLANTERS' WARD AT THE GENERAL HOSPITAL, COLOMBO, & AT THE BAKER WARD, NUWARA ELIYA.

Your Committee learns that the number of Planters treated in the Planters' Ward (Colombo) during 1902, was 59 and that at the Baker Ward, Nuwara Eliya 1. It may also be mentioned that at the Kandy Hospital 15 were treated, at Gampola Hospital 1, at Badulla Hospital 8, at Maskeliya, Dimbulula and Kegalle District Hospital 1 each respectively. The thanks of your Association is herein tendered to the Principal Civil Medical Officer and Inspector General of Hospitals and his Assistants for professional services and other courtesies and attentions extended. In Appendix F. an Official Return is given showing details as to Patients treated.

VISITORS TO HOSPITALS AND DISPENSARIES IN THE PLANTING DISTRICTS.

During the year various appointments as Visitors to Hospitals and Dispensaries in the Planting Districts as from time to time submitted for the approval of Government have been made. Your Committee believes that these arrangements work satisfactorily.

CEYLON NURSING ASSOCIATION.

A Sub-Committee of your Committee was recently appointed with a view to drawing the attention of Agents of Estates to the value of the Ceylon Nursing Association also inviting support and co-operation by permitting Superintendents of Estates employed by them to subscribe on Estate account annually. An appeal was at same time made to Superintendents to obtain permission of their firms to subscribe to the Nursing Association. The letters of appeal were sent to nearly 900 Superintendents and also to the Agents of Estates with interesting information and data. Some of the leading Agency Houses have prominently and cordially supported the appeal and your Committee has no doubt that the institution will receive still greater recognition of its value and usefulness to the Planting Community especially by regular and increased contributions hereafter.

DISTRICT ASSOCIATIONS.

Your Committee records herein an expression of grateful thanks on your behalf to the Office Bearers of the various affiliated District Associations for cordial co-operation and support during the past year in matters relating to the work and maintenance of the Planters' Association of Ceylon.

REPRESENTATIVE IN THE LEGISLATIVE COUNCIL.

Under the new Official Regulations the Hon. Mr. J. N. Campbell's term of Office having expired by effluxion of time Hon. Mr. E. Rosling was nominated by your Association for the approval of His Excellency the Governor as Planting Representative in the Legislative Council and was thereafter duly appointed. In General Meeting a hearty vote of thanks was tendered to Hon. Mr. Campbell for his many able services on your behalf and your Committee in again recording such here-in would add an expression of congratulation and thanks to Hon. Mr. Rosling also who as successor of previous distinguished Members has already earned your confidence and appreciation.

CEYLON PLANTERS' RIFLE CORPS.

In continuation of previous Reports it is interesting and useful for reference to place the following Return—supplied by the courtesy of the Adjutant, Ceylon Volunteer Force—of the total present strength of the Planters' Rifle Corps in the various Districts.

Table with 2 columns: District and Strength. Lists districts like Ambegamuwa, Darrawella, Maskeliya, Lower Maskeliya, Kandy, Matale, Madulikke, Rangalla, Hewaheta, Mattakelle, Egga Patna, Kotagala, Punduloya, Nuwara Eliya, Badulla, Haputale, Passara, Udupussellawa, Maturatta, Kalutara, Galle, Kelani Valley, Kurunegalle, Colombo, Pussellawa, Nawalapitiya, Dobsbage, Batticaloa, and a Total of 797.

At the request of Lieutenant-Colonel Farquharson, Commanding the Corps permission has been granted by your Committee to have the six Shields for Rifle Competition placed within the Victoria Commemoration Buildings, Kandy.

CEYLON CONTINGENT.

At a recent Meeting of your Committee a Sub-Committee was nominated to take steps in the matter of the proposed Monument to be erected in the Victoria Garden adjoining the Victoria Commemoration Buildings, Kandy. Subscription lists are now in circulation but it is too early to report how much has been collected or promised. No doubt in the New Year the Sub-Committee will be re-appointed and with the promised co-operation of the Ceylon Chamber of Commerce the matter will have renewed attention and monetary support.

GEORGE WALL REFERENCE LIBRARY AND TOWER.

The nucleus of valuable authoritative information for domicile in the George Wall Reference Library having been formed an effort has been made through the good Offices of Government to secure from the proper channels the Official Blue Books issued annually by the various Colonial Governments. Government has been good enough to state that the request has been transmitted to the Governor General of Australia and your Committee hopes shortly to have a favourable response. Your Committee has also asked the Ceylon Chamber of Commerce to kindly co-operate in obtaining Consular Reports and other similar data regarding trade and Ceylon Products through the various Consuls, London Chamber of Commerce etc. Your Committee mentions this as indicating that it is likely gradually to have available a sufficient collection of such interesting books of reference connected with the Colonial Governments and their Agricultural Statistics. The opportunity is availed of to again record herein an expression of thanks to His Excellency the Governor as well as to Societies, Departments and others for Blue Books, Sessional Papers, Reports and Year Books, courteously forwarded from time to time during the year.

PLANTERS' BENEVOLENT FUND.

ESTABLISHED TO COMMEMORATE THE JUBILEE OF HER MAJESTY QUEEN VICTORIA 1837-1887.

Your Committee is glad to report that subscriptions for the year, 1902, collected by the Hon. Treasurer of the Fund amounted to Rs. 2,885 against Rs. 2,640 in 1901 while donations aggregated Rs. 180 in 1902 as compared with Rs. 412-87 in 1901. The sum of Rs. 1,277-84 was credited as interest in 1902 and Refunds of Rs. 425 were also received. Assistance granted to various Planters and their families during 1902 showed a total of Rs. 2,729-82.

In recording the above your Committee again solicits a subscription or Donation from Members of the Planting Community who may rest assured that such will be usefully employed and help those where temporary assistance may be both pressing and indispensable. For the information of absent Proprietors, Agents of Companies and others, your Committee quotes the following Regulation and hopes that its perusal may lead to a considerable addition to the Roll of Patrons:—

"A Donor of Rs. 100-00 to the Benevolent Fund, or an annual subscriber of Rs. 20-00 for 5 years, will be welcomed as a patron, and have a copy of the proceedings of the standing Committee and statement of the Accounts of the Fund rendered to him, and such donor and his family shall be entitled to assistance from the Fund if in need of such. Should such sum of Rs. 100-00 be subscribed by the Proprietor of an estate on behalf of the estate then the Superintendent shall be entitled to assistance from this Fund if in need of such during the life and ownership of the donor."

OBITUARY.

Your Committee records with sincere regret the decease of the following Members of the Planting Community during the past year:—

J. Shelton Agar, G. B. Armitage, G. M. B. Bowhill, L. R. Biddell, R. Bartrum, Oliver Collett, J. J. Flyler, Thomas Fairhurst, J. N. Gordon, A. N. Greenhorn, T. J. Grigg, F. G. Hoste, W. H. Herbert, W. B. Kingsbury, W. Kent, W. D. Matland, J. J. O'Dowd, J. L. Phillips, Herbert William Parry, Norman Rettin, Tudor Stanton, Percy Scott, J. Shipton, R. H. Tennant, James M. Wright, David Webster, C. H. E. Wilkinson, J. D. Andrews, Reginald Gwillvie.

FINANCES.

The Statement of Accounts made up to the close of the financial year 31st January, 1903, and laid on the table to-day in terms of Rules VIII, XII and XIX of your Association show a credit balance of Rs. 8,234-18. Included in this amount however is the sum of Rs. 1,685, collected as a special fund towards the cost of the proposed Bust or Statue of our late Sovereign Majesty Queen Victoria to be placed in the Victoria Commemoration Buildings, Kandy, the balance of the Portrait fund Rs. 131-50, also Rs. 135 on account of the Ceylon Contingent Monument already referred to herein.

The year will be memorable by three Historic events—the conclusion of Peace at the close of the War in South Africa; the sudden, serious illness, and remarkable restoration to health of His Majesty King Edward the Seventh;—the Royal Coronation Celebration in Westminster Abbey, when Their Majesties the King Emperor, and Queen Alexandra were crowned. It goes without saying that Ceylon and Your Association evinced keen interest in these matters sharing with other Dependencies through the Planters' Contingent of Mounted Infantry in the defence of the British Dominions beyond the seas, and being honoured through His Excellency the Governor at the public pageants and festive functions of 1902. In resigning Office your Committee recommends a continuance of the efforts being made to obtain a reduction of the British Duty on Tea in Great Britain, expansion of the Green Tea Industry, avoidance of coarse plucking, control of the London Market, and the further exploitation of Ceylon Tea throughout the World with a view to increased demand for and consumption of your staple in all countries.

Unitas Salus Nostra.

APPENDIX A.

General Export from the Island of Ceylon in the Year 1902.

Large table with 5 columns: ARTICLES, QUANTITIES, VALUE IN CURRENCY, TEA FUND, MEDICAL AID. Lists various goods and their export values.

Table with columns: ARTICLES, QUANTITIES, VALUE IN CURRENCY, TEA FUND, MEDICAL AID. Includes entries for Philippines, Russia in Asia, South America, etc.

Table with columns: ARTICLES, QUANTITIES, VALUE IN CURRENCY. Includes entries for Japan, U.S. of America, Cotton Lace and Net, etc.

Table with columns: ARTICLES, QUANTITIES, VALUE IN CURRENCY. Includes entries for Pepper, United Kingdom, British India, etc.

Table with columns: QUANTITIES, VALUE IN CURRENCY. Includes entries for Appropriations from the Ceylon Tea Fund for 1903, Green Teas, etc.

Table with columns: ARTICLES, QUANTITIES, VALUE IN CURRENCY. Includes entries for Coffee Arablan Native, British India, Mauritius, etc.

Table with columns: ARTICLES, QUANTITIES, VALUE IN CURRENCY. Includes entries for Piece Goods - Bleached, British India, Maldives, etc.

Table with columns: ARTICLES, QUANTITIES, VALUE IN CURRENCY. Includes entries for Dyed, British India, Maldives, Straits Settlements, etc.

Table with columns: QUANTITIES, VALUE IN CURRENCY. Includes entries for Return of Planter Patients treated in Hospital during 1902, Nuwara Eliya Baker's Ward, etc.

Table with columns: ARTICLES, QUANTITIES, VALUE IN CURRENCY. Includes entries for Coffee Arablan Plantation, United Kingdom, British India, etc.

Table with columns: ARTICLES, QUANTITIES, VALUE IN CURRENCY. Includes entries for Cotton, Gray, United Kingdom, British India, etc.

Table with columns: ARTICLES, QUANTITIES, VALUE IN CURRENCY. Includes entries for Muslin, British India, Printed, etc.

Table with columns: QUANTITIES, VALUE IN CURRENCY. Includes entries for REPRESENTATIVE IN AMERICA, The Remittance made to Mr. Wm. Mackenzie, etc.

Table with columns: ARTICLES, QUANTITIES, VALUE IN CURRENCY. Includes entries for Coffee Liberlan, British India, Natal, etc.

Table with columns: ARTICLES, QUANTITIES, VALUE IN CURRENCY. Includes entries for Other, British India, Burma (Samples), etc.

Table with columns: ARTICLES, QUANTITIES, VALUE IN CURRENCY. Includes entries for Cotton Thread, British India, Cotton Tan and Twist Dyed, etc.

Report of the Thirty Committee.

Report of the "Thirty Committee" appointed to administer the proceeds of the Export Duty on Tea, levied under Ordinance No. 4 of 1894 for increasing the consumption of Ceylon Tea in foreign lands for the year 1902.

MEMBERS OF THE "THIRTY COMMITTEE," 1902. The following is a list of the "Thirty Committee" at 31st December, 1902.

Messrs. James Westland, C. E. Welldon, A. C. Kingsford, Frank S. Vowler, Hon'ble Mr. J. N. Campbell, Messrs. E. Webb, Alex. Wardrop, Edgar Turner, R. A. Galton, H. O. Hossain, Gordon Pyper, W. D. Bosanquet, T. C. Huxley, Wm. Forsythe, A. Philip, W. J. Smith, Joseph Fraser, W. R. Tatham, R. Morrison, Captain H. Gordon, Messrs. W. D. Gibbon, Hon'ble Mr. Edward Rosling, Messrs. Fred. Hadden, H. V. Masefield, W. Shakspeare, H. J. Scott, J. F. Headrick, G. H. Alston, A. J. Denison, Hon'ble Mr. Stanley Bois.

For part of the year Hon'ble Mr. W. Henry Figg, Messrs. J. B. Coles, Wm. Saunders, J. R. E. Ryan, E. D. Harrison, Oliver Collett, George Hathorn, G. F. Traill, R. S. Templer, Duncan Skrine, served as members.

FINANCES.

The total collections paid into the Ceylon Tea (New Markets) Fund on account of the Export Duty on tea from 1st January to 31st December, 1902, amounted to Rs. 374,450-65.

The usual interim summary of accounts for the half yearly periods ending 30th June, 1902, and 31st December, 1902, with various connected statements of Charges and Discharges are appended, also statements showing total Receipts and Expenditure as from 1894 to 31st December, 1902.

MINUTES OF PROCEEDINGS.

The Minutes of Proceedings of the Meetings of the "Thirty Committee" have been regularly forwarded to Government for information and guidance after confirmation.

GOVERNOR IN EXECUTIVE COUNCIL.

During the year the approval of the Governor in Executive Council was obtained to the following appropriations of the proceeds of the levy as from time to time desired and determined by the "Thirty Committee."

- 1. Ceylon Tea on the Continent of Europe. Amount appropriated and sanctioned by the Governor in Executive Council per letter dated 11th February, 1902, for advertising Ceylon Tea on the Continent of Europe during 1902, £2,500 Sterling at Exchange 1/4 per Rupee ... Rs. 37,500-00
2. Representative in America. Amount appropriated and sanctioned by the Governor in Executive Council per letter dated 11th February, 1902, for advertising Ceylon Tea in America during 1902, £4,000 @ 1/4 ... Rs. 60,000-00
3. Ceylon Green Teas 1901-1902 Grant. Amount appropriated and sanctioned by the Governor in Executive Council per letter dated 11th February, 1902, for the purpose of payments under above Grant ... Rs. 20,000-00

- 4. St. Petersburg Exhibition, 1902. Amount appropriated and sanctioned by the Governor in Executive Council per letter dated 7th April, 1902, 42,000 Sterling @ 1/4 ... 30,000-00
5. Ceylon Tea in Afghanistan. Amount appropriated and sanctioned by the Governor in Executive Council per letter dated 4th June, 1902, for advertising Ceylon Tea in Afghanistan, &c. ... Rs. 6,000-00
6. Ceylon Tea to Boer Prisoners of War. Amount appropriated and sanctioned by the Lieutenant-Governor in Executive Council per letter dated 29th July, 1902, for expenditure in presenting the Boer Prisoners of War who are returning to South Africa with Gifts of Ceylon Tea ... Rs. 5,000-00
7. Ceylon Tea in Honolulu, West Indies, South Africa, or North Africa. Amount appropriated and sanctioned by the Governor in Executive Council for advertising Ceylon Tea in Honolulu, West Indies, South Africa or North Africa per letter dated 9th September, 1902 ... 7,500-00

CEYLON COMMISSIONER FOR EUROPE. REPORT FOR 1902.

GENERAL. I am glad that it was found possible to considerably augment the original sum placed at my disposal for this year's work on the Continent. Owing to savings effected in the grant for 1901, in salary and in the St. Petersburg Exhibition, an extra £2,000 was made available; and though the total sum did not permit me to do all I should have liked to do, to extend the operations of the campaign, yet it has sufficed to keep most of those interested in the work, who received support last year, and to induce them to work even harder.

RUSSIA.

Table with columns: Expenditure connected with preparations for the Exhibition, Balance cost of chairs and tables, Cost of spoons, etc.

Table with columns: Eck Bros., Frankfurt, B. Walther, Munich, etc.

SUMMARY OF PROPAGANDA.

Distribution of about 800,000 circulars as a supplement in 14 weekly periodicals and various Sunday papers and magazines.

Advertisements in principal Munich and Provincial papers leaderettes in the papers and magazines entitled "Voices for the Public" post-cards.

200,000 price lists, 115,000 leaflets, advertisements in Berlin newspapers.

REMARKS.

Imports in 1902 4,800 lbs. Do 1901 4,200

Table with columns: Including: by Batoum Customhouse, Tiflis, etc.

(Then follow figures of imports each of these four sorts by the different customhouses of Central Asia, which, if necessary I can send you, Henry Cooke.)

Table with columns: By Russo-Chinese Frontier, etc.

Table with columns: Including: (then follow details for each Russo-Chinese Customhouse), etc.

Table with columns: By Siberian Customhouses, etc.

Table with columns: Including: By Tiumen Customhouse, etc.

Table with columns: By Irkutsk (via Kiakta) Customhouse, etc.

Table with columns: By Sretensk, etc.

Table with columns: By Nikolaioff on Amour, etc.

Table with columns: By Vladivostok, etc.

Table with columns: By Ussinsk Frontier, etc.

Total by all Frontiers: Green, highest sorts; Medium sorts; Lowest sorts.

== no import, * duty free, - no data, O (standing alone) = less than 20 fms.

HENRY COOKE, December 1st, 1902.

1 pound = (roughly) 36 English lbs. or (exactly) 80 1/2 lbs.

1 pound = 40 fms., 1 fms. = 1 1/2 lbs. or 902 lbs.

These figures are most disappointing. The consumption of all Tea in France is not increasing apparently. But until the 1902 figures are complete it is not fair to assert that the consumption of heylon is falling off.

IMPORTS OF TEA INTO FRANCE AS FURNISHED BY THE FRENCH CUSTOMS. QUANTITIES CLEARED FROM BOND.

THE WORLD'S TEA PRODUCTION AND CONSUMPTION.

July, 1902.

DEAR SIRS,

In view of the present condition of the Indian and Ceylon Tea-producing Industries, we think it not out of place to once more draw special attention to the **absolute necessity** for making more strenuous efforts to promote the use of British-grown Tea, both Black and Green, in every available market in the world, many of which have not yet been tried with our produce.

We are, Dear Sirs,

Yours faithfully,

GOW, WILSON & STANTON.

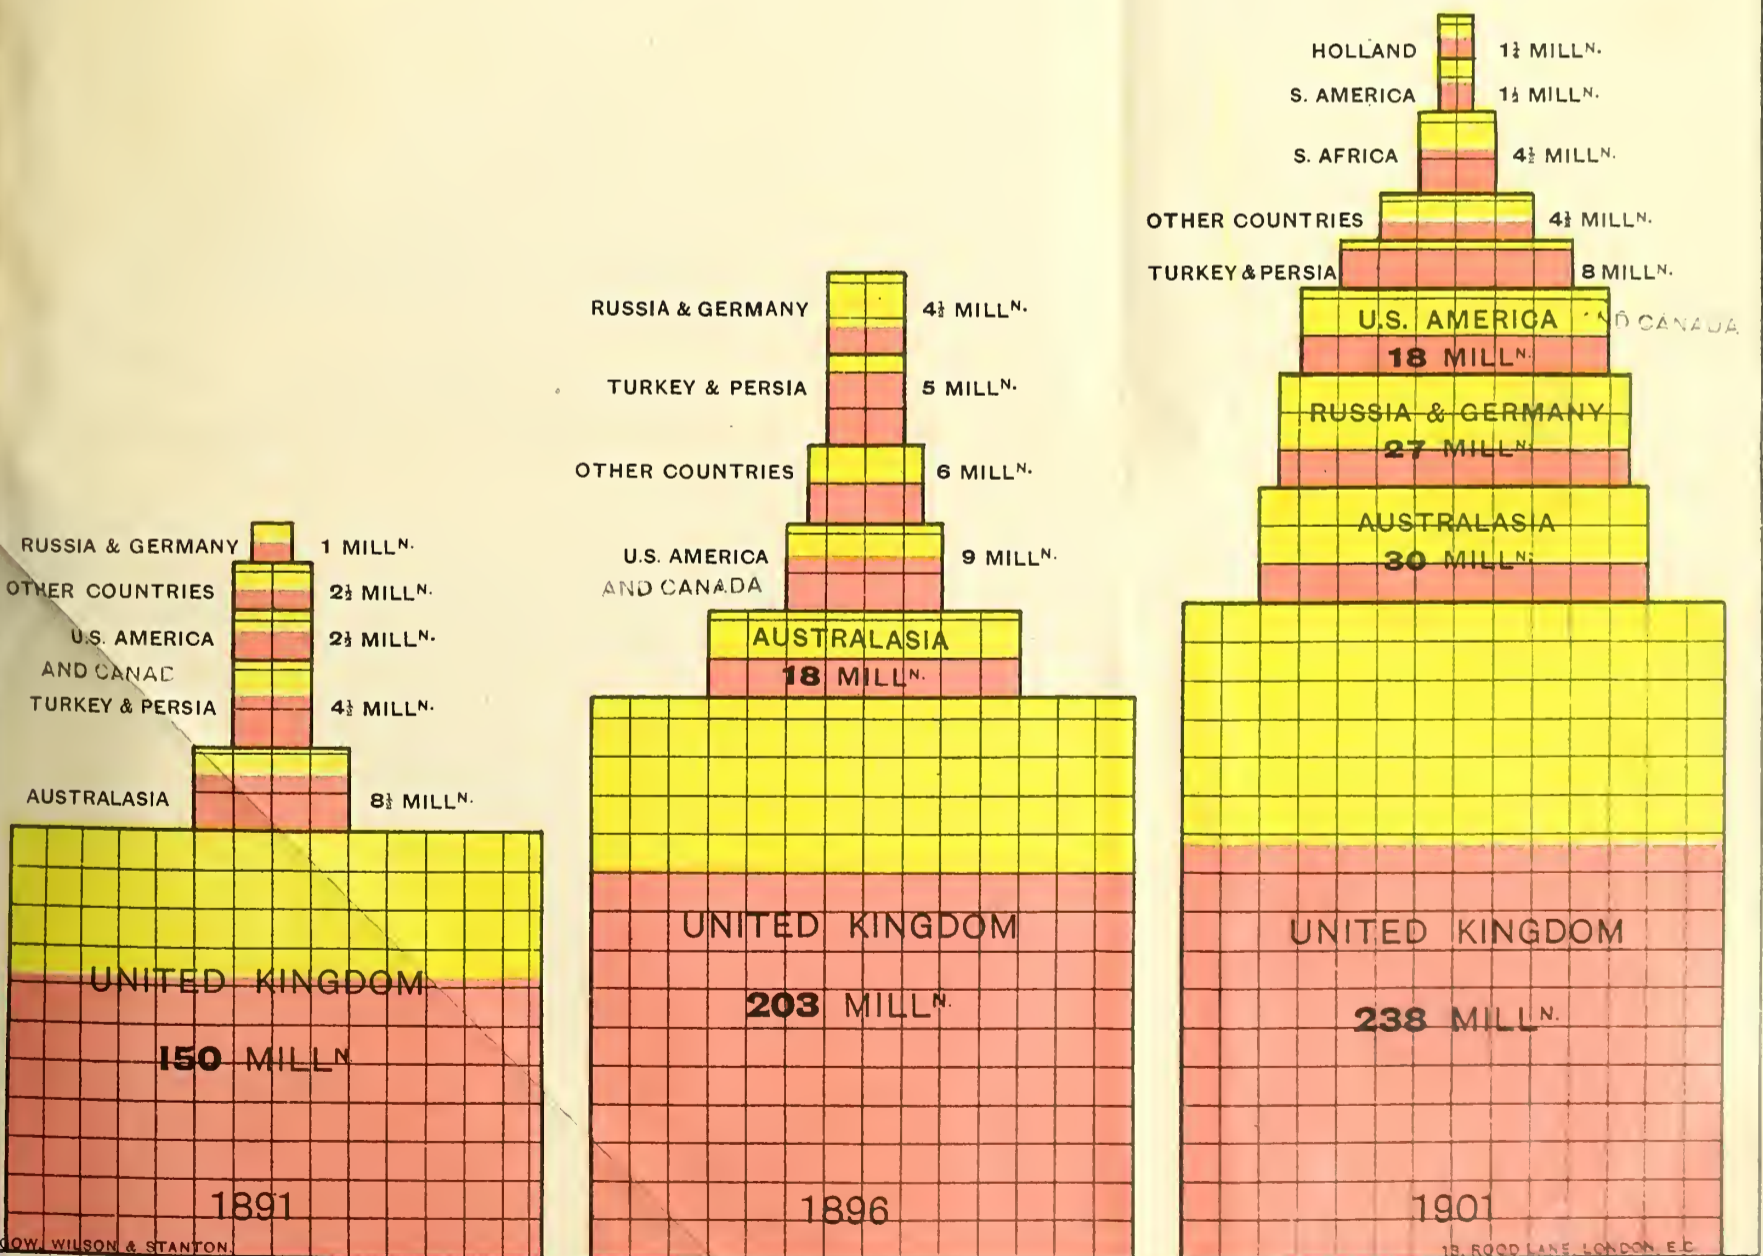

13, ROOD LANE, LONDON, E.C.

THE WORLD'S CONSUMPTION OF INDIAN & CEYLON TEA.

1891

1896

1901

EACH SQUARE REPRESENTS ONE MILLION POUNDS OF TEA. INDIAN BEING SHOWN IN RED AND CEYLON IN YELLOW.

GOW, WILSON & STANTON.

13, ROOD LANE, LONDON, E.C.

The large areas of land brought under Tea cultivation in India and Ceylon during recent years, which are now coming heavily into bearing, have caused a reduction in the value of Tea sufficiently serious to threaten the existence of the Industry.

INDIA.				CEYLON.					
	Area of Tea in acres.		Total Exports in lbs.		Area of Tea in acres.		Total Exports in lbs.		
1894	...	400,527	...	128,600,000	1894	...	289,000	...	84,591,714
1895	...	415,717	...	135,894,648	1895	...	305,000	...	97,939,871
1896	...	433,280	...	145,000,026	1896	...	330,000	...	108,141,412
1897	...	470,119	...	152,811,422	1897	...	350,000	...	116,054,567
1898	...	501,680	...	156,668,402	1898	...	364,000	...	119,769,071
1899	...	515,658	..	172,696,137	1899	...	378,000	...	129,894,156
1900	...	522,487	...	185,641,303	1900	...	384,000	...	148,431,639
1901	...	,	...	180,841,237	1901	...	387,000	...	146,310,638

In spite of constantly expanding outlets, consumption has proved unequal to compete with supply even at continually reducing prices. Many Estates do not pay at the present time, and unless a change for the better occurs, some properties must eventually go into liquidation.

Another feature may prove dangerous to the Industry, viz.: the possibility of China exporting larger quantities of common Tea now that the export tax has been reduced to an *ad valorem* duty and therefore falls but lightly on low-priced Tea, added to which the present low price of Silver is all in favour of increased export from China.

AVERAGE PRICE OF INDIAN & CEYLON TEA IN LONDON.

— The black line shows the average price of Indian Tea.
 The dotted " " " " Ceylon Tea.

Until consumption overtakes production the Industry cannot be in a healthy state.

To attain this end only two courses are open:—

The extension of markets—or the curtailment of supply.

Extension of markets seems the most feasible remedy, and has so far been attended with distinctly beneficial results, but a far more rapid development is necessary for the well-being of the Industry.

Now that Ceylon has increased its export tax on Tea by 50%, and thus raised its annual funds for developing new outlets from £20,000 to £30,000, there is good ground for hoping that greater efforts will be made, more especially by encouraging the manufacture of Green Tea.

Should India's petition to the Viceroy for an export tax on Tea be accorded, this should give her an annual sum of about £16,000 instead of the £6,000 so far annually raised by the voluntary levy; she would then have more funds for promoting the native consumption of Black Tea as well as for encouraging the manufacture of Green Tea.

The world's annual consumption of Green and Uncoloured Tea amounts to nearly 90 million pounds. Out of that total Ceylon last year contributed about 1 million pounds and India only 70,000 pounds. Surely it cannot be impossible for British Tea Planters to adapt the style of their produce to the wants of the large body of consumers of such Teas, and thus supply some portion at least of a new and almost untried market.

This Green Tea market appears to be the most promising field for exploiting at the present time. The manufacture of such Tea has the additional advantage of reducing the supply of Black, as for every pound of Green Tea made a pound of Black would be displaced. Hence the advantage obtained would be two-fold.

The curtailment of output is not such an easy matter and requires the co-operation of a large body of Planters both in India and Ceylon, whose interests are perhaps not on all points quite identical.

The diagram on the first page shows how rapidly the World's consumption of British-grown Tea has increased. The development in foreign markets during the last 11 years has been remarkable, and has had the effect of saving the Industry, so far, from a crisis such as may yet be probably averted if strenuous efforts are made in the way of more vigorously opening up existing outlets and finding new means of exploiting hitherto untried markets.

The World's production and consumption of Tea in the years 1895 and 1900, as nearly as can be ascertained, are shown below:—

1895.					1900.

				Surplus lbs.	47,166,178			Surplus lbs.	29,667,330	

In the former year production and consumption of Indian Tea pretty nearly balanced although China Tea was over-produced, with the result that exports from that country have rapidly declined ever since, and the average price has fallen to an extremely low point.

In 1900 production of British grown Tea was far in excess of requirements, the result being also a heavy fall in value. The moral to be drawn from the over-production of China may well be used as a lesson by Indian and Ceylon Tea Growers before disaster overtakes the Industry.

The Tea-drinking capacities of the world appear by no means exhausted, and there is therefore no reason why, with little Tea land being planted out either in India or Ceylon, consumption should not, with judicious energy on the part of Planters, soon overtake production.
