"Agriculture is the most healthful, most useful, and most noble employment of man."—WASHINGTON.

THE TROPICAL AGRICULTURIST:

(ESTABLISHED 1881.)

A MONTHLY RECORD OF INFORMATION FOR PLANTERS

OF

TEA, CACAO, COFFEE, PALMS, RUBBER, CINCHONA, SUGAR, FIBRES, COTTON, TOBACCO, SPICES, CAMPHOR, RICE,

AND OTHER PRODUCTS SUITED FOR CULTIVATION IN THE TROPICS:

Circulating in India, Ceylon, Burma, Straits, Java, Sumatra, Borneo, Northern Australia, Queensland, Fiji, Mauritius, Natal, East and West Africa, West Indies, South and Central America, California, Southern States, and throughout Great Britain.

EDITED BY

J. FERGUSON,

of the "CEYLON OBSERVER," "CEYLON HANDBOOK AND DIRECTORY," *&c.*

"It is both the duty and interest of every owner and cultivator of the soil to study the best means of rendering that soil subservient to his own and the general wants of the community; and he, who introduces, beneficially, a new and useful *Seed, Plant or Shrub* into his district, is a blessing and an honour to his country."—SIR J. SINCLAIR.

VOL. XX.

[Containing Numbers I. to XII.: July, 1900, to June, 1901.]

CEYLON: A. M. & J. FERGUSON, COLOMBO.

BATAVIA: G. KOLFF & CO.

1901.

TO OUR READERS.

In closing the Twentieth Volume of the "**Tropical Agriculturist,**" we would as usual direct attention to the large amount of useful information afforded and to the great variety of topics treated in the several numbers. From month to month, we have endeavoured to embody in these pages the latest results of practical experience and scientific teaching in all that concerns tropical agriculture; and our ambition has been to make this periodical not only indispensable to the planter, but of service to business-men and capitalists, never forgetting that agriculture trenches upon every department of human knowledge, besides being the basis of personal and communal wealth.

While directing our attention chiefly to the products prominently mentioned on our title-page, we have always taken care to notice minor industries likely to fit in with sub-tropical conditions; and our readers have an ample guarantee in the index pages before them, that, in the future, no pains will be spared to bring together all available information both from the West and East, the same being examined in the light of the teachings of common sense as well as of prolonged tropical experience in this, the leading Crown and Planting Colony of the British Empire.

Special attention has, during the past year, been given to the introduction and extension of an industry in rubber-yielding trees (more especially in the planting of Para and Castilloa trees), and much literature on the subject will be found throughout our pages; also on cacao in Central America and the West Indies as well as in Ceylon; to "Spices" of various kinds (nutmegs, camphor, &c.); to palms, especially "coconuts" in different districts; to coffee and allied products in Brazil, Mexico, Costa Rica, East Java, Nyassaland, British Central Africa; Liberian coffee in Sumatra, Java, the Straits Settlements; and to other new developments in palms and tobacco planting, &c., in the Malayan Peninsula, Sumatra and North Borneo, as well as in this Island.

The Tea-planting Industry has sprung into so much importance in India (South as well as North) and Ceylon, as also in Java, that a considerable amount of space is naturally given to this great staple; and with reference to all Companies' Reports, to Sales and Prices, as well as to hints for economising, we think it will be admitted by impartial judges that the *Tropical Agriculturist* should be filed, for the convenience of planters, in every Tea Factory in this Island, in India and in Java.

A full and accurate Index affords the means of ready reference to every subject treated in this, the Twentieth Volume, which we now place in our subscribers' hands, in the full confidence that it will be received with an amount of approval, at least equal to that which has been so kindly extended to its predecessors.

To show how fully other Products besides Tea are treated in this volume, we may mention the number of entries under several headings as follows:—Coffee (including Liberian) 44; Cacao 28; Indiarubber 70; many to Gutta Percha; to Coconuts and other Palms, Rice and other Grain, Cinchona, Camphor, Cloves, Fibres, Tobacco, Fruits and Miscellaneous Products nearly 1,000. In the 20 volumes, the references to Rubber, Cacao and Coffee number many thousands, as also to Coconuts and other Palms.

A "Topical Index" to the twenty volumes is in course of preparation.

We are convinced that no more suitable or useful addition can be made to a Planting Company's Library or gift to a tropical planter or agriculturist, whether he be about to enter on his career, or with many years of experience behind him, than the twenty volumes of our periodical which we have now made available. They are full of information bearing on every department and relating to nearly every product within the scope of sub-tropical industries.

In conclusion, we have to tender our thanks to readers and contributors, and our wish that all friends may continue to write instructively and to read with approval; for then, indeed, must the "**Tropical Agriculturist**" continue to do well.

"LITERARY REGISTER" SUPPLEMENT.

(See after the "Tropical Agriculturist" Volume).

☞ **All Planters of New Products or Pioneers in new lands should not fail to order this periodical as their best instructor—Every Tea Factory, Coconuts or Cacao Store ought to have a file of the TROPICAL AGRICULTURIST, which contains a vast amount of information about Tea, and a Record of the Tea and other Produce Sales.**

The Portraits and Biographies of some more OLD COLONISTS AND PLANTING PIONEERS are likely to appear in the next Volume.

ORDER FOR THE

"TROPICAL AGRICULTURIST."

.....

....1901.

Sirs,

Please forward the above publication from the beginning of Vol. XXI, *1st July, 1901.*

Please send also (lettered as for..... .....Estate) *Vols.* I, II, III, IV, V, VI, VII, VIII, IX, X, XI, XII, XIII, XIV, XV, XVI, XVII, XVIII, XIX AND/OR XX, *for* 1881-2, 1882-3, 1883-4, 1884-5, 1885-6, 1886-7, 1887-8, 1888-9, 1889-90, 1890-91, 1891-2, 1892-3, 1893-4, 1894-5, 1895-6, 1896-7, 1897-8, 1898-9, 1899-1900, AND/OR 1900-1901.

I am, Sirs,

Yours faithfully,

.....

To Messrs. A. M. & J. FERGUSON,

"CEYLON OBSERVER" OFFICE,

COLOMBO, CEYLON.

SUBSCRIBERS TO THE

"TROPICAL AGRICULTURIST"

are reminded that with the June Number, already received by them, and the Index and Title-page now issued, the TWENTIETH VOLUME (1890-1901) is closed.

SUBSCRIPTIONS are due payable in advance for 1901-1902, at the following rates:—

For Ceylon and India	Yearly ... R12		For Europe, &c.	Yearly £1 6.	
	Half-yearly ... R7			Half-yearly 15s.	

NB.—Subscribers to the *Ceylon Observer* or *Overland Ceylon Observer* R4 (6s.) LESS per annum.

Single copies, R1 ; *back copies*, R1½.

Per Bound Volume, R18 ; or £1 6s.

☞ Those who have not settled for past subscriptions are requested to do so by return of Post, and to send Cheque, Post Office Order, or Bank Draft in favour of A. M. & J. FERGUSON, Colombo.

Covers for binding the Twentieth Volume, July 1890 to June 1901 (878 pages) can be obtained for R1·50. Cost of binding and cover R2·50.

WHAT IS THOUGHT OF

THE "TROPICAL AGRICULTURIST."

A gentleman resident in the Central Province, who has as good opportunities of knowing what is of benefit to Planters as anyone we know, sent us the following explicit testimony to the value of the "*T.A.*":—

"Since its commencement, I have regularly seen and perused the *Tropical Agriculturist*. There can be but one opinion that its scope and object are highly important, and that it supplies a distinct desideratum, which it is to the interest of every estate proprietor, to have available in the bungalow for the use of his *locum tenens*, or superintendent. As a magazine it provides varied and instructive fresh literature at intervals; deprived, as most in Ceylon are, of easy access to libraries; and as years go by it will growingly become 'The Ceylon Encyclopædia' with reference to agricultural operations. Viewing estate property as practically a permanent investment to any proprietor, the trifling charge of R12 per annum—a rupee a month—is certainly of no account, provided the separate numbers are kept and bound together yearly as a book of reference for the benefit of the manager and his successors. In that light, as the property of an estate to be handed over just as much as its office furniture, few proprietors would probably refuse to authorise its being taken and filed regularly (if the periodical was brought under their notice), more especially as on looking over the most recent volume one cannot fail to see how much valuable information on 'Tea' has been collated. In the belief that 'Tea' has restored prosperity to Ceylon, and that plantation property is a good investment for capitalists, such should not omit the office and connected equipment so advisable on all 'pucka' estates, a part of which should be the *Tropical Agriculturist*. I find I have gone on writing, but, as I am getting the numbers for the past year ready to be bound, the volume is before me."

THE VALUE OF THE "*T.A.*" to CEYLON ESTATE OWNERS.—A planting correspondent wrote some time ago:—"I think proprietors should supply every tea estate with the *T.A.* The information in it with regard to everything in connection with tea, &c. is invaluable: it would pay its value over and over again. Owners of estates should not leave it to hard-up superintendents to take it in."

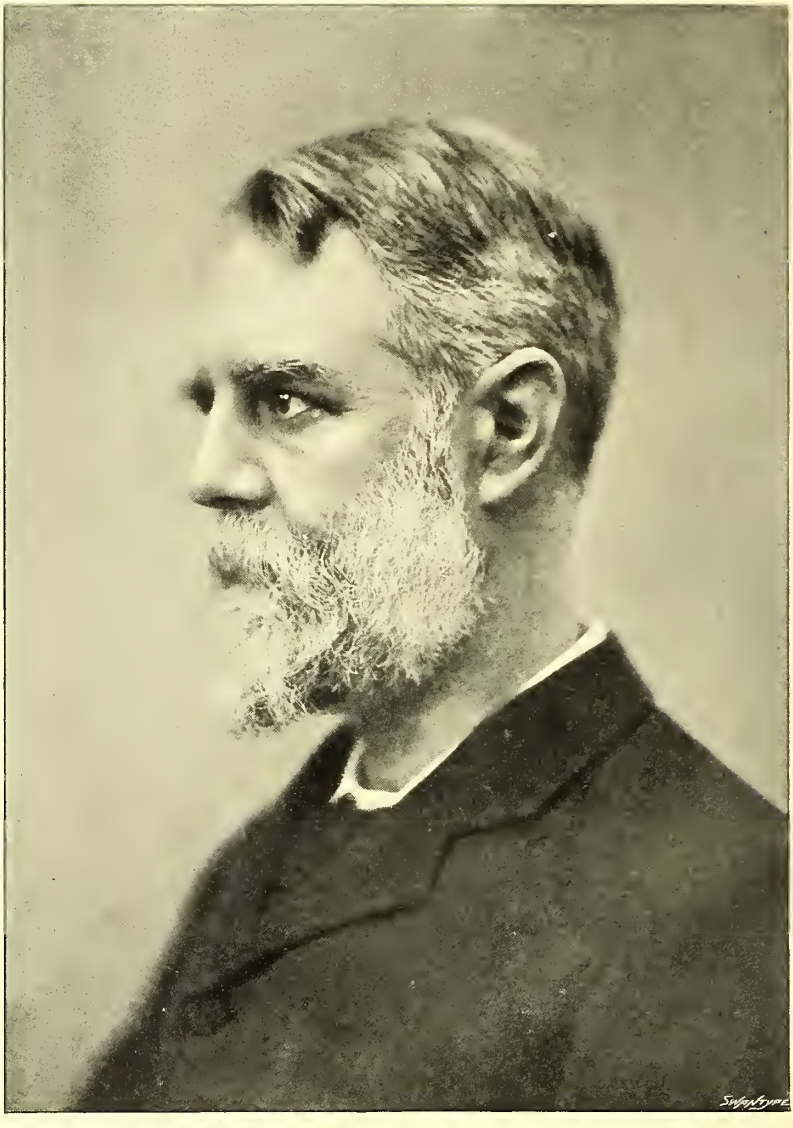
A Correspondent writes:—"I venture to say the volumes of the *Tropical Agriculturist* will be at a premium a few years hence: it is a book which is bound to rise in value as time rolls on, and subscribers will probably, if they so choose, be able to sell at a handsome profit, besides having had the benefit of using the information in the meantime."

From a Proprietor:—"I wonder how many planters know what they lose in not subscribing to your wonderful publication? The cost is absolutely nothing, compared to the convenience of having in a bound book all that is interesting and necessary in the literature of their calling. Information culled from a thousand sources, price lists of all produce sold locally, and home advertisements not seen elsewhere, and a hundred other things necessary for them to see and to know. The *T.A.* is, in fact, a convenient file of useful information daily arising and permanently preserved."

Sir W. T. Thistleton Dyer, F.R.S., F.L.S., C.M.G., of Kew Gardens:—"Sir Joseph Hooker and myself always look out for the successive numbers of the *T.A.* with eagerness, and I keep a file in my office for reference. It is impossible to speak too highly of the utility of such a publication and of the way it is managed."

Sir George King, late of the Calcutta Government Museum:—"I know your *Tropical Agriculturis* well, having carefully secured every number since the beginning. You have succeeded in making it a wonderfully useful magazine of information for planters."

Surgeon-Major Bidie, F.L.S., of the Government Central Museum, Madras:—I find the *Tropical Agricultrist* a most interesting and useful publication. It finds a place on the table of our Public Library and is much prized."



HENRY TRIMEN.

The TROPICAL AGRICULTURIST
MONTHLY.

Vol. XX. COLOMBO, JULY 2ND, 1900. No. 1.

"PIONEERS OF THE PLANTING ENTERPRISE IN CEYLON."

(Third Series.)

THE LATE HENRY TRIMEN,

F.R.S., F.L.S., M.B., &C.

THERE can be no difference of opinion as to the claim of the late "Dr. Trimen"—to quote the title by which he was universally known and esteemed in Ceylon—to a place in the portrait gallery and biographical series of our *Tropical Agriculturist*. His predecessor, Dr. Thwaites, has already been duly noticed; but Dr. Trimen, while an equally accomplished scientist, did far more in the direction of economic botany in Ceylon, and it was his fortune to watch the decay of *Coffea Arabica* and to encourage the succeeding industries in Cinchona and Cacao, and above everything to do all in his power to promote the success of our present staple Tea. The Annual Reports on the Royal Botanic Gardens, for which he was responsible, were models of what such Reports should be, and especially were they full and practical in their treatment of new economic products as may be judged from the many extracts we have embodied in the Planting and Agricultural Review of our "Ceylon Handbook and Directory." He was also a frequent contributor to our monthly periodical, the convenience and usefulness of which he much prized, and he never failed to give a prompt reply to the many letters of enquiry as to plant troubles, or experimental culture, made to him by us on behalf of planters up and down, and even from beyond, the Island. A more obliging official, more attentive correspondent, or more pleasant friend and genial man than Dr. Trimen never came to Ceylon. Apart from our own personal experience, we are simply echoing the very high opinion entertained by such competent judges as the late A. M. Ferguson, C.M.G., and W. Ferguson, F.L.S.; which his subordinates—native as well as European—were deeply attached to him.

With so much by way of preface, we will now proceed to extract from the "Journal of Botany" for December, 1896, the brief but appreciative memoir written by the editor, Mr. James Britten, F.L.S., Senior Assistant Department of Botany, British Museum (Natural History) South Kensington. Dr. Trimen himself had been editor of this Botanical periodical at one time and it was very fitting therefore that justice should have been done to his career and memory in its pages, as follows:—

IN MEMORY OF HENRY TRIMEN.

(WITH PORTRAIT.*)

Henry Trimen was born on October 26th, 1843, a 3, Park Place Villas, Paddington, London. He was educated at King's College, London, firstly in the school and subsequently on the medical side of the College. Very early in life he showed a strong animals and plants with much ardour. His elder

* We are indebted for a supply of this portrait to the printers of the "Journal of Botany."

liking for natural history, and collected specimens of brother Roland was devoted to the same pursuits, and well remembers how, when it became a matter of necessity to make a choice among the "omnium gatherum" of organic objects amassed, it was solemnly decided that Henry should restrict himself to the study of plants, while his senior was to devote his attention to insects. Holidays and half-holidays were almost always occupied by collecting excursions in the environs of London; and school vacations, with the annual visit of the family to the seaside, gave golden opportunities for field-work which were never neglected. While he was still at King's College School he had begun to form an herbarium, and frequently visited the Botanical Department of the British Museum for the determination of his collections. He was than a steady and careful worker, and a careful observer of all the conditions of plant-life.

He began his medical studies at Kings's College in the autumn of 1860. The winter of 1864 he spent at Edinburgh University, where, besides attending to his medical studies, he acted as clinical assistant to Prof. Bennett. He joined the Edinburgh Botanical Society, and secured the friendship of Prof. Balfour and many of the younger botanists of Edinburgh. He graduated M.B. with honours at London University in 1865, and for a short time he acted as district medical officer in the Strand district during an epidemic of cholera.

It was in 1864 that I made Dr. Trimen's personal acquaintance. The Society of Amateur Botanists, which had been established in 1862 and of which some account will be found in this Journal for 1864, p. 287, was then in the best period of its not very long existence, and Mr. Newbould took me to one of the meetings and introduced me to Mr. Trimen and to Mr. Dyer—two names which were then, like their possessors, intimately associated. To a lad of eighteen, strange to public meetings and shy of strangers, these young men of twenty-one seemed superior beings—an impression intensified by a certain loftiness of tone which, in Trimen's case, soon disappeared upon more intimate acquaintance. Trimen and Dyer were the leading spirits of the Society, which, however, also numbered men who have distinguished themselves in botanical work during later life (of whom Mr. W. G. Smith is a conspicuous example), as well as others whose attachment to botany was but temporary.

At this period, and for many years after, Trimen took a prominent part in the work of the Botanical Exchange Club, and this brought him into frequent communication with Mr. J. G. Baker, which developed into personal friendship when the latter came to town in 1866. Somewhat later than this he formed the acquaintance of the Hon. J. Leicester Warren (afterwards Lord de Tabley), who, with Mr. Newbould and Mr. Dyer, were his chief botanical friends. With the last of these he projected in 1866—in which year he added *Wolffia arrhiza* to our British list—the *Flora of Middlesex*, which, on its publication in 1869, was at once recognized as an epoch-making book in the history of British botany, and has formed a model for subsequent compilers of local floras. It is unnecessary to speak at length of a book so well known and so deservedly admired. It has always been supposed that Dr. Trimen was responsible for the larger portion of the undertaking; and the interleaved copy of the *Flora*, which, on going to Ceylon, he left in the Department of Botany, is full of MS. notes which will interest future investigators of the plants of the county.

Although he had completed his medical course with distinction, it was manifest that Trimen's vocation lay in the direction of botany. He was well acquainted with Mr. Bennett and with Mr. Carruthers, the latter of whom had shown every encouragement to him and to Mr. Dyer at the beginning of their botanical career, and had thus contracted a warm personal friendsoip with them, which in Trimen's case was never broken. Mr. Dyer had also a desire for botanical work, and, as I have said elsewhere,* it was only after much deliberation that Trimen was chosen to fill the post of Assistant in the Department of Botany in the British Museum. It is curious to speculate on the turn that events might have taken had the choice been otherwise. In 1877 Trimen became botanical lecturer to St. Mary's Hospital—a post which he retained for many years.

Although it was not till 1870 that Trimen's name appeared on the little-page of this Journal in the capacity of assistant-editor, he had for some time had much to do in its management. During Seeman's frequent absences from England, Mr. Carruthers had acted as editor, although his name never appeared in that capacity; but from 1870 onwards Trimen was responsible in every way for the conduct of the Journal, although his name did not appear as editor until after Seemann's death in 1871. He at once reduced the price of the Journal and introduced many new features, the result being an increased circulation and a much improved table of contents. The pecuniary loss entailed, however, was considerable, although towards the end of his editorship the Journal paid its way. The Journal has from the first been unofficially associated with the British Museum. Dr. Seemann found the Botanical Department a convenient place of reference, and subsequent editors have been members of the Museum staff, so that, although the Museum is in no way responsible for what may appear in its pages, it has furnished a convenient medium—more needed, perhaps, formerly than at present—for keeping the botanical world *au courant* with what is done in the National Herbarium. Dr. Trimen, as a loyal servant of the Trustees, systematically recorded the progress of the collections, and the importance of the records thus published is shown by the fact that in

* *Journ. Bot.* 1895, 183.

such works as De Candolle's *La Phytographie*, this Journal is frequently cited as the source whence information regarding the Museum collections has been derived. Besides the work of editing, Dr. Trimen enriched the Journal with numerous communications dealing with British plants from various aspects, bibliographical and other matters, descriptions of new genera and species, reviews of books, and the like. His work throughout is characterized by extreme care. He did much to elucidate the British species of such critical genera as *Polygonum* and *Rumex*, and in the latter genus he commemorated his friend Mr. Warren by naming in his honour a form subsequently identified with *R. Knafii*.* He also contributed to the Linnean Society's Journal and to other periodicals; fifty papers stand under his name in the Royal Society's *Catalogue of Scientific Papers*.

In 1872-3 Trimen took a leading part in the promotion of certain reforms in the Linnean Society, of which body he had become a Fellow in 1866. The bringing about of these was attended by a period of excitement rare in the annals of a learned body. Some account of what took place may be found in the Journal for these years; and the result was in every way beneficial, although in the course of the proceedings necessary to secure reform, certain regrettable incidents occurred. Those who remember the formal meetings of pre-reformation days will agree that the contrast between then and now is nothing short of startling. It is to Trimen that we owe the small but important regulation by which the dates of publication of each part of the Journal are printed on the back of the title to each volume.

In 1875 began the publication of what was in some respects Trimen's most noteworthy work—*Medicinal Plants*—which he undertook in collaboration with Prof. Bentley. This was not concluded until 1880, the last part having been published in February of that year, after Trimen had left England for Peradeniya. This important change in his career occurred in December, 1879, to the great regret of his colleagues in the Museum.

This seems a fitting place in which to pay a tribute to those personal characteristics which made Trimen popular among a large circle of friends. Bright and cheerful in manner, with a sufficient sense of humour and a good acquaintance with general affairs and literature, he was an extremely pleasant companion; while as a Museum official he was always courteous and helpful to enquirers, and both ready and willing to impart the knowledge he possessed. "His kind-hearted and cheerful nature," writes his brother, "with his unflagging zeal and activity in the pursuit of his favourite science, won him many faithful friends and associates—especially when he held the post of Lecturer on Botany at St. Mary's Hospital, and led his class in the field no less ably and enthusiastically than he did in the lecture-room. I think that his life," he adds, "was, until quite lately, a very happy one. He was able to give himself unrestricted to the work he loved best, and in its practical application to the tropical gardens of which he was in charge for sixteen years was unquestionably most successful. He was free from family cares or pecuniary anxieties, and up till two years ago enjoyed unusually good health, while he had the happy gift of winning the affection and respect of all those with whom he had to do."

On his arrival in Ceylon, Trimen threw himself with characteristic energy into the various branches of his work. This involved an entire rearrangement of the Gardens—a task the need and execution of which are well set forth by M. Treub, of Buitenzorg, a highly competent judge in such matters. The Garden, he says, was "for many years under the direction of Dr. Thwaites, a man of real merit, but who thought a botanic garden in a tropical country should be in some manner a reduced copy of the virgin forest. This system, more original than meritorious, excludes any methodical arrangement of plants and necessarily restricts the number of specimens. Dr. Trimen, as soon as he arrived in Ceylon, realized the disadvantages of the plan of his predecessor. To distribute over an area of sixty hectares, without any order, a great number of plants, for the most part not labelled, was fatally to embarrass the scientific use of the rich collections that had been brought together. So Dr. Trimen did not hesitate to adopt a new arrangement of plants according to the natural system, and to label them as far as it was possible for him to do so. With branch establishments upon the plain and upon the mountain, the garden of Peradeniya has before it a brilliant future."*

His life in Ceylon was very pleasant, any feeling of isolation being greatly modified by the visits of other botanists, such as Dr. Marshall Ward and Mr. H. N. Ridley, or of other scientific men, such as Prof. Ernest Haeckel, who, in his *Visit to Ceylon*, speaks warmly of Trimen's genial hospitality and "valuable instruction"—"the seven days I spent in his delightful bungalow were indeed to me seven days of creation." In such company Trimen would take expeditions into parts of the island hitherto unexplored by him, never failing to discover some interesting novelties.

This is not the place in which to consider Trimen's services to economic botany; his annual reports show that he developed the resources of the Garden in every direction, and his contributions to quinology were important. But something must be said about his botanical work in Ceylon. As soon as he had settled down, he became conscious of the need of a flora of the island. In 1885 he issued a catalogue of the plants, with the vernacular names and references to Thwaites's *Enumeratio*; and in this Journal for the same year he published a series of notes on

* See *Journ. Bot.* 1896, 79.

* *Annual Report of Smithsonian Institution*, 1889-90, p. 390.

Ceylon plants, in which were included many novelties: a further list of additions will be found in the volume for 1889. During a visit to England in 1886, he went carefully through Hermann's Ceylon Herbarium, the basis of Linnæus's *Flora Zeylanica*, and published in the Linnean Society's Journal (vol. xxiv.) a list of the plants therein contained, with the modern equivalents of the Linnæan names. The short preface to this is an excellent example of Trimen's work, giving as it does a history of the herbarium, and general notes upon its contents.

These of course were but preliminaries to what was to have been the great work of his life—which alas! he was not destined to finish. In 1893 appeared the first volume of the *Handbook to the Flora of Ceylon*—a work which as I said when reviewing it in these pages,* occupies towards colonial floras a position similar to that which the *Flora of Middlesex* holds with regard to that of this country. To that review readers must refer for an account of the work. Had the author been spared, it was his intention, as soon as this large undertaking was completed, to compile from it a Handbook of Ceylon Plants, analogous to Babington's *Manual*.

But it will cause no surprise to those who saw him when he was home last year that Trimen was unable to complete his enterprise. He had for years suffered from deafness, and this had become total, so that he was only able to carry on conversation with the aid of a pencil and paper. One leg was then entirely paralyzed, and although in spite of these and other troubles he maintained his old cheerfulness of demeanour, it was very painful to his old friends to see the state to which he had been reduced. We had hoped that he would not go back to Ceylon, but there were reasons—among them that anxiety to complete his Flora which, as we shall see, was with him literally to the last—which induced him to do so; and I think no one expected he would ever return to England.

I am indebted to his elder brother, Mr. Roland Trimen, a distinguished entomologist, for the following account of the closing scene of Trimen's earthly career:—

"After the attack in August last, which deprived him of all power in his left leg, my brother seemed to rally somewhat, though confined almost entirely to his room, being only taken out into the Gardens at his own request two or three times. On Wednesday morning, October 14th, he was suddenly seized with a feeling of chilliness and violent shakings of the hands and arms, his voice being at the same time somewhat affected. This he himself did not regard seriously, but Mr. Freeman at once went to Kandy to summon the doctor. He lay helpless all the day, and had to be fed with what little nourishment he was able to take. In the later half of the night he slept well, and on Thursday morning his first words were that he felt rather better, and must get up and do a little work at the 'Flora.' This he actually did in the afternoon, and with great effort made a few notes, which, Freeman writes, are scarcely decipherable. This pathetic endeavour still to work on seems to have been the last flicker of his strength; for during the sleepless night of Thursday, the 15th, his attempts to speak were almost inaudible, and on Friday he rapidly passed into a state of coma, though sometimes looking up and smiling when anything was done for him. He was evidently sinking all the afternoon and evening, but was as evidently free from any pain. Between nine and ten in the evening Mr. Freeman was called away for a little, and the hospital attendant on his return reported a change. As Mr Freeman entered the room Henry turned his head towards him, and then lay quietly back, and passed away without a tremour or movement of any kind.

"The funeral took place at Kandy on the morning of Sunday, October 18th, and was attended by two hundred of the European community and by a great number of natives, both headmen and Garden employes. Henry's old servant, Bob Appu, never left the back of the hearse throughout the route from Peradeniya; and on the previous day my nephew writes that he had about 400 applications from natives (old servants, village headmen, &c.) to see 'the old master.' The burial took place in the Mahaiyawa Cemetery, Henry's body being laid not far from the resting-place of his predecessor, Dr. Thwaites."

[The portrait here reproduced was taken by Messrs. Cameron during Dr. Trimen's visit to England in 1887.]

JAMES BRITTEN.

We may supplement the above with a few "notes" from a series of letters on local Botanists which recently appeared in the *Ceylon Observer*:—

The present state of knowledge of Ceylon Botany undoubtedly owes more to Dr. Trimen, who succeeded Dr. Thwaites in 1880, than even to the labours of his illustrious predecessors. Assuming the duties of head of our Botanical Department at the age of 39,* with an already established reputation in Europe as a botanist, he by his great acquirements and steady devotion to science rendered yeoman service to the botanical world generally for 16 years, his death, while truly in harness, occurring in October 1896. From the outset the reorganisation of his department upon more modern and utilitarian principles received his special attention, simultaneously with the investigation of the local flora, collecting and describing new species and elucidating ones hitherto imperfectly understood. He was an authority on Quinology, and in 1883 was engaged by the Madras Government to report on certain problems connected with the Cinchona industry of the Nilgiris. In 1886 he issued his Systematic Catalogue of *Flowering Plants and Ferns Indigenous to Ceylon* 8vo. now out of print; whilst in 1888 he published his *Hortus Zeylanicus*, being a classified list of plants grown in

* *Journ. Bot.* 1893, 375.

* Really in his 37th year.—ED. *T.A.*

the Royal Botanic Gardens at Peradeniya. As co-author of the voluminous and standard work, *Medicinal Plants* by Trimen and Bently, he was *au fait* in medical botany, which he turned to good purpose by establishing in Peradeniya Gardens a botanical Museum, containing collections of native and foreign drugs, fibres, timbers, grains, curiosities &c. Branch-gardens were founded by him at Anuradhapura and Badulla, in 1883 and 1886 respectively. The pages of various scientific journals, more particularly the *Journal of Botany*, of which he himself was editor from 1870 to 1880, were frequently enriched by Trimen's contributions on Ceylon Botany, and "no less than fifty papers" stand under his name at the Royal Society, of which he was a distinguished Fellow. His *magnum opus* is however, his *Flora of Ceylon*, which, unfortunately for the Colony, he did not live to finish. The completion of this work has, happily, been undertaken by the veteran Sir Joseph Hooker of Kew, Dr. Trimen having completed the first three volumes, with an atlas of plates, which bring the book as far down as Balanophoraceæ in the order of Bentham and Hookers Genera Plantarum, Sir Joseph has creditably accomplished his task, the fifth and last volume being now finished. The plan of Trimens's Flora is acknowledged to be a model of what such floras should be, it being, as far as completed by him, characterised by the critical insight and terse lucidity which always distinguished the author. Though the real value of Dr. Trimen's "Flora" cannot well be estimated, more especially as Thwaites' "Enumeratio" —though superseding preceding works—is of use to botanists only, an idea of its merit may be "inferred from the fact that, according to the preface one principal object of the work is to enable the observers to ascertain the name of any plant they may find growing wild;" afterwards learning "all that may may have been written about it, appreciating its relationship with other plants, tracing its geographical limits, and intelligently investigating its properties and uses." In 1896 shortly before his death, Dr. Trimen contributed to the "Journal of Botany," vol. XXXIV, *A preliminary List of Maldive Plants*, with notes, based on a collection of plants sent him from the Maldive Islands, it being his intention to write later a Flora of these islands. Trimen's name is perpetuated in *Ficus Trimeni* (and others); a tree of this species forms a handsome object in Peradeniya Gardens. Vol. XXXIV of the "Journal of Bombay" is dedicated to this *savant*, and the same volume contains a memoir and a portrait of him.

Still further we may give the closing passage of a brief notice by G. S. Boulger, F.L.S., F.G.S., Professor of Botany, City of London College, appended to Vol. V. of the "Ceylon Flora":—

The zeal with which, on his appointment as Director at Peradeniya in 1879, he took up Thwaites's work was seen in the thorough rearrangement of the plants in the Gardens in scientific order, in much work at economic botany, especially quinology, recorded in his annual official reports, and in a diligent exploration of the island for materials for the present work. He published 'Hortus Zeylanicus: A.... List of the Plants .... in the Royal Botanic Gardens, Peradeniya,' in 1888; a Catalogue of the Library .... in 1899; and a Hand-Guide to the .... Gardens,' in 1890, of which the last-named reached a fourth edition in 1894, whilst reference has also been made to his careful work upon Hermann's herbarium whilst in England in 1886. The climate of Ceylon, however, seems to have proved fatal to him. He aged prematurely, became totally deaf, and was partially paralysed; but, after being again in England during 1895, he insisted returning to Ceylon, hoping to finish the 'Handbook,' the publication of which had begun in 1893. Trimen died at Kandy, October 16th, 1896, and was buried near his predecessor in the Mahaiyawa Cemetery. His name was given by Dr. King, Calcutta, to the magnificent Singhalese banyan *Ficus Trimeni*. The memoir by Mr. James Britten in the 'Journal of Botany,' for 1896 (pp. 4-9-491), from which most of the above is taken, is accompanied by a portrait from a photograph; but his best memorial in the history of botany in Ceylon, is undoubtedly the present work, though he did not live to complete it. —G. S. BOULGER.

In conclusion, we give a couple of extracts from the *Ceylon Observer*. The first is part of an article written by us while absent in England, in defence of our friend against ignorant and impatient local criticism :—

'DR TRIMEN'S WORK IN CEYLON AND—LOCAL CRITICISM.

(From "*Ceylon Observer*," June 30th, 1896.)

"On the eve of the final departure of the Director of the Botanic Gardens, it may seem a little unkind and invidious to enter on controversy as to the merit and usefulness of his administrative, economic, and scientific services to the community. But to compare Dr. Trimen's work with that of Mr. —— of ———— —useful officer as the latter is in his own sphere—as was recently done by a planting correspondent of the *Ob erver*, is simply absurd. Take Dr. Trimen's latest work: "The FLORA of CEYLON" in three volumes—why, it is impossible to overestimate the value of this work for practical, educational, and scientific purposes in the Colony. For thirty years, we had been accustomed to listen to the late Mr. A. M. Ferguson's earnest desire that such a work should be prepared for the benefit of all who took an intelligent interest in the vegetation of the island. Dr. Thwaites' great work on Ceylon plants might well be complained of by any "practical planter" as above his head—being essentially a scientific botanists's book. But Dr. Trimen, while taking care to serve the purposes of science, and to be as full and correct as any reasonable botanist could desire, has added a series of most useful economic notes which simply makes his work a treasure house to the ordinary intelligent reader,—to all in fact who wish to know what can be said about each of our plants (useful and ornamental) and especially about the timber trees and economic products of the Island. That the highly accomplished and worthy Director should have persisted in this important undertaking to the sacrifice of his health, if not of all that makes life worth living, speaks highly for his conscientious devotion to duty and deserves the grateful acknowledgement, not only of the Government, but of every right-thinking man in the community. So much for the most important single work, perhaps, which has marked Dr. Trimen's Administration. But we are equally clear that never before in the history of the Island has more attention been given in our Botanic Gardens to every question bearing on the economic as well as scientific side of planting, and tropical agriculture generally, than during the past fifteen years. We speak of that we do know; for as editor both of daily and monthly issues, we have continuously been made the medium of requests for information, of puzzling questions, of plants forwarded for identification by planters—not to speak of our own many editorial queries—and we have never failed to receive the most prompt and satisfactory attention from Dr. Trimen."

Next we have the closing scene :—

"DEATH OF DR. TRIMEN.

(From "*Ceylon Observer*," Oct. 19th, 1896.)

"We regret to have to announce the death of Dr. Trimen, late Director of the Royal Botanic Gardens, which event took place on Friday

night at Peradeniya. The news of Dr. Trimen's death will be received not only in Ceylon, but in all scientific circles at home and abroad, with regret. His work was well-known and appreciated throughout Europe as an authority on many botanical questions, and it was in connection, with the completion of his Hand-book to the "Flora of Ceylon," that, after retiring from the active work of the position which he had held with so much distinction, he recently returned to Ceylon. When most men would have rested from labour Dr. Trimen, in face of trying deafness and weakness, bravely gathered his remaining strength to endeavour to finish the work he had taken in hand, "to enable observers in Ceylon to ascertain the name of any plant they may find growing wild...and to intelligently investigate its properties and uses." This work we hope, has, if not entirely, been almost completed. Dr. Trimen has died in harness, amidst the surroundings which marked a busy though quiet life. Our Kandy Correspondent writes:—"It is with deep regret that we chronicle the death of Dr. H. Trimen, late Director of the Royal Botanical Gardens, which occurred at the Director's bungalow, Peradenia on Friday night at ten o'clock. The deceased gentleman was in his usual health on Wednesday and was able to pay a visit to the Botanical Office, but he was seized with another attack of paralysis on Thursday, losing the use of his hands and his power of speech. In this state he remained till he expired on Friday night. The sad intelligence was received here on Saturday and came as a surprise to many. The deceased Director had served sixteen years under the Ceylon Government and his death is a very heavy loss to the island. Dr. Trimen even while ill and in bed was busily engaged on his monumental work, the Flora of Ceylon. The arrangements for the Funeral were made by the late Doctor's nephew Mr. Roland Trimen."

"THE FUNERAL.

"The Funeral cortege started from the Botanical Gardens, Peradeniya, at 7-15 on Sunday morning for St. Paul's Church, where the first portion of the funeral service was read. A large number of leading residents met the remains here. From the church the remains were conveyed to the General Cemetery, at Mahaiyawa, where a service was read by the Rev. E. A. Copleston who officiated. The coffin was covered with wreaths of flowers, which were afterwards placed on the grave. The Hon. A. C. Lawrie Puisne Judge, came specially for the funeral. Among those following the remains were the Hon. Allanson Bailey, District Judge de Saram, Messrs. Roland Trimen, Freeman, H. F. Macmillan (Curator), Vaughan, Munton, Ward, Fretsz, Bishop, Lowe, Alexander Philip, Caldecott, Gibbon, Siebel, Rix, Campbell, Skeen, Gray, Ralston White, Major Tranchell, Messrs, Tranchell Way, Sproule, Webb, Dove, De Lemos, Maddock, Gordon, Ferdinandus, Fleming, Captain Murray, Drs. Dias, Hardy, Anderson-Smith and Keith, Mrs. and Miss. Rouse, Mrs. and Miss Algernon Jonklas, Mrs. Skeen, and the Rev. Mr. Beven. Besides these there were following immediately behind the remains all the coolies, watchers and servants employed at the gardens. Dr. Willis, the Director, and Mr. Nock, Superintendent of Hakgalla Gardens were not present being engaged at Hakgalla, and a wire which was sent did not arrive in time to enable them to be present."

We take the following from *Men and Women* of the Time:—

"Trimen Henry, M.B., F.R.S., F.L.S., was born in London, Oct. 26, 1843, and was educated at King's College. He graduated M.B. at the University of London, 1865; was Curator of the Anatomical Museum of King's College, 1866-7; and Lecturer on Botany at St. Mary's Hospital Medical School 1867-72 He entered the Botanical Department of the British Museum, as Senior Assistant, May 1869, and held that appointment till Dec., 1879. He was appointed Director of the Royal Botanic Gardens, Ceylon, Jan. 1880, which post he still holds. He was editor of the *Journal of Botany*. 1872-79; and author of "Flora of Middlesex" (with Mr. Thiselton-Dyer), 1869; of the botanical portion of "Medicinal Plants," 4 vols., 1875-80; of a "Systematic Catalogue of the Plants of Ceylon," 1885; and of numerous papers on various branches of botanical science in the publications of the learned societies and scientific periodicals. Dr. Trimen has paid special attention to the economic aspects of Botany, particularly to the sources of drugs and other products, especially of tropical countries. In 1883, he was employed by the Madras Government to report on the botanical and cultural problems presented by the cinchona plantations in the Nilgiri Hills; and he has been the means of introducing into cultivation in Ceylon many useful and valuable products of other countries."

In conclusion we may quote the words of one who worked under him:—"I know nothing about Dr. Trimen but what is good, and I never had one single angry word from him. He was an excellent chief and a good and true friend, and I always felt as though I could do anything for him." Similar testimony is borne from all sides, and we may well say that in Dr. Trimen Ceylon lost one of its most distinguished, accomplished and useful public officers; while not a few officials, as well as Colonists and Ceylonese, lost a loyal and warm-hearted friend.

OVERHEAD NETTING FOR TOMATOES.

A correspondent of the *Garden and Field* says on this subject:—this is a plan I have not tried, but I know where it is used with success. A number of stakes 2 inches or so in thickness, and from 18 inches to 24 inches long, are prepared and driven in the ground at intervals along the row of plants, thus:—

o o o o o
o o o o
o o o o o
o o o o
o o o o o

The stakes are driven so that the tops are even and about 12 inches out of the ground; and over the whole a piece of wire netting of 2 or 3 inch mesh is stretched and nailed to the tops of the pegs. The plants are allowed to grow up through the netting and spread over the upper surface. I believe the plan answers well, and has the merit of being no trouble after being put up. In this case the growth of the plants is not regulated. I describe it for the benefit of readers, and am trying it on a row of plants. I shall, however, use a less number of pegs, and put crosspieces of batten to support the netting.

If the tomato plants show signs of disease by an unhealthy appearance of leaves, or scabby fruit, they should be at once sprayed with Bordeaux mixture of a strength of 4 lb. of bluestone, 4 to 6 lb. of quicklime, and 40 gallons of water.—*Queensland Agricultural Journal.*

PINK LILY OF THE VALLEY.—Dr. Houseman, of Houghton-le-Spring, sends us a spike of Lily of the Valley, in which the flowers are very small, but of a distinct rose-pink colour. The variety is now rarely met with, but in the time of our fore-fathers it was more frequent, though never abundant.—*Gardeners' Chronicle.*

AGRICULTURAL EDUCATION IN GREATER BRITAIN.

PAPER READ BEFORE THE FOREIGN AND COLONIAL SECTION OF THE SOCIETY OF ARTS, ON TUESDAY FEBRUARY 27, 1900.

BY R. HEDGER WALLACE.

(Continued from Vol. XIX., page 801.)

The two factors that must influence all efforts in the West Indies are the problems of tropical cultivation and the wants of a native peasantry. The first step taken, therefore, in what might be termed the new era of agricultural education in the West Indies, was the establishment and development of the institutions known as botanic stations. These are small and inexpensive gardens devised in order to afford practical instruction in the cultivation of tropical crops and were first intended to meet the special requirements and develop the agricultural resources of the smaller islands in the West Indies. The first stations started were at Grenada and Barbados in 1886. Since then stations have been started at Antigua, Bermuda, British Honduras, Dominica, Montserrat, St. Kitt's Nevis, St. Lucia, St. Vincent, and Tobago. There are now in all eleven stations in the West Indies and they are in close relationship with Kew.

The next step taken to advance the interests of agricultural education was the establishment at Barbados of an Imperial Department of Agriculture for the West Indies, with Dr. Morris as Commissioner. As regards agricultural education this Department has three objects in view:—

"(1) To start industrial schools for training boys in agricultural pursuits. (2) To encourage the theoretical (and to some slight extent the practical) teaching of agriculture in elementry schools. (3) To promote the teaching of scientific agriculture in college and schools."

I have been favoured with an advanced proof of the second West Indian Agricultural Conference which was held at Barbados on 6th January, 1900. In his opening address I note that Dr. Morris says:—

'The scheme of agricultural instruction suggested to meet the immediate requirements of elementary schools aims first of all at rendering the existing teachers competent to give simple object-lessons bearing on agriculture and illustrate them by experiments and actual specimens. Examples of growing plants should be grown in pots and boxes under the eyes of the children, and every stage of their growth as well as the conditions favourable for rapid and successful development should be clearly explained. This much is within the reach of the poorest school in the West Indies. All, however, depends on the amount of knowledge and the interest thrown into the subject on the part of the teachers. It is proposed to assist the teachers at present in charge of schools by affording them the means of attending courses of lectures during their holidays. While attending these lectures all out of pocket expenses (except in British Guiana, Trinidad, and Jamaica) are paid by the Imperial Department of Agriculture. Lectures to elementary teachers were started last year at Trinidad, St. Lucia, and Barbados—in each case with singular success. They will be continued next week (January, 1900) at Tobago, Grenada, St. Vincent, and Dominica. The teachers so far have shown themselves most anxious to acquire knowledge of the principles of agriculture, and it is anticipated that during the next two years most of the existing teachers throughout the West Indies will have passed through the initial course of training. The teachers now at the training colleges and all future students passing through such colleges should be fully instructed and be competent to teach agriculture before they are placed in charge of schools. For the present Blackie's "Tropical Readers," Books I. and II., are recommended for use in schools, but great care is required to prevent mere book knowledge, which is worthless, taking the place of the intellectual education and the hand and eye-training necessary for agricultural pursuits."

Dr. Morris further states that—

"As a higher stage in agricultural education it is proposed to maintain agricultural schools—the first at St. Vincent, St. Lucia, Dominica, and St. Kitts. The boys will be fed, clothed and trained free. Admission to these schools will be offered as an exhibition to boys in elementary schools of about 14 years of age who have passed the IV. standard and who show moral and intellectual aptitude for such instruction. We have next the scheme of instruction in agriculture to boys in Secondary and High Schools assisted by the special lectures in agriculture provided by the Imperial Department. At the same schools scholarships are offered to boys from the country districts, the sons of planters in moderate circumstances, who intend to devote themselves to agricultural pursuits. Lastly, there are lectures to the younger generation of planters and others engaged in agricultural pursuits to afford information and assistance in elucidating the scientific problems which undertake the practical work in which they are daily engaged."

So far then this describes what has been done generally in the West Indies in the interests of agricultural education. The work done specifically in some of the islands might also be mentioned. For instance in Jamaica there is now a Lecturer in Agricultural Science, and at the Hope Industrial School practical lectures in agriculture are given by the Superintendent of Hope Gardens. The Jamaican Education Department also offer, by grants, assistance to elementary schools for the teaching of agriculture as a special subject, and a practical elementary text book of tropical agriculture for use of the schools in Jamaica has been published. In addition it is stated all country schools are expected to teach the elementary principles of agriculture as a part of the general course. Two Jamaica readers—"tropical readers"—have been brought out by the Board of Education, and a supplementary reader in tropical agriculture is in contemplation. In the training colleges for teachers, the principles of agriculture are required to be taken up in the second year's course The question of providing higher agricultural education for those who may become proprietors and managers of estates have not yet been touched in Jamaica.

Coming next to the Leeward Islands, there is a botanic station at St. Kitts Nevis, but no attempt is made to teach agriculture in the schools there or at Anguilla.

Antigua, I find, has an officer who is called the agricultural superintendent of sugar-cane experiments. Formerly there was here a department of agriculture for the Leeward Islands under a scientific superintendent. It was founded in 1891, and abolished in 1894.

At Dominica there is an agricultural instructor attached to the botanic station, also an agricultural school with a qualified officer in charge. There is also an agricultural instructor attached to the botanic station at Montserrat.

St. Lucia is another island which has an agricultural instructor, and there is one also at St. Vincent. The latter island has in addition an agricultural school in charge of a separate officer.

At Barbados there is a Lecturer on agricultural Science at Harrison College, Bridgetown, who also holds the position of island Professor of agricultural Science. Agriculture is also taught practically at the boys' reformatory school at Dodds.

At Grenada efforts are being made to teach agriculture theoretically in the elementary schools, and to start school gardens, and also to utilise the services of the Curator of the Botanic Station to give lectures and demonstrations.

Tobago has a cacao instructor attached to the Botanic Station, but agriculture is not taught in the schools. Neither is it taught in the elementary

or insdustrial schools of Trinidad. It is stated, however, that lectures on agriculture are given at the Victoria Institute, Port of Spain. According to Mr. Moore, instruction in fruit and banana cultivation is also given in this island, and the school teachers are provided with various agricultural publications.

In British Guiana there is an agricultural assistant attached to the Botanic Gardens at Georgetown; and the Royal Agricultural Society in this colony, I am informed, approached the Governor in Council in 1898, with the view of having an agricultural school and experimental farm established and also of having plots of land attached to country schools, where pupils would spend a portion of their time daily in learning practical agriculture.

Leaving the islands of the West Indies, and the Crown colonies on the mainland, I now proceed to notice the several self-governing colonies which form the Australasian section of Greater Britain.

In the mother colony of New South Wales, agriculture is taught in the state schools, either under object-lessons or natural science. It is also an optional subject for teachers in the series of examinations they undergo to obtain promotion from one grade to another. An agricultural text book, for use in the schools, has also been published by the Department, and an itinerant lecturer on garden and farm work visits the more important schools.

Under the scheme of technical education, also carried out in Sydney and various country towns, courses of instruction in agriculture, sheep and wool-classing, wool-sorting, and veterinary science are provided.

Agricultural education, pure and simple, is however, in the hands of the Department of agriculture. There is, under this department, the Hawkesbury Agricultural College, with experimental farm attached located near the town of Richmond. The complete course of instruction at this institution covers a period of two years of four sessions, and the subjects taught are "practical agriculture, principles of agriculture, agricultural chemistry, botany, geology, entomology, farm-book keeping, veterinary science and practice, arithmetic and English, elementary surveying and mechanics." The practical work at which all students have to engage in is noted as follows:—

"(1) Milking cows, making butter, use of dairy appliances. (2) Killing and dressing sheep. (3) Carpentering work, such as mortising and cutting tenons, setting out roof. (4) Blacksmith's work, welding iron, making bolts, fitting and putting on horse-shoes. (5) Fencing, mortising posts, putting up wire or other fences. (6) Yoking up and driving bullocks, horse work, hay loading, farm implements, engine work."

Though the Hawkesbury College is the only one in the colony where the whole science and practice of agriculture is taught, the scheme of education originally formulated embraced the establisement of "certain farms and orchards typical of the most important climatic regions of the colony, where those who did not desire to undertake the comprehensive training of the college might be instructed pure y in the practice of the various branches of agriculture."

For such experimental farms have now been established. The Murrumbridgee, or Bomen Experimental Farm, near the southern town of Wagga-Wagga, represents the comparatively dry Riverina region; the Woollongbar Experimental Farm, in the Richmond River district, is in the sub-tropical region; the Bathurst Experimental Farm represents the western plains and colder portions of the colony; while the experimental farm at Coolabah, in the Bogan Scrub, has been established for experiment in the arid portion of the colony.

In all these experimental farms lectures on agriculture are given, and the course is for a year of two sessions. Students at the central college are advised to continue their course at one of these farms, for the student there is "afforded some practical experience of the cultivation of land in a climatic region typical of that in which he intended to settle." According to the Minister for Agriculture, "training at college would provide him with a general and practical acquaintance with farming in all its branches, but to enable him to become (for example) a successful western New South Wales cultivator a little practical experience of dry country method, is absouletely necessary."

Additional means of imparting information and instruction is further afforded by the employment of a dairy expert, a fruit expert, a viticultural expert and a travelling agricultural instructor, who for a number of years, was principal of the Agricultural College. An *Agricultural Gazette* is now published, which in value approaches some of the publications issued by the United States Department of Agriculture —a department which is generally admitted to be the best organised and most practical of any Government in the world. In passing, I may note that I find it stated in the Report of the the New South Wales Under Secretary for Agriculture, 1899, "that amongst the 130 odd young men undergoing the full course (at Hawkesbury College) are several from England, Cape Colony, the neighbouring colonies and Japan."

Respecting Queensland, the Agent-General for the colony has been good enough to reply to my enquiries as follows:—

"1. Agriculture is not taught in the elementary schools of the colony, but

"2 Four State bursaries are granted, giving free board and instruction to resident students for three years at the Government Agricultural College at Gatton. Admission is by competitive examination in reading, writing, arithmetic, English composition geography, mechanics, and drawing to scale. Candidates for these bursaries must be between 16 and 18 years of age, of sound constitution and good health, and themselves must have resided in the colony two years and their parents three years preceding the examination.

3. The agricultural College at Gatton was established in July, 1897. The college farm or ground comprises an area of 1,692 acres. Dormitory accommodation is provided for 56 students. The buildings include a chemical laboratory and lecture room, The fees, which cover instruction, board, washing, room rent and lights, are £25 per annum. The students are engaged for one half the time at manual labour, a day of out-door work alteruating with a day of study.

"4. Experts in dairying and other subjects are employed by the Department of Agriculture to travel throughout the colony and give personal instruction to farmers. Bulletins on various subjects of interest to farmers are also issued by the Department, which with the *Queensland Agricultural Journal*, are freely distributed."

EXPERIMENTS TO PRESERVE TIMBER.

Years ago experiments were made at Geisenheim, by Professor Giseyius, of Koenigsberg, with 6 feet long poles from pines, to be used for vines, and it was found that several fluids were better for preserving than merely burning the ends. Oil of tar and carbolineum were found useless, inasmuch as the creosote in them gave that taste to plants growing near, and other fluids were too expensive. But a solution of 2 lb. or 3 lb. of bluestone was found to be cheap, easy to use, and well preserving. Later experiments were made in the Agricultural School at Dahme, and at the hop garden at Sussenthal with pine and fir poles, 24 feet long, and with fencing posts. The solution impregnates, and rises within three or four days to the top if you remove the bark from freshly cut stems and place the lower end into it. In trees cut some days before they are peeled and put into the solution, it rose only from 3 feet to 6 feet high. If it freezes this method cannot be used; the warmer it is better. The casks must be very strong, and have to be filled up twice a day. For 90 hop poles, about 24 feet long, it required 6 lb. of bluestone.—*Queensland Agricultural Journal.*

TEA COMPANIES (LONDON-CEYLON):—AREA PLANTED AND CAPITAL.

One of the most complete lists of Ceylon Tea Companies registered in England, is that compiled by Mr. George Seton, of the Indian Tea Share Exchange, Bishopsgate Street, and it especially shows very clearly, the contrast between the area planted and the amount of capital raised, as also of debentures if any. The latest of these lists, made up to December 1899, is before us, and we have had the "capital" plus "debentures" divided by the "planted acres" in each case, in order to see at a glance how the several Companies work out. We need not tell Ceylon readers that, several other matters, besides the proportion of planted area to capital outstanding, have to be taken into account in appraising the actual value of a Company's properties. So much depends on district, soil, planting and jât of tea, that it is quite possible for a Company with a heavy capital outlay per acre, to be in a sounder position than another with not much more than half the same ratio of capital outstanding. Nevertheless, for a rough and ready test of the position and prospects of a Company—with certain important exceptions which can be allowed for—the capital outstanding per acre, is a very convenient form of reckoning.

First of all, we may mention that in the list before us, there are 68 Companies specified with an aggregate planted area of 137,657 acres (over one-third of the total in Ceylon) having a subscribed capital of £4,940,699, besides £1,244,353 of debentures—thus working out to an average of £45 per planted acre. If we now look for the two extremes in the list, we find the Lindoola Company on the one hand with 320 acres ("planted" will always be understood) and £39,000 capital, which works out at £122 per acre; and next to it "Gartmore," 454 acres and £48,000, making £106 per acre. At the other end of the scale, we have the "Ceylon Land and Produce," 4,038 acres, £68,300 capital plus £19,125 debentures, working out to £21 per acre; next to this Namunakula Estates Company 1,160 acres with £25,000 capital, also the Scottish Trust and Loan Co. 2,025 acres with £45,000 capital, both making £22 per acre; and then the "Ceylon Plantations," 10,820 acres with £248,460 capital, making £23 per acre.

Going on from the minimum side, we find nine more Companies which stand at under £30 per acre, namely "Ederapolla"—1,030 acres, £25,500 and Tyspane 778 acres, £19,500 capital and debentures:—both making £25 per acre; "Poonagalla," 1,149 acres, £30,000 capital and debentures, making £26; "Standard," 2,487, acres, £69,500 capital and debentures; "Rangalla," 782 acres £22,000; "Battalgalla," 677 acres and £19,000; "Burnside," 1,138 acres, £32,100; and "Kelani," 1,236 acres, £34,965:—all five Companies working out to £28 per acre; then there is the Scottish Ceylon with 1,720 acres against £50,000, working out to £29 per acre.

Next between £30 and £40 per acre, we have thirteen Companies, namely, Abbotsleigh; the Consolidated Estates (3,834 acres against £127,400 capital); Digalla, Midland and Eastern Produce and Estates Co.—each of which works out to about £33 per acre. The New Dimbula Company (with 2,345 acres cultivated and £78,954 capital) makes £34 per acre. The Goomera Company gives the same ratio of £34; while Bandarapolla equals £35; and both Carolina and Hunasgiriya work out to £36 per acre. Then three Companies—Ouvah, Craighead and Panawal—show an average of £38 per acre against capital.

Next we come to those between £40 and £50 per acre, of which there are nine Companies, namely, Ceylon Estates Investment, £40; Alliance, Anglo-Ceylon, and Kellie Companies, each £41; Duckwari, £43; Yatiyantota, £45; Central Province, and Ceylon and Indian P. A., each £47; and Sunnygama, £48 per acre.

Between £50 and £60, we find sixteen Companies, namely, Haputale and Central of Ceylon, £51; Lanka, Spring Valley and Nahalma, each £52; Imperial, South Wanarajah, Tea Corporation and United Planters, each £53; Ceylon Proprietary and Highland, each £54; Galaha, Mayfield and Ragalla, each £55; Associated Estates, £57; Punduloya, £58.

Finally, we have fifteen Companies from £60 to £91 per acre, namely, Caledonian £60; Korale Company, £61; Hornsey, £63; General Ceylon and Augusta, each £65; Vellekellie, £70; Maturatta, £71; Kandapolla, £73; Kintyre, £74; Portmore Company, £77; Dimbula Valley and Talawakelle, each £78; Balmoral £85; Nuwara Elliya, £88; and Bogawantalawa, £91; while we have already specified Gartmore £106 and Lindula £122 per. acre.

SOME USEFUL MEASUREMENTS.

For estimating the areas of paddocks and cultivated plots, the following figures will be found useful:—

60 feet	by	726 feet	...	...	1 acre

CUBING TIMBER.

To measure square timber: Multiply the length, width, and thickness together, and divide the product by 12.

How many square feet in a joist 2 x 8, 18 feet long?

2 x 8 x 18 = 288 ÷ 12 = 24 feet. Ans.

* A bonus of 3 per cent.

A FARMER'S EVERY DAY LIFE.

(By Cosmopolite.)

No. V.

The first great step that has to be taken, when about to commence a farming life, is to be sure that you have succeeded in leasing the sort of farm you wish for, and that you have it at

A FAIR RENT.

When a farm comes into the market, now a-days many outsiders enter the list of competitors for it, and such men as retired merchants and Ceylon planters, having no idea of the value of land, but only wishing to procure a home in the country for themselves, offer a much higher rent than a practical farmer would care to give, and so rents have been forced up to such an extent that I know several cases of professional farmers who are paying more rent for their farms than they consider them to be worth, simply because they feared to be left out in the cold, without a farm at all. I have seen the whole of the best land in Scotland, from the Howe o'Buchan to that wonderful pear garden, formerly the property of the monks of Jedburgh, and said to be the richest piece of soil in the whole of Great Britain, but there is not an acre of it that I would be inclined to give more than £1 a year of rent for, so long as I know that there are millions of acres, of far better land than anything that we have in this country, lying idle at the antipodes—land which is waiting to be purchased right out by any one, at a price varying from 5s to £2 an acre. It may be said that these acres lie too far from a market, but to that I reply that such is not the case, for the market of London is the market of the world, and thanks to steam, low freights and this parental Government of ours, which, to the best of its ability, fosters and encourages foreign agriculturists, whilst it tries in every way to discourage the native producer, The grain and mutton grown in Australia can be laid down at a cheaper rate, in London, than the same commodities can be which have been grown on the farms of Aberdeenshire. I make, of course, exceptions in the cases of

FARMS CLOSE TO TOWNS,

which can be utilized for dairy purposes and market gardening, and our merely referring to such as lie some miles from any town or village, and which would likely be taken on lease by retired East Indians. I have no hesitation, therefore, in stating that, for such a farm, a rent of £1 an acre, per annum, is the highest that anyone should pay, and expect to hold his own, or perhaps make a little profit, and this, I may remark, is the figure I pay for my own farm. One thing however I would caution an amateur farmer against, and that is—taking a farm because it is low rented. For example; I know one man, afar from practical farmer, who had leased a place at 25s an acre, but found, in the course of a few years, that he was losing money, so, having succeeded in breaking his lease, he went to the other extreme and rented one at 1ls; but the farm he threw up used to give him six quarters of oats to the acre,

whilst the one he took so cheaply only gave him three to four quarters, and so the last stage of that man was worse than the first. A very low rented farm is, generally, one that is not worth taking in at present, and only farms that can be worked up to the highest state of cultivation are worth taking on lease now-a-days. The low prices ruling for grain, beef and mutton compel one, not only to secure a good farm at a fair rent, but also to cultivate it at high pressure, in order to pay the labour bill and have something over. Farming on the cheap won't do at all, and, if high farming won't pay, certainly low farming will not do so.

Having secured the farm that he wishes, or perhaps has been obliged to take, for want of a better, the next step of greatest importance is the securing of the proper kind

OF LABOURERS,

and this is not such a difficult thing after all, in spite of the out cry about the scarcity of labour. The ordinary course is to go to a fee-ing market, and there engage the number of hands required, and these are engaged for six months, during which time their faults and failings are discovered, and a fresh lot is engaged at the next term. That has not been my policy, and I find my own way to work fully better than the usual custom of the district. I have never been at a fee-ing market yet. I engaged my men by their looks and the characters I had heard given to them, and these men have been with me ever since I came to this farm. I treat them well, and they treat me in the same way in return. They will work extra time and out of all hours without a grumble, and, when they want a day's leave, they know that they only have to ask for it, and they will get it. These men were in the habit of changing their places every six months, like other hands, before they came to me, but now they appear to have settled down for the term of their natural lives, and cultivate their bit of garden, as if they own it, and had no fear of its being taken from them. In New Zealand and Australia my servants never left me, after being engaged, and my coolies in Ceylon remained with me the whole time I was there; whilst my dressing-boy was with me during the whole time of my stay in your island.

Now I would recommend others to adopt the same policy with their hands, remembering that the frequent changes made by servants is accounted for, not so much because they are incapable, as because their masters are unreasonable. Many so-called gentlemen farmers think it degrades them to speak

IN A FRIENDLY WAY

to their hired servants, and so these can never have the same regard for their master's interests as they would, if treated in a more friendly way. My men have been so long with me that they can fit themselves to the work more systematically than could others, who are changed every six months; and so I know that I get much more work done, for my money, than my neighbours do. The labour bill is the bugbear of farmers: not only do they find a difficulty in getting hands, but they find a greater difficulty in getting as much work out of them as will pay their wages.

The custom which obtains, in Ceylon, of taking creepers at a high premium, and professing to teach them the noble art of tea planting is not singular in its conception, as a somewhat similar means of livelihood is indulged in, by farmers and even landed proprietors in this tight little island, who, for a tidy consideration, take

MUD-STUDENTS

into the bosom of their families, and make a pretence of teaching them to be practical farmers. There are no mud-students in this district of Scotland, but on the borders as many as three and four are to be found on various farms, paying from £300 to £400 per annum, which entitles them to keep a hunter, and to follow the hounds as often as their horse can be found capable of the exertion. Most of these young men, that I have come across, served in their salad days as soldiers, and consequently are quite unfit for any other profession, especially one that requires as much commonsense as farming does; but they live a rollicking life and no doubt get a full value of amusement in return for the premiums they pay. The hardest work that any of them does is executed to the strains of the "Blue Danube" or "Pas de Quatre;" and when the hunting season is past, they spend their time sitting on a log smoking extra strong tobacco. At fairs and sheep sales, on the borders, the mud-students assemble from far and near and are easily known because they are ever the horsiest in their outward appearance, just as you find the very plain young person is always keenest at the Sunday-school class. Military men don't look well on horseback; there is an old saying—"Riding straight up and down, like an officer"—which exactly expresses the attitude peculiar to the military rider. It has been truthfully said that riding seems a physical impossibility for sailors, tailors and dragoon officers; yet I have seen military men ride well to the front, both on the flat and over the sticks, although this might be accounted for, as a friend of mine once pertinently said, because the great art of jockeyship was in being on the best horse. The system of taking mud-students on, at high premiums, has helped to keep the ancestral roofs on many family mansions, and no doubt the creeper has been the means of enabling many a hard-up planter to pace his mortgaged verandah for some years longer than he otherwise might have done.

POULTRY FANCIERS

have been sadly depressed lately, owing to a sudden drop in the price of eggs, which fell, with a bang, from 18d to 6d a dozen. One of my neighbours had tears in her eyes as she told me the fateful news, and asked me if I could account for the sudden fall in price of her principal market staple. I tried to comfort her by saying that probably the quality had something to do with the matter for I believed that, at this season of the year, hens were frequently not very

well, and often laid bad eggs; but she refused to admit of any such suggestion. Another neighbour openly vowed that rather than sell at such a figure, she would have all the eggs from their poultry yard eaten in the family circle, and as they have about 500 able-bodied hens on the premises, they appear to have undertaken a pretty heavy contract.

NO. VI.

(*By Cosmopolite.*)

The worst kept part of a farm is generally the garden, which only receives attention when no other work of a remunerative nature has to be attended to. Pleasure is all that can be derived from a garden, and profit is conspicuous by its absence, and thus the farmer—the poor but honest agriculturist—can ill-afford the time and expense of keeping his garden in order. Some cranks—like the late Mr. Gladstone—rave about the possible profit from

FRUIT-GROWING

and jam-making, but this idea has, long since, been exploded, and my own practical experience may serve to explain the reason why. One year I put on pickers to clean up my fruit trees and bushes, and sent the result of their labour to the town, where I got the highest price agoing for it, the sum total of which, however, amounted only to a few shillings, *less* than it had taken to pay the wages of the pickers, to say nothing about the cost of manuring, pruning and general upkeep of the garden. Since that date my policy is to use as much of the fruit as I possibly can, in my own establishment, the balance being given to any of the neighbouring working-men's wives who care to come and take the trouble to pick it. When I came here, I found the black-currant bushes, in appearance, much like the coffee trees in the back fields of some of the old *totums*, of my own planting days. I promptly went in for a heavy pruning, and have used the knife freely, every year since, with the result that I see no black currants at all able to compare with my own in size and quality. I may here mention that I do my own gardening, and, as the ground extends to two acres besides lawn tennis green, &c., to be kept in order, those of my readers who know anything about gardening will understand that I have a good deal of work to do in my spare time, to say nothing of the fact that I feel the stooping and digging more exhausting than I did, before the microbe of corpulency laid its grim claws upon me.

GARDENING,

now-a-days, is a stiffer job than it was in the garden, of Eden before weeds had sported to any great extent, and when dockens and carlie-doddies were unknown. Beside that, my illustrious ancestor Adam never got into trouble with his wife, for spoiling his clothes, or making the knees of his trousers baggy through kneeling in the flower beds, as I find it necessary sometimes to do. In my planting days we were all great on hand weeding, and I, naturally, adopted the same policy in my own garden, but, although I kept my ground remarkably clean, I found my gooseberry, raspberry and currant bushes becoming, year by year, less productive. At once I jumped to the conclusion that it was from want of air at the roots, so I proceeded to dig up the ground as deep as I could with a grape, the result being like magic: the bushes took a new lease of life; the crop doubled itself and the actual labour of weeding was reduced to about one half. I remember once applying cattle manure to a coffee field, in Rangala, and having the whole surface dug over with grapes, and from that field, I got, by far and away, the best crop of the year. At that time I attributed this to the manure, although I wondered why the other fields, that had had the same sort of manure applied to the roots of the bushes, had not responded so well; but now I cannot help thinking that the digging, and the letting of the air into the ground, had more effect than the manure itself; perhaps some planter will try digging, on a portion of his estate, and report results. To me this season of the year, in the garden, is the most enjoyable, when the place fairly blazes with lilies, auriculas, primroses, wall flowers and others of like sorts, for these good old-fashioned flowers are the ones I most admire. Some people there are who can't get on without their begonias, orchids and ageratums; but these flowers are so associated, in my mind, with weeding contracts and ghastly outlays of rupees to keep them down, that I cannot go into ecstasies over their beauties.

OUR VILLAGE

was once again *en fete*. when, the other evening, the Episcopal Church social gathering took place, in the Church Hall situated at the east end of what the sanguine inhabitants denominate the High Street, a delightful break in the boundless monotony of farm life, and at which many members of other denominations put in an appearance, because it has become an understood thing that it is always the most enjoyable entertainment of the year in our village of sweet auburn We—I speak for myself and the other soges of the parish,—hold this opinion at any rate. After the company had listened to songs and music galore, had drunk blashes of tea and eaten variety biscuits to their heart's content, the seats were cleared away, and, to the inspiring strains of a string band of excellent calibre, we tripped the light fantastic toe till "the sma' oors ayont the twal" began to ring. Patti, Albani and other people have a good record as singers, and it would be hard to compete against them, but our village nightingales gave a wonderfully good account of themselves. One girl struck me all of a heap, and I fain would have danced with her; but she was so sought after by the young bloods that I felt convinced that an old buster like myself would have no chance, so I sat and gazed upon her from afar. The Johnnies, admiringly, christened her "The Rose of St. Fergus," and the name fitted her like a glove whilst she appeared to enjoy herself to the mast head. Perhaps she may come again, to our next social gathering, but alas! I won't be any younger than I am now, and so I will have no more chance of getting

A DANCE

with her, than I had this year. Some of the other girls were amazingly unattractive, and they also did as I gaze upon from afar, although I doubt not but what they would have gladly pranced through "The Flowers of Edinburgh" or the "Pas de Quatre" with one who, twenty years ago, was known by his coolies, in Rangala, as the *Kelavan dorai*. Some of my own past time partners were looking younger than ever, although approaching the dangerous and susceptible age of sixty, when a woman really begins to need looking after; But, let me change the subject lest, like King David, in my haste I might say things not palatable to my venerable contemporaries. Some of those gay old girls tootled on the piano themselves, and added much to the enjoyment of the evening. Several clergymen also took part in the entertainment, both with songs and speeches, and, as they put on no frills but were plain genial speakers, they went well with the audience. It is the parson whose oratory is pure pulpit oratory, of the unmistakable kirk type, that goes far to depress an audience at such an entertainment as this was, and we rejoiced that no such parson had been able to pass the door keeper. Unstinted applause was the order of the day, and I always think there is something intensely inspiriting to a nervous performer in the thump of a heavy stick or the clapping of a pair of large hands.

Easter brings with it a great boom in

SCHOLASTIC MATTERS,

the election of members of school boards being on the tapis, and so the public have had, at this time, the opportunity placed in their power of inflicting one worse degradation on a man than making him a Parish Councillor. They can make him a member of a School Board. Just as a Cardinal is made Pope because he is old, infirm and imbecile, so a member of a School Board is made such, because he is either worse educated or more wanting in common sense than his neighbours, and thus the only people who can be persuaded to stand for the doubtful honour of being made members of School Boards are clergymen and idlers, with a sprinkling of the less educated farmers, whose minds are thoroughly parochial, and who have sons old enough to look after the work at home, whilst they sit in solemn state, making fools of themselves as members of a Board that dare do nothing of their own free will, but who lie under the heel of a despotic educational visiting agent. The British Isles, now-a-days, seem to be dotted over with school buildings, and inhabited only by members of School Boards and school teachers, the latter a most useless class of girls, of electro-plate culture,—a process which throws a brilliant film of education over a foundation of ignorance, and who would be far more useful in the world if they had some slight knowledge of clear starching and pie-making. To see a teacher of the old school type is a rare thing indeed, and such an one would be pointed out, much in the same way as would be the sole survivor of the Balaclava charge or the last of the Mohicans. These triennial elections always remind me of the time when people paid no taxes for freely educating those who wished to remain ignorant. Oh! happy time. Oh! for the days that used to be. Oh! the dear dead past! The columns of the Agricultural Press have lately been crowded with questions and answers on the subject of "Gowk aits," the consensus of opinion being that these are oats sown on or after the first of April—that is gowk's day.—Farmers who take no trouble to observe things connected with their work, but go on, year by year, believing in old sayings and silly theories, dread being compelled, by a backward spring, to sow oats later than the first of April, as they are sure to be great sufferers thereby. This, however, is but a wild idea of our forefathers, and, as an ounce of practice is worth a pound of theory, I may mention that I seldom finish sowing before the 23rd of April; and yet I am generally about the first to begin harvesting in the district. On one occasion I sowed a field on the 3rd of May, and it was the first cut in the neighbourhood, and gave me the heaviest crop I have had in Buchan. So much for believing implicitly in old sayings.

THE CROW

—the farmers greatest enemy—is now busily engaged in building up rookeries wherever any one is foolish enough to grant him permission to do so. When I leased this farm the trees around my house were laden with nests, and the noise made by the colony, night and day, was deafening, presently the destructive wretches took to digging up my potato seed as fast as it was put in the ground, and I bore with them, because of the aristocratic associations connected with a rookery. When they killed my chickens and pulled my young turnips up by the acre I still stayed my hand; but when they took to killing my lambs, by digging out the poor creatures eyes, then I arose in my might and sent for all the boys in the district, who plumed themselves on their climbing abilities, and had every nest torn down, and this—my lead—has been followed by every owner of a rookery in the district, except one, and he, it is hoped, may yet learn wisdom, and clear his lot out also. Crows are very suspicious of man, yet, strange to say, they never live far from him; and it is said of them that they prefer the neighbourhood of aristocratic families. A story is told of an ancient mansion having changed hands, and a report reached the crows that the new proprietor bore the name of Smith, so the colony determined to depart. One curious bird, however, examined the labels on the luggage, and, finding the name spelt with a *y*, the crows unanimously agreed to postpone their departure. I don't mean to say that every rookery I have seen was owned by a family of blue-blood or of Vere-de-Vere extraction; some of these proprietors, indeed, were "too proud to care from whence they came," and, perhaps, it was just as well, for their pedigrees would not bear looking into.

THE TEA CLEARING HOUSE COMMITTEE have intimated their intention to increase the discount allowance on charges from ten per cent, to fifteen per cent on all rates, except that for "bulking and taring" which was reduced from March 1st last.—*Grocers' Journal* May 5.

NOTES ON THE CRUDE RUBBER INTEREST.

RUBBER PLANTING IN THE WEST INDIES.—At the second West Indian agricultural conference held on January 6 in Barbados, the president, Dr. Daniel Morris, C.M.G., who is the commissioner of the imperial department of agriculture for the West Indies, said in his inaugural address: "A regular plantation of India-rubber trees, the first in the West Indies, is being established at Tobago by Mr. Esmè Howard. The species selected is Central American rubber tree, known locally as 'ule' or 'caucho' (*Castilloa elastica*). It was recently reported that this tree was found wild in Cuba. This is evidently an error. Rubber trees are being planted in small plantations and in isolated groups also in Trinidad and Jamaica. The cultivation could be successfully established in some localities in British Guiana where, already, one or more valuable species are found in a wild state."

RUBBER FROM GERMAN AFRICA.—The exports of India-rubber from two of the German colonies in Africa have been as follows in the last two fiscal years, in English pounds:

	1897-98.	1898-99.
Togo ...	194,918	389,530
Kamerun ...	969,738	1,328,536

The rubber exported from Kamerun was valued at 1,177.715 marks in 1897-98 and 1,928,080 marks in 1898-99.

RUBBER PLANTING IN COSTA RICA.—Mention has been made from time to time in the *India Rubber World* of the experiments in India-rubber planting made in Costa Rica by Minor C. Keith, a former resident of Brooklyn, N. Y., and now first vice president of the United Fruit Co., who are interested so largely in the banana trade in Central America. Mr. Leith has more than once taken the liberal cash prizes awarded by the Costa Rican government to promote the planting of rubber in that republic. The *India Rubber World*, in response to an inquiry, has received a letter from John M. Keith, manager of the Costa Rica division of the United Fruit Co., from which the following extract is taken:

"We have a large number of rubber trees on our properties that have actually been planted and are in a most flourishing condition. The only difficulty that presents itself, in the way of securing lucrative results, is the impossibility of preventing poaching. We planted our trees when rubber was still at a low price, and scattered them throughout all our farms, and the greater part of the rubber yield has since been stolen, although every year we collect a considerable quantity. I have no doubt, however, that should any one plant thickly on land that could be easily guarded, the difficulty above referred to could be overcome. As you are aware, the greater part of the rubber in these parts is cut on government (or unclaimed) lands. Consequently the rubber cutters, who are, as a rule, a lawless set of men, disregard any proprietary rights to a rubber tree anywhere."

A RUBBER PLANTATION IN MEXICO.—La Zacualpa Rubber Plantation Co., a California corporation with a plantation at Tapachula, in the state of Chiapas, Mexico, where O. H. Harrison is resident director, have favored the *India Rubber World* with considerable printed matter of interest in relation to the results of their work and their prospects. A recent pamphlet contains a copy of a letter by Percy Christy, a son of Thomas Christy, of London, recounting his impressions on visiting the plantation. It appears that the former owner of the estate, José M. Pelaez, for several years collected and sold a considerable amount of rubber from the native trees found there. Mr. Christy, in his letter, mentions the native trees as still standing, besides which he was shown a number of trees represented to him as having been planted ten years ago. He was told that these were about 5,000 in number and he found them "most healthy looking trees, with a trunk diameter of 10 to 12 inches; these trees have been tapped for some years, and in talking it over with some of the Indian rubber gatherers, they assured me that each of these trees would produce from 2 to 3 pounds per year. . . . From this we visited a plantation of last year's planting, entirely in the open and without shade, and these all looked strong and healthy. I understand that there are 30,000; also I noticed that along the fencing of the property rubber trees had been planted. This idea pleased me exceedingly, as it will be a saving of labor, as the trees will serve as posts as well as being a source of profit.

THE "THIRTY COMMITTEE."

Minutes of proceedings of a meeting of the "Thirty Committee" held at the Victoria Commemoration Buildings, Kandy, on Saturday, the 12th day of May, at half-past seven o'clock (7.30 a. m.) in the morning. Present:—Mr. Edward Rosling (Chairman) Mr. A. Philip (Secretary), Hon. Mr. J. N. Campbell, Messrs. Stanley Bois, J. B. Coles, G. H. Alston, R. A. Galton, A. J. Denison, Hugh B Roberts, T. C. Huxley, J. A. Barnester, G. K. Deaker, Joseph Fraser, W. D. Gibbon, A. Melville White, Edgar Turner, James Westland, James Ryan and A. C. Kingsford.

The notice calling the meeting was read. The Minutes of proceedings of a meeting of the "Thirty Committee" held at Kandy, on Saturday, the 17th day of March, 1900, were submitted for confirmation. Resolved:—"That they be and they hereby are confirmed." Read letter from Messrs. Capper & Sons.

CORRESPONDENCE &C. CIRCULATED.

CEYLON TEA IN AMERICA.

Letters from Mr. William Mackenzie to Mr. Lane, dated 21st Feb., Mr. Larkin to Mr. Mackenzie, 17th Feb., *Journal of Commerce and Commercial Bulletin* to Mr. Mackenzie, do. Mr. Wm. Mackenzie to Mr. Lane, 25th Feb., do. 27th, 2nd March and do. 6th. Mr. P. C. Larkin to Mr. Wm. Mackenzie, 27th Feb.; Mr. Wm. Mackenzie to Mr. Rosliug 5th April. Table of revised tea statistics, Mr. Wm. Mackenzie to Secretary, 15th April.

UNIVERSAL INTERNATIONAL EHIBITION TO BE HELD AT PARIS, 1900.

Letters from Mr. Renton to Mr. Rosling, dated 9th March, 23rd March, 6th April.

CEYLON TEA (NEW MARKETS) FUND.

Sketch statement giving the yearly totals expended in each country from the commencement of operations as per abstracts to 31st December, 1899. Sketch memo. showing credits opened, payments made, and available balances as at 30th April.

MEMBERS OF COMMITTEE.

Read letter from Mr. W. Saunders stating that as he is leaving for England he tenders the resignation of his seat on the "Thirty Committee." Read letter from the Secretary, Ceylon Chamber of Commerce, intimating that Messrs. G. B. Leechman, G. F. Traill, and H. Tarrant, had been elected members of the "Thirty Committee" in place of Messrs. J. A. Henderson, J. H. Renton and E. M. Shattock. The members representing the Chamber at present are Messrs. G. B Leechman, E. C. Skrine, G. F. Traill, G. H. Alston, H. Tarrant and Stanley Bois. Read letter from Mr. George Kent Deaker. Read letter from Mr. Gordon Pyper resigning his seat on the Committee as he is leaving Ceylon. Resolved:—"That Messrs. E. H. Hutchinson and Robert Morison be elected members of the 'Thirty Committee' vice Messrs, W. Saunders and Gordon Pyper,"

MINUTES OF PROCEEDINGS.

Read letter from Government acknowledging copy of minutes of proceedings of a meeting of the "Thirty Committee" held at Kandy on Saturday, the 20th January, 1900.

FINANCES.

Submitted letters from the Treasurer of the Colony. Submitted memo. showing credits payable and available balances as at 30th April, 1900.

CEYLON TEA (NEW MARKETS) FUND.

Considered various memoranda showing the position of the Fund. Submitted statement giving the yearly totals expended in each country from the commencement of operations. Read letters from the National Bank of India, Limited, Colombo. Submitted sketch summary of receipts and expenditure Ceylon Tea (New Markets) Fund as per audited abstracts from 1894 to 31st December 1899. Resolved :—"That it be appended to the minutes."

COMMISSIONER ON THE CONTINENT OF EUROPE.

Read letter from Mr. J. H. Renton, dated Paris, 20th April, received since the circulation of previous correspondence. Read letter dated, Paris 9th March, *re* finance, and a consignment of tea regarding which he had been making enquiries.

PARIS INTERNATIONAL EXHIBITION, 1900.

Read letters from Messrs. Lipton, Limited, and submitted connected correspondence.

CEYLON TEA IN AMERICA.

Read lette from Mr. Mackenzie, dated London 17th April, received since the circulation of earlier correspondence. Submitted letters from the National Bank of India, Limited, and connected papers.

CEYLON GREEN TEAS.

Read correspondence. Intimated that payments had been made as under :—

March			
1900	4,700 lb.	Dewalakanda Green Teas	R470·00
Do.	8,175 ,,	Brunswick	817·50
April			
1900	638 ,,	Laymastotte do	66·80
Do.	5,240 ,,	Ceylon Green Teas per Whittall & Co.	524·00
Do.	4,470 ,,	do.	447·00
May			
1900	6,960 ,,	Brunswick Green Teas	696·00
Do.	5,450 ,,	Ceylon Green Teas per Whittall & Co.	545·00
Do.	4,906 ,,	Dewalakanda Green Teas	490·60
add total as per previous statement	110,089 lb.		11,008·90
	150,658 lb.		R15,065·80

Leaving the balance of R14,934·20 still available at date. Submitted printed card giving the process of the manufacture of green tea on Brunswick estate as drawn up and approved by Mr. A. E. Wright. Resolved :—"That copies be made available on application to the Secretary." Considered matters relating to the grant for green teas. Resolved :—"That the question of continuing the grant on Ceylon green teas be considered at next meeting of the 'Thirty Committee.'"

PROTECTION OF CEYLON TEAS IN PACKETS.

Discussed the present position of this question. Resolved :—"That reference be made to the Ceylon Chamber of Commerce *re* the practice of transhipment of Travancore teas at Colombo to London and Australia."

REPORT ON CEYLON TEA SOILS BY MR. KELWAY BAMBER.

Read letters from Government and Messrs Capper & Sons. Resolved :—"That the sanction of the Governor in Executive Council be obtained to an appropriation of R800 for printing and circulating the Report." The "Thirty Committee" then adjourned.

A. PHILIP,
Secretary to the "Thirty Committee."

SKETCH SUMMARY OF RECEIPTS AND EXPENDITURE CEYLON TEA (NEW MARKETS) FUND.

(As per audited Abstracts from 1894 to 31st December 1899.)

RECEIPTS.

SALE OF AN ESTATE.

We hear from Gampola that Messrs. Walker, Sons & Co., Ld., have sold the Bodawa estate for R25,000 to Mr. J. C. de Silva who owns a property adjoining it. Bodawa belonged to the bankrupt estate of Mr. de Vos. It is 122 acres with 50 in cultivation, tea, etc.

PRODUCE AND PLANTING.

INDIAN TEA CROPS.—"In commenting on the prospects for Indian tea a twelvemonth ago, we said that 'the more remunerative prices now current cannot fail to stimulate the Indian planters to still greater exertions' than in previous years, and the truth of this prediction is seen," says *The Grocer*, "in a materially larger production during 1899-1900 than the most sanguine of importers and dealers had anticipated. The particulars as just given by the Indian Tea Association (Calcutta and London) show that the actual yield of the crop for the season now drawing to a close reached the unprecedented total of 171,856,400 lb. (details of which are inserted in our usual market report), which was 21,956,200 lb. in excess of that in 1898 99, when a crop of 152,900,200 lb. was raised. For years past there has been an almost continuous expansion in the cultivation and importation of Indian tea. True, the crops in 1896 97 and 1897 98 were of similar extent, say a little over 148,000,000 lb., but that in the following season (1898 99) was increased to 152,900,000 lb.; and when we call to mind the fact that the entire crop in 1895 96 yielded not more than 135,479,000 lb., and also that in 1894-95 it was only about 127,100,000 lb., it is quite evident that remarkable progress has been made in the British tea industry of our Indian Empire within a comparatively short period."

DETAILS.—"Out of the above total of 174,856,400 lb., as representing what may now be considered as last season's crop, it is interesting to note that the amount reserved exclusively for shipment from Calcutta to Great Britain was scarcely, if at all, less than 149,000,000 lb., against 135,500,000 lb. 1898 99, and here alone appears an increase of 13,500,000 lb; all of which statements conclusively prove, if further proof were necessary the full magnitude of the scale on which the general operations in Indian-grown tea are conducted. In touching specially upon the character and outturn of the late season's crop, it may be remarked," says the journal we quote, "that its rapid augmentation was mainly due to the much more favourable weather experienced in the Sylhet and Cachar districts—the very districts where the drought was most severely felt in 1898—and likewise to the new system of coarser plucking, so that these two causes have combined to produce a larger make of common and inferior teas than has been known in any former seasons. Although the proportion of really fine and choice qualities has been less than usual, the 1899-1900 crop has undoubtedly been a very useful one in many respects to blenders and consumers, consisting of a desirable kind of leaf, of strength and colour in cup, with richness and flavour amongst the more delicate kinds sent from the Southern parts of India; and prices on the whole have been at a reasonable level for all parties. Alluding to the recent advance of 2d in the tea duty to 6d per lb, Messrs. George White and Co., brokers, observe that 'its effect is difficult to foresee; but should it lead to the extended use of medium and fine sorts, the former of which have been unduly depressed for months past, it will be a boon to many tea planters, both in India and Ceylon,' adding that 'the prospects, therefore, seem favourable to expansion in the sale of good liquoring descriptions, while that for very common may be partially abandoned, and the prevailing lowest retail price be 1s 4d per lb. If the purveyors to the public can induce their customers to purchase a slightly better blend than they have lately perhaps been accustomed to they would not only benefit themselves, but also the trade generally.'"—*Home and Colonial Mail*, April 13.

QUEENSLAND PRODUCTION FOR EXHIBITION.

The Queensland Department of Agriculture has prepared and shipped to the care of the Agent-General in London six boxes of specimens of the produce of the colony for exhibition in the museums at Stockholm and Christiania—three boxes to each place. The exhibits have been applied for by the authorities in the cities named, and the samples comprising them are made up in small bottles. There are included specimens of wool, sugar, wheat of various varieties, cornflour, arrowroot, sorghums, and millets, earth nuts, beans of different kinds, maize, and other grains. They have all been grown in Queensland, principally on the experimental farms. The department has also nearly completed the preparation of an exhibit for use in England by Mr. Randall, the Immigrant Agent. The hay is now awaited, and when that is secured the butter and cheese to be sent from the Gatton Agricultural College will be at once sent in and the exhibit will be complete. It is fully expected that it will be one well worthy of the colony. Some splendid samples of wheat and barley have been procured, and among the many articles included there will be preserved fruits, jams, jellies, candied fruits and others. The hay will be made into small bales, and will include oaten, wheaten, rye, lucerne and panicum. It may be mentioned that Queensland is the only colony apparently which is taking this means of placing the colony before people in Great Britain.—*Sydney Mail* April 14.

MANUFACTURE OF CRUDE QUININE.

The *Batavia Nbl.* learns from a well-informed quarter that two of the principal Java cinchona planters propose to set up on their grounds factories for the production of crude sulphate of quinine, which will subsequently be refined at the Bandung works. It is expected that this will result in an increased profit—quite twenty-five per cent—over that obtained from the sale of the bark in Amsterdam. The most important point, however, appears to be that it would have the effect of withdrawing something like ten or twelve tons of quinine from the European market, and that other planters will probably, in their own interest, follow the example, and in course of time erect similar works. Another advantage in connection with the proposed works is that inferior bark with one and half or two per cent of quinine-content, which is now either sold at a loss or simply thrown away, can then also be worked at a profit. It is stated that such an installation is not only inexpensive (costing not more than about £500 to £800 for a plant capable of dealing with five to ten cwt of bark per day), but moreover, the work is very simple and requires no great skill or experience. These details are based upon data obtained from similar works which have already been in operation for three years, and in which bark is used of such low quality that it would not pay the expense of shipment to Europe.

CURING OF LIBERIAN COFFEE.

One of the drawbacks to the use of Liberian Coffee has been a strong unpleasant taste, and various remedies have been suggested.

It has now been successfully overcome on the Borneo Coffee Co.'s estate in Marudu Bay by washing the coffee after pulping and before fermenting. The washed coffee is in this way cleaned from all the minute bits of pulp which doubtless imparted an unpleasant taste and before being placed in the fermenting cistern it is thrown into large baskets—"coal baskets"—for a few minutes to allow the surplus water to drain off and is then fermented in a comparatively dry state. To increase the heat, sacks are placed on the top of the coffee and after some hours the top layer is turned in below so as to ferment the parcel equally. Liberian Coffee, properly cured has a splendid flavour which is well known by the trade, who value it highly owing to the amount of chicory it can assimilate. As an after dinner coffee nothing comes up to pure Liberian Coffee if properly cured.—*British North Borneo Herald*.

A BATCH OF CEYLON TEA COMPANIES RESULTS.

(*Investors' Review*, April 21st.)

The reports of the smaller Ceylon Tea Companies so far published show

MUCH MORE SATISFACTORY RESULTS

for 1899 than for the preceding year. Generally speaking, there is a good deal of variation in the experience of these lesser companies, their plucking area being so small that they are more likely to be influenced severely by accidents and climatic conditions than the larger concerns, whose wide area enables the principle of averages to come into stronger play. On this occasion, however, the trend has been almost entirely in one direction, and that favourable, as the following figures will show :—

	Plucking Area.		Crop.		Price per lb.	
	1898. acres	1899. acres.	1898 lb.	1899. lb.	1898. d.	1899. d.
Bandarapola	478	576	395,270	524,259	6⅛	6⅝
Burnside	*	1,134	356,455	378,608	6¾	7 3-16
Ederapolla	853	996	447,026	466,149	6⅝	6 15-16
Highland	603	585	212,415	259,233	9	8½
Kelani Valley	1,200	1,211	578,169	575,255	6½	7
Panawal	577	590	293,933	334,922	6⅜	6½
Poonagalla	—	1,180	261,164	302,614	81-16	7½
Portmore	474	483	241,686	242,746	9¼	8⅞
Yatiyantota	2,240	2,376	1,135,794	1,343,387	5¾†	5 11-15†

* Not stated. † Net prices ; in othere cases prices are gross sale prices.

According to this statement, almost all the companies showed a much larger output, partly owing to larger plucking areas and partly to a better yield per acre. Movements in the average prices obtained varied to a greater extent, but only three out of the nine companies saw their average prices reduced, and in two of these cases the reduction in price was more than compensated by the increased quantity produced. We ought to lay stress on the fact that the prices obtained by the

YATIYANTOTA COMPANY

are strictly net prices, as that company only returns its average price in that form in consequence of the fact that it disposes of a large part of its crop in Colombo. Freight, dock charges, insurances, and other forms expenditure are not included in this price, and this represents quite ¾d to ⅞d per lb. at the lowest estimate. Little has been heard of the Yatiyantota Company until lately, but it promises to become an important concern later on. With 2,990 acres under plant, its revenue last year had to bear the cost of 636 acres not in full bearing and yet it fully earned a dividend of 7 per per cent, although its selling price was so low.

THE SECRET OF ITS PROSPERITY

is to be found in its low cost of production, which did not exceed 3½d per lb last year, which if ⅞d per lb. is added for London charges, would bring up the cost of production to 4⅜d per lb., a figure that should make many of the older managed concerns squirm in their hide-bound system of management.

We are particularly glad to be able to note that almost with one accord these

SMALL CEYLON COMPANIES

have taken the opportunity presented by larger profits to increase their accumulations, a statement borne out by the following table :—

	Net Profits.		Sums put to Depreciation, &c.		Dividend.	
	1898. £	1898. £	1898. £	1899. £	1898. per ct.	1899. per ct.
Bandarapola	1,488	3,924	432	1,823	5	10
Burnside	395	1,276	43	300	2	5
Ederapolla	2,068	2,921	793	800	5	8
Highland	1,879	3,006	125	766	5½	7
Kelani Valley	1,478	2,167	541	291	5	10
Panawal	1,814	3,208	750	1,135	4	10
Poonagalla	820	902	—	—	4	5
Portmore	5,405	4,559	489	159	12	11
Yatiyantota	7,666	12,117	1,639	3,200	4	7

In this it will be noted that all the companies excepting one—the Portmore—pay higher dividends, and that company, which produces a high-priced tea for Ceylon, suffered severely from a reduction in its average price, but even then its distribution is at the high rate of 11 per cent. Its attention, however, to depreciation and reserve was very slight. One other company, the Kelani Valley, did less in this respect, although it doubled its dividend. But it is relatively a strong company having a reserve of £4,500 invested outside the business. In other cases there is a most satisfactory

GROWTH IN THE SUMS PLACED TO RESERVE,

written off new extensions, or devoted to extinction of buildings and machinery accounts. This goes to show that the experience of the last few years has not been without its lesson to the boards, and consequently we may hear less of fluctuating dividends in the future. The level of the dividends declared is really good, and if profits can only be kept up to the record of last year, shareholders should not have much to grumble about. These Ceylon companies have certainly met the rise in exchange

FAR BETTER THAN THE INDIAN TEA COMPANIES.

Apart from one or two notorious examples, the companies were not usually overcapitalised, as many of the Indian companies have been ; and then there is less leakage in profits through poor management and exaggerated agency charges. The low charges of the Colombo agents is all the more remarkable, as their control is much more real than that of the Calcutta agents over Indian plantations. The distance from Colombo to the plantations is less, and this probably accounts for the manner in which the gardens are regularly visited by representatives of the agency firms. There are

TWO WEAKNESSES IN THE FINANCIAL MANAGEMENT

of these small Ceylon companies that must be mentioned before be leave the subject. The first is the large proportion of debenture capital which they have issued. Debenture apital may seem a cheap way of financing

a concern when everything is prosperous, but in a plantation industry this seldom occurs, while now and then one finds everything unpropitious. Debenture interest has to be met all the same, unless the company is prepared to lose its property, and the drain thus experienced sometimes leads to the shareholders receiving on the average lower distributions than the debenture holders. Shareholders should therefore impress upon their boards the need of reducing these debenture issues as quickly as possible. The other matter is one we have grumbled about before, viz., the manner in which profits are anticipated. Take, for instance, the Ederapolla Tea Company; its balance-sheet last December showed that it owed £4,200 on bills payable, £295 to creditors, and proposed to distribute £1,275 in dividend, against which it held £416 in cash, £2,952 of unrealised tea, and had investments and sundry debtors amounting to £1,544. Without drawing bills as fast as its tea is shipped, this company would have no funds out of which to distribute the profits it claims to have made, so that it is always eating its cake before it is fully baked. The same remark applies to many others, and the policy is the direct progenitor of the debenture issues.

MAYFIELD DIMBULLA TEA COMPANY.

Report of the Directors of the Mayfield (Dimbula) Tea Company of Ceylon, Ltd., to be submitted at the third annual general meeting, to be held at the Offices of the Company, No. 9, Mincing Lane, E.C., at 12-30 o'clock, on Tuesday, May 8.

The Directors herewith beg to submit their third annual report and balance sheet for the year ending 31st December, 1899.

The nett yield of Tea from the estates for the twelve months ending the 31st of December last was 459,098 lb. or an increase of 59,639 lb. over last year, which sold at an average price of 8·02d in the case of Mayfield, and 7·12d. in the case of Nicholaoya, or a combined average of 7·62d. per pound gross.

The nett cardamon crop was short of estimate by 1,406 lb. being 3,594 lb. as against 5,000 lb. estimated for, and sold at an average of 2s. 2d. per pound gross.

The profit and loss account, after providing for general expenses, writing off the remaining one-third of the preliminary charges, and charging all expenditure on capital account to revenue, shows a profit of £3,603 1s.; this, together with the balance brought forward from 1898 of £29 18s 1d., makes a total of £3,637 19s. 1d.

Of this, the preference dividend for 12 months ending 31st December, 1899, has absorbed £1,980, leaving a balance of £1,657 19s. 1d. still to be divided.

It is now proposed to pay a dividend of 5 per cent. on the ordinary capital, amounting to £1,531, leaving a balance of £126 19s. 1d. to be carried forward, which is subject to superintendent's commission for the year 1899.

The estates are reported to be in a greatly improved condition, and a further increase in crop may be looked for during the present season. Great credit is due to Mr. Cantlay and the staff in Ceylon for their conduct of the Company's affairs

Under clause 86 of the articles of Association of the Company, Mr. F W Jamieson one of the Directors, retires and, being eligible, offers himself for re-election.

Mr. J F Kane MacGwire, Chartered Accountant, also offers himself for re-election. JAMES SINCLAIR,
No 9, Mincing Lane, Chairman.
London, E.C., April 23rd, 1900.

CEYLON TEA COMPANIES:

A REVIEW OF THE BEST.

(*Financial Times*, May 4th.)

Most of the Ceylon Tea Companies which make up their accounts to December have now issued their reports, and under the circumstances they must be considered surprisingly good. There are one or two companies, such as the Consolidated Estates of Ceylon, the Dimbula Valley and the New Dimbula, whose financial year ends in June, the reports being consequently published in the autumn, but the majority adopt the Indian system, and follow the calendar year, although their reports are, as a rule, brought out considerably in advance of those of the Indian companies. It is not too much to say that even experts were agreeably disappointed by the results shown for 1899. The year was by no means altogether a favourable one as regards prices, particularly for high-class teas, and the fact that several of the companies have been able to increase their dividends, while adding to their allowances for reserve and depreciation, must be attributed mainly to more careful and economical management, which has led to savings in working charges. A general view of the results obtained by the leading companies during the year is presented in the subjoined table:—

Company.	Net Profit.		Appropriations for Reserve and Depreciation.		Dividend per cent.	
	1898.	1899.	1898.	1899.	1898.	1899.
	£	£	£	£	pc.	pc.
Ceylon Tea Plantations	41,380	43,664	10,000	10,000	15	18
Eastern Produce and Estates	27,913	28,615	nil	nil	7	7
Standard Tea Company	9,774	10,780	1,000	1,700	15	15
Nuwara Eliya	15,667	17,290	nil	2,300	6	7
Scottish Ceylon Tea	4,235	6,960	nil	1,400	10	12
Alliance Tea	5,205	7,900	300	1,000	7	8
Yatiyantota	7,666	12,120	1,000	1,000	4	7

It will be seen at once that out of the seven companies included in our list five have increased their distributions and four have increased their appropriations for reserve and depreciation. Taking the companies seriatim, we find the first in our table—the Ceylon Tea Plantations—occupying a very strong financial position. It has a reserve fund of £100,000, mainly accumulated during the past eleven years. From 1887 to 1898 inclusive it has paid regular 15 per cent. dividends, while for last year the distribution was raised to 18 per cent., and the carry forward amounted to £6,356. Adequate amounts have also been set apart out of revenue for depreciation, the appropriations during the past three years being £5,000 per annum. The Company has no Debentures and the issued capital is only £248,460, of which £81,080 is in Seven per Cent. Preference and £167,380 in Ordinary shares. A portion of the reserve is invested in coconut plantations, which

have proved very remunerative, the sales last year bringing in £17,591. The Company is to be commended for publishing with its report a tabular statement showing the results of working for thirteen years, a plan which might with advantage be adopted by other companies. Naturally, the £10 Ordinary shares stand at a considerable premium, the present price being about 26¼, but the yield at this figure is still 6⅜ per cent.

The Eastern Produce and Estates Company, the next on our list, cannot boast such a brilliant record, but within the last seven years it has gradually increased its dividend, and for three years past the shares have been on a seven per cent basis. The reserve fund, it is true, appears small, being only £25,000 for an issued share capital of £299,800, and it has not been added to for some years. But the Company has reduced its Debentures debt from £195,200 to 80,000, the amount so applied last year being £7,500. In reality, therefore, it has accumulated a considerable reserve fund, and it should be noted that when the Debentures are reduced to a total of £50,000 the sinking fund may cease. The balance carried forward from last year is the very considerable one of £9,800. A reference to our usual table of Indian and Ceylon Tea Planting Companies, shews that the shares can be purchased to yield about 6¾ per cent. The Standard Tea Company, our next selection, has an excellent record as a dividend payer, the distributions rising from 10 per cent. in 1893 and 12½ per cent, in 1894 to a level of 15 per cent. in 1896, which has been maintained ever since. The Company, though not paying more for last year, has set aside £700 additional for reserve and depreciation, and slightly increased the carry forward The paid-up capital is small, amounting to only £59,500 so that the reserve, which now reaches £11,000, is not altogether inadequate. Some objection may be taken to the fact that the majority of the £10 shares and those the most freely dealt in, are only £6 paid. But this state of things has its advantages, since, owing to this liability on the shares, the Company has no prior charges, and is able to borrow on very favourable terms. The good results shown by last year's working are the more creditable, as the Company produces a considerable quantity of fine teas, and the prices obtained for such qualities were, on the whole, unfavourable. The fourth concern on our list, the Nuwara Eliya, is rather heavily capitalised, having a subscribed share capital of £200,000, in addition to £30,000 of Debentures. It is a comparatively new undertaking, only registered in 1895, and so far has accumulated no reserve fund. The Directors, however, have been conservative in their distributions, and have only raised the dividend to 7 per cent. after maintaining it at 6 per cent. for the previous three years, while £2,599 is this time carried forward. The Company produces tea of fairly high average quality, and the report sets forth the profits made by the various estates very clearly. On the whole, the Nuwara, notwithstanding its capitalisation, may be said to occupy a sound position.

The Scottish Ceylon Company shows a large increase in profits last year, and after distributing 10 per cent. dividends for the past few years is now enabled to pay 12 per cent. It has also written off £1,000 from the estates account and £402 from capital expenditure, which was not done in the previous year. The issued share capital of this concern is only 50,000, of which £9,000 is in Seven Per Cent. Preference and the balance in Ordinary shares, and there are no Debentures. The reserve fund is £7,000. This Company made a very considerable stride forward last year, and the shareholders are to be congratulated on the improved position. The weak point about the Alliance Tea Company is that it has not succeeded in putting anything to reserve except a sum of £4,600, representing the premiums received on shares and Debentures. The issued share capital, it is true, is only £65,250, but the Debenture debt is close upon £45,000. Possibly instead of increasing the dividend from 7 to 8 per cent last year, it might have been more advantageous to have set apart something towards the formation of a reserve fund. However the Directors write off £1,000 for depreciation and carry forward £2,180, so it cannot be said that they have divided the profits absolutely up to the hilt. Our last Company, the Yatiyantota, is quite a young concern, only dating back to the end of 1896. Commencing with a 2 per cent dividend for 1897, it increased its distribution to 4 per cent for 1898, and pays 7 per cent for the past year. The property consists of lowland gardens, producing large quantities of lower-grade teas, and the Company benefited considerably last year by the high prices ruling for common teas, especially in the spring. That cannot, of course, always be the case, but an excellent feature of the working of this undertaking is the extraordinarily low cost of production, so that even on a less favourable market the Company should still be able to realise its produce at a good profit. The Company's issued share capital is £135,000, of which £45,000 consists of six per cent. Preference shares. The Ordinary share capital was issued at a high premium, so that although the Company has from this source a reserve of £45,000, it was provided by the shareholders themselves, and was not obtained out of revenue. Speaking generally of the Tea share market, it may be said that although there has been a moderate recovery from the lowest prices touched since the boom time, there is still a fair margin for further improvement, and many of the good shares, such as those indicated, are worth attention. As regards the future, the horizon is not quite free from the cloud of over-production, yet it is brightening. All large extensions of gardens are now practically stopped, while the foreign markets for Indian and Ceylon teas are steadily developing year by year. The Indian exchange question is now practically eliminated; producers have become habituated to a stable rupee and one element of uncertainty is thus abolished. The Ceylon Companies, as a whole, in addition to those dealt with the above, show excellent results for the past year, and they are the more creditable as they were achieved under conditions by no means entirely favourable.

UNDEVELOPED TIMBER WEALTH.—The *Bangkok Times*, in dwelling upon the restricted output of teak timber in Siam, points out that there are immense quantities of hard woods in the forests of the Siamese Malay Peninsula. But there are considerable difficulties in the way of obtaining leases to work these forests. Another difficulty is the uncertainty regarding the amount of the transit tax to be levied on woods.

SCOTTISH CEYLON TEA COMPANY, LTD.

ANNUAL REPORT.

The Directors have now the pleasure to submit to the shareholders the Accounts and Balace-sheet for the 12 months ending 31st December, 1899.

	£	s.	d.
The net profits for the year amount to £6,959 6s 2d, to which has to be added £456 4s 7d brought forward from previous accounts, giving a total to be dealt with of ..	7,415	10	9
An Interim Dividend on the Ordinary Shares of 5 per cent (free of Income Tax) paid in September, 1899, absorbed .. 2,050 0 0			
Dividends on the 7 per cent Preference Shares have also been paid, amounting to .. 630 0 0			
It is now proposed to pay a Final Dividend on the Ordinary Shares of 7 per cent (free of Income Tax, making 12 per cent for the year .. 2,870 0 0			
To write off the Capital Expenditure incurred during 1899 .. 402 14 9			
To write further off Estates Account .. 1,000 0 0			
	6,952	14	9
Leaving a balance to carry forward to next account of	£462	16	0

The total crops secured from the Company's properties during the year amounted to 819,704 lb., being 28,704 lb. over the estimate, and 60,705 lb. more than the previous year's outturn, which the Directors consider a satisfactory inorease.

In addition to the foregoing, 121,716 lb. of tea were manufactured for others giving a total output from the Company's Factories for the year of 941,420 lb. made tea.

The average yield per bearing acre was 480 lb. against 445 lb. for 1898, the rate of exchange was 1s 4⅜d per Rupee, against 1s 4¼d, and the average prices realized in the London and Colombo markets respectively were 7·707d and 35 cents against 7·869d and 32 cents for the previous year.

No additions have been made to the Company's acreage, which remains unaltered at 1,965 acres, including 1,720 acres under tea cultivation.

The eylon Manager, Mr Kerr, who is now on his way home on short furlough, reports that all the ompany's estates are in good heart, and his estimates for the current year point to a continuance of satisfactory returns.

The Directors would again take this opportunity of recording their appreciaton of the services of the staffs, both in eylon and London.

In accordance with the articles of Association, Mr. G G Anderson retires from the Board, and, being eligible, offers himself for re-election.

Mr. J B Laurie, C.A., also offers himself for re-election as Auditor.

MAYFIELD (DIMBULA) TEA COMPANY OF CEYLON (LIMITED.)

ANNUAL REPORT.

The report for the year 1899 states that the profit and loss account, after providing for general expenses, writing off the remaining one-third of the preliminary charges, and charging all expenditure on capital account to revenue, shows a profit of £3,608. This, altogether with the balance brought forward, makes a total of £3,638. It is proposed to pay a dividend of 5 per cent on the ordinary capital, leaving a balance of £127 to be carried forward, which is subject to superintendent's commission for the year 1899.—London *Times*, April 30.

OUVAH COFFEE COMPANY, LIMITED.

ANNUAL REPORT.

Presented to the fifth ordinary general meeting of the Company at No. 5, Dowgate Hill, London, on Wednesday, the 16th May, at noon.

Since tea has become the staple product on our estates it has been found that it will be more convenient to terminate the financial year on the 31st December in place of on the 31st July. Accounts are now therefore presented for a period of seventeen months, viz. :—

Balance sheet made up to 31st December, 1899.

Profit and loss account for seventeen months ended 31st December, 1899.

The receipts from the sale of produce were as under :—

	lb.	£	s.	d.
Tea from the Company's own Estates ..	953,150			
Tea made from bought leaf	136,341			
Total ...	1,089,491	34,330	1	6
Coffee 841 cwt. 1 qr. 19 lb. ..		3,178	3	7
Cocoa 77 cwt. 2 qr. 2 lb. ..		213	9	0
Cinchona 41,878 lb. ..		814	10	5
Plumbago 643 cwt. 3 qr. 7 lb. ..		1,157	2	9
Sundry sales in Ceylon ...		61	9	8
Total receipts ..		£39,754	16	11

The total expenditure in Ceylon and London amounted to £32,031 15s 5d, and deducting this from the value of the produce, a profit is shewn of £7,723 1s 6d. to which has to be added the balance of £409 4s 9d, brought forward from the previous year, making a total of £8,132 6s 3d.

From the above profit the Directors have transferred to the credit of Badulla Factory Account £1,030 6s 6d and to the credit of Plumbago Mining Account £700 0s 0d. The interim dividend of 2½ per cent paid on 23rd November, 1899 absorbed £2,500 and Income Tax £177 8s 0d, leaving a balance of £3,724 11s 9d, out of which it is proposed to pay a further dividend of 3½ per cent, making six per cent in all, and to carry forward to next account the sum of £224 11s 9d.

Drought and unfavourable weather continued to adversely affect the yield of tea. The seventeen months' crop, estimated at 1,025,188 lb., only realised 953,150 lb. of made tea; the yield per acre for the twelve months ended 31st July 1899, being 404 lb. against 438 lb. and 475 lb. respectively for the two preceding years.

The better prices secured during the early part of 1899 were not maintained, and our selling prices over the seventeen months averaged 7.56d per lb. as against 7·78d for the previous year.

The cost of planting an additional 18 acres of tea and the up-keep of 463 acres of young tea not in bearing are included in the ordinary expenditure.

In the month of June 1899, an outcrop of workable plumbago was discovered on the Company's land, and plumbago to the extent of 643cwt.

3 qrs. 7 lb. has been mined and sold for £1,157 2s 9d at a cost of £473 19s 5d.

We are advised that the veins now being worked are only off-shoots, and it is expected that a larger and more valuable body of mineral will be reached.

The plumbago already secured has been cheaply obtained as our tunnels are only as yet driven some 150 feet into the face of the hill. The working as it becomes deeper will be more expensive, and it is possible that pumping plant may be required later on.

The Directors have therefore determined to reserve the profit made on the plumbago already mined, to enable the Company to thoroughly prospect what may become a valuable source of revenue,

The tea crop for 1900 is estimated at 812,100 lb. Favourable weather has so far been experienced, the crop secured to the 7th April being 301,950 lb. or 123,560 lb. in excess of the crop secured during the same period last year.

The acreage of the Company's property is now as follows :—

		Acres.
Tea, over 5 years old	..	1,740
Do planted Nov.—Dec.	.. 1895	117
Do do	.. 1896	151
Do do	.. 1897	133
Do do	... 1898	23
Do do	.. 1899	18
Area under Tea	..	2,182
Area under Coffee and Cocoa		424
Area under Fuel	..	367
Forest Patna and Waste	..	515
Total Area	..	3,488 acres

Mr. P C Oswald, a member of the Board, retires on this occasion, and being eligible, offers himself for re-election.

Messrs. Deloitte, Dever, Griffiths & Co., the Auditors, also offer themselves for re-election.—By order, J. ALEC ROBERTS, Secretary.

SPRING VALLEY COFFEE CO., LD.

ANNUAL REPORT

Presented to the Thirty-sixth Ordinary General Meeting of the Company to be held at No. 5, Dowgate Hill, London, on Thursday, 17th May, at 12·30 p.m.

In accordance with the announcement contained in the last Annual Report, the Company's financial year will, for the future, terminate on the 31st December of each year in place of on the 31st July, and in order to bring this into effect and to comply with the provisions of the Companies' Acts, Accounts are now presented to Shareholders, viz.: Balance Sheet made up to 31st December, 1899; Profit and Loss Account for the five months ended 31st December, 1899.

The result for this incomplete period is a loss of £131 16s 3d, which falls to be deducted from the sum of £372 6s 7d brought forward from the previous year leaving £240 10s 4d to be carried forward to the current year.

Expenditure during the latter months of the year is always heavy in proportion to the crop secured, and this result must not therefore be accepted as a true index of the working of the property.

The unfavourable climatic conditions referred to in the two preceding Annual Reports continued without improvement to the end of the year, but the Directors are glad to be able to report that since then much better pluckings have been secured. Our Manager, writing on 9th April, states that fine showers had fallen, and that flushing will be heavy for some time. Crop secured to the 7th April shewed an increase of 42,540 lb. over that secured at the same date last year.

Mr. Leon Famin, a member of the Board, retires on this occasion, and, being eligible, offers himself for re-election. Messrs. Deloitte, Dever, Griffiths & Co., the Auditors, also offer themselves for re-election. By order,

J. ALEC ROBERTS, Secretary.

THE MIDLAND (CEYLON) TEA PLANTATIONS CO., LTD.

ANNUAL REPORT.

Report of the Directors, to be submitted to the Shareholders at the Ordinary General Meeting, to be held at 30, Mincing Lane, E.C., on Friday, 25th May, 1900, at 12 o'clock noon.

The Directors beg to submit the accounts, duly audited, for the year ending 31st December, 1899.

The Receipts for the Season are ..				£9,670 16 11
Less Working Expenses in Ceylon ..				7,011 8 0
Leaving Gross Profit ..				2,659 8 11
From which has to be deducted.—				
Debenture Interest—				
6 per cent. per annum on £15,000 ..	£900	0	0	
Interest on Loans ..	172	7	11	
Fees to Trustees and Auditors, Office Expenses in London, &c.	97	0	7	
Preliminary Expenses, Balance written off ..	133	5	6	
Depreciation on Machinery, &c. ..	400	0	0	
				1,702 14 0
				956 14 11
And the Balance of Loss at 31st December, 1898, being also chargeable ..				497 10 3
There remains a sum of				459 4 8
From which the Directors recommend a Dividend of 6 per cent. per annum on the Preference Shares, £2,000, amounting to				158 18 0
And propose carrying to the next Account the Balance of				£300 6 8

The results of the year's trading enable the Directors to write off all arrears, both for Preliminary Expenses and the balance at debit of Profit and Loss at 31st December, 1898 amounting together to £630 and also to recommend a dividend on £2,000 Cumulative Preference Shares from the dates of allotment. The London Agents have charged only a nominal sum for office rent and secretarial work, and the Directors, who have again waived their fees are glad to be able to place a sum of £400 to the credit of a Depreciation Fund.

The Tea sales for the year amounted to 386,313 lb., being an excess of 6,313 lb. over the estimate, and the net average price was 5·91d. per lb., or nearly ¼d. per lb. higher than that for the previous year. The Rupee exchange showed a slight advance, the average rate being 1s 4·31d per Rupee.

The acreages under cultivation are—

Over four years old.	Under two years old.	Total.
938	80	1,018 acres,

and the crop for the current season is estimated at 385,000 lb. Under the advice of Mr. Tatham, the Visiting Agent, the Directors have sanctioned the application of manure to a further 147 acres, the

outlay under this heading during last year having been well repaid by the vigorous growth of the Tea.

The Directors have authorised the opening into Tea of a further 30 acres of jungle, and the work was begnn at the end of January. The new clearing opened last year is doing well and is in good order. A small field of about 30 acres will be partly abandoned, as the returns are not sufficient to warrant its being permanently retained in cultivation; but for a few years it will still yield a certain amount of crop, and eventually will be more than replaced by the 30-acre clearing of last year.

In his last Report the Visiting Agent writes that the group of Estates has improved during the year, and he looks for larger crops in the future, care and attention having been bestowed on the property by the Superintendent.

Under the Articles of Association, Mr. R. C. Aitken retires from the Board, and, being eligible, offers himself for re-election.

The Auditors, Messrs. Brown, Fleming and Murray, also retire, and their re-appointment remains with the Shareholders.

GREAT WESTERN TEA CO. OF CEYLON, LD.

THE REPORT

of the directors for the past year was submitted Report as follows:—

The Directors submit their annual report and accounts for the season ending 31st March, 1900.

The yield of tea has been 415,975 lb. being an increase of 102,550 lb. on last season's crop; the price realized on 330,175 lb. for which account sales have been received is 48·96 cents per lb. against 48·74 cents last season and 40·47 cents in 1897-98.

The cost F. O. B. Colombo is 31·27 cents per lb. (including 4·23 cents for manuring) against 35·98 cents (including 3·56 cents for manuring) last season.

Estimating the unsold portion of the crop at a safe figure, the amount available for distribution, after setting aside R5,291·65 for depreciation, is R70,176·10, out of which the Directors recommend the payment of a dividend of 10 per cent absorbing R58,400 00

To place to Reserve Account a sum of	10,000	00
and to carry forward the balance of	1,776	10
Total ...	R70,176	10

The estimated crop for the current season is 440,000 lb. to cost R134,872·39 being at the rate of 30·65 cents per lb. tea inclusive of 4·06 cents for manuring.

In terms of the articles of Association Mr. A Cantlay retires by rotation and being eligible offers himself for re-election.

It will be necessary to appoint an Auditor for season 1900-1901.—By order of the Directors,

(Signed) J. M. ROBERTSON & Co.,
Agents and Secretaries.

Colombo, May 28th.

FORMOSAN CAMPHOR-MONOPOLY.

The interest of the drug-trade this week has been centred in camphor, news having come to hand that the Japanese Government have at last accomplished something definite with regard to the Formosan output. It was in June last that the Government definitely assumed control of the industry, and in August they framed regulations with regard to its working. Since then nothing but vague rumours have transpired as to what they were doing, it no doubt being a fact that they found the whole situation bristling with difficulties. Now, however, they appear to have awakened from their apparent lethargy, as it was announced on Monday that the monopoly had been put in the hands of one firm only—viz., Messrs. M. Samuel & Co., the well-known merchants of London and Japan, who have paid £250,000 for the concession. It appears that they were about twenty foreign firms competing for the monopoly from the Formosan Administration Office, including Jardine, Matheson & Co. The firm in question are in close touch with the Japanese Government, and have had many business transactions with them, the recent Japanese loan being placed in their hands. It appears also that the monopoly to sell the crude product has been granted for a term of five years, and that the price has already been fixed at about 180s. per cwt., c.i.f., at which figure forward contracts will be made.

We are informed that the Japanese Government have for the past six months been quietly buying all they could, and that they have now secured 12,000 piculs, leaving, it is said, 900 piculs not under their control.

It is said to be their intention to deal with consumers in the fairest possible manner, and to that end they guarantee that the quotation will not be reduced below the minimum of 180s.—in fact, it is likely to go higher, as they intend to limit the output by two-thirds, and the effect of this will be felt when once they have got the grip of the market. Of course they are anxious to avoid speculation, and they will endeavour by all possible means to prevent it by having as few fluctuations as possible consistent with the laws of supply and demand. They will also endeavour to control the shipments, so that no country—say, for instance, the United States—will be able to accumulate large stocks. One London firm is already reported to have approached the controllers with the idea of taking over the whole output, but the offer has not been entertained. The Government have also decided that no camphor manufactred in Japan will be allowed to be exported, as it will be required for their own consumption, so that henceforth all crude camphor will be known as Formosan.

Meanwhile importers and brokers are in a dilemma as to where they come in, for, as the matter now stands,

THE CRUDE-CAMPHOR BUSINESS

has been taken out of their hands. At the present time there is no business to be done except as regards spot stock, of which there is a fair quantity here, especially in second hands. It is estimated that the supply is sufficient to keep the whole consuming trade going for about six months, as there is a stock of 2,000 piculs on offer in the hands of London brokers. As it is, dealers here have already advanced their price to 185s., or 5s. over the Government price. Importers are naturally sceptical as to the working of the monopoly, and do not believe that it will put an end to speculation. They also contend that junkloads of crude camphor have been smuggled out of the island and conveyed to Hong Kong, but stringent measures have now been taken by the Government to put a stop to such actions. Refiners do not seem so awkwardly placed, as, once they have a fixed price for the crude, they will be able to regulate the refined accordingly. However, they may have the Japanese Government as a competitor, as it is their intention to refine a certain amount for their own consumption. Indeed, a parcel of refined from Formosa was offered at the drug-auctions in February, and sold at 1s. 10d. per lb. The establishment of this monopoly can have but one effect on the price of camphor, and that will be to place it at a higher figure. Were camphor simply used *per se* for domestic purposes, no advance would probably occur; but it now enters largely into the composition of celluloid and this will affect many things.

Reports which have been received from Formosa state that the island is now settling down to sound industrial development. The whole administration is being handled by experienced Japanese officials, and public works of various kinds are being undertaken. There is also a steady flow of American capital into the island.—*Chemist and Druggist*, March 31.

PLANTING NOTES.

NEW AREAS OF CULTIVATION.—913 acres were opened in tea, 49 in cacao, 358 in plantains, 92 in rubber, and 116 in cardamoms in the course of the year. The total acreage planted was 2,433. A much larger extent of land was sold in 1899 than in the previous year, when 328 acres only found purchasers.—*Mr. Hill.*

RUBBER.—The United States Government hoped to save some £6,000,000 worth of imported rubber annually by starting a new source of supply in their recently acquired Hawaii. It is said that the agents of the Agricultural Department will collect some 100,000 rubber-trees from Brazil, Mexico, and Central America, and begin planting in the island —*The Planter*, June 2.

CAMPHOR-TREES IN CEYLON.—Mr. Owen, of Lindula, has been making another experiment with camphor-tree prunings and has got about one per cent. camphor,—that is 7-lb. prunings from a 5-year old tree (from Hakgala) yielded about one ounce of solid camphor, besides oil. This indicates a paying industry, if an appreciable clearing and supply of prunings could be assured. Crude camphor realizes up to 200s per cwt.

EFFECTS OF SALT WATER ON THE SOIL.—A recent paper read before an English society deals with the chemical effect of a high tide on 30,000 acres of Essex soil. The last water injury lasts, according to various authorities, from five to twenty years. After the water had run off it was found that there was 2 per cent of the salt in the soil twenty times the normal amount, but not directly injurious. The damage seems to be chiefly due (says "Engineering") to the entire destruction of the earth-worms. The 1898 crop was very poor, and the following spring the state of the soil was also very unsatisfactory; still earth-worms began to appear, and nine-tenths of the salt has been washed out by rain. Apparently the soil has become gelatinous, owing to the action of the chloride on the silicates, the silicate of alumina remaining behind, while the other silicates are greatly reduced in percentage. The proper treatment seems to be to plough in green crops, dressing with lime and potash, and manuring.—*Exchange.*

PYTHON-BREEDING AT THE CALCUTTA ZOO.—It is not often that one has the opportunity of seeing a pythoness hatching its eggs, and those who were lucky enough to visit the Zoological Gardens last week might have witnessed the unique sight. The eggs are about twice the size of ducks' eggs, and exhibit a leathery crumpled up appearance, as if they were small bladders not properly distended with air; their colour, however, is a dirty white, and their covering might be compared to the skin of a mushroom. The pythoness which appears to be about thirteen feet in length, and whose body in its thickest part must be nearly two feet in diameter, is nursing her eggs in a curious manner. She has coiled herself up in a symmetrical heap till she resembles a basket of which the sides and the lid are her coils; and within this arrangement she has piled up the eggs, which she is so assiduously hatching. It will be interesting to see the little pythons when they make their entrance into the world, for, to judge from the size of the eggs, they should be quite six inches in length. The poor mother was so stared at by sightseers that authorities took pity upon her and covered up the glass face of the cage with a screen.—*Statesman*, May 24.

TRAVANCORE TEA.—Heavy yields are expected from various tea estates in Travancore, and in some quarters it is thought that quality as well as quantity will show improvement. We note that the North Travancore Land, Planting and Agricultural Society, Ld., has now been formally "absorbed" by the Kanan Devan Hills Produce Co., Ld. We are by no means sure that the planting industry in Travancore will gain by the steady aggrandisement of a company that has now acquired such a preponderating influence; but at least it is well that capital should be forthcoming for the development of work.—*Planting Opinion*, May 19.

REPRESENTATIVE TO PARA.—A suggestion has been made that the time has come for Malaya to send over a practical planter to Para to inquire into the condition of rubber cultivation in that country, methods of tapping in vogue, etc., and the Chairman of the United Planters' Association undertook to address a letter to the papers on the subject. This has been done and without exception the criticism evoked has been favourable, but the Committee of the Association think sufficient time has scarcely elapsed for them to give any further expression of opinion.—*Straits Times.*

A RUBBER PLANT FOR TEMPERATE CLIMES.—In a recent lecture at the Paris Académie des Sciences, says *Das Handelsmuseum*,. Messrs. I. Dybowski and G. Frou introduced a new rubber furnishing plant, a native of Northern China, which is at present cultivated with great success at the Jardin des Plantes, the Paris Horticultural Gardens. Up to the present time rubber has been extracted from trees only, and efforts have been made to acclimatise those from the Netherland East Indies in the French colonies, but, unfortunately, without any result whatever. This new plant, called *Encomia illinoides*, whose fruits, contain over twenty-seven per cent of indiarubber, has great economical advantage. It can easily be acclimatised and cultivated in countries of even a moderate climate.

THE NEW CUSTOMS ORDER IN REGARD TO TEA.—Last month there came into operation a new London Customs order introducing the weighment of tea with a half-pound weight in conformity with the agreement arrived at last year, the result of which will be a little gain to producers and buyers, we believe. On August 4th last, Messrs. Gow, Wilson & Stanton, commenting upon the agreement, said:—

The dispute concerning the overweight which growers of Indian and Ceylon Tea have formerly allowed buyers has been settled subject to the conditions being confirmed by a general meeting of importers to be held today, and the proposed method of weighing receiving the sanction of H.M. Customs. The main points of the agreement are as follows:—The 1-lb. trade draft to be allowed as heretofore. All Teas are to be weighed gross as formerly, odd ounces being disregarded and consequently given in buyers favour. The empty package is to be weighed to the ½-lb. (*a*) Should it weigh the exact even pound it is to be entered as such. (*b*) If it weighs the even ½-lb. or over it is to be entered as the next pound above. (*c*) If it weighs below the ½-lb. it is to be entered as the 1-lb. below. These regulations to come into force on the 2nd October, 1899. This agreement is generally considered, under all the circumstances, a reasonable compromise and one that growers can benefit by, if they exercise care in weighing gross and tare.

SUGAR looks strong from American news, but here people think advance gone far enough. Wheat and Corn should rise Coffee consumption is greater than supply and should rise. Iron, copper and tin are higher enough. Cotton growing crop 20 per cent. increase in acreage and fertilizers 28 per cent.—*Cor.*

MICA FROM CEYLON.—It will be a matter of interest to many that mica is becoming an article of export from this island. Small quantities are being sent now. The "City of Sparta," due here tomorrow, takes away 1 ton (23 cases) of mica. Last month 20 cases were sent. The article is sent to London. Mica is believed to exist in Ceylon extensively and should a demand for it be found, Ceylon ought to be able to supply it to any extent.—Local "Examiner."

THE ASSAM-BENGAL RAILWAY CO., are, we hear, taking the enterprising step of inducing one of the steamer companies who trade in our East Indies to provide a steamer service between Chittagong and London during the ensuing tea and jute season. It would mean 'full loads' either way, we should fancy, or at least hope so for the game to be worth the candle. Messrs. Duff Bruce & Co. are the new consulting Engineers at home to the Assam-Bengal Railway Company, in succession to Mr. William Duff Bruce.—*Indian and Eastern Engineer*, (May.)

INDIAN LABOUR APPLIED FOR FROM THE STRAITS!—We commend the following piece of Indian news to the enterprising Government that rules this land, a Government which for its size has more public works on its hands than any in the East and has as yet made no official announcement as to the steps it has taken to procure labour for those works:—

The following telegram from the Government of India was recently received by the Madras Government:—"Governor-General in Council learns that Protected States, Malay Peninsula, are anxious to recruit Indian labour this year in famine tracts Hoping to obtain better supply than in ordinary years they seek co-operation of Indian Government. Please consider whether any special facilities for obtaining labour can be given to Protected States exempted from Indian Emigration Act." In reply the Madras Government said:—"Instructions will be given to District Officers to allow the emigration agents of Straits Government to proceed with voluntary emigration without interference or obstruction."

ON THE COLLECTION OF RUBBER FROM CEARA TREES.—From the "Bulletin de l'Union Agricole Calédonienne" we translate the following:—"M. Godefroy-Lebeuf, the well-known and distinguished horticulturist, writes to us as follows: My Dear President,—I call your attention to the process for collecting ceara rubber which, Mr. Lecerf, my friend just now in Guinea, has made known to me. He soaks a sponge in lime juice or salt water, washes one side of the tree to be bled with this sponge, then makes some oblique incisions, one above the other. The milk escapes and the drops collect and form, in coagulating, a layer of rubber which is taken away the next morning. The trees used in the experiment were less than a year old Yours respectfully, Godefroy Lebœuf." Planters and others in Ceylon who freely grew the ceara tree some years ago, and then abandoned the culture as worthless, should experiment as above on some of the old trees and send us the result.

CHILLIES.—Mr. Stronach writes on another page for some practical information on the subject of cultivating chillies. Can any of our readers reply from actual and recent experience of their own?

WIPING OUT THE MOSQUITO.—Interesting experiments have been conducted in Sassari by Dr. Fermi, Dr. Lumbau, and Dr. Cossu Rocca, with the object of freeing that town from mosquitoes. The larvæ were destroyed by means of petroleum placed in the puddles and other breeding-grounds twice a month, and the mosquitoes were exterminated by means of chlorine and other destructive agents. Dr. Fermi considers it possible to free any town from mosquitoes by this method, unless its situation is exceptionally unfavourable. The expense, for a town of 50,000 people, is from £40 to £60 a year.—*Daily Mail*, May 12.

A VALUABLE TESTIMONY TO "TEA"—has just been paid by Professor Victor Horsley F.R.S., in the second "Lees and Raper Memorial Lecture" in St. James's Hall, when Mr. Augustine Birrell, Q.C., M.P., presided. The subject was "alcohol and the brain" and the reference to tea is found in the following paragraph of which "the Thirsty Committee" and its agents ought to make the most:—

Now was to be considered the effect of alcohol upon voluntary movements—those performed by the central part of the great brain. It had been discovered that this part of the brain does not act uniformly and steadily, but that it gives out energy intermittently, in a tremulous way, by a rhythmic succession of impulses. Careful investigation had shown that alcohol increased this tremulousness, and also reduced the power of action. Krepelin found, in experiments with the dynamometer, that, after a small dose of alcohol, at first an additional amount of power was put out, but that it was quickly followed by a lowering effect. *He found also the interesting fact that after a dose of tea there was no lowering effect.* Further experiments had been made in which a certain amount of *thought* was combined with voluntary movements. Compositors offered themselves as subjects for this experiment, and by careful measurement it had been clearly demonstrated that small doses of alcohol had a deleterious effect. So in the case of Arctic expeditions and other undertakings experience had shown that alcohol as an article of diet should be excluded.

INDIA-RUBBER.—It is extraordinary the interest taken in this product all round the tropical world and beyond it as shown by the Indian Government deciding to open a 10,000 acres plantation on the Burma Coast. Our latest enquiry comes from Port-au-Prince, from a former Gardener at Kew, who is now engaged in Rubber Cultivation in Hayti for a large Belgian Commercial House. Besides growing Heveas, Castilloa, 'Manihot,' and 'Supinon' (*sic*) on a large scale, he intends trying a number of other rubber-yielding plants. From Paris, we have an interesting but rather puzzling letter from Mr. A. Godefroy-Lebeuf, which, written in English, we interpret in some parts as well as we can. The sample of rubber sent to us is very peculiar coarse and by no means clean—but still rubber. It can be seen at our office by anyone interested. There should be no difficulty in getting the pieces of bark for experiment, as desired by our correspondent; but he gives us no dimensions will strips an inch wide, by a foot in length, do?

THE ADVANTAGES OF AN AGRICULTURAL DEPARTMENT.

"Camellia," who writes some of the most interesting and sagacious letters appearing in the *Pioneer*, has a communication in a recent issue from which we extract the following, as of special interest to us in Ceylon, who already have the nucleus of our coming Agricultural Department:—At the present moment it is indisputable the three great planting industries of the country—I refer to

TEA,

coffee, and indigo—have entered on a critical period, at all events financially; and I do not think the most expert of either of the above will be found venturing on any sort of confident forecast for the future of either of the above noted industries,—certainly the great palmy days of all are past. Now it is worth while briefly considering first tea, if the splendid province of Assam is due to anybody it surely is the tea planters, and British capital in the main. Assam tea has been fairly floated now over fifty years. During that time it has paid Her Majesty's Government an enormous sum in revenue, it has been the life-blood of many Calcutta firms, river companies, docks companies and created a large number of Government officials, and added very largely to Indian revenue in many ways, in short it has been one of the greatest factors of the century in India's prosperity and commercial enterprise. This being so I would maintain it is the duty of Government to assist it in every possible way, practically and scientifically, and when it is borne in mind what America, Canada, and all the Australian Governments are doing for their chief staples and have been doing for years past, it is nothing short of a disgrace that the tea industry in India at this time of day is without a mycologist, and only now just on the point of bringing out an agriculturist chemist 'tis true. Dr. Watt made a valuable investigation into the insect pests of tea no great time ago. Subsequently what did he say? That he knew of nothing so beset with empirical methods as tea; yet at this present moment

THE INDUSTRY IS ABSOLUTELY BEREFT

of a single Government Officer, systematically employed to investigate these empirical methods referred to by Dr. Watt. I do not think it is too much to say as our American cousins would certainly say,—"Guess we would made things hum differently." And I feel sure if Mr. Stebbing or any one else cares to make enquiry, he will find planters now-a-days in India have quite all they know what to do, to figure out accounts on the right side; and while I fancy none of them want charity a first rate case could be easily made out for a far more liberal and just treatment at the hands of Government, especially in the way of a searching enquiry into all things appertaining to tea. Here with an Agricultural Department, worked on Canadian or American lines, there would surely be a tea section in which experts would work out the problems and eliminate the empiricism from beginning to end. It is altogether too much to expect at this time of day when these industries have certainly got into troublesome times to expect private individuals or associations of individuals can do much. Time is required money is required, laboratory and instruments and above all

PERSISTENT CONTINUOUS INVESTIGATION

in all these things nigh every individual comes to grief in some one particular or another, and no sort of solid progress is made or possible.

Furthermore I apprehend it is extremely few among planters and agriculturist who are scientifically trained to carry scientific experiments and research very far. About two years ago the Madras planters thought to import the lady bird for their estates, and sent all the way to Australia. They spent, I believe, over R3,000 and arrived back with a perfectly dead cargo of lady birds. And the Himalayas, at all events, teeming with the lady bird, some fifteen months ago, I believe with the aid of a score of boys and R100. I could in one part of the Himalayas alone have collected easily ten to twenty thousand within a week. I mention this to show what strange things may be done from disjointed private efforts, and to illustrate how really urgent the

NEED IS FOR AN ALL-EMBRACING GOVERNMENT DEPARTMENT

that should be the planter's and agriculturist's true philosopher and friend in all things affecting soils, crops, insect pests, and remedies, and cultural methods, manures and values and so forth; and by creating a Department filled with men whose sole business were these matters, there would at once arise that fellow feeling that makes for wondrous kindness among men of the same calling: the planter and the agriculturist, would immediately be at home with his Government brother of similar instincts and aspirations. I will venture the opinion that no Civil Service, devoid of practical and scientific training, will ever induce this feeling. This is how it comes that in America, Australia, the West Indies, and Canada the same idea has just been ably taken up where quite a number of agricultural teachers have gone from England under the control and supervision of Dr. Morris, late Assistant Director of the Royal Gardens, Kew. You find the Departments and the practical agriculturalist bound mutually together in many ways, and in these countries it is conspicuously clear that the Governments very fully recognise that

BY THIS METHOD, YOU EXPLOIT THE LAND

and country, and increase its wealth, revenue, and stability. In South Australia our agricultural colonists are doing bravely under anything but Eldorado conditions; indeed when the many practical difficulties and extremely moderate crops are fully taken into account, it is surprising what they do under the generous help and guidance of their very helpful Agricultural Department. Let India do likewise and then agriculturally we shall begin to live. All through I have quoted America, Canada, and the Australian Colonies by way of example merely. We can have none of these places in India, and yet it is certain that in some things we could go better than any of them,—parodying a certain celebrated jingle I would say: "We've got the country, and the money, but we havn't got the men,"—that is in the Indian Agricultural Department.

NUTMEGS IN WEST AFRICA.—An attempt has lately been made to acclimatise the nutmeg tree in German West Africa, but only in the botanical gardens. We have not as yet heard the results of the experiments made.—*Indian Planters' Gazette*, June 2.

PLANTING LIFE IN FIJI.

BY AN OLD RESIDENT.

In the year 1867, on a fine and pleasant tropical eveninig, we dropped anchor in Levuka harbour, after a very enjoyable trip in the barque "City of Melbourne" from Sydney. After a short stay of two months in Levuka, we left for the interior of Viti Levu, to take up our residence and prepare a future home for our family. The first sight of our future home was anything but promising, on account of uncertainty of the feeling then existing amongst the natives, and the denseness of the timber land on which we had determined to settle. The nearest neighbour was at a distance of several miles. The natives were very treacherous and uncertain in those days, and you never knew how to take them until it was too late. I remember distinctly the first time we had to fire on them, when they started to destroy the cattle fences; fortunately none were ever hurt, and I have ascertained since that the shots were fired simply to frighten them, and had very little effect.

We secured the estate known in those days as Nai Vuka, the bundaries of which were two creeks running into the main river. Since then it has gradually become an Indian settlement called Illahabad. We cleared off the dense scrub and bush, and had all the land ploughed up and planted with cotton, which certainly flourished in those days, and fortune smiled on us for a very short period, until we witnessed our first hurricane. It started blowing a fresh breeze about three o'clock in the afternoon, and gradually increased in violence as the darkness came. We sat around the dining-table watching the barometer very closely and anxiously till about two in tho morning. The glass showed 27·29, and we thought it advisable to take to the hills, as the river was rising so rapidly and the house collapsing on all sides. About half an hour after leaving the dwelling, the whole building fell in, carrying destruction everywhere. When the wind subsided, we left the hills to view the damage; we had to man the whaleboat and row over the estate as far as our former habitation, which then had about five feet of water inside the remains. Out of about ten buildings not one remained standing; we took refuge under the lee of a blown-down bungalow, and prepared a meal, the first for twenty-four hours; and by night on the third day we had a temporary residence erected. The main portion of the estate was under water for about six days, the men in the meantime, some eighty of them, existing by driving for food on the plantation. It was a heartrendingsight to witness the complete destruction everywhere the eye could see. Everything looked so well and promising for a big crop, and in forty-eight hours we were, comparatively speaking, ruined,

I have witnessed some fourteen hurricanes since, but none to compare with my first hurricane. Every planter on the Riva river suffered very severely, and it took them years of hard work and economy to get their heads above water and make another start. Our first shipment of cotton, some sixty odd bales, brought us only a poor return, and barely paid the expenses of ginning, labour and freight, and left us such a small margin for profit that planters gave up cotton planting. They then went in for sugar-growing, which also proved such ruination that many growers were hopelessly in debt, and they were unable to recover themselves, mainly because the first sugar-mill ordered did not come to hand, and the crops were allowed to rot where they were grown; and then hurricane No. 2 did the rest,—it was indeed a case of the last straw that broke the camel's back.

The average cotton-planter expected to have his fortune made in first years at most. The truth is, that many a planter is a man of birth, education, and talents, a gentleman who would be an ornament to any society, but having the misfortune to have a limited supply of money, not enough to maintain him in the society to which he has been accustomed, he, with the pluck and enterprise of the Anglo-Saxon race, throws himself into a far country to battle with the soil, and wring a fortune from Mother Earth. Unfortunately Mother Earth is not always kind, and many of these gallant fellows are struggling on in debt and poverty, though still gentlemen, and keeping a firm face to the foe. Others are retired naval or military officers, who during the cotton excitement sold up, retired, and thought in a few short years to realise what a lifetime of professional exertion would never have done. Professional men abound; impatient of their slow toil in the colonies or the mother country, they too rushed to the land of promise, and drifted into the position of planters. But the majority of successful men are the canny Scotch agriculturists, who simply invested their little money here because the land was good. We have also the experienced, sturdy, bnt withal gentlemanly and well-educated Australians, who being disappointed by the depreciation of squatting property in their own colony, have come to woo success as squatters in a new country.

ROBERT CRAWFORD BENTLEY.

—*Caledonian Jottings.*

MALARIAL MOSQUITO.

AN EXPEDITION TO THE FEVER-STRICKEN CAMPAGNA.

A scheme, somewhat dramatic in its details, has been sanctioned, says Reuter's Agency, by the Colonial Office, to prove to the public at large that malarial fever is directly attributable to mosquito bite.

Two doctors who have never suffered from malaria have volunteered to live in a specially constructed hut in what Dr. Manson, of the Colonial Office, describes as one of the deadliest places on earth, for the whole of this summer. These gentlemen are Dr. Louis Sambon and Dr. G C Low, and both have made special studies of tropical diseases. Dr. Low, only a few days ago, made the important discovery that elephantiasis is distinctly traceable to mosquito bite and not to drinking impure water. Dr. Sambon has given some particulars of the expedition, which begins work on 1st June. It is intended to prove that malarial fever is caused by inoculation from infected mosquitos, and that a person who has never had malarial can live with safety in a malarial region provided he be not bitten by these insects. To this end Dr. Manson, Dr. Sambon, and a number of other doctors visited Italy and arranged a conference with the Italian doctors in Rome.

ONE OF THE DEADLIEST SPOTS.

"We then went out to the Roman Campagna," said Dr. Sambon, "and it was there and then decided that no better place could be found for

our experiment. No worse form of malaria is to be found anywhere than that which exists in this fever-stricken area. It is indeed one of the deadliest spots on the globe. There are, of course, places just as bad in tropical Africa, but in the Campagna, while it is possible to live under the worst imaginable conditions, one is within few yards of all the civilisation and resources of Rome, which is, I should add, itself perfectly healthy. The few people who live in the Campagna are the very lowest type of Italians. They suffer terribly from malaria and the unfortunate railway men and others who have to seek their living in this swamp have to be constantly changed. Even with these precautions the death rate is terribly high. A specially constructed mosquito-proof house has been designed in which we are to spend the summer, and a spot chosen for its erection. We have hit upon a locality on the line of railway running from Rome to Tivoli. The house will be put together at a spot about a mile from the little station of Cervellata, thirty minutes' run by rail from Rome, where a colony of Lombards are trying to reclaim that part of the Campagna.

PRECAUTIONS AGAINST BEING BITTEN.

"Acting on the theory that the disease is due solely to mosquito bite we must see in it that we are not bitten. So during every night, the chief time of attack, we shall see ourselves up in our mosquito-proof house. In the daytime we shall, of course, go out and pursue our work in the open air but the chances of being bitten by this special species of mosquito in the day time are very small. Our contract with the Colonial Office is to live here and not to get bitten. If we do not get fever it will be proof positive that our theory is correct, but if, on the other hand, we do get malaria it will not prove the contrary, but will be merely evidence that we have been bitten. The house in which we shall live is a specially constructed wooden building with double casements all carefully covered with special zinc mosquito proof netting. This material has also been placed under the eaves of the roof, and we have a special system of double doors and curtains in the entrance porch. There are, of course no chimneys. In addition to bedrooms for ourselves and our servants and a diningroom there will be a specially fitted laboratory. Besides these precautions we shall also have mosquito nets round the beds.

INOCULATION EXPERIMENTS.

"Another part of our experiment will be the dispatch to London of live mosquitos, that have sucked the blood from cases of benign tertain fever (the mild form of the disease). These will be sent to the School of Tropical Medicine, and Dr. Manson's son and other doctors there will, by thrusting their bare arms into a box of these infected insects, allow themselves to be inoculated."

Dr. Patrick Manson, Medical Adviser to the Colonial Office, confirmed what Dr. Sambon had said, and added that malaria infected mosquitos which are to be sent home will be used to inoculate certain volunteers in England.—*Home paper*, May 5.

CEYLON PLANTERS IN THE WYNAAD.

The Wynaad correspondent of the *Times of Malabar* writes:—"The following ex-Ceylon planters are either residents now in Wynaad, or have acquired valuable properties in the taluk;—Messrs. Hugh Parry, E De Fonblanque, J S Nicolls, R Glennie, E H F Day, Stewart Robinson, and W Q Wright. Mr. Robinson, during a trip home last year, volunteered for the Yeomanry, and is reported to be in South Africa now, while illness recently compelled Mr. Wright to seek a change out of India, but we have hopes of welcoming these popular members of the community back later on."

TO BANISH FLIES.

Flies are a great nuisance in summer time around the house. They are a greater nuisance when the barn is filthy, or if it is too near the house. Where it is desired to get rid of flies, the following is recommended:—One part of benzoin and one of balsam tolu, five parts of charcoal, one and a-half of common insect powder, and one-half part of saltpetre; add sufficient water to knead a stiff paste. Roll into pastels and dry them. One will burn for some time in a room, and the fumes will destroy flies, mosquitoes, and vermin without injuring furniture or fine curtains.—"AUGUSTUS," in Park and Cemetery.—*Queensland Agricultural Journal*, April 1.

RUBBER: RANDOM NOTES FROM PARA.

The figures herewith indicate how important the ports of Iquitos and Manaos are becoming as points of shipment for rubber. The shipments direct from those ports have increased as follows:

Year.	Tons.	Year.	Tons.	Year.	Tons.
1880	... 373	1887	.. 1,688	1894	... 3,953
1881	.. 307	1888	... 2,141	1895	... 5,433
1882	... 430	1889	... 3,255	1896	... 6,827
1883	... 655	1890	... 3,693	1897	.. 7,523
1884	...1,013	1891	... 3,991	1898	... 7,173
1885	...1,462	1892	... 8,812	1899	... 7,853
1886	...1,574	1893	.. 3,745		

Albert Courbain, the illustrious Belgian explorer at present on the river Jurua, writes to the Belgian consul at Para: "I have acquired some knowledge of the Indian tribes between the Jarua and the Javary, of some of whom I have taken photographs. The soil is most rich in rubber and caucho. I can affirm the existence of a new tree, of whose leaves, seeds, and plants I shall send specimens to Para. It is abundant, the milk is rich, and the rubber is similar to sernamby. After smoking, it is flexible and elastic. These regions are in a great part unknown."

GRAO PARA.

Para, Brazil, March 7th, 1900.—*The India Rubber World.*

OVERHEAD NETTING FOR TOMATOES.

Referring to an extract from *Garden and Field* in our last issue on tomato growing, Mr. W Hobart, Main Range, Toowoomba, writes: I have grown tomatoes on overhead netting for years, and I find it the best of many plans I have tried. The young stalks must be properly guided and trained through the meshes and not be allowed to fall back again. When the vines are full grown, the top of the netting is a complete mass of fruit and leaves, and all the fruit is clean. I make the frame of stout hardwood pegs, 18 inches above ground. Hardwood betens are nailed on the top, and the wire stretched across it. Such a framework is easily taken to pieces and put up again where required.—*Queensland Agricultural Journal*, April 1.

THE NEW CONDITIONS OF TEA SALE.

(Draft proposals.)

1. The highest bidder to be the Purchaser, and any dispute that may arise as to bidding to be settled by the Selling Broker.

2. Brokers must declare, in writing, their Principals (to be approved by the Selling Brokers) within 24 hours after the purchase, or be held responsible; and those who may execute orders at this Sale for parties not resident in London shall produce a known Agent here, who shall undertake to complete the Contract; in failure of which the broker so buying shall be held responsible; and if any Broker shall purchase for any person or persons under age, he shall be held responsible. In the case of teas sold for cash, the Buying Broker to be held responsible.

3. Every person who shall be declared the highest bidder shall pay to the Selling Broker a deposit of £1 per chest at the time of sale, if demanded, or on the Saturday following the day of sale, or on the delivery of the Weight Notes; the remainder of the purchase-money to be paid on or before Friday,..... Interest at the rate of £5 per cent. per annum will be allowed on payment of the deposit, and on the remainder from the day of payment to the prompt day. The tea to be taken by the Buyers at the Customs landing weight, delivery in bond, with the Customs' tare. Draft as usual. The Customs' landing weight shall mean the full weight of the package as landed, and shall include the odd ounces which the package may weigh in excess of the Customs' inscribed weight. The only tea which may be taken from the packages before delivering them to the Buyers shall be that drawn for merchants' samples which samples shall not in the whole exceed two lb. in weight from each entire lot. The buyer will, however, have the option of taking up any entire lot or lots as printed by Prime Warrant, and if the buyer wishes to exercise this option he shall give notice to that effect to the Selling Broker not later than 5·30 p.m. on the day of sale, when the lot or lots notified to be taken under Prime Warrant shall be prompt on the Saturday following the day of sale, but the buyer shall be entitled to the usual five per cent. Cash Discount, calculated to the date of the three months' prompt, and, in addition, to a cash allowance equal to six weeks' rent. The seller shall pay rent on lots taken up under Prime Warrant, up to the Friday following the day of payment.

4. Before they were placed on show these teas have been bulked (in the country of production or London). They have been inspected and the packages weighed and tared, the leads, linings or lids properly fixed down, and in the case of London bulked teas they have been re-weighed and all the packages will be nailed or screwed down by the evening of the third day after the day of sale. Delivery will be given on the day after the day of sale, and, up to the delivery of the Weight Notes, on notice being given in writing the day before it is required to the selling broker and warehousekeeper. The buyer to have the option of refusing any packages as to which the above conditions have not been complied with.

5. Three clear working days are to be allowed for delivery of weight notes. The buyer to have the option of refusing to accept any lot or lots for which Weight Notes have not been delivered by the evening of the third day, by giving a written notice to that effect to the Selling Broker on the following morning, if, on application, he cannot then obtain them. Missing packages if equal to bulk, and not more than five per cent, are exempted from this condition, and are to be taken by the Buyer at the original price and prompt if tendered within fourteen working days from date of contract.

Old Clause 5.

6. No claim for difference in bulk from show or selling sample will be entertained unless notified in writing to the Selling Broker within three working days from the day of sale.

7. No allowance will be made on account of any damage, rubbish, false package, or unequal goodness, found, or alleged to be found, after the goods have been taken from the warehouses.

8. Lot money to the Selling Broker as usual.

9. All tea sold at this sale to be at the risk of the sellers until the prompt day, unless paid for previously, but only to the extent of market value. In the event of non-delivery by loss from fire, the contract for such portion to be void, and the deposit paid to be returned. Rent to commence from the prompt day.

10. Particulars as to whether Calcutta, London or Factory Bulked, whether average or separated tare and description of the kind of package shall be printed against each lot.

11. Any dispute that may arise concerning any parcel sold in this catalogue to be referred to two arbitraters (who must be members of either the Indian Tea Association, the Ceylon Association in London, the Tea Buyers' Association, or of the Tea Brokers' Association of London) to be mutually chosen, and who are to appoint an Umpire, if necessary, the loser to pay the fees (two guineas) to each arbitrator, and two guineas to the Umpire if called in; the fee to include attendance at the warehouses if necessary.

12. If any buyer shall fail to comply with the above conditions, the vendors shall be at liberty to re-sell the teas either by public or private sale, the deficiency, if any, with interests of money, from the prompt day, warehouse rent, and all other charges and damages of every kind, to be chargeable to such defaulter, and be recoverable against him at Law.

THE PLUMBAGO TRADE IN LONDON.

Plumbago is an article which passes through such narrow channels that one might work for years in the tea trade without hearing anything about it, though its headquarters are also in Mincing Lane. So many people in Ceylon now are on the look-out for this mineral, that I thought it might be of interest to your readers to have some information from one of the few who are really in the know. I accordingly obtained an introduction to Mr. Marshall, of Messrs. Marshall and French, who kindly placed the following at my disposal. My first question related to the reasons for the recent heavy fall in price. This I understood was not due to the supply exceeding the demand or to any marked increase in the exports, but rather to buyers holding off in the belief that, with so many Companies and proprietors prospecting, there was likely to be an increase sooner or later. Mr. Marshall thought, however, that with the monsoon almost due, it was quite possible that there might shortly be a recovery, as supplies generally fell off in the wet weather. The recovery, if it came, would be most marked in the fine qualities, for which even now there was a strong demand —£70 being offered for lumps, without business following. My informant was not sanguine as to the prospects for "common lead" with which the market was rather overstocked, and in this class a further fall was almost inevitable, but, as long as the demand for crucibles and for carbon for electric lighting went on, prospects for good plumbago were bright enough. It was reported in London that native exporters in Ceylon had formed a kind of ring, with the view of maintaining rates, but their efforts had been without success. As illustrating the enormous rise which took place

not long ago, Mr. Marshall told me of a native merchant, who had offered him 700 tons at £11. No bids could be obtained at this limit, and shortly after the price went right away to £40. "There was," as Mr. Marshall said, "a fortune in it."

Efforts are being made, I understand, from information received in other quarters, to form a more open market in plumbago, and it is hinted that, sending the stuff to the brokers who do the bulk of the present business, means simply getting the price which the Morgan Crucible Company care to pay. I do not know how this may be, but Mr. Marshall told me an amusing story of the result of an attempt recently made to effect a sale through a broker who got a consignment and who had to come to Mr. Marshall to get him to value it for him. A monopoly does not generally conduce to good prices being paid for any article, but the recent rise goes to show that, in the case of plumbago, the Morgan Crucible Company does not always have things its own way. —London Cor. of local "Times."

ON RICE MEAL.

A SUGGESTION FOR INDIAN FAMINE RELIEF.

(By George S. Keith, M.D., Author of A Plea for a Simpler Life, Fads of an Old Physician, &c.)

I have always believed—and this is the general belief—that rice, which is the principal food of the natives in many parts of India, is mostly a pure starch, and contains very little from which to form a strong body of muscle and bone. I was undeceived as to this when on a recent voyage to Rangoon. I had asked if brown bread was to be had on board, and was told that it was not, and that there was no wheaten flour to make it from. A few days after I was surprised to see it on the table, and of excellent quality. On inquiring of the baker, a very intelligent Scot, he told me the bread was made from white flour and rice-meal, four parts of the former to one part of the latter. He had used this for more than twelve months when brown bread was asked for. This rice-meal is got in

THE PROCESS OF CLEANING RICE

in the rice-mills of India. From the rough *paddy* the husk is first rubbed off; part of it is used in the mill as fuel, and the rest is thrown into the sea. What is next removed is the rice-meal. This is sent to England, and is given to the pigs or made into oil-cake for fattening cattle. On my return voyage the vessel brought nearly one thousand tons of it in bags to Liverpool, where it is in great demand. It is not known to any of the corn-dealers in Edinburgh. Twelve months ago it was selling at about three pounds a ton; lately, owing to the high price of all feeding-stuffs, it has been quoted at from four pounds fifteen shillings to five pounds. I brought some of it home, and it makes excellent brown bread when used in the above proportions. I have also some of the partly-cleaned rice, from the further cleaning of which the rice-meal is obtained in quantity varying from 7 to 16 per cent. In a specimen of the partially-cleaned rice which I got from the largest mill in Rangoon, a considerable portion of the rice meal has evidently been lost in cleaning off the husk, as only 10 or 12 per cent. of the grain, and this the smaller size, has retained its natural red colour, which is somewhat darker than the natural grain of wheat. Hence it is probable that the rice could give even a higher proportion of meal than 16 per cent. I have got

AN ANALYSIS

made of this meal by the chemist of Messrs. Duncan & Flockhart, Edinburgh, and, although it had lost some of its flesh-and-bone-making ingredients, it was found to contain 12½ per cent. albuminoids, and 4½ per cent. phosphoric acid, which, in union with lime, as phosphate of lime, makes up the greater part of the ash, amounting to 7¾ per cent. The meal is thus very rich in albuminoids and phosphates. On the bank of the Irrawaddy I happened to see about a ton of rice which had been freed from the husk, but still retained its red colour; and I was told in Rangoon that the natives sometimes clean the rice for themselves, and use it in the form in which I saw it. I heard recently from an engineer who has for some time been in charge of railways in Assam that red rice used by the natives, who are a finer and stronger race than the Hindus. I have also been told of a family in the West of Scotland who have been in the habit of

GETTING RED RICE REGULARLY FROM CEYLON.

In this country the value of rice as a food is reduced still further by the mode of cooking. It is boiled in a large quantity of water. This takes out most of the albuminoids, and as the water is thrown away, these are lost. In India the water used is just enough to swell the rice, and everything is preserved. Parkes gives 5 per cent, as the proportion of albuminoids in white rice, and 11 per cent. in white flour. I have endeavoured to get the Government of India interested in the rice-meal question. It is a pity that the best part of the rice should be sent to this country for cattle when it is so much needed in India, especially for the young. As a matter of pure economy it is important that it be retained in the country. Two parts of our brown wheaten bread go as far as three parts of white bread, both in satisfying the appetite and in supplying the wants of the system. If the same ratio holds as to red rice and white rice, a great money-saving would be effected by substituting the former for the latter. The price of rice-meal got in cleaning white rice for this and other countries is also less than that of white rice; but this is of small importance compared with its value as a food. It makes excellent porridge. A time of famine may be the best for introducing

A CHANGE

in the habits of the people. As red rice is already used in some parts of India, its general use should not be a great difficulty. When we consider that brown bread is so little used among ourselves, though its use is increasing among the upper classes, and that as yet for the greater quantity of wheat consumed in this country goes to the pigs, we need not be surprised that in India also this thriftless system prevails, to the deterioration of many millions of people. In this country the matter is of less importance as, overfeeding being the rule, the poor white loaf may often do less harm than the richer brown one. In a poor country like India, where the people are underfed, the case is very different.—*Chambers' Journal.*

THE CEYLON PEARL FISHERIES: SIR WILLIAM TWYNAM'S REPORT— WHAT IS TO BE DONE WITH IT?

We have now concluded our perusal of Sir William Twynam's elaborate and historic Report, of twenty-six foolscap printed pages, on our Pearl Fisheries and made special reference to some forty pages of appendices. To one who was generally acquainted with the writings of Capt. James Steuart, Mr. Thomas, of the Madras Civil Service, Mr. Houldsworth, Capt. Donnan and others, we cannot say, there is much that is new in the bulky Sessional Paper before us. But Sir William has very fully and faithfully fulfilled the task imposed on him by the Government in May, 1899, when his advice was requested with reference to the serious disappearance of 72 millions of pearl oysters from a bank where they were so promising two years before, as reported by Capt. Donnan last year. In replying, Sir William Twynam has, as we have said, gone into the whole history of our Pearl Fisheries and referred to every available writing on the subject within his reach. No man living has had a longer experience of the Fisheries than himself, Capt. Donnan coming next; and they have both had the benefit of all that the late Capt. Steuart and Mr. Vane could tell them, besides the Reports to Sir Hercules Robinson's Government of the Naturalist, Mr. Houldsworth, and to the Madras Government of the accomplished Mr. Thomas of its service on the Tuticorin Fisheries. Now there is no reason at all why we should follow Sir William through the history of the Fisheries, or the contents of the various Reports. No more concise or practical summary of the former can be compiled than that given in our "Ceylon Handbook and Directory" where, the years of successful fisheries, and of blanks, can be seen at a glance as also the number of fishing days, the receipts, as well as expenditure, the number of oysters fished and sold for Government, and the prices obtained per thousand. Sir William Twynam writes of the Pearl Fisheries having realised from first to last one million pounds sterling to the British Government in Ceylon. In our "Handbook," we state that Capt. James Steuart made out the total net revenue from 1796 to 1837 inclusive to be £524,522; but a careful statement prepared for Sir Henry Ward by the late Mr. J L Siebel, Chief Clerk of the Colonial Secretary's Office, showed a net return of £595,051 for the same period. To this we have to add the net receipts from 1838 to 1891 –the year of the last successful fishery—which will be found as follows:—

Total Receipts ...	...	£614,597
,, Expenditure...	...	126,356
		£488,241
Add above ...	...	595,051
Giving net revenue from 1796 to date as ...	...	£1,083.292

—so that Sir William is well on the safe side.

Now, this "harvest of the seas" which gave the Ceylon Government, nine years ago, as much as R963,749 of revenue during six weeks' fishing, against a total outlay of about R100,000,—surely deserves the very best attention of the Executive Council, and it was quite time such a history as that of Sir Wm. Twynam should be prepared, in order that full consideration might be given to the whole subject. If we were inclined to be critical, we might complain of the tautology and repetition in the pages before us. But the fault is one on the right side, and we look rather for the facts brought to light which justify fresh scientific investigation or reference. In the first place, we are reminded that the Naturalist, Mr. Holdsworth, got out by Sir Hercules Robinson, although out here five years (1865-1869) *never saw* a *fishery* or a bank covered with mature, or even young oysters, and therefore got a most imperfect idea of the main features of the enterprise he came to investigate. This fact, of itself, in our opinion, justifies fresh scientific investigation. Mr. Holdsworth, too, seems to have been taken up with "false spat"—not the real spat of the pearl oyster – another fact which must have vitiated much of his work. Sir Wm. Twynam does not seem to favour the further interference of science. He thinks, perhaps, that Mr. Thomas has about said the last word in that direction and that another Naturalist will not be of much more practical service than was Mr. Holdsworth. But thirty years form a long period in the history of science —even of marine Zoology—and perhaps in what has been learned of all kinds of oysters, mussels and other shell fish. Sir William quotes with approval the pithy saying of Capt. Worsley, at one time Inspector, as to the sensible policy in reference to Pearl Oysters:—"Find them; Watch them; Fish them." Very practical and important indeed. But we want to know whether something cannot be done after "finding," to *conserve* or *preserve*, as well as watch the young oysters We entirely approve Sir William's one practical suggestion about more *inspections*; in fact that there should be a system of inspection all the year round or nearly constant watching, if feasible; and we trust Government will give effect to this suggestion, and vote the needful expenditure, at any rate for two or three years, so that we may know all that can be learned from "watching." We are not entering on the large subject of "enemies" of the oysters, save to say that the system of watching established, should settle the vexed question between Sir William and Capt. Donnan, as to whether muddy floods in our North-Western rivers have, at times, been responsible for the disappearance of millions of oysters from the nearest banks. Capt. Donnan does not believe the flood water can reach the Banks: Sir William holds the opposite opinion.

Here there is one useful outcome from Sir William Twynam's Report,—that a more continuous, constant system of Inspections and Watching, as to invasions of the Banks by Flood or Muddy water, Coast Currents, enemies in Skates, &c.; and that careful observations be made and recorded. Also, perhaps that a profitable Chank Fishery may well be established south of Arripu. But

we go further than this and trust the aid of science will be invoked. In our recent Lecture before the Society of Arts, in referring to our Pearl Oyster Fisheries, we said:—

Considering all that scienee and practical skill have done in the breeding of the edible oyster off the British, French, and Italian coasts, and of the increased knowledge of ocean currents and marine zoology generally within the past thirty years, I think the time has come for a fresh scientific inquiry into the Pearl Oyster Fisheries of the Gulf of Mannar, by calling in the most competent naturalists and experts available. In this inquiry, the Indian might well join with the Ceylon Government, because the former owns certain banks in the proximity of Tuticorin which occasionally yield a fishery.

Now, we are not asking His Excellency Sir West Ridgeway to do anything rash. The Governor may very well at the outset confine himself to asking Mr. Chamberlain to lay copies of this Report—as well as Mr. Holdsworth's and Mr. Thomas's Reports, if procurable, (if not the extracts in appendices will do) before the leading home scientists:—the Presidents of the Royal and Zoological Societies and of the British Association for Science, in order to ask their opinion as to whether further scientific investigation and experimental work on the spot is desirable. This can do no harm. It may lead to notable results. Then copies of Sir William Twynam's Report should be sent by the Ceylon Government to the Indian Government asking that their may be referred to their best authorities for any comment. Copies should also be sent to the Queensland and West Australian Governments with a request for any information on the subject of Pearl Oyster or Shell Fisheries embodied by them in Reports or other State Papers. The United States Government should also have a copy and be asked to exchange. We saw some years ago Reports on Californian and Central American Pearl Fisheries which would certainly be useful. We fear there is no authority to tell us about the Pearl Oyster Fisheries of the Persian Gulf; but no effort should be spared at this time in bringing together all the available information, appertaining to civilized Governments and their officers on this interesting and important subject; while the experience of marine Zoological stations (at Naples and in the Isle of Man, for instance) may throw light on "spat" and other problems which puzzled Mr. Holdsworth thirty years ago, and Mr. Thomas at a later date. At any rate the highly placed scientific Presidents we have mentioned, will be sure, if the matter is referred to them to give a conscentious opinion to Mr. Chamberlain for the guidance of Governor Sir West Ridgeway and his Executive Council. Meantime, Sir Wm. Twynam deserves special thanks for the important service he has added to the long list appertaining to his very meritorious career as a Public Servant in Ceylon.

NEW COMPANY.

Ramie Fibre Spinning Syndicate, Limited, (65,443).—Registered March 23rd, with capital £15,000 in £1 shares, to adopt an agreement with J. F. Woods, and to grow, cultivate, manufacture and deal in rhea and other fibre. The subscribers are:—

JAVA GOVERNMENT CINCHONA PLANTATIONS.

The official report on the Government cinchona-plantations in Java for the quarter ending December, 1899, states that owing to the late monsoon the rainfall has been abnormally low. The drought caused much delay in the operations, which, this season, consisted principally of the planting out of the young plants reared in the nurseries. In other respects, however (such as damage caused by insect-pests, &c.), the conditions were favourable. An interesting part of the report is that dealing with the experiments made with different manures in order to ascertain their action on the content of alkaloid in the bark. It was found that the application of artifical manures, after twelve months' trial, led to no increase in the alkaloid-content, but that, on the other hand, the content had increased where stable manure had been used. Possibly a longer trial may produce better results from the application of artificial manures; if so, it would prove a great boon for plantations situated at a high elevation and at a considerable distance from human habitations, as stable-manure is there very scarce, and an efficient and inexpensive artificial manure would be invaluable. A very useful substance appears to have been found in the residue from the castor-oil presses—*i. e.*, that derived from the *Ricinus spectabilis*, which is already known in the cultivation of sugar-cane, where it gives excellent results. This residue contains 6·7 per cent. of nitrogen (other samples obtained elsewhere contained only 5·46 per cent.) Sundry trials, in which about 5½lb. of this residue had been used per "boom," showed an increase in the quinine-content of the bark, varying from 0·82 to 0·96 per cent., but until the experiments are completed the results cannot be accepted as definite. Should they prove reliable, the cultivation of *Ricinus spectabilis* will no doubt be taken up on a large scale near cinchona-plantations.

In November an auction was held at Bandong of cinchona-seeds from the Government plantations, producing a total of about 760*l*. Twenty packets of Ledgeriana seed, containing 25 grammes (less than 1 oz.) each, were sold in the aggregate for 7,455fl (more than 620*l*.), while 60 packets of 50 grammes each Succirubra seed were sold for about 34*l*.

The number of cinchona-plants in the nurseries was 1,415,000 Ledgeriana, 267,000 Succirubra, and 25,000 hybrids, or 1,707.000 in all, and in the open ground 1,561,000 Ledgeriana, 490,000 hybrids 468,000 Succirubra, and 48,000 officinalis, a total of 2,567,000 plants.—*Planting Opinion*, May 26.

"COW TAIL HAIR."—Mr. Hamel Smith, of Fenchurch Street, London, reports on 12th April:—"The demand for Cow Tail Hair, if of good length, well-washed, and free of skin and bone, is still very good. Such hair is now selling readily at 11d per lb., against 6d or 7d a year or so ago. The hair is sent over from India, press packed in bales of 300 to 400 lb. each."

TEA CLEARING HOUSE.

CHARGES ON TEA.

To apply to all parcels by Ships reporting on and after 1st July, 1900, and to New Season's China Tea arriving prior to that date.

PER PACKAGE WEIGHING GROSS.

	250 lb.	160 lb. to 199 lb.	130 lb. to 159 lb.	90 lb. to 129 lb.	80 lb. to 89 lb.	60 lb. to 79 lb.	45 lb. to 59 lb.	35 lb. to 44 lb.	17 lb. to 34 lb.	Not exceeding 16 lb.
	s d	s d	s d	s d	s d	s d	s d	s d	s d	s d
Landing and Housing Rate	2 3	1 11	1 7	1 3	1 2	1 1	0 10	0 8½	0 5	0 3

Bulking, Taring, or Weighing net separately ..	1 6	1 3	1 1	0 10	0 9	0 8½	0 7	0 5	0 4	0 3
Rent ...	01	0 1	0 0¾	0 0½	0 0½	0 0½	0 0½	0 0¼	0 0¼	0 0¼

* Old rate less 15 % 1s. 6¾d.

N.B.—The whole of above charges are NET, with the exception of Rent, which is subject to 15 per cent Discount.

The rates are chargeable on the average gross weight of each break. When the fraction of the average weight is half-a-pound or more, the higher rate will apply.

Thus :—The average of a break being 79½ lb. gross, the whole break will be rated at 80/89 lb., but the average being less than 79½ lb. the whole break will be rated at 60/79 lb.

TEA CLEARING HOUSE,
21, MINCING LANE, E.C.,
30th April, 1900.

By order.
GEO. T. POCOCK,
Secretary.

HUNASGERIA TEA CO., LTD.

The following is the report of the Directors presented at the fifteenth ordinary general meeting of the Company on Thursday, May 17.

The following accounts are now presented to shareholders, viz. :—Balance sheet made up to 31st December, 1899 and profit and loss account for year ended 31st December, 1899. The tea crop amounted to 462,555 lb., of which 374,415 lb. were sold in London, at an average selling price of 6·67d. per lb. The balance of the crop, 88,140 lb., was sold in Colombo, and realised 4·91d. per lb. net. The total receipts from sales of tea amounted to £12,216 11s. 10d. The ordinary expenditure in Ceylon and London amounted to £9,769 1s. 8d., shewing a profit of £2,447 10s. 2d. on the year's working. A debit balance of £1,609 16s. 9d. was brought forward from last year, and after deducting this, there remains a sum of £837 13s. 5d. at the credit of profit and loss account. The Directors recommend the payment of the dividends due on the preference share capital for the two years ended 31st December last, which will absorb £684 17s. 5d., and that the balance of £152 16s. 0d. be carried forward to next year. On capial-account there has been expended during the past year a sum of £115 15s. 4d. This money has been spent on the completion of the lower division factory and its equipment. During the past year the tea area has been surveyed, and it is found that we possess 763 acres as against an estimated area of 789 acres; of this 732 acres are matured tea, and plucking over the remaining 31 acres will commence next year. The yield for 1899 amounted to 613 lb. of made tea per acre, comparing with 414 lb. secured during the previous year. The more favourable results are due to the higher cultivation now in force, to seasonable weather, and to the better prices realised. A system of manuring has now been established over the whole bearing area, which it is expected, will, in the course of a few years, materially increase both the quantity and quality of our crop. The estimated crop for 1900 is 460,000 lb. of made tea; and if given favourable weather it is expected that this will be secured. Mr. J G Wardrop, a member of the Board, retires from office on this occasion, and, being eligible, offers himself for re-election.

THE CULTIVATION OF YAMS.

A letter was received by the Department of Agriculture from Mr. G. Heinzman, of Albany, asking whether the department could recommend for cultivation the common yam. Mr. Cooper, the chief clerk, replied to the effect that the matter had been referred to Dr. Morrison, the botanist of the department, who stated that the yam in question was cultivated in tropical countries, and could not be expected to grow at Albany, but it might succeed in the southern districts of the colony. He recommended the cultivation of the Croscorea hastifolia, which is found growing wild from Pinjarrah to the Murchison Rivon and, according to Baron von Mueller, is the only plant on which the natives bestow any kind for

cultivation. Dry country with calcareous soil is most suitable for its growth. Dr. Morrison considers that tubers, such as the Ipomœa Batalas or Batalas edulis, which are grown with success in New Zealand and Victoria, should be cultivated in this colony. The tubers are said to be more nutritious than potatoes, and the Ipomœa Chrysorhiza, which is a native of New Zealand, has been cultivated with great success in Mildura, where tubers weighing 15lb. were produced, and an acre was found to yield 12 tons.—*Perth Morning Herald.*

THE NAHALMA TEA ESTATE CO., LTD.

REPORT OF THE DIRECTORS.

The Directors beg to submit the general balance sheet and profit and loss account for the twelve months ending 31st December, 1899, duly audited, which results in a profit for the year ending 31st December, 1899, after providing for general expenses, Directors' and Auditors' fees, interest on debentures, &c., of £244 1s. 10d., from which has to be deducted the debit balance brought forward from last year, viz. £143 7s 2d. And they recommend that the remaining credit balance shall be carried forward to the next season, in £100 14s 8d. The Directors beg to hand their report for 1899, which, though unfavourable, is somewhat better than had been expected after the disastrous season of 1898. The crop obtained was 202,943 lb. as against an estimate of 260,000 lb. Energetic efforts are still being made to combat the blight of helopeltis, which shews signs of abatement, but there are still signs that the pest has not yet been thoroughly eradicated; the latest advices from the estate are, however, hopeful. The Directors have decided to increase the annual expenditure upon manure during this season, and hope the result will be satisfactory. Two of the Company's debentures have been redeemed during the financial year ending 31st December, 1899, thus reducing the Company's liability upon its debenture debt to £9,000 or about £20 per cultivated acre. Mr. William Forsythe, the Director, retiring by rotation, being eligible, offers himself for re-election.

PRODUCE AND PLANTING.

A SUGGESTED SUBSTITUTE FOR COFFEE.—Coffee planters will not be pleased to learn that another addition to the many substitutes for coffee is in use. The "Bulletin" of the Algerian Government publishes particulars of this substitute for coffee, or at least an element of admixture with coffee, the consumption of which has already become extensive in Austria, Roumania, Bulgaria, and Servia. The commodity is known as the "Horbas fig." It is roasted and powdered, and in this state bears a close resemblance to ground coffee. The fig is largely grown in Algeria, and the exports thence to Austria are said to have reached last year the surprising amount of 120,000 quintals, or 11,785 tons. When roasted it is known as "feigan kaffe," and is very largely used by the Austrian lower middle class. It reduces the bitterness of the coffee with which it is mixed and gives it a slightly oily flavour.—*Home and Colonial Mail*, May 4.

THE CHINA TEA TRADE.—In commenting on the new season for China teas the *Grocer* says: "That it will be more fortunate than the last is the hope of many importers, for in 1899 English, Australian, Russian, and other buyers were all 'hit' by severe losses on too hasty purchases. The mistakes then made arose from the idea, generally entertained, that there was to be a shrinkage in the production of tea all round; but subsequent events proved the very reverse, and, instead of a palpable deficiency, there was an enormous and cumbersome excess. For instance, China produced 6,000,000 lb. more tea last year than in 1898; India in 1899 turned out 13,000,000 lb. beyond the quantity raised in the former season, and Ceylon shipped a larger quantity by 11,000,000 lb. than it did in the previous year. These increases in the separate sources of supply put together represented an aggregate surplus of about 30,000,000 lb., as the additional amount of tea grown in a single season, over and above the total crops gathered in the three countries named during 1898 99. The result, as may be imagined, was disastrous to the shippers, for China teas, if no other, which in May last were bought at Hankow on terms equivalent to 1s 6d and 1s 8d per lb., have lately been smashed out here at 6d to 7d per lb.—a good 1s per lb. being thus practically knock, off and lost from the prices originally paid by the China merchants at the opening of the season in 1899. The consequence is that China teas at about 9d per lb. and under show wonderful value for money, and it is rather surprising that the wholesale dealers do not purchase these growths, since they are immensely superior to others that hail from India and Ceylon. The reason of this seeming neglect of good useful China teas is, we think, to be traced to the uncertainty with regard to a constant and unfailing supply of these China teas through the season. If a plentiful and varied assortment of good common and fine medium qualities of China tea could be guaranteed and depended upon throughout the year, the blenders, no doubt, would readily respond to the call for their attention, and the London market for China tea would not suffer so much from fits of depression and prolonged flatness as it has done during the past six months."

HOW THE MARKET IS REGULATED.—"As things are the chief business in China teas too often consists of what is passing in the choice and fancy kinds, which are required only by a select class of consumers, who will have them almost regardless of price. In its general working and the course it pursues the market for China tea," continues the *Grocer*, "is not regulated so completely by the prices ruling as by the nature and extent of the demand and supply at certain critical periods of the season. The tea is invariably cheap when there is plenty on offer and more than is really wanted, and for the converse reason it is dear only when the quantity of certain sorts coming forward is too small to satisfy all purchasers for immediate use. Another circumstance that strongly affects the home market for tea is expansion or diminution in the inquiries from exporters, who operate here as agents for the continental markets, according as direct arrivals from China, India, and Ceylon flow into or fall off from the several ports of Eastern Europe. This they appear to do more frequently now than in former years, and, as the competition between shippers and the dealers quickens or flags, so the current prices of the day advance or decline. For the ensuing season quotations for new China teas, for the reasons already given, are expected to open rather moderately, as representative buyers from all quarters, having learned a lesson of caution, will fight shy of paying extravagant rates this time."

THE COCOA TRADE IN BRISTOL.—The Bristol Chamber of Commerce has issued a report on the cocoa trade in the city. It states that in the last two decades the cocoa crop has about doubled, and the biggest customers have been Great Britain, the United States, and Germany. Humboldt, a recognised authority, estimates the consumption of cocoa in Europe at upwards of 100,000,000 lb. as against 23,000,000 lb. per annum in the early years of the century. In Great Britain the consumption has risen from a quarter of an ounce per inhabitant in 1831 to 14 oz in 1887, since which date the figures have still further gone ahead; in fact, cocoa is largely displacing coffee as an article of diet. The past year has been one of the busiest known for a considerable time, and that is, of course, a matter of considerable interest locally, having regard to the important position held by the cocoa trade amongst Bristol industries.—*Home and Colonial Mail*, May 11.

TEA GARDENS IN THE SOUTH,

PLANTING AND PLUCKING AT PINEHURST—THE TEA SCHOOL—NEW PLANTATIONS.

The picturesque and profitable industry of tea-culture, whose successful prosecution has hitherto been confined to the Orient, seems to be gaining ground in this country. The introduction and progress of any occupation, affording healthy out-door work to men and women, and to little children under conditions not operating against their mental advancement, is well worthy to be chronicled in a religious journal; and *The Christian Herald* presents with pleasure some interesting facts and pictures supplied through courtesy of Dr. Charles U. Shepard, Special Government Agent in charge of tea culture investigation. Dr. Shepard may be called the father of the industry in this country, for although the problem had been under discussion for many years and several fairly successful efforts to solve it had been made, it is to the practical and persistent demonstrations afforded in his tea-gardens at Pinehurst, Summerville, S.C., that we owe renewed governmental appropriations to the project.

The experimentation at Pinehurst began about ten years ago on a small scale, gradually enlarged as results justified, until about fifty acres are now planted in tea, which should produce about 10,000 pounds in full bearing. The problem for providing labor for picking tea leaf has been solved, so far as a steady, and skilful band of nimble-fingered children goes; but its price—extremely high as compared with the price of labor in the Orient—materially effects the question of profit in home-grown tea. It was indispensable to procure a reliable corps of pickers. To meet this condition, there was built a comfortable schoolhouse and a competent teacher engaged. The colored families of the neighbourhood were then invited to send their children to the school free of charge. They would be instructed in the ordinary branches, and also taught how to pick tea, and so earn money to buy food and clothing. The offer was accepted, and now there is a good list of pupils to draw pickers from as required; only children of suitable age and size are permitted in the gardens. The older children earn from thirty to fifty cents a day in tea-picking season; younger ones in proportion. In one season, the gardens were picked twenty times, or once every ten days, and it took three days for the force of children to make the rounds. The establishment of such tea-picking schools as Pinehurst's will be a moral as well as intellectual and industrial influence favorable to inhabitants of the Black Belt.

Dr. Shephard has had no difficulty in selling all Pinehurst tea (black) at one dollar a pound, retail. He says: "Without undue endeavour I sold my crop of 1898, about three thousand pounds, as also about five hundred pounds, of the previous year., altogether about three thousand five hundred pounds, at a reasonable profit, although there is no protective duty on tea."

Dr. Shepard sensibly suggests: "There is a class of people who might profitably add the cultivation of tea to that of flowers and vegetables, filling out the corners of their gardens and home fields with tea bushes, as they do in China, or substituting useful as well as ornamental hedges of that plant for fences. As one result, families would be able to supply their own tea, fresh, pure and invigorating. As another, the multiplication of little tea-gardens would mean the establishment of tea-factories in neighbourhoods where the product would be bought and sold for commercial purposes." The industry can be undertaken, however only in sections where the temperature rarely falls below 25 degrees F., and never below zero; there must be abundant water supply.

Pinehurst has a well-equipped factory. Two of the processes of manufacturing green tea is shown on this page; the fresh leaf is roasted in an iron pot and then rolled by hand on a table; no mechanical substitute for these combined operations has been invented, and the necessity for hand labor is the factor which raises the cost of green tea. The green color of the Pinehurst brand has attracted much attention. Oriental teas, lose it, and other qualities that go with it, before reaching this country. A journey through the tea-gardens of Pinehurst, when the workers are among the velvety green bushes, and over the factory where children are bringing in trout baskets filled with the leaves, and men are busy spreading these out in the drying-room, and rolling and packing tea in other departments, is quite interesting, and to the Eastern traveler somewhat like a chapter out of the Orient.—*Christian Herald and Signs of Our Times*, May 2.

TEA IN ST. HELENA.

According to official reports, that tea will grow in St. Helena is proved by the existence of some China plants which were introduced in the time of the East India Company. The experiment was tried in 1896, a native of India who had been for nine years an overseer on a tea estate in Assam was taken out. Seed was procured and a number of plants were reared, but the Governor having to return to England and recall his tea-planter, the plants were left unprotected; on his revisiting the Island, he found that the rabbits had devoured the young tea seedlings, and so ended an experiment which cost nearly a hundred pounds.—*Planting Opinion*, April 28.

CINCHONA AND QUININE.

The Java correspondent of the *Straits Budget* reports that the cinchona planters have latterly grown weary of being fleeced by bark and quinine dealers in Europe, who had combined to secure low market rates for raw material. The planters struck the first blow at the ring by starting a factory at Bandong to manufacture quinine from the bark locally produced. The quinine was sent to Europe for sale. The ring so managed matters that the planters failed to get fairly remunerative prices for the Java-made drug. The planters upon this, decided to sell their quinine at Batavia. The first auction sale proved to be a great success, and the prices realised far excceeded the limit. The continuance of quinine auction sales at that port is now a certainty. —*Chemist and Druggist*, April 14.

DENDROBIUM FALCONERI.—A very fine specimen of this graceful and showy Dendrobium is in flower at the present time in the collection of H T Pitt, Esq., Rosslyn, Stamford Hill. There were at one time no fewer than 106 fully expanded blooms on the plant. D. Falconeri, which was first described by Dr. Lindley in the *Gardeners' Chronicle*, 1856, p. 692, has, since then, been imported from various districts in the highlands of Hindostan, but owing to its requirements not being generally understood by cultivators, few have succeeded in making it grow satisfactorily for any length of time. The best position for it is said to be one that is close to the glazed end of a moist intermediate-house, or in some similar position where its slender, knotted stems can be sustained in a plump condition. Light spraying daily during growing time is also recommended. The flowers on Mr. Pitt's plant are three inches across, white, tipped with amethyst-purple; the lip having a maroon-purple disc, with orange blotches on each side.—*Gardeners' Chronicle*, May 26.

PLANTING IN MEXICO:

RUBBER—COFFEE—AND CACAO.

We direct attention to another interesting letter from Mr. E. O. Darley, well-known as a Knuckles' planter in the coffee days of Ceylon, and who, after some experience of Mexico, is full of belief in its future as a planting country. On the present occasion, however, he gives us some idea of the drawbacks to pioneers in this new planting region, although he still holds to phenomenal rates of production for our old staple coffee, as well as for cacao and rubber. As regards the testimony enclosed in his letter by Mr. Darley, we can only say it carries us back to the days when cinchona was going to make the fortune of every second planter in Ceylon and when such a result could be incontestably demonstrated by "facts and figures,"——on paper. For instance, what are we to make of the following cutting from an American paper—*The Trader*—sent us by Mr. Darley?—

The following is a copy in part of a letter written by a very prominent and competent Mexican to his brother-in-law: "I advise that at once you commence planting hule, or rubber. In order that you may have an idea of the importance of the advice which I take the liberty of offering you, I refer you to a fact which has really occurred in this State (Chiapas). In an hacienda called Dona Felipa Ortiz, in the department of Pichucalco (near El Salto) there were planted four years ago some 10,000 rubber trees to serve as shade for the cacao trees, instead of raising other trees for this purpose, which would have no value except for shade. Lately a house in Tabasco offered 50 cents per tree for the privilege of extracting the milk once, and to pay $1.00 for each tree which should be dried up by bad treatment. The proprietor did not accept the offer, believing he could realize more money by taking care not to allow any more juice to be extracted each year than ought to be. He only permitted 3 lb. to be taken from each tree, which yielded $1.25 per tree net profit. The whole expense of collection did not exceed $300. A single man can cut in a day 300 cuttings of rubber tree for planting, ¾ inch thick and one yard long. Ten men in a day will cut 3,000 cuttings, which in a month, not including Sundays, would amount to 78,000 cuttings.

If each man receives 75 cents a day, the 26 would cost	$ 195 00
two carts with two men and two pair of oxen to carry the cuttings (where required) at $10 per day, eight days ...	80 00
One man can in a day make the holes and plant 200 cuttings, so the planting will cost, a little more or less ...	300 00
Other expenses, not provided for ...	150 00
	$725 00

Simply by planting alone, the value of the property would be enhanced as soon as the cuttings take root. The cuttings will take root in four months; three years afterwards the 78,000 rubber trees will each be worth $1.00, thus increasing the value of the property by $78,000. The trees should be planted six yards apart, so that 78,000 trees would occupy 1/10 of a league about 500 acres. A league would be sufficient for about 780,000 rubber trees, etc., etc. You thus see a single league of land, will, if well planted in rubber trees, be worth in three years (without counting its value for grazing purposes, for as soon as the young-trees are well rooted the cattle may be permitted to graze on the land) $780,000 and this result can be obtained at an expense not exceeding $7,000 without counting the cost of the land. I am aware that to persons, not cognizant with the conditions existing here, the above statements will seem exaggerated. The rubber trees may be planted on the same land as cacao, the latter being put at a distance of 12 feet apart, or 300 to the acre. These trees, at four years of age, will, with proper attention, yield from four to eight pounds of cacao, worth at present in Mexico, $1·00 per lb.; so that a league of good land should after four years produce yearly in cacao 867,676 lb.: or four pounds per tree, which is a small product. As before stated, the rubber trees, which serve as shade trees for the cacao, trees, would at the same time produce their valuable milk."

It is right to mention that the above was written some time ago, so that the conditions as to prices may have changed, though we suppose, productiveness has not fallen off. All the same, it is surely time now to hear not so much of Americans rushing into Mexico, but of some of our Yankee cousins as well as of Britishers coming back with "fortunes"—as they ought to do since the "boom" has extended back at least five, if not more, years. What can be more tempting than the following programme of products and crops grown on the lands of one American Company who invite settlers and offer for sale 90,000 acres:—

PRODUCTS OF THE GRIJALVA LAND.

Corn.—Three crops per annum. Wheat.—Two crops.

Alfalfa.—Seven cuttings. Sisal Hemp.—Four cuttings.

Potatoes.—Two crops. Indigo.—Two crops.

Cotton.—Matures in three months; plant once in three years.

Sugar.—Planted once in 10 years; matures in eight months; nets $300 per acre.

Tobacco.—Matures in four months; nets $400 to $500 per acre.

Pineapples.—Bear in two years; net $200 to $250 per acre.

Vanilla.—Matures in two years; nets $200 to $300 per acre.

Coffee.—Matures in three years; nets $150 to $200 per acre.

Cacao bears in four years; nets $300 to $500 per acre.

Rubber in six years; nets $400 to $600 per acre.

Coconuts in five years; net $250 to $400 per acre.

Most of the garden products, such as Peas, Beans, Turnips, Radishes, Tomatoes Melons, Onions, can be planted each month in the year. While of fruits, you can grow Oranges, Lemons, Bananas, Granadas, Zapotes, Mangoes, Pears, Peaches, Plums, Grapes, Guavas, Dates and Figs, Walnuts, Almonds, Peanuts, Chestnuts and Pecans can also be grown.

Instead of being housed by sleet and snow during the winter season, you can serve fresh vegetables from your garden every month in the year.

There is a very great profit in raising Cattle and Hogs for market. A steer can be fatte ned in ninety days on one acre of land set in pa ıar grass, and mast for hogs is abundant.

Note.—The above estimates are in Mexican money.

Now, the wonder to hard-headed as well as stay-at-home Ceylon planters must be, how there can be an acre of such marvellously productive land left in the open market. Look at coffee, realizing in three years £30

(or to be quite safe in allowing for depreciation in Mexican money, let us say £15) per acre *nett*; cacao double that profit in four years; and if the planter only goes in for rubber and waits six years, a still higher income per acre is promised. Can Mr. Darley tell us if he has ever seen the cocoanut palms, which, in five years, bear so heavily as to net from 250 to 400 dollars per acre, that is from 3 to 5 dollars per tree? We should much like to see a photograph of such palms with their heads of nuts. Meantime, will Mr. Darley kindly keep us and our readers apprised as to results, and we should much like to know what acreage of each product he has under his own care; what number of labourers he has to aid him; their cost per month, and the amount of work done by them; and the actual crops gathered. It is quite possible that exact information on these points would draw men with some capital and experience from the East, because it is evident that competition is running too keenly out here and in India with tea.

A FARMER'S EVERY DAY LIFE.

No. VII.

(By Cosmopolite.)

FARMING

is the only business that I know of, in which a man, who gets ahead of his neighbours, may become a general benefactor. If his crop excels, the agricultural eye of the district is upon him. The sort of stock he keeps is carefully noted, and how he treats that stock is the theme of his neighbour's conversation. They watch for him to begin ploughing, sowing and harvesting, and they follow closely in his wake. When he tries to hide his light under a bushel, they lift it up and expose him to the glare of the whole world, and would fain throw a calcium upon him and play slow music, whilst they save money by following his successes. But they neither pay him nor thank him for the good his example furnishes them, and no one loses by his success. He has hobbies, no doubt, has the successful farmer, principally of an agricultural turn; and he is merciless when once he gets hold of a listener; but his name is a byword for success in the district, and he is an authority in the pages of the agricultural press. He works hard, seldom goes from home, takes few pleasures and only rejoices in the thought that

"One crowded hour of glorious life
Is worth a world without a name."

Even Sunday brings no rest to a farmer, for many works of necessity and mercy may happen on a farm, and the master's eye and hand must always be ready, if success is to be attained. Although he may go to church, wearing

THE WHITE BELL TOPPER OF A BLAMELESS LIFE,

he probably returns home, not to rest his weary limbs by idly thinking over the sermon he has just listened to, but to find some of his stock ill, and which must be doctored; the hydraulic ram may have struck work and his water supply be cut off; or a hundred different things which he, and he only, can attend to: and, be it remembered, you can never keep up with the work on a farm if you ever put off till tomorrow what can be done today. His only consolation is that he is no worse off than other people who wish to set aside the sacred day for rest, but who never get it. What rest, for instance, has the small tradesman who spends Sunday in struggling with his books, and trying to strike a balance, the labour of which is the weightiest burden of all to the white man? What rest has the owner of a bicycle, who wears out more tissue in trying to break records, on Sunday, than he does in working hard during the other six days of the week? What rest has the policeman who risks his life trying to catch scorchers,—or the parson who has to preach three sermons,—or even the common labourer who slaves away greasing his boots, oiling his hair, and dressing himself in his best clothes, in which attire he is more uncomfortable than words can express? So, after all, if the British farmer has not one day of rest in the week assured to him, he is no worse off than residents in towns, and he has one advantage over these, namely, a more healthy life. It has been said that the British farmer would live for ever, such is the healthiness of his occupation, did not a mysterious Providence impel him to establish a muck-heap opposite his back door: but to these heaps I have a very strong objection, and I have broken in all my men to hold the same extreme views on the subject, so that no such heaps exist on my farm, propagating germs, bacilli and all the other terrible things that doctors and scientists try to frighten us to death with.

There are many things in Nature that we still cannot account for, however clever we may fancy ourselves, and one of these is the coming and going of our

SUMMER BIRDS.

Take the swallow, for instance; during the past 18 years I find, by reference to my diaries, that these birds arrived 16 times on the 27th of April, once on the 28th, and this year on the 29th. They have, during these years, invariably left us on the 28th of September, with the exception of last year when, owing, no doubt, to the extraordinary warm autumn, they postponed their departure till the 2nd of October. It must be a surprise to any one, who takes thought of the matter, that they should know, to a very day, when they are due to migrate from one place to another, and one can only put it down as being one of those things that "no fellah can understand."

FARMERS AND THE WEATHER.

Sailors and others, whose business compels them to go down to the sea in ships, are supposed to be more skilful in the signs of the weather than any others; but why this is so I cannot understand, for no men are more dependent on the weather than are farmers, and yet, I am bound to confess, these are not as a class gifted with any great knowledge in this respect, nor do they seem ever to attempt to read or forecast the signs of the weather. It had been said that

the biggest fool in the village is always the weather prophet, and there may be some truth in this: for to prophesy a year in advance what the weather is to be is a bold undertaking, indeed, especially in a country like Scotland that has such a lot of climates and which all keep so close together, there being sometimes as many as five varieties in one day. There are too many orange-peels, so to speak, on the pathway to success, for one to prove a successful prophet in a country of such climatic variety. We have our Zadkiel, Raphael and Falb annually prophesying for all they are worth with regard to the weather and proving themselves false prophets all along the line, so that farmers have long since lost all confidence in them. I have always had a weakness for checking off the weather in whatever part of the world I happened to be living, and since coming here I have made a study of the deplorably erratic climate of this district. Mine, however, is not a policy of prophecy, but of average, and after having carefully noted the various changes for twelve years, I proceeded to strike an average taking into consideration the phases of the moon and other astronomical particulars; and with this data to go upon, I tried to forecast the weather of the coming year. Every year adds some more information to my stock of knowledge, and so I find that I can now hit off a wonderfully accurate forecast. Stimulated by success I once published in a local weekly, an account of the probable weather to be endured by the residents of the district in the coming year, and so remarkable were the results that I might without fear have set myself up as a prophet of the first degree. I will give two examples out of many scores, just to show my readers the superior claims of average over prophecy.

THE DISTRICT PLOUGHING MATCH

was held in one of my fields, and meeting the secretary one day, shortly before the event, I asked him why he had advertised the match for the 18th of December, when had he taken the trouble to keep a copy of the paper in which my forecast had been published, he would have seen that the 18th of December is *always* a rainy day in Buchan. He laughed at my remark, but his mirth was changed to gloom when, although we had had lovely open weather up to the night of the 17th, the rain then began, and it poured like a S.-W. monsoon all through the 18th, after which it cleared up for another spell of fine weather. Of course, the match was a failure, only the half of those who had entered having put in an appearance. On another occasion, the steam mill had arrived—in a gale of wind—to thrash my crop, and my grieve suggested that we might put off the thrashing for a day in hopes that the wind might fall. I told him, however, that we had better not delay, because in my forecast I had it entered that there would be "heavy snow" that evening. He smiled as he pointed to the bright, cloudless sky, but went away and got the mill started to work At 5 o'clock that evening there were three inches of snow all over the country and I did not get another chance to thrash for a month and would have been badly off for straw to feed my stock, had I not insisted on thrashing when I did. Need I say that my men have the utmost belief in my forecast now, and I have been saved from a good many climatic annoyances by my own belief in it. And, let me add, I believe that anyone could make as useful a forecast for the district he lives in, if he would only take the trouble to check off the weather for a considerable number of years before striking the average.

BOUND TO THE FRONT.

The only function of importance that has occurred in our rural district since I last wrote, has been the "send off" to a member of our village rifle corps who has volunteered for the front and who was presented by his brother citizen soldiers with a pipe and some tobacco, to say nothing of a real silver match-box. A deputation from the Company went to the county town to make the purchase in preference to patronising the local tobacconist, at whose shop the choice of pipes was considered to be somewhat limited; and in presenting the testimonial, the commanding officer hoped that their gallant brother in arms would never disgrace the colours of the regiment in which he was to serve. He hoped also that their comrade, as he lay smoking his pipe behind some kopje, or spreading himself across the veldt in search of the enemy, would sometimes call to mind those he had left behind, struggling to make themselves proficient in the hands of the sergeant-instructor; and with his blessing and these few articles of considerable intrinsic value, he wished his gallant private a pleasant voyage, a glorious round of fighting and that he might come back, safe and sound, to marry the girl who had reached his heart. Tremendous applause followed and everyone began talking about Majuba Hill, Spionkop, Magersfontein and other battles which required to be explained away. In this age of presentations, if one was to limit his acquaintance to men who had not for some reason or other been presented with a Waterbury watch or a pipe and tobacco, he would have to be contented with a very small circle of friends. So common has the habit become and so monotonous the deadly uniformity of the gifts, that in our district, at least, men who wear watches or smoke pipes of their own buying are beginning to feel themselves *très distingués*.

THE ROYAL PALM.

Our illustration for which we are indebted to Mr. H F Macmillan, shows the avenue of noble Palms in the Peradeniya Botanic Garden, Ceylon, constituted by Oreodoxa regia. The magnificent gardens at Peradeniya, have been presided over by such men as Gardner, Thwaites and Trimen, all old friends of the *Gardners' Chronicle*, and of its editors, and are now under the direction of Mr. Willis, who is endeavouring with success to rival the Buitenzorg Botanical Institute under the direction of Prof. Treub. We hope shortly to publish other illustrations of this noble tropical garden.—*Gardners' Chronicle*, May 12. [The illustration is beautifully clear and distinct,—ED. *T.A.*]

THE CACAO INDUSTRY IN TRINIDAD:

"THOUSANDS OF ACRES OF YOUNG CULTIVATION."

We gather some interesting information from the address of the Chairman at a meeting of gentlemen interested in this product, held in the Trinidad Council Chamber. We extract as follows:—

Trinidad had now from 200,000 to 225,000 acres of land in the hands of large and small proprietors. For the last ten years there has been an immense quantity of land purchased from the Government and laid out for planting cacao trees. All of that land is intended to be put in cacao cultivation and the greater portion is already covered with young cacao trees. Trinidad had shipped last year a good crop—150,000 bags; in making out his figures, he had taken an average of six bags of cocoa per 1,000 trees. It was well known that an acre contains only 250 trees; therefore it would take four acres for 1,000 trees, which would bring it to a bag and a half per acre, so that 150,000 bags [168 to 180 lb. each?—ED.] *T.A.*] represent the 225,000 acres stated above. He had also prepared a return to show how the production had increased and to be able to give reliable figures he had obtained the following from the Customs officers.

In 1890 the value of cocoa exported was £531,545; in 1891 £439,786; in 1892 £648,103; in 1893 £535,055; in 1894 £509,808; in 1895 £620,634; 1896 £452,131; in 1897 £532,123; in 1898 £705,956; in 1899 £780,000.

The figures, as you will observe, show how rapidly the Cacao Industry was increasing in Trinidad, and, taking into account the thousands of acres of young cultivation, which will be increasing the return every year (be wished to mention here that a cacao estate in full bearing gives an average of 12 bags per 1,000 trees) there would be nothing astonishing in the near future—say 20 to 25 years hence—to see Trinidad export as much cocoa as any other large cocoa producing country. With the population increasing every year from the neighbouring islands, coupled with the assistance of cooly immigration, Trinidad must in the very near future export more than Guayaquil, the largest country exporting cocoa, as it must be remembered that we still have fully one-third more land in high forest, good virgin soil admirably adapted for cacao cultivation. He would be pardoned if he made a small comparison in order to show the rapid progress of the cacao industry with what was once the most important industry of the island, namely sugar. He has already told them that the value of cocoa exported last year (1899) amounted £780,000; well, from figures he had been able to obtain of sugar exported in the same year 1899 (58,000 to 60,000 tons), the value would be about £730,000 to £750,000; therefore it is seen that cocoa has topped sugar by fully £25,000 to £30,000. If these figures were wrong, he would be glad to be corrected. He only made this comparison *en passant*, simply wishing to show that the Cacao Industry had made a stride and, what was very certain that it would not remain at the present figures but would push rapidly forward.

A discussion followed which brought out some interesting facts:—

Mr. Rene de Verteuil, who followed the Chairman, said that our agricultural industries were to be gauged almost entirely by the value of the exports, because the local consumption, both of sugar and cacao was very small indeed as compared with the export, and he thought he was safe in saying that the proportion of the two staples consumed in the island was very much the same. He was inclined to think that the Cacao Industry was more important to us here in this island than the Sugar Industry. It was because the Cacao Industry here was in the hands, chiefly of the residents of the island. Such a large majority of the estates were held by residents who were descendants of the old families of the island either before or after the apitulation, that they considered it a home industry altogether, and consequently the value of the produce, such as it was whether exported or consumed locally, was really our own, that was to say, that the residents spent the value of that industry in the island, and consequently contributed to a much larger extent than, for example, sugar, on account of the indirect taxation which the people interested in, and carrying on that industry contributed towards the general revenue—because if they took, for example, say that of last year, the value of the sugar exported was some £50,000 or £60,000 below that of cocoa, they saw the only part of the money which had remained in the country was the amount which had been spent in wages and salaries, because the interest paid on the capital was chiefly to return to England—the commission also went to England, and whatever profits—and he was sorry to say they had not been great of late, but whatever profits there had been had gone to England and had been spent there, whereas nearly all the value of the cocoa they had produced and which they could not estimate exactly, had been spent in the island—even the interest on the capital which had worked those cacao estates remained in the hands of local capitalists because all the moneyed men here and those who claimed to be capitalists invested their money in the cacao properties of the island. Not only that, but, as Mr. Leotaud had remarked, the Cacao Industry was an industry that was developing very fast in the island. The whole country was being opened up and he thought he was safe in saying that four-fifths of the land now alienated was being planted in cacao, so that within a very short time the value of cacao would considerably exceed that of sugar and would probably top in importance the Sugar Industry by as much as in past days, the Sugar Industry topped the other industries of the island. It was to be borne in mind also that there were two classes of cacao proprietors—the larger and the smaller proprietors. The smaller proprietors, even more than the larger proprietors, spent the value of the cocoa they produced, in the island, and it was greatly due to those small proprietors that the trade of the island had prospered to the degree it had in past years; and he thought this was a sufficient explanation why, whilst other colonies such as Demerara, Barbados and the Leeward Islands especially, had suffered so much from the sugar crisis, Trinidad had been able to bear up with it without our revenue falling off and without, he might say, the consequences of the great depression in the Sugar Industry. That alone, he considered secured for cocoa a paramount place amongst the industries of Trinidad. Now, it might be asked whether the Cacao Industry had been favoured by the Government in the same way that the Sugar Industry had been. Evidently we could not expect that it could have been so, because sugar had been a settled industry and an important industry long before cocoa, but now that the Government was selling so fast the Crown lands of the colony, and those Crown lands were being taken up to be planted in cacao he thought they should look round, and it was their duty to communicate with the West India Committee to the fullest extent and explain to them the position in that respect—that the cacao properties were in the interior of the island, and that the interior of the island, although it had been opened up for many years, was still entirely void of proper means of communication. There were properties established for the last twenty-five or thirty years, to which there was hardly a track today, or if there was a track, it was a track over which you could only convey your produce on mule back or donkey back. Very few places in the interior were favoured with cart roads. It is true they had railways already in the country but with the exception of the Sangre Grande and expenditure was in excess of the revenue. He (Mr. de Ver Caparo) Valley railways, they were of use chiefly to the Sugar Industry. The Arima railway tapped some part of the eastern district, and so did the San Fernando railway tap part of the Montserrat, but that was nothing at all compared to the new districts to which the new lines of railway were destined. He thought they might arrive at some arrangement by which the immigration tax was to be distributed

—say two-thirds amongst the producers of sugar and the remaining one-third amongst the producers of cocoa and coconuts and that would come to a fair distribution. Some time ago when they called attention to the necessity of helping to put down

THE ADULTERATION OF COCOA,

the West India Committee in London wrote back and told them that they had better keep quiet and leave people as they were, because in England people were accustomed to drink a certain mixture which they called cocoa or chocolate and were altogether in favour of that description of beverage and consequently if they tried to force people to consume pure and unadulterated cocoa probably we would find that we would be losing our best customers. He (Mr. de Verteuil) did not know how far that was correct. He did not himself see why, if some persons preferred to take cocoa mixed with arrowroot and sugar, they should not be shown some other substance in which there was no arrowroot and sugar and in which there was simply cocoa and sugar—he did not see any harm in it, and he thought they would remember that some years ago when the beet producers brought into the English market an imitation of Demerara crystals, the West India Committee very keenly exacted that the composition called "Demerara Crystals" had no right to be so called and could not be sold as such, and he believed an action was brought in the Courts and it was held that the beet sugar so sold should be labelled as an imitation of Demerara Crystals. That was the result of a prosecution instituted, he believed by the West India Committee.

Mr. Aspinall said he thought the prosecution was due to private initiative, but he remembered the circumstance.

Mr. R. de Verteuil said that at any rate if the West India Committee took up their interest a great deal could be done. He preferred chocolate to pure cocoa, but those who had a taste for pure cocoa ought to have the pure article and not the adulterated article which was being sold in a great many instances now.

Mr. A. Warner said he had proposed to say a few words at this meeting but Mr. de Verteuil had left him little to say. He fully endorsed everything said by Mr. de Verteuil, and thought it would be a very happy thing if they could get the West India Committee to help them, especially in the question of roads and railways in developing the island. The particular point he proposed to refer to was known to all of them—that there was a penny a pound import duty levied in England, which was 14s or 15s a bag. There was also a similar tax on tea. The two taxes were, he believed, the survival of a very long time ago and had remained on because no one had had the energy to try and get rid of them, and he believed if they made representations to the West India Committee it would not be long before these taxes were removed. He had been told the removal would principally benefit the consumer, but it seemed to him that as cocoa was bought in bond into England the removal of a tax which had to be paid by the purchaser before he could get what he bought out of bond would go almost exclusively to benefit the producer, because the purchaser by bidding so much would have a margin of 15s a bag to buy on, and therefore a very large proportion of the tax would go into the planters' pockets, but even if it went into the consumers' pocket so much the better for the industry, as it would make the consumption of cocoa larger than it was, and it seemed to him that in a country like England which boasted of a free breakfast table such a tax ought not to exist. He did not believe any serious effort had been made to get rid of this tax; it had been mentioned to the West India Committee but never had been worked out or brought to the knowledge of Her Majesty's Government, and that, he thought, was one of those things in which the West Indian Committee could very well help them.

Mr. R. de Verteuil said he believed the estimated acreage in cacao cultivation last year was only 102,000.

Mr. Leotaud said he had spoken of the land held by cacao proprietors. There was 100,000 acres belonging to the sugar proprietors, but there was only 57,000 acres in sugar cultivation. His cacao cultivation at Maracas did not cover the whole area, but he was paying the tax for it.

MEXICAN COFFEE.

The *Brazilian Review* remarks:—"The *Dos Rios* Coffee planting Company of Mexico, which describes itself as the model plantation of Mexico and the largest in the world outside of Brazil (it has 2,000,000 coffee trees and 1½ million of rubber) has issued the following prospectus on which comments seem unnecessary. How long prices are likely to remain at 13 cents, if only half what is promised can be substantiated, or why the company should be so anxious to give away such valuable properties at such a sacrifice instead of sticking to them itself, are two of the points that in our opinion seem to want explanation before rushing to invest.

"Each tract of one hundred acres, when turned over to the purchaser at the end of the fifth year, shall have forty acres improved and under cultivation, upon which there shall be 30,000 Coffee Trees five years old and 1,000 Rubber Trees 5 years old, all to be in perfect and well cared for condition. On a conservative basis the income from this property during the sixth, seventh and eight years can be estimated at $4,800·00 per annum, being the crop of 30,000 coffee-trees yielding two pounds each and worth 13 cents per pound less 5 cents for care of plantation, picking, milling, sacking, freight, insurance and brokerage, leaving a net profit of 8 cents per pound on the annual yield of 60,000 pounds. The ninth year this income will be increased $10.000 per annum by the net profit from the product of the 10,000 rubber-trees, *making a total annual net income of* $15,000·00 which can be relied upon without any fear of diminution for at least twenty-five years thereafter. This income can be still further increased by the owner diverting a portion of his profits to the planting of additional coffee and rubber in the portion of his land remaining undeveloped. At the present time the lowest cash value of such a plantation is $50,000·00 and one could readily be sold at that price, *and this we offer for a cash outlay on the part of the purchaser of only five thousand dollars extended over a period of five years.*"

EUCALYPTUS GLOBULUS IN THE OPEN.—I regret to report that trees here after attaining the height 20 feet, and in spite of the stems having been wholly protected with hay-bands, have been killed to the ground during the past winter. We have registered frosts of 25 degrees and upwards.—*A. R. Pearce Braymead Gardens. Berkshire.—Gardeners' Chronicle*, May 26.

THE BENGAL TOBACCO TRADE.—It will come as a surprise to many to know that for several years past the imports into Calcutta of tobacco grown in Bengal Proper have averaged nearly five lakhs of maunds per annum. About a lakh of maunds also arrives from Behar, while the average from Madras during the three years 1896 97, 1897-98, and 1898-99, for which statistics are now published, was under four thousand maunds per annum. Calcutta's largest customer in the matter of tobacco is Burma, which in 1898-99 took fourteen million pounds, part of which no doubt comes back in the form of Burma cheroots, Madras took 800,000 lb., the United Kingdom 22,000 lb. and France 19,000 lb. The amount exported, however, accounts for only about half the total. The other half, apparently, is consumed in Calcutta, where the hubble-bubble presumably accounts for the annual disappearance of some two lakhs of maunds.—*Friend of India*, May 24.

Correspondence.

To the Editor.

COFFEE PLANTING IN NYASSALAND

BY AN EX-CEYLON PLANTER.

Mlanji, B.C. Africa.

DEAR SIR,—Your letter of 9th February came duly to hand. I shall send specimens of our spotted bug to Mr. Green's friend in Surrey, England. From experiments carried on by myself, imprisoning our bugs in a muslin bag with newly formed berries, medium sized, and fully matured ones, I find that the bugs, puncturing the young fruit up to two months or so, damage them and by sucking the juice, producing black and empty berries after two months and up to four months; the berries when damaged by bugs are spotted black and brown, not entirely destroying the fruit. When the parchment forms after four months or so no damage appears to be done by this bug. The natural enemy of this bug is the soldier ant, identical with our Ceylon tiger. I have had a bug put beside those ants and they devoured it ravenously.

This bug is blamed in British Central Africa for causing so much unsound coffee. We are troubled with much worse enemies, however: borer and periodical droughts which do the maximum of damage to our coffee. Some old estates where no bug is to be found have 80 to 90 per cent spotted and light berry caused by those enemies. Shade mitigates those two evils, fosters the red ant and other natural enemies of our insect pests and is a cure for sunstroke and canker in our coffee fields. It will take a year or two yet to tell what the result of shade will be on coffee here. So far, however, it beats all I have ever seen anywhere. From two year old trees I picked off two leaves and enclose them for your inspection, measuring green 9 by 4 inches. I do not think Arabica coffee leaves can be found in Ceylon to beat those. This coffee, two years old or two years and eight months from seed, is being topped at 5 feet 6 inches and it has a crop just ripening on the trees of about 1 cwt. per acre. Coffee, in the open here, yields a heavy crop or two: 7 to 8 cwt per acre is common enough, and 10 cwt has been secured at three and four years old; but sooner or later it gets such a scorching that it never recovers and must be cut down or abandoned. Cutting down even does not always prove a success as the trees are often damaged right into the ground especially in very light friable soil.

I am trying to get up an acreage of tea and have now got 12 acres planted with a very good jât. I was a long time in the country before I learnt how to keep *good* health here: the secret is quinine taken whenever I feel I want it and most old residents can tell when quinine is wanted. One gets heavy and it's a trouble to go about and attend to one's work; then is the time to take freely of quinine and an opening dose or two.

I often remember how true William Smith the Patriarch of Dimbula's words were, when he said to me just before leaving for Africa: "Keep your quinine bottle on your side-table or side-board and take a dose any day, the same as you would your early tea. I had to do so when living in Kurunegala and Africa must be as bad."

Whyte is now in Uganda: he kept very good health when here; Lloyd, Tunbridge, Moggridge and others, who came from Ceylon, seem to keep good health, they all know of course, how to live in the tropics. Those who have broken down in this country are mostly young men who ought never to have come here at all or those who won't learn how to live here and no experience teaches them either. I have been home once and that only for two months during my ten years in Mlanji. It was not owing to ill-health that I went home. I landed in Ceylon in 1872 and never left till I came to Africa in 1890. My S. D. days were spent in Dimbula under the late James Ryan, opening Glenomera and Stirling, and when the estates were leased to H. S. S. & Co., I went to Matale. Most of the men in Dimbula in my day, have either left or gone over to the majority; few remain who were at the ball given to Sir Wm. Gregory in Middleton Store and were photographed on the patana afterwards. I was over the Nyassaland Co. Lirchemya's Estate the other day and think it should pay its way from now and make something for the shareholders in about two years' time *if carefully managed*.

The war does not affect us yet, but it is very probable we shall be joined to South Africa with the B. S. A. Co. territory, all under one Government, and get our railway, etc., after the war is over. Salaams!—Yours sincerely,

HENRY BROWN.

6

A NEW (?) INSECT PEST IN CEYLON.

DEAR SIR,—I read in the *Auckland News* that importers of plants from Japan are warned against the introduction of a scale insect known as *Diaspis amygdali*, which is said to be a dangerous pest and may even outstrip the alarming San José scale. The insect in question first attracted attention in the United States, "where it was found to be a serious pest on the plum and the peach; also on almond trees and tea bushes, which had been imported from Japan. In the latter country, it has been found destructive to the mulberry trees. *In Ceylon* it is partial to the Pelargonium, and it feeds on many species of plants."

Seeing that the native habitat of the Pelargonium has no connection with Ceylon, the plant being only grown for ornament round upcountry bungalows, the location of the scale here is probably a mistake. Could you kindly enlighten us as to this?—Yours faithfully,

X.

[We have referred the matter to Mr. E. E. Green, the Government Entomologist, who kindly sends us the following:—"*Diaspis amygdali* is a common scale-insect in Ceylon—see 'Coccidae of Ceylon,' Part I, p. 87, Plate xxiv. It is particularly noticeable on Geranium plants grown under shelter of verandah or eaves of bungalows, where the masses of small white scales (of the male insect) appear like white mildew on the stems of the plants. It also affects many indigenous plants, *e.g.*, *Callicarpa lanata*, *Tylophora asthmatica*, etc. Curiously, although it occasionally occurs on cultivated peach trees in Ceylon—it does not seem to flourish on that plant in this country. It earned its specific name from its destruc-

tiveness to peach trees in Australia. The species is very possibly an importation in Ceylon; but its introduction must have been somewhat remote, as it has already acquired a large number of natural enemies (chiefly hymenopterous parasites) which serve to keep it in partial check."—ED. *T.A.*]

PLANTING IN MEXICO—RUBBER, COFFEE, CACAO—THE DRAWBACKS AND ADVANTAGES.

(By an ex-Ceylon Planter.)

Mexico, April 10.

DEAR SIR,—I have received your paper of 5th January, and note your remarks *re* my letter you published in it. You ask what are the drawbacks here. Much the same, I imagine, that the pioneer planter of Ceylon had to contend with 60 years ago, the principal ones being lack of roads and scarcity of labor. The Mexican peon in the tropics will not work, unless in debt and obliged to do so and then does not compare with the East Indian cooly, except for clearing new land at which work he is pretty good. Any one having sufficient capital would import Chinese coolies, which are in the end much cheaper than the native peon. Taxes are low enough. This Company owns 100,000 acres and the tax is only some $400 £40) a year. The personal tax on each man is $1·50 (one doller fifty cents) and school tax ·80c (eighty cents) per annum. Bank cheques require a stamp of 5c (five cents) each and bills of sale and receipts 10c (ten cents) per $100. New colonies of agriculturalists and new manufactures generally can get exempted from *all* taxes for ten years. There is a Federal tax on the manufacture of rum and tobacco, which is not very high, but I have not the exact figures by me.

Mexico is well policed and any plantation can have a resident policeman by applying to the Tefe Politico of his district and paying wages of same, some $20 per month. You ask why do not British and American capitalists take up land? The latter are doing so in enormous quantities every year. The whole of the Isthmus land suitable for coffee, rubber and cacao is now practically owned by Americans who are rapidly colonising to and the Vera Cruz and Alourado Rail-road; iand the Tehuantepce Rail-road has passed into the hands of Sir Weetman Pearson and he has built a new railroad from Tinto to San Juan Evangelista, and put a large fleet of new passenger steamers on the rivers connecting with his railroads,—all since your hard-headed friends from Ceylon visited Mexico,—two of whom did me the honour to visit my camp in that part of Mexico. The railroad from Cordoba to Santa Lucretia is also now being built on past my old camp Several of the American Companies have also put steamers on the rivers so that, so ar as that part of Mexico is concerned, transport facilities have been pretty well revolutionised since the aforesaid hard-hearded Ceylon planters visited there.

You doubt cacao bearing 16 cwt. per acre. or selling for 90 shillings. I do not claim that all cacao does so; but that well-cultivated cacao plantations on this rich soil in Tabasco will do so and do do so, is beyond doubt. I was asked to value the crop on 6,000 six-year old cacao trees bearing their first crop last month. I counted on many trees 135 pods and could only find a few having 53 to 55 pods, the average was over 70 pods. There were 400 trees per acre, which, at 20 pods per lb., is easily producing 12 cwt. per acre. The owner told me he estimated he spent (3c) three cents per tree per year on cultivation which consisted only in cutting down the weeds every three or four months. Cacao is quoted today in Mexico city at $1-15c per kilo as you will see by sale list enclosed: in New York, 35c silver per lb. I have not been long enough in this country to plant and take in a crop of either rubber or cacao, but I have gathered three lbs. of coffee per tree from three-year old trees of my own planting. No one not having seen the crops produced on this fertile soil can imagine the crop coffee gives here: it is, however, of low class at this elevation. High grown Colima and Cardoba bring good prices; but the crops are smaller, ½ to 1 lb. per tree. In Mexico all crops—coffee, rubber, cacao—are estimated by the tree, not the acre: at this elevation 500 feet coffee is planted 12 ft. by 12 and covers the ground; at 3,000 feet, it is planted 5 by 5 ft.

Life on a plantation here, so far as society and comforts are concerned, does not begin to compare with Ceylon life of the 1870's—no races, no elk hunts, no gymkhanas. It is a new country and unless a man is willing to give up all that he had better not come. Anyone having a knowledge of planting and some capital, can make money here; if he has neither of these he is better away.—Yours truly, E. DARLEY.

LIGHTNING—NARROW ESCAPES FROM, IN CEYLON.—No. II.

SIR,—You ask for narrow escapes from lightning Mr. Stewart Taylor had one, two or three years ago at Passara. Lightning burnt the toe of his slippers and played havoc with the contents of his bungalow. Mr. Harvey, of Cattarem, in Dolosbage, had two very narrow escapes. There are certain parts of Ceylon that one wishes not to be in when there are thunderstorms:—El Teb or its neighbourhood in Passara, Cattarem in Dolosbage, and Mr. Duncan's bungalow site in Rangala.—Yours truly,

PLANTER.

No. III.

SIR,—The letter of "Planter" reminds me of the Cattarem Bungalow being wrecked by a flash of lightning, while the late Mr. Cottell and I were sitting at table, taking early breakfast one morning in 1864. It gave us a bit of start, for it came with a report like a cannon and sent the chimney through the roof about our lugs, smashing a large clock and pictures, etc. The whole bungalow was injured and the lightning tore a hole in the wall of one of the bedrooms, large enough for me to go through.

A.

SINHALESE CATTLE IN TRINIDAD.

Government Farm Trinidad, B.W.I., 20th April, 1900.

DEAR SIR,—Will you kindly accept my annual report for the past year and also my best thanks for your notice of that of the previous year.

Enclosed are photos of crossbred cattle—Zebu and Redpoll cross; the cross has been successful, a useful animal being the result. The bull at two years weighed 900 lb. and cost some £3. He

has all the appearance of a good beef beast. The heifers are now coming into milk and their yield is from 8 to 10 quarts per day of excellent quality.

You will perhaps remember our getting some small cattle from Ceylon. We have not done so well with them as was anticipated. There has been no increase amongst them and unfortunately the bull has broken his leg. The leg has been set, but from his restlessness there are no great hopes of repair,—I am, yours truly,

C. W. MEADEN.

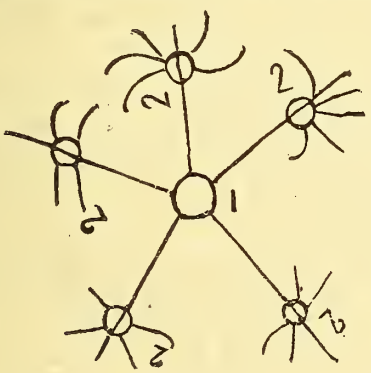
[The photographs—very fine ones—can be seen at our office. The Report will be reviewed in due course.—ED. *T.A.*]

EXPERIMENTS WITH INDIARUBBER.

Paris, 29th April.

DEAR SIR,—I should like to know if I could procure in Ceylon, dry corks or bark (écorces) of Indiarubber plants for experiments such as Alstonia, Hevea, Urceola, etc. For the species of little development, few stems will be sufficient. You know that I have attracted the attention of chemists to the possibility of extraction of rubber by dissolvents and that the results have proved that for Landolphia, etc., etc., dissolvents are not needed and extraction can be purely mechanical. I have sent twice to America for samples of leaves of Castilloa, but the experiments have been totally unsuccessful; but it is not the same with corks of Landolphia particularly if (? preserved) on the roots.

Curiously, and you will easily understand the fact of plants one year old, when I say at two months old, if they do not show nearly any rubber in the stems, are very rich in the roots. So I beg the planters on the Colony if they have Laudolphia under hand, to marsol (? sic) to layer the stems all around the mother plants and when hour of exportation come, to whig (? pull) out all the children around the mother. Do you understand what I mean?



1 is the mother plant which must never be touched; 2 are the children layered in the soil where they have much roots. These can be digged out and all the cork (? bark) from the stems or the roots be sent to manufacture and the planter can begin again with new shoots from the mother plants. Landolphia Hendelotii gives easily 8 per cent of good rubber from the stems and ten to eleven per cent from the roots,—which you can easily see by the samples I sent to you.

You must understand the interest for me to know the value of the corks (? bark) of any rubber plant —Yours most truly,

A GODEFROY-LEBEUF,
Horticulture.

SEYCHELLES GUANO AND MR. BAMBER'S REPORT ON CEYLON TEA ESTATES.

Analytical Laboratory, 79, Mark Lane,
London, E.C., May 11.

SIR,—Just a few lines to say that I have only this week seen a copy of Mr. Bamber's report; indeed, I doubt if I should have done so, only Mr. Talbot called on Monday to consult me in reference to the use of the Seychelles Guano as a phosphatic ingredient of tea manures, and in the course of conversation asked me if I had seen his report, to which I replied that up to the present time no copy had been sent me. The publication which apparently has only been privately circulated, is very interesting, especially the portion referring to the manufacture of tea, concerning which, you will remember, I originally made some urgent recommendations, pointing out how very useful careful investigations made in the factory must prove in the future.

In reference to the system of manuring suggested by Mr. Bamber, I refrain from going into details, as I may be consulted professionally, and have already reported on some of his soil analyses.—Yours faithfully,

JOHN HUGHES.

WHO WILL TELL US MORE ABOUT "CHILLIES."?

Aberfoyle, Rakwana, May 15.

DEAR SIR,—I shall be very much obliged if you could give me any information by post or through your Journal regarding chillies:—

1. The most suitable kind for local and home consumption.
2. Method of planting, from nursery, or sown broadcast.
3. Safe estimate of crop for one year's bearing.
4. How long each bush lasts from time of coming into bearing, and when the bush comes into bearing from time of planting or sowing.
5. What enemies to fear or pests?

You have had some information in the *T.A.* on this subject, but not giving any of the information now asked for.—Thanking you in anticipation, I am, sir, yours faithfully, W. G. B. STRONACH.

[We shall be obliged if any cultivator who has had actual experience in raising "chillies" will send us answers to the above questions.—Meanwhile we quote the following from the *Treasury of Botany.*—ED. *T.A.*]

Capsicum annuum a native of South America, but introduced into India and elsewhere, furnishes the fruits known as Chillies; these, as well as the fruits of *C. frutescens*, and several other species or varieties, are used to form Cayenne pepper. The species of *Capsicum* are chiefly natives of the East and West Indies, China, Brazil and Egypt, where they are much esteemed for their pungent fruit and seeds, which, under the name of Cayenne Pepper, or chillies, form an indispensable condiment which Nature herself appear to have pointed out to persons resident within the tropics. According to Sir R. Schomburgk, the natives in Guiana eat the fruit of these plants in such abundance as would not be credited by a European unless he were to see it [*Jour. Hort. Soc.* ii 153). In Jamaica the species most esteemed

is the Bonnet Pepper (*C. tetragonum*), the fruits of which are very fleshy, and have a depressed form, like a Scotch bonnet. The shrubby Capsicum, or Spur Pepper, (*C. frutescens*), is a native of the East Indies, and has been in our gardens since 1656. It forms a dwarf bushy shrub, with white flowers, and bears numerous small oblong obtuse pods which are very pungent, and in their green and ripe state are used for pickling, as well as for making Chilli vinegar. This is done by merely putting a handful of pods into a bottle, and afterwards filling it with best vinegar, which in several weeks will be fit for use. But the chief purpose for which this species is cultivated is for making Cayenne pepper, which is often prepared by drying the pods on a hot plate, or in a slow oven, and then pounding them in a mortar, and passing them through a hand-mill until the whole is reduced to the finest possible state. After this has been done, the powder is to be sifted through a thin muslin sieve, and preserved in well-corked glass bottles for use. The common annual Capsicum, or Guinea Pepper (*C. annuum*), was introduced into Europe by the Spaniards. It was cultivated in England in 1548, and is sufficiently hardy to thrive in summer against a south wall in the open air, and nature its fruit. The colour, direction, and figure of the latter is very variable—some being yellow, others red, and others black. In a green state they are used for pickling, and when ripe are mixed with tomatoes, &c., to form sauces. They are also dried and ground for use like Cayenne pepper. The Berry-bearing Capsicum, or Bird Pepper (*C. baccatum*), is indigenous to both the East and West Indies, and has been grown in this country since 1731. Its pods are erect, roundish, egg-shaped, very pungent, and when ripe are dried and used for the same purposes as those of other kinds of *Capsicum*. They also form one of the chief ingredients in the preparation known in the West Indies as *man-dram*, which is usually resorted to by those affected with loss of appetite or weak digestion, and consists of cucumbers sliced very thin, shallots or onions chopped very fine, a little lime juice and Maderia wine, to which is added a handful of the pods of this pepper, and the whole are then mashed together, and mixed with as much liquid as may be thought necessary. Besides the three species noticed as being the kinds most generally cultivated, there are many other species and varieties occasionally grown for the sake of their pods, all of which yield a warm acrid oil, which acts powerfully on the stomach, and is thought to correct flatulency, and assist digestion. [W. B. B.]

THE INDIAN CURRENCY AND EXPORTING INDUSTRIES.

London, 25th May, 1900.

SIR,—Last Thursday I attended Mr. Baines's lecture on the Industries of India, and spoke in the discussion, and showed that in consequence of the currency measures, all industries must decline. In a word, I showed that the Government, by their method of giving stability to the exchange value of the rupee, had given an unstable value to property. That it had declined in value since 1893, and was liable to be again diminished in value should the needs of the Government compel it again to raise the exchange. I also showed that the withdrawal of capital was proved by diminishing wages, and diminishing means of employment. When Lord George Hamilton attempted to answer me he avoided India altogether and, as a reply to what I had pointed out as to the decrease in cooly immigration into Ceylon, merely said that the report on the island was favorable. When Mr. Rees (who is in the Council at Calcutta) attempted an answer, it was merely to say that he knew of a considerable sum that was about to be spent in planting in Travancore. But, of course, no answer was possible. Formerly we stood on an automatic currency which kept us on even terms with our silver-using rivals in other parts of the world. whereas now we are not only heavily handicapped in our competition, but may be much more so, if recurring famines cause the Government, as is very probable, to again force up the rate of exchange.—Obediently yours,

ROBERT H. ELLIOT.

P. S—You will observe remarks by Mr. Vithaldon D. Thackersey in *Weekly Times of India* for May 5th, on how the Bombay Cotton Mills have been suffering from the currency legislation, but, of course, every kind of productive enterprise must suffer. The Mysore gold mines managed by a single agency lose upwards of £31,000 a year for every penny the exchange has been forced up, and considering thatthe exchange ought now to be at 1s 1d, and that their operation have increased since the above calculation was made, the present loss is probably about £100,000 per annum, or say £90,000 if we allow £10,000 for saving on purchases from this side.—R.H.E.

A TAMIL TREATISE ON AGRICULTURE.

(Communicated.)

Mylapore, June 1st, 1900.

SIR,—In a separate packet I send for your kind perusal and early review my book on Agriculture in Tamil. The book contains a collection of agricultural practices explaining the principle underlying them, thus solving the problems of Tree-growing, Village Sanitation, etc. Attempt was made to write it in a village Tamil, so that every Tamil-knowing individual may understand the contents of the book.

My 15 years' experience in questions connected with Agriculture warrants me to present a publication to my countrymen. The publication is no commercial concern. It is done with love—the local papers have recommended the book to the notice of the Government so that it may be popularized in villages and made a subject of study in schools.

If you think the book is deserving of the above recommendation I request you will also help me in taking it to the notice of Ceylon authorities: I shall thank you much. I require only fair play. In conclusion I request you will send me the issue containing the review for my information. An early review is solicited.—Yours faithfully,

G. RAJAGOPAL NAIDU,
Agricultural Inspector.

Mylapore: Madras.

(Review—Communicated.)

'VIVASAYA VILAKKAM" or "Agriculture Explained" is the title of a Tamil treatise on Improved Agriculture by Agricultural Inspector Rajagopal Naidu of Madras, late Superintendent Lashio Farm, Burma. This book bears on its title-page the appropriate motto "India's need is improved Agriculture," and is dedicated to Mr. Charles Benson, Deputy Director of Land Records and Agriculture, Madras.

The opening lines of the author's preface rendered into English would read thus:—"The necessity for the improvement of agriculture in a country like India where it forms the mainstay of the people will be evident to all. An attempt at such improvement is, however, beset with difficulties. Nevertheless I have ventured to set forth in the following pages, for the benefit of the ryots, some information which has struck me as essential to agricultural reform after fifteen years' personal observation of the agricultural customs in different countries and a study of English works on

SCIENTIFIC AGRICULTURE.

"Although this little book may not be productive of any marked benefit, I hope it will, at least, create an interest in agricultural matters in the minds of the ryots. Such an interest once engendered will ultimately lead to agricultural improvement. Ryots, who are desirous of attempting the improved methods suggested here, would do well first to try them on a small scale and, after they are satisfied that they would suit the conditions of their soil, climate, &c., carry them out extensively."

The author displays a deal of good sense and caution by giving this last piece of advice, for in a large country like India where the conditions of soil, climate, &c., differ rather widely in various parts, an experiment, on a small scale, would be very prudent, before the general introduction of a new method that has been found to succeed elsewhere, even in another part of India itself.

The first chapter is introductory and shows the dignity and importance of agriculture and the need for agricultural reform. The second is about the different kinds of soil. The third chapter treats of certain preliminary operations and auxiliaries to agriculture such as levelling, fencing, the different kinds of trees used for live fences and boundaries, irrigation and the sinking of wells. The author's remarks under the last heading show that he is free from the usual oriental superstitions which many natives of India and Ceylon, even of the educated classes, find difficult to get rid of. He says—"It is a common custom in this country to consult an astrologer in selecting a site for sinking a well. This is like the blind leading the blind. For we do not find either astrologers or Brahmins who ascertain the truth and impart it to others. Many have been ruined by trusting false astrologers who make a vain profession, merely for the sake of earning a livelihood. But Europeans use a borer, called the 'Auger,' in order to find out whether water can be obtained at a certain site or not. When this instrument is inserted in the ground and worked, so as to reach deep enough, the different strata underground can be ascertained, and we can not only find out at what depth water is obtainable, but also whether the water is fresh or brackish. When this test is made use of we can know with something like mathematical certainty, the best sites for wells and dig them without undergoing loss or disappointment." The fourth chapter which deals with

AGRICULTURAL IMPLEMENTS

compares the ordinary native plough of the ryots with the improved plough, and shows the superiority of the latter by means of facts, figures and illustrations.

In India where unlike Ceylon, dry cultivation is done on an extensive scale, there are several native implements used to economise manual labour and to expedite work in the cultivation of dry crops. The seed drill, an illustration of which appears on page 44 is one of these. This implement which can be easily drawn by a pair of ordinary country bullocks, goes on sowing three rows at a time. It is said that Sir James Caird, one of the famine commissioners appointed in 1876, was agreeably surprised at the work done by this seed-drill and remarked that it served just as well as an English seed drill which would cost from five hundred to eight hundred rupees. The other labour-saving implements treated of in this book are, a leveller and clod-crusher used after ploughing, a weeding machine that can be used between the rows till the plants are about eighteen inches high, a sickle-shaped hand-weeder, a roller which can also be used for separating the larger variety of grains, such as sorghum from the stalks, and the wheel barrow. The fifth chapter deals at length with the different sorts of

MANURES

and how they can be utilized for Indian crops and soils. The next treats of the different kinds of crops such as cereals, peas and beans, fibre plants, root and leaf crops and several other varieties including fruit trees. There is a strange botanical inaccuracy in the classification of the grape vine, for it is said that it belongs to the same family as the tobacco. In other respects the information given about that plant may be useful. The following is what is said about its culture:—"The grape-vine is a long-lived creeper and requires frequent manuring and abundant watering. It is usually grown either from layers or cuttings. In the latter case, cuttings of branches of more than a year's growth are planted in prepared soil, covered with straw. In Europe the vines are planted at a distance of ten feet apart. Fish manure is highly suited to this plant. The soil round the vines should be frequently stirred. During the first year it is customary to grow some tall-growing crops between them. Pruning is indispensable in grape culture, and it is owing to the gardener's ignorance of this fact that vines which bear for some time are found to stop bearing afterwards."

In describing the method of

PRUNING,

it is recommended to allow three nodes in each branchlet, the shoot from the terminal node of these three being nipped off after having made sure that the other two nodes send off good, healthy shoots. The time recommended for pruning the grape vine is when the plant shews signs of wintering by the shedding of the leaves and by the dry grey appearance of the little branches. Time and space will not allow justice being done to this interesting chapter: but it may be mentioned *en passant* that the part dealing with the preserving of ripe fruit for transport contains most interesting and useful information.

The seventh chapter aptly commencing with an illustration of the four stages of metamorphic insects shows how plants are destroyed by them and suggests powerful remedies such as Paris green, London purple and other similar preparations which, owing to their poisonous character, have to be used with caution.

The concluding chapter on Live Stock treats not only of the more important species which are quadrupeds, but also of the various domestic fowls and birds, including the turkey and the pigeon. The commoner ailments of live-stock, their breeding, rearing, management, etc., are suitably treated of in this chapter.

Altogether the book contains a good deal of valuable matter covering over 200 pages and will well repay perusal. Notwithstanding the slight difference in dialect from Ceylon Tamil, its language is easily intelligible a simple style being used for the most part. The price of the book (twelve annas) places it within the reach of the poorest ryot, and it is to be hoped that the Tamil agriculturists of Southern India and Ceylon will not be slow to profit by the fund of useful information offered to them in such handy form.

No. I.—SNAKES ALIVE! A FATAL ACCIDENT IN COLOMBO.

Colombo, June 3.

DEAR SIR,—I can vouch for the following fatal results from snakebite in reference to enquiry from "Constant Reader" appearing in yesterday's *Ceylon Observer*—though the occurrence was nigh 40 years ago.

A son of the late Mr. H M Fernando, of Ferryside Mansion, Mattakuliya, lost his life by dropping from a cadju apple tree at "Crow Island" and alighting on a tic polonga or cobra—I am not sure which—when he was stung by the reptile—was brought across the river in a faint and died within two hours of his arrival at home. You will find this reported in the *Observer* of that period.—Yours faithfully,

RESIDENT.

TEA PLANTING IN THE CAUCASUS.

PLANTERS' ASSOCIATION OF CEYLON.

Kandy, 2nd June, 1900.

Sir,—I herein enclose copy of an interesting communication in reference to tea planting in the Caucasus.—I am, sir, yours faithfully,

A. PHILIP,

Secretary to the Planters' Association of Ceylon.

Colonial Secretary's Office,
Colombo, 31st May, 1900

Sir,—I am directed to transmit for your information a copy of a report by Sir Henry Cooke on the subject of tea planting in the Caucasus, forwarded to this office by the Right Hon. the Secretary of State for the Colonies.—I am, sir, your obedient servant,

(Signed) A. E. CLAYTON,
for Colonial Secretary.

The Secretary, Planters' Association, Kandy.

(Copy referred to.)

A report was lately read at St. Petersburg by Mr. I. Klingell, giving the first results of the experiments made by the Imperial appanage in tea-planting in the valley of the Chakva, on the South-eastern coast of the Black Sea. The factory on the estate was built in 1899 with exclusively English machinery. In July 1899 there were 55 dessiatines* under tea culture, mostly Chinese plants, specially imported from China. Three crops were taken during the year, yielding 27½ poods (1 pood=36 lb.) The best in quality was the second. Four funts of green tea-leaves were needed for one funt of prepared tea (1 funt 14½ oz.) In type, Caucasian tea resembles Ceylon of very good quality. According to experts it will find a good sale. The prices obtained are 1st brand R1·90 cents and 2nd R1·60 cents the funt. By the Spring of 1900 there will be 102 dessiatines under plantation and in the near future 126, and, if the results continue favourable they will be extended to 500. The further development should go hand in hand with colonization. With rational culture and proper protection from cold winds the crops should yield 600 funts per dessiatine, and not 400 as at present calculated. The plantations are expected to reach economic maturity by 1905, yielding by then a clear profit on outlay. But to effect the results desired there should be introduced a persistent and rational system of colonization, and technical improvements all round.

Samples of Chakva tea in London received a very favourable report, experts even doubting whether they came from the Caucasus at all, as it was supposed only brick tea could be produced there. The majority of those who tasted it found it satisfactory, and only with fixed tastes preferring Ceylon tea. But as the latter is developing by great strides in Russia (in 1895 the consumption was 2,000,000lb, and in 1899 over 10,000,000). The amount of Ceylon teas consumed in Russia of late years is 6,000,000lb in 1897, 11,000,000lb in 1898, 17,000,000lb estimate for 1899, there need be no fear of Caucasian tea ousting it from the market.—"Commercial and Industrial Gazette of St. Petersburg."

(Signed) HENRY COOKE.

* 1 dessiatine equal 2.7 acres.

PLANTING NOTES.

M. GUYON—Administrateur des Colonies, Tannanarivo, Madagascar, who has been learning all he can about British and Dutch Colonial Administration in the Eastern tropics, went home by the French mail steamer on the 15th June.

A COMPLIMENT.—A Publishing and Bookselling Firm in Paris, in ordering our *Tropical Agriculturist* for Brazil, adds:—

We have seen with pleasure your Books at the Exhibition. The Ceylon Exhibition is one of the most interesting of all.

SINHALESE CATTLE IN TRINIDAD.—We regret to learn from Mr. Meaden of the Government Farm, Trinidad—see his letter on page 42—that the importation of small cattle from Ceylon has not been a success. They were very carefully selected and looked a choice lot as we saw them at the Agricultural School grounds before their shipment.

JAVA CINCHONA.—From the extract on page 32, dealing with the latest official report on Java cinchona, it will be seen that the product is prospering, though not so much from artificial as natural manures. A substance, "Ricinus spectabilis," obtained from castor-oil presses, is said to be very beneficial for the growth of the tree. Proprietors of castor-oil trees, who are unaware of this, will do well to note the fact.

PLANTING IN NYASSALAND.—An interesting letter from our correspondent, Mr. Henry Brown, formerly of Dimbula and Matale, will be found on page 41. He gives us a good deal of information and speaks well of the prospects of coffee and of the Nyassaland Company's estate. Mr. Brown's Ceylon reminiscences carry him back to early days under the late Messrs. Ryan and Wm. Smith in Dimbula. As regards the spotted bug referred to by Mr. Brown, we learn from Mr. E E Green that it proves to be *Antestia variegata* var. *lineaticollis*, said to be a well-known coffee pest in Africa. The coffee leaves sent by Mr. Brown are certainly very fine.

INDIA-RUBBER IN BEIRA.—According to a British consular report, the planting of India-rubber and coconut trees has been seriously taken up in the Beira district, and should in course of time become a thriving and profitable industry the soil and climate being, in the opinion of experts, all that can be desired. The cultivation of economic plants and trees in the valleys of the Zambesi, Buzi, and Sabi Rivers has been an industry too long neglected. The fertility of the soil and its capacity to give good returns for capital expended has been long recognised, but until quite recently entirely neglected on a large scale.—*Planting Opinion*, June 16.

TEA MANURING AND SEVERE PRUNING CONDEMNED.

(From a Correspondent.)

"I am very much surprised at the manuring and pruning that is now going on in the island. To me it is burning both ends of the candle. You see fine tea cut down to the ground: the prunings buried and more or less rich manure put in to force the trees to give big yields, and, as far as I can learn, with loss of flavour, though an increase of yield, I see tea treated this way in the —— that to my thought, does not require manure for years, and I am not alone in this view. All very well to manure in the poorer districts to get an increase of yield, where estates can barely pay without; but in this fine district, with its splendid tea, to me, it is agricultural murder and must do in the end no end of harm. But what I most wish to find fault with is the extremely severe pruning tea is subjected to. I have seen tea hacked down to 6" or 8" with large Assam pruners, but often without any slope, and after a year or so you find rot right down the centre of the tree. This cutting is done for cheapness and to force a crop. I hear of fields abandoned, that a few years ago were subjected to this treatment, and that by a well-known V.A., who now says Ceylon tea will not last. No, I should say not. The whole of this treatment to me spells ruin."

[But then the ruin has been "lang o' comin": look at Mariawatte for systematic manuring and pruning, for instance—it goes on giving 1,000 to 1,100 lb. made tea per acre year by year and seems none the worse. Still there is no doubt room for considering what our correspondent srys above, in some other cases.—ED. *T.A.*]

CATTLE SALE AT THE AGRICULTURAL SCHOOL, CEYLON.

The periodical sale of calves at the Agricultural Dairy Farm last month was not so well attended as usual nor the competition so spirited. This was partly due to the calves not being so well up to the mark. Some 14 were sold, including a cow and calf, chiefly to country native gentlemen, and the prices of the calves ranged from R22 to R50, the cow realizing R70. All were of the Scinde stock which does so well, both for dairy and breeding purposes at the Farm. Scinde cattle were first recommended to Mr. Drieberg by his Edinburgh schoolfellow, Mr. Mollison, now in charge of the Poonah Dairy Farm. Aden cattle seemed to be even more suitable; but they are very difficult to get. Mr. Rodrigo has now some 87 cows, 4 bulls and some 70 calves under his care on the local Farm and all look very healthy and in fair condition.

Unfortunately most of the villagers cannot afford the price of one of these calves. We would suggest that some of them be given away as prizes at Agricultural Shows or for meritorious conduct otherwise.

Nothing more has been heard of the Commission on the Agricultural School, of which the Hon. W. T. Taylor is Chairman, with Messrs. Ellis, Burrows and Willis. It is very questionable if it would be wise to move the School from the lowcountry and certainly it would never do to locate the Royal College, where the Agricultural and other connected Schools now stand. A prudent plan would be to retain the present institution and establish a Branch Farm and School near Heneratgoda, or Veyangoda, and indeed Mr. Willis might have a third branch near Kandy. As the improvement of farming and cattle in the *low country* is one chief object of the School and Farm, it would seem only reasonable to work under much the same conditions.

GUNS AND ELEPHANTS INUVA, CEYLON.

(From Mr. Baumgartner's Report.)

The number of gun licenses issued in the past three years was—in 1897, 248; in 1898, 202; in 1899, 514. Details are given in the Appendix.

The game licenses issued in 1899 were—to Europeans, 34; to others, 21.

Elephants were numerous in the Province. From my own observations I can speak to their prevalence in many localities: *e.g.*, in Wellawaya division near Kataragama, and again near Tanamalwila, where I saw two on the high road on the 24th July; also near Balaharuwa and Hambegamuwa in herds: also between Hambegamuwa and Kotawera-mankanda they are numerous, and included a solitary elephant of large size known as "Kurakkan-hora." This elephant was sought after by a sportsman, but not found, for the jungle scene at the Paris Exhibition.

In Buttala division, with its immense unbroken stretch of forest, elephants are plentiful, and it was here, near the Kumbukkan-oya, that sixteen elephants were captured under licenses in 1899. Six more were captured without license, but were allowed to be kept on payment of R50 each.

In Wellassa, not far from Siyambala Anduwa, I saw tracks of a very large herd on 2nd April. They are also fairly plentiful about Dambagalla and thence towards Nilgala. They are found in Bintenna and in Wiyaluwa within twenty miles of Badulla.

They do much damage to crops in outlying places. I have also seen about fifteen cocoanut trees in a poor villager's garden laid low and torn to pieces by elephants. This was at Ulwita in Buttala Wedirata.

TEA IN RUSSIA.—Some interesting correspondence—sent by the Planters' Association—will be found on page 46. The experiment in growing tea near the Caucasus need not alarm us any more than what is done in Natal, or in Carolina, U.S., by worthy Mr. Shepherd. It is, however, specially interesting to learn that the consumption of Ceylon Tea in Russia is increasing so rapidly as these figures show:—

1895	...	...	2,000,000 lb.
1897	...	...	6,000,000 ,,
1898	...	...	11,000,000 ,,
1899	Estimate	...	17,000,090 ,, (?)

COCONUT PLANTING AND WEATHER NOTES FROM THE N.-W.P., CEYLON.

MARAWILA, June 2.

It is a comfort to be assured, on so high an anthority as that of Captain Donnan, that we have yet to experience the "burst" of the big monsoon. Otherwise the prospect before coconut-growers, especially in the drier districts of the Island, will be very gloomy indeed. The rainfall we have had so far has been very deficient and has gone but a very little way to counteract the effects of the previous droughts (plura') on the north of Chilaw, before the rains of April. Water was not to be had for man or beast, except in the bed of tanks and of the Deduru-oya. A water-service had to be established for the coolies. Work had to be knocked off two or three hours earlier than usual on several days in the week and the coolies driven like cattle to the river to bathe and to wash their clothes, in order to keep them in health, a penalty being attached to those who did not go. The water-service for a bachelor's bungalow alone cost about six coolies a day. Rain fell heavily in April, four inches in one day, and about four times that during that month and yet the complaint is want of water. Those south of Chilaw were not so badly off for water as depicted above, as the lands are low-lying and the soil sandy and water nearer the surface, yet nearly 12 inches of rainfall in April did not saturate the soil below a few feet. May has been a dry month with us; rain has fallen on only six days and averaging a little over one-and-a-half inches, Under these circumstances it can well be imagined with what feelings of joy and hopefulness we read Captain Donnan's opinion.

It was only last week you repeated an oft made request for an Observatory for Ceylon It is passing strange that an omniscient newspaper editor did not then know that on the 24th May there landed in Ceylon from India a gentleman connected with the Meteorological Department of Madras. I heard him described as the Astronomer Royal of Madras. He had certain packages marked "Meteorological Department, India." Possibly he came over to take observations of the recent solar eclipse. [Which, if our correspondent had read the *Observer*, he would have known was invisible in Ceylon.—ED. *T.A.*]

SUGAR IN CEYLON IN DAYS OF OLD:

NEGOMBO, June 6.—The account of your visit to Baddegama, published in one of the back numbers of the *Observer*, in which you make reference to sugar cultivation in the Southern Province in the olden days, brought vividly to my recollection the attempted sugar industry in the Negombo District in the outlying villages of Katukenda, Petigoda, Delpakadawara, Dalupathgedera, &c., in the "forties." A French gentleman, named M. Chermont, acquired from Government considerable land in the villages mentioned, and, with the aid of the others, who I think formed a syndicate, parcelled them up in lots of hundreds of acres and commenced planting sugar-cane. Among the Superintendents were

MESSRS. STEWART AND FRASER.

The sugar plantation was carried on, on a rather lavish and expensive scale, the superintendents and others drawing very large salaries and horse allowance. The outturn of sugar was coarse and rather brown and I think it did not come up to the price first calculated upon. The whole concern went to smash in the end of the "forties" or beginning of the "fifties." I remember, as a boy, the large copper vats being carted from Katukenda, drawn by a large number of cattle and deposited near the Negombo Resthouse, where they were lying for sometime before removal to Colombo. The Company, after abandoning the sugar cultivation, sold up the land in parcels which fetched at the rate of *five shillings* the acre! These (about 3,000 acres) were all bought up by Hendrick Kure, commouly called Andris Baas, late of Moratuwa.

In one of these parcels of land, now owned by Lady De Soysa and called Katukenda Sugar Estate, might be seen the site of a former sugar mill. At the present time these lands are all flourishing coconut estates.—J. K.

THE PAPAYA AS A PROFITABLE CROP.

Now is the time to select large, well-formed fruit—*fruit that has ripened on the tree*—for seed. After consuming the fruit, select all the *dark-coloured* seeds, rejecting the rest; dry them in the sun, and sow in brandy cases, pots or pans, filled with leafmould and garden loam. When the plants are from three to five inches high, transplant singly into small pots filled with the same mixture. About the beginning of July put out into the permanent quarters the plants are to occupy. Here dig holes, ten feet apart either way, two feet wide and two feet deep. Fill these with well decayed cow manure and garden soil in equal parts, into which plant the seedings. Here they may be left to take care of themselves. They will grow apace most luxuriantly. When they begin to flower, watch should be kept for male and female trees, so that the male trees may be left alone, and attention directed to giving an occasional surface-dressing of cow manure to the female trees. The fruits usually set very close together; but they should be thinned out at an early stage, to give the others an opportunity of swelling and ripening. It is only by this means that you can obtain large well-formed fruit. The fruit ripens best during the hot, dry months of March, April and May. At this time heavy watering would spoil the flavour of the fruit; therefore, just sufficient water should be given to enable the fruit to swell. If you want good fruit, don't pluck till nearly ripe; then keep for 24 or 48 hours, according to the stage of ripeness, before using.

I was much struck by "Hortus's" remark in his article referred to above. He says: By a careful selection of seeds from male trees, which seem to have a special tendency for producing hermaphrodite flowers, I do not doubt that a variety could be produced in a few years in which this tendency should become fixed, and form the special character.

In the Calcutta market Papaya fruit realise from one anna to eight annas each according to size. A single tree, bearing from twenty to thirty fruits at an average of four annas each, would give a return of six rupees per tree. A plot of ground, 100 feet square, would carry 100 trees, which, at even an average of four rupees per tree, would give a return of R400, of which, say, R350 would be net profit. Here is something that promise to yield a good profit. —*Indian Agriculturist*, June 1.

THE OUTTURN OF THE MYSORE MINES.—The Director-General of Statistics in India having applied for particulars as to the quantity of gold in ounces and value in rupees produced by the Kolar Gold Mines from April 1899, to 31st March 1900. Messrs. Binny & Co., of Madras, have been requested by the Mining Board to furnish complete returns to the Director-General. The National Bank of India, Bombay, have been written to supply them with particulars of gold delivered to the Bombay Mint since January, 1900.—*Pioneer*, June 10.

"THE MANUFACTURE OF PLUMBAGO OR GRAPHITE":

IS IT TO BE ACCOMPLISHED "AS EASY AS SOAP" AT NIAGARA? ALSO THE MAKING OF REAL DIAMONDS EVENTUALLY?

We all know that the diamond and carbon are, in substance, identical. Indeed, this is practically true of the following substances which may all be put in the same category, and which owe their distinctiveness to different degrees of heat and pressure, namely :—PETROLEUM, PEAT, COAL, PLUMBAGO, AMBER, DIAMOND. A due amount of heat and pressure would have turned our plumbago into diamonds and made the Western portion of this island as rich a mining district as that of Kimberley. But today we have to deal with information which goes to show that there is a possibility of both plumbago and diamonds being manufactured on a scale that may seriously interfere with mining industries. Of course, the artificial, chemical manufacture of the diamond has been a very old threatened discovery; but we have not before heard of graphite being coupled with it, nor of operations on the large scale that is now revealed. We refer to a paper on "Hottest Heat and Electric Furnaces" by Sturgis B. Rand in the *Windsor Magazine* for May. We must say, in the first place, that if there was any immediate risk of graphite being economically and plentifully manufactured, an ever-watchful trade both in America and England would have had an inkling of what was approaching, long before the subject got into a monthly magazine, and we should have seen the result in altered prices. Still, although there is no immediate danger of the Ceylon Plumbago Industry being closed or even adversely affected by a manufactured article, which at first, at least, is likely to be both more costly and inferior in quality; yet we do not think the prospective manufacture is to be altogether ignored. It is an indisputable fact that the hottest furnaces in the world are now being operated by the Niagara Falls, and this is what Mr. Rand has to say of the result :—

Here clay is melted in vast quantities to form aluminium, a metal as preeious a few years ago as gold. Here lime and earbon, the most infusible of all the elements, are joined by intense heat in the eurious new eompound, calcium earbide, a bit of whieh dropped in water deeomposes almost explosively, produeing the new illuminating gas, aeetylene. Here also pure phosphorus and the phosphates are made in large quantities; and here is made carborundum—gem-crystals as hard as the diamond and as beautiful as the ruby. Just now, too, an extensive plant is building for the manufacture of graphite, such as is used in making lead-pencils, lubrieants, eleetrical appliances, stove-blacking, and so on. Graphite has been mined from the earth for thousands of years; it is pure carbon, first cousin to the diamond. Ten years ago the possibility of its manufaeture would have been scouted as ridieulous; and yet in these wonderful furnaees, which repeat so nearly the processes of Creation, graphite is as easily made as soap. The marvel-workers at Niagara Falls have not yet been able to make diamonds—in quantities. The distinguished French ehemist Moissan has produced them in his laboratory furnaees—small ones, it is true, but diamonds; and one day they may be shipped in peek boxes from the great furnaees at Niagara Falls. This is no mere dream; the eommereial manufaeture of diamonds has already had the serious consideration of level-he ded, far-seeing business men, and it may be aecounted a distinct probability.

As regards graphite, we repeat that, if it "were as easily made as soap," it is incredible that Ceylon plumbago should have recently been in unprecedented demand and at unprecedentedly high prices. Nevertheless, who is to dispute the possibilities of furnaces heated by electricity generated by the power of Niagara? We are told of one furnace so built that an amount of heat energy, equivalent to 700 horse-power, is produced in an arc cavity not larger than an ordinary water tumbler! As to the crystals or gems made, so great an authority as Geikie, the Scotch Geologist, was deceived: on being told they were manufactured, he exclaimed testily :—"These Americans! What won't they claim next? Why, man, those crystals have been in the earth a million years!" It seems to have been through the manufacture of the gems that artificial graphite was accidentally noticed. Thus we read :—

At the end of thirty-six hours the current is eut off and the furnaee is allowed to eool, the workmen pulling down the briek as rapidly as they dare. At the eentre of the furnaee, surrounding the eore, there remains a solid mass of carborundum as large in diameter as a hogshead. Portions of this mass are sometimes found to be composed of pure, beautifully erystalline graphite This in itself is a surprising and significant product, and it has opened the way direetly to graphite-making on a large scale. An important and interesting feature of the new graphite industry is the utilisation it has effeeted of a product from the coke regions of Pennsylvania which was formerly absolute waste.

It is a pity that the opinion of a crucible-maker on the quality of the so-called graphite is not given. But Mr. Acheson, the investigator, confesses that there is much to learn yet of Nature's secret of great pressure in regard to "Diamonds" and th e same may be true of "Graphite." Nevertheless, the potentialities of the "Electric Furnace" are, quite probably, beyond all present conjecture and we shall have more to say on the subject later on.

VANILLA.—Any one interested in Vanilla Culture should read the account of a successful experiment in Bengal recorded on page 52.

CACAO POD.—We have seldom seen a finer cacao pod of the yellow or Forestero variety than has been sent us by Mr. Drieberg from the Agricultural School. It is 9½ inches long by 11 inches in girth and weighs 2¼ lb., thereby beating the champion pod sent us some years ago by Mr. Drummond and recorded in our Directory's Planting Review. This is another evidence of how suited cacao growing must be for the majority of village gardens in the Western Province.

PLANTING IN LOWER PERAK.

This purely agricultural district is making steady progress. The revenue has again increased by 10 per cent., of which more than one half is due to a permanent increase in land rents. It will be remembered that some 14,000 acres were alienated in the previous year for sugar, coconut and rubber cultivation. In 1899 a further 640 acres were granted to Tek Kwi with 1,280 acres in reserve, and another 300 acres to Karmarasamy with a reserve of 200 acres, in addition to 1,056 applications for native holdings which were entertained for an area comprising some 7,000 acres. I have said that this is a purely agricultural district and so it has always been, but during the year 18 applications, comprising some 275 acres, have been lodged for mining land at Pasir Laut, marking a quite new departure in the development of this district. The opening of Mr. Turner's new estate of 1,100 acres is making great strides. —*Official Report.* [This is the new Sugar Plantation of Mr. Turner's Syndicate who mean one day to try sugar in North-East Ceylon.—ED. *T A.*]

KUALA LUMPUR.

It was not anticipated, as a reference to last year's report will show, that any substantial rise in the revenue of this district would take place, nevertheless the revenue for 1898 was slightly exceeded in 1899. The depression in agriculture, particularly as regards products cultivated under European supervision in Selangor, is a matter of common knowledge, and it is therefore gratifying to find that rents on European estates have not fallen into arrears, with one exception.—*Official Report.*

KUALA SELANGOR.

This district does not show such encouraging results. The revenue not only fell far short of the estimate, but was less than that collected in 1898. The Collector of Land Revenue explains that rent and arrears, amounting to $2,443, were not paid on one large estate, but I cannot reconcile his statement that this sum will become payable in 1900, with another to the effect that the total arrears brought forward into the 1900 rent rolls amount to only $331.20. Possibly there is some special arrangement of which I have not been informed. A sum of $349 has been written off as irrecoverable. Licenses show an increase, but estimates for this district appear to have been somewhat over-sanguine. The cultivation of coconuts is largely on the increase, but wild pig are doing enormous damage. The District Officer says: "The Selangor Coconut Oil Company Mill has been in working order throughout the year. This district does not supply sufficient copra to enable the factory to keep going, but a certain amount is imported into Kuala Selangor from Jeram, Bernam and Telok Anson. I understand from the Manager, Mr. R S Meikle, that there is a ready sale for the 'poonac,' the refuse of the copra when the oil has been extracted. It is used for feeding horses, cattle and pigs, and is, I believe, extremely nourishing. Most of it is shipped to Australia, but a portion is sold locally and in Kuala Lumpur." I agree with the District Officer that it is a question whether the Government should not offer special advantages in order to encourage European capitalists to take up land in this district for sugar and other products similar to those grown in the Krian district of Perak.—*Official Report.*

A VISIT TO HULTSDORP MILLS.

THE NEW DEVELOPMENT IN MANURE WORKS, CHEMICAL LABORATORY, &c.

Hulftsdorp Mills were probably the first established in Asia for the manufacture of coconut oil, coir-matting, etc. The late Mr, David Wilson may be said to have been their founder, and the "Price Candle Company" had at one time a good deal to do with them. They afterwards became the property of Messrs. Antony Gibbs & Sons, of London, who, in 1885, appointed Messrs. Freudenberg & Co.—at that time a Colombo Firm of twelve years' standing—their Managers and Agents. So much by way of introduction to the following:—

Comparatively few residents in suburban Colombo are aware of the large extent of ground covered by the mills and storehouses of Fort firms, in the region alongside the canal between the Kelaniganga and St. Sebastian; establishments of which the largest and oldest is so well-known by the name Hulftsdorp. Of such mills there is none, moreover, more extensive or more picturesquely situated than this one, which is owned by Messrs. Freudenberg & Company, occupying as it does an area of fully 12½ acres, across an interesting bit of water as one approaches from Maradana. The mills are bounded by the canal along which produce, firewood, etc., are brought by natives for disposal to the mills. Several landing jetties are visible, and the selection of one of these, whenever there are goods to be deposited, is made by the authority in charge, according to the location of the store to which the produce will be transferred.

Calling the other morning, soon after 6 a.m., at which hour Mr. Walter Freudenberg is accustomed to go his rounds, our representative was shown over the various buildings by this chief representative (in Ceylon) of Messrs. Freudenberg's well-known Firm, accompanied by his able assistants—Mr. Brandis, who is in charge of the Hulftsdorp buildings, and Dr. Koller, the expert German chemist, late lecturer at Geneva University, who superintends the numerous chemical operations which are constantly being required.

Over the khaki-coloured gateway, one's attention is arrested by the date 1835 at which

THE FIRST MILLS

were built here—before entering the actual precincts. Before us was a large open space, looking comparatively quiet, no shipments of goods being at the moment in progress, but one which is bounded by a long array of warehouses and stores full of produce ready for sale or shipment. Across this we proceeded to inspect a new 400 horse-power engine, made by Messrs. John Fowler, of Leeds, the biggest mill-engine of its kind in Ceylon. It was put up in a remarkably short space of time, only 17 days being spent in the job—the foundations having been carefully prepared; the latter gave some trouble, both rock and water being found at no great depth. This engine was erected in

order to work the oil-crushing presses which are found in an adjoining room ; these, however, were temporarily out of use, pending the arrival of new crushing machinery.

From here we were shown the first long store of manure material, down the centre of which runs a toy tramway, where coolies were in course of piling up and then moving a trolley-load of full sacks. Sacks were piled nearly to the ceiling in every direction, containing pretty well every ingredient known, at least to the intelligent novice in agricultural chemistry—fish, bones, patent steam bone dust, bonemeal, rape seed cake, sulphate of potash, basic slag, sulphate of ammonia, nitrate of soda (a first shipment, by the way), nitrate of potash, muriate of potash, sulphate of iron, saltpetre, etc., etc.—20 substances in all, so the foreman stated.

There is, we believe, an impression abroad, amongst a portion of the planting community, that

CHEMICAL MANURE MANUFACTURERS

like Messrs. Freudenburg, will only supply prescriptions of their own and will not reveal the contents of the manure supplied. This may be the way with some, but, in the case before us, a visit to Messrs. Freudenberg's Hulftsdorp Mills would entirely remove such an impression. Here is an exceptionally large variety of chemical materials, ready to be made up according to any prescription the planter-proprietor or superintendent may desire, or may—from his own or others' experimental knowledge—have seen fit to apply ; and, further, (the more frequent method) according to any of Messrs. Freudenberg's tried formulae, which is always communicated to the recipient whenever required. In all this immense store, to which we have just referred, contained no less than 2,500 tons of chemical substances from which to draw from. In another spacious shed, on the site of an old soap factory, we passed through dense piles of sacks of castor-cake and bones, stacked ready for crushing. With regard to the bones, we should add that quantities are placed in large iron cylinders through which steam passes and renders the bones quite soft, reducing them to a crumbled state like that of broken shells on the seashore. The bone material is then ready for final crushing which produces the fine patent steam bone-meal, a favourite ingredient in manure mixtures owing to the fact that it decomposes in the soil more readily and thoroughly than almost any other. Near to the steam-fed cylinders is a 40-horse-power steam-engine which works a powerful grinding machine, used for reducing castor-cake to the finest powder ; with the various sieves provided upon it, the cake is divided very finely. This immense "crusher" disposes of as much as 40-tons of castor cake in the day.

From here one passes into the specially

ODORIFEROUS ROOM, THE BONE MILL,

where a cigar, with or without a scented pocket-hankerchief, is felt to be a great, if not an absolutely necessary boon. For this is the room in which fish and bones are crushed.

Until lately "manure" fish had been easily obtainable from the Indian Coast in large quantities, and so popular among planters was the manure containing fish, that orders amounting to 200 tons had been on the firm's books at one time. But lately, plague regulations have interfered with the supply of this fish and for some time it has been unprocurable. Recently, however, imports of edible fish having proved excessive, native speculators had brought small quantities for sale at the mills—of their superfluous stock ; at first this was tentative, but the price obtained being satisfactory, further supplies had come in and to some small extent the lack of "manure" fish proper had been temporarily remedied.

It was interesting to watch the steady way in which the coolies went on poking away at the bone material (assisting its passage as it passed along the pipes into the crushing machines) ; others, handling fish, were quite heedless of odours disturbing to the more sensitive European as he pays but a butterfly visit. Looking back, the air appeared rather cleaner than might be expected where so many dried and separating particles were being set in motion ; but we were informed that the atmospheric excellence was due to a fan, put up by Mr. Maguire of the Sirocco Works, which carried off a large quantity of the dusty impurities of the air and lessened the objectionable smells considerably. In reference to fish manure we were informed that one favourite receipt used to run as follows :—

$\frac{3}{4}$ fish
$\frac{1}{4}$ bonemeal
$\frac{1}{8}$ castor cake

The next move, after visiting a landing jetty where copra brought down the canal could be landed under shelter, ready for transport to the store selected for it, was made in the direction of

THE LABORATORY.

Here we were struck not only with the cleanliness of the whole department, but with the convenient arrangement of the various shelves of chemicals and with one or two special apparatuses, such as are not found in any but experimental rooms where the most accurate work is required ; there were one or two revolving holders for bottles the contents of which required to be mixed. Another elaborate apparatus stood apart, for distilling water, according to latest improved methods. Most delicate of all, however, were a special set of scales, of a mechanism sensitive to the last degree, kept in a glass case and regulated by a series of screws working from different points, and weighing—to the 1—10,000th part of a gramme! Dr. Koller has evidently the means and the ability to carry out every description of work appertaining to the Chemical Analyst, and not only soils but products and parts of growing plants should be sent his way. Analyses of soil are made here free of charge and every planter is able, by having the soil of the estate analysed, to apply such manures as are most suitable for that particular soil. Dr. Koller gives all information that buyers or intending buyers of manures may wish to possess and advises them as to the mixtures required. Any soil can be analysed and the

planter can be advised for what produce the soil is most suitable.

From here our way lay by

THE COOPERS' YARD

where scantily-clad athletic Sinhalese, were busy,—some, moving round blazing fires, hammering hoops downward around the staves that bent before this pressure and under the influence of the flaming heat within, while others were attending to casks in various stages of construction and engaged in testing the reliability of the finished casks. These were, of course, intended to hold coconut oil and a little further an immense yard was covered with huge oil-casks all more or less seasoned. It takes about six weeks for a cask to be thoroughly seasoned and tested. Many of the new casks are out in the yard a very short time before the oil penetrates between the fissures and parts of the surfaces shew the exuding oil: the casks are then marked by the inspector to be "pumped" and this is done into another cask by means of a hand-pump. The working of this hand-pump is only performed by natives of considerable muscular power, and the suppleness of their arms and wrists are brought into full play as the required twist is given to the instruments as they are raised and lowered with wonderful evenness. The unsound cask is then taken to have its bands tightened.

From here we made our way back to the entrance at one side of which was a small building devoted to

COIR WORK.

In the verandah door-mats were being made, while inside, in the nearer room, matting was being pieced together, and in the further the hand looms were at work, producing the matting material that is used for special carpeting and also for ordinary matting. Bags were being made out of the matting. These, we were surprised to learn, were in increasing demand, as they were taking the place of the large baskets for bringing tea leaf on the estates along wire shoots. There is much to be said for the new article, perhaps even as leaf-holders on the backs of pluckers in the field? They are probably cheaper and are at any rate far easier for transport in an empty state.

Proceeding to the opposite building, where the mill offices are situated, we were shown various specimens of extra refined coconut oil (such as one sees at very few Shows, even) and, in the course of further conversation, learnt more definitely of the magnitude of the work carried on. The acreage of the ground covered, as we have already stated, was not far short of 13 acres; while as to the number of natives employed, we may state that in the oil mill alone, when it is in full working order, there are no less than 200 hands engaged; while about 200 more find employment in the other Departments. We left Messrs. Freudenberg's Hulftsdorp Mills with an increased sense of the importance and practical usefulness of the large and varied work being carried on there, both to the native and the planting community.

Before modern scientific manuring was introduced by this firm in 1897 and notice taken of it in an article in the *Ceylon Observer* that year, there were used in Ceylon for manuring purposes almost alone:—

Castor cake
Patent steamed bone
Bone meal and
Fish manure

—a list which contrasts well with that of the substances used today, which we have already detailed.

The Firm is sole agent in Ceylon for the United German and Austrian Thomas Phosphate Works—the largest concern of its kind in the world,—and also for the United Stassfurt Potash Works, which are by far the largest manufacturers of potash salts in the world. It is, therefore, naturally in a position to provide the best and cheapest basic slag and potash salts. The planter has many a want supplied by the produce of the Hulftsdorp Mills, from reliable manure, made precisely to his order, to the tea bag—used for estate transport, but perhaps some day to relieve the pluckers' baskets in the field; whereas the native curing his copra around his jungle home may always be certain of a ready sale of his goods when brought to the large mills of Messrs. Freudenberg at Hulftsdorp.

VANILLA CULTIVATION IN BENGAL.

A SUCCESSFUL EXPERIMENT.

During these last few years attention has been greatly drawn to products which were likely to succeed in India and give satisfactory results. The cultivation of Vanilla has been taken in hand more than once, but somehow it has never had, really speaking, a thorough trial; the trial was not carried on long enough, although it was shown that this plant grows and fruits in Bengal without any difficulty. The experiments in the Alipore Gardens have not been carried out on such an elaborate scale as were attempted in several places in Bengal some years ago: in fact the plants were here growing almost in a wild state in a mango grove, and such as they were, they served all the more to show what little trouble there is attached to their cultivation. This experiment has been conducted under the above-mentioned conditions just to show that anybody possessing a grove of mango trees can raise a crop of Vanilla without any further expense than the purchase of the plants to form a stock. In the gardens the Vanilla was planted at the base of the trees in good leaf mould, mixed with plenty of brick refuse, as drainage for the young plants; one put down they practically grew at their own sweet will, and soon attained fine vigorous growth. If this was done with a view of continuous production, the plants should not be allowed to grow over a certain height, say fifteen feet, as a maximum; if allowed to climb higher up, the work of fertilising the flowers would become almost impossible. Last year, in the beginning of March, the plants showed their flower buds, the plants then were occasionally syringed, and by the 10th April the first flowers were fertilized. At the end of that month the flowers, which had set, looked dried up but still stuck to the pods, which were then beginning to lengthen out.

The main thing in growing Vanilla is of course the time when the flowers must be fertilised. This has to be done artificially. If left to themselves, perhaps, not one in a thousand would give a pod. This operation is thus of the greatest importance, and should be done very carefully: on it depends the whole result of one year's trouble. The *modus operandi* can, of course, better be shown than described, and it requires a little practice and a steady hand before one can do it quickly without spoiling the flowers or losing the pollen, etc. One must first of all prepare a

little piece of bamboo cut into the shape of a toothpick: in fact, I have done the fertilization with this last named article and it answered admirably.

The anatomy of the Vanilla flower is somewhat different from the general run of other Orchid flowers. At the extremity of the gynostemium there is a little cap covering the pollen; the first operation is thus to lift this cap and carefully take the pollen masses out on the end of the toothpick. Beneath this first receptable is another little lip covering the stigma; under this lip will be found the stigma covered with a sticky liquid. The second operation consists in lifting this lip with the very point of the toothpick, holding already the pollen; then, when the stigma is fully exposed, by a gentle twist apply the pollen on to it. When one has repeated this operation systematically a few times, it is really wonderful how quickly one can perform it. The segments of the flowers should be drawn well back so as to facilitate the operation, and held with the left hand together with the ovary; the operation of applying the pollen should be performed with the right, at the same time join the tips of the little fingers to steady both hands.

The pollen adheres very firmly to the stigma, and when once properly applied, there is little chance of its falling off. After the operation of fertilizing has been attended to, very little remains to be done. Nature then takes the matter in hand, and one has but patiently to wait the further development. The first sign by which one can detect whether the flower has set to fruit, is the way in which the segments stick to the top of the ovary. If not successful after a day, perhaps, a couple of days, these segments drop, leaving only the ovary, which soon drops in its turn. The pods after the first two or three weeks grow very steadily and attain their full size about the beginning of November. Then they gradually begin to lose the bright green colour, and by December the nose of the pod turns yellow first, then slightly brown; this is the time to gather the pods. The plucking of course must be done every day, for all pods do not ripen at the same time, and only those that part easily from the flower stem should be taken down.

After the gathering comes the curing. Having only a limited number of pods, they were sundried, wrapped up in woollen cloth, which I found answered very well. The pods developed a fine aroma and soon assumed that dark chocolate tint which I believe is recognized as very good.—A. J. B. GISSELEIRE, Superintendent, Agri-Horticultural Society's Gardens, Calcutta.—*Indian Gardening and Planting*, June 7.

FRUIT FARMING IN MYSORE.

In a recent official report, Mr. John Cameron commented on the backward condition of Fruit Culture in the Kadur district, remarking:—"With the exception of orange trees, which are found on some estates, fruits are not abundant; nor did I observe any organised attempt to grow this class of produce in quantity. Mr. Kirwan has in his fine garden at Santaveri a number of fruiting plants such as pine-apple, strawberry, peach, orange, hill-gooseberry and banana. But they are grown on a limited scale, and more to represent their class than with a view to economy." As, however, "most of the kinds were growing well," there is no apparent reason why fruit farming should not prove a very useful adjunct to coffee-planting in Kadur. The inimical factors are said to be (*a*) the length of the monsoon accompanied by dense fogs and much cloudy weather; (*b*) the prevalence of fruit-eating birds, and (*c*) the pilfering habits of estate coolies. The first is a difficulty that may prove insurmountable in some places, but there are certainly remedies for (*b*) and (*c*); and we do not believe that any planter eagerly bent on pushing fruit cultivation would allow himself to be deterred from carrying out his plans by either feathered or human biped. The true difficulty appears to lie in finding a market. As things stand at present, there is not bulk enough to secure a minimum of transport expense, nor enterprise enough to set about *making* a market. Referring to this point, Mr. Cameron remarks that fruit must either be preserved on the spot, or conveyed by rail to the cities on the plains. In this connection it may be observed that, although there is at present no factory for the manufacture of jams and preserves on a large scale, one would probably soon be forthcoming if a sufficient fruit supply could be assured at a convenient centre. Then, too, there are well-known methods of drying fruit; while fruits such as oranges, apples, etc., are easily transportable to even distant places.

The orange itself affords perhaps the best proof available of the general indifference manifested with respect to the cultivation of fruit. In Kadur Mr. Cameron only found one variety, the "Coorg loose-jacket." Good as this is, we are not surprised that Mr. Cameron should suggest the introduction of other good varieties, such as the Seville, Malta blood and St. Michael's. Variety would certainly give an impetus to demand, and moreover it is fairly certain that all the above varieties would not ripen at one time, so that the measure suggested might lengthen the "season" during which oranges are obtainable. Mr. Cameron further recommends for cultivation in the drier parts of the hill zone (that is, the eastern and southern faces of the lower hills having a rainfall of 45 to 80):—

Apple	Dwarf bushes or maidens imported from California, Italy and Japan.
Peach	Ditto from Florida, Italy and Japan.
Plum	From Malta and Japan.
Pear	From California, France and Italy.
Mulberry	From Japan and China.
Pineapple	From Ceylon and Singapore.
Fig	From Southern Europe and Turkey.
Raspberry	Best English.
Strawberry	Ditto.

He remarks that raspberries and mulberries would stand a good deal of rain and cloudy weather; but in regard to fruit culture generally he considers that operations should be confined to the drier parts of the district, where there is elevation, in addition to shelter and means of irrigation. Many positions of this class would possibly be found on the lower slopes of the Baba Budans facing towards the east and south; but more particularly amongst the smaller hills dwindling down in the same direction to the plains. Except for oranges of sorts, the western portion of the district is too wet and gloomy during several months of the year. In addition to the exotic plants already recommended, the following novelties are mentioned for trial:—

Loquat	..	Eriobotria japonica
Sapodilla plum	..	Achras sapota
Litchi	..	Nephelium litchi
Alligator pear	..	Persia gratissima
Parangi	..	Carica Papaya.

He did not observe any spot sufficiently tropical and sheltered, as at Burliar on the Nilgiri ghat, for the cultivation of the Durian and Mangosteen. Neither are there suitable localities for the fruits of cold temperate climates, such as cherry, gooseberry, currant, etc.

As to conditions of cultivation, Mr. Cameron gives the following practical advice:—"A fruit garden should be fully exposed to sunlight. The land should be fairly good to start with and should be entirely free of roots from adjacent trees or crops. A sufficient water-supply must be available at a higher level or in wells to irrigate the whole of the garden. Land chosen for fruit culture should, in preference, be of the calcareous class. It may be level throughout or terraced. Very steep land is undesirable, and in cold situations a southern aspect is best. By efficient systems of drainage, and the judicious application of suitable manures the land would soon improve in quality. But it must not be forgotten that fruit crops are exhaustive to the soil in proportion to their outturn and duration. Therefore, the richness of the soil has to be carefully maintained as long as the production of fruit continues. The first operation, which consists of

trenching the land to a depth of 2 to 3 feet, reveals the nature of the subsoil and usually decides to what extent artificial draining is necessary. Subsoils of gravel, laterite, and sand would mostly afford natural drainage, except where the situation is lower than its surroundings. Drainage is most necessary in the case of a stiff clay. Fruiting plants are impatient of stagnant moisture at their roots. For this and other reasons the latter should be kept as near the surface as possible. It is only in the case of large trees, such as the coconut and jak, that deep land is needed for the cultivation of fruit.' Mr. Cameron concludes this interesting section of the report under notice by saying that all, or nearly all, the indigenous fruits would succeed in the *maidan* part of the district. The hog-plum, *Spondias magnifera*; hill-gooseberry, *Physalis peruviana*; Korinda, *Carrissa carandas*; and at least three species of Ruhus (raspberry) were commonly found all over the hills. Bananas and plantains are not uncommon in the hamlets skirting the paddy-fields up to 4,000 feet.—*Planting Opinion.*

UNITED PLANTERS' ASSOCIATION (FEDERATED MALAY STATES).

[EXTRACTS:] LATEST MEETING, MAY 7TH.

COFFEE.

The CHAIRMAN said that at the general meeting held on 14th August last the Association had expressed its cordial approval of a scheme for stimulating the consumption of coffee, proposed by the *South American Journal*, and he had written to the Editor to that effect. Subsequently, the Editor abandoned his original suggestion and proposed instead that a coffee roasting company or syndicate should be formed and invited our Association to take shares and supply coffee. This matter was considered at a Committee meeting on 12th January last, and it was decided that the Chairman should write and inform the Editor that we were not in favour of this idea and could only support the original proposal, which had been done. In an editorial on 17th February, 1900, the Editor expressed his pity that we should have come to such an important conclusion, especially after the arguments he had advauced, but we have our own opinion on that point and there the matter may rest.

Mr. T H HILL had written several letters to the Hon. Secretary, on the subject of sending regular supplies of coffee to Messrs. Sanderson and Company in London, with the view of bringing our coffee more into favour, and after consideration by the Committee the Chairman was asked to write to Messrs. Sanderson and Company on the subject, at the same time sending samples of machine-dried and sun-dried coffee and asking their advice as to which was most suitable. This the Chairman had done, having sent two samples of machine-dried and two samples of sun-dried coffee, and nothing further could be done until we heard from Messrs. Sanderson and Company. Mr. Hill had also suggested that a small shipment of coffee should be sent to Aden and had taken a great deal of trouble to arrange for the treatment of the coffee there. The Committee thought favourably of the experiment, and the Co-operative Coffee Trading Company. Port Dickson, were prepared to arrange for the shipment. It was, however, stipulated that a sample of the coffee sent should be submitted to the United Planters' Association Committee, and also that the coffee should be submitted to an expert in London before being handed over to the Kajang Coffee Company for sale. The Chairman said he thought this a matter which the Association might well take up, and it was for the meeting to decide as to guaranteeing payment for the coffee or not. After some discussion, it was resolved unanimously that the Association should guarantee the payment.

RUBBER.

The CHAIRMAN said there had been an idea that it would be a good thing to send a practical man to Brazil to enquire into the Para and other rubber questions, and he had been asked by the Committee to write to the newspapers on the subject, which he did. The article had been favourably received, but since then he had met Mr. Michie, a well-known Ceylon gentleman, who had spent about a year in Brazil, and his opinion was that there was nothing to be learned by going to that country and any money could be much better spent here. The whole of the system of tapping and curing was carried ont in a crude and primitive way and no cultivation was attempted. Mr. Coates corroborated what Mr. Michie had said, as he was in Brazil with him when he made the enquiries. Mr. Bailey said he, also, was of opinion that we could spend the money much better by experimenting ourselves on trees in the Malay States and the Colony. The Chairman said he was also of that opinion, particularly as a qualified man from Kew would soon be available to carry out such experiments, and in the meantime the Committee had instructed the Hon. Secretary to write to the Resident-General's Office asking them to get all possible information about Para rubber and gutta rambong—such as method of tapping, yield, etc.—and suggesting Sumatra as a likely place to get information about rambong.

PROSPECTS.

The CHAIRMAN said: Coffee was higher than last year, and, although there had been a slight drop in the market lately, the opinion of those in the trade was that the present depresssion could not last much longer. Rubber of all kinds was doing well in these States and coconnts also promised to be a good source of revenue. Our labour market was in a better position than it had ever been, no doubt greatly owing to the Indian famine, but they had also to thank the Resident-General for what he had done for them in connection with the extension of the cheap-ticket system and the importation of labour by Government for Public Works. The Experimental Garden and Agricultural Department had been, at last, brought to a definite conclusion, and they had also to thank Sir Frank Swettenham for what he had done for them in this matter. As they would see in the report, there were now 95 members on the roll, against 99 last year, and he regretted to say that Perak was responsible for this falling off, their 16 having dwindled away to two. He hoped that Perak would soon reconstruct their district Association.

Mr. E. V. Carey was re-elected Chairman, and as Mr. Tom Gibson could not stand again, Mr. M. Sidney Parry was elected Hon. Secretary.

GUTTA IN THE STRAITS.

THE NEED OF PLANTING AND PROTECTION.

(*From Pahang Administration Report for 1899.*)

The gutta percha producing tree (*Dichopsis gutta*), known locally and in Singapore as "getah taban merah," is the one most in need of protection. It is a very slow-growing tree, and, when it has obtained a girth of three feet in circumference, which it takes about thirty years to do, it yields about two katies, or 2⅔lb. of gutta, and the collection of this involves the felling of the tree. It is an essential material in the construction of submarine cables, and it is only to be found in the southern part of the Malay Peninsula, Sumatra and Borneo. It consequently commands a much higher price than any of the other guttas, and, for this reason, is much more liable to extermination. It is laid down in the Farm Rules that no trees of less than three feet in circumference are to be felled, but it is almost impossible to enforce this rule, and there is no doubt that a large number of immature trees of less than the prescribed girth are being destroyed. Recently, a system of rewards for information leading to a conviction for breach of the rules has been introduced. It is probable that this, when it becomes well known, will prove more efficacious in preventing the felling

of immature trees than any other method yet tried, but it is not likely to put an entire stop to the practice. Though saplings still exist in large numbers, there are very few fully matured trees. In fact, up to the present time, I have not met anyone who can show me one anywhere, except in the very remotest parts of the State. If these are felled and the younger trees cut down before they are old enough to bear seed, the jungle will, in a few years, become entirely denuded of these valuable trees, and the greatest care will have to be taken to prevent this. In an earlier paragraph of this report I have alluded to the probable necessity of prohibiting, for a term of years, the collection of gutta, after the expiration of the present Gutta Farms in July next; but, though such prohibition is likely to be desirable, it may prove quite impossible to enforce, except at very great expense.

The above facts all point to the necessity of opening large plantations of "taban" trees. Unfortunately, owing to the tree being such a very slow-growing one, it is not a form of planting that could be profitably pursued by private individuals or firms. It must, therefore, if it is to be done at all, be undertaken by the Government. Gutta from Pahang commands a higher price in the Singapore market than that from any other part of the Peninsula or elsewhere. The climatic conditions and nature of the soil in Pahang appear to be more favourable to its growth than are those of the Western States. It would, therefore, most probably be the best State in which to commence planting gutta percha on an extensive scale. As Pahang does not possess the funds requisite for this, it might with advantage be made a Federal charge, each State sharing, in proportion to the amount of its contributions, in such profits as might eventually accrue.

PRODUCE AND PLANTING.

THE TEA TRADE OF JAPAN.—The tea trade of Japan cannot be considered as flourishing. Mr. A. H. Lay, the British Assistant-Consul at Tokio, in his report on the trade of Japan, gives some interesting information in regard to the tea industry. The quantity of tea exported from Japan during 1899, he says, exceeded that shipped abroad during 1898; but all the same the tea business in Japan is becoming more and more unsatisfactory each year, and, for the foreign merchant, at any rate, there is, little or nothing to be made out of it. In quality the tea of 1899 compared unfavourably with the crop of 1898. The practice of picking the young leaves in the early spring before they are properly matured, for the sake of obtaining exorbitant prices for small quantities, is undoubtedly having a very injurious effect on the plants, and it is surprising that Japanese tea growers do not realise this fact. But it is not only from the effects of the injudicious system of picking that the Japanese tea industry is suffering. The trade with Canada, Mr. Lay points out, is appreciably affected by the competition of the Ceylon and India growers, who, by extensive advertising and other methods, are bringing their produce prominently before the public. The Japanese, on the other hand, are making no efforts whatever to advance the sale of their teas, and as Ceylon green teas are now making their appearance in Canada, where their sale will be vigorously pushed, the future of Japanese tea in that market cannot be regarded as bright.

THE TEA TRADE OF ICHANG.—A Consular report states that the trade of Ichang, China, is entirely with native treaty ports. There is no direct foreign trade. Exports include tea, which is prepared for export at the place of production, Ta-ch'i-k'ou, about a hundred miles west of Ichang; 74,800lb. of this tea were exported to Hankow, but resulted in a financial loss. The advent of steamers to run between Ichang and Chung-king is expected to increase exports from and ultimately imports to Chungking, and thereby increase imports into and re-exports from Ichang.—*H. C. Mail*, June 1.

SCIENTIFIC MANURING.

Four years ago we wrote as follows on this subject:—

There is, perhaps, no direction in which money can be more easily wasted in connection with the cultivation of tropical products, than in the purchase and application of manures. Not only should the fertiliser purchased be tested by the analyst; but also the soil to which manure is to be applied. Not only does the soil of one district differ from another; but it may be that adjacent plantations require very different treatment. But there is the great temptation among planters to follow some one particular lead; or there is the feeling that for Ceylon tea bushes. "bones and castor-cake or fish manure" cannot fail to do good. Possibly not; but it is equally certain that a previous examination of the soil might supply information which would lead to considerable economy or to a great deal more lasting benefit from the application of fertilizers.

At that time, the supply of fertilizers according to scientific investigation was in its infancy amongst us and we believe not more than four distinct substances were in use. The great advance made in the interval will be best understood from a perusal of an account of a visit to the Hulfsdorf Manure Establishment and Laboratory, which is given on page 50, and which, we feel sure, will be perused with interest, especially by planters.

PLANTING NOTES.

GUTTA PERCHA.—The Straits authorities are awaking to a sense of the need of protecting their very profitable gutta-yielding tree (*Dichopsis gutta*) and also of putting out trees on special plantations of the same. We refer to interesting remarks on the subject from the Administration Report on Pahang, given on page 54.

RUBBER IN SUMATRA.—Gutta plantations have largely been started on the East Coast of Sumatra. The Russian-American India Rubber Company have just begun operations there. The Tanah Priok Cultivation Company now follows suit. It proposes to grow rubber on a scale sufficient to admit of 240,000 trees being available in seven year's time. Rubber grows wild in large quantities in East Sumatra.—*Straits Times.*

SUN-FLOWER OIL.—We have at times drawn het attention of our readers to the commercial valne of the cultivated Sun-flower, and have advocated its being planted out on waste plots. We now learn from a Russian chemist that the plant is extensively cultivated in Russia, which produces nearly 300,000,000 pounds of seed from 216,000 acres. The seed yield—oil and seed cake—is good food for poultry, and the flower produces a yellow dye, honey and wax. Potash is derived from the stalks, which are also used as fuel. Cigars are made from the leaves, and it is claimed that the plant is a preventive of fevers, and is at the same time a good cattle food. The oil is pale yellow in colour, thicker than hempseed oil, flavourless but palatable. Mr. Machalske obtained from 1,300 lb. of seed kernels 34 per cent. of raw oil having the appearance of the best qualities of refined cotton seed oil.—*Indian Planters' Gazette*, June 2.

M. PRUDHOMME—our French Agricultural visitor (Director-General of the Department in Madagascar)—left for Europe by the French mail-steamer last month. He has now been travelling for six months, visiting Java, Sumatra, the Straits Settlements, Ceylon and Calcutta; but he comes back after a couple of years, to give some weeks or months to India by itself.

TEA PLANTING AT MALACCA.—A Colonial Office Report, from Singapore, on planting in the Straits Settlements, says that a good tea plantation has been thoroughly established in Malacca, which finds a local market for its produce. An enterprising syndicate of Chinese has taken up the business.—*Pioneer*, June 20.

NEW DUTIES IN FRANCE.—The new French duties to come into force on 1st September bear very hardly on Ceylon produce, and the doubling of the tax on tea will go far to destroy any benefit that might have accrued to tea industry from the Paris Exhibition. The Ceylon Association is in communication with the Colonial Office on the subject, and it is understood that the London Chamber of Commerce will also take the matter up. The enhanced rates are as follows :—

				kilos.
Coffee	from	156 to 300	francs per	100
Tea	do	208 to 400	do do	100
Pepper	do	208 to 400	do do	100
Cloves	do	208 to 440	do do	100
Shelled Nutmegs & Mace	do	312 to 600	do do	100
Vanilla	do	416 to 800	do do	100

—London Cor., local "Times," communicated.

[The new French Duty on tea will, therefore, be a fraction over 1s. 6d. per pound !—ED. *T.A.*]

A FRENCH "PLANTERS' ASSOCIATION."—In a recent issue of the Tonkin French paper *L'Avenir du Tonkin*, we notice that a "Syndicate of the Planters of Tonkin" was about to be formed. From the proposed rules of the Syndicate, subscribed to by a membership of 91, we learn that its object is to centralise at the headquarters of the Syndicate information of every kind, documents, specimens, &c., and to bring mutual assistance to the planters and facilitate operations of sale and purchase. For active membership all settlers in the colony and companies or persons owning estates or plantations are eligible; for associate membership, all settlers or companies without such property. Active members alone will have the right to effect sales or purchases, through the intermediary of the Syndicate; these transactions are to be gratuitous and will not require any commission. The headquarters of the Syndicate will be at Hanoi and its affairs will be managed by a Committee of ten (elected by the active members) who will settle the dates of the annual meetings and arrange where they are to be held. The work of such a Syndicate, it will be seen, will be, if the initial rules are adhered to, confined far more to internal trading than the opening of foreign markets for local produce or influencing the local and home Governments with a view to beneficial legislation—such as our Ceylon P. A. aims at.

THE DEAR ELEPHANTS.—The teak trade in Siam is hampered by the increasing dearness of the elephants which drag the logs from the forests. Five years ago, elephants cost only 1,000 to 1,500 rupees each. At present, the price is from 3,500 to 4,000 rupees. The cost of labour, too, has risen over 50 per cent.—*Straits Times*, June 15.

THE DUTY ON TEA IN FRANCE—which is now about 11½d per lb. (or 208 francs per 100 kilos)—will after September 1st be a fraction over 1s 6d per lb. (400 francs per 100 kilos), unless the remonstrances now being offered to the French fiscal authorities, prevent this backward step. Little Belgium has actually no duty on tea.

CEYLON PUBLICATIONS IN PARIS.—The editor of the *Revue des Cultures Coloniale* has given several favourable notices of works that have issued from the *Observer* Press and that bear on agricultural topics, showing how keenly they are alive to what may help French colonists abroad. He especially notes the *Ceylon Handbook and Directory* and refers to "two portions of extreme "interest, namely that on the Meteorology "of Ceylon and the general sketch of the "Agriculture of Ceylon, covering nearly 200 "pages."

GEMMING IN CEYLON.—From the Administration Report for 1899, Mr. L. W. Booth, Government Agent, of the Province of Sabaragamuwa, we make two extracts :—

GEMMING.—It may be said that plumbago drove gems out of the market last year. Gemming, never a paying industry, is much less so now, as most of the accessible localities likely to contain gems have been searched. It will however continue to exercise its fascination, for if the blanks are many, the few prizes are dazzling. There was a general impression that if European and scientific methods were substituted for the primitive and crude ones now obtaining, the industry could be made a remunerative one. But the death-blow to that impression was dealt by the failure during the year of the European syndicate who laid out a large sum on plant and employed highly-paid experts. Their failure was due to the bad choice of a site and the expensiveness of their establishment. A better fate might have attended search in river beds conducted on scientific but less extravagant methods. The beds of rivers are supposed to be rich in gems, and they have not been explored to the same extent as valleys, owing to the greater difficulties which attend search in them and obtaining of licenses and the unsuitability of the Sinhalese methods for places where the water is deep. Gemming in navigable streams is not allowed for obvious reasons. Gemming in streams that are not navigable is not, as a rule, allowed, as the people living in villages through which the streams flow are dependent on them for their water supply both for drinking and irrigating purposes. Licenses are however issued to gem in parts of streams where it is shown that no inconvenience to the public will result by gemming. The lease of the right to gem in a section of the Niri-ella stream was sold from 1898 to 1899 for R760, and as the digging was very successful the lease for 1899 to 1901 fetched R2,020. The only innovation as yet adopted in river gemming is the use of the diving machine. One similar to that used by the Austrian Navy was recently worked by an Austrian, with, it is believed, good results.

CAMPHOR.

Of all exotics that are used for ornamental purposes, none has taken so kindly to New South Wales as the Camphor tree. On hard stiff clays, and in barren sand, and even in paved yards, this beautiful evergreen can be found flourishing most luxuriantly. Nothing appears to attack its foliage or wood, and if a tree gets too big for its surroundings and is ruthlessly pruned, not many months elapse before it sprouts again, and becomes a mass of delicate and fragrant verdure. Until quite recently the demand for the well-known resin of this tree was not extraordinary, being confined to the requirements of the druggist; but of late years it has been used in continually increasing quantities in the conversion of collodion cotton with the material known as celluloid, which is applied to the manufacture of imitation ivory, tortoise shell, horn, and a great variety of ingenious deceptions. It is easy to understand that anything that can be utilised in the substitution of artificial for fast disappearing natural production has a great future, and since the tree grows like a weed in so many parts of this Colony, it is worth while considering whether local manufacture of camphor could not be successfully attempted here.

The following details concerning the tree, and its products are taken from a special report written in 1897 by Mr. Lyster H. Dewey, of the United States Division of Botany, and reprinted in Kew Bulletin:—

Native Range.

The camphor tree is native in the coast countries of Eastern Asia from Cochin China nearly to the mouth of the Yang-tse-kiang, and on the adjacent islands from the southern part of the Japanese Empire, including Formosa and the Loochoo Islands, to Hainan, off the coast of Cochin China. Its range also extends into the interior of China as far as the province of Hupeh, about 500 miles from the coast on the Yang-tse-kiang, in latitude 30° north. This area, extending from 100° to 34° north latitude and from 105° to 130° east longitude, is all embraced in the eastern monsoon region, which is remarkable for abundant rains in summer.

The Camphor trees growing wild in the native range are usually most abundant on hillsides and in mountain valleys where there is good atmospheric as well as soil drainage. The temperature in the greater part of this region, which is partly within the tropics and partly subtropical, rarely falls below freezing. The tree is an evergreen, changing its leaves generally in April, and therefore the winter temperature is a factor of more importance than would be the case with a deciduous tree.

Description.

The camphor tree is an evergreen, related to the bay and to the sassafras of the United States. In its native habitat it attains a height of 60 to 100 feet, with wide-spreading branches and a trunk 20 to 40 inches in diameter. The leaves are broadly lanceolate in form, acuminate at both base and apex, of a light green colour, smooth and shining above and whitish or glaucous on the under surface. The lower pair of lateral veins are more prominent than the others, but the leaves are not as distinctly three-nerved as those of the cinnamon and many other species of the genus. The small white or greenish-white flowers are borne in axillary racemes from February to April on shoots of the previous season, and are followed in October by berry-like, one-seeded fruits about three-eighths of an inch in diameter. The fruiting pedicles terminate in a saucer-shaped disc, perishing after the mature fruit has fallen.

Range under Cultivation.

Notwithstanding the comparatively narrow limits of its natural environment, the camphor tree grows well in cultivation under widely different conditions. It has become abundantly naturalised in Madagascar. It flourishes at Buenos Ayres. It thrives in Egypt, in the Canary Islands, in south-eastern France, and in the San Joaquin Valley in California, where the summers are hot and dry. Large trees, at least 200 years old, are growing in the temple courts at Tokyo, where they are subject to a winter of seventy to eighty nights of frost, with an occasional minimum temperature as low as 12° to 16° F. The most northern localities in the United States, where the camphor tree has been grown successfully out of doors, are Charleston and Summerville, in South Carolina, Augusta, Ga., and Oakland, Cal.

At Charleston Sommerville, and Augusta the trees have withstood a minimum temperature of 15° F., but they have been protected by surrounding trees and buildings. At Mobile, Ala., the trees have grown and fruited in protected situations, while in exposed places they have been repeatedly destroyed by frosts. While the camphor tree will grow on almost any soil that is not too wet, it does best on a well-trained sandy or loamy soil, and it responds remarkably well to the application of fertilizers. Its growth is comparatively slow on sterile soils, but under favourable conditions it sometimes grows very rapidly. An instance is recorded of a camphor tree in Italy a foot in diameter and 90 feet high, eight years from the seed. Under ordinary conditions, however, such a girth is not often attained in less than twenty-five years, and such a height is rarely attained in a century. Under favourable conditions an average of 30 feet in height, with trunks 6 to 8 inches in diameter at the base, may be expected in trees ten years from the seed.

Uses of the Tree and its Products.

The principal commercial uses of the camphor trees are for the production of camphor and camphor oil. Camphor is employed extensively in medicine. It enters into the composition of many kinds of liniments for external application. For liniment it is used especially in combination with olive oil. It is taken internally for hysteria, nervousness, nervous headaches, diarrhœa, and diseases affecting the alimentary canal. It is a specific in cases of typhoid fever and cholera. Camphor fumes have been used with success in cases of asthma. It has been used very extensively to keep insects out of furs, woollens, etc. In Japan, camphor and camphor-oil are used in lacquer work. The oil is somewhat similar to turpentine, and could doubtless be used to advantage in varnishes and shellacs. It is now used in the manufacture of toilet soaps. In Japan and China it has been used for illuminating purposes, but it produces a smoky flame.

Among the secondary uses of the camphor tree the most important is for ornamental planting. Its bright evergreen leaves, rapid growth, and long life make it valuable for this purpose. In Japan and China it has been the principal tree planted in the temple courts for many centuries, and in those countries, it takes the place of the historic oaks of England. It has been extensively introduced into Southern Europe and South America for ornamental purposes.

The wood, with its close grain, yellow colour, and susceptibility to polish, taking a kind of satin-like finish, is exceedingly valuable in cabinet-work, especially for making drawers, chests, and cupboards proof against insects. The leaves and young branches, although they have but a slight odour of camphor, are packed with clothing or scattered about unused rooms to guard against insects.

The tree produces an abundance of berry-like fruits, which are used in Japan and China to make a kind of tallow. The fruits are greedily eaten by chickens and birds.

Conditions of Successful Cultivation.

For most of the secondary purposes, the camphor tree may well be cultivated wherever it can be made to live; but for commercial distillation, and for the production of wood for cabinet purposes, it must be grown under the most favourable conditions. The minimum winter temperature should not be below 20° F., and this minimum should be of rare occur-

rence. The soil, preferably sandy and well drained, should be irrigated unless there are abundant rains. Fifty inches of water during the warm growing season is desirable, and much more may well be used where the air is very dry.

An abundance of plant-food, rich in nitrogen, is required for rapid growth, but the kind of fertilizer that can be most profitably applied will vary according to the character of the soil in each locality. In the absence of definite information in this regard the kind of fertilizer producing most rapid growth of wood in the orange or in other fruit trees may be taken as an index,

Propagation.

Camphor trees may be grown either from seed or from cuttings. They are usually grown from seed, as the trees fruit abundantly, and seedlings can be grown more easily than cuttings. The seeds are collected at maturity in October and November, and after drying are packed in sharp white sand or some similar material to keep them fresh until the time of planting in spring. About the last of March they are shown in drills in the seed bed.

The soil of the seed bed should be a good sandy loam mixed with about one-third leaf mould. The seed bed should be kept moist, but not too wet, and should be shaded from the direct rays of the sun if the weather is warm. The best soil temperature for germinating camphor seeds is from 70° to 75° F. The temperature of the atmosphere may be ten degrees higher. The seedlings will grow well at higher temperatures, but are likely to lack vigour and hardiness.

The seedlings may be grown in pots, which will facilitate transplanting at any time, or they may be transplanted in nursery rows early in April when one year old. Plants two years old are generally regarded as best for final planting. At this age they vary from 20 to 40 inches in height.

Planting and Cultivation.

In Japan, where the law requires that a new tree shall be set out for every one cut, they are not generally set in strait orchard rows, but cultivation there is performed almost exclusively by hand labour. There are no records showing results or regular orchard planting, hence the distances at which trees should be planted must be determined by the size and form of the trees and the methods of cultivation and of procuring the gum. They may be set closely in rows about 10 feet apart, and alternate rows cut and reset every five years, thus producing bush-like plants of ten years' growth. They may be planted in checks 10 feet square, and alternate trees cut every ten or twelve years, or they may be planted in larger checks, and all of the trees be cut at the age of fifteen or twenty years.

There are not sufficient data obtainable upon which to base definite statements as to the best methods of planting, or the age at which the trees may be cut with greatest profit. A recent English consular report from Japan states that, "although hitherto the youngest wood from which camphor was extracted was about seventy to eighty years old, it is expected that under the present scientific management the trees will give equally good results after twenty-five or thirty years." Camphor of good quality has been produced in Florida from the leaves and twigs of trees less than twenty years old, 1 lb. of crude camphor being obtained from 77 lb. of leaves and twigs.

The trees will endure severe pruning with little apparent injury. One-third of the leaves and young shoots may be removed at one time without materially checking the growth of the tree. The largest proportion of camphor is contained in the older, larger roots; the trunk, limbs, twigs, and leaves containing successively a decreasing proportion. When the camphor tree is killed nearly to the ground by frost it sends up vigorous shoots from the base. It may be expected to do the same when cut, especially if cut late in the fall. Experiments are needed to determine whether this growth may be depended upon or whether it will be more profitable to dig out the larger roots and set out new seedlings.

Distillation.

In the native forests in Formosa, Fukien, and Japan, camphor is distilled almost exclusively from the wood of the trunks, roots, and larger branches. The work is performed by hand labour, and the methods employed seem rather crude. Different methods of distillation are employed in different districts, but those in use in the province of Tosa, in Japan, appear to be the most skilful. The camphor trees are felled, and the trunk, larger limbs, and sometimes the roots, are cut into chips by hand labour with a sharp concave adze.

The fresh chips are placed in a wooden tub about 40 inches high and 20 inches in diameter at the base, tapering toward the top like an old-fashioned churn. The perforated bottom of the tub fits tightly over an iron pan of water on furnace of masonry. The tub has a tight-fitting cover, which may be removed to put in the chips. It is surrounded by a layer of earth about 6 inches thick to aid in retaining a uniform temperature. A bamboo tube extends from near the top of the tub into the condenser. This consists of two wooden tubs of different sizes, the larger one right side up, kept about two-thirds full of water from a continuous stream which runs out of a hole in one side. The smaller one is inverted with its edges below the water, forming an air-tight chamber. This air chamber is kept cool by the water falling on the top and running down over the sides. The upper part of the air chamber is sometimes filled with clean rice straw, on which the camphor crystallizes, while the oil drips down and collects on the surface of the water. In some cases the camphor and oil are allowed to collect together on the surface of the water and are afterward separated by filtration through rice straw or by pressure.

About 12 hours are required for distilling a tub-ful by this method. Then the chips are removed and dried for use in the furnace, and a new charge is put in. At the same time the camphor and oil are removed from the condenser. By this method 20 to 40 lb. of chips are required for 1 lb. of crude camphor.

The principles generally held to be essential in distilling camphor of good quality are:—(1) The heat must be uniform and not too great, producing a steady supply of steam; (2) the steam after liberating the camphor must not come in contact with metal, that is, the tub and condensing apparatus must be of wood.

Suggested Improvements.

Many improvements upon the methods described can doubtless be made, tending both to a reduction in cost and an increase in the proportion of crude material obtained. Instead of an adze wielded by hand labour a machine similar to the "hog" used for grinding up waste slabs in sawmills may be used to reduce camphor limbs to the requisite fineness for distillation. Better distilling apparatus can probably be devised. Thermometers may be introduced to determine the heat in the distilling tub, and the furnace may be so arranged as to permit better control and greater economy in fuel. Camphor and camphor-oil are both slightly soluble in water, and the condensing chamber should be improved so as to recover the product that is being constantly carried off in the running stream which cools the chamber.

Outlook for Future Market.

The consumption of camphor in the United States, as measured by the importations, has been decreasing during the past ten years, while the price has been increasing.

The Tariff Act, approved July 27, 1897, imposes a duty of 6 cents per pound on refined camphor, and leaves crude camphor on the free list, as heretofore.

There has been an increase in importations of refined camphor, due to improved methods of refin-

ing and packing in Japan and to changes in the tariff, but this increase has been much more than counterbalanced by the decrease in importation of crude camphor. The decrease may be attributed to the following causes:—(1) the exhaustion of the supply of the available camphor trees near the shipping ports; (2) the governmental restrictions on the trade in camphor in Formosa; (3) government taxes on the exportation of camphor from Formosa; (4) hostilities and wanton destruction of camphor stills by the natives in Formosa; (5) disturbances in the camphor-producing district of China; (6) the China-Japan war; (7) attempts by speculators to corner the market.

These causes have increased the price of camphor, and this in turn has led to the introduction of substitutes. Menthol and other peppermint derivatives or compounds, carbolic acid and its derivatives, naphthalin, formalin, and insect-powder are now used for various purposes where camphor was formerly employed. Camphor has been manufactured artificially, at a cost leaving a margin of profit at present prices. It is therefore apparent that if the production of camphor from the trees is to be carried on with profit in this country, and the industry increased to any considerable extent, the price of camphor must be reduced to compete with the prices of substitutes now taking its place.

Camphor has been obtained from several other plants not at all related to the ordinary camphor tree, but only two kinds. Borneo camphor and Blumea camphor, are of any importance commercially.

Borneo camphor is obtained from the camphor tree of Borneo and Sumatra, *Drybalanops aromatica*. It is deposited in clefts and hollows in the wood, and has simply to be taken out. This camphor is comparatively rare, and the supply is consumed almost exclusively in China, where it is valued at from thirty to ninety times as much as ordinary camphor.

Blumea camphor is obtained by distillation from *Blumea balsamifera*, a shrub growing in Burma and the Malay Peninsula. This is usually refined in Canton, whence about 10,000 lb. are exported annually. The source of this supply is abundant, and as the industry develops it is likely to enter more into competition with ordinary camphor. Neither of these plants can be grown in the United States, except possibly in Southern Florida, without protection against cold.—*Agricultural Gazette, N. S. Wales.*

PLANTING IN GERMAN EAST AFRICA.

In the December issue of *Der Tropenpflanzer*, Berlin, are the following interesting accounts of G. E. A.:—

The Coffee plantation Sakarre (Usambara). The annual report of the financial year 1898-99 shows that the plantation situated in west Usambara suffered less from the drought of the preceding year than the coffee plantations situated in the eastern slopes of the Handai mountains. In the summer of 1898, *i. e.* at the beginning of the financial year, the plantation numbered 300,000 trees and in the course of the year *i. e.* until the end of July, 220,000 more were planted, so that the entire plantation consists of 520,000 trees, which gives the plantation in respect of size the third place among the coffee plantations of Usambara (coming next to Magrotto and (Union). A dwelling-house, an office and two stables have been erected in place of the temporary buildings. Besides the plantation roads, preparatory works on the high road which is to connect Sakarre with the future railway station Korogwe have also been completed. On this road, near the river Garia, the storehouses are to be built. The number of labourers varied between 300 and 400, for the greater Wanyamwesi. The village Sakarre has become an important market place, to which even the inhabitants of distant villages send their produce. The original capital of 700,000 marks has been raised to 1,200,000 marks in an extraordinary sitting on the 16th of May, and the new shares have been nearly all taken up by the former shareholders. The accounts show that the cost of each tree up to now, including buildings, management, etc., is about one mark.

This plantation is therefore one of the most cheaply managed in Usambara.

What account a plantation costs in German East Africa.—In the "German East African Zeitung" of October 7th is to be found the following rough estimate of a plantation of 10,000 palms made by an expert:—

Purchase of young palms, R. 40-50 per 1000	R.	400-501
Carrying them to their respective places	,,	100-150
Planting 10,000 palms, 4 labourers 50 days @	R. ½ ,,	100-125
Total	R.	600-675 (*sic*)

Generally speaking the cost of one palm until the time of bearing may be estimated at R1½. There may however be favourable conditions under which a coconut plantation does not incur further expense than the cost of buying the land or paying the rent. This is the case when there is a concession to settle down on the plantation a number of families for the space of six years. They receive the right to plant muhogo and bananas in return for a third of the produce and the obligation to look after a certain number of palms. The muhogo at the same time serves for shading the young trees. This third part of the produce of the soil should cover the purchase of the seedlings and young palms. The *Tropenpflanzer* also has the following about the fibre plantation at Kurasini, Dares-Salaam:—The original plantations consisting of 150 hektars, were bought later on. At first only about 30 labourers were employed as it was an experiment. Work was begun on April 25th, 1895. The first 45 nurseries were laid out in June 1895 and in the beginning of 1896 the first plants were put out. Up to spring 1897, 27 hektar had been planted; on the 26th March 1898 150 hektars were covered. The species cultivated is the Manritius hemp (Furcroya gigantea) the fibre of which is of less value than sisal hemp, but the plant is more easily grown.

The plants were set 9 by 9 ft. apart which gives 111 plants to 1 hektar.

The machine for cleaning has been at work since December 12th, 1898. It gives about 140 lbs. per day. In August the first 45 bales, of 250 lb,, were shipped. A light railway has been constructed, 1½ km. of which are already in use. There are actually 60,000 plants ripe for harvest. It is estimated that from the time of planting plants are ready for harvest in about 3 years time. Each leaf weighs about 2 kgr. At the first cutting each plant had about 70-80 leaves; 1,000 leaves give on an average 40 lb. dry fibre so that one hektar produces about 1,000-1,250 kar. (1-tons; the fibre was 1-1½ m. long and had a nice whit appearance.

A ton of fibre fetched during the last year 400-500 marks in Hamburg. If the whole plantation were laid out at the same time 240 hektars would in three years produce 300 tons of fibre, worth 120,000 marks.

Compared to other products the cultivation of fibre is very simple and cheap. As long as the price does not fall from overproduction my opinion is that the cultivation of fibre is very profitable.

AN INCH OF RAIN.

What does an inch of rain mean? Few person have a definite idea as to what is involved in the term. It may aid those whose opinion on the matter is not as fixed and positive as it might be to follow this calculation: An acre is equal to 6,272,640 square inches. An inch deep of water on this acre will be as many cubic inches of water, which at 231 to the gallon is 27,154 gallons. This immense quantity of water will weigh 228,190 lb. or 114 tons. One-hundredth of an inch (·01) alone is equal to over one ton of water to the acre.—*Queensland Agricultural Journal.*

PRODUCTION OF IPECACUANHA.

One of the most widely used of all vegetable drugs is the powerful emetic ipecacuanha, which is obtained from a Brazilian shrub. The French Consellier de Commerce, at Cuyaba, in the State of Matto Grosso, Brazil, gives in a recent report an interesting account of this plant, which has in that State and the neighbouring districts its only habitat. The drug is obtained from plants which attain a height of from 12 to 16 inches. The leaves are oval, dark green, and sharply ribbed, and the white flowers give place to an ovoid fruit containing black seeds. Besides the *Ipecacuanha Cephoelis*, or the "white ipecacuanha," as it is generally known, there are several other varieties which are somewhat different, but all are used for the same purpose, and are distinguished as brown, black, and striated ipecacuanha. The drug is obtained from the root of the plant, where it occurs in quantities about the size of a quill, between the layers. The taste is acrid and bitter, and the odour is nauseating. That found next to the bark is most active in its effects, having in the highest degree the emetic property, due to the active principle known as 'Emetine." The state of Matto Grosso which as before observed, is the habitat of the plant, is one of the richest in Brazil, among its many natural products being gold and diamonds, rubber, sarsaparilla, jalap, jaborandi, copaiba, various gums and drugs of several kinds. Ipecacuanha is found in the north and north-west of the San Luiz-de-Caceres, formerly in the Villa Maria region, and its habitat covers an immense area comprised between a network of rivers in Brazil, Bolivia, and Paraguay. The dense of foliage of the forests of this region provide the dank and humid conditions which favour the growth of the shrub. The Brazilian product is known as Rio Ipecacuanha, and the product secured from similar shrubs in other countries passes under the name of the port from which it is shipped. Attempts have been made to transplant the shrub and to cultivate it in British colonies in various parts of the world, but without success, and Brazil continues to be the only source of supply for the best grade. The process of gathering the plant is perfectly simple, and during the rainy season, while the ground is soft, is very easy. A stick is inserted under the root, and while this is raised with one hand the entire plant is pulled out with the other. As little care is given to the protection of enough plants to secure a future supply, the output is growing smaller and the price consequently higher each year. The scarcity of workmen is a great difficulty. In the dry season the roots cannot be gathered, and it is at this season when any one adapted to the work is engaged in gathering rubber. During the rainy season, from October to to April, when the plants may be easily drawn from the ground, women are usually employed for the work.—*Journal of the Society of Arts.*

WEEDS ON PATHS.

These may be destroyed without breaking up the paths by treating with hot brine—1 lb. salt to 1 gallon water; or 1 part sulphuric acid to 30 parts water; or 1 oz. carbolic acid to 1 gallon water; or 1 lb. powdered arsenic in 10 gallons water. To dissolve the arsenic, place it in 3 gallons cold water, bring up to boil and keep stirring, then while boiling add 7 gallons water and 2 lb. washing soda.—*Queensland Agricultural Journal.*

GOOD MANURES.

For Potatoes.—3 cwt. superphosphate, 2 cwt. kainit, and 1 cwt. sulpbate of ammonia. Mix before planting.

For Cabbages and Cauliflowers.—3 cwt. bonedust, 1 ewt. sulphate of potash per acre, followed by a top dressing, after the plants have recovered from transplanting and commeneed to grow, of 1½ ewt. of sulphate of ammonia, mixed with soil and sprinkled round the plants.—*Queensland Agricultural Journal.*

COFFEE SHADE TREES.

[SPECIALLY TRANSLATED FOR "INDIAN GARDENING."]

M. PIERRE, late Director of the Jardin d'essai of Saigon, in reply to a request of the Editor of the *Revue des Cultures Coloniales*, treats in the January number of that Journal, of the Kapok tree utilised in Java as a shade tree for coffee. He states that there are two trees known in Malaya as the "Kapok ootan" and the "Kapok." *Kapok ootan.*—Bombax ceiba L.; Bombax malabaricum D. C., Salmalia malabarica Sch. et. Endl. This is a tree of 60 to 90 feet, which attains a considerable diameter, 18 to 36 inches. It secretes a gum known in India under the name of *Muchi*. With age the trunk becomes hollow. Its wood is white with loose fibres, not durable, very light, and has but small value relatively to its employment in the manufacture of buoys, boxes and toys. The endocarp of its fruit is covered inside with a silky gloss of short fibres of which the only use is to stuff certain articles of furniture, cushions, pillows, mattresses, etc. Perhaps it might be used in hat making. It is certain that no one has yet succeeded in spinning the fibre.

The fact that it loses its leaves in the dry season contests its utility as a protective tree in coffee plantations. However, it might be found of advantage when a rapid result is desired, because its branches have the property of striking root at all times in soil the least favourable.

Kapok.—Ceiba pentandra (L) Gærtn; Eriodendron anfractuosum, D. C. Bombax pentandrum L. This is the "silk-cotton tree" of the English and the "ouatier" of the French colonies. All the properties of the *Bombax ceiba* are those of the *Ceiba pentandra*, and in order to be complete it may be said that oil in small quantities may be extracted from the seeds of the two species."

It appears then (continues M. Pierre). that the only advantage of these trees in a coffee plantation is to take root quickly from cuttings; thus quick-set hedges in Indo-China and elsewhere are made rapidly, completely and very economically by setting the best developed branches particularly those of *Ceiba pentandra*. Their produce in wood, silk, resinous gum and the oil from their seeds, does not appear to me of sufficient importance to take into account.

To shade a coffee plantation with trees losing their foliage in the dry season seems to me of an utility little demonstrable, if it is remembered that it is positively in that season that the effects of reverberation make themselves felt.

That is a personal opinion which may be contested. Nevertheless, it is permitted to me to think that it would be more practical to make trial with other growths, even though their foliage should offer the same drawback with those of the Kapok; and in that way I make allusion to rubber plants such as Hevea, Manihot, etc.; necessarily many other useful plants might combine with the cultivation of coffee. Their number is considerable: first, at the commencement of a coffee plantation, bananas, above all the Musa textilis, would reduce in a large measure the expenses of planting, all in fulfilling the role of protection from or straining the sunlight, claimed for the Kapok. The Bread-fruit tree, the Jak, the Garcinias productive of gamboge, the Ochowa Gabonii, so rich in sebaceous matter and in the same order, the Pentadesma butyracea and leptonema, the Allanblackia Klainii, Sailenxii and Stuhlmanii, the Poga and Paud oleosa, the Ongokea Gore, the Vitellaria paradoxa (which is always wrongly called the Butyrospermum Parkii), etc.—*Indian Gardening.*

THE CABLE LAID FROM PARA up the Amazon was quickly destroyed by the driftwood of the mighty river, and a landline is now in course of construction. About 180 miles of it are completed, notwithstanding the expense and difficulty of cutting a way through the tropical forests.—*Globe, June 1.*

TEA IN JAPAN.

Mr. A. H. Lay, the British Assistant-Consul at Tokio, in his report on the trade of Japan, gives some interesting information in regard to tea industry in that country. The quantity of tea exported from Japan during 1899, he says, exceeded that shipped abroad during 1898; but all the same the tea business in Japan is becoming more and more unsatisfactory each year, and, for the foreign merchant at any rate, there is little or nothing to be made out of it. In quality the tea of 1899 compared unfavourably with the crop of 1898. The practice of picking the young leaves in the early spring before they are properly matured, for the sake of obtaining exorbitant prices for small quantities, is undoubtedly having a very injurious effect on the plants, and it is surprising that Japanese tea growers do not realise this fact. But it is not only from the effects of the injudicious system of picking that the Japanese tea industry is suffering. The trade with Canada, Mr. Lady points out, is appreciably affected by the competition of the Ceylon and India growers, who, by extensive advertising and other methods, are bringing their produce prominently before the public. The Japanese on the other hand, are making no efforts whatever to advance the sale of their teas, and as Ceylon green teas are now making their appearance in Canada, where their sale will be vigorously pushed, the future of Japanese tea in that market cannot be regarded as bright.—*Financial Times*, May 31.

CEYLON TEA COMPANY.

The Directors submit the Ninth Annual Report for the year ending 31st March, 1900

The considerable sum standing to debit of Profit and Loss Account, including also the amount irrecoverable owing to the failure of the New Oriental Bank Corporation, Limited, has now been reduced to R550·31 only, so that from next year a dividend is likely to become payable.

The position of the Company is sound, while the important work of pushing and advertising pure Ceylon Tea at the Tea Kiosk in Colombo and throughout the world has been maintained. The quality of the Tea supplied in the dry state and the excellence of the Tea in cup as served to Visitors at the Kiosk have been subject of favourable remark during the year.

As usual a memo of places to which Tea has been sent during 1899-1900 is appended. It includes:—

Australia, Austria, America, Burma, Belgium, Canada, China, Denmark, Egypt, France, Germany, India, Italy Madagascar, New Zealand, Nova Scotia, Norway, Syria, Sumatra, Straits Settlements, Great Britain and Ireland.

THE
AGRICULTURAL MAGAZINE,
COLOMBO.

Added as a Supplement Monthly to the "TROPICAL AGRICULTURIST."

The following pages include the Contents of the *Agricultural Magazine* for July :—

Vol. XII.] JULY, 1900. [No. 1.

THE AGRICULTURAL COMMISSION AND THE IMPROVEMENT OF NATIVE AGRICULTURE.

THE Report of the Commission appointed to report on the advisability of a Department of Agriculture being established for Ceylon has at last been made public, and it would appear from reviews of it published in the Press, that the general opinion with regard to the document is to the effect that it affords exceedingly interesting reading, containing as it does the views of high Government officials as well as of private gentlemen of standing, but that it has failed to enunciate a practical scheme for dealing with the native agriculture of the country.

In this connection we might refer to another scheme which we understand has been forwarded to Government—the author of which is Mr. E. Elliott, late Government Agent of the Southern Province, who since his retirement has been working as a private agriculturist; and so, having experience (and that varied and extensive) of native agriculture both as an official and an unofficial, is eminently qualified to advise on a question of this nature. We understand that Mr. Elliott deprecates the merging of the interests of what is known as European agriculture with those of Native agriculture, as there is so little in common between the two. Besides, the latter has its own powerful machinery in the Planters Association of Ceylon to protect its own interests, while the Government of the Colony has liberally provided help in the appointment of a number of expert scientists to further protect those interests. Mr. Elliott's scheme provides for a re-orgainsed Central School, of Agriculture, which already exists, and a Central Experimental Farm not far from Colombo, with branch experimental gardens all over the country. His whole scheme is calculated to directly reach the village cultivator, and to this end he recommends that the men to be trained at the Central School should be drawn from the cultivating classes, that the teaching should be in the vernacular, and that the curiculum should be so revised as to entirely serve the requirements of the classes to be reached. The scheme further advises the retention of the mechanism for controlling and working this sub-department of agriculture in the department of Public Instruction, which is already so closely in touch with the village population through its extensive system of vernacular education. We cannot do more than generally indicate the outlines of this excellent scheme, which novel and original though it is, appears to us to be better calculated to effect the object which the Government has so long striven, but unsuccessfully, to attain,

OCCASIONAL NOTES.

The following analysis of Plantain Flour made in Ceylon should prove of interest :—

Moisture	11·74	%
Mineral ash	2·28	,,
Glucose	1·02	,,
Crystallizable Sugar ...	·20	,,
Total saccharifiable matter expressed as Glucose	81·96	,,
,, Starch ...	73·76	,,

It is said that the small percentage of sugar should make Plantain Flour a suitable diet for diabetics, and that a food substance entirely free from sugar ought to bring a fortune to the producer. The absurdly low price asked for the Flour (70 to 75 shillings per ton c. i. f.) will, however, prevent anyone from embarking on the Plantain Flour industry.

We note that Sir W. W. Mitchell, writing from Paris, refers to the caju-nut as a possible article of export, as the samples sent to the Ceylon Court have been favourably reported on, while almonds (for which the nuts are a good substitute) are not so plentiful in the market as they used to be. We understand, however, from a correspondent in Paris, that to sell well, caju-nuts must be priced at much less than 12 cents a hundred, as ground nuts from India are so much cheaper. Here, again, the price put upon the article is far too low to encourage the cultivation of the tree (*Anacardium occidentale*) which produces the nut, unless some use could be found for the so-called fruit (swollen peduncle) in the manufacture of spirit, as we believe was once suggested and even tried in Ceylon. The local value of a hundred good caju-nuts varies, according to the season, from 10 to 25 cents, so that there would seem to be a poor chance of making money by selling for less than 12 cents per 100.

We would draw attention to the directions for the prevention of rinderpest issued by the acting Government Veterinary Surgeon, Mr. E. T. Hoole.

Mr. Christian Fernando, a late student of the School of Agriculture and Forestry School, as well as a late member of the Forest Department of Ceylon, left the Island on the 24th June by the S.S. "Secundra" for Natal, whither he has proceeded with a view to finding employment. Mr. Fernando had a creditable career in both the above-named institutions, and with his intelligence and energy should find no difficulty in finding some suitable work to do in South Africa.

A sale of cattle, principally young calves, was held at the Government Dairy on the 8th June, twelve weaned calves together with a cow and calf at foot fetching Rs. 499·33.

The following is the latest analysis of a sample of dairy milk made by the City Analyst on the 6th June:—

Sp. Gravity ... at 84° F.		1·030
Fat		4·12
Casein and Sugar ...		8·31
Ash (suets) ...		·72
Total solids... ...		13·15
Water		86·85
Solids not fat ...		9·03

PRACTICAL HINTS TO HORSE-OWNERS.

By A. CHINNIAH, C.B.V.C.

CHAPTER II. (*contd.*)—FOOD AND FEEDING.

Horse gram or kollu (*Dolichos biflorus*) is the common horse food in the Madras Presidency. Prof. Church gives the nutrient ratio of kollu as 1: 2·7 and the nutrient co-efficient as 83. The ash contains nearly $\frac{1}{3}$ of its weight of phosphoric acid. Kollu seeds, owing to their hardness, are not digested properly when given whole or even crushed. If soaked and given kollu brings on colic, so that it has to be boiled before feeding, and this, of course, is rather an objection, as a great amount of heat is necessary for boiling and the cost of fuel is a consideration. Another drawback is that pebbles are generally found mixed with kollu, and these cannot be easily separated owing to the grain being as heavy as the pebbles. Long continued use of kollu is regarded as objectionable. It is said to cause œdematous swellings which are to be attributed to its highly-nitrogenous character, for œdema may be caused by want of nutrition as well as by over-nutrition.

Black gram or ulundu (*Phaseolus mungo var. radiatus*) is as nutritious as Bengal gram. According to Prof. Church one hundred parts of the unhusked grain contain: water, 10·1; albumenoids, 22·7; starch, 55·8; oil 2·2; fibre, 4·8; and ash 4·4 (of which 1·1 consists of phosphoric acid). It is considered a very 'cooling' diet, and this may be ascribed to its mucilagenous character. Ulundu has to be boiled before it is given to horses.

Green gram or mung (*Phaseolus mungo*) differs little from the last, which is only a variety of it. One hundred parts (according to Church) contain: water, 10·8 to 11·4; albumenoids 22·2 to 23·8; starch, 56·1 to 54·8; oil, 2·7 to 2·0; fibre, 5·8 to 4·2; ash, 4·4 to 3·8. The former figures are for typical green-seeded mung, the latter for typical yellow-seeded. In unhusked

beans the fibre is reduced to 1·1 per cent, all other constituents being proportionately increased. Green gram has also to be given after boiling.

Having considered the chief leguminous horse foods of the East, viz., Bengal gram, horse gram, black gram and green gram, I will now go on to refer to the chief cereal food. Paddy (*Oryza sativa*) which is the staple food of the people in the form of rice or husked paddy, is also largely used for horses—in the unhusked state, mixed with gram. Though some have a prejudice against the use of paddy as a horse food, it forms a good enough diet when given mixed with gram. Paddy is rich in starch but very poor in nitrogenous constituents and fat.

Though rice is the staple food of the people in the East, it is invariably eaten with either meat, ghee, dhall, or some preparation containing coconut milk, for it was found by experience, long before the chemist settled the fact by analysis, that it was wanting in nutritive properties owing to the absence of nitrogenous constituents and fat, so that flesh-forming and fatty substances had to be added to make it a suitable diet. The same necessity has given rise to the use of gram with paddy as a horse food. Doubtless the husk of paddy has like bran a mechanical stimulating effect on the intestines. To counteract this, paddy has to be first ground separately. But even a mixed diet of paddy and gram contains a small proportion of fat, and I am inclined to think that we shall be taught by experience to add a third ingredient to make up the deficiency in fat, say some form of oil-cake.

SOME BIBLE PLANTS OF CEYLON.

II. Cinnamon.

This plant common enough in Ceylon is the *Cinnamomum Zeylanicum* of botanists. In the Old Testament cinnamon is referred to in more than one place as Kinnamon.

It would be useless to describe the plant or the method by which the cinnamon of commerce is prepared from the bark, as both are too well-known even out of Ceylon. It is not generally known, however, that in addition to the oil of cinnamon which is distilled from both bark and leaves, (though the latter is infinitely superior and therefore considerably more expensive than the latter), a fat can also be extracted by boiling the macerated fruit. This substance has been called "cinnamon suet," and was used by the Portuguese to make scented candles for use in their churches. These candles are, however, not manufactured in the Island in the present day, and when samples of cinnamon suet were required by the late Dr. Trimen for the Imperial Institute collection, they had to be specially made by Mr. J. F. Drieberg, cinnamon planter of Jaela, Ekele. Cinnamon has in the past always been highly valued as a spice and a perfume, and is said to have been one of the principal spices employed in the manufacture of precious ointment for the tabernacle (Exodus xxx. 22-25). Solomon speaks of it as one of the frankincense plants: "Calamus, cinnamon, with all trees of frankincense (Songs of Solomon iv. 14). Its use as a perfume is referred to in Proverbs vii. 17: "I have, perfumed my bed with myrrh, aloes, and cinnamon." The merchandise of it is noticed in an account of the destruction of the Apocalyptic Babylon: "Cinnamon, and odours, and ointments, and frankincense (Revelations xviii. 3).

Besides the true cinnamon should be noted another species known as Cassia, and mentioned in the Bible under the names of Kiddah. It was an ingredient of the holy ointment already referred to, and is referred to by Ezekiel among the merchandise of Tyre (Ezekiel xxvii. 19). This plant is understood to be *Cinnamomum Cassia*, the bark of which is generally known as Cassia bark. It is thought to be inferior to true cinnamon, being coarser and more pungent, with a certain amount of bitterness. The leaves when chewed taste of cinnamon, but those of the true cinnamon plants have more the flavour of Cloves. Cassia oil and Cassia buds appear to be produced by the same tree, which grows both in India and China.

THE TRINIDAD STOCK FARM.

The report of the Manager of the Trinidad Government Farm for 1899, which has been kindly sent to us, speaks of the year having proved an exceptionally trying one for the management of a large herd on a limited area of land, aggravated by the drying up of the pastures and the prevalence of hot winds. As a result the yield of milk was lower and the cost of upkeep of the animals higher. The milch herd consists of 100 animals: 114,737 quarts of milch were produced as against 130,977 quarts last year, that is, 16,140 quarts less from about the same number of cows, 52. The following breeds are kept on the Farm:—Pure zebu, Sinhalese, Red Poll cross and Guernsey cross, besides what is described as the general milch herd. The particular breed of Indian cattle referred to as Zebu (a general term for the humped cattle of India) is not mentioned. The following reference is made to the Sinhalese cattle which were taken over from Ceylon some time ago:—

"A small herd of Sinhalese cattle were introduced from Ceylon. These miniature animals would be of excellent service on cocoa estates, as they could pass freely under the trees when crooking. They are very strong, quick and hardy; for cane farmers they could take the place of mules, do the same work, and cost a third less, in fact, prove the poor man's beast. There has been no increase as yet in the herd."

With the high opinion entertained of the utility of Sinhalese cattle, it would, we think, be as well to introduce at least another pair into Trinidad with a view to increasing the stock. (In this connection we might add that the latest demand for Sinhalese cattle came from Austria for the Emperor's Zoological Gardens. The animals were selected for the local agents by Veterinary Surgeon Chinniah.)

The profit during the year's working of the Trinidad Farm is given as 5·6 per cent on the capital outlay. We should mention that besides the dairy a horse-breeding and poultry farm is also maintained.

The following table giving the analysis of the morning and evening milk produced on the farm is worthy of note for purposes of comparison, and as showing how the composition and specific gravity of milk varies in different seasons:—

	MORNING.			EVENING.		
	Fat.	Solids—not Fat.	S.G.	Fat.	Solids—not Fat.	S.G.
February	4·25	8·97	1028	4·23	8·51	1027
March	3·57	8·74	1028	4·66	8·91	1027
April	3·16	8·97	1030	4·64	8·75	1026

November	3·91	9·33	1029	4·22	9·52	1029
December	3·65	9·40	1029	4·93	9·33	1026

THE DYEING OF MATERIALS USED FOR KALUTARA BASKET MAKING.

The following communication addressed by the Secretary of the local Paris Exhibition Committee to the representative of the Ceylon Government at Paris is worth reproducing as dealing with the development of an industry, the products of which are becoming very popular. The Assistant Government Agent of Kalutara and Mrs. Vigors are deserving of the gratitude of the basket-makers of Kalutara for the interest they are taking in the improvement of the industry associated with their district:—

"I am instructed by the Chairman of the local Paris Exhibition Committee to forward a bundle of dried leaves of the wild date (*Phœnix zeylanica*) used for basket-making in the Kalutara district, and to ask you to be good enough to make enquiries as to the possibility of fixing permanent colours in such material. I would refer to the many artistic shades used in dyeing straw for hats and bonnets in Europe, and how little, if at all, the colour is affected by light, whereas the imported dyes now used in dyeing the material for local baskets and mats fade rapidly. In the correspondence with reference to the use of dyes carried on by the Assistant Government Agent, Kalutara, with his headmen, it is stated that though imported dyes (as sold in the village bazaars) produce more brilliant colours, these colours are not so durable as those produced by native methods of dyeing. From enquiries made the following appear to be the indigenous dye stuffs used by the natives for dyeing the materials for making baskets, mats, and hats.

1. Pathangi, from the wood of *Cæsalpinia sapan* (red).

2. Marithondi, from the fruits of *Lawsonia alba* (orange yellow).

3. Welikaha from the leaves of *Memecylon capitellatum* (yellow).

A black colour is induced by first dyeing red with No. 1, then burying the dyed material in mud for a period, next steeping it in a mixture of water and the ash of burnt plantain leaves (*Musa sapientum*), and finally washing and dyeing! I enclose specimens of the leaves dyed according to the native method as well as by means of the imported dyes referred to. The people are taking to the latter owing to the simpler treatment they involve, as compared with the comparatively laborious native processes. It is surmised by the Assistant Government Agent of Kalutara that the imported bazaar dyes now used are of an inferior description, and that it would be possible to introduce into the colony superior dyes such as are used for colouring straws in Europe. As the basket industry of the Kalutara district is one of some importance, the Chairman will be glad to hear from you with reference to the desired improvement in the matter of dyeing the material used."

PREVENTION OF RINDERPEST.

Rules to be observed when the Disease has broken out in or near the District.

The following directions for the prevention and suppression of rinderpest are specially drawn up for the benefit of owners of large cattle establishments on estates:—

1. The method for the prevention of rinderpest can be summed up in the words "Keep out all sources of infection and contagion."

2. Cart bulls might bring the contagion with them and introduce the disease. They should therefore be housed separately, and as far away as possible from the dairy and other cattle on the estate.

3. Carters are careless about the safety of their masters' cattle, and they often house the cart bulls in infected galas on the way regardless of consequences. Every effort should be made to prevent this by putting up extra temporary galas for healthy cattle and exercising strict supervision and control in the matter. Infected galas should be closed for healthy cattle and notices put up to the effect.

4. If cart bulls have of necessity to frequent infected localities, it would be advisable to have them inoculated with glycerinated bile and keep them strictly isolated and under observation for ten days, after which period they may be used in carts.

5. Inoculated cattle and those that have previously recovered from an attack of rinderpest, although they may be proof to the disease themselves, may yet convey it to other cattle on their return from an infected area. So they should be housed separately on their return.

6. Men, dogs, crows—in fact, anything that has been in contact with rinderpest cattle, their discharges or excreta—should be considered sources of infection. The carting of manure from an infected locality to the estate should also be avoided.

7. Ten to fifteen drops of Jeyes' fluid may be given daily to healthy cattle with poonac water or conjee as an aid to prevention. After giving it for three or four days the Jeyes' fluid should be discontinued for a couple of days and then

given again for another four days, and so on. A due allowance of salt should be given to all the cattle and their bowels kept in good order.

8. If rinderpest breaks out on the estate, an attempt should at once be made to stamp it out by immediately destroying the first one or two cases and thoroughly disinfecting the place. As fever is one of the earliest symptoms, the temperature of the remaining cattle should be taken every day, and any showing a temperature of over 103° F. should be removed and isolated at once, before they spread the infection to their neighbours. All the cattle on the estate may now be inoculated.

9. If the disease threatens to spread further, of if the outbreak on the estate has somewhat advanced, the inoculation of all the cattle becomes a positive necessity. But it would not be necessary to have *all* the cattle (including dairy cattle, stud bulls, &c.) inoculated unless there is rinderpest on the estate itself or in its immediate vicinity.

10. Inoculation will be done by the officers of the Government Veterinary Department gratis or at a very moderate expense to the owners, when application is made in case of actual necessity.

11. Rinderpest carcases should be buried six feet deep, and as far away as possible from human habitation, public roads, water-courses, cattle sheds, and grazing grounds. Carcases should not be dragged along the ground, but should be lifted up by coolies suspended on strong sticks. The quartering of carcases before burial should not be allowed, as well as the consumption of rinderpest meat by coolies. These are sure means of spreading the disease.

12. Disinfectants (such as a one or two per cent. solution of carbolic acid or Jeyes' fluid) should be freely used when rinderpest is prevalent, and anything known or suspected to be infected (including coolies who have buried the carcases) should be thoroughly disinfected. The fumes of burning sulphur are very useful for disinfecting the air of cattle sheds, &c. Fire is one of the best and cheapest disinfectants, and any infected matter that can be burned or even charred, such as litter, should be so treated.

E. T. HOOLE,
Acting Govt. Veteriuary Surgeon.

A REPORT ON EDIBLE OILS.

One of the latest numbers of the *Agricultural Ledger Series* treats of Indian Edible Oils, and contains a report by Prof. Dunstane, F.R.S., Director of the Scientific Department of the Imperial Institute.

Prof. Duustane prefaces his report with the following remarks :—Among the subjects awaiting investigation by the Scientific Department at the begiuning of the present year was that of Indian Edible Oils, samples of which have been collected in India during the last two years under the supervision of the Reporter on Economic Products to the Government of India and despatched by him to the Imperial Institute. As the subject is an important one, and the entire staff of the Department was, and is now, occupied with other investigations, most of them on Indian subjects, I decided to arrange for these oils to be examined in my laboratory at St. Thomas' Hospital by two young assistants specially competent to engage in such work, Dr. H. W. Crossley, M.Sc. Ph.D., and Mr. H. R. LeSueur, B.Sc. The Government Grant Committee of the Royal Society were good enough to make a small grant from the Government Fund for Scientific Research to defray the expenses connected with these experiments.

The plan of investigation which seemed to me likely to be serviceable was to examine in the first instance the chief physical and chemical characters of each oil, so as to furnish a basis for their comparison with well-known and largely-used edible oils, and thus to render it possible to obtain a report on the commercial value of the Indian samples. After this preliminary survey of the entire collection it might prove to be worth while to examine more minutely the chemistry of those oils which appeared to present features of novelty. The preliminary examination of the oils has now been completed by Messrs. Crossley and LeSueur, who will present an account of their results to the Society of Chemical Industry, which will subsequently be printed in the journal of the Society. By this means it is hoped that the attention of oil brokers and merchants will be directed to the variety of excellent oils belonging to almost every class which are obtainable in India, and that the experimental data will enable us to obtain a trustworthy opinion as to commercial uses and value. I ought to say that when the oils were first received, I made several attempts to ascertain their market value but entirely without success, as no scientific data existed as to their composition and quality.

Then follows a list of the oils which were examined.

The reference to coconut oil is naturally of primary interest to us. The samples were drawn from Malabar, Bengal and Bombay, and the following results of the examination of the chemical and physical characters were noted in the three samples :—

	Malabar.	Bengal.	Bombay
Specific gravity	·9030	·9040	·9042
Acid value as K.O.H	35·21	11·84	9·95
„ as Oleic acid	8·86	2·98	2·50
Saponification value	25·82	255·6	255·5
Iodine value	8·54	8·41	8·25
Reichert-Meissel value	6·71	6·79	6·65
Insoluble fatty acids	—	82·35	—
Melting point	23·5	24·5	25·0

The percentage yield of oil from Bengal and Bombay are given as 52·3 and 57·1. The constants, says Prof. Dunstance, of these Iudian species agree with those on record for this oil, except the Reichert-Meissel value which is markedly higher,

The following reference to the composition and properties of coconut oil (and Ceylon coconut oil in particular) occur in Cochran's Manual of Chemical Analysis :—

The soap made from it is soluble to a larger extent in saline and alkaline water than most other kinds of soap, hence it is used for the manufac-

ture of marine soaps. It does not make a good lubricant as it contains free acids. In addition to the other uses enumerated, it has been in considerable quantities in recent years for the manufacture of a butter substitute, known in commerce as coconut butter. [A sample of coconut butter can be seen at our office. The latest developement in connection with coconut produce, is the manufacture of a substance—entirely by mechanical means—from the fresh coconut, and known as "Edible coconut oil." A correspondent from the Paris Exhibition mentions that Mr. G. G. Warr (who was for some time in Ceylon) is expected there with sample packets of the "edible oil" for distribution to the trade, with the help of Sir W. W. Mitchell of the Ceylon Court.—ED. *A.M.*]

Coconut oil has a very complex constitution. The following fatty acids have been found in it:—Lauric acid, C_{12} H_{24} O_2; Myristic acid, C_{14} H_{28} O_2; acids having the composition C_{11} H_{22} O_2; and C_{12} H_{26} O; also Palmatic acid, C_{16} H_{32} O_2; and stearic acid, C_{18} H_{36} O_2.

When coconut oil has solidified, which it does at the comparatively high temperature of 78° F., it can be readily separated by pressure into a solid body, stearine, and a liquid called oleine. The former substance is used in the manufacture of candles, the latter, after being purified with sulphuric acid, is used as a burning oil.

A sample of ordinary coconut oil from the bazaar had a specific gravity ·9207 at 85° F. (29·4° C.) A sample of Hultsdorf pure king coconut oil at the same temperature had a specific gravity of ·9186. The specific gravity of coconut oil given by European writers is for the temperature 212°F. (100° C.) ·868.

CLASSIFICATION OF FIBRES.

[DR. DODGE.]

D. BRUSH FIBRES.

1. *Brushes manufactured from prepared Fibre.*

a. For soft brushes (substitutes for animal bristles, such as Tampico).

b. For hard brushes (ex. palmetto, palmyra, kitul, &c.)

2. Brooms and Whisks.

a. Grass-like fibres (broom root, broom corn, &c.)

b. Bass fibres, also for coarse brushes and sweepers (monkey bass, piassaba, &c.).

3. Very Coarse Brushes and Brooms.

Materials used in street sweeping, &c. Usually twigs and splints.

E. PLAITING AND ROUGH WEAVING FIBRES.

1. Used in articles for attire as Hats, Sandals, &c.

a. Straw plaits. From wheat, rye, barley, and rice straw (ex. the commercial Tuscan and Japanese braids).

b. Plaits from split leaves, chiefly palms and allied forms of vegetation. (Ex. the celebrated Panama hats, from the finely-divided leaves of *Carludovica palmata*).

c. Plaits from various materials used entire and without preparation. (Ex. basts and thin woods used in millinery trimmings, &c. Chinese sandals from rushes).

2. Mats and Matting; also Thatch Materials.

a. The commercial mattings from eastern countries.

b. Sleeping mats and other forms of mats or matting. Screens, &c., made by natives for their own use.

c. Thatch or other covering or protection from the elements, made of tree basts, palm leaves, grasses, &c.

3. Basketry.

a. Manufactures from woody fibre. (Commercial examples: Osier and splint baskets; the same forms produced by Indians and including also manufactures from sumac and other twigs, roots of spruce, &c.)

b. From the whole or split leaves or stems of endogens, or from any rigid fibrous material, including also the culms of grasses. (Chiefly Indian or native manufactures from Yucca leaves, palm leaves, reeds, grasses, &c., used individually or in combinations).

4. Miscellaneous Manufactures.

Willow ware in various forms, chair bottoms from splints, rushes, &c.

F. STUFFING OR UPHOLSTERY.

a. Wadding, batting, &c., usually, commercially prepared lint cotton.

b. Feather substitutes. For filling cushions, pillows, &c., cotton; seed hairs or silk cotton, such as kapok, Asclepias down, &c.; tomentum from the surface of leaves, stems and leaf buds of plants; other similar soft fibrous material.

c. Mattress and furniture filling. The tow or waste of prepared fibre, unprepared bast; straw and grasses; substitutes for curled hair, as Spanish moss, crin végétal, maize husks, &c.

2. Caulking.

a. Filling the seams in vessels, &c., oakum from various fibres.

b. Filling the seams in casks, barrels, &c., leaves of reeds and giant grasses.

3. Stiffening.

In the manufacture of "staff" for building purposes, and as substitutes for cow's hair in plaster. New Zealand flax; palmetto fibre.

4. Packing.

a. In bulk heads, &c. (as in armoured vessels). Ex. coir, cellulose of corn pith, &c. In machinery, as the valves of steam engines, various soft fibres.

b. For protection, usually in transportation; various fibres and soft grasses; marine weeds, excelsior; also stuffing and upholstery materials generally.

G. PAPER MATERIALS.

1. Textile Papers.

a. The spinning fibres in the raw state. The secondary qualities, or the waste, from spinning mills, which may be used for paper stock, including tow, jute butts, Manilla rope, &c.

b. Cotton or flax fibre that has already been spun and woven, but which as rags find use as a paper material.

2 Bast Papers.

This includes Japanese papers from soft basts, such as the paper mulberry (Broussonetia) or species of the genus Edgeworthia.

3. Palm Papers.

From the fibrous material of palms and similar monocotyledonous plants. Ex. Palmetto and Yucca papers.

4. Bamboo and Grass Papers.

This includes all paper material from graminaceous plants, including the bamboos, esparto, maize, and true grasses.

5. Woodpulp and Cellulose.

The wood of spruce, poplar and similar "paper-pulp" woods, prepared by various chemical and mechanical processes.

It should be noted that an absolute economic classification of uses with relation to species is impossible, as the same fibre may be used in several ways. Manilla hemp is manufactured into rope, and old Manilla rope into Manilla paper. Cotton is used for fabrics, as a netting fibre, for cordage, in upholstery, and in paper. In fact there are very few fibres which are not made into paper, the amount of cellulose they contain and the cost of the processes by which they are converted being the main considerations. The same plant may also yield two kinds of fibres, as lint cotton covering the seed, and cotton bast, stripped from the stalk.

[*Conclusion.*]

CEYLON CATTLE AS DAIRY STOCK.

No one will deny that the native cattle of Ceylon have hopelessly degenerated especially as milking stock if indeed they even excelled as such.

A cow may be said to be a milk-making machine, and every cow can be made to yield a quantity of milk commensurate with the care and feeding bestowed on her. There are different organs in the body, and their development depends greatly on the attention paid to them. So if attention is paid to the milk-secreting organ of the cow, within the course of a few generations, Ceylon cattle may also be made to supply fairly good dairy stock. I remember a lady upcountry remarking that English and Australian calves very soon take to hand feeding, and that it takes a long time to teach the country calf to feed in this way. The only reason which I could assign on being questioned as to the cause, was that the difficulty was due to hereditary defect, and any improvement or change must not be looked forward to till the next generation, and that, too, provided the greatest attention be given to the improvement of the habit complained of. The villagers do not realize the essential conditions required for producing milk cattle. I will try to explain some of these :—

1. *Feeding.*—The milk producing animal requires highly albuminous and fatty foods, that is to say, it needs foods which supply the ingredients required to produce milk, after having supplied all bodily wants. Such food as native cattle pick up generally only suffices to maintain animal heat, and to some extent to repair the wear and tear of the tissues, and leaves no balance for laying on fat or for producing milk.

2. *Temperament.*—Native cattle are more or less wild animals. The reason of this is that they are not properly fed and tended; they are, on the other hand, roughly handled by man and allowed to roam about in search for food exposed to all sorts of risks, and are frequently disturbed and frightened by other beasts. Hence they grow timid. Such spare energy as they possess is expended in unnecessary excitement and exercise.

The cow has first got to be made docile before we can expect to make a milking animal of her. The promiscuous mixing of heifers, cows in milk and in calf, young stock and bull of all ages, is most reprehensible, and such a state of things makes the possibility of breeding out good milch cows an utter impossibility. First and foremost, there should be a selection of bulls made, all weedy males being castrated. Next the herd should as far as possible be divided into different lots when at grass, one lot consisting of cows in milk, another of cows in calf, &c. It is only in this way that a beginning could be made of making the future native milch cow a docile creature, for an excitable animal will never settle down to milk secretion. A. CHINNIAH.

THE POONA DAIRY.

(*From the last Report.*)

The profit for the year was R2,470. There were 194 animals in the herd at the end of the year as compared with 187 at the beginning. Fifty animals, chiefly young he-buffaloes and old cows, were sold. The herd was healthy throughout the year, and the present strength is about the full limit that can be conveniently maintained. In the cattle-breeding and dairy operations certain definite aims are kept in view :—

(i.) To breed up to a higher standard certain of the breeds of India as regards their milking capacity, and to maintain, or, if possible, improve the usefulness of the same breeds for draft purposes.

(ii.) To supply pure milk and other dairy products to the sick in hospital, and, as far as possible, to the public in Poona at rates which are kept so high that our operations do not interfere with private enterprise.

(iii.) To shew by precept and example the advantages of cleanliness and improved methods and appliances in dairy management, and the necessity of careful management and feeding for dairy cattle.

(iv.) To teach dairy methods, the manipulation of dairy machinery and cattle management to those who attend at the farm for the purpose of being taught. Mere onlookers are not admitted to these privileges. Men who come to learn must also work.

It may be definitely said that progress in all the directions indicated above has been made from year to year, and there has been no backsliding in the year under report.

Young cows bred on the farm are proving themselves excellent milkers. The sales of milk and butter could be greatly increased, but with present facilities any increase is impossible. A number of soldiers were sent for instruction in order to be able to manage dairies and milk cattle in other cantonments. The department can take credit for initiating in India an enterprise which has had a material influence on agricultural prosperity on the improvement of of Indian butter, and its export trade.

The services of farm bulls are given gratis to all healthy cows.

AN AGRICULTURAL DEPARTMENT FOR CEYLON.

REPORT OF COMMISSIONERS.*

In obedience to the Commission to us directed, we have inquired into the advisability of establishing a Department of Agriculture.

We advise the establishment of such a Department, and we recommend the appointment of a Director of Agriculture.

The officer selected for this appointment should have local experience and knowledge of local conditions and acquaintance with the people. His office should rank in the First Class, and he should be a Member of the Executive and Legislative Councils.

The duty of the Director would be to advise the Government in matters concerning the improvement of agriculture and the extension of cultivation. It would be within the scope of his labours to direct inquiries into the suitability of soils for certain products; to cause inquiries to be made as to the origin and causes of diseases affecting useful plants, and as to the best means of arresting and destroying such diseases; to cause measures to be adopted for the improvement of the various descriptions of produce now cultivated, either by the introduction of new seed or by the application of special manures or otherwise; to take measures for the establishment of Schools of Agriculture; and to suggest action for the improvement of native cattle and horses.

He should be assisted by an Advisory Board, of which he should be President, analogous in its constitution to the Central Board of Irrigation. Boards similar to the Provincial Irrigation Boards, and having the same relation to the Central Board, should be established at the provincial centres. The establishment of these Boards would enlist local influence and local headmen in the work of the Department.

There should be attached to the Department of Agriculture the Director of the Botanic Gardens, a Mycologist, Agricultural Chemist, Entomologist and Veterinary Surgeon.

The intimate connection between Agriculture and Irrigation renders it, in the opinion of a majority of the Commission, advisable that the Irrigation Department should be combined with the Department of Agriculture.

It has been suggested that the Departments of the Conservator of Forests and of the Director of the Botanic Gardens, and the future Department of Mines (including the Geological Survey), should be combined with the Department of Agriculture, in so far that the business of these Departments with the Government should go through the Director of Agriculture, who would be adviser of the Government in relation to the affairs of these Departments, and relieve the Governor and the Colonial Secretary of minor administrative details relating to them: but the majority of the Commission doubt the expediency of giving effect to this suggestion.

To the Department of Agriculture would be assigned the preparation of statistical information relating to agriculture and the areas of cultivation.

The immediate expenditure necessary to carry out the suggestions of the Commission would include the salaries of the Director and of his expert advisers and the funds required for the payment of the clerical establishment. A lump sum should also be provided to enable the Director to give immediate effect to approved proposals for the improvement of agriculture.

As the Department extends its operations and gives evidence of its usefulness further expenditure will be required; and the Commission desires to record its opinion that it will be futile to adopt its suggestions as to the establishment of a Department without recognition on the part of Government of its duty to provide the funds to give effect to its proposals. Its initial work must be largely experimental, and its expenditure cannot be justly submitted to the test of its pecuniary productiveness.

A. C. Lawrie	S. D. Bandaranaike*
L. F. Lee	P. Coomaraswamy*
A. De A. Seneviratne*	F. G. A. Lane
J. N. Campbell	J. H. Starey
A. F. Broun*	J. C. Willis.*

October 31st, 1899.

* See their remarks.

We dissent from the above report on the following points:—

The appointment of a Director of Agriculture is in our opinion unnecessary. The duties detailed in paragraph 4 of the report should be exercised by a Board of Agriculture analogous in its constitution to the Central Irrigation Board, and having a Member of the Executive Council as its President. Until the Government is in a position to judge of the working of the new Department the expense of a paid Director need not be incurred.

The interests of the paddy cultivation will, we think, suffer by combining the Irrigation Department with the Department of Agriculture. The object of the Irrigation Department is the irrigation and cultivation of paddy lands, and that Department is worked under the immediate and personal supervision and control of His Excellency the Governor. The withdrawal of the Governor's personal supervision from that Department cannot but be prejudicial to paddy cultivation, and the proposal to combine that Department with another, which deals with not only larger and more varied interests, but such as at times may be conflicting, cannot meet with the approval of the paddy cultivator. There is also the possibility, however remote, that such combination may lead to the use of irrigation funds for purposes other than irrigation.

A. de A. Seneviratna | S. D. Bandarnayake

P. Coomaraswamy.

I agree with the above gentlemen's views as regards the proposed appointment of a Director of Agriculture.—A. F. BROUN.

I agree with the views above expressed as to the proposal to create a Department with a Director. I think a Board should first be tried, with, if possible, His Excellency the Governor as Chairman. In this event I should not object to a combined Board of Agriculture and irrigation (with Sub-Committees for each Branch); otherwise I agree with the views of Mr. Seneviratna that these two departments of work should be kept separate.—JOHN C. WILLIS.

---

* Commissioners appointed by H.E. the Governor:—

Mr. Justice A. C. Lawrie, Chairman; Hons. F. R. Ellis, L. F. Lee, A. de A. Seneviratne, and John N. Campbell; and Messrs. A. F. Broun, S. D. Bandaranaike, Maha Mudaliyar, P. Coomaraswamy, John Ferguson, F. G. A. Lane, J. H. Starey, J. C. Willis, and C. Drieberg (Secretary).

MR. JOHN FERGUSON.

The views of Mr. John Ferguson will be found in the following Draft Report drawn up by him at the request of the Chairman, prior to his degarture for England in August, 1899.—

The Commission appointed by His Excellency the Governor to inquire into and report on the advisability of establishing a Department of Agriculture have the honor to submit the following report with appended papers.

1. The Commission have only held four meetings, but careful consideration has been given by the memoers to a series of papers on the subject of an Agricultural Department, drawn up especiallyby the Director of the Botanic Gardens at an early stage of the proceedings and in addition the opinions of the several Government Agents and their Assistants have been invited, and obtained, of certain specified questions bearing on the subject of inquiry.

2. The Commission would direct attention to the several papers and answers appended to their report, and would confess to a considerable diversity of opinion, both among the members and Revenue Officers, on the advisability of establishing a Department of Agriculture.

3. It seems clear to the majority of the Commission that any step taken at this time should be primarily with a view to the improvement and expansion of native agriculture, and that whatever be the directing, supervising, and advising body, the Revenue Officers of Provinces and Districts should be the medium for reaching and influencing the people.

4. That the great defect hitherto attending experiments for the improvement of native agriculture has been—in the words of the Government Agent for the Northern Province—"the absence of continuity of work at any one subject." He tells us one Provincial or District Officer's fad "is irrigation; another's, gardening; another's, stock improvement or horses; another's paddy or cocoanuts; and so on. Owing to the frequent changes in Administration (Provincial), each man s scheme, good in itself, is gradually dropped by his successor, and so the changes are rung to little or no ultimate benefit. It was the discovery of this as regards Irrigation which led to the formation of the Irrigation Boards, with the best results."

5. The Commission have no doubt that all branches of Agriculture in Ceylon—those of grain and palm-growing, equally with the tea, cacao and other industries of the planter—stand in need of scientific aid and advice from time to time, and that this can best be afforded by the Director of the Botanic Gardens and a staff of scientists at Peradeniya.

6. The Commission have also no doubt as to the value of experimental gardens or model farms being opened, with the full concurrence of the Government Agents and under their control, in every Province and ultimately in every Revenue District of the Island; and they consider it desirable that an Agri-Horticultural Show, suited to the importance or necessity of the Province or District, should be held once a year either at the capital of the Province or in a district town.

7. The Commission further think the Agricultural School should be placed on a new basis and that its transfer to the neighbourhood of Kandy, as recommended by the Director of the Botanic Gardens, is desirable.

8. In order to secure uniformity in controlling and directing improvements in different branches of Agriculture in the various Provinces, and to consider the special needs of particular industries from time to time, the Commission would recommend the establishment of a Central Board of Agriculture, with a member of the Executive Council as President, with one or two Government Agents and the Director of the Botanic Gardens as official members, and with two or more unofficial members while all Government Agents and their Assistants should be corresponding members. This Board would receive reports of all improvements in existing branches of Agriculture of experiments with new products, of inquiries into diseases or other enemies of plants, &c., and would furnish Government once a year with a full and comparative report as to the work it the different Provinces, while advising from timn to time on any agricultural question that mighe arise. To such Board might be left for consideration and report the question if further scientists should be temporarily or permanently attached to Peradeniya at this time; also the details and working out of several other improvements suggested in the Memoranda, Notes, or other papers of the Director of the Gardens, the Government Agents and other writers, which will befound in the Appendix to this report.

9. As the agricultural resources and prosperity of the Colony develop, the Commission would like to see a special Agricultural Department gradually evolved, the Board being presided over by the most efficient of the Government Agents (who should also be a member of the Executive Council), with Provincial and District Boards to correspond with the central institution. But at the outset, the Commission think a start may well be made with one Central Board (utilizing existing means), and having for its main object the maintenance of continuity of attention by the Revenue Officers and Headmen to any well-considered schemes for improvement in cereal or garden cultivation, or in live stock, which have once been fairly started in their Provinces or districts, while also taking cognizance of the great planting industries, of diseases affecting them, or of proposals of for their improvement, or for adding to the list new products deserving of practical attention.

10. Finally, the Commission would recommend that some encouragement be held out to young Civilian Cadets to qualify for their duties by a course of agricultural study in Europe before coming to Ceylon.

The TROPICAL AGRICULTURIST

MONTHLY.

Vol. XX. COLOMBO, AUGUST 1st, 1900. No. 2.

CHILLIES:—THEIR CULTIVATION AND USES.

CAPSICUM, *Linn.; Gen. Pl., II., 892.*

(From "Economic Products of India.")

THE greatest confusion exists in Indian literature as to the cultivated species of Capsicum. Popularly the larger fruits are usually designated Capsicums, and the smaller Chillies. According to Firminger, the powdered seeds of the latter constitutes Cayenne pepper. That author, in his *Manual of Gardening for India*, states that there are a great many varieties of Capsicum grown in India, some of which are very ornamental when grouped together.

The writer can at most hope that he has thrown the various vernacular names approximately under their corresponding botanical species. Much remains still to be done in order to clear up the ambiguities which exists in the literature of the Indian Capsicums. Many of the vernacular names appear to be given to all the species alike.

Habitat.—A native of equinoctial America, most probably of Brazil. Commonly cultivated for its fruit throughout the plains of India, and on the lower hills such as in Kashmir, and in the Chenab valley up to altitude 6,500 feet. When grown on the hills it is said to be very pungent. There are seven varieties, differing chiefly in the length, shape and colour of the fruit, some being round, others oblong, obtuse, pointed or bifid, smooth or rugose; and red, white, yellow, or variegated. It is probable that most Indian authors have confused this species with C. minimum, which see.

History.—"This species has a number of different names in European languages, which all indicate a foreign origin, and the resemblance of the taste to that of pepper. In French it is often called *poivre de Guinee* (Guinea pepper), but also *poivre du Bresil, d'Inde* (Indian, Brazilian pepper), &c., denominations to which no importance can be attributed. Its cultivation was introduced into Europe in the sixteenth century. It was one of the peppers that Piso and Maxgraf saw grown in Brazil under the name *quija* or *quiya*. They say nothing as to its origin." (*DC. Orig. of Cult. Pl.*) Chillies are not mentioned by any Sanskrit writer, consequently their introduction into India must have taken place at a comparatively recent date. It is probable that the Portuguese brought the fruit from the West Indies. Up to the present time the cultivation of the plant is carried on more extensively at Goa than at any other place on the western coast, and capsicums are well-known in Bombay by the name of *Gowai mirchi* (Goa pepper)" (*Dr. Dymock, Mat Med. W. Ind.*). Hove alludes to Capsicum as grown in Bombay in 1787 and expresses no astonishment at its existence in India.

CULTIVATION OF CAPSICUMS.—"A light well-manured soil is the best for all kinds, in which the plants should be picked out at about four inches apart when they attain a growth of three inches; and afterwards put out into a bed of rich light earth when they attain six inches in height, giving them a good supply of water and keeping them clear from weeds" (*The Gardener*).

Medicine.—Dr. Stewart says that the fruit is used externally in the form of plasters and taken internally in cholera; it is eaten from a conviction that it counteracts the effects of bad climates.

As a drug, red pepper is considered by the natives as stomachic and stimulant, and is used externally as a rubefacient (*Dymock*). "It has been employed with success as a topical application to elongated uvula and relaxation of the pendulous veil of the palate. Made into a lozenge, with sugar and traga-

canth, it is a favourite remedy for hoarseness with professional singers and public speakers. In purid sore-throat whether symptomatic or strictly local, gargles of an infusion of red pepper are often very usefully resorted to" (*O'Shaughnessy, Beng. Dispens. 468*). "It is employd in medicine in combination with ciuchona in intermittent and lethargic affections and also in atonic gout. It is a valuable adjunct to bitter tonics, and other stimulants in weak states of the stomach; in cold leucophlegmatic habits, dyspepsia and flatulence, and as a gargle in relaxed states of the throat it is highly extolled and has also been used with success in the advanced stages of rheumatism. In native practice it is given, in conjunction with asafœtida and sweet flag root, in cholera. By German physicians it is supposed to be particularly injurious in gonorrhœa,' (*Murray's Pl. and drugs of Sind*).

Dr. Sakharam Arjun says that the fruit is used as a stimulant in snake-bite.

Chemical composition.—"Bucholz, in 1816, and about the same time Braconnot, traced the acridity of capsicum to a substance called *casicin*. It is obtained by treating the alcoholic extract of ether, and is a thick yellowish red liquid, but slightly soluble in water. When gently heated it becomes very fluid, and at a higher temperature is dissipated in fumes which are extremely irritating to respiration. It is evidently a mixed substance consisting of resinous and fatty matters.

"Felletar, in 1869, exhausted capsicum fruits with dilute sulphuric acid and distilled the decoction with potash. The distillate, which was strongly alkaline and smelt like *conine*, was saturated with sulphuric acid, evaported to dryness and exhausted with absolute alcohol. The solution, after evaporation of the alcohol, was treated with potash, and yielded by distillation a volatile alkaloid having the odour of conine.

"From experiments made by one of us (F.) we can fully confirm the observations of Felletar. We have obtained the volatile base in question, and find it to have the smell of conine. It occurs both in the pericarp and in the seeds, but in so small a proportion that we were unsuccessful in isolating it in sufficient quantity to allow of accurate examination.

"Dragendorf states (1871) that petroleum either is the best solvent for the alkaloid of capsicum; he obtained crystals of its hydrochlorate, the aqueous solution of which was precipitated by most of the usual tests, but not by tannic acid.

"The colouring matter of capsicum fruits is sparingly soluble in alcohol, but readily in chloroform. After evaporation an intensely red soft mass is obtained, which is not much altered by potash; it turns first blue, then black, with concentrated sulphuric acid, like many other yellow colouring substances. By alcohol chiefly *palmatic* acid is extracted from the fruit, as shown by Thresh in 1877.

"The fruits of Capsicum fastigiatum have a somewhat strong odour; on distilling consecutively two quantities, each of 50lb, we obtained a scanty amount of flocculent fatty matter which possesses an odour suggestive of parsley. Both this matter, as well as the distilled water, were neutral to litmus-paper and the water tasteless. We separated the latter and exposed the remaining greasy mass to a temperature of about 50°C., when it for the most part melted. The clear liquid on cooling solidified and now consisted of tufted crystals, which we further purified by recrystallization from alcohol. Thus about two centigrammes were obtained of a natural white stearoptene having a decidedly aromatic, not very persistent taste, and by *no means acrid*, but rather like that of essential oil of parsley. The crystals melted at 38°C. On keeping them for some days at the temperature of the water-bath, covered with a watch-glass, some drops of essential oil were volatilized, which had the same taste and did not solidify; the crystals were subsequently accompanied by a liquid oil When kept for some days more in that condition, the crystals themselves began to be volatilized, and the part remaining behind acquired a brownish hue. This, no doubt, points out another impurity, as we ascertained by the following experiment. With boiling solution of potash, the stearoptene produces a kind of soap which on cooling yields a transparent jelly. If this is dissolved and diluted, it becomes turbid by addition of an acid. This probably depends upon the presence of a little fatty matter (a suggestion which is confirmed by the somewhat offensive smell given off by our stearoptene if it is heated in a glass tube.

"Buchheim's 'Capsicol' is in our opinion a doubtful substance.

"Thresh (1876-77) succeeded in isolating a well-defined, highly active principle, the *Capsaicin*, from the extract which he obtained by exhausting Cayenne pepper with petroleum. From the red liquor dilute caustic lye removes *capsaicin*, which is to be precipitated in minute crystals by passing carbonic acid through the alkline solution. They may be purified by recrystallizing them for either alcohol, either, benzine, glacial acetic acid, or hot bisulphide of carbon; in petroleum *capsaicin* is but very sparingly soluble, yet dissolves abundantly on addition of fatty oil. The latter being present in the pericarp is the cause why *capsaicin* can be extracted by the above process.

"The crystals of *capsaicin* are colourless and answer to the formula $C_9H_{14}O_2$; they melt at 59°C., and begin to volatilize at 115°C.; but decomposition can only be avoided by great care. The vapours of *capsaicin* are of the most *dreadful aridity*, and even the ordinary manipulation of that substance requires much precaution. *Capsaicin* is not a glucoside: it is a powerful rubifacie t, and taken internally produces very violent burning in the stomach" (*Pharmacographia*),

Special Opinions.—§"Stimulant and rubefacient, useful in dyspepsia; recommeuded in infusion as an external application to the eye" *Assistant Surgeon Nehal Sing, Shaharanpur*). "Chiefly used as a condiment and considered to be stomachic" (*Assistant Surgeon Anund Chunder Mookerji, Noakhally*). "Antimalarious to a certain extent" (*H. D. Masani, Surgeon H. M.'s 30th N. I., Bombay Karachi*). "Carminative, cooling medicine. The decoction with opium and friend asafœtida seeds is used in cholera. In the form of gargle it is useful in stomatitis and sore-throat. It is an ingredient in what is called *masala* in the Decan, Guzerat, and Cutch" (*W Barren Surgeon H. M S. 25th N. L. I., Bombay Bhuj Cutch*). "The capsule is innocuous; the seeds, as well known are powerfully irritant" (*R. T. H. Morar*). Chillies are applied by natives to dog-bites. An infusion made with 4 drams of chillies and a bottle of boiling water has been found useful in severe sore-throat" (*Assistant Surgeon Bhagwan Dass, Rawal Pindi*), "In delirium tremens in 20-grain doses" (*Surgeon-Major George Cumberland Ross, Delhi*). "Is used in liniments as a rubefacient; in cholera pills with camphor and assafœtida; as an application to elongated uvula and relaxed throat it is very useful" (*A. Surgeon*). "Active principle, an acrid oil-capsaicin. In dyspepsia, a good pill is made with equal parts of capsicum, rhubarb, and ginger" *C. M. Russel Civil Surgeon Sarun Bengal* "Internally it has a stimulant action on the bowels and helps to relieve constipation" (*Surgeon-Major A. S. G. Fayakar Muskat*.

Food.—The fruit when green is used for pickling and when ripe is mixed with tomatos, &c., to make sauces. It is also dried and ground for use like Cayenne pepper (*Treasury of Botany.*)

The consumption of chillies is very great, and both rich and poor daily use them; they form the principal ingredient in all chutnies and curries; ground into a paste, between two stones, with a little mustard oil, ginger, and salt, they form the only seasoning which the millions of poor can obtain to eat with their rice (*Balfour's Cyclop.*) Dr. Dymock gives

the value of Ghati chillies at R3½ per maund, and Gowav, R2½ to 4 per maund of 28lb in Bombay.

Capsicum, fastigiatum, *Blume*. See C. minimum, *Roxb.*

C. frutescens, *Linn.*; *Fl Br. Ind. IV., 239.*

Habitat.—An annual, cultivated throughout India. Supposed to have been recently, comparatively speaking, introduced from South America. Accordiug to the best authorities, this and the other species of Capsicum, now cultivated in India, have no Sanskrit names. Of the Indian cultivated species this is perhaps the commonest, as it is also the largest, being sometimes cultivated in the hedges around fields. It is grown during the cold weather ou light sandy soil in most parts of the country, and especially so iu Bengal, Orissa and Madras. The Fruit, when ripe, is generally of a bright red colour; it is then picked and laid out on mats to dry in the sun.

Opinions differ slightly as to the plants which afford Cayenue pepper. Speaking of this species, De Candolle says: "The great part of the so-called Cayenne pepper is made from it, but this name is given also to the product of other peppers. Roxburgh, the author who is most attentive to the origin of Indian plants, does not consider it to be wild in India" (*Orig. Cult. Pl*) Simmonds writes that "the Cayenne pepper of commerce is obtained chiefly from the pulverised chillies or fruit pods of one or two species of Capsicum (C. annuum, *Linn.*, and C. fastigiatum, *Blume*). So also in the *Kew Official Guide* (p. 100) the dried and pulverised rind of the pods of C. annuum and its allies is said to make the best Cayenne pepper.

Medicine.—Chillies are used as medicine in typhus and intermittent fevers and in dropsy; they are regarded as stomachic and rubefacient. In native practice they are prescribed iu gout, dyspepsia, cholera, and ague *(Atkinson)*.

Special Opinions.—§ "When taken iu curry in unusual quantities, chillies cause, in many iustances, great irritation and burning in the rectum, especially after defecatiou, attended also with scalding and frequent desire to urinate; mixed with ginger and mustard, they form a powerful rubefacient paste" (*Assistant Surgeon Shib Chunder Bhattacharji, Chanda, Central Provinces*). "A dose of ten grains of finely powdered capsicum seed, given with an ounce of hot water, two or three times a day, sometimes shows wonderful effects in cases of delirium tremens" (*Surgeon R Gray, Lahore*) "Stimulant, aromatic, and stomachic. I use the tincture and powder largely in the preparation of cholera mixture and pills, also in gargles for sore-throat" (*Brigade-Surgeon S. M. Shircore, Murshedabad*) "A powerful stimulant used as a gargle in sore-throat, also in dyspepsia and loss of appetite" (*Brig.-Surgeon F H Thorton Monghir*).

Food.—In every Indian bazar chillies may be purchased although not natives of India, the cultivated forms, at the present date, are everywhere met with and constitute an indispensable ingredient in native curry. They are "much used for flavouring pickles. By pouring hot vinegar upon the fruits all the essential qualities are procured, which cannot be effected hy drying them, owing to their oleaginous properties; hence chilli-vinegar is in repute as a flavouring substance. In Bengal the natives make an extract from the chillies which is about the consistence and colour of treacle. A form of soluble Cayenne was sent from British Guiana in 1867 in the collection forwarded to the Paris Exhibition" (*Simmonds, Trop, Agri, 480.*)

The pods are dried on a hot plate or in a slow oven and then pounded in a mortar. This powder is then passed through a handmill until it is brought to the finest possible state, thereafter it is well sifted and preserved in corked glass bottles for use (*Treasury of Botany.*)

Capsicum grossum, *Willd Fl. Br. Ind. IV. 239.*

Bell Pepper.

Habitat.—Not much cultivated in India; native place uncertain,

Food.—Cultivated to a limited extent iu gardens, but chiefly for Europeans, who either cut this capsicum in stews or have it opened, stuffed with certain spices, and pickled iu vinegar. The thick fleshy skin is not so hot as that of the other species.

C. minimum, *Roxb.*; *Fl. Br. Ind., IV., 239*; *Wight Ic., t. 1617.*

Bird's-eye Chilli.

Habitat—Cultivated throughout India, but not extensively; closely resembles C. annuum, but is distinguished by the more acute corolla lobes, the smaller seeds, and by the pod being erect, nearly cylindrical and yellow when ripe. It is generally knowu as Bird's-eye Chilli. This "is found in many parts of India, principally in the southern districts, growing in waste places, gardens &c., in an apparently wild state. It is also found abundantly in Java and other parts of the Eastern Archipelago under similar conditions. There is, however, good reason to believe that, in common with the rest of the genus, it was originally brought from some part of the American Continent. It is now cultivated to a large extent in the tropics of both the old and new worlds" *(Bentley and Trimen.)*

Medicine.—The *Pharmacopœia of India* describes the fruit as an acrid stimulant. "In atonic dyspepsia, and in diarrhœa arising from putrid or crude ingesta in the intestines, and iu the vomiting of bilious remittent fever, it acts beneficially. In scarlatina it has been used with great repute in the West Indies. In various forms of cynanohe, and in hoarseness or aphonia, depending upon a relaxed condition of the *chordæ vocales*, it has been found a useful adjunct to gargles. As a rubefacient and counter-irritant, the bruised fruit, in the form of poultice, acts energetically; added to sinapisms it greatly increases their activity." Acts as an acrid stimulant, and externally as a rubefacient used in putrid sore-throat and scarlatiua; also in ordinary sore-throat, hoarseness, dyspepsia. and yellow fever, and ia diarrhœa occasionally also in piles" *(Baden Powell)*.

"In *Scarlatina*, the following mixture has attained much repute in the West Indies: Take two table spoonsful of bruised Capsicum and two teaspoonsful of Salt; beat them into a paste and add half a pint of boiling water; when cold, straiu and add half-a pint of Vinegar. Dose for an addult, one tablespoonful every four hours; to be diminished for children according to age or the severity of the attack. The same formula forms an excellent gargle in the *sore-throat which accompanies this disease* as well as in ordinary *relaxed, sore-throat, hoarseness* &c." *(Waring, Medicines.)*

Food.—This small "chilli" is rarely used by natives, but by Europeans is steeped in vinegar and mixed with salt; in this form it is employed as a seasoning in stews, chops &c.

(From "Treasury of Botany.")

Capsicum.—One of the genera of *Solanaceæ*, deriving its name from the Greek word signifying 'to bite,' in allusion to the hot pungent properties possessed by the fruits and seeds. The genus consists of annual or biennial plants, frequently with a somewhat woody and bushy stem; a wheel-shaped corolla; five stamens protruding from the corolla, their anthers converging at their points, and opening by longitudinal slits; and a two to four-celled ovary, becoming, when ripe, a membranous pod containing several seeds. The shape of the fruit varies very much in the different species of the genus.

C. annuum, a native originally of South America, but introduced into India and elsewhere, furnishes the fruits known as Chillies; these, as well as the fruits of *C. frutescens*, and several other species or varieties, are used to form Cayenne pepper. For this purpose the ripe fruits are dried in the sun or in an oven, and then ground to powder, which is mixed with a large quantity of wheat flour. The mixed power is then made into cakes with leaven, these are baked till they are as hard as biscuit, and are then ground and sifted. The Cayeune pepper of the shops is, however, usually largely adulterated

with red lead and other less objectionable substances. The hot taste seems to be due to a peculiar acrid fluid called *capsicin*, which is so pungent that half a grain of it volatilised in a large room, causes all who respire the contained air to cough and sneeze. It is remarkable that the narcotic properties, which are possessed by most of the *Solanaceæ* to a greater or less extent, are not present in *Capsicum* – though this is open to some doubt, as it is said that some of the American species have narcotic properties residing in the pulpy matter in which the seeds are imbedded, this pulp being absent in those kinds which are used for their pungent properties.

Capsicum fruits are used medicinally, in powder or as a tincture, as an external application, or as a gargle in certain cases of sore throat, particularly those of a malignant character, and internally as a stimulant in cases of impaired digestion, &c. Several kinds are cultivated in this country, as objects of curiosity, and for the sake of their fruits. [M.T.M]

The species of *Capsicum* are chiefly natives of the East and West Indies, China, Brazil, and Egypt, where they are much esteemed for their pungent fruit and seeds, which, under the name of Cayenne Pepper, or Chillies, form an indispensable condiment, which Nature herself appears to have pointed out to persons resident within the tropics. According to Sir R. Schomburgk, the natives in Guiana eat the fruit of these plants in such abundance as would not be credited by a European unless he were to see it (*Jour. Hort. Soc.* ii. 153). In Jamaica the species most esteemed is the Bonnet Pepper (*C. tetragonum*), the fruits of which are very fleshy, and have a depressed form, like a Scotch bonnet. The shrubby Capsicum, or Spur Pepper (*C. frutescens*), is a native of the East Indies, and has been in our gardens since 1656. It forms a dwarf bushy shrub, with white flowers, and bears numerous small oblong obtuse pods, which are very pungent, and in their green and ripe state are used for pickling, as well as for making Chilli vinegar. This is done by merely putting a handful of pods into a bottle, and afterwards filling it with best vinegar, which in several weeks will be fit for use. But the chief purpose for which this species is cultivated is for making Cayenne pepper, which is often prepared by drying the pods on a hot plate, or in a slow oven, and then pounding them in a mortar, and passing them through a hand-mill until the whole is reduced to the finest possible state. After this has been done, the powder is to be sifted through a thin muslin sieve, and preserved in well-corked glass bottles for use. The common annual Capsicum, or Guinea Pepper (*C. annuum*), was introduced into Europe by the Spaniards. It was cultivated in England in 1548, and is sufficiently hardy to thrive in summer against a south wall in the open air, and mature its fruit. The colour, direction, and figure of the latter is very variable—some being yellow, others red, and others black. In a green state they are used for pickling, and when ripe are mixed with tomatos, &c., to form sauces. They are also dried and ground for use like Cayenne pepper. The Berry-bearing Capsicum, or Bird Pepper (*C. baccatum*), is indigenous to both the East and West Indies, and has been grown in this country since 1731. Its pods are erect, roundish, egg-shaped, very pungent, and when ripe are dried and used for the same purposes as those of other kinds of *Capsicum*. They also form one of the chief ingredients in the preparation known in the West Indies as *man dram*, which is usually resorted to by those effected with loss of appetite or weak digestion, and consists of cucumbers sliced very thin, shallots or onions chopped very fine, a little lime juice and Madeira wine, to which is added a handful of the pods of this pepper, and the whole are then mashed together, and mixed with as much liquid as may be thought necessary. Besides the three species noticed as being the kinds most generally cultivated, there are many other species and varieties occasionally grown for the sake of their pods, all of which yield a warm acrid oil, which acts powerfully on the stomach, and is thought to correct flatulency, and assist digestion. [W.B.B.]

AGRICULTURAL EDUCATION IN GREATER BRITAIN.

PAPER READ BEFORE THE FOREIGN AND COLONIAL SECTION OF THE SOCIETY OF ARTS, ON TUESDAY, FEBRUARY 27, 1900.

By R. Hedger Wallace.

(Continued from Vol. XX., page 7.)

It is a matter of regret to learn that agriculture is not yet taught in the schools of this colony, for, in the paper read at the "International Congress on Technical Education" by the Emigration Agent for the Colony of Queensland, it is stated that lessons in agricultre had been introduced into the programme of instruction for country schools, with practical lessons in horticulture, for the school children of Brisbane and suburbs. Queensland is, however, peculiarly situated, as within its borders both branches of agriculture are carried on—the tropical and the temperate.

The college lately established is near Brisbane, and the three years' course of study includes the following subjects.—

First Year.—Agriculture, horticulture, dairying, carpentry (industrial), agriculture, horticulture, (lectures) arithmetic, book keeping, chemistry, drawing, English composition.

Second Year.—Agriculture, horticulture, dairying, blacksmithing, (industrial), agriculture, horticulture, dairying (lectures), anatomy and physiology, botany, chemistry, entomology, geology, physics, surveying.

Third Year.—Industrial (special work), agriculture (lectures), agricultural chemistry, bacteriology, botany landscape gardening, meterology, mechanics, veterinary science, zoology.

There are also four State Farms in Queensland, at Westbrook, Hermitage, Gindie, and Beggenden, and their object is to carry out experiments for the benefit of the farming community in the district where they are located. (Unlike the farms in New South Wales, facilities for students gaining experience is not afforded at these Queensland State Farms.) Agricultural education is also furthered by the employment of instructors in fruit culture, viticulture, tobacco culture, and coffee culture, and the issue of various publications.

Passing now to Victoria, it may be said that agricultual education in this colony follows very much on the same lines as that of New South Wales. Agriculture can be taught in the State Schools, and it is an optional subject in some of the teachers examinations. It used to be taught in the State School Teachers' Training Institute, before that institution was abandoned. Lectures on dairying are being given at present in the country schools, and proving a success. Nothing however, has yet been done in regard to school gardens, or the practical demonstration of agricultural principles in rural schools, as is done in South Australia. In the Schools of Mines throughout the colony, both agriculture and agricultural chemistry may be taught, and the curriculum of the Victorian Technical Schools includes agriculture, fruit-growing, and veterinary science. A Royal Commission, I may note, has lately been appointed, and is now dealing with the present educational system of the colony, and investigating as to the best systems of teachnical and agricultural teaching, as found in Europe and America. The whole system of teaching in the colony is therefore likely soon to be re-modelled.

The interest of purely agricultural education are in this colony entrusted to a Council of Agricultural Education, which represents the Agricultural Societies and the Government. Two colleges have been established by this Council—one at Dookie, in the north-eastern district and near to Sheppartoin; the other at Longerenong, in the Wimmera district, and near to Horsham. The latter college, which is placed near the Mallee lands, and admirably adapted for demonstraining what can be done in farming with

irrigation, has been, however, closed for some time, but it seems to have been only a temporary measure, for I believe it is now again ready to receive students.

It was originally intended, I believe, to found two more colleges one in the south-eastern and the other in the south-western districts, but this intention has not been carried ont. The great feature in the colleges controlled by the Council of Agricultnral Education in Victoria is that the instrucrion is free, the only charge being for maintenance. It is optional with students to remain one or more sessions at the colleges, but before a student can obtain his diploma he must have been in attendance for at least two years, while the maximum term of attendance permitted is three years. The course of instrnction is the same in both colleges, and comprises elementry chemistry, botany and geology, some agricultural chemistry and economic entomology, advanced English to the understanding of technical expressions, arithmetic, mensuration, surveying, book-keeping, practical work on the farm, instruction in field operations, the nse of farm implements and machinery, and the management of stock. Very special prominence is given to practical work at these colleges, and half of the students' time is devoted to field work. All students must be over the age of fourteen on admission and each college has accomodation for forty students.

A new school of viticultnre has recently been established at Rutherglen in the northeastern district and is directed by an expert from the college of viticnlture at Montpelier, France. A school of horticnlture has also been in operation for many years at the Government Horticultural Gardens at Burnley, near Melbourne. Here the number of students are limited to 25, and the term is also restricted to one year, the instruction being free. A Government scent farm was also carried on for some years to give instruction in scent flower farming, but is now closed for the time being, as sufficient interest was not taken in the industry. A small experimental tobacco farm has, however, been recently established near Wangaratta by the Government tobacco expert, who was engaged from the United States and for the past two years has been giving instruction to growers. It is now proposed, I am informed, to still further extend the scope of agricultnral education by the establishment of a dairy and cheese school, and a large sum of money has recently been voted for the purpose, so that these institutions will probably be established shortly. Like the other colonies, Victoria also employs experts to give instruction in dairying, fruit growing, viticulture tobacco growing, and the cultivation of fibre and oil-producing plants, and issues bulletins.

Next I note what has been done in respect of agricultural education in the adjoining colony of South Australia. Though this colony extends through the continent, and within its boundaries you find tropical, subtropical, and temperate, cultivation, education in agriculture is limited to the southern portion of the colony. In reply to my enquiries, the Agent-General for the colony, who when in South Australia was mainly instrumental in introducing the teaching of agricultnre into the State schools, was good enough to advise me that—

"(1) Agricnlture is taught as a specific subject in the elementry state school, in the *country*. (2) There are no farm schools, bnt several secondary agricultnral schools for lads of 12 or 13 years. (3) We have the Roseworthy Agricnltural College, and one high technical school of agriculture. (4) The study is encouraged in primary schools, where teachings can rise the percentage of their results by teaching agriculture and similar subjects."

The technical school of agriculture mentioned was opened in 1898 in Adelaide. At this school the subjects tanght are Englsh literatnre, composition, advanced arithmetic, algebra, plane geometry, mensuration and land surveying, mechanical drawing agriculture (theoretical and practical) frnit culture,, and viticulture. For instruction in chemistry, physics and carpentery, the scholars attend the School of Mines. Students from the Teachers' Training College also attend this school to get from the master a practical insight into the methods of teaching agricultnre, so that in due course they might be appointed to schools where instruction in agriculture is to form an important feature of the work. From the report of the South Australian Minister of Education for 1898, it seems that the Board of Inspectors in the colony are in favour of the teaching of agriculture in the schools. This deserves notice, for a study of the reports of the Departments of Education in the other colonies will show that a good deal of opposition to the introduction of agricultural teachiug in these colonies has come from members of the Inspectorate.

Passing next to the technical schools in South Australia, their curriculum also includes wool sorting and dairy work as subjects of instruction. Turning now to purely agricultural education, like the other colonies already mentioned, South Australia has an Agricultural College, located at Roseworthy, about 35 miles from Adelaide. This college was opened in 1885, and the corse of instruction includes practical agriculture, chemistry, botany, geology, surveying, levelling mensnration, book-keeping, entomology, and veterinary science, and also viticultnre, œnology, fruit culture, and wool sorting. The course is a two years' one but students who fail to obtain a diploma may remain a third year. The age for admission is 14, and all students are required to take part in farm work; but only half the time considered necessary in the Victorian colleges to be devoted to practical farm work is insisted upon at Reseworthy. The laboratory and science teaching generally is however recognised to be at Roseworthy in advance of that at the Victorian institutions. Again, like the other colonies, South Australia employs experts to give instruction in viticulture, horticulture, and dairying, and publishes a journal.

The last colony on the Australian continent yet to be mentioned is Western Australia, the Agent General of which advises me that:—

"(1) Agricultnre is partially tanght in the State schools of Western Australia. (2) There are no farm schools in the colony. (3) At present no agricultural school exists, but the desirablity of establishing such a college has been brought before the Government. (4) The Educational Department encourages agricultural training in the State schools"

I have been unable, however, to learn in time or this paper how agricultural training is encouraged, and what methods of teaching agriculture, in the State schools of this colony, are employed.

Coming now to Tasmania, this colony has what is termed a "Practical School of Agriculture" at Ulverstone, on the north-west coast. This school is nnder the patronage of the Tasmanian Government and has been selected by that Government to afford technical instructions in agricnltnre in the colony, and is subsidised also by the Government in order that special classes may be held at a low fee open to farmers and others in the district. Unlike the other Australian agricnltural schools or colleges, it is not a Government institution. The basis or foundation of school is the Ulverstone Grammar School to which first an agricultnral side has been added for boys, and then a further addition of a distinct and separate branch, including a farm, for grown up students. Agriculture is not taught in the elementary schools of this colony, but theoretical tuition in agricultural chemistry is sometimes given in the higher grade schools or colleges, though nothing of a very definite natnre is taught. Occasionally lecturers are engaged to travel through the country and give instruction on agricultural subjects. There is also what is practically a department of Agricultnre, which issues publications, and can command some scientific advice.

In New Zealand the circumstances are different, for agriculture can be tanght in the elementry schools in

Standards IV., V., and VI., and its teaching is encouraged by a provision that "if agricultural chemistry be efficiently taught, no other elementary science shall be required in these Standards." I have already drawn attention to the favourable opinion held of agriculture as a subject of instruction by the South Australian Board of School Inspectors, but in the report of the New Zealand Education Department, 1889, I find the reverse of the picture. The Chief Inspector, for instance, in his report, says, "The general science course, again being taken up in a good many schools where agricultural science was formerly preferred. This is a change to be welcomed, for the educative value of the two courses, and the facilities they offer for experimental illustration, are very unequal." In the same paragraph he further states that "with history treated only as a subject for reading, and the extravagances of the syllabus in geography, higher arithmetic, and agricultural, science rigidly pruned, there would be time to do honest educational work all round, and little excuse, but incapacity for not doing it." This is, of course, a matter for debate among experts. I simply regard it from what might be termed the ordinary ratepayers' point of view, and would say that the teaching of agriculture in the schools cannot be successful when the subject is regarded by the inspectorate in the light these extracts indicate. Like the neighbouring colonies, New Zealand also has an Agricultural College at Lincoln, near Christchurch. This college is one of the affiliated colleges of the University of New Zealand, which grants certificates and a degree (Bachelor of Science) in agriculture to those students who follow the prescribed course and pass the necessary examinations. For the degree in agriculture a student must first pass the matriculation examination, and attend two years at a university college and then two succeeding years at this Agricultural College. The course of instruction at Lincoln extends over two years, and students are not received if under sixteen years of age. The students' time is also equally divided between lectures and practical work as follows:—On one day the first-year students receive lectures, and the second-year students work on the farm; on the following day the second-year students receive lectures, and the first-year students work on the farm, and so on. The subjects taught are agriculture, chemistry, general and agricultural; botany, general and practical; entomology, general and agricultural; geology physiography, and meteorology; veterinary science, applied mathematics and mechanics, land surveying and levelling, drawing, and book-keeping.

In addition to this general agricultural college, a dairy school, is about to be established, and instructors from Canada have already been appointed.

CULTIVATION OF PEPPER IN THE BOMBAY PRESIDENCY.

A *Note by* J. W. Mollison, Esq., M.R.A.C., *Deputy Director of Agriculture, Poona. To which is added an account of Manures used in Spice Gardens.*

The two useful papers, by Mr. Mollison, given in these pages, are reproduced from the *Bombay Bulletin* by the courteous permission of the Survey Commissioner and Director, Land records and Agriculture, Bombay.

The commercial product here dealt with is the dried fruit of a vine-like plant which is found wild in the forests of Malabar and Travancore. The plant is cultivated largely in Southern India, Siam, Malay, Cochin-China, and other tropical parts with moist hot climates. A rainfall of 100 inches or more appears to be necessary. The plant is a large climber. The leaves are glossy, acute, cordate. The flowers are pendulous spikes and the fruit red berries, the size of peas in racemes. The berries are fleshy. The pulp covers a soft stone. The plants in climbing cling by adventitious roots very closely to any support. In the Kanora gardens pepper is trained on the *supari* palm trees.

How Propagated.—The plant is propagated by layering or from cuttings. The former is the preferable plan. When the betel palms have been seven or eight years permanently planted, pepper is planted at the roots of the trees. If a long healthy vine, from an established plant, can be stretched to reach the root of the betel palm, this vine is layered in the leaf-mould manure which surrounds the roots of the palm. The pepper vine takes root freely in this manure, and when it has done so, is severed from the parent plant and trained on the palm stem. Two or three vines are layered to one palm. The best months for propagating by layering or otherwise are June or July. The young pepper plant grows rapidly. The main vine should branch freely into subordinate vines, so that a number of vines can be trained straight up the palm. They are fully secured to the stem by bands stripped from the sheaths of fallen leaves of the betel palm. The bands are tied about a foot apart, and in well-managed gardens are renewed annually at the top and twice a year at the bottom, but in a young plantation a band must be put on from time to time as the vines grow. The main and subordinate vines grow up the tree to a height of five feet or more per annum. Luxuriant growth and free branching are encouraged by heavy applications of good manure given annually for three years after plantation. Subsequently the pepper participates in the general cultivation given to the betel palms and an application of manure is given for both crops every second year. The manure is heaped over the bared roots of the betel trees and pepper plants in a circle round the stems, and if plentiful a big basketful is given to each betel palm, less being given if manure is scant. The basket is saucer-shaped, about 3 feet in diameter and 15"—18" deep in the centre. The best manure for pepper, betelnut, and all other crops of the garden is made from green leaves and twigs plucked or pruned in the monsoon and used as litter in the byres where buffaloes and other cattle stand, and thence removed to a deep manure pit every day or second day with the dung and urine of the cattle. This manure is sufficiently decayed by the following March, and is applied in that month or in April. The pepper plants in an established plantation rise to a height of 15 to 20 feet. Throughout their whole length they send out horizontal branches which are generally about 18" long. The foliage in healthy plants is from the ground upwards fairly dense, but in an established plantation some of the older vines die. Then the foliage becomes less dense unless the plants are renewed by new layers. A plantation is in bearing three or four years after it is started, and if the old vines as they get worn out are at once replaced by new layers, the plantation should keep in vigorous growth and bearing for a long period. The flowers appear in July and August and the berries are ripe in March. The yield depends upon liberality in manuring and careful management, also upon the rainfall. The rainfalls of June and July are important as these cause the plants to produce many flowers, but if the rains come in heavy downpours subsequently the inflorescence may be destroyed before it fairly sets. If there is a long break after the first rains the flowers may wither. With light showers, however, a full crop may be expected.

Its Yield.—The vines on one palm when in full bearing yield in a good season about 1,000 clusters on an average. The clusters vary in size; but 1,000 should yield about 7 seers of dried pepper (a seer*= 24 tolas).

The plants, the flowers, and the fruit are delicate in the sense that they are damaged by rough handling. Therefore ladders are used when the vines are bound to the palms and the berries plucked. The ladders are straight single bamboos, with the alternate side branches cut off about a foot from the stem. These provide the steps of the ladder. A wooden hook is rigidly attached at the top end of the ladder and

* 1 Bombay seer=·7 lb.

secnres it to the palm above the level of the tallest pepper plants. The ladder is slightly inclined iu a certain direction when in proper position and then cau be safely used as it cannot well slip.

How Plucked.—The hunches are plucked hy hand and placed in an oblong cane basket slung horizontally behind the workman hy a rope round his waist. The rounded ends of the hasket project a little on either side so that the basket can he conveniently filled hy either hand of the workman. When plucked all the berries in a bunch may he equally and fully ripe, hut ordinarily the hunches are plucked when the berries are mostly green and just changing in colour. The heirries may or may not be sorted as they are plucked. If they are sorted those fully ripe are separated. These are soaked in water for seven or eight days or heaped, so that the pulp ferments and then rubhed hy hand or on a coarse cloth if the quantity is small or trampled under the feet of coolies if large. The pulp is thus rubbed off the inner "stone." The stone furnishes the white pepper of commerce. The pnlp is completely removed by washing in baskets in running water. The pepper is then dried by exposure to the sun for ahout a week. This has also a bleaching effect, and the pepper hecomes pale-grey or pale-drab in colour. It can be bleached a whiter colour by chemical agency. This white pepper is only prepared to a limited extent in the Kanara forests. The chief product is hlack pepper. It is got from nnsorted berries which are heaped up for four days. The green herries then get softer and change colour, and the pulp of all is more or less squashed. Then the herries are spread out aod dried. The skin and part of the pnlp adhere as a dry, dark-coloured wrinkled covering to stones and the pepper is hlack in appearance. White pepper is worth R10 to 11 per maund. Black pepper is worth R7 to 8 psr maund.

Manures used in Kanara Spice Gardens.

The owners of spice gardens in Kanara depend chiefly upon leaf-mould for manure. They have never nsed manure of any other description and have no faith that ordinary cow-dung manure, oilcakes, or other concentrated manures would serve thier purpose equally well. They consider that the best leaf-mould manure is got from the green leaves and small succulent branches of certain trees which during the monsoon are nsed as litter under the feet of cattle tied during night and the greater portion of the day in sheds. This litter is freely used—five large head-loads heing brought daily for above twelve cattle. The litter having absorbed the nriue and dung is removed daily or every second day and put in square pits which are generally abont 8 feet deep. These pits are dug in situations where they catch the whole direct rainfall, which is very heavy, and possihly also a good deal of drainage water from higher levels. The subsoil is very retentive, and there is probably not much drainage through the subsoil from the manure pits, but the contents of these pits must be continuously wet duriog the monsoon. For each acre of garden an owner would like to have four cattle. He owns always a milch buffalo or huffalocs, but keeps no work cattle as all the garden babour is manual. If he does not own sufficieut cattle, he hires them, feeding them gratis for the value of the manure produced. The hiring of cattle is a common practice. They are chiefly fed on dry grass which is of very inferior description. They prohably also eat part of the litter as some of the leaves used are liked by cattle. Milch buffaloes get safflower cake or cotton seed, hoth imported from Hubli Dhárwári District), and it is rather significaut that the gardeners think leaf-mould got from buffalo litter is hest for manure. Some owners feed cotton seed or cake to all their cattle in the monsoon, and I have no doubt they find it pays to do so, because ordinarily the cattle are, during this season, miserably thin and nnhealthy. Many cattle are brought in from Dharwar, but only snrvive a few seasons in the feverish climate of Kanara.

In the fair season the cattle get a good deal more freedom, still they are kept in the sheds for probably about fifteen hours in the twenty-four and the sheds are littered freely. The rough grass is supposed to he given as fodder, but is spread all over the floor in the sheds aud the cattle eat only a small proportion of it. Again, at this season dry leaves are collected and also used as bedding. But the gardeners think dry fallen leaves poor stuff and discount the value of such as manure. The manure put iu the pits in the hot weather has a full year to decay, the manure being used always in February and March. That which is made during the monsoon has less time to decay, and the gardeners attach particular value to the green leaves and twigs of certain trees collected during the monsoou because such decay very quickly. Such leaves are generally large and fleshy and are much more easily collected than smaller ones. A man can collect and carry to the cattle shed five head-loads per day. The leaves and hraoches of other trees are also held in high esteem for leaf-mould, because the manure produced has tho reputation of destroying iusects and grubs which would he harm-fnl to the plants in the garden. The trees which provide leaves of the latter class havc all unquestionably astringent properties, and it is perhaps reasonable to believe that vegetable matter containing astringent resins or volatile oils might destroy insect life or that insects would not he likely to harbour in such material. The gardeners assert that since they have been denied the use of the leaves of certain reserved trees grubs and horers have become destructive to their cardamom plants and betel palms, these insects causing damage first at the roots.

It is impossible for me to say what weight of manure is actually applied per acre. But judged by the eye, I think it is certain that the application is at least equal to a heavy dressing for ordinary garden crops. It probably approximates thirty ordinary cart-loads per acre per annum, perhaps more.

The invariable practice is to put the leaf-mould immediately over the roots round the stems. The circle would be 3 or 3½ feet in diameter. It is urged that the leaf-mould, if unprotected, would be washed away by heavy rainfall, and this is perhaps true, and in consequence a good deal of branchwood cut green in the hot weather, so that the leaves adhere, is used to cover the leaf-mould. The branchwood which is most desirable is such as will slowly decay aod has astringent properties, *i.e.*, has the power of keeping destructive insects away. The branches of *Fambe* (Xylia dolabriformis) aod *Nelli* (Phyllanthus Emblica) have the two qualities referred to in a special degree. The branchwood nsed does not readily decay. It affords considerabl protection to the leaf-mould. A year after it is applied the leaves have decayed and the brauches are partly rotten, still they would break the force of heavy rain. It might he urged that a covering of soil over the leaf-mould would he sufficient protection, especially as the soil of these gardens is of a decidedly adhesive character. It is possible that this adhesiveness would tend to exolude air and moisture from the leaf-mould and prevent it serving its purpose as manure. But I do not believe such would he the case. At Bassein in the Thana district, with a rainfall as heavy as that in Kanara, the manure given is put round the roots of the plantains, betel-vines, and other crops much in the same way as at Kanara and protected by a covering of soil. The soil is, however, a light alluvial sand and the manure is not washed away. The manure used at Thana is cow-dung manure and castor-cake, chiefly the latter, and it is given in several applications every year. The question is, can a manure of this class he economically substituted for a portion at least of the very heavy and very expensive dressings of leaf-mould now applied. I consider that the leaf-mould manure is expensive, even although its production requires only labour in collection and the keeping and feeding of cattle.

Castor-cake and safflower cakes are produced on a large scale in the Dharwar district and are obtainable at very moderate rates by the Kanara gardeners. It might, therefore, be advisable to experiment with these manures and prove their effect.—*Agricultural Ledger*.

THE TAPPING OF **RUBBER** TREES IN THE CHARDUAR RUBBER PLANTATION, ASSAM, 1899.

In the Assam Secretariat letter No. 9 Forests—388R. of 23rd January 1899, the Chief Commissioner's sanction was given to the experimental tapping of the rubber trees in compartments Nos. 1 to 4 of the Charduar plantations. The following report shows the results of the operations:—

2 *Results of Operations.*—The accompanying statement gives these results:—the areas of the operations, the numbers of trees tapped, the yield in rubber, the average yield per tree and per acre, and the cost of the operation. The areas include the above four compartments, and also the 8 acres of the Bamoni Hill plantation in Tezpur, the results for each being shown separately.

3. In the statement attached, a distinction is made between—

(*a*) Trees tapped, which had been previously untapped, or only moderately tapped.

(*b*) Trees previously heavily tapped, or suppressed trees.

The results were, from the four compartments:—
for (*a*) trees ·90 lb. per tree;
for (*b*) „ ·23 „ „ „

The total yield of the four compartments was 2,947 lb. of rubber. As will be seen from the following remarks, the low outturn is probably partly due to rain, which, during the operations, washed away a considerable proportion of the rubber before it was dry. The rubber was sent to London and sold, the results appear below.

4. *Description of Operations.*—Mr. D. P. Copeland, Deputy Conservator of Forests, Darrang Division, in his report on the operations which he conducted, refers to the close supervision required to prevent theft, and describes in detail the operations of tapping, collecting, drying, etc.

In accordance with instructions, the girth of the bole and the measurements of the crown were recorded in the cases of 10 per cent. of the trees tapped, and these trees were labelled.

The work of tapping and collecting the rubber, which commenced on 24th January, and continued till 31st March, was at first tried with Mikir and a few Garo coolies on the daily wages usual in the locality—8 annas a day. Owing to the unsettled weather, it was found that this system was too costly, the rain necessitated stoppage of operations from time to time, and work elsewhere had to be found for the tappers; again, the coolies had no interest in the outturn. After the tapping operations had been completed in compartments Nos. 1 and 2, the work in compartments Nos. 3 and 4 was therefore given out on contract, under close supervision to prevent theft, to a Nepalese contractor at R30 a maund, and to local Assamese, not so good at the work, at R20 a maund, the cleaning being arranged for separately at one anna a seer. The results in the yield per tree and cost of tapping and collecting were therefore better in the cases of compartments Nos. 3 and 4. It appears that the Nepalese are the best men for this work.

Position of cuts.—In compartments Nos. 1 and 2, treated by Mikir labour, the system adopted was to make the cuts regularly one foot apart down the stem of the tree, these cuts being horizontal, and not exceeding 8 inches in length and 2 inches width. Aerial roots and branches, less than a foot in girth, were not tapped. It was afterwards found that no fixed rule could be laid down, and that the experienced Nepalese tappers make the cuts 2 feet, and often further, apart, and the length of the cuts varies with the girth of the bole. Again, they avoid making the cuts immediately one below the other, and locate them alternately, as below:—

The position of the cuts appears to have more effect on the yield than their number.

Collecting.—In compartments Nos. 3 and 4 the contractor included the tapping, and the work of pulling the rubber off the tree after coagulation. The rubber takes four or five days to "set" on the surface of the tree before it can be collected. This work of collecting took as long as the tapping.

Weather.—One of the essentials for success is said by Mr. Copeland, to be settled weather. If rain occurs within two days of tapping, the milk is washed away, and the loss is heavy, while which remains on the stems loses part of its elasticity, becomes brittle and discoloured. The operations were greatly hindered by the frequent rain, both in outturn of rubber and in cost of labour, since work had to be stopped and employment found elsewhere for the labour.

Tarring.—As soon as the rubber was pulled off the trees, the cuts were coal-tarred, 17 barrels of tar being used for the 322 acres.

Cleaning.—Unless the rubber was cleaned immediately after collection, pieces of bark and chips of wood and other impurities imbedded in it were difficult of removal. The work of picking out these foreign matters was done by contractor at one anna a seer, the loss in weight on the first weightments being about 8 per cent.

Drying.—After this cleaning, the rubber was spread to dry—at first in the sun—but as this seemed to make some of the rubber brittle and discoloured, and made some to melt, the system of drying in the shade was adopted. The loss from dryage is reported to be about 1 per cent. only.

Yield.—Weighment of the rubber was made for each compartment separately on the spot, as soon as it was pulled off the trees. A reference to the statement will show that for compartments Nos. 1 and 2, the yield from the trees of the (*a*) class was 0·79 lb. per tree. For compartments Nos. 3 and 4, however, the trees of which were tapped by skilled labour, the yield was 0·97 lb. per tree, or 22·8 per cent. more than for compartments Nos. 1 and 2. Mr. Copeland thinks the difference would have been still more marked, had it not been for the rain, which did more damage to rubber in course of collection in the last two compartments than in compartments Nos. 1 and 2. The yield per tree is given in the statement, as also the yield per acre.

Cost of Operation.—The statement gives the cost of the operations of tapping the trees and collecting and cleaning the rubber, which comes to seven annas two pies per pound of rubber. At the foot of the statements, however, are given the details of other expenditure incurred on the operations, the whole being about three times the above sum per pound of rubber. To this it is necessary to add the cost of freight to London, insurance and agents' expenses, as is done below. Mr. Home was present during part of the operations.

5. In future operations, the work should be done earlier in the season, so as to avoid the rains of February to March.

6. The question of re-tapping the same trees next season and annually, as originally proposed, is under consideration.—*Indian Forester.* E. G. Chester.

RUSTY NAIL WOUNDS.

Treading on an upturned rusty nail sticking out of an old board is a very common accident. Children who are in the habit or running about barefooted are especially liable to such an accident, and fatal consequences often ensue, lockjaw and subsequent death being often the result. "Pansy" contributes to the *Australian Farm and Home* the following very simple remedy in such cases, which is at all events well worth a trial:—The remedy is simple, always on hand, and can be applied by anyone; and what is better, it is infalliable. It is simply to smoke the wound, or any bruise or wound that is inflamed, with burning wool or woollen cloth. Twenty minutes in the smoke will take the pain out of the worst case of inflammation arising from the wound. People may sneer at this remedy as much as they please, but when they are afflicted just let them try it.—*Queensland Agricultural Journal.*

THE TEA AND PRODUCE COMMITTEE.

REPORT FOR THE YEAR 1899-1900.

The Committee has held four meetings during the year.

The chief business of the year has been the work carried on by the India and Ceylon Joint Committee in respect of the attempt to abolish the 1-lb. draft allowance per package of Tea, and the subsequent prolonged negotiations with the Tea Buyers as to the agreement arrived at in August last for a new system of weighment of Tea by the Customs. It is unnecessary here to go into the details of the various incidents in the dispute, which were set forth at length in the exhaustive minute issued by the Joint Committee on 12th December last. The issue in November last by the Board of Customs of Port Order 39-1899 seemed for a few days to have brought the matter to a settlement, but the subsequent suspension of that order before the date when it was to come into force quickly reopened the controversy. The Tea Buyers then suggested as an alternative settlement the acceptance of Port Order 39-1899 in consideration of certain alteration in the Sales Conditions being agreed to, and proposed a Conference of Buyers and Importers to consider these alterations. Your Committee on 11th December last nominated Mr. Alfred Brown to represent Ceylon interests at the Conference, and for the intervening five months that gentleman has been constantly engaged in the negotiations. The thanks of the Committee are due to him for his labours.

No agreement has yet been come to in regard to the propoaed alterations, but in view of the recent reduction in the Bulking and Taring rate for Tea at the London Warehouses and the consequent withdrawal of objection to the separate taring of London bulked Teas, your Committee recommended a settlement of the long pending dispute on the terms of the original agreement of 2nd August last. This has now been brought into effect by the issue by the Board of Customs of PortOrder 42-1909, which comes into operation on 1st June.

The Committee is glad to be able to report that some measure of success has attended the efforts, made in conjunction with the Indian Tea Association, to obtain a reduction in the London Warehouse charges on Tea. The reduced scale of rates for Bulking and Taring mentioned above came into force on 1st March, and it is now announced that the Tea Clearing House has decided to increase the discount allowed on other charges from 10 per cent to 15 per cent. The Committee does not consider this last concession to be adequate, and will not relax its efforts until a further reduction is obtained.

Matters of minor importance that have engaged the attention of the Committee are the import from Ceylon into this country of spurious Cinnamon, Mr Hughes' report on selected samples of prepared Cocoa, and the equalization of tares in the case of Tea by the insertion into the packages of loose pieces of lead or wood.

At the request of the Committee of the Planters' Association of Ceylon, representation has been made to the London Fire Offices Committee for a reduction of the rates of premium for Fire Insurance in Ceylon.

The duty on Tea imported into this country was raised in March from 4d to 6d per pound.

UDAGAMA TEA AND TIMBER CO.

REPORT.

The report now before the shareholders embrace a period of 15 months from 30th September, 1898, to 31st December, 1899.

During the early portion of the period under review the weather was very unfavorable for tea and later on some crop was lost through want of labour (Singhalese). Only 142,879 lb. of tea were obtained from all the estates; nevertheless the loss of the previous year (R8,162·09) was turned into a small profit of R2,070·81.

Prices obtained were encouragiug 32·45 cents per lb. being the average for the 15 months. The cost however was heavy—31 cents. Plucking and weeding were both very expensive.

A crop of 170,000 lb. has been estimated for 1900, it is hoped that it will not cost 25 cents per lb. The new clearings present a splendid appearance and will give a very large yield in 1901. The effect of manure also on the older estates is now shewing itself, Ginnidomine is looking very well and will give a very good crop.

Homadola has never been of much value to the Company being widely apart from the rest of the estates and situated eight to nine miles from the Factory, your Directors have therefore accepted an offer for its lease for five years for the sum of R1,100 per annum.

A block of 754 acres of forest on Homadola was sold early in 1899 for R25 per acre, the proceeds were applied to the cost of the new factory under arrangements with the debenture holders.

Sawmills.—The profit made during 15 months amounted to R1,759·68; the work was very much impeded by the great difficulty in obtaining labour owing to the rush for plumbago. Transport of timber from the forests was very expensive and mill hands scarce and dear.

Only 49,685 chests were made during the 15 months against 58,210 during the previous 12 months. The price of tea chests have now risen very considerably there is a prospect of a much better result during the ensuing year.

In addition to the loss in interest shewn in the accounts a sum of R8,199·50 is due to the preference shareholders for interest. This is not payable until sufficient profit has been made to meet it.

It is the duty of the shareholders to appoint an Auditor for the year 1900, and a Director in the place of Mr. R D Kershaw who retires by rotation and eligible for re-election.

Tea Consumption among Natives.—The Manager of Messrs. Lipton Ld. writes to the *Indian Planters' Gazette* as follows:—"I notice a paragraph in your issue of 23rd instant written on somewhat the same lines as your leading article of 2nd June, in which you appear to take it for granted that nothing is being done to approach the European population in India regarding the consumption of Indian tea. I would point out that there is one firm in India which has done, and is still doing, more towards bringing Indian teas to the notice of the inhabitants (both European and natives) of this country, than is done probably by anyone else. In nearly every bazaar in India, you will find that (thanks to the labours of Lipton Ld.) Indian tea is being sold, and is thereby being brought to the notice of an increasing number every day, and it is, therefore, hardly correct to say that there is no organized effort to push Indian teas among the inhabitants of India."—We wonder if the same policy is being pursued by Messrs. Lipton, Ld, in Ceylon, or if natives are left to find out the advantages of tea-drinking by themselves.

TRINIDAD BOTANICAL DEPARTMENT:

(EXTRACTS FROM THE ANNUAL REPORT OF THE SUPERINTENDENT ROYAL BOTANIC GARDENS, (J. L. HART, ESQ., F.L.S.,) FOR 1899.)

ESTABLISHMENT.—Mr. Millen acted as Assistant Superintendent from November to March when he was succeeded by Mr. W Leslie from Royal Gardens, Kew. Mr. Millen took up the duties as Curator of the new Botanic Station which was started in Tobago, in March.

The staff is now as follows :—

1 Superintendent, J H Hart, F.L.S.; 2 Curator, Tobago, H Millen; 3 Assistant Superintendent, W Leslie; 4 Clerk, H C Massy; 5 Gardner, Government House, J Bailey; 6 Cacao Instructor, Tobago, W E Caines; and 7 Herbarium Assistant, Pauline McLean.

METEOROLOGY.—The rainfall of the year was very small, and the driest since 1885, only 46·76 inches having fallen. In 1885 only 43·22 inches fell.

HERBARIUM.—Over 200 sheets of specimens have recently been returned from Kew where they had been sent for determination. Among the plants new to Trinidad, are several Mainland species, as was to be expected. Last year I recorded the determination of a new species of Lucuma, and I have collected seed specimens during the year which show that there is yet another undescribed species, of this genus to be registered for Trinidad. Growing seeds were secured, and we have numerous young plants at the Experiment Station at St. Clair where the plants can be grown on to maturity. Cacao disease has demanded attention, and a report received from Mr. Massee of Kew shows that in all probability the diseases prevalent in Trinidad are similar, if not identical with those of Ceylon. The disease causing the death of Tangerine oranges has also been studied during the year and found to be due to a micro-fungus which attacks the stem of the plants at the ground line. This was sent for examination to Kew. Mr. Massee's report runs as follows :—

DECEASED ORANGE TREE FROM TRINIDAD.—The tree has been killed by a fungus called *Botryodiplodia diplocarpa Ellis & Everht*, which appears on the surface of the stem under the form of black warts that have burst through the bark. The fungus was first observed attacking orange trees at Pointe a la Hach, La, U. S. A. (Signed) GEORGE MASSEE, 8th January, 1900.

This fungus is most destructive to varieties of *Citrus nobilis* (Tangerine, Manderine, &c.) and also the St. Michael's. It is less so to the Seville or bitter orange. It is probable therefore, that by grafting on the latter stock, the effects of the disease may be largely mitigated. In some districts in Trinidad it is almost impossible to get the Tangerine to live but for a short time, and many trees are suddenly killed out, which a few weeks previous were pictures of health. The disease is seldom discovered until it has gone beyond remedy, and I would therefore counsel frequent examination of the stems at the ground line, and when found to be effected they should be dressed with a wash of sulphate of copper and lime, which we have commenced to use apparently with success.

Margravia elegans, Kr. & Urban; M. Hartii, Kr. et Urban; Duguetia lucida, Urban, and *Inoa Hartii, Urban*, are the names of four new species sent on to us from the Berlin Herbarium. *Polypodium lijuccanum*, Radd., was also registered for the first time as a Trinidad plant during the year by our *confrère* of British Guiana, G S Jenman, Esq. In 1895 I reported that the Herbarium Cabinets were full, but as yet no new ones have been added. This work will be more conveniently carried out at St. Clair, and will be commenced I trust during the ensuing year. Our Cabinets are all made of West Indian Cedar *(Cedrela odorata)* from trees cut upon the Establishment, and are made by the regular employés of the department.

Considerable interest has lately been shown in connection with leguminous plants as agents by which nitrogen is made available in the soil for the use of other plants.

Several genera and species have been examined, and the nodules containing the nitrifying bacteria have been examined, the bacteria found, coloured, and mounted for future reference. The "Saman" tree, *Pithecolobium Saman*, has been found to produce *nodules* containing abundant bacteria.

A very large number of specimens of the local flora have been brought in during the year, dried and mounted; and our work in the old quarters is now cramped for want of room. His Excellency the Governor has authorized a provision on the estimates of £500, for the erection of a new office and Herbarium at St. Clair, where ample room will be arranged for. The Herbarium will be transferred as soon as the new quarters are ready, and subsequently all office work of the Department will be done at St. Clair. Provision has also been made on the Estimates for a new microscope of modern pattern with apparatus for biological work; and in the new quarters a suitable room will be provided for its use. The microscopic work on the cacao fungus, carried on during 1899 in the Trinidad Herbarium, elicited commendations from the Director Royal Gardens in the Kew Bulletin, when reporting work on the fungus by the Kew Staff.

Reports on the above were published in the Trinidad Bulletin at the time they were received. The main points were, first: That a fungus, *Phytophthora omnivora*, was found to be very destructive to full grown cacao pods; second: A fungus *Nectria Bainii* was also found upon the pods, whether parasitic or not has not been determined: third: Upon the bark of cankered trees another species of *Nectria* was also found which is supposed to be similar to that causing canker in Ceylon. (Signed) —GEORGE MASSEE.

EXPERIMENT STATION, ST. CLAIR.—All the work on the new establishment was last year recorded under the head "Economic Section." The new station is, however, primarily, an establishment for carrying out the larger portion of the work of the Botanical Department, and embraces Agricultural, Horticultural, Arboricultural and Botanical duties, with various sub-divisions. The station itself is divided into three principal sections. The 1st or eastern section is principally devoted to fruit culture. The 2nd division is being laid for Botanical purposes chiefly, and will contain the new offices of the Department (shortly to be erected) and all cultivations of Botanical interest, or of scientific and decorative value. The third division is laid out in trial plots for the various economic plants, and for the raising and testing of seedling canes. It contains the nurseries, tool houses, experiment and potting sheds, propagating houses, stables and work-yards, &c., &c.

The work carried on by the Department when all arrangements are completed will be as follows :—

1. Agricultural and Horticultural experiments and trials including the raising and testing of seedling canes.
2. The propagation and distribution of timber trees, economic and decorative plants (by sale or otherwise.)
3. The cultivation and trial of different classes of native and imported trees and plants of Botanical interest.
4. The study of diseases of plants, occasioned by insects, fungi, &c., &c.
5. The collection from forest and roadside of Botanical specimens, in view of the preparation of a Flora of the island of Trinidad, and for scientific reference.
6. Collecting, importing, and growing the best varieties of tropical fruits, to prove their value for Trinidad.

7. (A.) Training men and boys in Agricultural and Horticultural work. (*B.*) Training young men after leaving school who intended becoming Planters. (*C*) Providing lectnres for the school teachers of the Educational Department, who are to teach Elementary Agriculture in schools.

8. Distributing information by Bulletins, Reports and Correspondence.

9. The importation and growing of newly discovered plants from various countries.

10. The maintaining of exchanges of plants, seeds and specimens with Botanical establishments—Foreign and Colonial.

11. Conducting Agricultural Examinations of men boys, cadets, school teachers, &c., &c.

12. Keeping and recording Meteorological and Seismographical Observations.

13. Overlooking current Foreign and Colonial Literature and Exchange, for articles on tropical ultures likely to be of use locally.

14. Inspection of Railway Stations annually. Official attendance at Agricultural Society's meetings, and other miscellaneous duties.

Mr. Leslie who was appointed to the department as Assistant Superintendent, has immediate charge of St. Clair, and is practically its "Curator." The work is, however, directed by the Superintendent, who makes long visits for the purpose, and who, when the department office is ready, will of necessity spend the greater part of his time at this establishment. The St Clair Establishment has been proclaimed under the Ordinance No. 33 of 1898 as set apart for the cultivation of vegetable products, and Regulations have been made for the good government thereof.

PEPPER NIGRUM.—Some few years ago an attempt was made to grow and fruit Piper Nigrum which was partially successful, and ripe berries in fair quantity were produced. Many of the vines planted however did not assume the fruiting stage. It was observed that during the vegetation period the leaves of the vines were *cordate* in form, but that when fruiting is about to commence it may be known by the difference in the shape of the leaves, as the plant is then clothed with leaves which are decidedly *lanceolate* in form. As soon as the latter appear the flowers follow.* Grown as we now grow it, the crop sets and ripens readily, and we are able to obtain yearly supplies of well ripened berries, these have been in some demand for seed purposes with European seedsmen, our vines being the most easily available, and probably the only source of supply in this hemisphere. The vines are planted at the foot of trees of *Erythrina corollodendron*, which are planted in rows ten feet apart and six feet in the row. There appears to be no special difficulty in growing regular crops, as we have had them under these conditions for the past four years. Much has been said about male and female forms of vine, but it has been observed here that when planted in a proper place and under suitable conditions, all the forms of *Piper Nigrum* will seed freely. There is a form, however, which if propagated will fruit when in a diminutive state and does not climb, which produces berries at one foot from the ground. We have one-tenth of an acre of *Piper Nigrum* at St. Clair growing extremely well.

RUBBER—(*Hevea brasiliensis*) "*Para Rubber.*"—This tree grows well with us but the yield of *latex* appears from a single experiment to be insufficient to warrant its being largely planted except on swampy or riverside lands subject to floods. Our largest tree has a girth at 3 feet above ground of 58 inches, and is 40 feet in height. Young trees at St. Clair planted in ordinary soil in July 1898, are now 14 feet in height, and in diameter at the ground line 1·6 inches. Our largest tree bore a shot crop of seed this year, but sufficient plants have been raised to satisfy the demand. Trees of *Hevea confusa* are bearing seeds, but these have not been largely sown as the rubber produce by this tree, so far, is found to be of inferior character.

We recently sent seed safely by post from Trinidad to British Honduras. From seeds of the Orinoco rubber sent us by Dr. Bovallius only four plants were raised. These have been planted out and are growing slowly on our south-western boundry, St Clair. *Kicksia Africana* or "*Iré Rubber.*"*—Our block of this, is one-fifth of an acre in extent, the oldest trees of which are over 8 feet in height. They commenced flowering early in 1899, and towards the end of the year several have seed well advanced to maturity. In my last Annual Report, I called attention to the fact that a species of *Kicksia* was said not to produce rubber. That our plant produces good rubber is not left to doubt, as rubber of excellent quality has been made from it. A specimen of the fruit has been sent to England by request of the Kew Authorities to determine points of nomenclature which had arisen. The tree appears to thrive in our climate, and if it will produce sufficient rubber must become valuable. We shall be able at an early date to test the trees. So far there appears to be abundance of *latex* even in the driest weather; although the tree can stand a large amount of sun, it appears to grow quicker in the young stage when it is fairly shaded.

Central American Rubber.—(CASTILLOA ELASTICA).—This plant thrives well in Trinidad and has proved itself very hardy under trying conditions. We have reports which show that although the weather has been extremely dry, many lots of plants have stood the hardship extremely well. Several thousands of plants have been sold and also large quantities of seed. Our largest tree planted by Mr. Prestoe many years ago is over 60 feet in height and yields large crops of seed yearly. A tree planted in 1888 is over 40 feet in height and 51 inches in girth at 3 feet from the ground. It yields abundant latex. The plantation of this rubber made at St. Clair in July 1898 has grown well, some of the plants are 11 feet high and over 2·86 inches in girth at the ground line. Later on, it is intended to test these trees for *latex*, and they are planted thickly for the purpose.

A simple machine has been brought out by Messrs. Christy & Co. of 25, Lime Street, London, for preparing the latex from Castilloa. It is called the "Beta" Separator and is an improved creaming or washing process. Rubber made with one of these machines has been shown and pronounced very fine in Mincing Lane, London. The machine is simple in the extreme, and its working easily understood from the concise direction issued. It can be worked by a man and a boy, and will coagulate 50 to 100 lb of rubber per day. The machine is small and sufficiently handy to be carried to the trees, but a stream or well of clean water is required for washing the *latex*. Castilloa promises the best of any of the rubbers, so far local cultivation.

THE DATE PALM, *(Phœnix dactylifera,)*—For many years seedlings of this plant have produced fruit and seed very freely, the size of the fruit varying on different plants. Learning that the best kinds of dates were borne by trees raised from "suckers," an application was made to the Government to allow of an importation being secured of the best marketable kind. It was ascertained that these could be obtained from Algeria, and a vote was sanctioned in 1899 Estimates for this purpose, a part of which was expended in preliminary expenses. It is intended to plant these trees in a small grove at St. Clair. The Date Palm has always been associated with the arid Desert, and formerly everyone was content to grow them in the driest and poorest possible position. It now appears that the best Dates are grown in rich valleys. By following this initiative, it is hoped that we may succeed in producing good yearly crops. Our trees are expected to arrive during 1900. The fruit of our seedling trees like all other seedlings, is variable in quality, but in some instances sweet and wholesome, though too small to be of value.

COFFEE.—*Coffea Stenophylla.*—The plantation of *Coffea Stenophylla* in common with everything else has suffered from drought, but in the best shaded por-

* See figures I. and II.

* Now Funtumia elastica.

tions, the trees are doing well. Our largest trees at the old garden have again borne well and the coffee produced has been shewn to be excellent in quality, the bean resembling that of the Mocha variety of Central Arabia. Among the seedlings raised are plants so distinct from the type that there can be little doubt that they are either natural hybrids, or widely ranging seminal varieties. These plants have flowered and the flower is larger than that of the type and somewhat different in form. When the fruit appears there will be further indication of origin, as the purple colour of the berry of the type is a well marked feature. In the second year's showing, there has also appeared one or two of the same type. The leaves are larger, darker in colour, and the plant grows and stands drought and sun far better than the type.

ABBEOKUTA COFFEE.—Trees of this coffee have fruited for the first time, and their appearance indicates that this kind is merely a form of *Coffea Liberica*. It has, however, a somewhat different habit of growth, and appears to be even hardier than that kind, and stands the sun better. The berries are much smaller than Liberian and have much less mucilage surrounding the parchment covering, yet the beans are of fair size. It is a kind which deserves extensive trial.

MINERVA COFFEE.—This coffee has again produced a good crop, and I consider is one to be highly recommended for general culture. This year's crop has been largely sold to French buyers for their Colonial possessions but sufficient is on hand to supply the local demand.

GOLDEN DROP COFFEE.—This is an Indian variety planted at St. Clair, as reported last year. It is now flowering, and a crop of fruit will, I trust, be ripened in due course. It is extremely healthy and is growing rapidly and well.

ORANGES (*Citrus auran tium.*)—The orange trees in the avenue planted last year have grown well and produced fruit, but have been attacked by fungus at the base of the stem. Some little attention has been paid to grafting and budding oranges and a few of the best varieties have been secured, but for want of proper appliances (which it is hoped to provide this year) no large numbers could be worked off. It is found that neither grafts nor buds can be depended upon to grow if left in the open; and close cases to maintain a certain and regular humidity, must be put in use, before any quantity can be established in this manner. In a large grove of some 2 acres of seedling oranges planted by my predecessors there is ample evidence of the variation which occurwhen the sweet orange is raised from seed; for all though the oranges have a family likeness, still, the flavour and character of the pulp is found to vary in a very wide degree, for on no two trees is fruit to be found the same in appearance and quality. The following testimony in favour of Trinidad oranges has been received from His Grace the Duke of Rutland, to whom a small parcel was sent from trees growing in the Garden attached to the Superintendent's quarters:—"I thank you heartily for the basket of Trinidad oranges. They were served at desert yesterday and voted excellent. They were ripe, with thin skins AND OF FINE FLAVOUR. Such oranges ought to command a ready market in England, and I hope the efforts you speak of will have the effect of opening a good market for them here. (Signed) RUTLAND."

BERGAMOT ORANGE.—A section of land one-tenth of an acre is planted with seedling Bergamot oranges. The plants were raised from seeds received from the district in Italy whence comes the famous Bergamot oil. The variation in the leaves of these plants is clearly marked. Many so called "Bergamots" exist in the West Indies, but it is doubtful if any of the best oil producing kinds exist. The variation is perhaps more marked than with any other species of the *Genus, Citrus*; but it is hoped that some of our seedlings will prove to be the true oil producing variety. To make sure, however, that we have the right kind, we shall endeavour to import grafted plants direct from the districts known to produce the best oils.

TANGERINE ORANGE *(Citrus nobilis).*—A grove of the above, planted in 1892, has fruited for the first time this year, and the flavour and size of the fruit is quite as variable as with the ordinary sweet orange. It must therefore be concluded that no reliance can be placed upon any variety of the Genus, Citrus, coming entirely true from seed. Two trees of the variety of *Citrus nobilis* mentioned in former reports, as the "Grenadine" orange fruited together during 1899. These two trees were raised from seeds taken from a single Grenada fruit in 1883. The one tree produced fruit four to five inches, while the other gave oranges only two to three inches in diameter, and the quality and size were equally at variance.

FODDER PLANT (*Pennisetum tri florum*).—This is a grass originally introduced and grown in Jamaica at the Government Cinchona plantation, while the writer was in charge. It was sent from thence to the St. Lucia Station, and thence on to Trinidad. An accurate area of one-fortieth of an acre was planted and cuttings were made as follows:—

July,	1899 ...	407 lb.
August,	,, ...	443 ,,
October,	,, ...	279 ,,
December,	,, ...	246 ,,
		1,378 lb.

This gives a value of nearly twenty-five tons to the acre per annum of the green product. The experiment will be continued to determine its value in comparison with other grasses. It is certain, however, that the unedible portion is quite small when compared with the popular Guinea grass, but this must be shown exactly as also must the loss in drying to enable its true value to be ascertained. We hope to get a full analysis during the coming year in connection with these details.

FRUIT TREES.—A number of the best varieties of MANGOES have been planted, and the following kinds are growing freely:—Gordon, Peach, Malda, Peters, *Amelie, Divine Julie, Chinoise*, or Chinese, Father Louis, De Boissiere, No. 11, *D'Or*, Mistake, Nina, Apricot, Maraval, *Dudouce*. A large area of seedlings have planted to prove the amount of variation from seed. Our best kinds of mangoes have been largely propagated by grafting, and the demand is steadily increasing. Grafted plants of the best French kinds were introduced from Martinique, and His Excellency the Governor has sanctioned the importation of sets of the best East Indian kinds from Bengal, Madras and Bombay, which it is hoped will add to our list of first-class kinds. It is to be noted that trees of the old East Indian kinds were introduced under the names of "Malda," "Peach" and "Peters." Looking up the nomenclature in Watt's "Economic Products of India," it appears that in "Malda" we have the name of a race or class of Mango, and it cannot be doubted by those who know them that the three fruits mentioned are simply varieties of the one class, and indeed little worthy of distinctive names. Dr. Watts after stating that he is indebted to Mr. Maries of Darbhangah for the information states: "The cultivated Mangoes of India have arrived at a great stage of perfection and consist of very numerous races, although these are unknown to most people, except as Bombay's, Lungrah's, and Malda's. The many dozens of sorts sold in the Bazaars under these three names have given the idea that there are only three Mangos fit to eat. These three names really represent three distinct strains of cultivated fruits. It is interesting to note the changes that have taken place in these fruits. The form and shape has continued almost the same as the wild varieties, but the flavour has developed from "*tow and turpentine*" to something too exquisite to express in words, each variety having a flavour of its own." From a following paragraph it is apparent that the East Indian kinds have been secured by practising

selection from seedling kinds, for Dr. Watts says: "The sweet ones were allowed to grow while the sour and worthless were cut down and used as firewood." Mr. Maries reports further of the cultivated sorts of Mangos, he says: "I have collected upwards of 500, and from these have selected 100 good ones; and these have been grown on model plantations." A numerous list of varieties with Indian names is given, among which appears the "Peters" and "Malda." The "Afooz" is the so called Bombay Mango, of this it is said: "It is really not a Bombay fruit at all.' The Bombay Mango of the upcountry gardens is said to be "Durbhangah Bombay." Of the Gopalbogh it is said "A Malda sort." This is the celebrated Malda kind said to be equal to the "Afooz." The "Afooz" is classed with the "Malda" and all are of the so called Bombay type. It is to this class that the Mangos belong—called in the Trinidad garden "Peters," "Peach" and "Malda." The "Gonraya Malda" is spoken of as one of the finest Mangos of India. A second class of Mangos is called Kerbuzza Mangos, called Kerbuzzas or Melons from the musk scent they possess. Of these it is stated there are three good kinds. The third class of Mangos are called Budayas or true Malda's and of these several varieties are mentioned. Two other classes are noted but the produce is of no importance.

It will thus be seen that the nomenclature of mangos is somewhat indefinite, even in India, and considering the numerous seminal varieties which have sprung up since the introduction of the tree to the West Indies, it is not to be wondered at that differences of name should arise in the Western tropics. Our work in Bulletin giving figures of the varieties will help to correct the nomenclature in no little degree, as has already been seen.

Fibres.—A section was devoted to the growth of of the native Abutilon *Aperiplocifolium*. The produce was sent to England and reported on as being worth £16 per ton. The facility with which this fibre can be prepared by hand, points it out as a suitable article for cultivation where cheap labour can be had.

The yield was as follows:—1—Per acre. Raw material 1·08 tons; 2—Percentage of dry fibre obtainable from raw material 42·6 per cent; 3—Yield per acre, dry fibre 9·25cwt; 4—Value per acre £7 8 0.

Sisal Hemp.—The plant producing Sisal Hemp (*Agave rigida var. sisalana*) grows very fast in Trinidad and produces fibre of the finest quality. I do not consider however that it is likely to be largely planted, while Cacao and Sugarcane can hold their own. A nursery reserve is always maintained and plants can be had at all times.

Yams. (*Dioscorea of sps.*)—The cultivation of yam has been continued, and the 1899 trial gave following return:—

Variety.	Average yield per plant.		
Red yam	11 plants gave	7 lb.	per plant
Seedling	11 ,,	9·27	,,
White yam	50 ,,	17 58	,,
St. Lucia	16 ,,	25·18	,,
Cush-cush	66 ,,	6 07	,,
Negro yam	19 ,,	17 57	,,
Yellow yam	5 ,,	10·00	,,
Chinese yam	10 ,,	19·80	,,

The "St. Lucia" yam is a large and coarse white kind of very good flavour. The "Negro yam" is the best white yam of the set, and the "Yellow yam" is the best of the other kinds. The Red yam is a variety of the ordinary white, and is of good flavour.

Sugar.—Mr. John Turner, Attorney for the Straits Sugar Planting Co. Ltd., has recently been prospecting Batu Pahat in Johore, with a view to obtaining a concession of 500 acres of land there, for the purpose of sugar planting. The Company is making giant strides, in the direction of extending its sphere of labour and business.—*Perak Pioneer*, June 20th.

A FARMER'S EVERYDAY LIFE.

(*By Cosmopolite.*)

No. VIII.

The latter part of the month of May is devoted, almost entirely, by farmers to getting the ground ready for

THE TURNIP CROP,

and in sowing the seed, what with ploughing and grubbing the ground, collecting the growth, setting up the drills, and then manuring, covering and sowing the seed, this may be considered the most important and most laborious work in connection with the cropping of the land. According to the rules of good husbandry the allowance of manure to the acre is estimated at 12 loads of cattle and 5 cwts. of artificial, but as I have already stated, not being a believer in the latter class of manure, I, in preference, put 25 loads of cattle or other bulky manure to the acre, and find that although entailing a much greater amount of carting and labour in general, the result is always a very much better crop. The idea of using artificial manure at all is in order to bring the plants rapidly up to the hoe, and for this purpose quick-acting fertilizers, such as superphosphate, nitrate of soda or potash are used, but as a matter of fact if the land is in good heart, no such assistance is required, and I find my turnip plants ready for hoeing, without any help from artificials, quite as soon as those of my neighbours; and not having been forced at all, they run less risk of *setting* and are in no danger from canker or finger and toe disease. When I first came to this farm the turnip break was so diseased that about 20 loads of roots to the acre was all the crop I got, but 40 to 45 loads is now my average, and disease is unknown. I may say, therefore, without undue boasting, that my system has proved both satisfactory and profitable. It is not my desire in these articles to lay down the law to any one who intends to adopt farming as a pursuit; I merely wish to give instances in my own experience which appear to me to have worked out more successfully than would have been the case, had I followed the rule of thumb-style of procedure, so common amongst agriculturists. Who am I that I should dogmatize on a subject that has been before the public ever since Adam delved in the garden of Eden, and for the first time set his early ash-leaf kidney potatoes, or whatever his specially favorite vegetable was. If I wished to give a reason to my readers as to why they should believe in the system of farming which I have adopted in opposition to the customs of followers in the old beaten track, I might hint at my own age and the many years I have devoted to farming, but I know that that would be considered but a feeble reason and I might bring upon myself the accusation of being my own brass band, for in this age of free education and enlightenment, we do not hold the aged in respect because of the experience they have gained, but because it is mostly the old men that have all the money. But to return to my muttons—and for want of a better, le

MUTTON

be the theme of my following remarks.

Last autumn the price of breeding ewes, for some reason or another, went up very considerably, and at the same time a drop of several shillings per head took place in the price of feeding sheep. In this district every one began plunging on the former class, while the latter kind were practically unsalcable and as is my usual custom I at once proceeded to do what my neighbours were *not* doing and rushed all my breeding ewes into the market, where I got extravagant prices for them, filling their places at home by the purchase of feeders. I had remarked that owing to drought in Australia the statistics of that country showed a reduction in the number of sheep there of 20 millions, which in my opinion meant a shortage in the supply of frozen mutton to this country. The war in South Africa, which had just broken out, I knew would be the means of diverting transport vessels from their regular beat between this and America, and so the supply of cattle and sheep from the West would undoubtedly be curtailed. Putting therefore two and two together I felt convinced that fat sheep would be booming in the near future, so I plunged to a certain extent, and bought a few hundred more than I usually do at that season. Things turned out exactly as I had hoped they would, and mutton has been throughout the past six months higher in price than for 18 years and the sheep which I bought in autumn, I have resold at from two to three times the price I paid for them. Nothing surprises me more than the indifference paid by my brother farmers to

THE PRICES QUOTED IN FOREIGN MARKETS

when, if they would only take the trouble to think for a moment, it must be patent to them that it is the foreign market which rules the home one and not *vice versa*. The grain merchant who purchases my oats asked me once, how it happened that I always sold to him just before a big drop took place in the price of corn. My answer seemed to surprise him. I told him that in my foreign papers I noted when a number of ships laden with oats cleared for this country and calculating as to the time when they might be due here, I sold the week in advance--before the importation had brought down the price. He seemed to think that I exhibited a vast amount of cleverness in so doing, but I myself fail to see it in that light, merely considering my action as that of one of ordinary common-sense. There are some who might object to doing as I did with regard to the purchase of feeding sheep as being of too speculative a nature; but speculation enters into every action that one does, even to going to church. How often does not put a rupee into the plate at the door of the Kirk, fondly hoping to hear in return a sermon worth more than that sum, and yet finds that the discourse which he is favoured with cannot be valued by the most liberal of valuators at more than two annas! In another case, however, my foresight was at fault. I read, in my New Zealand papers, that owing to the war

THE PRICE OF OATS

in that country had gone up with a bound from 8s to 16s per quarter, and naturally I concluded that we home farmers would benefit also, so I held my crop for a rise. Alas! however, the rise never came, and rather than sell at the price offered by the grain merchants, I fed my sheep on oats, and refused to buy feeding stuffs from the dealers; so that they, by refusing to give us the rise which we were justly entitled, to lost two commissions, one on the purchase of grain, and one on the sale of feeding condiments. I speak in the plural because I succeeded in persuading many of my neighbours to do as I myself was doing, and so this has not been a very successful year for the grain merchants, who, no doubt, will bear this in mind when we have another little war on our hands, and when, I hope, they will give us poor down-trodden farmers, the rise in the price of our grain to which we may be considered justly entitled.

PLANTING IN SUMATRA.

NOTE FROM SERDANG : EAST COAST OF SUMATRA.

The Coffee Dealers are having a long innings this time at the expense of the unlucky producer. Four years or so ago, Liberian Coffee was quoted for a considerable time in Singapore at $45 per picul of 133⅓ lb, the top price touched, if I remember right, being $57·50. Then without a word of warning, it went "just plunk," as they say in Drumtochty, to $16 and slowly recovering to about $20 has remained there or thereabouts for a weary enough time. For a few days last January and February it received to about $25 and many of us were then hopeful that the cycle of low prices was at end, and better days were in view: but it appears that we were mistaken and the last Singapore quotation is $19 only. Verily pride goeth before a fall, and a haughty spirit is brought low by over-production. It has however been proved that a stand-out lot will always command its own figure in Europe, and the secret of a good sample of Liberian Coffee is quick drying.

Our stand-by in Serdang as I have written before is

CROPS.

These continue abundant, and low prices are not such a serious matter as they would be in less favoured parts. Pests are fortunately almost unknown. The foe H V is like the poor in that it is always with us. But, thanks be, our poor are few and far between ; and no one's rest is as yet disturbed by dreams of leafless estates. The conditions are much in our favor. The soil is, as I have often remarked, first class, and there is no overcrowding. The total area under coffee in not 15,000 acres, and all this is interspersed with jungle, big and small, and lalang.

It is worth noting that a bad tree is invariably bad

FROM THE ROOTS.

Be it bad with leaf-disease, canker, or even attacked by caterpillars, pull it up and you will find the roots either double fanged, cork-screwed, bumble-toed, or club-footed. To me the most remarkable thing is the avoidance of healthy trees by caterpillars. We have no Egyptian plague of these, as in the Native States a year

or two ago, but occasionally there is a small visitation of a beast that appears to be the same as the cinchona caterpillar which wrought such havoc in Ceylon in years gone by. But in no single instance have I known it attack a healthy tree. It is ever useful in young coffee in drawing attention to "wasters" which otherwise might escape notice. Out with such an one, and, as sure as cows have tails, the roots will be found defective.

It should further be remembered that here in Serdang, coffee is a comparatively new introduction and its natural enemies when attempting to establish themselves find, owing to the richness of the soil, such a lusty bush, that they can make little or no impression on it, and retire discomfited. I may in fact say that a bad plant is only owing to bad planting.

W. T. M'K.

10th June.

IMPORTATION OF TEA INTO FRANCE (EXPORTS DEDUCTED.)

[Extract from *Le Travail National*, 13th May, 1900.]

Years.	Kilos.	Increase per cent.
1880 ..	408,000 ..	100
1881 ..	438,000 ..	107
1882 ..	456,000 ..	112
1883 ..	491,000 ...	120
1884 ..	523,000 ...	128
1885 ..	473,000 ..	116
1886 ..	542,000 ..	133
1887 ..	543,000 ...	133
1888 ...	491,000 ...	120
1889 ..	523,000 ..	128
1890 ..	603,000 ..	148
1891 ..	602,000 ..	147
1892 ..	645,000 ..	158
1893 ...	676,000 ..	165
1894 ..	692,000 ..	169
1895 ..	718,000 ..	174
1896 ..	754,000 ...	184
1897 ...	765,000 ..	187
1898 ..	826.000 ..	202
1899 ..	876,000 ..	214

Remarks.—This represents the excess of imports of tea into France over exports. Much tea is imported into France and held in Bond in Marseilles and elsewhere for exportation to Switzerland, Spain, Italy Algeria, Morocco and Dahomey. Some even goes to Turkey. None of them is shown, nor does it shew the country of origin.

THE BANANA AND TYPHOID.—The uses of the banana are claimed to be many and various. The latest is both unique and important. According to the belief of Mr. William C Usery, M D of St. Louis, the banana is the very best food obtainable for typhoid fever patients. In this disease he explains, the lining membrance of the small intestines becomes intensely inflamed and gorged. Eventually it begins sloughing away in spots, leaving well-defined ulcers. At these places the intestinal walls become dangerously thin. A solid food, if taken into the stomach, is likely to produce perforation of the intestines, and dire results will follow. Therefore, solid food or foods containing a large amount of innutritious substances are dangerous, and are to be avoided. The banana, although it may be classed as a solid food containing as it does 95 per cent nutrition, does not possess sufficient waste to irritate these sore spots. Nearly the whole amount taken into the stomach is absorbed and gives the patient more strength than can be obtained from other food.—*P M Herald*, June 20,

INDIAN TEA SEASON 1990.

PRACTICAL CRITICISM OF CURING AND MARKET.

The two opening sales of the season have, so far, not done much to raise a planter's spirits, for the prices obtained are very near the cost of production, in some instances below. The brokers say that, so far, no good teas, or teas of special merit, have as yet turned up, but we fail entirely to see how this can be the case from all districts. It is quite possible that one or two districts might show inferior quality, but the universal condemnation takes us somewhat aback. If it is true, the sooner an enquiry is made into the cause the better it will be for the industry, and at present an excellent opportunity for the New Agricultural Chemist just arrived for proving his merit. We can scarcely put it down to our planters having lost their cunning, for every year sees them supplied with new machinery, supposed to be of a modern and better type, and with closer attention to plucking and cultivation, we must say, we fail to fathom it. In former years Assam teas commanded a very much higher average than the other districts, but sales so far this year bring those down to the level of Cachar and Sylhets, and considering how much more expensively the Assam Valley gardens are worked than those in the Surma Valley, the same prices spell ruin. In former years, there were many notable marks in Cachar especially, that commanded Assam prices, but, lo! the mighty have fallen also, and those marks which it would be invidious to mention are down on a level with the "ruck." Can the brokers or agents explain how this phenomenon has come about? for phenomenon it is. The teas, so far as one can judge by appearance, are as good as ever they were, yet they don't bring the money—and this is the main thing. Has the exhaustion of the soil anything to do with it? Have the seasons changed, or what? There is no doubt the chemistry of tea is in its infancy yet; but still, we fail to see how teas turned out in identically the same manner, with better machinery, fetch annas less per pound than they did even, say, a couple of years ago. Has anything gone wrong with the new machinery that the planter did not bargain for? Do the new dryers not retain the volatile oils so well as the old ones, or what? The brokers may, we allow, underestimate the dullness of the market, but they cannot surely do this so much as the extent of the drop in prices would lead one to believe. Allowing for a drop of, say, two or three annas within the last three years, *i.e.*, about an anna annually, the average price of the whole crop sold in London does not indicate this over all: but it is most distinct in particular cases; and it is this we would like to see explained away satisfactorily. Has the new drying machine deteriorated the leaf in manufacturing, producing only what a broker would call a *dry* tea, *i.e.*, a tea without much in it? Another point worthy of consideration is the amount of rolling given. This has been gradually increasing until now nearly double the time is given on the rolling table to what was a few years ago. Has this extra rolling anything to do with the poverty in cup? We do not say that these, or any other processes during manufacture (to which we may allude), are answerable for the poor teas now being produced; but merely suggest them as points for our practical planters to consider and weigh well. There has been also a great craze for cool fermentation or oxidisation, but we do not know how far the industry has been benefited by it, or

if any planter could say what actually has been the benefit. Then, again, the planter may be wrong in his modes of cultivation, and thus tend to weaken the bush; but this question should soon be set at rest by Mr. Mann, who has come out from home with very high certificates of merit, and there is no doubt there is ample scope for his abilities in the different districts, and it is fortunate he has been engaged for a number of years. A few years ago, when *bhil* gardens were opened up, there was a great hue and cry about their produce, that there was nothing but water on infusion in the cup, &c., but if one looks over the sales nowadays there is nothing like the difference existing in price that used to be the case; and Sephinjuri Bheel Company this year, with between a 6d. and 7d. average, have done almost, if not quite, a record in profits. Undoubtedly the 2d. per lb. extra duty has had a good deal to say to the great depression now existing; but we consider this is now as much below reality as the opening sales of 1899 were above that, and although we do not think 1900 will be a record year for prices, we think that prices just now are unduly depressed, considering that the figures of export are only about half last year, and are probably a true index of the state of manufacture in the districts. The Dooars are all behind, we believe, as also many parts of Assam, Cachar, and Sylhet, which, as we are now getting well into June, means an average crop; at any rate not a bumper one like last year. With the war now nearly over we hope the market may look up a little; but we trust our planter friends will try and solve the reason of the poorness in cup, and be able to counteract it, either by other modes of manufacture, or improved methods of cultivation, or both combined.—*Indian Planters' Gazette.*

TEA WEIGHING IN LONDON.

NEW CUSTOMS REGULATIONS, 1st JUNE, 1900.

The following is the wording of the Customs General Order 42-1900 *re* Tea Taring, which came into force on the 1st June, 1900.

"When the scales have been carefully balanced, a half pound weight is to be placed in, or attached to, the weight scale; the weight of the packages must then be taken to the pound only, the weight scale preponderating according to the usual practice in taring. The half pound weight placed in the scale is to be ignored in recording the tare."

TARES.—In order to obtain full benefit from this new regulation, Managers should arrange that the weight of the empty packages (including, lead, nails, screws, bands, etc.) should be SOME 3 OR 4 OUNCES *under* THE HALF POUND, say for example, 20lb. 5oz. The Customs would then take the weight of the package as 20lb.

GROSS WEIGHT.—Having made the tares of an equal weight, the package should be filled with as much Tea as it will conveniently hold, the gross weight to be A FEW OUNCES *over* THE POUND.

There being no occasion for the net weights to be alike, it is unnecessary to crush the Tea into any particular package.

As the Customers disregard all odd ounces in weighing gross, it is not to the advantage of the Producer for the package to weigh many ounces over the pound, four or five being sufficient to allow for evaporation, leakage and variation in scales.

The following are examples of good and bad packing under the new Customs methods of weighing:—

GOOD PACKING.

	lb.	oz.		lb.
Actual gross weight of package ..	124	4	Taken by Customs as	124
Actual Tare of package	24	4	do do	24
Actual net weight of package ...	100	0	Taken by Customs as	100

there being no loss in weight, a condition which could never have occurred under the previous method of weighing, the odd ounces both in gross and tare having been given against the Producer; these totalled from a few ounces to nearly two pounds, irrespective of the one pound draft allowance.

BAD PACKING.

	lb.	oz.		lb.
Actual gross weight of package ...	124	15	Taken by Customs as	124
Actual Tare of package	24	9	do do	25
Actual net weight of package ..	100	6	Taken by Customs as	99

showing a loss of as much as 1-lb. 6-oz., besides the 1-lb. trade draft.

GOW, WILSON & STANTON, *Tea Brokers*, London, E.C

"TROPICAL AGRICULTURIST."—Planters and others who have preserved the back numbers of volumes of this publication will be glad to learn that the long-desired "Topical Index" to the whole 19 volumes will shortly appear and a copy will be forwarded to each subscriber.

REASONING POWER OF PLANTS.—Do plants reason? This seems a strange question but it is asked by the daughter of a prominent Mexican planter, who has been making a series of experiments, and publishing the results in a Mexican newspaper. Among the many expeririments made by this young lady naturalist of Mexico the most suggestive was made with a morning glory plant. This young lady drove a nail in the wall some distance from the tendril of a morning glory plant. The tendril began at once to grow toward the nail. The nail was shifted; the tendril shifted its course. Five times the nail was shifted, and five times the tendril shifted its course. Finally a cord was hung up to tempt the tendril, and it shifted its course toward the cord and left the nail which it had five times persisted in following. The young lady asks: How did the plant know that the nail was there? And how did it know that the nail was shifted? When the cord was stretched at an equal distance away, how did it know the difference between the cord and the nail? She also asks: Why do the tendrils of the morning glory prefer a cord of continuous support, such as a cord, wire, or lath, or rail, rather than a peg or nail, which does not give this continuous support? Why when presented with on equal choice between the two, will they invariably choose the continuous support? After asking a series of questions logically springing from the facts cited and others, she concludes by asserting that plants really reason.—*Indian Gardening.*

THE TEA MARKET.

ANNUAL REVIEW.

38, MINCING LANE, June, 1900.

The issue by the London Brokers' Association of statistics for the twelve months ending 31st May brings an opportunity of looking into the position and prospects of tea, and of trying to find out what light the past season throws upon the future.

The task is rendered difficult by the unusual events which have occurred to disturb the regular course of business and to place the figures relating to consumption in a position which makes them for a time of little value for the purpose of comparison with statistics of previous years.

At the beginning the position was a strong one. The increased use of Indian tea during 1898-99 had reduced stocks to a low point; had raised prices for both Ceylon and Indian to a level which promised well for growers; and had made it evident that larger supplies could be taken here, and were necessary in order to satisfy the demands of other markets. For reasons connected with the nature of the competition among distributors, which we explained at the time, prospects were then especially good for planters who could secure heavy crops at a low cost price, and for those who could produce tea of fine quality. These prospects have for the most part been realized; but results have been very irregular, and the unequal distribution of the good profit attaching to the production of tea has caused embarrassment, and disappointment to many who have been accustomed to rely upon the security of an average yield of good medium quality.

The hope of an active business at the outset was deferred by the dispute arising from the proposal to do away with the 1 lb. draft. A settlement based upon a compromise was agreed upon, but when this was found not to be acceptable to all concerned, Her Majesty's Customs declined to carry it out in face of the objections raised.

A new and more equitable method of

WEIGHING THE CHESTS

has however, at length been adopted, which should to some extent lessen the loss in weight sustained by Importers. It is a difficult matter to reconcile conflicting interests when touching customs of trade, especially when, as in this case, they have the prescription of nearly a century's usage, being based upon the "East India Conditions" prevailing in the days of the old Company.

The friction caused by the dispute subsided, but business was interrupted and a counter-combination was organised by the buyers. To meet this, concerted action on the part of the Indian Importers followed, in order to control the quantity brought to Auction —while the Ceylon Importers, having to deal with a crop arriving all the year round, preferred to go on selling as before.

Opinions differ whether the regulation of the

INDIAN AUCTIONS

has been beneficial. It was probably instrumental in maintaining quotations for common teas, notwithstanding the great increase in their production —which is held by some to account for the decline in the value of good medium grades—but it has not been altogether agreeable to those who had to keep back tea that it was inexpedient to hold. We doubt, however, if the average value of the crop has been affected, for subject to variation in quality this must always depend upon the relation which the total supply bears to the total requirement, and not upon mechanical arrangements governing a week's or a month's sales.

When free supplies were eventually brought to sale the usual active autumn trade developed, marked by the high prices paid for a while for fine tea, and by the anomaly of declining prices for good medium kinds whilst common sorts were rising above the level of last season. Later on came the unfortunate catastrophe in Darjeeling; the signs that production, stimulated by the high price of common tea, was exceeding estimates; and the sharp advance in the Bank rate—affecting the stability of the market.

In January and February the large purchases made by those who anticipated an increased duty enabled importers to sell freely though prices were gradually weakening: but they had not sold enough when the premature announcement of the Budget brought business to a standstill. The incidents connected with the Budget are too recent to need recapitulation, beyond recording that the strain upon the Trade's resources entailed by the clearance of some 40 million lb. in advance of requirements left them unready buyers and was followed by changes in price adverse to holders.

Some time may pass before the effect of the

ADVANCE IN DUTY

becomes clear. The fall in the value of inferior kinds since the Budget is a natural result of superabundant supply, and has, we think, no connection with the higher duty, which would be more likely to increase the demand for the cheaper sorts if, as we fear may be the case, distributors find that owing to the advance in the retail quotations their sale of low-priced teas increases at the expense of those of higher value.

It is so difficult to find a reason for taxing to the extent of 75 per cent of its value a product of British industry now regarded as a necessary of life to the working classes, that reduction of the tax will naturally be expected when the emergency is past; we must, therefore, be prepared for interesting if somewhat restless markets in the future before each successive Budget day.

In the meantime we do not fear any serious reduction in the quantity actually used here, because tea is such a cheap and wholesome beverage,—but hand-to-mouth trading will be more than ever the retailers' policy, and may cause some shrinkage in the quantity cleared. The range of value will depend upon the character and dimension of the crops. It will be well if they are of somewhat higher class than the last crops, for if the supplies show a large increase two years in succession, failing the attraction of better quality, lower prices will be needed to draw buyers and stimulate trade. It must not be forgotten that every producing country has increased its contribution to the world's requirements—the total increase being more than 50 million lb.—and that no market is now likely to be short of stock.

Writing a year ago we intimated that we could use a total of 275 million lb. Had our importations been confined to that or a little more, producers would have done extremely well, notwithstanding high rates of exchange and freight; but 300 millions have been sent (weighing in London 293 millions), an increase of 32 millions upon last season's supply, which has proved to be more than the market could absorb without a reduction in the average value.

It is not certain to what extent

HOME CONSUMPTION

has expanded during the year, the increased clearances since 1st January being misleading. Taking the Board of Trade returns, as the most complete, it is seen that from 1st June to 31st December there was an increase of four million pounds in the quantity duty paid, being at the rate of about seven millions per annum; but during that time common teas were so dear that retailers were working on the smallest stocks possible, we, therefore, think that the increase may have been as much as ten million pounds during the year, an opinion to which the very prosperous condition of trade and industry lends support. On this assumption, had nothing occurred to disturb the figures we should now be recording that about 278 or 280 millions had been used at home or sent abroad, and that in place of the inadequate stocks held a year ago we had now in hand only the supplies necessary for working a trade of the large dimensions now reached.

Believing this to be a reasonable estimate of the position, we contemplate with composure a total im-

portation of 285 or 290 million lb. during the coming season, to include about 150 millions from India, about 110 millions from Ceylon, with 25 or 30 millions from China and Java. This would seem to be as much as will be required; unless, therefore, some limit of production be found, it will be necessary to dispose of larger quantities of Ceylon and Indian tea abroad in order to avoid an over-supply here. The probabilities are that a limit will be reached by natural process, and that neither India nor Ceylon will for the second time give a yield largely in excess of expectation; there is not, moreover, the same inducement to pluck freely as there was a year ago, when common teas were 1d to 2d higher than they are now.

The possibility of

HEAVIER SHIPMENTS FROM CHINA

is a contingency, its total export having recovered from 107 millions in 1898-9 to 115 millions in 1899 1900, but there is little reason to fear it, seeing that the quotation of 6d. for common tea ruling here last year did not attract very much more than when the price was 4½d. The fact is that retailers only use it in the last resort, and *good* China tea cannot be obtained cheaply enough or in sufficient quantity to affect the position. Japan continues a strenuous competitor in the States and Canada, but not elsewhere. The produce of Java finds increasing favour now that so much grown from Assam seed is coming in: the shipments were nearly 13 millions in 1899.

We record with satisfaction an increase in the amount of business transacted by

PRIVATE CONTRACT

sometimes at separate quotations, sometimes at an all-round price, and chiefly in low or medium grades sent in large lines, negotiations over the smaller quantities of finer tea being usually too prolonged to enable much business in these kinds to be adjusted in the time at the disposal of buyers. The drawback of being tied to the Auction Room and the advantage of an alternative have been realized, and it is seen that a free private-contract market open to any sellers wishing to make use of it would lessen some of the difficulties that meet them.

The

STATISTICS

at foot speak for themselves, and disclose a larger business at a lower average price, with steady, if not rapid increase in the Colonial and foreign demand for our teas. With the permission of our friends we add the particulars of some of their Indian crops sold in London.

Wm. Jas. & Hy. THOMPSON.

Summary of the exports to all parts from the several sources of production:—

	1898.	1899.
From Indian (season) ..	157,210,000	175,000,000
Ceylon do ..	119,000,009	138,000,000
*China do ..	107,000,000	115,000,000
Japan (year) ..	40,500,000	45,830,000
Java do ..	9,720,000	12,850,000
	433,430,000	486,680,000

SUGAR AND PINEAPPLES.

We extract the following from the report by Mr. Chas. Ford, Superintendent of the Botanical and Afforestation Department:—

Forestry.—Planting to the extent of 54,582 trees has been continued in the island, and Kowloon in ten different localities, and in various new and old roads where trees would thrive.

NEW TERRITORY.

His Excellency the Governor when travelling in the territory came to the conclusion after seeing the Sugar-cane growing there, that new varieties of cane might be introduced, and at His Excellency's request I have made arrangements for new varieties to be obtained from different countries, some of which have arrived and been planted near Ha Tsun.

His Excellency also obtained two Chatanooga Sugar Mills, which this department had fixed in the new territory, and exhibited the working of to the sugar-growers there. The advantages these mills possess over the native mills may lead to their extended introduction.

I have also obtained improved varieties of Pine-apple-plants from Ceylon, which will be useful introductions to the districts where Pineapples are now cultivated to a considerable extent. The best fruits from the new territory are now brought over to Hong-Kong, and canned at a factory at West Point.—*Gardeners' Chronicle*, June 23rd.

* Not including about 34,000,000 lb. sent overland to Russia, and 64,000,000 lb. of Brick Tea sent abroad in 1899.

BRAZIL COFFEE NOTES.

A correspondent writes to the *Imperio* that the coffee crop along the lines of the Paulista railway is small and of inferior quality.

A telegram of the 25th instant states that the S. Paulo coffee crop has been injured by heavy rains. In districts in which the gathering of the crop had commenced the loss is estimated at twenty per cent.

It may be confidently assumed that the losses incurred in the coffee market through the imposition of quarantines on account of the bubonic pest will have to be borne by the planters. The heavy crops and the large stocks in consuming markets will give the buyer sufficient advantage over the seller to enable him to dictate terms.—*Rio News.*

THE INDIAN TEA TRADE.

The export figures for the year 1899-1900, ending 31st March, are as follows in the Indian Customs Accounts:—

12 MONTHS, 1ST APRIL TO 31ST MARCH.

Tea—	1897-98. lb.	1898-99. lb.	1899-1900 lb.
To United Kingdom	137,655,857	139,245,995	154,161,492
Russia ..	689,271	500,889	467,451
Canada ..	593,532	1,044,256	1,932,943
United States ..	929,704	1,413,624	2,744,854
China ..	565,274	883,307	1,248,857
Persia ..	1,464,394	3,456,791	1,953,900
Turkey in Asia..	1,336,970	2,598,281	2,149,414
Australia ..	6,792,654	6,306,135	8,362,797
Other Countries	1,424,161	2,021,394	2,016,419
Total lb...	151,451,817	157,470,672	175,038,127

For imports we have:—

12 MONTHS, 1ST APRIL TO 31ST MARCH.

Tea—	1897-98. lb.	1898-99. lb.	1899-1900 lb.
From Ceylon ..	1,059,716	1,108,686	570,161
China ..	1,689,564	1,751,653	1,921,826
Other Countries	765,733	799,103	711,124
Total lb. ..	3,515,013	3,659,442	3,203,111

Tea, Cinnamon, Coconuts and Rubber.—Mr. Vigors, in his Administration Report on Kalutara District for 1899, states that about 300 acres were added to the area in Tea, and 297 to that of Cinnamon, about 50 acres of Coconuts; while Para Rubber was freely put out in tea and special lots were likely to be bought to be planted this year with Rubber.

ADVERTISING OF INDIAN TEA.

AMERICAN AND FOREIGN MARKETS FUND.

Indian Tea Association,
Royal Exchange Building, Calcutta, 16 June.
(TO ALL PROPRIETORS AND AGENTS OF TEA ESTATES.)

DEAR SIRS,—I am now directed by the General Committee of the Indian Tea Association to invite contributions from All Proprietors and Agents of tea estates to this Fund for the year 1900-1901.

2. During the past year the Committee of the Association in London in administering the Fund, and in projecting measures for future work, have devoted their attention mainly to three objects. Firstly, to the continuance of the work in America; secondly, to the best means of developing the tea trade on the Continent of Europe; and, thirdly, to the effective representation of Indian tea at the Paris Exhibition.

3. The work in America has been carried on by this Association conjointly with the Ceylon Association. The representative in the United States of the latter body—Mr. W. Mackenzie—has acted during the year as joint agent of the both Associations. His efforts in behalf of the industry have been eminently successful, the quantity of Indian and Ceylon tea taken by the United States and Canada in 1899 being 17,226,000 lb., as compared with 13,609,000 lb. in 1898. This is, the Committee think, a most gratifying increase; and they propose to continue, and, if possible, extend their operations in the coming year both in the United States and in Canada. They will again co-operate with the Ceylon Association; and they are confident that the satisfactory results of the past year will be repeated.

4. The second main object which the London Committee have kept steadily in view throughout the year is the development of the markets in the various countries of Europe. To that end they have deputed Mr. J E Musgrave Harington on a mission of enquiry into the conditions and prospects of the trade in Russia, Germany, Turkey, Greece, Italy, Holland and elsewhere. Mr. Harington is making special enquiries into the facilities now existing in those countries for supplying tea; and also into the question of the possibility of increasing the demand for it. On receiving his report the London Committee propose to follow it up by active measures of exploitation on lines somewhat similar to those adopted in America by Mr. Blechynden. That is to say by an extensive system of advertising; by assisting those already engaged in trade; and by establishing new agencies at places as may be deemed advisable.

5. The work which is being done in connection with the Paris Exhibition is so well known as to need only a passing reference. Every effort is being made to direct the attention of visitors to the Exhibition to Indian tea, and to encourage them to use it. Facilities are also afforded to purchasers for obtaining supplies outside the Exhibition. There is good reason to hope that, as a result of the representation, a considerable impetus will be given to the consumption of tea in France, where at present the trade is comparatively insignificant.

6. I am now to turn to the question of the increased production of Indian and Ceylon teas, which in the opinion of both the London and Calcutta Committees, constitues the chief reason at the present time for extending consumption in foreign markets. From the figures * it will be seen that while production during the past five years has increased by 30 per cent., consumption in the United Kingdom has risen by only 15 per cent. With an enhanced import duty there is not the smallest ground for assuming that in the near future consumption will show a more rapid rate of increase But, on the other hand, it is practically certain that the production of tea will be considerably augmented in the present and following seasons. The extensions now coming into bearing, and the more general application of scientific principles to cultivation, leave little room for doubt as to the accuracy of this assumption.

7. It is therefore evident that unless vigorous and determined measures are now taken to stimulate consumption in countries other than the United Kingdom, it will soon be impossible to avoid an overstocked market and lower prices in London. That those evils should be avoided is essential to the well-being of the industry; and the Committee accordingly now appeal to all Proprietors and Agents to contribute in behalf of the gardens under their direction in order that a comprehensive foreign market programme may be undertaken. What that programme is to be has already been indicated; and ample funds will be required if it is to be carried out in an efficient and satisfactory manner.

8. The Committee would particularly appeal to all Proprietors and Agents who have hitherto held aloof from the Fund. That the extension of consumption in foreign markets has now become a matter of vital importance to the industry has already been shown; and it is therefore clearly necessary that the measures now being taken by the Association to promote that extension should be supported by the industry with complete unanimity. By no other means can success be fully achieved; and as the resulting advantages are shared proportionately by all, it is but reasonable that the funds required should be similarly raised.

9. The basis for contributions will be the same as in previous years, viz.:—

4 annas per acre on the area under cultivation; and
½ anna per maund on the production;

and I am to ask if you will be good enough to intimate not later than the 15th August next on the subjoined form your willingness to support the Fund on this basis.

Yours faithfully, W. PARSONS, Secretary.

COORG COFFEE: RECORD PRICES.

Record prices were obtained at the public sale in Mincing Lane on the 22nd ultimo, when Messrs. R J Rouse and Co, put up seven bags shipped by Messrs. Morgan and Son marked "C I Palkimad" presented by Mr. Coolavandra Appiah, of Coorg, to be sold for the benefit of the Disabled and Wounded Soldiers' Fund. The lots were advertised to be sub-divided, if necessary, to suit the requirements of patriotic consumers, and they realised the following prices :—

Bag		cwt.			s.	
1	..	1	2	...	152	per cwt.
1	..	1	2	...	169	do
1	..	1	2	...	162	do
1	..	1	2	...	165	do
1	..	1	2	...	200	do
1	..	1	2	...	199	do
1	..	1	2	...	204	to 230

The last bag was divided into six lots, and the samples realised 5 shillings per lb. The sale began by a reference from the Chai man (Mr. Rouse) to the relief of Mafeking and to its gallant defenee, in which the whole Empire took the utmost interest, the universal feeling being that what effected one portion of the Empire affected the whole—this being exemp'ified by this sale. Three cheers were given for Lieutenant-General Baden-Powell and his gallant garrison. At the conclusion of the sale, after singing the National Anthem, it was resolved that the best thanks of the coffee trade be tendered to Mr. Coolavandra Appiah for his donation, and the meeting concluded by singing "For he is a joily good fellow." —*Madras Mail*, June 20.

A FARMER'S EVERY-DAY LIFE.

No. IX.

(By Cosmopolite.)

For some years now the burning question amongst agriculturists has been

"THE LABOUR BILL,"

which goes on increasing yearly in the same ratio that prices decrease for farming products.—which is another way of saying that a farmer is, in a manner of speaking, obliged to burn the candle of his capital at both ends. It is not that farmers grudge giving good wages to their servants, far from it, indeed they would gladly give them double the amount if the prices they obtain for their stock and grain would go up, so as to justify them in so doing. Residents in the cities complain that the agriculturists are all leaving the country and migrating to the towns, where they do the work at half the wages which formerly obtained there, but these grumblers don't—or wont—see that they themselves are to blame for the present state of affairs. If they would eschew from buying frozen tuberculous beef, from Australia, margarine butter, from the horse ranches of America, weevilly oats from Russia and the slops and refuse of other countries which are shot into our markets, as if Britain was the great dumping ground of the world, then farmers would be encouraged to cultivate more land at home than they do, would find employment for those men whose presence is objected to, in the cities, and thus there would be retained, in our own country, millions of money which, at present, goes to provide our enemies with the means of keeping up armies and navies for our undoing. I fear, however, that the dwellers in towns will not do anything of the sort; they prefer eating the cheap but nasty food of our enemies, even although they see their children, when fed on this offal, growing up a degenerate race, because it leaves themselves all the more money to spend in drink and amusements. It is a grievous thing to see men and women, who have been accustomed to farm work and the fresh air of heaven all their lives, driven to the towns for employment which they are not accustomed to, and to eat food which soon takes the colour of health from their children's cheeks, and causes themselves to seek, in drink, the forgetfulness of their own miserable existence of semi-poverty and of the poisonous atmosphere of their cheap lodgings in town. When I came to this farm the labour question was raging, and to reduce his labour bill, was the aim and object of every intelligent farmer. At that time no one in this district, had endeavoured to

REDUCE EXPENDITURE BY CULTIVATING LESS LAND,

so I, as usual, proceeded to do what my neighbours were *not* doing and at once laid down so much land in permanent grass, that I reduced the staff of labours, usual for a farm of this size, from 10 men to three, and from four pairs of horses to one pair. Of course my policy, at once, became the talk of the district—and contemptuous sort of talk at that—and several practical farmers spoke to me, in a friendly spirit, warning me against the errors of my ways, and telling me that from their own personal knowledge of my farm, it would never lie down in permanent pasture. That the last four or five tenants had all tried it, and that the grass had died out during the third year, compelling them to fall back on cropping. Whilst thanking them for their good advice, which I know was well meant and in all good faith, with the pig-headedness of the Scot, I went on my own way, and succeeded in laying down permanent pasture of excellent quality, which every year is improving, till at the present time, some that I have, which is 10 and 12 years old, now carries just three times the stock per acre to what it did when I took the farm. But perhaps my greatest triumph has fallen to my lot this year, when owing to a cold, hard and backward spring, the grass in the district can scarcely provide a bite for the cattle. In my case the old grass with its close sole, retains every drop of dew that falls which has helped on the grass, and the stock in my parts are wading in luxuriant feed, while those same practical farmers, who warned me against attempting to grow permanent pasture on my farm, have sent me 150 of their cattle to graze in my parks, paying me 2s a head per week, and this because their own barren pastures were starving the stock.

ANOTHER GREAT ADVANTAGE

which is derived from the laying down of permanent pasture, beside reducing the labour bill is found in the long rest which the land gets during the time it lies in grass, for; when put into crop again after a dozen years of grazing, the crop is generally found to be a double one, whilst the turnips which follow are not only a heavier crop, but are of better quality and free from all disease.

The month of June sees the last of the sheep-shearing in our district, a work that I am particularly fond of, reminding me as it does of those early days, forty years ago, when I learned the noble art in the back blocks of New Zealand and afterwards burst forth in Australia as a perfect "ringer" of the shed; and how pleasant are those thoughts, for surely one may be said to live twice who can enjoy the recollection of his former life! Farmers twenty years my junior, when they see me on the shearing-floor, going round a sheep with the old "ringer's" stroke of my youth, confess that they cannot buckle to such a job: that only a man with a first-class guttapercha back, with a hinge in the middle of it, need attempt that, hardest job a farmer can set himself to do. But to me it is work and pleasure combined and I hope I may long be able to hold my own with the shears. It may not be generally known that up to this time I have been, I believe, the only exporter of

WOOL FROM CEYLON.

It happened so long ago as in 1875, when a flock of fifty sheep arrived in Colombo from Australia and owing to the heat experienced during the voyage their fleeces were all hanging about them in tatters and they looked a disreputable lot indeed. I volun-

teered to shear them if I got the wool to myself and the agents gratefully consented to this. I sent a Tamby into the Pettah to hunt up a pair of shears for me, which after much trouble he succeeded in doing—an old blunt and rusty pair, but which I promptly got in working order—and next morning I polished off 28 of the sheep before breakfast, finishing the remainder on the following morning. The appearance of the sheep was so greatly improved that they fetched excellent prices, averaging 48s each, and I shipped the wool home to London receiving in due course, upwards of £10 as the nett result of the sale. Sheep have always been a specially attractive study to me, and I have been exceedingly fortunate in my dealings with them. Some years ago I noticed that, in our local markets, black sheep always fetched a better price than white ones, and being ever ready to take advantage of any such fancy on the part of the public, I determined to breed black sheep. At that time a pure Shropshire Down ram lamb was born on my farm, which could only be considered as a freak of nature, as it was jet black. This lamb I kept for stud work and mated it with a lot of Shropshire Down ewes, the result of which was about 80 per cent of black lambs. As these lambs came to maturity, they not only proved larger than ordinary Shrops, but gave heavier fleeces, and the wool realized a better price. The sheep themselves sold in the market at extraordinary prices and my black Shrops have now, for some years been celebrated in the district. Need I say that I have continued to breed these ever since, although the original ram has departed this life long ago and one of his descendants reigns in his stead.

No doubt readers of these notes will have remarked by this time, that my policy has always been to avoid the beaten track, and to farm in my own way. An article that everyone has for sale cannot be expected to give other than a very ordinary price ; but that which only one man has it in his power to place on the market, brings as a general rule, nothing short of a fancy price. While on the subject of sheep let me mention another operation in which I have proved most successful. About ten years ago farmers got an awful scare from the reckless way in which Government permitted cattle suffering from tuberculosis and pleura to be landed from America and the Continent, spreading disease all over Britain. Like my neighbours, I took fright and promptly sold off all my cattle, as there happened to be good prices agoing at the time, replacing them by purchasing sheep, which are not liable to take the diseases above mentioned. Then I converted my cattle byres so as to feed sheep in them, and proceeded to fatten these during the months of winter and spring, sending them to market at a time when few fat sheep are for sale, and consequently, prices rule high, and, by this means I have been able to turn off 300 to 400 fat sheep every winter. About 18 months ago the agricultural press went crazy on the subject of

THE HOUSE FEEDING OF SHEEP,

and since then the subject has been thrashed bare, each one giving his experiences, none of which, however, appear to me to have been very successful. Lately it has come to the knowledge of the public that I have been engaged in this work for ten years, and with great success, so I have been receiving letters from all conditions of men, asking my advice, and how to go about the feeding of sheep in the house, what food to give them, how to treat them, and in short, to tell them all I know on the subject,—so that they might go in and oppose me in the fat market. Not being a born idiot, I have succeeded so far in not giving myself away, but merely writing a few platitudes on the subject, winding up by saying that the only royal road to success in the house feeding of sheep is *to look after the work yourself* Doubtless, in course of time, others will learn for themthemselves, as I did, and feeding sheep under cover will become as general as feeding cattle, and when that day comes, I suppose I will be obliged to pull myself together, and think of some other operation that my brother farmers are *not* doing, and set to work again in order to keep a few years in advance of those agriculturists who stick to the beaten track and the rule of thumb.

PLANTING IN STRAITS SETTLEMENTS: SELANGOR.

The acreage under European cultivation has been fully maintained in the face of a bad year and a large additional area has now come into bearing. It is to be feared that most of the native coffee plantations, which were started when prices were high and have since been abandoned, are now too far gone to be capable of resuscitation. Planters have paid much attention to rubber, especially the Para variety (*Hevea Braziliensis*), of which a number of plants approaching one million were put out in 1899. The trees have been in some places set out among the coffee, in others they are in plantations by themselves. The cultivation of the indigenous native rubber, Rambong *Ficus elastica*, has also received attention. When the prospects of Liberian coffee were at their worst, the cultivation of coconuts was resorted to as an alternative source of profitable planting. The industry has been steadily continued, both by Europeans and natives, and a reliable source of future profit thus brought into existence. The single estate upon which ramie has been grown is still in the experimental stage. The questions remaining for solution relate more to the nature of the machinery and the cost of preparation, than to the growth of the fibre. The proprietors are well satisfied so far as they have gone, and propose to further extend their operations in the near future.

As stated in an earlier paragraph, the European Planters have been striving against adverse market rates, as to which a measure of relief came only with the end of the year. That all should have persevered in the face of on apparently hopeless outlook reflects great credit upon our proprietors, and though it would perhaps be premature yet to predict that better times are in store for coffee, it is satisfactory to know that the difficulties which have had to be faced have created and fostered economical methods of working which will be of value to the estate owners for all time. Nor will the hardships which have been experienced be devoid of benefit if they have the effect of impressing upon the pro-

pretors of coffee lands the necessity of seeing that their produce is well cured in addition to being well grown. It appears to be admitted that insufficient attention was paid to this point in the past; that the prevalence of high ruling rates rendered growers less careful than they should have been of the condition of the exported article; but now that the Selangor Planters' Association has in its recently published annual report publicly called upon its members to co-operate in effecting an improvement in this respect, and that admonition has been productive of a generally expressed desire to obtain better machinery, we may reasonably expect that the produce of the future will no longer occupy an inferior place in public estimation on account of want of condition. So much capital is now being invested in rubber planting, that it may be well that means should be taken, before the trees arrive at maturity, to acquire, possibly by examination in other countries, a practical working knowledge of the most effective and most economical methods of collecting, treating and shipping the produce. That which is new to planters in the Malay Peninsula is well understood elsewhere, and it would be a thousand pities that the supply of the future should be effected, either as to its quantity or quality, by the effort to acquire the necessary experience by unassisted endeavour.

Very little advance was made in native plantations in 1899. The scheme for the cultivation of rice by His Highness the Sultan, referred to in the Administration Report for 1898, still remains in abeyance. Rice growing in the district of Kuala Selangor has made some little progress, but the unhealthiness of the Coast districts has lately been such that all forms of industry have been somewhat suspended. Effective drainage works were again carried out in Kuala Selangor, and a commencement was made with the formation of the channels for the irrigation of a selected area of land in the Kuang district of Ulu Selangor, the whole of which will eventually be occupied by rice planters. A consignment of seed padi was obtained from Siam, and distributed among the districts for the purpose of improving this year's rice crop.

KUALA LANGAT DISTRICT,

RAMIE, COFFEE RUBBER, COCONUTS.

Progress of Cultivation and Ramie.—The progress of Mr. Cyril Baxendale's experiment in the cultivation of ramie constitutes one of the most interesting events in the agricultural history of Kuala Langat. On Jugra Estate there are now some 44 acres planted with several varieties of ramie; the largest of which attains a height of some nine or ten feet and flourishes with considerable luxuriance. My taking charge of the district was almost contemporaneous with the starting of this valuable experiment, and I have been much impressed by the thorough and business-like way in which it has been carried out. At the beginning of the year, a machine for producing fibre was worked on the estate. In September Mr. Baxendale brought out from England a machine to produce ribbons, and this appears to give satisfactory results. The experiment having occupied a longer period than was anticipated, an extension of the reserve of 2,000 acres granted in 1898 has been applied for. Amongst the ramie, coconuts, rubber and bananas are planted, and an additional 120 acres have been opened for the two former products.

Rubber and Coconuts.—The other estates of 100 acres and upwards are extending cultivation by planting rubber and coconuts. For this purpose 80 acres at Bandar have been felled by His Highness the Sultan, and 120 acres are being opened on Klanang Estate, which will bring up the cultivated area on the latter estate to nearly 400 acres. On Denmark Estate rubber and coconuts are being planted amongst the coffee. Most applications for small holdings in the Jugra portion of the district are made on an undertaking to plant coconuts. Said Ahmit, son-in-law of the late Sultan, has felled and fenced for his purpose 70 acres of recently obtained land. But in many cases the actual planting has not progressed as quickly as I should desire. Owing to the number of wild pigs in the district, the planting of coconuts in small holdings, unless preceded by fencing, is a Sisyphean task; and I am afraid that many of the natives, more especially the Malays, have not yet sufficiently recovered from unfortunate ventures in the cultivation of coffee, to brace themselves for another serious agricultural effort.

Coffee.—Those cultivators whose coffee was well advanced before the slump in prices have kept their gardens in a condition, which, under the circumstances, is surprisingly good; though I fear that comparatively few understand the economy of systematic weeding. Owing to the relative quickness of returns, coffee is a form of cultivation which, provided only that fairly good prices are anticipated, has considerable attractions for the native cultivator. In this connection, it is interesting to record the receipt in June of fifteen applications from Chinese for small holdings at Telok, made with a view to planting coffee as a catch crop for rubber.

Pepper and Gambier.—The pepper crop on the Sepang Estate of the Chee Woh Kongsi amounted to 5,212.13 pikuls, as compared with 4,639.76 pikuls in 1898. The quantity of gambier collected was rather less than in the previous year, but this was partly due to a difficulty in procuring and keeping labour, owing to the much higher wages obtainable on the construction of the Labu Valley Railway. Encouraged by the high price of pepper, the owners of this estate are making additions and improvements to their pepper plantations. In January 214 Chinese applied for small holdings, of 25 acres or less, for the planting of gambier and pepper between the boundaries of this estate and the Labu River. The coconut trees round Jugra Hill are answering to systematic treatment and have greatly improved in appearance. In other parts of the district the beetle gives but little trouble.

COCONUTS IN KUALA SELANGOR DISTRICT, 1899.

I am glad to report that the cultivation of coconuts is largely on the increase. Wild pigs, however, do enormous damage amongst the younger trees and cannot in some places even be kept out by the ordinary sized "gagar" enclosing the plantation. I have been shown places, at Ujong Parmatang, where the young trees have had to be renewed perhaps four or five times before they have grown up. Barbed wire fencing would keep them out, but the

"raiats," are not sufficiently well off, they say, to bear the initial expense of procuring it.

The Selangor Coconut Oil Company's mill has been in working order throughout the year This district does not supply sufficient copra to enable the factory to keep going, but a certain amount is imported into Kuala Selangor from Jeram, Bernam and Telok Anson. I understand from the Manager, Mr. R S Meikle, that there is a ready sale for the "poonac"—the refuse of the copra when the oil has been extracted—it is used for feeding horses, cattle and pigs, and is, I believe, extremely nourishing. Most of it is shipped to Australia, but a portion is sold locally and in Kuala Lumpur.

The cocoanut beetle does not appear to do a great deal of harm, except in a few places in this district, and the provisions of the Enactment for the preservation of coconut trees enables the District Officer to deal with cases reported where owners have taken no measures for checking the inroad or increase of the beetles on their estates.—*Administration Reports.*

NEGRI SEMBILAN.

Planting in Straits.

From the Report for 1899 of Mr. E W Birch as British Resident, we quote a few passages:—

It is a pleasant duty to again report upon a year of great prosperity for the Negri Sembilan and my only regret is that the Coffee Planters did not share in that prosperity. Some valuable estates were sold at prices which must prove remunerative to the purchasers unless the cultivation of coffee is to be entirely abandoned, an eventuality which, in view of the ups and downs of the market for agricultural produce during the past twenty years, it is unnecessary to consider seriously. I am glad to state that the Coffee Curing Mill, which I have long advocated, has been established at Port Dickson. The price of Tin fluctuated between £89 and £150 per ton, remaining for about three months at over $80 per pikul. The average price for the year works out at about $72 and to it may be attributed a great increase in the Revenue of the State, very appreciable profits to the Miners, immense returns to the Farmers and a large influx of Chinese labourers. The Duty of Tin produced no no less a sum than $556,858, which is almost equal to the whole revenue of the State in 1897. Itexceeded my estimate by over $330,000. The value of Tin exported was more than four and a quarter millions of dollars. The most satisfactory feature, however, is that the output was 57,300 pikuls, or 11,150 pikuls more than in 1898.

GREEN TEA MANUFACTURE:

PROCESS OF MANUFACTURE ON BRUNSWICK ESTATE.

(BY THE H. DRUMMOND DEANE SYSTEM.)

[Although already published, it is well at this time, to repeat these instructions again.—Ed. *T.A.*]

(I) Take the green leaf straight from the field and steam at once in Deane & Rae's Machine (a long narrow revolving box); full steam must be turned on for 5 minutes and then shut off, the leaf is then kept in a steam box for another 10 minutes, the box kept revolving meanwhile, in order that each leaf may get the full benefit of the steam. The leaf is then examined, and if found pliable (like slightly under withered leaf) it is taken out and spread on tats to drain off the superfluous water; if the leaf is not found to be sufficiently pliable another 2 minutes in box should be allowed. Some time should be allowed for draining off the water.

(II) A suitable quantity is then taken to the roller and rolled for half an hour *lightly*, after being discharged, all lumps (of which a great many will be in evidence) must be carefully broken by hand, or it may be put into dryer for a short time before going to roller.

(III) The roll is then taken to the drier and partially fired to rid it of excess of moisture, care being taken not to allow it to become crisp.

(IV) It is then rolled again for one hour. Owing to the brittle quality of the leaf after it has been submitted to the steaming process, it is not possible at any time to apply weight to it in rolling. After discharge from roller, the leaf must be again carefully broken by hand.

(V) Then final fired. This last operation must be thoroughly completed, care however being taken that temperature is not allowed too high (say D.D. Sirocco 210 degrees to 220 degrees should be the maximum), as the leaf very easily *blisters*, also a "toasted" flavour (which is objectionable) may be imparted to the tea. Firing should be as brisk as possible, as it adds to the pungency of the tea, the points mentioned above being carefully observed.

SIFTING PROCESS.

The bulk is first passed through a

No. 12 sieve and called young Hyson

then ,, 10 ,, ,, Hyson

,, ,, 8 ,, ,, Hyson No. 2

and what remains on top of No. 8 has to be broken through it.

Dust from Young Hyson should be mixed with the lower grades.

There should not be more than from 10 to 12 per cent of dust altogether from the other grades, which is called "Twanky," and is sometimes mixed with Hyson and Hyson No. 2.

AMERICA'S NEW POSSESSIONS.

ENORMOUS GROWTH OF AMERICAN TRADE.

Here are figures showing how American exports to Cuba, Porto Rico, Hawaii, and the Philippines have grown in three years :—

Fiscal Years.	Cuba. Dollars.	Porto Rico. Dollars.	Hawaii. Dollars.	Philippines. Dollars.
1898	9,561,656	1,505,046	5,907,155	127,804
1899	10,619,377	2,685,848	9,305,470	404,193
*1900	25,000,000	3,600,000	14,500,000	2,500,000

* May and June, 1900 ,estimated.

—*Sell's Commercial Intelligence.*

Electric Light on a Perak Sugar Estate.—What is believed to be the first electric lighting plant in Perak, was installed in Gedong Sugar Estate, Began Serai, a few days ago. It is working most satisfactorily. The above Estate, expects to receive very shortly, the materials for a factory of the latest type, the mill and crushing plant of which, will be the largest ever imported into the East, with a new type of evaporators and crystallizers, altogether capable of turning out about 40 tons of sugar daily.—*Perak Pioneer*, June 20.

THE MANUFACTURE OF "GREEN TEAS" IN CEYLON.

No one has a better right to discourse on the subject of pure "green" teas in connection with our Ceylon industry than Mr. Drummond Deane; for the pages of our *Tropical Agriculturist* bear witness to the fact, of Mr. Deane having been about the very first to experiment in the manufacture of green teas and to offer to instruct his brother planters in regard to the same. If we are not mistaken, Mr. A. E. Wright got his first lesson from his neighbour, the whilom "laird of Kintyre."

We direct attention to the long letter on the subject which has reached us from Travancore. In it Mr. Deane refers to his early experience as a maker of green tea; to the great praise given, both locally and in America, by experts as to the quality of his product, and to the fact that he had brought out a small patent in connection with the preparation. But when all is said and done, we may ask what came of the industry which was then the subject of so much encouragement and praise? It is quite evident that it would not have been abandoned, even temporarily, by Mr. Deane, or Mr. Wright, had it shown much profit; and that of course must continue to be the practical test to apply at the present time. Apart from the "bonus" which, even if renewed, cannot do more than provide for a very limited quantity, the individual planter will be sure to ask, "If I make green, in place of black, tea, am I likely to get 1d, ½d, or even ¼d more per lb."? If, on the other hand, he finds that, while for his "black" tea he can get 6½d a lb., for the green he can at most secure 6d, no amount of persuasion is likely to change his course. We speak of the individual planter. The case is rather different in respect of large Companies or extensive proprietors. It may be very good policy for such to make a proportion of "green tea" even if it fetches a poor price comparatively, in order to relieve the pressure on the "black tea" market; and it is here where the Colony will look for a good lead from some of our more extensive and prosperous Tea Companies. In Travancore, too, a good deal of green tea ought to be made to supplement the shipments from Ceylon.

OUR PEARL FISHERIES: THE NEED OF SCIENTIFIC INVESTIGATION; AND OF A MARINE BIOLOGICAL STATION ON THE COAST OF CEYLON.

We direct attention to a long and thoughtful letter on the above subject from Mr. Oliver Collett, of Lower Dikoya, who is well-known to scientists, as well as his brother-planters, as an enthusiastic Naturalist of no mean attainments in the Department which he has made more peculiarly his own. We say so much in order that his letter may receive the attention it deserves from the local Government, and that it may especially come under the notice of His Excellency the Governor. Sir West Ridgeway is aware of the important scientific, as well as practical, work performed at the Marine Biological station at Port Erin in the Isle of Man. We had the pleasure of learning a good deal about this station in 1896, with a party of the British Association, guided, if we remember rightly, by Dr. Herdman, F.R.S, &c., Professor of Natural History in University College, Liverpool. We are not going into any details; but curiously enough we find that Professor Herdman, along with Professor R. W. Boyce, Mr. G. C. Bourne, and Professor C. S. Sherrington, was appointed in 1895, "to report on the Elucidation of the "Life Conditions of the Oyster under Normal "and Abnormal Environment, including in "the latter the effect of sewage matter and "pathogenic organisms." This investigation was carried on—and was the subject of successive Reports to the British Association all through 1896, 1897, and 1898. We may, therefore, conclude that Professor Herdman—who, from his connection with the Isle of Man, is, probably, well-known to Sir West Ridgeway—would be about the very best scientific authority to advise the Ceylon Government at this time on what should follow on Sir Wm. Twynam's History and Report, and whether a scientific investigation and the establishment of a Marine Biological Station near the site of our Pearl Fisheries is justified by the circumstances. Professor Herdman is too busy and important a man to come to Ceylon himself—except it were on a flying visit—and therefore our Government may be sure of an impartial opinion on the Papers placed before him.

We have no doubt there are some amongst the community who entertain strong doubts as to science being able to help us in this matter, and that our proposition, if carried out, would simply mean a waste of public money without any practical results; and they point to the mission of Mr. Holdsworth, F.Z.S., with its absolutely negative result, and still later to the investigation held by Mr. Edgar Thurston for the Madras Government. Now, it is quite true that Mr. Holdsworth's inability to help us, after five years' labour on our shores, was a bitter disappointment to Governor Sir Hercules Robinson and the whole community; and served to cast discredit on scientific aid from that day to this. But what does Sir Wm. Twynam show (as repeated by Mr. Collett) —that Mr. Holdsworth never saw a Pearl Fishery and never even during his five years as Ceylon Naturalist, had the opportunity of joining in an inspection of a bed of pearl-oysters on one of the banks off our shores. His five years were absolute blanks in these respects. Then let us think of scientific progress since 1865-1870! Why, Marine Biology was an unknown study thirty years ago. Sir Wm. Twynam, oo, is ignorant of the fact that, apart from Mr. Thurston's Monograph, there is much useful information to be gathered from other Colonies and countries bearing on Pearl Oysters. We have before us, as we write, for instance a Report by "W. Saville Kent, F.L.S., F.Z.S. Commissioner of Fisheries, Queensland" on "Oysters and Oyster Fisheries of Queensland" dated 30th June, 1891, which deals with pearl-shell fisheries and is illustrated by coloured plates of the various oysters and of some of their enemies, and with pictures of oyster banks, collections of spat, and plates illustrating the Embryology of the oyster. This Report we received from Dr. Haddon, of the Royal College of Science,

Dublin (since F.R.S., and Professor of Cambridge University) who wrote of "Saville-Kent" as an able man and that he was going on a special mission to North-West Australia, to study the Fisheries there. What further Reports Mr. Saville-Kent has published, we do not know; but enquiry ought to be made of both the Queensland and West Australian Governments as the owners of Pearl Shell as well as Pearl Fisheries. Then we have also dug out of our collections, a "Report upon the Pearl Fishery of the Gulf of California by Charles Townsend"—illustrated with photographs; and a "Report upon certain Investigations relating to the Planting of Oysters in Southern California, by Charles H. Gibbert," also with plates—both Reports being dated 1891 and addressed to the Washington authorities. Most probably the investigation was continued and further Reports followed, and perhaps, from California, Sir Wm. Twynam might learn of Pearl Oysters being artificially cultivated. But, in any case, we think Mr. Collett and ourselves have said enough to show that the Ceylon Government should take action—and if Professor Herdman were consulted, he could probably lay his hands on *all* the literature on the subject from America, Australia and India (and possibly referring to Chinese experiments with Pearl Oysters) before giving his opinion as to what could be done by Science in connection with the CEYLON PEARL FISHERIES.

OUR PEARL FISHERIES.

A PLEA FOR SCIENTIFIC INVESTIGATION.

Watawala, July 1.

DEAR SIR,—After reading your recent editorial remarks (see above) upon Sir William Twynam's Report on our Pearl Fisheries, and after a perusal of that valuable and elaborate account, the question is naturally forced upon one: Is it not passing strange that we still remain, after more than a hundred years of occupation of the island, in almost complete ignorance of the habits and instincts of the pearl-bearing mussels of the Gulf of Mannar?

The paramount importance of the question becomes evident when we remember that the total revenue derived from the Pearl Fisheries since 1796, amounts to no less than one million pounds sterling; and this in spite of the fact that some of the most promising of our fisheries were spoiled by the remarkable, and, so far altogether unaccounted for, disappearance of the "oysters," just as they were about to arrive at maturity.

The fact that the two oldest authorities upon our Pearl Fisheries (Sir W Twynam and Captain Dounan) hold diverse opinions regarding the probable cause or causes of these disappearances, shews how very much there is yet to be learned of the whole subject.

To the zoologist, it is at once clear that this and other vexed questions can only be set at rest by a thorough and systematic investigation into the Natural History and Life Conditions of the Pearl Oyster—more particularly in its early and post-larval stages.

At present we are without any reliable data or accurate information upon those points; and it is not impossible that it may be found that there are many agencies affecting the health and well-being of the pearl-oyster which may be brought, in a greater or less degree, beneath artificial control.

The few attempts at systematic investigation that have been made, appear to have been abandoned before any real knowledge of the subject had been gained. The labours of Dr. Kelaart (1857-9), which gave promise of the best results, were unfortunately brought to an end by his sudden death; and the employment of Mr. Holdsworth by Government in 1864 for a period of five years, appears to have led to no increase in our knowledge of the subject: for the simple reason that his energies were never properly applied. Sir W Twyman tells us that "he did not see a fishery, and did not witness an inspection of a bank with a bed of oysters on it, young or old." He also points out that "as the supposed term of a Pearl-oyster's existence is seven years, a Naturalist would not be able in five years to complete his researches and be in a position to lay anything definite before Government." And, finally, Sir William says: "No Naturalist has yet, so far as I am aware, reared Pearl-oysters in an aquarium, tank, reservoir, or enclosed portion of the sea from minute spat to maturity, ascertaining their exact condition at various stages of growth."

But while we in Ceylon have been content to remain in ignorance, the study of Marine Zoology in other parts of the world has during the last quarter of a century, made remarkable progress. The return home of the "Challenger" expedition in 1874 gave an impetus to the investigation of this important branch of natural science which has already led to valuable results. Marine Biological Stations have been established in different parts of Europe and America, which have greatly facilitated methods of research. The life-history of a number of our principal food-fishes has been worked out, and we are now familiar with many of the conditions of life in the sea which were formerly quite unknown.

For instance, it has been ascertained that marine life is, in many respects, almost as localized as that of the land; and that certain groups of plants and animals are *characteristic* of particular areas. We also now know that certain depths of the ocean contain organisms which are only to be met with in their own particular water strata—in accordance with what is known as the law of bathymetrical distribution.

Again, it has been discovered that almost all marine animals and plants are extremely sensitive to variations in the temperature, and in the specific gravity, and salinity, of the medium in which they live. These facts make it at once evident that all of these conditions must be observed and recorded before any attempt at artificial propagation, or cultivation, in any particular locality, can be expected to be successful.

No planter would attempt to grow tea in Jaffna, or coconuts in Nuwara Eliya; and, arguing by analogy, it is possible—nay, probable—that the marine life of our shores will be found to vary with every increase in the depth of the water, in precisely the same way that our land fauna and flora are modified by every change in the elevation of the land; climate in Ceylon being almost entirely determined by altitude.

Now, the *Mollusca* are—perhaps more than any other class of animals—greatly influenced by their environment. Take the land-shells for example. Their distribution is so local that an experienced collector can at once name the locality in which any particular species is likely to be found. In

Ceylon, it is almost always possible to judge the altitude at which any special kinds are to be sought for; and it cannot be doubted that similar conditions will be found to apply to our marine shells.

Thus, while the Tamblegam pearl-oyster (*Placuna placenta*) can easily be propagated and reared in the shallow waters near Trincomalee, as Dr. Kelaart amply shewed, the true oriental pearl-oyster (*Meleagrina fucata*) of the Gulf of Mannar, will only flourish at a depth of from 6to8 fathoms,—and this is perhaps the reason why all attempts at cultivation both here and off Southern India have hitherto failed.

It is possible that the oysters live far out at this depth in the Gulf of Mannar* in order to avoid the floods and sand storms from the northern rivers. The antipathy of oysters to sand was long since pointed out by the late Frank Buckland. The following allusion to it is to be found in the pages of "Punch" (1880):—

'Tis the voice of the oyster—I hear him complain,
"I *can't* live in this place; here's a sandstorm again!
I had settled at rest 'mid the rocks and the tiles,
They had made me a home, but this sand, how it riles,
It gets into my shell and the delicate fringe
That I use when I breathe; and I can't shut my hinge
When the grit lodges there; so the crabs come at will,
Since my poor mouth is open, they feed and they kill.
I've complained to Frank Buckland who quite nnderstands
But he can't undertake to abolish the sands."

In 1892 a proposal was made by Lady Blake that a Marine Biological Station should be established in Jamaica as a memorial to Colombus. The idea was warmly supported by Professors Huxley and Ray Lankester, who suggested that the Government of Jamaica should initiate the scheme, and make the proposed Laboratory part of a Biological and Physical Survey of the Island. Special stress was laid upon the importance of having an observing station of this kind *in the tropics*, where the fauna and flora of the sea are so marvellously rich and varied.

The coasts of Ceylon are swarming with interesting forms of life, as we know from the writings of Hæckel and the brothers Sarasin; and while there are our Pearl-fisheries, of immense value, to be safe-guarded, there is also an important Chank fishery, which is undoubtedly capable of considerable development. An Experimental Station established at Negombo or Mannar for the investigation of the entire Natural History of the Gulf would almost certainly quickly repay the cost of its initiation and upkeep.

And the issues at stake are surely sufficiently large to justify the establishment of a small but first-class Marine Biological Station, similar to that which is doing such splendid work under Professor Herdman at Port Erin in the Isle of Man?—Yours truly.

OLIVER COLLETT.

"Para" Investments.—The American consul at Para is still trumpeting for the investmeut of American capital in the Amazon valley—in rubber estates, railways and all sorts of things. No one should be misled in this matter. If the American capitalist is inclined to take any such risk he should spend at least six months at Para and Manaos before deciding.—*Rio News*, May 22.

Correspondence.

To the Editor.

"GREEN TEAS IN CEYLON."

Stagbrook Estate, Peermaad, June 24.

(To the Editor, "Times of Ceylon.")

Sir,—I notice in your leading article on June 20th, you are dead against the production of green teas, and quote an extract from a letter of Mr. A E Wright to support your argument.

As against that view of the matter allow me to quote from Mr. F F Street, which appeared in the *Ceylon Observer* and "Times of Ceylon" on 21st January, 1890:—

"I consider there is a great future for Ceylon green teas of the quality and character lately produced by Mr. Deane, and I am decidedly of the opinion, that when these teas are made in sufficient quantity and become known that they will in time drive the China article out of consumption, in the same way as Indian and Ceylon black teas have and are still doing.

"These are the teas the Ceylon Planters' American Tea Company would do well to begin the campaign with in America, as the taste is already established there for these unfermented teas. Americans will then have an opportunity of judging of the *superior quality* of pure Ceylon greens as compared with faced China teas of the same class." Then he goes on to say:—

"As specimens of what green teas should be in cup, and infused leaf they are about as desirable as it is possible to make them."

So much for your argument that it will take us some time to learn how to suit the world's markets with green teas.

Again I quote from a letter published in the *Ceylon Observer*, of April 11th, 1890, (and I think "Times of Ceylon"?) from Messrs. Busk and Jevons, of New York:—

"We have shown these teas to several of the trade, and they invariably pronounce them finest to choicest Japans in the cup, and say they will have to be sold as such."

Many more such opinions could be quoted were I able to collect all the correspondence I had on the subject. Among others a letter from one of the largest houses in Japan, Messrs. Fraser Farley and Varnum of Yokohama in which they reported on my samples as superior in liquor and flavour to anything they could get, but not up to their Japan teas in appearance.

I now come to Mr. Wright's reply to your questions, and I must say it is a very unsatisfactory one, as it is misleading. It is true that green tea manufacture is, when a factory is making black and not green teas, a source of trouble—otherwise the one is as simple as the other. It is true also that rather more firewood is used, but even if Mr. Wright's figure of *double* is correct (which I beg leave to doubt) it is only an extra cent per lb. probably, and against this you have the entire saving of withering accommodation and spreading of leaf.

Your readers may take it from me that the cost of making green tea is no more than manufacturing black, and if green tea alone

is made, the outlay in withering accommodation is at once saved. It would be cheaper all round in manufacture I am certain, but the outturn is not more than 22 per cent., as against 25 per cent. of black.

If Mr. Wright would publish the invoices and account sales of all the teas he has sold, and been paid a bonus on (which in itself is a big profit in these days) it would be of great use, and if you will add here the enclosed cutting from the *American Grocer* it will speak for itself as I believe the teas referred to are from Mr. Wright? Mr. Rutherford and Mr. Mackenzie are level-headed men, and know what they are doing, and I believe that so soon as green teas are shipped in any quantity, a market will arise and prices be remunerative to many estates which are now averaging from 7d to 7½d or even less for Black Teas. Will you kindly insert at foot of this letter copy of my letter to the *Ceylon Observer*, and I think yourselves of 1st August, 1890, which I enclose describing the patent held by myself and Mr. Rae, as newcomers may unwittingly infringe that patent which not only applies to the "machine" but to the process of applying steam to green tea leaf.—Yours, &c.,

H. DRUMMOND DEANE.

(*Enclosure referred to.*)

CEYLON GREEN TEAS.—Thus the *Canadian-Grocer*:—"Yes green Ceylon teas are a great factor on the Canadian and American markets at present, and are going to grow very rapidly," said P C Larkin, of The 'Salada' Tea Co. "We had shipments on the ss. "Maria," ss. "Beatrice" and ss. 'Clan MacLean,' all arriving within in ten days of each other, and they go out just about as fast as they come in. We had four repeat orders by mail in one day; that is, four orders without any solicitation came in direct on post-cards or letters, These remember, are 'repeats,' showing that the goods 'are going,' and that they please the public. We notice lots of others now taking up Ceylon greens, but there are Ceylon greens and Ceylon greens. In the course of a couple of years, they will have the same position in the green tea trade that Ceylon blacks have today in the black tea trade. To be sure, they cost a little more than Japan teas, but they give the dealer better profit, and, as they are much stronger than Japan teas, they go further and are, therefore, just as cheap to use, besides being of very much finer flavour and strictly without coloring."

GREEN TEAS: PATENT PREPARATION OF, IN CEYLON.

To the Editor Ceylon *Observer*,

DEAR SIR,—Some particulars of our invention which renders the manufacture of true green teas, simple and inexpensive, may b of use to your readers. We have, as you are aware, patented the method as well as the machine in Ceylon, and hope shortly to do so in India. Our patent covers—(1) A method of rendering tea leaf pliable for purposes of rolling or twisting without resort to the process known as withering. (2) A machine for carrying out this method on a scale large enough to suit the largest factories. Green teas may be divided into two classes—Oolongs or Semi-green teas, which are partially fermented, and true green teas, which are wholly unfermented. These teas are the most popular class of tea in use in North America as shown by the fact reported to the inventors by Mr. F. Street, the local tea expert, that, out of a total export of 51,000,000 lb. of China tea to the United States last season up to the middle of November, only a very little over 1,000,000 lb. of tea corresponding to the ordinary Ceylon black leaf was imported, while of Oolongs there were imported 14,000,000 lb. and of the unfermented class, which are the true green teas. no less than 32,000,000 lb.

In view of the desire in Ceylon to introduce teas of this island into the American market it is thus shown to be highly desirable that teas should be manufactured of the unfermented class, and that a method and apparatus for insuring the manufacture thereof should be perfected.

Oolongs consist of tea leaves, withered either artificially or naturally, by hot air or on hot plates, sufficient to enable them to be rolled, when they are straightway fired.

The result of this process is that the effect called by some fermentation and by others oxidization is partically produced, and this effect prevents the leaves from being uniform in colour and causes them to vary from an olive green to a light brown.

True green teas are made only of leaf which has never been fermented or oxidized and, when infused, should show a uniform yellowish green colour which could never be obtained had either oxidization or fermentation taken place. The production of these teas has hitherto been found impracticable in Ceylon, because leaf could not be rendered sufficiently soft or pliable to be rolled or twisted unless by its being withered either naturally or artificially by hot air or hot plates, which withering is in itself a degree of fermentation or oxidization.

It was therefore requisitive to find a method of obtaining pliability necessary for the rolling or twisting process by other means which would prevent all fermentation or oxidizations. The inventors claim to have discovered after long experiment, and to have been the first in Ceylon to practise their discovery of a method by which tea leaf is rendered sufficiently pliable for rolling by a method heretofore entirely novel in Ceylon, which process not only produces pliability but absolutely checks all fermentation or oxidization. Full particulars of the machine can be obtained from Messrs. Brown Rae & Co., our Agents at Hatton, and, with each machine, instructions necessary for its use will be issued.—Yours faithfully, (Signed) H. D. DEANE.

August 1st 1890.

FURTHER NOTES FROM MR. DRUMMOND DEANE.

Travancore, July 9.

DEAR SIR,—In *re* your leading article of 29th June, anent manufacture of "green teas," you say:—"It is quite evident that it would not have been abandoned, even temporarily, by Mr. Deane or Mr. Wright, had it shown much profit." The reason, I abandoned it was twofold:—

1. I had at that time (10 years ago) a contract with a well-known Queensland firm to give them as much "pekoe" as I could make at 9d per pound sterling f.o b. in Colombo. My black teas, by *this contract*, were then averaging about *10d per pound*. It was impossible to make only the "finer" and "common" grades into "greens", and though the average I was then getting, of nearly 9d nett, per pound on green teas, was satisfactory, there was a drawback.

No. 2 (which would not affect a Company, but seriously affected the private producer) viz. whereas by selling pekoes in Queensland, I got cash on the nail with the Bill of Lading, and by

selling in London I would (10 years ago, remember) draw (free of charge) up to 10d per pound under my Letter of Credit against Bill of Lading.

By shipping green teas, then quite a new industry, I could draw nothing on my American friends; but all teas were sold at my risk, and account sales and their result remitted in due course which meant at least three months. What present average prices for "greens" may be in America, I cannot say?

Mr. A. E. Wright could to a certain extent solve that problem, "an' he would" indeed. I think it only due to the "Thirty Committee" who have paid him a handsome bonus, that they should ask him for his invoices for publication, and if the prices are better than many sceptics think, it is all the more reason he should continue to enjoy his bonus as the fruit of his pioneering, but *if* the prices are very poor, though deplorable, it does not at all follow that others may not obtain better ones. Indeed if he practises the *exact* method of sorting as published by him in his memo of manufacture to the "Thirty Committee," I feel sure better results could be obtained. Again, be it noted, it is impossible to make green teas and black teas together, without sacrificing the care needed in the manufacture of each class. I have yesterday written to your contemporary, the "Times of Ceylon", fully, perhaps too fully, on the question of green tea manufacture, and asked him to pass it over to you in case you are prepared to give up so much space in your paper. The most important point in *that* letter, and one which I hope, Sir, you will use your influence to bring about, is; that the "Thirty Committee" should not blindly hand over ten cents per pound on every invoice of green tea *shipped*, but should appoint a paid green tea expert) I know of none better than Mr F. Street) to sample one package of each grade of each invoice on which royalty is paid. I should not, by this, mean in any way, that no lower grade teas were to get the royalty, far from it. But I most strongly hold the opinion, that, until more is known of the method of making "green teas", much harm may be done by the shipment of an article, fondly imagined by its exporter to be a true "green tea," and yet something entirely different. To a certain extent this view is borne out by "J. B.'s" letter to the "Times of Ceylon" of 2nd July, recommending Messrs. Davidson's "withering machine" for the manufacture of green tea; also their roller. Now the latter suggestion is quite sound and I have, some days before, written Messrs. Davidson on the subject giving them two suggestions, which, if they carry out, will probably make their roller the best green tea roller in the market, viz.:—1. A movable screw weight that can be clipped to the sides of the machine, and removed at will, for pressing the steamed juice (or water and juice) out of the roller before *commencing* the roll. 2. Having holes drilled at bottom of roller to take away the said water and juice rapidly. But of his first suggestion to use their "withering machine" he would by so doing completely prevent the making of "green tea',', the very essence of the manufacture of which is that there must be no oxidisation or fermentation of the leaf. If therefore, our friend "J. B.'s" advice were followed, the result would be an "'Oolong' and not a *green tea*.

I am open to correction on the following point at the moment, but am certain it was the case years ago, that ordinary "Oolongs" were not in it with pure "greens;" in fact my opinion is that, as a rule, "greens" that by accident had got more or less oxidized or fermented were shipped as "Oolongs."

The Formosa Oolong is quite a different article, but I have never heard of their being made successfully out of "Formosa", and plenty of people have tried to my knowledge with the best information before them, which point to soil and climate being the chief factor as regards their flavour. Apologizing for the length of this yarn.—I am, sir, yours faithfully,

H. DRUMMOND DEANE.

HOW TO MAKE GOOD GREEN TEAS.

A VALUABLE LETTER OF ADVICE.

DEAR SIR,—I am afraid I am taking up too much of your space; but, after reading your report of Mr. Rutherford's views on the green-tea question, would ask your indulgence once more, to put the following opinions before those who are starting green-tea manufacture. If these teas are to be a success from the first—and there is no reason why this should not be the case with care—let me beg of those commencing to be in no frantic hurry to start off with large breaks of tea before they have thoroughly mastered the details of manufacture. Like all new industries, there is a certain unwritten law that can only be learnt by experience, no matter how clear the rules for manufacture are, as explained by myself, Mr. Wright or other pioneers; and it is probable that there will be found several petty obstacles to be overcome. What suits one set of machinery will be slightly different with another, and so on. What I would suggest, at any rate for a month, is that not more than one roll of green-tea should be made a day in each factory new to the work. This, though giving a little trouble in washing the roller out and cleaning the firing machine trays, can easily be done "if insisted on" in any reasonably well-equipped factory. If leaf was brought in, say, at 8 a.m. for a roll, it could be finished before noon and put away With these small lots of tea every two or three days, I would suggest careful sorting, and the proportions being taken and samples sent to Mr. F F Street or any other "green-tea" expert, for report as to liquor and make. By the end of a month the manufacturer will know exactly what is wanted, and what he can do with the machinery at his disposal. By several men starting on these lines Ceylon green teas will be all of a class, and will command attention in America; otherwise, if all the first experiments are made in large quantities and shipped, the result will be disastrous to all concerned, and a bad name earned to start with. The following hints may prove of service:—

Plucking may be *coarser* without detriment, provided "hard," "bhanji" is strictly eliminated from the basket; *whole leaf* teas *must be aimed at*, and all fannings eliminated and kept separate; a good "broken pekoe" grade would be a *bad*, almost unsaleable green-tea; the small strong fannings from broken pekoes and pekoes can be kept separate and shipped as "Hyson" fannings; the coarser fannings as "Twankay." These teas are made into cakes or brick-teas as they are called. Now, in steaming, do not oversteam, or you will get a pulp; nor understeam, or your leaf will break in the roll; in rolling the less

weight used the better; but, before the machine is started, there is no objection to putting down the weight to get rid of steam water.

For every sorting a small lot of little round globules often occur. Keep these, and when sufficient, glaze them and class them as "gunpowder." With leaf coming in the evening, it can, after the first passage through the dryer, be left until morning to be rolled and finished off. It is (except in very wet cold weather) dangerous to keep leaf unsteamed through the night, as a small percentage of withered leaves spoils the appearance of your infused leaves in the cup, and gives a distinctly different taste to the tea, of what, I believe, is called the "Oolong" flavor.

In packing your finest teas I should use 3/8 in. boards of Cryptomeria Japonica, and this thickness is sufficient for 60 lb. and under, if matted or sewn in Hessian of a cheap variety. The cost is only fractional over the cost of half-inch packages, and the hoop-iron and hooping nails, both of which are saved in the *matted* package. Neatness of marking is advisable and two to three oz. over the nett lb. should be put in each package.

If "Momi" wood chests are used, use nothing under half an inch. All Japan teas, however, go in 3/8 in. Cryptomeria wood. I would suggest that if the Planters' Association give the present bonus, that they should only do so on teas *passed by Mr. Street* or any expert in Colombo, as sound good teas. If this is not done, a lot of rubbish will shortly find its way to America and do more harm than good. At present there is nothing to prevent a man sending away any rubbish he likes and claiming the ten cents. I consider this of vital importance, and urge the immediate attention of the "Thirty Committee" to this point.

I also hope the "Thirty Committee" will ask Mr. Wright to give them for publication invoices of all the teas they have paid him a bonus on. It will be interesting to follow the prices and the proportions of the grades in each invoice.—Yours, &c.,

H. DRUMMOND DEANE.

Peermaad, July 7.

P.S.—The teamaker at the Kellie Group factory was with me through all my experiments (Mr. H Patterson). I am glad he has a good situation. If his services could be spared to one or two of the larger concerns starting green tea manufacture, he would probably be of great use in helping to avoid mistakes.

THE TEA INDUSTRY: HOW TO SECURE THE 8D. AVERAGE AGAIN.

Sir,—Take a

200 acre estate giving 500 lb. per acre = 100,000 @ 6½d	£2,708
180 acre, (*i.e.*, = 200 less 10 per cent) giving 500 lb. per acre = 90,000 @ 8d...	£3,000
His gain on a year's working is =	£292
Deduct cost of simply weeding the 20 acres out of plucking at 1/ = (75 cts) = ...	£1
	£291

If therefore, we can, by reducing our output by 10 per cent, bring prices back to an 8d average, it will be clearly good policy to reduce our acreage, but, will men do it? No, they will not, unless a bonus is paid them out of the Cess, sufficient to cover cost of weeding the acreage out of plucking. There must be some inducement?—Yours truly,

OLD PLANTER.

THE POSITION OF THE TEA INDUSTRY.

London, June 20.

Dear Sir,—The speech of Mr. Rutherford at the meeting of the Ceylon Association last week, following on the very interesting and valuable circular of Messrs. Gow, Wilson & Stanton, will furnish reflection to everyone interested in the tea growing industry of Ceylon and India.

Rapid as has been the increase in consumption of British-grown teas of late years, production has now far out-stripped it. The balance on hand from last year was enormous, and so far this year the shipments to all countries from Ceylon are far ahead of last year. It is too soon to estimate the Indian outcome, but there is no reason to suppose it will be under that of 1899.

The market is now getting the benefit of the crops from the enormous areas planted in 1896, 1897, 1898, the full effects of which, however, are still to come. So far as we know, a comparatively small area of new land has been opened since 1898; but in Ceylon manuring is now helping to swell the output, and to complete the demoralization of prices already injuriously affected by extensions of area.

The rapacity of London dealers has often, and with reason, been blamed as the cause of the gradual yearly fall in prices—a fall that went on inexorably whether supply exceeded demand or fell short of it:—

In 1890 the production of Ceylon and Indian teas was	..	152 millions.
Consumption in all countries	..	150½ ,,
In 1898 Production was	...	273 ,,
Consumption in all countries	...	278 ,,

Yet the average price in 1890 was 10½d and in 1898, 8d.

The price has fallen regularly about ¼d a year, whether production exceeded consumption or not.

AVERAGE PRICE, CEYLON AND INDIAN TEAS.

1890.	1891.	1892.	1893.	1894.	1895.	1896.	1897.	1898.
10½	10⅓	9¾	9¼	9	8¾	8½	8½	8

Seeing that during those nine years our teas had practically secured the whole British trade, while exports to other countries rose from 16 to 62 millions, we might have expected prices to have been maintained, instead of which, however, they fell 25 per cent.

The public did not reap a corresponding advantage, for packet teas remained at prices fixed ten years ago—for instance 1s, 1s 4d, and 1s 7d. Wholesale prices are now much lower than in 1898, the fall being now in pence instead of farthings; yet except for alteration in duty, the public pays the same price.

The recent fall needs no rapacity to explain it. It is due entirely to over-production, and the question is, How can Tea Garden owners apply such a remedy as will speedily give them a living wage, or interest on their investments?

Two or three methods suggest themselves—the first and most certain and immediate in its effects would be that all tea grown, say in July, should be either destroyed or held off the

London market. It might be shipped to Russia and sold there for whatever it would fetch, but for the danger that it might be sent from there to London. It is beyond doubt that were 10 or 12 millions diverted in some such way from this market and a shortness of supply thus created, more money would be got for the remainder of the crop than for the whole at present prices.

As a case in point, taking the last series of ten years — the year which gave the shortest crop of Australian wool, had the largest return in total price. Again coffee has risen 30 per cent on what is a still unconfirmed short estimate of the Brazil crop.

A second method, equally sure, though slower in its action, would be that planters should aim at quality rather than quantity, and pluck 10 per cent less.

A third method is to make the teas the American public drink. This I have constantly urged for five years, but, of course, while tea planting was profitable, there was no chance of an audience. *No*, with true British stubborn wrong-headedness, we said :— "Let the American tea drinker abandon his coffee and green teas and pay his devotion to the Ceylon article, just as we choose to make it." The American ear is not so easily tickled. Our black tea has displaced black Chinas in America to a considerable extent, but we have made no progress against green teas, which are used to three times the quantity black teas are. Had we been sensible enough to begin to make teas for America five years ago, our present difficulties would not have arisen. But then the extension of planting would have gone on, and we must in the end have out-paced consumption. Our blind persistence in trying to make converts, has perhaps happily allowed the evils of over-production to be earlier apparent to us.

To get speedy relief in this way, Ceylon might make during the next few months, say three to four million lb. of green teas—*entirely uncoloured artificially* (Such teas have already been made from sea-level up to nearly 5,000 ft.) and ship them to America. If carefully made, I believe, these teas would sell at a price quite as good as we are now getting for black teas. But even were there a loss on them, the gain by taking that quantity off the market here would amply compensate.

India could make the same quantity of coloured greens, and dispose of them in a similar way. There are such a number of varieties of unfermented or under-fermented teas ranging from pure Japans to Formosas and Oolongs used in America, that the teas would sell, even if not true to any particular type.

But shippers would require to have Agents to protect their interests, unless prepared to sell them at ANY PRICE, as the few large importers would do all they can to have the goods "smashed" out at auction. And we cannot blame them :— they have costly establishments in China, Formosa and Japan. They have had the trade in their hands for many years, and are not likely tamely to submit to have it snatched from them. As Mr. Rutherford pointed out, it would pay Ceylon and India to get a quantity off this market, even if growers of black tea made good the loss on green teas.

If either of the first two methods is adopted to help us *speedily*, I believe the green tea business will increase so rapidly in America as to prevent our again falling into the present slough. What it wants now is *careful nursing and direction*. The chief difficulty just at present is to get the tea; but arrangements now being made will, I hope, overcome this, without at the same time flooding our young market too soon with crude or faulty teas, which might upset the good opinion many judges in America have formed of Ceylon greens.

Then, as Messrs. Gow, Wilson and Stanton suggest, the South American markets might be tried. Russia too is making remarkable progress with our teas. One gentleman asked at the meeting what Green teas were worth in America. Well, like Ceylon, the prices quoted in papers just to hand, ranged from 5d. to 1s. 1d. One report I see is to the effect that Japans are stronger and rising in price, while Ceylons and Indians are weaker on reports from London. There is more sale for Japans over 8d. than for Ceylons over that price.

All we want is *unanimity*, which should easily be attained in the community of educated men, when faced by what is, if not *ruin* to all, at least *that* to many, and pinched rations to the rest. The only question is, Has the true cause of this "lash of necessity" yet been recognised? What can it be but over-production? Shorten the supply and instead of a ring of buyers, organized to dole out to the grower only as much as will keep him alive, you would find them as Americans would say, "tumbling over one another" to get the stuff.

In a case before the Courts today, I see that peaches costing ½d. each at the Cape, were sold here at 65s a dozen. Why? *Because scarce* at a certain season of the year.

These suggestions are to meet the need for *immediate relief*. For the future, say beginning early next year, what is needed is much more extensive pruning before the great rush of leaf, which comes with the April rains. Teas made in April and May lack quality, and their quantity is so great that they smash the price every year in May and June. A leading distributor here said to me quite recently :—"We have no sympathy with the Ceylon planter now. Here you are pouring in millions of pounds of poor, pointless teas, which, if we buy, we must get into consumption within two months, as after that time they are worthless, except to make bulk in blends. They have no keeping quality."

WM. MACKENZIE.

OUR TEA INDUSTRY: HOW AN "OUTSIDER" VIEWS IT.

The Jungle, July 10.

DEAR SIR,—I am not a tea planter, but take a general interest in our staple interest, and have been reading the recent utterances of various authorities on Over-production and Reduction of Prices It has struck me that one branch of the subject has not received any elucidation, viz, the additional income from the additional quantity produced, and the reduction in cost of production in dealing with larger quantities. Do not these savings act as offsets to

the reduction in price. Thus an increase in production from 350 to 500 lb. per acre would stand as follows :—

	d	c	
350 @	10	= 70 @ 1/2	= R255*
500 ,,	8	= 50 ,, 1/4	= 250
		Loss per acre	= R5

or 1 cent a lb.—to be covered by reduced cost of production, less cost of manure and other charges attendant on dealing with the increase in bulk, *i.e*, transport, chests, etc.

I cannot follow the question further, but would be glad to see it worked out and ventilated.—Yours truly,

IGNORAMUS.

*["Ignoramus" is true to his name, seeing he works out 350 @ 70 c to equal R255 in place of R245—where is the loss? There is actually a gain of R5 per acre so strengthening his argument; but 50 cents is too high an average—many do not get 35 cents —Ed. *T.A.*]

OUR TEA INDUSTRY—THE QUESTION OF THE DAY.

Upcountry, July 10th.

Dear Sir,—It is highly interesting to me to read all the different schemes which are appearing in our local papers with regard to the best way to face the burning question of our planting day.

First, let us take Mr. Rutherford's plan of making 25 per cent. of an output into green teas and try if we can't ram, cram, and jam it down the throats of the Americans and Canadians.

If Mr. Rutherford is sure we can produce as good an article, and place it in those markets as cheaply as they are now shipped from Japan and China across the Pacific, by all means let independent planters and Companies shew us the way as you wisely suggest. My impression is that this tea is landed and sold much cheaper than we can do it and that practically we shall be trying to capture these great tea-drinking countries to little or no purpose or at any rate it will take a long time to get the wedge in.

Those in the trade have always held, I believe, that the nearer we get to China and Japan in prices the better our Indian and Ceylon Teas will take everywhere for the simple reason they are better worth the money, and the result will be, I think, that while the ousting process goes on our prices will harden. It is just possible we may manage to ship in the future 10 per cent. at least of our teas as greens, but it appears to me that it would pay us better than going on spending the cess money in pushing and advertising our products in places where they simply don't want black teas, if the Planters' Association would pay our planters a bounty on all greens we ship and at the same time promise a yearly bonus on every acre now in bearing they discontinue plucking and pruning and allow to rest, sufficient to defray the cost of weeding such resting acreage. It would do our estates no harm to let 10 per cent of the plucking area grow up for a year or two taking another portion of the estate in due course, if kept free of weeds. By these means, I have no doubt our total export will be reduced quite 25 per cent, thus arresting, in a great measure, overproduction which is pulling us down to close on non-paying point. Manuring and increasing the yield would find their own level, and, so long as the former is not increased and our plucking acreage is reduced, we need not fear; and further extensions, too, will, I think, be reduced to a mere nothing, once people see we are compelled to *put on the breaks.*

By a judicious planting of shade trees in suitable localities, thereby reducing cost of weeding, I think a considerable saving can be effected, for practically there will be no weeds; at any rate. This work can easily be done by the pluckers, they being made to weed each square before plucking. Doing this work in this way three or four times per mensem, there should be little weeding to do. Ramasamy, who has had a grand innings the last decade or two, should be made to give up his high-flown ideas *re* advances, which he has little intention of paying, and head kanganis' pay and kanganis' names should be *stoutly refused.* A long pull and a strong one, and a pull all together and we may get the ship off the rocks; but, something, both here and in India, must be done or she'll bump herself to pieces. Railway freight should be reduced on our best paying lines at once, on all up and down estate traffic.

Direct supply of our teas should be encouraged by every possible means and thereby get rid of that monster, the middleman.—Yours faithfully,

SYN AR Y HUND.

FODDER, GRASS AND AUSTRALIAN TREES.

British and Colonial Seed Warehouse,

Swanston Street, Melbourne, 22nd June, 1900.

Dear Sir,—We thank you for copy of your valuable paper of 16th May, duly to hand and note remarks *re* "Maram Grass," We are at a loss to understand how it could be described as "A splendid fodder both for fattening and milk production," it being worthless for such purposes. This view is borne out by reference to the following authorities :—Baron F Von Mueller, the well-known scientist and for many years Government Botanist for Victoria, in his work "Select extra-tropical Plants," page 337, he says, "like Psamma Baltica and Elymus arenarius, they can be used for paper material, for tying, and for mats. *They are not touched by grazing animals,*" London's Encyclopedia, page 57, describes its use for fixing sand against the action of winds and tides, adding :—"Mats are made of it, and it is used as thatch." Vilmorin Andrieux & Co. simply describe it as Reed grass, Seasand grass.

We think these statements fully justify our description which was based on local observation and render any further comment unnecessary.—We are, dear sir, faithfully yours,

LAW SOMNER & CO.

P.S.—By this mail we are sending you our catalogue thinking you may feel interested in the timber trees of Australia now being largely introduced into India and South Africa, see pages 98, 99 and 100.

L. S. & Co.

[The above letter refers to an extract given some time ago by a correspondent from a colonial journal praising "Maram Grass" for fodder purposes.—The catalogue sent us is a very full one and the list of the "Hardwood Timber Trees of Australia" is particularly attractive.—Ed. *T.A.*]

NEW LONDON CUSTOMS RULES: TEA TARING IN LONDON.

(General Order 42, 1900 Customs House, May 28th 1900.)

Tea Taring.—Regulations as to weighing with an added half-pound weight, increase in number of "Tarers" for averaging, and separate taring of bulked tea.

(1) The Board direct that, on and after the 1st June, 1900, in taring whether separately or for averaging purposes, any package of tea of which the gross landing weight was more than 28 lb. the weight of the empty package be ascertained as follows:—

When the scales have been carefully balanced, a half-pound weight is to be placed in, or attached to, the weight scale. The weight of the package must then be taken to the pound only, the weight scale preponderating according to the usual practice in taring. The half-pound weight placed in the scale is to be ignored in recording the tare.

(2) The Board further direct that, for average taring, the number of packages for "Tarers" prescribed by paragraph 61 of General Order, 127/1892, be increased as follows:—

When in a chop or bed, the number of packages of the same size and description of tea is

20 or less	3	tares	to be taken	and
from 21 to 60	5	,,	,,	,,
,, 61 ,, 120	7	,,	,,	,,
,, 121 ,, 400	9	,,	,,	,,
,, 401 ,, 700	11	,,	,,	,,
,, 701 and upwards	13	,,	,,	,,

Two or more beds in one chop may be tared together on the foregoing scale.

(3) Every package of tea bulked in the United Kingdom shall be separately tared.

General Order 102/1894, respecting taring of bulked teas, and the as yet suspended London Port Order 39/1899 are hereby cancelled.—By order of the Board, (Signed) John Courroux.

A NEW TEA DISEASE.

Mr. A. Brown, of the Glenfruen Estate, Devala, brought before the meeting of the Planters' Association in Ootacamund on the 10th instant, the correspondence that has passed between himself and the District authorities regarding the ravages of a new tea malady of a fungus character. It appeared in May of this year in a nursery, and destroyed no less than 75,000 seedlings. In 1898 and 1899 Mr. Brown's seedlings perished, as he supposed, at the time, from drought, but as he now suspects from this new disease. He addressed Dr. Watt on the subject last year and forwarded samples of the diseased seedlings but these were not received in a condition to admit of examination when Dr. Watt returned to Calcutta from Burma, and he therefore was not able to accurately determine the disease. Dr. Watt sent some of the seeds to England, and received a reply in May last, from which he gathered that the seedlings were affected by eelworms. This malady, he said, was of a very alarming nature. For some years past it had been rapidly extending all over the world, and attacking every class of plant. Dr. Watt further informed Mr. Brown that his were the first samples of tea affected by the disease that he had received, remarked that he had met with what appeared to be eelworms in coffee during his late visit to the Wynaad, and concluded by asking that fresh samples of the diseased plants might be sent, promising to offer suggestions as to treatment. In an earlier communication on this subject, Dr. Watt recommended washing the plots affected thoroughly and repeatedly with Bordeaux mixture, which consists of 50 gallons of water, 6lbs. of copper sulphate and 4 lbs. of unslaked lime.—*Madras Mail*, July 12.

AGRICULTURE IN THE WEST AND EAST.

We cannot forego the pleasure of publishing the following gratifying letter received by a recent mail from Dr. Morris, C.M.G., Imperial Commissioner for Agriculture in the West Indies:—

Imperial Department of Agriculture for the West Indies, Barbados, 30th May, 1900.

I am in receipt of your letter of the 20th April, and I am greatly concerned to find that you have not received the publications of this Department. Your name was amongst the first to whom I had arranged to forward every thing published at this office. I cannot understand how it is that our sendings have gone wrong.

I have pleasure in forwarding, by this mail, copies, of the "West Indian Bulletin" Nos. I and II, and a Pamphlet issued on "Moth Borer in Sugar Cane." The third Number of the "Bulletin" will be out in the course of another week and a copy will be sent to you in regular course. I assure you that I shall be happy at all times to be of service to you in this part of the world, as I entertain the warmest appreciation of your kindness in regard to everything connected with the *Ceylon Observer*, and your numerous publications on planting subjects in the tropics.—With very kind wishes. Believe me, Very sincerely yours, D. Morris.

IMPROVEMENT IN TEA MANUFACTURE.

It is very satisfactory to know that "perfection" has, by no means, been attained, in respect of the various processes observed, or in the final result as regards the preparation of the tea leaf for market and consumption. There is plenty of room in several directions for the exercise of the inventive faculties, of our planters, engineers, etc. And it is especially interesting to note that the latest alleged improvement—and patent machine—comes from a gentleman who bears an historic name in the mercantile and pioneering annals of Ceylon. Mr. John Armitage, in the "forties" and "fifties," was one of the most prominently enterprising and successful of our colonists: he had brought from South America a great deal of experience to turn to account here; and he rapidly became a leader among our merchants. The present inventor of an improvement in tea manufacture is his son, Mr. H. T. Armitage, and elsewhere we take from our evening contemporary, an interesting account of the process. We shall be glad to learn what other practical planters think of it. Already it has secured a special measure of success; and we heartily trust it will do for many more estates, what it has realised for Dunbar in raising the average value of its teas, some nine cents per lb.

OVER PRODUCTION OF TEAS.

To the Editor of the *Home and Colonial Mail.*

Sir,—It would perhaps be unnecessary to reply to Mr. Hughes' letter in your last issue, were it not that he appears—unintentionally, no doubt—to have drawn wrong inferences from my letter, in order to air his hobby of manuring.

I pointed out that the average fall of one farthing per pound per annum for ten years was due to the rapacity of dealers rather than to over-production, but that over-production was clearly the cause of the recent much more rapid fall. Mr. Hughes says the steady fall is probably due to a decline in quality. But the fall has been in both Indian and Ceylon teas, practically the only teas consumed. The prices of 1s, 1s 4d, and 1s 7d, seem fixed to consumers. If rapacity has nothing to do with this steady fall, where do dealers buy the finer and dearer teas to blend with the teas of Ceylon and India so as to justify the same price to consumers as was charged ten years ago, when teas cost them 3d. more?

I did not say teas made in July were inferior—on the contrary we know they are about our best teas. I did say the most certain method of improving the price was to keep a month's crop off the London market. This merely to emphasize the fact of over-production.

He who would advise general manuring under present circumstances, with the certain result of further over-production, would deserve to rank with those who refuse help to drowning men, unless such help is paid for. I quite agree with Mr. Hughes when he says "there is plenty of scope for a higher individual price." But where is the foolish Quixotic dealer who would pay this higher price while over-production is rampant. Again, a general, not individual, higher price is necessary to sustain the industry.—Yours faithfully,

Wm. Mackenzie.

July 4, 1900.

TEA SAMPLING.

TO THE EDITOR OF THE HOME AND COLONIAL MAIL.

Sir,—I venture to draw your attention to a matter which in my judgment merits the strongest condemnation, namely, the manner in which tea is sampled at present in many of the dock warehouses. A dealer buys a break of, say, 100 chests in sale, on a sample which possibly weighs three ounces. Immediately after sale he sends to the warehouse for, say, eight pounds from eight of the chests; and the supposition has always been that the dock company opened eight chests and furnished him with a pound from each, charging 4d per chest for the service rendered. But, can it be believed that in numbers of tea warehouse two or three pounds are taken from one chest—possibly from a chest already open, so that the benefit to the buyer of getting eight separate samples from as many different chests, not previously sampled, to enable him to check his purchase, is entirely lost. But he is nevertheless charged 4d. per package for opening eight chests, and at the same time deprived of the power to ascertain if the bulk is equal to sample or whether the break is regular in quality or not; in fact, it is quite possible for the dock company to scamp the bulking of the tea, and escape detection afterwards till the buyers chance of establishing a claim for irregularity has lapsed under the public sale conditions. Surely this is a matter which the Brokers' Association should look into if the honourable traditions of the tea trade are still to be maintained.—I am, &c,

D. F. Shillington.

THREE NEW SPECIES OF EUCALYPTUS.

By R. T. Baker, F.L.S., Curator, Technological Museum, Sydney.

Eucalyptus Oreades, sp.nov. A "Mountain Ash."—A tall tree with a smooth whitish bark down to the ground, or sometimes leaving a lighter rough bark 6—8 feet from the ground.

E. Maculosa, "Spotted Gum."—A tree rarely exceeding 60 feet in height, usually from 20—40 feet (W.B.). Bark smooth to the ground.

Eucalyptus Patentinervis, "Bastard Mahogany."—A medium-sized tree as far as seen, with a stringy bark similar to that of *E. resinifera* Sm

On two New Species of Casuarina.—By R T Baker, F.L.S., Curator, Technological Museum, Sydney. From the proceedings of the Linnean Society of New South Wales, 1899, Part 4, October 25th. Casuarina Cambagei, sp. nov. —"Belah."—A tree attaining a height of from 70 to 100 feet, dioecious, glabrous; branchlets glaucous or dark green in the slender form, ascending, internodes varying in length up to half an inch; not prominently angled. Casuarina Luehmanni, sp. nov.—"Bull Oak."—A fair-sized tree, attaining a height of 70 to 80 feet, or rarely 100 feet, and a diameter of from 1 to 1½ feet, rarely 2 feet. Bark furrowed, brittle, and easily removed. Branchlets robust, light coloured or glaucous, under a line (½) in diameter, about the same thickness as in *C. glauca*, Sieb. the internodes ribbed, 6 lines long, glaucous, the nodes yellow, sheath-teeth brown or black, short, acute, 9 to 12 in the thorl, mostly 11.

BRAZIL COFFEE NOTES.

Telegrams from abroad state an accord has been reached between Brazil and Italy in regard to the duties on Brazilian coffee. It is also said that France has consented to knock off 20 francs, which in our opinion is not sufficient.

The *Commercio de S. Poulo* of the 23th ult., says that recent torrential rains have greatly prejudiced the coffee crop in the Ribeirão Preto district. At Mocóca and other points the rains have knocked off much fruit, the damage being estimated at one-third of the crop.—*Rio News* June 5.

A São Paulo telegram of the 10th inst., says that in three Italian steamers 3,000 Italian laborers had left that state for Italy. This at the beginning of the coffee picking season is a bad sign. The planters cannot be managing well if laborers are leaving the country just at the time when they are most wanted.—*Rio News.*

America to Grow Green Teas!—Just as we in Ceylon are making every effort to send green teas to the American continents, lo and behold! the black-tea-producing country in South Carolina intends to take up the pursuit. We quote as follows from the *Planter* of June 7th, but let no local planter be alarmed, in spite of the apparent success of the Carolina plantation:—

Dr. Charles U. Shepard, Special Agent in charge tea culture investigations, writes to us from "Pinehurst," Summerville, South Carolina:—"The experimental irrigation which I am now introducing into my tea gardens should materially increase the leaf production. According to my best results, it would seem possible to produce decidedly more than 500 lb. of dry tea per annum per acre. Can you favour me by sending any printed data as to the best methods followed in India in the manufacture of *Green* tea? . . . As yet I believe no good results have followed the attempts to apply mechanical processes to this manufacture."

DIMBULA VALLEY (CEYLON) TEA COMPANY, LD.

ANNUAL REPORT.

Directors' Report to be submitted to the Shareholders at the fourth annual ordinary general meeting to be held at the Cannon Street Hotel, on Monday, the 25th day of June, 1900, at 12 o'clock noon. The Directors beg to submit the General Balance Sheet and Profit and Loss Account for the year ending 31st March last. After bringing forward £802 12s 9d from last accounts and providing for general expenses, London office expenses, and £500 for depreciation, the net amount at credit of Profit and Loss Account is £18,894 5s 8d.

Dividends aggregating 6 per cent. less Income Tax have been paid for the 12 months on the Preference Shares amounting to ..	£3,440	2	0
An Interim dividend of 4 per cent, less Income Tax on the Ordinary Shares, has been paid, and amounted to	4,586	12	0
It is proposed to pay a final dividend of 6 per cent on the Ordinary shares making 10 per cent. for the year, and which will amount to	6,879	18	1
It is proposed to carry to a Reserve Fund	2,000	0	0
Thus leaving to be carried forward to next year a balance of ..	1,987	13	7
	18,894	5	8

The past season was a normal one in the Dimbula District, the yield from the Company's estates being at the rate of 512 lb. per acre from tea in bearing, or a total of 1,079,829 lb. against the previous year 930,281 lb.

The cost of cultivation and placing the crop on board ship in Colombo was 25·77 cents per lb. as against 29 cents for '98-'99 crop.

The total crop realised (including 110 cwt. coffee) £42,558 10s 7d or an average for the tea of 9·49d per lb., against £39,127 13s 4d or 10·09d per lb. the previous year. Exchange averaged 1/4 15/32 per rupee, against 1/4·29.

The freight, warehousing and selling in London, including Fire and Marine Insurance from the field to the prompt date, cost ·90 of a penny, and too much credit cannot be given to the Agents for their care and economical working.

The estates are as usual in a good state of cultivation, and the thanks of the Company are due to the Manager and his Staff for the ready and willing manner in which they have co-operated with your Board to this end.

To be in accordance with the usual custom of Tea Companies, and to facilitate the operations on the estates, the Directors consider it advisable that the Financial Year be closed on the 31st December annually, instead of 31st March as at present. They propose bringing this alteration into effect forthwith, making the present year one of nine months only.

During the year Mr. T C Owen was elected a Director in the place of the late Mr. C J Rowe.

Mr. W Forbes Laurie retires by rotation, but being eligible, offers himself for re-election.

Messrs. Singleton, Fabian & Co., the Auditors to the Company, retire, and being eligible, offer themselves for re-election.

JAMES SINCLAIR, Managing Director.
BERTRAM F. WHITE, Secretary.

14th June, 1900.

BOGAWANTALAWA DISTRICT TEA CO.

ANNUAL REPORT.

Report presented at the Third Ordinary Annual General meeting of the Company, held at the office of the Company on Wednesday, 27th June.

The Directors have the pleasure to submit the balance sheet and accounts of the Company for the year ending 31st March 1900, duly audited.

The yield of Tea largely exceeded the estimate and the cost of production has again been reduced, but the average price of the Tea sold in London compares unfavourably with that of the previous year, the market having been very dull for the last three months.

The Ceylon expenditure includes £300 13s 7d spent on planting 84 acres with Tea and felling and clearing a further 13 acres, as well as £420 13s 2d the cost of a new Turbine and of altering the watercourse in Elbedde.

The total yield was 1,209,451 lb. Tea plucked off 2,185 acres, of which 1 4 acres are only in partial bearing, being at the rate of 553 lb. per acre all round, costing free on board at Colombo 22·61 cents or 3·69d per lb. The gross average price of the 1,186,433 lb. sold in London was 7·98 per lb.

The crops for the current season are estimated at 1,121,000 lb. tea.

The gross average at which drafts were negociated was 1/4 5-16 per rupee against 1/4 5-32 and 1/3 9-19 in the two previous seasons.

The Directors desire to place on record their appreciation of the services of their Manager and his staff in Ceylon.

STATEMENT SHEWING RESULTS OF WORKING FOR THE THREE YEARS ENDING 31ST MARCH.

Season.	Acreage Plucked.	Total Tea Crop.	Yield per Acre.	Cost of Crop per lb. f.o.b., Colombo.	Gross average per lb. Tea sold in London.	Average rate of exchange per Rupee.	Dividends Preference.	Dividends Ordinary.

CEYLON ESTATES INVESTMENT ASSOCIATION, LIMITED.

ANNUAL REPORT.

The Directors beg to submit the Accounts for the year ending 31st March 1900. The crop harvested amounted to 296,673 lb or 59,521 lb in excess of the previous year. The average price obtained was, however, about ¾d per lb lower.

The Balance at the credit of Profit and Loss Account, including £207 15s 11d brought forward from last year is	£1,879 10 8	
which the Directors propose should be applied in payment of a Dividend at the rate of 5 per annum, free of Income Tax,	1,550 0 0	
and that the balance of		£329 10 8

be carried forward to next year.

The Directors who retire at this time in conformity with the Articles of Association are Mr. Robert King and Rev. Peter Grant, D.D. They are eligible and offer themselves for re-election, and the Directors recommend the election of Mr. Gavin Whitelaw as Director. The Auditors, Messrs. Moores, Carson & Watson, C.A., also retire, but are eligible to be re-appointed.

ROBERT KING, Chairman; BROWN, FLEMING and MURRAY, Secretaries.

DUMONT COFFEE COMPANY, LIMITED.

ANNUAL REPORT.

Report to be presented at the Fourth Annual General meeting of the Dumont Coffee Company, Limited, to be held at Winchester House, Old Broad Street, London, E.C., on Friday, the 22nd day of June, 1900, at 12 noon.

The Directors submit the General Balance Sheet and Profit and Loss Accounts for the year ending 31st December, 1899. The profit for the year amounted to the sum of £41,731 4s 5d; carried forward from 1898, £2 325 8s 3d = £14,086 12s 8d. Interest at 5½ per cent per annum has been paid on the Debentures amounting to £21,989 0s 0d; interim dividend on the Preference Shares paid in July, 1898 (together with income tax thereon), brought forward in the balance sheet last year £15,000 00d = £36,989 0s 0d; leaving a balance proposed to be carried forward of £7,097 12s 8d. The coffee crop amounted to 93,301 cwt., against 41,476 cwt, for the previous year. Of this, 31,687 cwt. were sold in London, and the remainder in Santos and New York. The gross average price realised for all the Coffee was equivalent to 29s 4½d, landed in London, taking the exchange at 7½d per milreis, which is the rate fixed by the auditors for the year's accounts. During the greater portion of the selling season, the coffee market was at a lower level than ever recorded during the last half-century, and for this reason, the average price obtained for the Company's crop was unfortunately extremely low. The spot price for good average Santos coffee for the five months, June to October, 1899, was 26s 10d per cwt., the rise in the coffee market not taking place until the end of 1899, and the beginning of 1900, by which time the greater portion of the Company's crop had been sold; the present price is about 38s 6d per cwt. As the Company's pulped coffee formed the greater portion of the earlier part of the crop, it obtained a lower average than the unpulped coffee, which did not come forward for sale until the latter part of the season. The Directors have satisfaction in recording that the large crop of 93,301 cwt. was well harvested in good time, which was due to the now completed railway system over the property, and to a well organised labour force under European management. The Shareholders will be glad to know that "Dumont" coffee has established a good name in European markets on account of its superior flavour as compared with Santos coffee generally, and now commands a better price than other Brazilian coffees on the London market. This the Directors consider attributable to the complete system of drying grounds and strong sheds with which the properties have been equipped, as well as to the careful work of the staff. Mr. G A Talbot visited the property in September last, in accordance with the desire of the Shareholders as expressed at the last annual general meeting. He was then able to go carefully into all details of expenditure with the Company's manager and staff, with the result that the Directors have been able to effect economies in working. The manager reports favourably on the condition of the coffee trees, both old and young, and estimates the current crop at 75,000 cwt., which at present prices would yield a considerably increased profit as compared with the year under review. The weather recently has been somewhat unfavourable, but cabling on the 31st May last, the manager reports:—"I have hope that 'Dumont' estimate may probably be obtained." There are now 10,918 acres in bearing, and 2,343 acres of young coffee, making a total of 13,261 acres planted. Major F B McCrea and Mr. C A Carlisle have, since the last meeting, ceased to be Directors of the Company, and Mr. Stratten Boulnois has been appointed to a seat on the board. Mr. H K Rutherford and Mr. G Talbot are the retiring Directors, and, being eligible, offer themselves for re-elec tion

KELLIE (CEYLON) TEA PLANTATION COMPANY.

ANNUAL REPORT.

The following is the report of the directors submitted at the meeting held on the 5th inst., for which we are indebted to Messrs. Aitken, Spence & Co.:—The directors beg to submit herewith the accounts for the year ending March 31st, 1900.

The balance of profit and loss account, after writing off 10 per cent. depreciation in value of machinery and buildings is (including £333 7s 9d brought forward from last year)..	£342	1	0
Out of this sum the Directors recommend a dividend of 3½ per cent. on the preference shares	350	0	0
Leaving to be carried forward to next year	£492	1	0

The tea crop for last season amounting to 345,220 lb. is largely in excess of any past year, mainly attributable to the careful application of artificial manure on different parts of the Estates. The Directors purpose continuing the treatment as may be required.

Prices for tea have not been maintained, and the average of the Company's crop is barely 5½d per lb., against fully 6¾d per lb. last season. This has negatived almost entirely the profit which was expected from the increased yield.

The Directors have excellent accounts of the cardamom clearing, and have decided to increase it from 40 acres to 70 acres. This work is now in hand. A small quantity of cardamoms have been taken off the 40 acre clearing, which shews good quality.

The Engine and Boiler being too small for present requirements, besides being considerably worn after so many years use, the Directors have decided to replace at a cost of between £500 and £600. The order has been entrusted to Messrs. Brown & May.

One Debenture Bond for £500 has been paid off during the year. Mr. Spence retires, by rotation, from the Direction, and being eligible, offers himself for re-election. The Auditors, Messrs. Brown, Fleming and Murray, also retire, and offer themselves for re-appointment.

RHEA AGAIN.—We have not lately heard much of rhea locally; but with the Northern line open, we should hear more of it in a few years. The following news published by the *Friend of India*, is encouraging:—"A new demand, which promises to be permanent, has arisen for rhea. Messrs. Thirkell & Co., of Fenchurch Street, London, have written to the Secretary and Curator in the Indian Section of the Imperial Institute, to say that they are prepared to take at £15 per ton, all the rhea ribbons that India can produce for some years to come, and they offer to supply at £40 each, decorticators which are capable of preparing about ten cwt of stuff a day. Government has been asked to foster the cultivation of rhea as much as possible. In forwarding the correspondence on the subject to the Bengal Chamber of Commerce, Dr. Watt, the Reporter on Economic Products, observe that Messrs. Thirkell & Co. require the rhea ribbons in ther crudest form."

TEA ESTATE CULTIVATION IN CEYLON.

(By Chairman Dimbula Valley Co., Mr. John Sinclair.)

THE QUESTION OF USING ARTIFICIAL MANURES

I shall quote a paragraph from an otherwise interesting circular issued by a firm of tea brokers, Messrs. Gow, Wilson nda Stanton, to whom, by the way, tea planters owe much for information which they evidently spare no trouble or expense in obtaining from all parts of the world. The paragraph is as follows:—"Again have producers asked themselves whether manuring will develop permanent strength and vigour sufficient to withstand the strain of continued pluckings, especially in the event of over-production reducing the prices so low that artificial manure cannot be afforded." Now, apart altogether from scientific opinion, the question has been abundantly answered by experience of at least twelve years that artificial manures not only do not develop weakness, but absolutely the reverse, even when applied with the specific object of increasing the yield, and that by these repeated applications not only are the owners of estates not living on their capital—as it was rather inaptly termed by a gentleman recently in explaining to his shareholders his ideas on the subject, and to whom I shall have presently to refer—but, as I will show, are adding to the capital value of their gardens. If tea drops below the price at which artificial manure can be afforded, woe betide those gardens, which, without it, never yield over 300 lb. per acre. I will tell Messrs. Gow, Wilson and Stanton that but for the use of the very manure they depreciate, a very large number of tea gardens could not for some time now have met expenditure, to say nothing of leaving profit. There are many gardens which have been, by the judicious use of artificial manure, brought from maximum crops of 300 lb. per acre per annum to 700 lb. and over yearly—the former only capable of being laid in London at about 6d per lb. and which, whilst the average price was 8d, left some profit, but which for some time now, and certainly today, would barely have paid cost of production; while 700 lb. has been put in London for less money—namely, 4½d to 4¾d per lb., also a better tea, and even today leaving something for profit—the bushes, too, after all those years of the treatment I speak of, as vigorous as could be wished for, in fact, raised in many cases from having a low job appearance to the very best. Whatever apprehension is professed by some, a walk round the gardens I refer to will demonstrate to the merest tyro that there is no sign of defunction about, and those who saw the places prior to manurial applications can have but one opinion—namely, that the estates are better in every way, and look like lasting longer than non-manured ones.

SCIENTIFIC OPINION.

Now for a little scientific opinion. Probably many of you will have heard of the discussion which has taken place in Ceylon regarding a speech made in London by a director of a large and successful tea Company at a recent meeting of shareholders, the purport of which, I rather gather, took the shape of a warning to planters and those interested in tea to avoid the use of artificial manures, or, to put it more correctly, forcing manures, otherwise the effect would be

dangerous. Now I think I know most of the fertilisers used and the quantities applied, and in no case is there, in my opinion, an approach to overforcing. Now, as more weight may be given to this gentleman's words than they are entitled to, and holding the position he does in one of the most successful tea companies in Ceylon—a success, as he would be the first to admit, not in any sense owing to the exercise of special acquaintance with manuring operations applied to tea—I cannot let his views pass unnoticed, especially as he quoted, in support of them, the authority of perhaps the greatest living scientist of the day—namely, Sir John Lawes, Bart., of Rothamsted. It is of the greatest importance that it be known that the gentleman I refer to has evidently misunderstood Sir John. I trust, therefore, you will bear with me in giving you the facts regarding that, as well as my own opinions derived from a practical experience of 40 years of agriculture in this country and in Ceylon. The director I refer to was telling his shareholders and the world the policy he recommends in the cultivation of that company's gardens, and warning all and sundry against the use of artificial manures, more especially sulphate of ammonia, as being too forcing and exhausting. He winds up with the following words :—"I have also consulted Sir John Lawes, who, you all know is a great authority on agricultural chemistry and he deprecates the use of forcing manures, such as sulphate of ammonia, as being undesirable to use." Now, gentlemen, this rather astounded me, for I have kept myself all these years fairly in touch with the experiments made by Sir John Lawes and his collaborateur at Rothamsted, and applying what I had gathered from that source to tea cultivation, I felt that either the gentleman had not supplied Sir John with all the data which would be necessary for him to form an opinion as to what would be the most suitable manure for the tea plant, with which he (Sir John) had probably no practical acquaintance, or what was even more likely, that Mr. ——had misunderstood what had been said to him. I wrote to Sir John to that effect, giving him all the information I could regarding the tea plant, and I quoted the opinion which had been attributed to him in the above-mentioned speech.

SIR JOHN LAWES'S OPINION.

It was as I had supposed, but his letter speaks for itself. It begins :—"I regret to find that Mr. ——has somehow mistaken my views in regard to the character of manures suitable to the tea plant. This is rather singular, as I told him that some very fine Peruvian guano, said to contain 8 to 10 per cent. of ammonia, had been imported, and I thought it would be a valuable manure for the tea plant. Except tobacco, I should think that the tea plant would require a greater abundance and more forcing manure than any other crop grown." There is more to the same effect, but that, gentlemen, is Sir John's opinion. I would only add that the utmost care should be exercised by planters in obtaining opinions from scientific authorities on points on which, without all the data, it is impossible for them to arrive at a correct conclusion ; and when they do obtain it to be sure they understand it, otherwise, as in the case I mention, much harm may follow. If a scientist in agriculture, who never saw a tea bush growing or cultivated, were asked whether this or that manure would be too forcing or cause exhaustion in the long run, the answer would probably be :—"Yes," because he could only bring to bear on the subject his knowledge of what those manures would do for a turnip, wheat or hay crop ; but there is a great difference. A tea bush on your properties is pruned, or more correctly speaking, is cut across the hard wood say, 2 feet or less from the ground ; the next knifing it gets is 24 months after ! In the meantime it has thrown out shoots and grown up to a height of 5½ feet and has produced something like 4,000 lb. of succulent leaf per acre, which, when manufactured, turns out 1,000 lb. of tea. This, gentlemen, is all that is removed from the soil—namely, 500 lb. per acre per annum ; the bush before pruning has a mass of green leaf and stalk, as well as matured wood, which, when cut off, weighs not less than 5 lb. per bush, or a total per acre of 20,000 lb., which, if dug into the soil, probably returns more plant food to the roots than has been removed in crop, and for the reason that the tea bush derives a great deal of its nourishment from the atmosphere, the larger proportion of which, along with that derived from the soil, being returned to it in prunings. There, gentlemen, is all the difference between the tea and the hay, wheat and turnip crops which are entirely removed from the soil, and to which if forcing manure only were applied the soil would cease to respond. The tea bush is not usually grown for its seed, which is, of course, a greater strain than growing leaf only. Were it grown for seed production, stimulating manures would have to be avoided. The finest soil, whatever the altitude above sea level, produces in greatest abundance the highest class of tea—that is, the soil which contains in an available form for assimilation by the roots all the different ingredients required for the plant's nourishment. If it is not there in its proper proportion or if any are wanting you will never get a healthy bush or a good tea. Place them within reach of the roots and you constitute a condition even in poor soil which will give you a higher class of tea than your neighbour who does not.

THE MAIN CAUSES OF EXHAUSTION.

You will naturally ask. Why require to add anything further than your prunings, since you say your tea crop does not exhaust the soil ? Well, if cropping were the only cause of exhaustion that might be pertinent, but there are two other sources vastly more impoverishing than that of the removal of 500 lb. per annum of tea crop, and these are points which men, seeking aid from a scientist in this country, should not overlook, these are—however well drained the field may be—the removal of the soil by the tropical showers falling on our steep hill-sides and carrying it to the rivers ; and even worse than that, the washing in solution to the nearest drain of much of the food ingredients. It is a mistake to suppose that during the heaviest rain, even although wash is not apparent on the surface, it all sinks into the soil ; a great deal of it oozes below the surface—carrying, as I say, in solution, much plant food—to the nearest drain, especially where surface soil has been disturbed for manuring purposes. This can often be proved by the appearance of a saline deposit on the upper side or walls of the drain. Entirely different is the case in this country ; rarely, if ever, is soil washed away, and rain which falls on the comparatively flat fields finds its way to the subsoil drains, and carries little or nothing away in solution. In tea fields there is no such thing as a subsoil drain

they are open surface drains and act in the manner stated. These, in my opinion, are the main causes of exhaustion on Ceylon tea gardens, and is the reason why additional fertilisers, other than prunings, become necessary in a lesser or greater degree, turning on the configuration of the field and the methods adopted immediately after planting, to stem the wash of soil as well as to protect as much as possible this oozing away by the heavy rains we are subject to. Old coffee estates, such as those I spoke of as yielding but 300 lb. an acre, which suffered from both causes, besides from heavy coffee crops, could only have paid as tea estates for the last year or two by the use of fertilisers, and proprietors of such would indeed be short-sighted to give up their manuring operations with the idea of leaving a better margin of profit. But there is another class of garden, such as those comprising the Dimbula Valley Company's, or, indeed, the bulk of those which were in the coffee days called the young districts, taken from jungle between the years 1865-1885, and which, owing to leaf disease, had their coffee fields denuded of coffee before exhaustion from cropping could take effect, and which by experience gained in the older districts, whereby protection from wash was seen to be imperative, were drained, even before planting with coffee, and so had their original soil practically untouched when the tea plant was substituted for coffee. This is another class of garden, requiring different treatment and justifying a different aim altogether from that followed on the older estates.

THE POLICY OF THE BOARD.

As this is what must interest you, as proprietors of the Dimbula Valley Estates, I will now explain the policy we have hitherto followed in cultivating your properties, and which will assuredly be followed, if I can have my way, so long as I have anything to do with the management. It is well known that if tea bushes on such gardens can be kept in condition, the more frequently they can be plucked the better will be the class of tea produced. Well, our aim is in this direction, and if by plucking every eighth day, or even less, all the year round, you can succeed in getting a strong and vigorous flush—by helping the bush with fertilisers—every eight days, instead of, perhaps, every ten or twelve, you will get, not a larger quantity, but the same quantity as if the bush got no assistance, but of a much higher class of tea. I think it would be a great mistake on an estate with a normal yield of about 500 lb. an acre, without assistance from manure, to add manure in order to get 700 lb. or 800 lb. of inferior tea, which latter is perfectly possible on such estates. Support your bushes for quality, not quantity and in doing so you will in your prunings return more to the soil than is removed in crop. This, gentlemen, is the policy which we are carrying out on your estates, and if the proprietors or company who go to sleep at such a time as we are passing through in tea do not wake up, but adopt some retrograde policy such as that advocated by Messrs. Gow. Wilson and Stanton, woe betide them. You will see that our yield last season was but 512 lbs. per acre, whilst it could readily have been made one-third more. You see, its cost f.o.b. was 25·77 cents per lb. You also see our net profits, and can therefore quite easily judge whether the policy we are carrying out is a sound one. I have no manner of doubt myself, and I am sure the best experts will agree with me.—*Financial Times*, June 26.

TEA TRADE OF KIUKIANG IN 1899.

The annual reports of Mr. T F Hughes, Commissioner of Customs at Kiukiang, are always worth reading, Mr. Hughes's long experience and his habits of observation making his remarks on the course of trade as interesting as the facts on which he bases them. When Kiukiang was opened to foreign trade, it was prominently a tea port; its prominence in this direction dwindled away as the United States took to drinking Japanese tea and Great Britain Indian and Ceylon tea. But Mr. Hughes thinks that the tea business is not irretrievably lost. He says :—

The export of Black Tea in the year under review amounted to 131,145 piculs, or more than 9,000 piculs in excess of the quantity in the preceding year which was itself an advance on the figures of the year before. Brick Tea has also been steadily progressing during the last few years : its export in 1897 was 52,839 piculs, in 1898 it advanced to 33,831 piculs, whilst in 1899 it totalled 43,352 piculs. Green Tea also shows signs of improvement, but as it chiefly passes through this port now to be dealt with at Shanghai, it need not be further dwelt upon here. The reports by experts on the Tea market of the year under review are not so rose-coloured as our figures might lead one to expect. It seems the Keemuns were not, on the whole, as good as in the previous year, whilst the Ningchows were disappointing, the famous Ningchow district, in fact, being likely to be outdone by the preference shown nowadays for the stronger Hankow Oanfa district Teas. A gentleman well versed in the trade favours me with the following interesting remarks:—"The demand for Indian and Ceylon Teas is growing more and more all over the world, and as Chinese teamen refuse to introduce machinery, it is only a matter of time until the China Tea trade dwindles down to a very small item. To an educated palate a fine Keemun is much preferable to Ceylon or Indian ; but it is 'strength' (strong cup) that the public now calls for, and the Indian and Ceylon Teas supply this, owing to careful cultivation and machinery preparation. The export of Indian and Ceylon Teas to Russia (hitherto China's biggest Tea customer) is increasing by leaps and bounds." This authority evidently believes, like many others, that by the aid of machinery and more careful cultivation, the Chinese could easily produce Tea in abundance, to suit the present taste of the public, just as Ceylon and Indian teamen do ; and if the Government went further and did what other Governments, with such an ancient and valuable industry to revive and foster, would be almost sure to do, namely reduce the export taxes and duty, it is, I think, almost certain that the Tea export from China would ere long regain its old supremacy ; indeed it would be hardly too much to say, anomalous as it may appear, that the very reduction of the Tea duty would, by the expansion it would create in the export, before long increase the Tea revenue, whilst the augmented wealth and prosperity of the producing districts would give an impetus and activity to general trade which would be far-reaching in its effects, and would ultimately redound to the well-being of the Government and the country.—*N.-C. Herald*, June 27.

"THE SULPHATE OF AMMONIA" misconception, as finally described by Mr. Melville White, elsewhere, does not reflect credit on Mr. G. A. Talbot's estimate of the amount of commonsense appertaining to his brother-planters. To suppose that anyone applied this artificial manure by itself for a series of years to tea, and that it was to have the same effect as on grass land at home, is rather too—too much altogether!

PLANTING NOTES.

Tea Planting: Guatemala and India Contrasted.—Tea planting in the Guatemala, we are aware, could never become a great industry, but we merely mention the fact of the desire of the Government of that State to develope the resources of the country, whereas in this highly civilised land it is the other way about. Every possible check is put to the progress and growth of private enterprise by Europeans, whom the jealous officials still appear to regard in the light more or less of interlopers.—*I. P. G.*, July 14.

Green Teas.—We hear of considerable activity in a number of factories towards beginning the manufacture of green teas; and it is quite expected that half a million lb. will be exported by the end of this year and not less than two millions of "greens" next year. If India gives a fair trial (and its offer of about nine cents a lb. should be an inducement) and makes three or four millions lb., by the end of 1901, the American market should be fully tested so far as British-made "greens" are concerned.

Empire of India and Ceylon Tea Company (Limited).—The report for 1899 states that for the greater part of the year there was good seasons to expect satisfactory results, but at the height of the selling season the market value of medium and fine teas fell heavily, and the fall in price from the beginning of November represents a loss of fully £10,000. The excess of the Indian crop over the outturn of the previous year affected general prices unfavourably, except those of low grades which were maintained by exceptional causes. The mismanagement reported to the shareholders last year necessitated heavy expenditure on some of the gardens in order to bring them up to a high state of efficiency. The net profit for 1899 is £19,853, to which must be added £146 brought forward, together £19,999 After providing for the dividend on the preference capital there will remain a balance of £9,049. The directors recommend a final dividend of 3s. 6d, per share, making, with the interim dividend already paid, a total distribution of 4½ per cent. per annum on the ordinary capital, carrying forward £60.—London *Times*, June 25

Anglo-Ceylon and General Estate, Co.—We publish on another page today the annual report of this Company in which the directors recommend a dividend of 4 per cent on the consolidated stock. There was a large increase in the crop obtained from the tea estates in Ceylon and the quality had been well maintained, but there was a falling-off in price owing to the state of the market. The year had also been more favourable than the previous one for the production of cocoa and the price had advanced. Owing to wet weather there had been a diminution in the sugar crop in Mauritius. Interesting statistics are given as to the acreage in different products. On the Ceylon properties there are 5,696 acres of tea in bearing, 285 in cardamoms and 991 in cacao in bearing interplanted with coconuts not in bearing. In Selangor there are 191 acres of coffee not in bearing interplanted with coconuts and rubber and 95 in coconuts and rubber; while in Mauritius the Company owns 4,270 acres (principally of course in sugar) besides being interested in other estates.

Tobacco at Jaffna.—This staple product of this Peninsula is now sold here at a fancy price. The average price of a *Param* of tobacco is R250 as against R150 in previous years. This rise in the price is owing to the heavy damage caused to the crop by the floods of April last. The quantity of tobacco usually exported from here to Travancore and Cochin was between 50,000 and 60,000 bales. It is estimated that only about 35,000 bales will be available for export this year. The merchants have already purchased more than half the quantity grown here this year and the remaining quantity also will be in the hands of merchants in another fortnight. The tobacco used in the manufacture of cigars also commands unusually high price. Jaffna is not, therefore, a loser by the destructive floods of April last.—"Hindu Organ," June 27th.

The Rubber Industry in India.—The *Pioneer* of the 5th July gives the following concise summary of what has been done by the Indian Government to foster a rubber-producing industry:—

The great demand for indiarubber in the European and American markets, due in great measure to the bicycle-craze and to the use of rubber-tyres on cabs and carriages, should be carefully noted in this country. Mr. Ribbentrop, in his recent pamphlet on Forestry, gives a short history of the rubber industry in Assam, which is instructive in its way. In 1873 Mr. Gustav Mann, foreseeing that the natural rubber-resources of the Province would dry up sooner or later, started the Chardnar plantation, and by the end of 1884 some 890 acres had been stocked with *Ficus lastica*. Mr. Mann wished to add at least 200 acres annually for an indefinite period and the Government of India favoured this proposal, but the Local Government, having no spare cash, took but a languid interest in the operations and in 1889 the plantation only covered 1,043 acres. Then the Inspector-General of Forests took up the matter and in the next four years 860 acres were added, or slightly more than the annual increase advocated by Mr. Mann. In 8194 the Local Government again threw cold water on the scheme: a calculation was made showing that the net profit realised amounted to only R60 per maund, and this was not sufficient to justify further expenditure. The fact was that the planting had been badly done. The establishment of new nurseries had been neglected, and, "instead of providing a proper continuity of healthy young nursery plants, the undersized and suppressed specimens from the old nurseries were used, which accounted for the comparative want of success in the final plantings of 1893." Matters rested until 1896 when Mr. Hill, then officiating as Inspector-General of Forests, visited the plantation and recommended that the work should vigorously be taken in hand again. New nurseries were established and better results were obtained. In 1898 99 experimental tapping of the trees was tried, and when the rubber was put on the market the net profit realised was R93 or 50 per cent more than that earned in 1893. It has now been temporarily settled to extend the plantation by another 1,000 acres in the next five years. The moral of the story is that unless new nurseries are formed every year, good planting material will not be forthcoming and the industry will lapse into its old state. There is no financial difficulty connected with these nurseries if properly managed; and, moreover, it should be noted that the tea-planters lately have begun to grow *Ficus elastica* on their waste lands, seeing a possible source of extra income from the rubber-tree. In this adventure they should receive every encouragement and the surplus saplings from the nurseries might well be made over to them free of charge as suggested by Mr. Ribbentrop. The Assam rubber-industry is well worth fostering, particularly just now when the profits from many tea-gardens are so small.

THE ROYAL BOTANIC GARDENS, PERADENIYA.

CEYLON.

A few notes, written in the middle of February, on what may be termed a typical tropical garden, may have some interest. Probably at no other time of the year is the contrast between such a garden and an English one greater; not, however, that the latter is without charms even now, more especially in the memory of residents in a land where perpetual summer reigns, and Nature is practically never at rest.

Situated at an elevation of about 1,500 feet above the level of the sea 7° north of the equator, and with a mean annual temperature of 77° Fahr. (as low as 68° being seldom experienced), the features of the vegetation at the above headquarters of the Botanical Department in Ceylon may claim to be fairly representative of those which generally characterise the equatorial regions, and which, when available, are an unfailing source of interest and fascination to the botanist and horticulturist alike. Flanking the approach to these gardens of 150 acres, and close on a century old, is a row of tall, spreading trees, about 140 feet high, with remarkable buttressed trunks and flattened roots, the latter meandering over the ground, suggesting huge saurians. These the new-comer will be surprised to learn, notwithstanding a fair acquaintance with hot-house plants, upon which he is likely to reflect with pardonable pride, are Ficus elastica, an old favourite pot-plant.

On either side of the principal entrance stands a stately African Oil Palm (Elæis guineensis), the gate pillars being completely draped with Bignonia unguis-cati of Brazil, which bears a profusion of beautiful yellow flowers, and occasionally its curious long pods, which are from three feet to five feet in length. Immediately on entering, the visitor is confronted with a very fine oval group of Palms, containing some sixty species, representing all parts of the tropics; whilst forming an effective undergrowth amongst these are several species of Cycads. Overshading the drive on the left is seen a good example of the amazingly luxuriant habit, combined with extreme beauty, which is peculiar to certain tropical climbers; this is the Thunbergia grandiflora, which, though soon becoming an unmanageable weed if permitted, is here allowed to form a dense screen of evergreen foliage, studded with large mauve flowers, reaching, by the support of tall trees, to a height of from 70 feet to 80 feet from the ground. Passing round to the right the completely shaded Nutmeg-walk is reached, and few walks offer more temptation to visit than this. The Nectarine-like fruits hanging from the Nutmeg-trees in abundance, and in all stages of development, mixed with the flowers, some just "setting," others ripe and splitting open, displaying the large brown nut enclosed in the pretty bright red mace; the various other spice-trees—Clove, Allspice, Cinnamon, &c.—all are apt to make the stranger find some justification in Heber's "spicy breezes"—

> "Where every prospect pleases,
> And only man is vile."

Stretching out from the oval Palm group is the straight main central drive (see Supplement in present issue), which shows a portion of this, but it is impossible, even for the camera, to do justice to the scene, such is the wealth of colouring, the grateful coolness (which can only be fully appreciated in the tropics) from the chequered light, the indescribable mixture of odours, the chatter and cooing of bright-plumaged birds, and the murmur and buzzing of insects. Rising gradually from verges of Amaryllids, is a diversified collection of flowering and foliage shrubs, herbaceous and bulbous plants, shaded by a background of tall trees, interspersed with Palms.

One of the photographs sent represents the Monument Road, which leads to a cenotaph erected to the memory of a former director of the gardens. This stands on a knoll overlooking large expanses of undulating lawns, the lake, the Talipot Avenue (Corypha umbraculifera, the giant of Palms), the handsome bridge of Satinwood (Chloroxylon Swietenia) spanning the river which forms the boundary of the gardens. Along either side of the road is a row of circular beds, planted with more attractive or unique shrubs, and fringed by the large white-flowered Amaryllis solandræflora and others. Over-arching the nearer end are two of the gorgeous-flowered Flamboyant trees (Poinciana regia), half hidden by Petræa volubilis, an exceedingly beautiful climber, producing here in great profusion its sprays of violet and turquoise-blue flowers; whilst the farther end is shaded by magnificent specimens of Terminalia Belerica, Pometia eximia, &c., attaining to gigantic proportions; here also are some Australian Coniferæ—Agathis robusta, Araucaria Cooki, A. Bidwilli, &c.; whilst close to these are such interesting and handsome trees as the Durian tree (Durio zibethinus), which produces excellent but malodorous fruit; the famous Upas tree (Antiaris toxicaria) of Java; the double Cocoanut-Palm (Lodoicea sechellarum); the Mammee-Apple (Mammea americana) of the West Indies; the Brazil-nut tree (Bertholetia excelsa); and the brilliant-flowered Amherstia nobilis and Lager-stroemia Flos-reginæ.

Passing through the Liane Drive there are seen some splendid Lianes, the great copyright of the tropics. Here in the tangle of untraceable festoons of huge and embracing climbers, which soar to the highest tree-top, abound the flying squirrel (Pteromys Oral), an animal of nocturnal habits, similar to a light-brown cat in appearance, and measuring over four feet from head to end of tail, and about the same in expanse of wings. Different from this, and somewhat smaller, is the Flying-fox (Pteropus Edwardsii), a reddish-brown frugivorous creature, of gregarious and nocturnal habits. Certain trees, if tall enough, find special favour with the Flying-fox, colonies of which sleep together during the day, suspending themselves by their hind-legs to the branches, and thus sway gently in the breeze till dusk. Sir John Lubbock said that in the tropics "everything seemed to climb to the light." Plants, beasts, insects, and reptiles climb, the latter including snakes as well as lizards, from a few inches to five and six feet in length.

Continuing on from Liane Drive, a fine solitary specimen of Ficus elastica is suddenly presented in view. The extraordinary character of the roots, resembling bulwarks or fortifications, may be seen to advantage. Creeping up to the topmost branches is the large white-flowered Cereus triangularis.

Incidentally, a tree of Ficus religiosa at Anuradhapura — once an imposing city, and capital of Ceylon, which the merciless jungle buried for centuries, but the ruins of which have lately been partly unearthed—is the oldest historical tree in existence. It was planted 288 years B.C., so that it is at least 2188 years old! This species is endowed with miraculous powers in native religion, and promotes the spiritual welfare of the Sinhalese and other Asiatics. A true Buddhist will sooner sacrifice his pay than cut a twig or pull a seedling of this tree.

In the flower-garden is an octagonal plant-house to the right. Appearing above the latter is the crown of the wild Date-palm (Phœnix sylvestris), next to this being the straight and spiny stemmed Acrocoryue sclerocarpa. A tall cluster of Palms with slender stems is Oncosperma filamentosa, and in front to the left is a handsome specimen of Phœnix reclinata, behind which are Calyptrocalyx spicatus, Livistonas, &c. Here also is a variety of the more ornamental tropical climbers trained on trellis-work arbours, where they are seen to advantage. In the beds and borders the most

showy Cannas, the variegated red and white Pine-apple (Ananas sativus, var. variegata), Caladiums, &c., make a brilliant display.

Passing through a Fernery and the Palmyra Avenue (Borassus flabelliformis), the visitor comes upon the imposing avenue of Royal Palms (Oreodoxa regia, see *Gardeners' Chronicle*, May 12th, 1900, fig. 96). New and longer avenues of this and other handsome Palms which have of late been planted, may be expected to form in time striking features in the landscape of these gardens.

Purely deciduous trees in the tropics are comparatively rare, and when they do occur they generally do not cast their leaves for the purpose of resting, but for bursting into blossom, followed by the fruit. A good example of this is the silk Cotton-tree (Bombax malabaricum), the large red, edible flowers of which cover the ground for weeks after the leaves have disappeared. Nothing can be more suggestive of a snow storm than when the pods of this tree burst, during wind and rain, and their cottony contents are wafted about thickly in the air.

Taking the river-drive round the arboretum, the scenery is most picturesque. Mirrored in the Mahaweli river (the largest in Ceylon), which surrounds the gardens on three sides, are the feathery plumes of tall Bamboos, giant trees and Palms draped with luxuriant climbers, with imposing hills in the background. A single clump of Dendrocalamus giganteus ("Giant Bamboo," and monarch of the grass family), over 120 feet high, curves gracefully over the river (see *Gardeners' Chronicle*, August 27th, 1881, fig. 54). Apart from the scientific department—the Herbarium, Library, Museum, and Research Laboratory, &c.—there are other features in these gardens which prove equally attractive and interesting to the stranger, but fear of trespassing on your space forbids the mention of more.—*H. F. Macmillan*, June 23rd.

PLANTING IN NYASSALAND, B.C. AFRICA.

22nd May, 1900.

We have the same

BLIGHT ON TEA

here as your estates are troubled with. It came on my tea for the first time during a spell of dry weather in the middle of our rainy season. I also noticed jungle plants, chillies, sou-sop, and bullock heart trees had the same blight, losing their flush of tender leaves and their growth was retarded for about a month. I have no doubt this blight was due to the sudden stoppage of rain, a very unusual thing at that time of year. The tea seems to have recovered and is growing well again. I have just finished gathering a crop from my

FIRST SHADE COFFEE

of over eight hundredweights per acre. The plants are three years old last month, and look as if they had not borne a bean so fresh and green with only a yellow tree here and there where overborne. I do not intend to extend tea cultivation, but in case of accidents to shade coffee (as experienced by the scorching of one's coffee in the open) I mean to have 8 to 10 acres to fall back upon for seed.

CEARA RUBBER

does well here. I have trees four years old 15 feet high with a stem 14 inches in circumference, but what the yield of rubber may be, later on, remains to be seen. I will tap one or two trees in about 18 months' time and let you know the result. Our climate seems to suit Ceara, and if tapped when the sap begins to rise, after the tree is done wintering, the yield should be as much as in its own country.

CACAO.

Only one tree that I know of exists in the country and Mr. Moir of Landerdale is the lucky owner. This climate, however, does not seem to suit this product, for the tree is only about 5 feet high with 3 feet branches and is now some six years in the country. Every care has been taken to keep wind and weather from the plant, and manure has been lavished on it, but it does not thrive; our winter months nearly kill it. Thermometer goes down to 48° and we have often frost in June at night.

GREVILLEAS AND GUMS

do well here: what do you think of Grevillea Robusta eight years old, 100 feet high and 5 feet in circumference at 3 feet from the ground?

I am going to try a kraal this coming dry season,

ZEBRAS

swarm in a certain locality I know of, well suited for the job; and the natives delight in such vacations. In the olden days they used to dig pits and erect fences and drive the game into the pits, but they do not understand catching game alive, they want "nyama" meat. I will let you know my success.—Adieu! H.B.

P.S.—I never get an *Observer* that I do not see the death of somebody I knew when in Ceylon: fancy good John Fraser, John Bagra, and Alex. Ross gone over to the majority, it makes one wonder, when such men go over the border so early, when our turn will come, warning one to watch and be ready. H.B.

PLANTING IN PERAK.

(From the *Administration Report* for 1899.)

The total area of agricultural land alienated in Perak amounts to 244,215 acres, and the chief products

RICE, SUGAR, COCONUTS, LIBERIAN COFFEE, AND RUBBER.

Rice is cultivated throughout the State, but especially in the districts of Krianand Kuala Kangsar, and a large proportion of the Krian *padi*, which is planted almost exclusively by Malays, is sent to be husked in the mills at Penang, whence it is returned to Perak in the form of rice. Irrigation schemes, in connection with the cultivation of rice, are being carried out by Government, or with Government assistance, in every district, and the last harvest was a good one; but the supply of locally grown rice is still quite insufficient to meet the requirements of the State. The cultivation of sugar is being rapidly extended, both on European and Chinese plantations, in all the coast districts. Owing to the low market price of coffee, especially during the earlier months of the year, little, if any, new land was brought under cultivation, but large areas were planted with rubber of various kinds, chiefly *Parà Rambong*. The revenue collected by the Forest Department amounted to $122,616. The work carried out chiefly consisted in the demarcation of reserves, the establishment of nurseries, and the issue and supervision of passes for taking timber and jungle produce. Thirty miles of forest reserve boundaries were cleared and demarcated during the year; nurseries and plantations of rubber (Parà and Rambong), and valuable timber (Merbau. Chengal and Mahogany) were established at Taiping and Pondok Tanjong, in the District of Larut; and, owing to the strict supervision of the Forest Officer and his Assistants, there is now comparatively little illicit cutting of timber and collection of jungle produce, although

the export duties are not infrequently evaded by Chinese smuggling firewood to Penang from the coast districts. This system of smuggling, however, which is chiefly carried out by means of *tongkangs* (Chinese sailing boats), will soon be rendered much more difficult, if not entirely suppressed, by placing a steam launch at the disposal of the Forest Department. The high price of tin has caused an exceptional demand for timber and firewood, in connection with pumping engines and smelting furnaces; and the export duty on Mangrove, the best kind of firewood, has been specially raised, as the supply is scarcely sufficient for local requirements. The Government nurseries are well stocked with tropical fruit trees, as well as with pepper and nutmegs, and the following economic plants, not hitherto grown here, have been added during the year and are so far doing well:—Jamaica Grape Fruit, Cola Nut, Central American Rubber (*Castilloa elastica*), and Japanese oranges. Owing to the great demand for seeds of the various rubber-and gutta-producing trees, special attention has been paid to the cultivation of these trees, including Para Rubber (*Hevea brasiliensis*), Getah Rambong (*Ficus elastica*) and Ceara Rubber (*Manihot glaziovii*). The vegetables and roses grown on the Larut hills were less successfully cultivated than usual, and this comparative want of success is ascribed by the Superintendent to an abnormally wet season.

BURMA AS A COUNTRY FOR SETTLERS: UNOCCUPIED HILL RANGES.

A very instructive contribution on the above topic has appeared in a recent number of the *Pioneer*, setting forth the too little known advantages of Burma as a land where colonists will find it to their advantage to settle and utilise the resources of the country. The article is signed "M. H."—initials to which we can attach no name with any degree of certainty; but it is evidently written by one who has the future development of Burma at heart, and yet knows the country sufficiently well to be aware of its disadvantages which he does not conceal from his readers. Rice, the cultivation and export of rice in Lower Burma, was the first product to bring the country into notice, coffee following in its train. But it was not till Upper Burma was annexed that European attention was turned to the new territory, where hitherto it was thought that natives alone could live:

Thus it was, no doubt, that Burma became known as a country unsuitable for European settlers or planters, such as have taken up land in Ceylon and in various suitable districts of both Northern and Southern India, and until the annexation of Upper Burma there is no doubt that this generally accepted view of the resources of the country was a fairly correct one. It is true that even before the annexation of the Upper Provinces, attempts were made to grow coffee in one or two districts where a sufficient altitude could be obtained, but the character of the country of Lower Burma, lying as it does for the most part only a hundred feet or so above sea level, precluded the possibility of favourable climate being found, except in one or two exceptional localities. Such coffee as was produced, however, has been pronounced to be of excellent quality, and to have held its own in the market against that grown either in Ceylon or in India.

The annexation of the new territory brought within our rule a vast dry tract, extending from the old frontier of British Burma to the borders of Assam and China. East north and west of this, is the untried field whose "points" the geographical advocate would define:—

Commencing on the west, if we refer to a map we see that the hills which contain the Irrawaddy Valley on this side are the ranges called the Chin Hills, and that the average distance from the river, to which they may be said to run parallel, is some 30 miles, roughly speaking. Now in these hills without penetrating very far from the plains altitudes of up to 5,000 and 6,000 feet are obtainable, and although, perhaps, only the higher peaks reach the latter height yet plateaus, suitable for cultivation, may be found averaging the former height, while lower than this localities abound which appear suitable from the point of view of space, soil, water, and drainage, for the cultivation of tea, coffee, wheat and rubber, as well as for the growth of European fruits, which have been already tried in these hills and found to do well. The country is, however, for the most part densely wooded, and a certain outlay of time and capital would necessarily have to be expended in clearing the ground, but this is also the case in most new districts either in Ceylon or India. Two advantages are most evident in the districts to which I refer firstly, that these hills are most excellently supplied with water, streams and small rivers intersecting them in all directions, some of the latter being navigable for country boats, and thus establishing communication with the Irrawaddy, into which they all eventually find their way; and, secondly, that as the hills run generally parallel to the Irrawaddy for many miles north and south suitable localities for every sort of cultivation can be found within a large area, the whole of which is within easy and reasonable distance of the great trade artery of Burma leading to the third largest seaport of our Indian Empire.

The supply of hired labour, it is stated, would depend on the goodwill of the people —up till recently somewhat turbulent, among the Chin Hills; but likely to improve as the feeling of trust is inculcated by our rule. Passing round to the east of the hills running from Rangoon to Mandalay, the writer comes upon the Shan States whose great recommendation (in contrast with the country just described) is its peaceful character.

Commencing then with the Southern Shan States we have a territory of some 40,000 square miles, a hilly country with mountain ranges running through it from north to south, the intervening space between these almost parallel ranges being high-lying table lands of considerable extent. This table-land consists largely of rolling undulating country, sparsely dotted with clumps of bamboo surrounding villages of Shans and other hill tribes, its width from west to east is some forty miles and roughly it may be said to include about 2,000 or more square miles. The soil is clay gravel and sand, and for miles the eye sweeps over masses of grassy upland, no jungle and in fact few trees appearing, beyond clumps of pine and bamboo in feathery patches. The people who inhabit this country are a different race to the Burmans although there is no doubt, a certain admixture of Burman blood amongst them. They have, however, one common characteristic that of a quiet peaceable disposition, and in this respect differ entirely from the hill tribes living to the west and north of Burma.

Coffee and tea, it is believed, would grow well in the land above alluded to,

As far as coffee is concerned we have a certain amount of data to go upon, the most important of which is that coffee is already grown successfully in the Karen Hills, which lie only a little to the south of the part of the Shan States here alluded to. This one coffee plantation is not of new formation, but has been producing successfully for many years, and although of small extent it yields most excellent returns. There can then be very little doubt that similar ground suitable for coffee may be found in the above portion of the Shan States, which lies only some 100 miles north of the existing plantations, and in the hills which, as will appear from the map, are a part of the same range as those of Karenni.

Lastly we have the question of climate, reference to which is still more encouraging, and a general summing-up of the conditions of life and work in the Shan States, which should tempt many dissatisfied colonists from elsewhere to the heart of this attractive region:—

The climate is a delightful one for Europeans. There is no part of the year when out-door work cannot be engaged in throughout the whole of the day, and with due precautions as to clothing and good housing there is absolutely no doubt that the climate is an exceedingly healthy and bracing one. There are now large tracts of country as peaceful and well governed as any of the districts in Ceylon, India, or Assam, where life and property would be absolutely secure, both in the Southern and also in the Northern Shan States. There is suitable soil and climate, and a very large choice of locality and altitude.

After this well-informed eulogium, we can hear a few of our readers exclaiming: "Who would not go to Burma?" But what to grow: why not cinchona and camphor trees? Any planter dissatisfied with tea sales at 6½d and in search of "fresh fields and pastures new," might do worse than ship to Burma, and proceed

"from Rangoon to Mandalay."

A FARMER'S EVERY-DAY LIFE.

No. X.

(*By "Cosmopolite."*)

In these notes I have frequently made use of the expression

"A PRACTICAL FARMER,"

and, perhaps, it would be as well for me to give some definition of this somewhat vague appellation, such at least as I have been given to understand the expression to mean. A practical farmer is said to be one who thinks he knows a deal more than he really does, and, whenever I have heard a man boastfully priding himself on being a practical farmer, I have surely found, on enquiry or from personal knowledge, that such a man is one who is self-opinionated and who speaks contemptuously of those who try to be guided by science as "book-farmers." Such a contempt has he for this class that he shows it by reading no books himself; by possessing a greatness that never descends to reading an agricultural paper, and by blindly walking along the track that his father and grandfather went before him. He farms on the old short course shift, has more weeds than crop on his ground, wastes his time by attending every market within a radius of twenty miles and bemoans the hard times, instead of taking the goods the Gods provide him and trying to be thankful. But what, more than anything else, I notice about the self-styled practical farmer is the slovenly state of his steading; straw and turnips lying about wasting, the dykes broken down, and the liquid manure running across the roads and down past his dwelling-house. Of course, the practical farmer grows poor crops, nor will he try to learn how to improve them, because, forsooth, he considers that what he does not know about farming is not worth learning. Another peculiarity of the practical farmer is his

DISINCLINATION TO PAY HIS MEN,

the wages due to them; he invariably does so with a very bad grace, and, not unfrequently, gets rid of the man who asks for the money to which he is justly entitled. Some of them even make a point of getting drunk when asked by any of their servants for some of their wages, a proceeding for which I can find no excuse. I have always considered it a very humiliating thing for any one to be compelled to ask for what is his own, so that I have made a point since I took this farm of paying my men every fourth Monday which enables them to go with cash in hand to the shops, and thus buy goods at a much lower rate than if they had to ask for credit. I see no reason therefore, for a practical farmer becoming suddenly and dangerously excited, because asked to pay what he knows is justly due to his men; he himself is paid hard cash for everything that he sells—stock, wool or grain—and why should he not also pay cash? Now that Government is sending to the different parishes,

LECTURERS ON VARIOUS SUBJECTS,

the practical farmer may be improved of himself, for, although he would never dream of listening to any lecture on any farming subject, feeling convinced in his own mind that he knows more about it than the lecturer does, still his own children go—just for the fun of the thing—and they pick up a few new notions which in course of time they may utilise. Lately I took a ride on my bike round a district which is still celebrated as the home of many practical farmers, and I felt quite melancholy as I gazed on the many nice homesteads surrounded by fine trees, looking gloomy, deserted and disreputable. Here and there a farm, evidently in the hands of an *un*-practical farmer, looked like an oasis in a desert, its garden as trim and well kept as those of the practical farmers were weedy, overgrown and desolate. I was told that the laird of the property on which these farm were was in the hands of mortgagees, and could not afford to help his poor struggling tenantry. But I failed to see what claim the tenantry had for help; they took their farms at their own valuation, and should have been prepared to implement the conditions of their leases without bemoaning their fate; and the fact of some of them doing well, although by no means holding the best farms, showed that it was the illiterate practical farmer

who was the stumbling-block, and not the man who was ever ready to go with the tide and fit his work to the present times regardless of what his father did before him. I returned home from my trip, well-pleased that I lived in a district where the practical farmer is practically unknown and the pushful, hardworking one is the general sample. Referring to the

GOVERNMENT LECTURERS

that have visited our parish, let me say a word. The dairy-maid, who gave a course of lectures on the making of butter and cheese, received, I am sorry to say, scant courtesy from her audience, each farmer's wife or daughter, who attended, having openly declared that she did not know her work, because they each considered their own commodities superior to anything that could be made from instructions out of a book. Here the cloven hoof of the practical farmer showed conspicuously in the behaviour of his wife and daughter. The cooking classes, however, were a great success, the only fault the pupils had to find with their teacher was that she did not show them enough of ways of making fancy biscuits, toffee and sweets of all sorts. One lady, a wistful *ingènue* of about fifty, who attended these lectures, and who is a bit of an amateur cook in her own way, went so far as to praise the work of the teacher, and what more could be wanted than that as setting the seal of superiority on her efforts? The laundry classes also proved the source of much improvement in the style of washing and clear starching in the district. Farmers, who formerly came to church with collars hanging limp-like around their necks, after the fashion of those of the late Mr. Gladstone, now have them standing erect at the sides of their heads, like the blinkers of a horse, and the flannel shirt front, which was once conspicuous at markets, has now given place to the immaculate dickie, like to the product of a steam-laundry, My own experience and observation lead me to the conclusion that the farmer who is constantly boasting about his being so practical is one whose example is to be avoided. His regular attendance at sales and markets seems to have the effect of transforming him, in a few short years, into a first-class tippler and a scandal to his relatives. When the rèveille from the poultry yard wakens him in the small morning hours after a market day, he possesses a thirst worth pounds to a publican and no liquor to be had, nor money wherewith to buy it. Then he curses his fate and wishes he had been appointed a parish councillor or member of a school-board, for well he knows that those who get the handling of the charities of a town are the ones who grow rich and have always plenty of money wherewith to quench their thirst and this he says with a blushing nose and 16 annas worth of scorn in his voice. How many of those practical farmers have I not seen, who, having lost their farms through drink and ignorance, have gravitated to the cities where they are lost in the crowd and the only difference their presence seems to effect there is the enlargement of the police station. But enough of the self-styled practical farmer, and as the Maori would say "Let the *tangata haurangi* (drunken man) slide."

I am sure no one would fancy that any connection existed between

THE WAR IN SOUTH AFRICA AND THE PEAT BOGS OF BUCHAN,

but that such is the case, I think I can show. When our Government determined for the good of mankind to kill off the few thousand Boer farmers in the Free States, they not only sent upwards of 100,000 troops to Africa besides some 30,000 colonials, but they called up all the militiamen and reservists in the country to go into active service. At first the farmers in Britain rejoiced at the removal of these, because those two classes of men are the lowest of the low and from their ranks come all the tramps, incendiaries and light-fingered vagrants. But when the time came for casting the peats, behold the labour for that purpose was found conspicuous by its absence—for these very reservists, etc., are the class that generally do this work; and now we find the price of peats has gone up considerably, not because coals are dearer, not because peat bogs are scarcer, but because the militiaman and reservist are wanted to fight for the shareholders of the mines of South Africa. "Sweet are the uses of adversity," some one says, but however admirable that sentiment may be in the abstract or when applied to others, none of us have any desire for a practical and personal test. Therefore we object to the rise in the price of peats and wish the war was finished and our medal-bedecked vagrants and tramps told off to the duty of casting peats once again.

FERMENTING TEAS BY THE REFRIGERATING PROCESS.

A VISIT TO DUNBAR ESTATE AND AN EXPLANATION OF THE PROCESS BY THE PATENTEE.

[A representative of our evening contemporary furnishes the following report regarding the cool fermentation of tea patented by Mr. H. T. Armitage of Dunbar estate.]

The process of cool fermentation of tea up to the present, has shown results of a highly satisfactory character; in fact, so successful has the new system turned out that ti is considered that since its inauguration in August of last year, the price of Dunbar tea has risen nine cents per lb. This is not, of course, divulging a secret, as the fact is made clear by a comparison of the published price list.

THE PROCESS.

The process which Mr. Armitage has patented, and for which he holds the rights in India and Ceylon, is that of fermenting teas by means of a refrigerating machine worked by compressed ammonia and connected with hermetically-sealed cold rooms by a coil or pipe, which enters a tank fixed above the cooling rooms. "One advantage," Mr. Armitage remarked "is that the same ammonia goes through the machine continuously, so that you only have to renew it when a leakage occurs, or something of that nature happens."

The temperance, could be brought down to freezing point, but that there was no necessity to bring it down below 45 degrees, at which point it has been found that fermentation ceases. The process does away with the water tanks, cold cloths, fans, etc., which are at present in general use, and substitutes cold-rooms in their stead. This means, practically, bringing the Nuwara Eliya temperature right down into the low-country. When we saw the machine at work the temperature inside the cold-rooms was 50 deg., whilst the temperature in the factory at four o'clock on a rainy afternoon stood at 67 deg. Generally the temperature outside is about 70 deg.

A NEAT MACHINE.

The refrigerating machine is neat in appearance, and takes up very little room. It is named the "North Pole" and is of Danish manufacture, and turned out by Taxen, and Hammerich on Schous' patent. Mr. Armitage's machine takes about 2½ horse-power to drive it, the power being supplied by a water wheel (an alternative to which is an oil engine), and has a cooling capacity of about 3,800 cubic feet; that is to say, it would keep a room of 3,800 cubic feet in size at a temperature of 40 deg. It is capable of cooling about 250,000 lb. of made tea per annum.

ITS COST.

Regarding the cost of the machine, Mr. Armitage stated that there was very little to reckon with beyond the initial cost. "This machine," he said, "delivered free on board at Copenhagen, cost about £280, including royalty. The next size machine requires 3¾ horse-power to drive it, and is, of course, more expensive and has a larger cooling capacity."

There are, of course, a great many ice-making machines in Ceylon, but the one in Mr. Armitage's possession is the only one that has yet been applied to the manufacture of tea. It may be interesting to state how the idea occurred to Mr. Armitage. On a voyage home he noticed the cold-rooms on board, and the idea struck him that this process of cooling might be made suitable for fermenting tea. He ultimately carried this idea into effect with the satisfactory results already indicated.

ITS ADOPTION IN THE LOW-COUNTRY.

Speaking with regard to the adoption of the process in the low-country, Mr. Armitage stated that there the machine would require a little more horse-power to work it, because of the higher temperature of the water. "We have tried some experiments with low-country as well as up-country leaf, which has been sent us by rail, and the results have turned out most satisfactorily," he said. Mr. Armitage's tea-maker tends the machine, and this would probably be the case on most other estates, as the attention required is not a serious matter. The Sole Agents for the machine in Ceylon are Messrs. Brown & Co., who lay themselves out to arrange for the importation of the machine and, doubtless, could supply estimates for putting up the whole plant.

THE COLD-ROOMS.

Mr. Armitage has a couple of cold-rooms, with a cubic capacity of about 800 feet, and this requires the running of the machine for only three or four hours a day. The walls are first of cement and brick, next is a filling of coir fibre, which is considered to be a non-conductor, and then comes an inner wall of cement and brick. The doors, similarly constructed show a depth of over nine inches. Inside the rooms are angle iron ledges upon which the trays are run in. Above the door of the first room is an apparatus by which a single tray can be taken out so that some idea can be had of how the fermentation is going on, and avoiding the necessity of opening the main door and letting in the warmer atmosphere. The object, too, of having two cold-rooms, is that one is a criterion of what the other is like, the advantage of which is obvious. A record is taken of the temperature at the time the tea is put into the rooms, and during the process of fermentation the average is 51° or 52°. It may be mentioned, in passing, that no fans are used, and one great advantage of the cold-room is that there is a total absence of draught.

"The merit of this process," observed Mr. Armitage, is that we are not plucking fine. Except the newly pruned tea, we are plucking to the extent of two-and-a-half leaves and the bud. Other people who pluck fine get a higher price for their tea, but our prices, if you consider the medium plucking, are very satisfactory."

From the results so far achieved it would appear that the process fully justifies a trial of it in other parts of the island, where anything that will help to raise the price of tea will be cordially welcomed.

INSTRUCTIONS FOR MAKING GREEN TEAS.

FOR EXCELSIOR ROLLER AND TWO 8-TRAY SIROCCOS.

1. Warm the machine by turning on full steam for half a minute. Then place 200 lb. leaf in the machine (freshly gathered) and with 20 to 25 lb. steam in the boiler, steam for 2 to 3 minutes; with 40 lb. steam, 1½ to 2 minutes is sufficient.

The cylinder should never be filled more than on a level with the two steam pipe nozzles at a time, or the leaf will not be evenly steamed. If more leaf is wanted to fill the rollers, it can easily be steamed while the first lot is being put in the roller. The cylinder must be turned round slowly by coolies.

2. When the requisite amount of leaf is in the roller, put on full weight and stand a cooly on top without working the roller for two minutes; this will get rid of most, if not all the water caused by steam, and this must be thrown away. The leaf, before going into the roller, should be perfectly flaccid.

3.—Roll five minutes without weight, and throw away that water or juice; then roll ten minutes half weight; then pour back the juice from this roll into the roller and roll five minutes with hardly any pressure, so as to retain as much juice as possible.

4.—Put this semi-rolled leaf on to Sirocco temperature about 260 degree—and fire for about twenty-five minutes, passing the trays backwards and forwards pretty smartly, and turning the leaf as the trays come out. At the end of this time the leaf should begin to turn an olive green, and feel quite gummy, and be no longer wet.

5.—Take the semi-fired leaf from the Sirocco and put back in roller. Roll five minutes lightly, five minutes hard, and five minutes medium, then break roll (in Souter's breaker); be careful after breaking thus, whether by breaker or by hand;

to thoroughly break up the balls or clots into which the Tea forms. I greatly recommend a Souter's breaker.

6. The leaf being thoroughly broken up, replace in Sirocco, and with temperature of 230 to 280, fire for about 15 minutes until the leaf is like chamois leather—soft, with a tendency to getting crisp, but yet not crisp.

7. Roll again: first five minutes hard, and then about five minutes more, lightly, to get twist, then break roll once more, and finish by final firing at a temperature of 200.

The sieves I used for my break were Nos. 12 and 10, and the balance broken through a No. 8. All the fannings must be most carefully taken out as well as the dust. What Tea will not go through an "8" can be broken up and mixed with the fannings.

I named the Teas:—

No. 1. New Season's Extra Choicest Green Tea.
No. 2. do. Choicest Ceylon Green Tea.
No. 3. do. Choice do. do.
No. 4. do. Green Tea Fannings,
No. 5. do. do. Dust.

and headed the Invoice with the words "Ceylon Uncolored Green Teas."

H. D. Deane.

MANUFACTURE OF GREEN TEAS:

IN DEHRA DOON.

The method of manufacturing green tea in the Dehra Doon district for the Central Asian market, is as follows:—

Manufacture can be commenced as soon as the leaf is plucked, but as it is more convenient to manufacture a day's plucking at once, the leaf plucked during the day is allowed to be all night in the leaf shed, spread out from two to four inches deep, and is constantly turned over to prevent heating.

The process of manufacture is as follows:—A large iron *karai* or pan 36″ in diameter by 12″ deep, is heated almost red hot, and when ready is filled with green leaf, which is rapidly turned about to prevent burning, until it has become quite soft, and the mass reduced to about half its former size. This process takes about three minutes. It is then thrown on the rolling table and while the next panful is being prepared, is rolled by the tea-makers. As the leaf is perfectly soft and flaccid, the rolling is done in the same time as the panning takes. If there is any sun, the rolled leaf is then thinly spread out in it until it becomes a blackish green and is very sticky to the touch or if cloudy, is put in *chalnies* over charcoal fires until in the same condition. It is then put into smaller iron pans 25″ in diameter by 12″ deep, which are only heated to such a degree that the hand cannot be kept on the iron. These pans are about half filled, and the leaf is kept turning over until it has become quite soft again, when it is again rolled. When the day's batch has all been rolled a second time, the small pans are filled to the brim, the heat being gradually lowered, and the leaf is cooked, being constantly turned about as before for about four hours, when it is almost dry to the touch. If a large quantity of the two classes of gunpowder are required, it is then screwed up in bags (as described in our last issue) but this is not necessary nor indeed advisable at present, as the gunpowders do not bring the same prices as Young Hyson and Hyson, a quantity of which classes become gunpowder in the screwing. The tea may now be left for weeks in the bins before being classed and coloured, but we will suppose that the next process takes place next morning. The small pans should be heated to the extent of burning the hand if kept on the iron for a short time, and about half filled with the tea, which is worked rapidly from side to side until it assumes a light greenish tint, which will take about an hour and-a-half. It should then be classed, fanned and picked. Before being bagged for market, about the same quantity is put into the pans, heated to the same degree as before and is again worked rapidly to and fro for about two hours until it has assumed all the bloom it will take,—usually a whitish green; but if the leaf is hard and old when plucked, the colour will turn out yellow green, and will require colouring matter, usually pounded soapstone. It is in this last panning that the colouring-matter is put in, but I believe the Europeans in this district do not use it unless requested to do so by the native buyers. It is easily detected by taking a handful of unadulterated tea and breathing on it, when it will be found that as the damp dries off the bloom will return, but will entirely disappear in adulterated tea. The tea is then packed hot in 200-lb bags composed of an inner cloth and an outer gunny bag, and is despatched in this state to market. In heating the pans, wood is always used, as it is quite as efficient as, and much cheaper than charcoal.

IN ASSAM.

The following method of making green tea in Assam is furnished by an old tea planter:—In making green tea, the flush, *i.e.*, the bud and first two leaves of the young shoot, after being picked and weighed, is carried at once into the factory, and large iron pans, twent-five inches in diameter, and five inches deep, fixed in brick-work over hot wood fires, are piled up with the fresh leaves. The operator in charge then rapidly turns the leaves round, at first with his hand, but afterwards, when the leaves get too hot, with a couple of pieces of wood, like large spoons, until they become perfectly flaccid. The contents of the pans are then thrown out on the rolling table or if machinery is used into the rolling machine, and thoroughly rolled with a sort of figure-of-eight motion until every individual leaf has become twisted and lost some of its sap. The leaf is then taken and spread out thinly on sheets in the sun, or if there is none, as is often the case in the manufacturing season, on fine wire gauze or bamboo trays over charcoal fires, until it turns a greenish-black, and becomes very sticky to the touch. It is then transferred to the rolling tables or machine, and gets a few minutes rolling to retwist any of the leaves that may have been uncurled, and is then put into deep iron pans, measuring thirteen inches in diameter by nine in depth, fixed like the large ones, but slightly sloping forward, in brick work over furnaces, in which there is a hot fire. A man stands opposite each pan, which is filled full, and the mass is turned over and over slowly for about three hours, when it has become almost dry. It is then put into long narrow bags, which are filled as full as possible, and then screwed up tightly, this operation having the effect of turning a large quantity of the larger and coarser leaves into gunpowder, and thereby enhancing their value. Next day the bags are opened, and

the contents—exactly resembling in appearance the Carrigean moss used in Ireland in boiling linens—transferred to the storing bins, where the tea will keep in this state for a long time. To complete the process, as soon as the factory hands have leisure, a slow fire is lighted in the furnaces under the deep pans, which are filled about one-third, full of the unfinished tea, and an operator then proceeds to work the tea to and fro in each pan with his bare hand as hard as ever he can for about an hour, until the combined friction and heat have caused each individual particle of tea to assume the beautiful green bloom that distinguishes green from black tea. It is at this point that the Chinese colour their teas with foreign substances, as, unless the tea has been made from young succulent leaf, it will now appear of a dirty yellow colour, instead of being greyish green. I never knew Indian green tea to be adulterated with any deleterious colouring matter, although we have sometimes been asked by the Central Asian merchants to put a little ground soapstone in to give the deep green colour that their customers appreciate.

After this colouring process the tea is sieved into different classes and is then ready for packing. It is usually put into 200 lb. cloth and gunny bags, as it does not require lead-line chests like black tea.

Green tea-making, although taking a longer time than black tea, is a comparatively simple process, and does not require the anxious attention which must be given to the manufacture of black tea to make one a successful manager.

IN JAPAN.

The following explains the mode of preparation of green tea in Japan. "The firing and preparation of tea for market, as practised in Japan, is as follows:—The Japanese green tea may be divided into three general classes; coloured, uncoloured, and basket fired. The leaf used for all these is from the same plant, differing only in quality, condition, etc. All teas used by foreigners are first fired by the natives in the places where grown. If a grade of coloured tea is to be made this fired leaf (four or five pounds) is taken and put into iron pans or bowls, which are heated sometimes up to a temperature of 212° Fahrenheit. The leaves are then rapidly stirred by hand against the smooth iron surfaces some twenty minutes. A teaspoonful of thoroughly pulverised soapstone (saponite) and five grains, or so, of powdered Chinese indigo are placed in the pan, and thoroughly rubbed into the leaf for about 20 minutes more, when half a teaspoonful of soapstone or gypsum and pulverised tamarack bark (a species of larch) is added, and the stirring and rubbing is continued for 20 minutes more. It is then put into cold pans and simply cold rubbed against the iron surfaces until it has the required polish, which is arrived at in from 40 minutes to an hour. This is the ordinary way of preparing coloured tea. Other materials are perhaps sometimes used, but, so far as I can learn, all are as harmless as these mentioned. The different manufacturers, of course, vary the process a little now and then to produce slight changes of colour. The leaf is then run through three to five sizes of sieves, till all the dust and loose colouring matter is separated. The shrinkage is about 12 per cent. This colouring process is considered beneficial to the leaf, tending to preserve its shape and flavour. There can be no doubt that the Japanese prepared teas are far superior in purity to the Chinese. In colouring Chinese teas various drugs are used that are deleterious to health, unless it be that the heat to which they are subjected render them innocuous. Prussian blue is frequently used instead of indigo in their green, and black lead in their black teas. Uncoloured teas are made in the same way and quantities, and rubbed against the iron pans until the surfaces have the desired polish, and are then sifted until nothing but the whole leaves are left. Basket-firing is done in bamboo baskets, shaped something like our hour glasses, which are shaken over hot pans. The leaf is put into the upper lobe of the basket and worked into the lower, and so, back and forth, until finished. The loss of weight is about 3 per cent." —*The Planter*, July 14.

PLANTING NOTES.

A Plague of Caterpillars in Jamaica.—Specimens of a large caterpillar from the tobacco plantations of Jamaica were exhibited at the Royal Botanic Society on Saturday. During the past year or two they have increased so rapidly that negro children are employed to collect them, and on one plantation where 5,000,000 have been destroyed.—*Daily Chronicle*, June 25.

Empire of India and Ceylon Tea Company.—The working of this Company during the past year has not been so successful as anticipated, but in the circumstances a dividend of 4½ per cent must be considered satisfactory. The properties in Assam are reported to be in good condition, but the Ceylon gardens are said to require very careful looking into.

Forest Tree Culture in Mysore.—From a Mysore Forest Conservancy Report some time ago we take a suggestive passage. Close planting is properly advocated and it is indicated that the casuarinas in India, like the larches in Britain, rapidly and largely improve poor soil by the deposits of their foliage and the effects of shade and moisture. Mr. Hutchins also advocates close planting. His remarks on the subject are extracted below :—

"With the exception of two plantations, Kadgudi and Benganur, now the best, all the old planting was done at five yards apart. All the planting is now being done at three yards apart which gives 538 trees to the acre. I estimate that the first thinning would be necessary in about eleven years, when a quarter of the stock would be taken out and that the yield of the poles at that age would reimburse the extra cost of thick planting. From a cultural point of view, there is no doubt of the great superiority of dense over sparse planting. Many trees on ordinary soil in this climate remain bushes unless planted close. *Cassi Florida* is an example of this. This is the best tree I am acquainted with for sowings and one of the worst for planting. In the growth of a plantation, the point at which the trees meet in a mass overhead and kill the ground herbage, is well marked, and the sooner it is arrived at, for many obvious reasons, the better. This is the more to be striven for with casuarina on account of the excellent forest soil which forms rapidly as soon as this stage is reached. When planting on inferior soils, no satisfactory growth can be expected till this soil is formed The plantations east of Bangalore are on soil good, bad and indifferent. Most of it belongs to the last class, but there is a great deal too bad to plant, and here seed is being sown. As yet this closing overhead has only been quite reached in the Benganur plantation. The above remarks apply to forest trees, especially those raised by sowing the seeds broad-cast or in shallow pits, as distinguished from fruit trees regularly planted in deep pits and watered."

Correspondence.

To the Editor.

OVER-PRODUCTION OF INDIAN AND CEYLON TEA AND THE REMEDIES.

London, E C., July 5.

Dear Sir,—I do not know whether your attention has already been directed to the letter of Mr. William Mackenzie, which appeared in the *Home and Colonial Mail*, of June 22nd; but, if not, I should like to do so now, and at the same time to add that I sent a criticism of the same by myself which appeared in the issue of the 29th.

Curiously enough, the paper containing my communication contains also a full report of the speech of Mr. James Sinclair, the Chairman of the Dimbula Valley Tea Company, on the occasion of the 4th annual meeting, of the speeches made at which I was quite ignorant. You will see that Mr. Sinclair recognises that for estates whose present average outturn does not exceed 300 lb. tea per annum, manuring is necessary in order to make such estates produce remunerative results at the present low prices, and that if such estates cannot afford the cost of manuring woe betide such gardens.

As pointed out in my letter our most experienced agriculturists fully recognise the necessity of some kind of manuring for all crops, and provided that the climate and rainfall are suitable, the poverty of the soil need be no bar to successful cropping under the influence of judicious manuring.

Of course, economy and suitability must be studied in the selection of the particular manures, and these manures should further be adapted to the soil and elevation of the estate, for the higher the elevation the more nitrogen is required.

Certainly there are estates the soil of which is of so coarse a character, and so poor in quality, that it would be better to allow such land to go out of cultivation and to concentrate attention upon the cultivation and manuring of land better adapted to tea.

It is to points such as these that proprietors and shareholders should direct energetic action, for in these times of low prices, it is essential that personal attention should be given to the management.—Yours faithfully,

JOHN HUGHES.

THE CULTIVATION AND MANURING OF TEA:

REFERENCE TO SIR JOHN LAWES, BART.

Binfield Manor, Bracknell, July 6.

Sir,—Mr. Talbot, under date the 2nd instant, has favored me with a copy of the letter sent you by last mail. He does not in so many words say so, and I have had no opportunity of seeing him on the subject; but I take it he is under the impression, from the quotation he gives you from Sir John Lawes' letter of the 28th June, that he did not misunderstand that gentleman as I stated he did in the reference to it in my speech to the Dimbula Valley shareholders,

At the risk of appearing to labour the point, whether he did or not, whilst I am willing to leave my letter to Sir John Lawes, (copy of which I enclose) and the quotation from his reply read at the annual meeting of the Dimbula Valley Company to speak for themselves, I must dwell on the fact in order that planters may have the fullest information on the points at issue. With regard to the further opinion which he obtained in writing from Sir John, so that there should be no "misconception on the point", I am afraid Mr. Talbot himself hardly grasps it. In his speech at the C.T.P. Co. meeting he was deprecating the use of forcing manures and referred to sulphate of ammonia as one he deprecated the use of, and intimated that he was backed up in this by Sir John Lawes. Sir John, however, in his letter to me expresses surprise that Mr. Talbot should have misunderstood him, vide quotation from Sir John Lawes's letter to me. The further opinion, although to some extent a qualification of what he wrote to me and for a reason I shall explain, bears out my contention that he does not think that sulphate of ammonia is too forcing, in ordinary doses of course. He says: "My objection to sulphate of ammonia does not arise *because it is a highly nitrogenous manure* (the italics are mine) but because it removes lime from the soil and I find that the Ceylon soils are rather poor in lime"—that is, he does not object to it because it is a forcing manure but because it exhausts the soil of lime. Excepting that he would not disapprove of its use unless on the score that he does not think it the most economical medium of giving a continuous supply of nitrogen to the plants, this is entirely different from saying it is too forcing or dangerous to the life of the tea plant.

At the date Sir John expressed surprise at being misunderstood by Mr. Talbot he was not aware that our soils were deficient in lime, and only came to know of it when he perused the soil analysis given in Messrs. Bamber's last pamphlet, which I presented him with, after the Dimbula Valley meeting; and in talking the subject over with him, he told me that his conversation on the subject of ammonia salts with Mr. Talbot was quite in a casual way; he thus had not the data at that time to enable him to arrive at the somewhat modified opinion he now gives. No one who knows Mr. Talbot would ascribe to him a desire to mislead his fellow planters; but in studying the Rothamsted experiments which he clearly does not fully comprehend and in making his deduction public he is not only doing so, but himself as well. For instance, his personal opinion is "seeing that where sulphate of ammonia has been applied for a series of years on permanent pastures patches of grass are dying out," he is "more than ever convinced that the use of this manure is attended with risk to the tea plant." Now in the first place he is in error in calling the experiment one on "permanent pasture." *It is on permanent grass land* producing hay which has been mowed and carried off the field, every pound of it, twice each year for a series of years, and not *pasture for grazing purposes.* In one case the ammonia, *and that fertiliser only*, let it be noticed, has been applied for a series of years. If it had been grazed upon, and only the nitrogen and phosphates removed in the proeess of cattle-feeding on the field, Sir John would tell him even sulphate of ammonia used by itself would not have had the effect he describes. But where can Mr. Talbot point to a single instance

of a tea field having been manured with sulphate of ammonia alone, or to the extent of two to three cwts. per acre as in the Rothamsted experiments. Half of the smaller dose named and that always in combination with other manures is the quantity generally applied in Ceylon. One may just as well conclude that salt is dangerous to the human race because it would be attended with fatal results if no other food were taken.

I hope at an early date to meet Mr. Talbot at Rothamsted and to see him convinced that there is much yet to be learned before he can venture to apply what he sees there to tea planting and I regret there has not been an opportunity of doing so before, but I could not allow his speech on these matters to pass unnoticed, if for no other reason than that his remarks seemed to me to reflect on those who differ from him and who know he spoke without book, which the London tea shareholder could not.—Yours faithfully

JAMES SINCLAIR.

(Copy.)

1st June, 1900.

Sir John Lawes, Bart, Rothamsted.—Dear Sir,—I take the liberty of addressing you on a subject which is causing some commotion amongst tea planters in Ceylon in respect of manuring Tea Plantations, and as your authority has been given for a statement made by Mr. Talbot, who is a director of a large Tea Company, in recently addressing his shareholders, I am most anxious to have it verified by you as I cannot help thinking that by a misapprehension on the part of Mr. Talbot an opinion has been attributed to you which, if all the conditions under which the tea-bush is planted, grown and cultivated, had been laid before you, you would not have given. I am well aware how frequently opinions are attributed to scientific men which have been formed through incorrect data having been supplied to them. I may mention that I was a practical agriculturist in this country from 1859 to 1868, having been born on a farm and brought up to farming, and for 32 years have been in the management of coffee, cinchona, and tea estates. During that time I have kept myself in touch with your experiments at Rothamsted whenever I could find an account of them in print. When, however, I come to apply what I have gatbered from my study of these to tea cultivation, I am disposed to think that Mr. Talbot has unwittingly misinterpreted you or that, perhaps when you have the data which I shall here supply, you may modify the opinion attributed to you. Mr. Talbot in his speech, in referring to the danger of using forcing manures, to the tea plant is reported to have said:—"I have also had the advantage of consulting Sir John Lawes whom you all know as a great authority on Agricultural Chemistry and he deprecates the use of forcing manures such as sulphate of ammonia as being undesirable to use." Now I have no doubt that manures, such as sulphate of ammonia and nitrate of potash, etc., used immoderately are to be deprecated as a fertiliser for tea, but I differ entirely from Mr. Talbot when he holds, as he seems to, that those who have been cultivating largely and applying these manures are doing it to an extent which will endanger the normal life of the tea bush by forcing or impoverishing their soils,

To enable you to form an opinion on this and to give your advice as to whether any of the ingredients of the Mixture I, in common with most others in use, I give you the analysis of a fair sample of the soil to which it is applied. (Here follows soil analysis and description and quantities of different manures applied). On the high lands of Ceylon the bush is pruned, or more properly speaking, cut across the hard wood two inches above the previous pruning and practically all the foliage thus pruned falls on the ground, the healthier and more manured the bush bas been tbe greater the bulk of green foliage, but on an average on the estates I refer to each bush gives not less than 5 lb. of prunings which are often left to decay on the surface, but on well-managed estates are buried in holes or mulched in with some such mixture as I have given above. This pruning is done once in 24 months, the weight of prunings therefore, combined with tbe natural fall of the leaf during the 24 months would run to about 9 tons per acre when green. During the two years between prunings the green leaf taken off the bush for manufacture into tea would weigh about 4,000 lb. before being manufactured: this is all that is removed from the soil per acre as against five times the weight of prunings returned to it. The questions therefore I would ask are the following:—

1. Considering the amount of prunings returned to tbe soil whether mulched in or not, do you think any of the mixtures named too forcing, and if not, were the quantities doubled what would be the result?

2. Could the castor or rape cakes or any part of the mixture be left from a soil such as that of which I have given an analysis provided the prunings are carefully mulched in a green condition?

To make it more clear to you, I ought to have stated that the tea bush being an evergreen its prunings are quite unlike that of any bush in this pruned in the early spring, the green portion would probably be two-thirds of the whole weight, one-third being matured wood. It is very difficult to say what the life of a tea bush is under normal conditions, but if we take it at 50 years I think the yield would be 350 lb. per acre per annum with no aid from fertilizers, thus the total yield would be 17,500 lb. during its life. Against tbis on a similar soil the same yield would be got in 32 years with the cultivation we give our estates.

Is there any reason to conclude that tbe latter would be nearer its limit of life tban the former? My experience of 10 or 12 years' manuring operations points to the contrary, but I should be very glad to have your opinion.—I am, dear sir, yours faithfully, (Signed) JAMES SINCLAIR.

[*Please note.*—The answer to this letter was quoted by me in addressing the meeting of the Dimbula Valley shareholders.]—J. S.—See page 112.

GREEN TEA MANUFACTURE.

Stagbrook, Peermaad, Travancore, July 11.

Sir,—In *re* your article* of July 6th in which you ask what my terms for "royalty" on my "process" and "machine" are, I may briefly state that the price of the machine *covers all royalties*, and in comparison with other patent tea machines, the price as advertised by my agents, Messrs. Brown & Co., is a moderate one. What I wish the public to understand is that, if they prefer to use any other "steaming machine" or process of applying steam to "green tea leaf," which is the substance of what I believe my patent covers, that in *that case*, I hold them liable for a special royalty of R250, which must be paid to my agents, Messrs. Brown & Co., for myself and partner in the patent. I do not, of course, expect to exact a royalty on *all* green tea manufactured in Ceylon. "Oolongs," which as most planters are aware, are a *species of Green Tea*, have been made before my patent, and can be made, free of royalty, so far as I am concerned. The leaf for them is rendered pliable by *hot air*, but the fermentation or oxidization is not *ever thoroughly checked* by that process, and, therefore, the

* Local "Times."

"infusions" more or less show signs of fermentation; and, when this is the case, would only get "Oolong" prices and not be classed as "Pure Green Teas," however they were marked.

I have today wired my agents, Messrs, Brown & Co., to advertise that the "royalties" are all *covered in the price of the machine*, and I trust this will be satisfactory to the planting community.—I am, etc.,

H. DRUMMOND DEANE,

THE MANURING OF TEA: DIFFERENT VIEWS.

London, June 29.

Sir,—At the annual meeting of a Ceylon Tea Company held this week the Chairman took me to task—he did not mention my name, but it is obvious he meant me—for the opinion I had expressed deprecating the use of what I termed forcing manures and quoting an extract from a letter from Sir John Lawes to show I had mistaken the opinion he had given me on the use of Sulphate of Ammonia. As I am most unwilling that there should be any misconception on this point and wish that cultivators in Ceylon should have all the information possible on it, I asked Sir John Lawes to give me his opinion in writing and he has been good enough to write to me as follows:—

"June 28.

"Dear Mr. Talbot.—My objection to Sulphate of Ammonia does not arise because it is a highly nitrogenous and soluble manure, but because it removed lime from the soil and I understand that the Ceylon Soils are rather poor in lime." * * *

As far as my own personal opinion goes I must say that after again studying the Rothamstead experiments and seeing that where Sulphate of Ammonia has been applied by itself for a series of years to the permanent pasture, patches of grass are dying out, I am more than ever convinced that the use of this manure is attended with risk to the tea plant.

I have learnt, too from the Rothamstead experiments that when Sulphate of Ammonia is applied, it forms nitrates and a certain proportion of nitrogen passes away quickly with the rain whereas this does not occur where potash and superphosphates are used—hence the advisability of using Basic Slag with Cake Manures.—Yours truly.

G. A. TALBOT.

MR. TALBOT'S EXPLANATION.

July 17.

Sir,—Mr. Talbot's explanation does not seem to simplify the difficulty very much. He agrees that, because sulphate of ammonia *applied by itself* over a series of years, to grass land, appears to be detrimental, therefore, it is so also to tea. Herein, are two fallacies; (1) tea and grass land are scarcely identical and (2) no one in Ceylon, so far as I know, except Mr. Talbot perhaps, has applied sulphate of ammonia, by itself, for a series of years, to tea. Where, then, is the so-called explanation?

Of course, what Sir John Lawes says about its removing lime from the soil is true enough and if carried to excess is detrimental; but this is a difficulty which the practical man can meet and does.—I am, &c.,

A MELVILLE WHITE.

CAMPHOR CULTIVATION.

Kandy, July 18th.

Sir,—At the request of the Committee I herewith transmit copy of a letter received from the Director, Royal Botanic Gardens, on the subject of camphor cultivation.—I am, sir, yours faithfully,

A. PHILIP,
Secretary to the Planters' Association of Ceylon.

Royal Botanic Gardens, Peradeniya, July 11th.

Sir,—The rise in price of camphor, caused by the recent establishment of a monopoly by the Government of Japan, renders it possible that camphor may become a profitable minor product here. I am carrying out a series of experiments with this in view, and should be grateful to you if you would lay this letter before your Association at its next meeting and obtain for me, if you can, any information on the following points:—

(1) Names of estates trying camphor (a good many plants have been sold by this department in recent years). (2) Approximate age of trees, number growing, soil, climate and elevation in which growing, and present size of trees, and whether they grow freely and branch and leaf much. (3) Whether owners are willing to supply a few lb. of prunings for experiments in distillation of camphor.

I propose to work up all information received and all elsewhere available on the subject, with instructions for cultivation, results of distillations, &c., into a circular to be published later in the year.

Any who care to try the cultivation can obtain plants from the Superintendent, Hakgala Gardens, Nuwara Eliya, at 25 cts. per plant.—I am, sir, your obedient servant,

(Signed) John C. Willis, Director, R.B.G.

PRODUCE AND PLANTING.

Japanese Tea.—We recently referred to a Consular report from Tokio which did not take a very cheerful view of the outlook for Japanese tea. A Yokohama report is in a similar strain. It points out that although a yearly grant of 70,000 yen (£7,000 is made by the Japanese Government to the tea guilds for the purpose of extending the sale of Japan teas, no improvement is taking place; on the contrary, the export of Japan teas has been decreasing for some years past. "Nor," adds the Consul quoted, "have foreign tea merchants, who are equally interested with the Japanese dealers in the practical and profitable disposal of this sum, appeared to have participated in any of the benefits—if such have resulted—which this measure was intended to confer." The chairman of the Yokohama Chamber of Commerce paid a visit to the United States with the object of inquiring into the conditions of the tea trade, and seeking the removal of the duty on tea by directly conferring with the President of the United States. The result of his mission we have yet to learn, and meanwhile the Japanese are reminded that in Canada, thanks to "extensive advertising" and such methods, the teas of Ceylon have made rapid progress. In this connection it may be mentioned that the growth of the trans-Pacific trade between the United States and Japan has apparently suggested that higher freight rates may be safely imposed. The representatives of steam lines between Japan and San Francisco have lately held a conference at the American Pacific port, the result of which has been a decision to raise the freight rates for tea, curios, matting, raw silk, and silk fabrics imported into the United States from Japan. The rates for imports from the United States to Japan were also, it is stated, to be raised on the average about 25 per cent.

Tea Sampling.—A correspondent above draws attention to a state of affairs at many of the London Tea Warehouses which is scarcely credible. If the facts be as stated a case for immediate investigation by some competent authority is urgently called for. What guarantee can a buyer have if all the samples which are furnished to him at the docks are taken from one chests? Of course this is a matter which does not immediately concern planters, but we feel sure they would strongly condemn any such practices if they were brought under their notice; and we can scarcely believe that the management of the various tea warehouses can have the remotest idea of such reprehensible conduct on the part of their servants. But it is proper that inquiry should be made, as the complaint is a serious one.

OVER-PRODUCTION OF INDIAN AND CEYLON TEA, AND THE REMEDIES.

(To the Editor of the *Home and Colonial Mail*).

Sir,—I was unable to be present at the annual meeting of the Ceylon Association, but I have carefully read the interesting communication from Mr. William Mackenzie, published in your issue of the 22nd, and can imagine the feelings of despondence, if not of positive despair, that the views expressed in that letter are likely to produce in the minds of shareholders in at present unsuccessful tea companies. In the first part of the letter it is stated that "production has far out-stripped consumption," and further on that "in Ceylon manuring is now helping to swell the output, and to complete the demoralisation of prices already injuriously affected by extensions of area." But after these two statements comes the following: "The price has fallen regularly about ¼d a year, whether production exceeded consumption or not."

If the last statement is correct, there has been a steady fall in prices quite irrespective of relative production or consumption. This steady fall is probably due to a decline in quality, and the only really practical method of removing this pretty generally admitted fact must be the adoption of improved cultivation, judicious manuring, and scientific manufature. Instead of regarding manuring as deterimental to the tea industry, it may fairly be contended that the planter is only following in the steps of all experienced agriculturists, who have found that every crop requires some kind of manuring.

It is now upwards of twenty-two years since I went out in 1877 officially for the Ceylon Planters Association to report as an agricultural analyst upon the manures best adapted to Ceylon coffee and tea soils. After making a very extensive tour of seven weeks through the planting districts, several months were devoted to the analyses of the soil sent from these localities, and since then at great number of soils have been forwarded to me for examination and report, especially during the last two years. With the knowledge thus obtained I have every hope that the application of judicious manuring will be of the very greatest benefit to the Ceylon tea crops. The soils for the most part are poor in the important elements of plant food, but the climate and rainfall are both most favourable in Ceylon to the production of frequent flushes of leaf; so that I do not think proprietors should be discouraged by present prices, but rather bestir themselves to energetic action.

I cannot agree with the first remedy suggested by Mr. Mackenzie, namely, that all tea grown in July should be either destroyed or held off the London market, for, instead of doing this, if July tea is inferior, I should recommend that no tea should be made in July; certainly it should not "be shipped to Russia and sold there for whatever it would fetch," because that proceeding would be calculated to prejudice the name of Ceylon tea.

With the second remedy recommended, namely, to pluck 10 per cent. less and aim at quality rather than quantity, I however, fully agree; for it is to the improvement in quality that planterrs should look to if they wish to improve prices.

Tea is judged by its quality and purchased according to its quality and strength, so that each individual estate or groups of estates under one management should seek to get a better price according to the care taken in cultivation, manuring pruning, and manufacture.

As to the third remedy suggested, namely to make teas suitable to the American palate, that is a matter that may safely be left in the hands of the author, whose experience of American tastes rightly places his opinion above any doubt, and I think planters would do well to follow the advice given on this point. In spite of the general increased production of Indian and Ceylon tea there is plenty of scope for a higher individual price if attention is properly directed to the points named. Some of our poorest soils can be, and have been, made to yield remunerative crops under the influence of suitable manures, a favourable climate, and personal attention; as, for instance, the early crops of potatoes in Jersey and the spring flowers in the Scilly Isles.

Tea planters, therefore, and those interested in tea properties need not despair, but rather direct attention to careful detail in the growth and manufacture of tea.—Yours faithfully,

John Hughes, F.I.C., Agricultural Analyst,
79, Mark Lane, E.C., June 26, 1900.

THE STRENGTH OF CEYLON TIMBERS.

The current number of the *Imperial Institute Journal* has an interesting article by Prof. W. C. Unwin giving a comparison of the strength of Ceylon and European timbers. Very definite deductions from any set of tests on a limited number of logs must be accepted as subject to correction, but Mr. Unwin has compiled a table of European timbers representing fairly, as he thinks, what is accepted as the average of such results as are most trustworthy. Oak, elm, ash and red pine are included, and it is shown that their heaviness in pounds per cubic foot, W, is 52, 54, 47 and 37 respectively; their crushing strength in pounds per square inch, f.c. 10,000, 10,300, 9000, and 5,800; their transverse strength in pounds per square inch, 12,000, 8,000, 13,000, and 8,300; f.c. W 193, 320, 191, and 157; f.b. W 230, 235, 277, and 224 Broadly speaking, the strength of timber increases with its heaviness. The most valuable timbers for structural purposes are those which have considerable strength without excessive heaviness. The pine timbers so largely used are not only easy to work, but they have good strength in proportion to their heaviness. In the figures just quoted the strengths have been divided by the weights per cubic foot, and the results are given in the last two sets. Com-

pared in this way, elm is superior to oak, and even red pine is not much inferior. The second table deals with Ceylon light, medium, and heavy timbers under the same headings. Sapu, Lunumidella and Walukina as light woods stand at 41·4, 20·4 and 32·4 respectively in heaviness; 3,490, 3,200, and 6,100 in crushing strength; 7,820, 9,510, 5,720, and 9,010 in transverse strength; 84, 157 and 188 f.c. W; and 188, 280 and 280 f b. W. In medium woods the heaviness of Jak is given as 43·4, the crushing weight 7,55), transverse strength 6,840; f.c. W 174; and f.b. W 157; Del 48·1, 6,500, 9,310, 135 and 193; Halmilla 49·9, 7,630, 15,450, 153, and 310; and Suriya 50·3, 6,230, 11,600, 124 and 233. With regard to heavy timbers the figures for Satinwood are 64·3, 5,350, 8,740, 86 and 140, and for Milla 60 9, 6,630, 14,760, 109 and 242 respectively. Taking the light wood, it is clear that as regards strength in proportion to weight, Lunumidella and Walukina stand best. Lunumidella, is not absolutely as strong as red pine; but in proportion to its weight it is even a better timber. Walukina is weaker than ash, and about the same strength as red pine. Of the medium woods, Halmilla is strongest in proportion to its weight, and Suriyamara stands next. The heavy timbers do not give very high results. Satinwood has greater transverse strength than oak, but the strength in proportion to weight is not so good. Milla and Chomuntiri have a little greater transverse strength, but their crushing resistance is low.

COFFEE IN BRAZIL: THE DUMONT CO.

To understand the position properly it is necessary to go back to the statements in the prospectus issued in 1896, and the following table shows the yield of coffee for each of the past eight years:—

	Yield in Cwts.		Yield in Cwts.
1892 ...	34,000	1896 ...	74,400
1893 ...	37,000	1897 ...	66,600
1894 ..	45,000	1898 ...	41,500
1895 ...	75,000	1899 ...	93,000

The prospectus stated that there were 7,000 acres in bearing, for which the company paid £910,000; 6,000 acres of young coffee, for which £240,000 was paid; and £50,000 was included in the purchase price for land alleged to be suitable for coffee planting. A certificate was given that in June, 1896, there were 4,426,600 coffee trees on the estate, which, at the usual average of 300 trees per acre, would give an area of 14,750 acres planted, and of these 194,000 trees, or 650 acres, were planted in October and November, 1895. At the present time, therefore, the youngest trees on the estate as acquired must be five years old, and, as the plants come into bearing at four years, the whole of the new ground should have yielded berries last season Yet, curiously enough, Mr. Talbot, who visited the property last year, gave the following figures as to the age of the different fields in September last:—

4,000 acres, 17 years and over
6,300 do between 4 and 17 y ears
3,000 do under 4 years.

It would be extremely interesting to know when and where these 3,0 :0 acres of young trees were planted, but we cannot throw any light on the mystery, which is deepened by the repeated assertions at the meeting that the yield of 93,000 cwt. represented an average of 8½ cwt. per acre. The area in bearing on this calculation would therefore be about 11,000 acres, whereas according to the prospectus there ought to be at least 13,000 acres in bearing. The only conclusion we can arrive at is that 2,000 acres (nearly one-third) of the old ground, for which the company paid £910,000, have already gone out of cultivation; and if 3,000 acres are under four years of age they must have been planted since the property was taken over on land which, probably, is not suitable for coffee cultivation. All that Mr. Talbot could say about the land (for which £50,000 was paid) outside the Dumont property was that the directors "believed" that it was good for coffee, although it had not as yet been proved. But then the directors are apparently prepared to believe anything.

Another point to which we would direct attention is that according to Mr. Talbot's own figures, there are now 4,000 acres over seventeen years old. Writing about the company's affairs a year ago, we were able to give the directors some information about the peculiarities of coffee-growing, and the had evidently profited by it, for they now tacitly admit the accuracy of our statements on matters which they either ignored or suppressed when the prospectus was issued to the public. We pointed out that coffee plants reached their maximum bearing at the age of from twelve to sixteen years, and that thereafter they yield good and bad crops alternately for a few years, the average steadily decreasing till the land is completely exhausted and no more use for coffee growing. We showed that a good crop was due in 1899, and that the directors' estimate of 75,000 cwt. would probably be exceeded, having regard to the new ground coming into bearing. As a matter of fact the yield was 93,000 cwt., but, according to the ignorant and misleading prospectus estimate, it should have been 130,000 cwt. For the current year the estimate is only 73,000 cwts., although part of the 3,000 acres of young coffee should come into bearing, so that the directors have been forced to admit the truth about the alternate bad crops, although a year ago they scoffed at the theory as inapplicable to the Dumont property.

Obviously, therefore, the 4,000 acres over seventeen years of age will soon cease to yield and, on the assumption that between 2,000 and 3,000 acres have already been abandoned, £910,000 of capital will have been wiped out of existence before the shareholders receive any return on their investment. Mr. Talbot made a great point of the fact that the fields between six and ten years old in 1896 had improved when he saw them again in 1899, but that is exactly what any coffee-planter would have expected. On the other hand, he admitted that the younger fields were very disappointing, and that tends to confirm our view that planting has been attempted on land totally unsuited for the purpose.

ANGLO-CEYLON AND GENERAL ESTATES COMPANY, LTD.

EXTRACTS FROM ANNUAL REPORT.

The net profit, with the balance of profit carried forward from the previous year, after debiting the Debenture Interest and placing £5,007 12s 11d to Reserve, as shown in the audited accounts annexed hereto, amounts to £17,201 1s 5d, and the Directors recommend the payment thereout of a Dividend of 4 per cent. on the Consolidated Stock of the Company, leaving a balance of £7,201 1s 5d to be carried

forward. This Dividend will, if assented to by the meeting, be payable on the 20th July, 1900, at the London Office of the Company's Bankers.

The year in Ceylon was favorable to the production of Tea, and partly on this account, and owing also to the considerable acreage of young Tea which has recently come into bearing, a large increase was obtained from the Company's Estates. The Tea crop, which in the previous year amounted to 1,541,691 lb. from the Estates' leaf and 25,121 lb. from bought leaf, rose to 2,064,515 lb. and 70,103 lb. from the Estates and bought leaf respectively. The crop of Cocoa amounted to 1,938 cwt. as against 274 cwt. in the previous, very unfavorable year. The gross price of the Company's Tea was equal to 7.70 pence per lb. as against 8.59 pence per lb. in the year 1898-99; this difference is fully accounted for by the general fall of prices in the market, the quality of the Company's Teas having been well maintained. The average price of the Cocoa was 73/3 as against 70/1 the previous year.

In Mauritius continued rains during the months of August and September delayed the ripening of the canes, and caused a considerable diminution of the expected crop, for the canes, though large, were inferior in quality, and the general yield of Sugar was poor. Prices for Sugar in Bombay ruled low until almost the end of the financial year, and increased rates were only obtainable for the latter part of the Company's crop. 116,187 tons of canes were handled on all the Estates in which the Company is interested, and produced a crop of 10,723 tons of Sugar, as against 13,526 tons in the year 1898-99. Owing to the poorness of the season under review the realisations from La Flora and the Highlands Company's lands sold to cultivators were somewhat restricted. Out of R81,564 received, R50,000 were diverted to pay off the remaining charges and of the rest, part was employed in providing cheaper transport for Britannia, while the balance has been applied to the reduction of the value of the Mauritius Assets.

The result of the working of the Estates in Ceylon and Mauritius respectively is given in the Profit and Loss Account, calculated at the average rate of exchange of 1/4⅜ as against 1/4¼ in the year 1898-99.

The prospects of the current year and the condition of the Estates, both in Mauritius and Ceylon, are reported to be good. A statement of the acrages is given in the Schedule annexed hereto.

Mr. C E S Bishop, under the provisions of the Articles of Association, retires from the Board, and, being eligible, offers himself for re-election.

The Auditors, Messrs. Welton, Jones & Co., also retire from office, and have expressed their readiness to act if re-elected.—By Order of the Board,

21st June, 1900, HENRY GREEY, Secretary.

FRUIT IN SOUTH AFRICA.

A man who has a very large estate with millions of fruit trees in South Africa finds that it takes two years for well-trained English gardeners to get used to the soil and atmosphere before they will succeed out there. Trees and grain need very different planting in South Africa, the English modes do not answer there,

The correspondent to the "Women's Agricultural Times," who gives this information, says that as the railway freight makes produce grown far from the coast valueless for England, this estate owner thinks of having his fruit tinned and dried, and for this he might employ ladies who might develop the industry very much. Grapes, oranges, cherries, pears, lovely apples, blackberries, peaches, strawberries, apricots, and even English gooseberries (which require frost), grow in that part of the Orange Free State bordering on Basutoland, yet tons of fruit must rot yearly for lack of means to get it to the coast.—*Home paper*, July 3.

ZOOLOGICAL GARDENS FOR COLOMBO.

A proposal has been made to establish zoological gardens. The position of Colombo is so exceptionally favourable that the success of such an institution is practically assured, but it is open to question how far it should be supported by Government, and how far left to private enterprise.

There may be some difficulty in reconciling the ends of science with those of the promoters. If the institution receives Government support, it must be of value from a scientific point of view, and must not degenerate into a bear-garden, while a number of cheap and common specimens sufficient to attack the ordinary sight-seer would probably serve the purpose of a company better than a really valuable zoological collection.

The question of a site is a serious difficulty owing to the greatly enhanced value of land in the vicinity of Colombo, but this can doubtless be overcome if the undertaking receives the support of Government.—(*Mr. Fowler's Administration Report on Western Province for 1899.*)

A YOUNG SCIENTIST AND PATENTEE.

We are much pleased to have the following information from Mr. Carruthers, respecting the son of an old and esteemed friend, and one who will yet, we believe, reflect great honour on Ceylon, the place of his birth :—

"*Re* your note in the *Observer* about H. Martin Leake who is going in for plant pathology, much to my delight, as I am sure no one ever regrets choosing such an intensely interesting corner of biology—this cutting (from advertisements of "Nature" this week) will show that he (H. M. Leake) has already been of use to workers at science by the Microtome which he patented: he made a model for his own use and it had so many improved points, as compared with the 'Cambridge rocker' and other instruments, that on advice and hints from different people, he has patented it. I got the first one made, which I am using now in the Laboratory here, and am quite as pleased with it as I thought I should be, when I talked it over with him and we tested it in the Botanical Laboratory at the British Museum." The advertisement is as follows :—

W. G. Pye & Co., "Granta" Works, Mill Lane, Cambridge. Makers of Physical, Physiological, and other Scientific Instruments. Sole Makers of Leake's Patent Flat-cutting Rocking Microtome. Unsurpassed for ordinary work, unequalled for Botanical work. Price, as illustrated, in Case, £6 6s 0d.

PLANTING NOTES.

Mr. Hart, of the Botanical Department, is offering plants of *Kicksia elastica* for sale. This produces the Ire rubber of the West Coast of Africa, and is doing remarkably well in Trinidad. —*India Rubber Journal.*

Rubber.—The Sandakan correspondent of the *Singapore Free Press* writes :—"I hear it is intended to turn Mr. De Nijs' rubber plantation on the Labuk River into a Company shortly, but whether any shares will be offered to the public or not has as yet not been announced."

Ceylon Tea Plantations Company,—We are very glad to learn that Mr. William Herbert Anderson has joined the Board of the Ceylon Tea Plantations Company, Ld., in place of the late Mr. Henry Tod. It will be remembered that Mr. Anderson sold his Waverley and East Holyrood estates to the Company some years ago; while all who know him will agree with us that we should have difficulty in finding a better man than Mr. W. Herbert Anderson in connection with the Ceylon Planting Enterprise.

The Society of Experimental Fish Culture—held a meeting at the Crystal Palace, not long ago, at which (*inter alia*) Mr. Alfred Allison pointed out that the "society could not have been organised except at great expense, but for the facilities which the Crystal Palace afforded. Anyone who examined the aquaria as he had done would know they were the best in the land. Abundant basins, &c., were there, and in them he had, on bright days, seen fish basking in the sun—a sure sign that they could and did thrive in the Palace waters. With regard to the hatcheries, he believed the shrewd curator used purified water, as he should do, and the comparatively small quantity required for this purpose was quite easily obtainable. By promoting the culture of fish, apart from the likings of fishermen, additional pleasure and most instructive education would be given to the public. Only the other day he had heard from Ceylon of the successful operation there in connection with fish culture, and if they could succeed it was perfectly certain we could also." The correspondent who calls our attention to the above, pertinently asks :—"Why not have an aquarium for pearl oysters attached to the proposed Zoological Gardens for Colombo?" Why not indeed; but first we must get the Zoological Gardens.

FRUIT CULTURE IN QUEENSLAND.

By Albert H. Benson.

THE COMPOSITION AND APPLICATION OF MANURES.

In the previous part of this article I have endeavoured to show the necessity for manuring, how plants feed, and what foods are required by them. I have endeavoured to show that plants require various foods in order to produce payable returns, and that the fertility of a soil is dependent on its containing these plant-foods in an available form. I now come to the import question of the composition of the various manures, and the methods of applying them in order to obtain the best results from any particular fruit or farm crop to which they are applied.

The old definition of the term "manure" was a very comprehensive one, as it practically included every material the application of which to the soil would more or less increase its productiveness.

This has, however, been considered too vague, and the term "manure" is now commonly understood to refer to farm manure, or, as it is commonly called, farmyard manure, stable manure, dung or muck which consists of the solid and liquid excrements of the various farm stock, mixed with more or less straw or other absorbent matter, or to any other refuse matter, mulch, compost heap, &c., obtainable on the farm. All other manures are classed as commercial fertilisers, as in the majority of cases they are not produced by the farmer, but have to be purchased by him.

Farm Manure.

As already stated, this manure is composed of the solid and liquid excrements of all kinds of farm stock, mixed with a greater or smaller propo rtion of absorben matter. Such absorbent matter consists of straw, dried grass or weeds, ferns, cornstalks, &c., or often, in the case of animals kept in towns, of sawdust ashes, road scrapings, &c. It is a general or complete manure—that is to say, it contains all the essential elements of plant food in a more less available form, though not always in the most desirable proportions for all plants. Farm manure is greatly neglected in this colony, and even where conserved, it is usually so badly handled that the greater portion of its manurial value is either leached out or burnt out before it is applied to the land.

The composition of farm manure varies considerably, and depends largely on the kind and condition of stock producing it, the food they are getting, and the care given to the manure when produced.

Thus the excreta of young animals is alawys inferior to that of adults, as they extract more from their food. The excreta of cows and pregnant animals is also inferior in that they abstract more from their food to produce the milk or foetus respectively. The quality of the food always influences the value of the excreta; thus when stock are fed on foods rich in albuminous matter such as cow peas, beans, cotton-seed, &c., the excreta is rich in nitrogen. The excreta from well-fed animals is also superior to that of ill-fed animals or those in which the food ration is badly proportioned. The kind and amount of the absorbent material used also influence the value of the manure; so does the treatment that it received before it is applied to the land. If thrown out in the open, and the sun, wind, and rain have free access to it, from one-half to two-thirds of its manurial value is rapidly extracted from it, but if kept covered and looked after the loss is only slight. It will thus be seen that it is an exceedingly difficult matter to determine the value of farm manure produced in this colony, especially as there is no analytical data to go on, and the values given by English, German, and American authorities are of little if any guide here, as the conditions under which the manure is produced are totally distinct. However, in the case of well-fed cows, pigs or horses the manure, if well cared for should be worth at least 5s. to 6s. per ton according to the Sydney standard of manurial values, though the best American anthorities consider that 10s. is a fair average for weel-made mixed farm manure. Besides its purely manurial value, farm manure has several valuable properties, and it is to this that it is owes its especial value in this colony.

Farm manure contains a large proportion of organic matter which, when added to the soil, tends to improve its physical condition, making it easier to work and more friable. It also tends to increase the powder or the soil to absorb and retain mostnre—a most important consideration in a climate such as this when dry spells are more or less frequent. It also tends to free nnavailable plant food present in the soil and to retain nitrogen.

Most of our soils are deficient in organic matter and nitrogen; hence anything that will tend to improve them in this respect is of the greatest value to our cultivators. Before leaving the question of farm manure there is one other point to be considered, and that is the utilisation of waste farm prodncts and converting same into compost heaps with or without the addition of lime or commercial fertilisers. As a rule, these waste prodncts are burnt or otherwise destroyed, and, in the case of orchards especially, their loss is a very serions one. All weeds, corn stalks, pumkin, vines, banana stalks, leaves, bush scrapings, and all so-called rubbish, which is usually burnt, should be gathered and placed into a heap together with the cleanings out of any ditches, drains, or road sides. The heap should be carefully built, and have sufficient soil mixed with it to keep it firm and cause it to rot properly, and should be covered by sheets of bark or iron, or by 6 inches or more of soil, to keep off heavy rains when once well wetted through. When partially rotten it should be turned over, and, if desirable, lime can be added, but lime will free the nitrogen present, and if there is not sufficient soil to absorb it as soon as it is freed it will be lost. If desired, phosphatic or potash fertilisers can also be added to the heap when turning and this will greatly increase its manurial value. Such a compost heap shoud be made on every orange-orchard, especially those that have been in bearing for some years, as it will be found to be the best and cheapest way of keeping up the fertility of the soil. The old orange-growers of Cumberland County, New South Wales, always considered a good top dressing of bush rakings and soil—which was practically a compost—the best possible application to the soil, and they often consider that the deterioration of many orchards is due to their inability of recent years to obtain the requisite amount of bush scraping needed for the top dressing of their trees.

There are other manurial agents about the farm that are often neglected, such as the fowl manure and nightsoil, and both of these can either be mixed with the manure or compost heaps with beneficial results.

Farm manure, including compost heaps, can be applied to fruit trees either in the form of a mulch, or it may be spread over the grounnd and lightly ploughed or forked in. In the case of farm manure to be used as a mulch, the sooner it is used after it is made the better, as there is little if any loss once it is spread over the surface of the land. The disadvantage of fresh manure is that is apt to produce an enormous crop of weeds, whereas, when properly made, the fermentation it has undergone has been sufficient to destroy all weed seeds contained to it. In the case of farm crops it is usually best applied by being spread broadcast over the land and then ploughed in, or if desired it may be placed in drills, and the plants, such as cabbages, potatoes, &c., planted on top of it; for this purpose, however, it is advisable that it be well rotted, as if too fresh it is apt to keep the soil too loose, especially if it is of a sandy nature, and thus cause the plans to dry out should a dry spell ensue. In heavy clay soils that are deficient in organic matter it is

best to apply the manure fresh, as in this state it tends to keep the soil open, and thus render it more friable. No farmer or fruitgrower can afford to neglect farm manure, as is the common practice at present, as, no matter how rich the soil, continuous cropping is bound to deplete it of its available plant foods; and our heavy rains and high temperature rapidly exhaust the humus or organic matter in our best scrub soils, thus rendering them more difficult to work, less retentive of moisture, and deficient in nitrogen. I cannot emphasise too strongly the importance of conserving all farm manures, and I strongly recommend all fruitgrowers and farmers to make the most of all home resources of fertility before they spend their money on commercial fertilisers. Home manures should always form the basis of all manuring, and they should be supplemented.

Commercial fertilisers may be divided into two classes; complete fertilisers and especial or incomplete fertilisers. The former contain all the principal plant foods such as nitrogen, phosphgric acid, and potash, in varying proportions, whereas the latter contain only one or sometimes two of these essential elements.

There are a large number of commercial fertilisers now on the market, a considerable proportion of which cousist of the refuse of our meatworks and boiling-down establishmeuts. These fertilisers consist mainly of blood, bones either fine or coarse, and dried refuse flesh. They very considerably in their composition, owing to the source from which they are obtained, and are valuable on account of the nitrogen and phosphoric acid they contain, but as they contain practically no potash they rank as incomplete fertilisers.

A good average sample of a bone and blood fertiliser should contain from 6 to 7 per cent. of nitrogen, and from 12 to 14 per ceut. of phosphoric acid, and be worth from £4 4s. to £5 per ton. The nitrogen is available, and is valued at 10s. per unit—that is to say, each per cent. of nitrogen present in the fertiliser is worth 10s. per ton. The phosphoric acid is insoluble, and is only worth 2s. per unit, and the rapidly with which it becomes available for plant food depends on the fineness to which it has been ground: thus, fine bonemeal is rapidly acted upon by the carbonic acid in the soil, and rendered soluble and available for plant food, whereas coarse bones only become available slowly, and their action lasts over a considerable time. When quick results are required the manure should be ground as finely as possible; but for crops such as fruit trees, which occupy the soil for many years, it is advisable to have a proportion of coars material mixed with the fine, so that the action of the fertiliser may be more lasting. The proportion of nitrogen and phosphoric acid in such manures varies considerably, and it is dependent on the amount of dried blood, bone matter, or dried flesh present. When there is a large portion of dried blood or flesh, then the nitrogen is high: but when there is a greater proportion of bone matter, then the nitrogen is lower and the phosphoric acid higher.

Instead of mixing the blood, bones, &c., together, they are sometimes kept separate and sold as either bonedust or blood-manure.

A good sample of bonedust should contain from 50 to 55 per cent. of bone phosphate, equal to 23 to 25 per cent. in round figures of insolublo phosphoric acid, and about 3 per cent. of nitrogen, and be worth from £4 to £4 5s. per ton.

A good samplo of dried blood should contain 12½ per cent. of nitrogen, and be worth £6 5s. per ton; and of nipho, 12 per cent. of nitrogen, worth £6 per ton.

Bonedust is most advantageously applied in conjunction with other manures, such as superphosphate, sulphato of ammonia, or sulphato of potash, but if it is used alone it should be applied to the land some time before it is required; otherwise it will not be available on account of its insolubility, but will tell more on the succeeding crops than to that to which it is applied. Blood and nipho, on the other hand, are in a readily available condition, and the crop to which they are applied derives a quick benefit therefrom. They can, therefore, either be applied at the time of planting the crop or can be used as a top dressing by being applied broadcast, and either harrowed, cultivated, or chipped in according to the nature of the crop to which they are applied. Neither blood nor nipho are complete fertilisers, as their manurial value depends entirely on the nitrogen they contain, and, before they can be made complete, must have phosphoric acid and potash added.

A second class of commercial fertilisers are these special fertilisers containing only one element of plant food, usually either nitrogen or potash—such as sulphate of ammonia, nitrate of soda, sulphate of potash, muriate of potash, and kainit.—*Queensland Agricultural Journal.*

(*To be continued*).

OSIER OR WILLOW, CULTURE FOR INDIA AND CEYLON.

The cultivation of Osiers, *i.e.*, species or varieties of Willow which are specially adapted for basket-making, should prove successful, if not a profitable industry, in the hill districts of India and Ceylon. This perhaps is already an established fact in the former country, though apparently Willow culture has never tempted a proper trial in Ceylon. Considering the importance of this industry in Europe, more especially in France and Germany, where it gives employment to many thousands of persons, it is not surprising to hear of fresh interest being manifested in its development in America and Australia. The U. S. Department of Agriculture, Division of Forestry, has lately issued a pamphlet on the subject, dealing with the cultivation and use of Osiers, together with notes on their geographical distribution and characteristics.

Willow-ware should win popularity in India, where the best of timbers are affected by the climate, becoming expanded in wet, and contracted in dry weather. Considering also the universal habit of the natives in carrying everything on their heads—which with even field or factory labourers is practically the only mode of transport—and the immense number of baskets which must consequently be used in the various agricultural and other industries, light Willow baskets should, in certain districts, find a ready demand. Though bamboo or rattan wares, perhaps, answer the purpose equally well, these are not everywhere easily procurable, and in some localities their cost is probably more than what the Willow article could be supplied for. Besides transport-baskets, tea-baskets, manure-baskets, etc., the flexible Willow shoots are fitted for a great variety of useful and ornamental articles of wicker-work, the making of which should prove a favourite and remunerative occupation for many natives.

Willow cultivation involves but little care or expense. A marshy soil by the side of streams or rivers, or round lagoons, such as is unfit for other agricultural pursuits, is the most suitable. No manuring is required, and a renewal of plants is seldom necessary. Propagation is usually effected by cuttings, which should be about 15 inches long and planted in lines 2 feet apart. A crop may be expected in the second or third year. Planted on sloping swampy land, Willows should also serve the purpose of binding the soil and preventing it being washed away in heavy rains.

Among the best Willows for basket-making are: *Salix amygdalina, S. viminalis, S. purpurea S. lucida,* and *S. caprea.*—H. F. Macmillan, Peradeniya, Ceylon. —*Indian Gardening.*

ON CEYLON ROCKS AND GRAPHITES *

BY A. K. COOMARA SWAMY, F.G.S.

Ceylon is surrounded by raised beaches, and has been elevated in recent geological times; fluviatile deposits also occur; the gems for which Ceylon is famous are obtained from gravels in the Ratnapura district. With the exception of these recent deposits, the island probably consists entirely of ancient crystalline rocks. Pyroxene-granulites are recorded from several localities; they are dark in colour and greasy in lustre. Foliation is not evident, but it may appear in thin slices. The minerals most frequently present are augite or hypersthene, or both, plagioclase (usually labradorite), orthoclase-microphorite, garnet, quartz, amphibole, magnetite, apatite, zircon, and biotite—the pyroxene and felspar alone being essential constituents. Varieties approach gabbro and eclogite. The texture is granulitic or granular. Centric structures are very characteristic, probably resulting from the corrosion of garnets. Normal granulites are white or grey and usually contain red garnets. The minerals are quartz, orthoclase, and microline-microperthite, plagioclase, and garnet; biotite, magnetite, ilmenite, apatite, and zircon are often present; and the texture is granulitic. Microcline-gneiss, sometimes with hornblende, occurs in conical hills, originating the term domoid gneiss employed by Prof. Walther. The minerals include orthoclase and microcline-microperthite, quartz, plagioclase, biotite, pyroxene, amphibole, pyrite, magnetite, apatite, and zircon. Anorthosite-gneiss, gneissic granite, and pegmatite are also described. Dark diorites (containing amphibole, plagioclase, quartz pyroxene, biotite, magnetite, apatite, and zircon), dolerite, hornblende-gabbro, and ophitic quartz-norite are also present. The white, crystalline limestones usually contain pale mica and blue apatite; sometimes also colourless pyroxene. Banded scapolite and wollastonite bearing rocks are found at Galle. Certain rocks, apparently vein products are also described, which contain quartz and calcite micrographically intergrown.

Graphite occurs chiefly in branching veins in igneous rocks, which at Ragedara are granulites and pyroxene granulites. The relations to the matrix are described, and are held to favour the idea of the deposition of the mineral as a sublimation product (Walther), or from the decomposition of liquid hydrocarbons (Diersche). Analyses of several of the minerals, including manganhedenbergite, are given, and a bibliography of the geology of the island is appended.

DISCUSSION.

Professor BONNEY expressed his sense of the importance of this paper, on which he knew that the author had expended great labour. It was interesting to find so great a mass of ancient crystalline rocks practically unaffected by pressure. The relations of the garnets, felspar, and pyroxene were most interesting and suggestive, and so, too, was the mode of occurrence of the graphite. He thought the paper was very valuable as illustrating the formation of a root-like graphic structure, which he thought implied crystallisation under obstruction, while the ordinary rectilinear "graphic" structure (to which the name was originally given) implied that one of the two minerals was not resisted by the other.

Dr. J. W. EVANS referred to the resemblance between the rocks described in the paper and those of Southern India, of which Ceylon was geologically an integral part. Towards the south of the Indian peninsula the ancient sedimentary rocks disappeared, though the extensive granitoid gneiss still continued. The most remarkable fact, however, was the extraordinary development of the chamochite series of Mr. Holland, which appeared to be identical with the present author's pyroxene-granulities. These formed the lofty mountain masses of the Nilgris and Annamalais, and were, it seemed, the chief feature of the most elevated regions of Ceylon. Graphite also occurred in Southern India, not only in dykes in Tavancore, but in flakes in holocrystalline igneous rocks both in Mysore and in British India.

The PRESIDENT also spoke.

The AUTHOR stated, in reply to Dr. EVANS, that small flakes of disseminated graphite occurred in several of the igneous rocks of Ceylon. He distinguished between the graphite occurring thus as a subordinate rock-forming mineral, and the vein graphite which had been deposited after the consolidation of the rocks in which it was found. In conclusion, he heartily thanked the Fellows for the very kind way in which they had received his paper.—*Mining Journal*, June 23.

* Paper read before the Geological Society of London.

PRODUCE AND PLANTING.

ARTFUL JAPANESE.—Japanese tea dealers, with the object of securing good prices, have been diligently spreading reports this season of a shortage of 15 to 20 per cent., in the first crop. It is now said to have been ascertained that the crop is fully up to the average, and even shows an excess as regards the yield of fine teas, considerable stocks of which are being held up-country. Adverse reports were also being circulated respecting the second picking, but here again it is positively asserted, in contradictions of these reports that the conditions have been extremely favourable to increased supplies this year, and that the third and fourth crops will also be abundant.

THE WORLD'S RUBBER SUPPLY.—The total world's supply of rubber today is about 120,000,000 to 130,000,000 lb, valued at about £15,000,000. At the present time lactiferous plants yielding "caoutchouc," or "rubber," are being worked for commercial purposes in Brazil, Bolivia, Central America, East and West Africa whence come the chief supplies, whilst Guiana, the Eastern Archipelago, Madagascar, India, and Ceylon contribute a small quantity to the general stock. More than half the total supply is exported from the Amazon district. Owing to the recuperative power of the tree it is improbable that the available supply of rubber from the Amazon valley will be exhausted in the near future. Also the enormous area over which the estates extend makes it unlikely that unexpected events should occur by which the industry as a whole would be damaged. For the same reason, and owing to the scarcity of labour, it is improbable that any very sudden increase or decrease of the annual production will occur. The tendency is at present for a slight increase of the total production each year.—*H. and C. Mail*, July 13.

CACAO FERMENTATION.—A report as to experiments on the fermentation of cacao in Grenada forwarded by the Secretary of the Grenada Agricultural Society was referred to the Trinidad Cacao Committee with a view to local experiments of the same nature. They reported that there is no appreciable difference in the ultimate weight of cured cacao by reason of a short or long period of fermentation.—*Trinidad Agricultural Journal.*

ABOUT MALACCA TEA.

(By an Expert.)

I have been reminded about tea from Malacca tea having come into the market; and on tasting it, I find it most excellent tea, and able to hold its own alongside of Indian tea, at a smaller price. My knowledge of tea goes back to a very early period, having hobnobbed in 1863 with old C. A. Bruce who (in 1825) was the discoverer of the tea plant in Assam. He was charged by the old East India Company with starting the proper cultivation of the plant and manufacture of the leaf—the first efforts made to grow and make tea out of China, which has now spread all over India north and south, Ceylon, Natal, Java, the Fiji islands, and now to Malacca! He had a large staff of Chinese workmen placed under him imported from China; and many a story I could relate of his narrow escapes from the wild animals which then abounded in Assam, and from the wilder and more savage tribes who in those days made Upper Assam the scene of their predatory attempts. On one occasion—and this happened in Tezpur which he had made his headquarters and where he had his bungalow with his wife and children—while he was seated with his family having his evening tea, a wild elephant walked inside the house, carrying door-frames and all round his neck, crushing the frail mat walls, and putting every one to a speedy flight. When I add that tiger used to walk about the then newly-laid-out streets of Gowhatty, which afterwards became the capital of the province, it will be seen through what dangers Mr. Bruce and the early officials there had to go. However pleasant—for they were pleasant—early reminiscences of the early days of Assam and the first growth of tea outside China may be, I cannot linger on them.

I feel sure, and do not make the least doubt, that whoever has begun the tea industry in Malacca knows his work well and thoroughly. I say this from the excellent quality and flavour of "Malacca tea."—*Straits Times*, July 19.

RUBBER CULTURE IN COSTA RICA.

(From a London Merchant.)

You may be interested to hear that rubber is being freely cultivated in the Sarapiqui district and we are starting in the same direction. The Castilloa is a hardier plant than most rubber trees, needs very little weeding after the first year and grows like the jungle tree. Some say that there is no need to fell any of the jungle trees save only the undergrowth, a small distance round the new plant, but I think the sounder opinion is that a little felling is good, though certainly not to the extent that has been carried on in other countries. When Costa Rica is well opened up it will supply a substantial percentage of the world's rubber.

A BICENTENARY CELEBRATION.

The sweet pea is to have a bicentenary celebration of its own; there is to be a conference of a sweet pea growers in London, and an exhibition wholly devoted to specimens of this fragrant and beautiful flower. We can only say it deserves thoroughly all the honours which can be paid to it. The sweet pea is said by some to have been introduced to Britain from Sicily in 1700—hence the bicentenary of this month—but according to another version two varieties made their appearance about the same time, one from the sunny shores of the Mediterranean and the other from Ceylon, and were combined to form the flower as we have it now. It was in its original form of a modest bluish-purple, the exquisite varieties which are now to be found in our gardens having been gradually developed by the Horticulturist's Art; indeed, it may generally be said that, contrary to the common belief, no familiar flower has undergone so great a transformation. The sweet pea has not been much sung by poets, though Keats has an exquisite allusion to it as "on tip toe for a flight" in some of his earliest verses. No nation has taken it for its emblem; it has not ever had any political significance thrust upon it. But its delicious fragrance, its elegant and graceful form, and its adaptability to a great number of decorative purposes make it an immense favorite everywhere. Rich and poor cultivate it alike, and it is an absolutely essential denizen of those sweet old-fashioned gardens which so many talented pens have recently translated into literature for those not fortunate enough to possess them.—*Home Paper.*

JAMAICA PINEAPPLES.

Another shipment of pineapples from Jamaica has been put upon the market, and has again caused a stir in Covent Garden. They consisted of over 500 packages of fruits, and they were in very fine condition when they came to hand. This forms the second direct shipment into this country, the first parcel being sold at prices ranging from 1s 6d to 2s 6d per pine, and the first announcement of which was published in the *Globe* at the time. From an interview with one of the largest importers in the trade, it would seem that the direct trade in pineapples, between Jamaica and London, may now be considered as established on a business footing.—*Globe*, July 12.

THE

AGRICULTURAL MAGAZINE,

COLOMBO.

Added as a Supplement Monthly to the "TROPICAL AGRICULTURIST."

The following pages include the Contents of the *Agricultural Magazine* for August:—

Vol. XII.] AUGUST, 1900. [No. 2.

OCCASIONAL NOTES.

AMONG the more interesting contributions to the latest number of the Royal Agricultural Society's Journal (issued June 30th) are the following:—Fumigation for Insect Pests by William E. Bear; The Comparative Value of Nitrate of Sodium and Sulphate of Ammonium as Manures, by Pro. R. Warrington, M.A., F.R.S.; Experiments on Lucerne by Bernard Dyer, D.Sc. We reproduce elsewhere a note on Artificial Changes of Physical Properties of Soils.

We find that we have omitted to refer to a useful Circular issued from the Royal Botanic Gardens, drawn up by Mr. H. MacMillan, the Curator of the Gardens. This Circular deals with fruit trees suitable for cultivation in the low-country and for moderate elevations. It contains general directions regarding planting, propagation, &c., in addition to a list of fruit trees with short notes on each. In a Circular of this nature one does not expect to find a treatise on fruit cultivation, but to those who would desire to have fuller instruction regarding the cultivation of fruit trees we would commend a handy but most instructive publication issued by the Agricultural Department of the Cape of Good Hope, the authors of which are Messrs. P. MacOwan, F.L.S., Colonial Botanist, and Eutace Pillo" Agricultural Assistant. It is entitled a "Manual of Practical Orchard Work," and the general instructions on the subject are well worth the study of local fruit growers.

We direct attention to still another scheme that has been put forward by a practical hand for the agricultural education of the people of the country. There are many excellent suggestions in it, which deserve the attention of those who have been entrusted with the duty of reorganising the system of Agricultural Education in the Island. Of schemes there have been enough put forward already, and it is for the wise heads concerned with the settlement of the question at issue to sift all these and make out a policy acceptable to the Government and calculated to serve the agricultural interests of the native communities.

The fifth and last volume of Dr. Trimen's Flora has just come to hand, though it has been issued some little time now. This volume is principally taken up with the grasses (Graminee), but it contains as appendices a key to the Orders Genera and Aberant species of Ceylon Flowering Plants, Diagnostic characters of the orders to which the Flowering Plants of Ceylon belong, a paper on the Forests and Waste Lands of Ceylon by Mr. A. F. Broun, Conservator of Forests. A paper on the Distribution of Rainfall in Ceylon by Mr. F. Lewis of the Forest Department. A History of

Ceylon Botany by Mr. G. S. Boulger F.L.S., of the City of London College, Additions and Corrections, Indices of Botanical, English and Nativel names.

We have just received a useful little pamphlet, issued as a Circular from the Royal Botanic Gardens, Peradeniya, dealing with the trees suitable for shade, wind-belts, timber and fue reserves, &c.

CLINICAL NOTES.

Two successful Cases of High Neurotomy (Bracheal).

I performed this operation on the first occasion in December, 1899, on a gharry horse with pegged splints. In this case the animal was operated on under chloroform and the healing was rapid, and the animal was able to be used after three weeks. In the second instance the operation was performed on a horse for ring bones. I prefer this to the ordinary medium or low neurotomy. The operation was performed without chloroform as the patient was very weak. The healing was tardy, yet the animal went alright after three weeks.

Incision of a section of the lateral tendon of the extensor metatarsi.

Two cases of bad spvain were brought for treatment, and these were operated on without chloroform, and the wounds were left opened after the dissection of the tendon. One animal soon after the operation did not show any lameness, and walked pretty will, improving very much in course of time. This animal is now working. The other had to be lifted up after the operation, but it improved after the healing was completed.

Amputation of the Penis in a Bullock.

A bullock was brought with the history that the animal had suffered from a bull-burnt condition of the organ, that a native doctor had advised the client to keep the animal in a pond covering the inflamed organ, that the animal was bitten by a crab, and that putrefaction of the organ continued as an effect of the bite. When the animal was thrown down for operation I had to slit open the whole sheath, and found at last that the penis had to be amputated. Another opening was made about two inches from the scrotoum as the organ was too short for the natural prepuce. The healing was on the whole satisfactory, and I have seen the animal after six months in good working order, and the artificial prepuce doing the duty of a natural one.

D. A. Chinniah,
Veterinary Surgeon.

PRACTICAL HINTS TO HORSE-OWNERS

By A. Chinniah, G.B.V.C.

Chapter II. (*contd.*)—Food and Feeding.

Groundnuts or Earthnuts (*Arachis Hypogœa*) belongs to the natural order leguminosæ, and as may be expected it is highly nitrogenous. Another important property of groundnuts is that they are equally rich in hydrocarbonatious matter. The seeds are not in use as a horse food, but I am referring to them in connection with my previous remarks when writing about paddy, viz., that if some oleaginal ingredient were mixed with paddy and gram, the mixture should form a standard horse food. Further, it has been found that groundnuts like codliver oil are a specific in some forms of chonic pulmonary disease. Asthma, or broken wind of the horse, is caused pathologists find, by chronic indigestion. This incurable complaint is very common in horses and vulgarly spoken of as "panting" in Ceylon.

Groundnuts are grown in Southern India to a very great extent, and exported to Marseilles for the extraction of oil, by a process kept secret by the French manufacturers. The plant grows fairly well in Ceylon. Groundnut cake is used for feeding dairy cattle in Europe.

Grasses—Grass either dry or green, as I have already remarked, is the food of the herbevera in a state of naturl. In Ceylon only rice stalks are used in a dry state for feeding cattle. For horses it is only of value as bedding in the stable.

Hay is never made here, but it is imported from Australia. It is far more nutritious than straw, for the reason that before the stalks are fully matured, this is cut and turned into hay, and in this process only loose moisture, whereas in the case of straw, the seeds of which are used as horse food, there is very little nutriment left. In Ceylon we do not find the wild grass which grows in the rainy season in India, and which is generally turned into hay; hence the process of hay-making as carried on in India need not be described, but would repeat that good hay ranks as a standard fodder food for horses. In Ceylon hay is so expensive that it can only be used along with other concentrated foods with the object of ensuring proper mastication. On the other hand there are some good natural grasses to take the place of hay.

The Hariali or Dhub grass (known in Tami as 'Arugam pillu,') is botanically named Cynodonl dactylon. This is a sacred grass of the Hindus and it is largely used for feeding milch cows. Its roots and stems are succulent and the woody fibre is easily digested. The grass is so delicate and succulent that horses and cattle relish it highly. It may be said to grow on all soils, and unlike many other grasses it has numerous creeping stems. Another advantage of this grass is that the rootlets are fine and short, springing generally at each node, and hence it can be easily pulled out of the ground and easily got from sand and earth sticking to the roots. I may in this connection remark that it is important that ordinary wild grass as supplied to horses should be free from earthy matter, which when it enters the stomach cause nternal irritation and result in colic.

APICULTURE AT THE SCHOOL OF AGRICULTURE.

Mr. Chas. Andree, the experienced bee-keeper, visited the school at the request of the Superintendent of the institution, with the sanction of the Director, to report on the progress of the experiment in apiculture.

Mr. Andree examined the hives on the 25th July, in the presence of the students, and found two strong swarms at work, but the combs, he unfortunately found, were being irregularly built, and as a result the attempt to manipulate the frames caused injury to the bees and infuriated them. Mr. Andree advised that the hives with irregularly built combs (due to the frames not having been arranged equi-distantly) should be left alone, and fitted with a "super" to induce the bees to build in it. With Mr. Andree's help a convenient super was placed on the hive and we await results. As regards the bees themselves, Mr. Andree described them as a wild tribe of the Apis Indica, and thought that they would prove a constant source of trouble. These bees as we have previously stated were captured at Cotta. In order to facilitate matters, Mr. Andree has kindly promsied to secure one or two swarms of the less belligerent type of bee and send them here from Kurunegala. On the 26th Mr. Andree supervised the building of two hives on the premises. These hives will be probably sent to Kurunegala to be stocked and brought down. The hives on transverse section measure 15 inches square and have a depth of 9 inches. On two sides are frames (which might be made of jak or halmilla wood) into which a glass is fitted, with a wooden shutter over it. The rest of the hive may be made of deal-wood. The wood forming each of the eleven parallel frames within the hive is one-third of an inch thick and seven-eighths of an inch wide. The frames move freely on two rests made of zinc, but are kept at a distance of quarter of an inch apart by means of small nails. The frames as they are arranged in the box should have a space of quarter of an inch between them and the bottom top and sides of the hive. The bars of the frames should run parallel with the side having the glass window. In the new hives Mr. Andree has adopted a new arrangement for the bee hole. Instead of the old single hole 5 inches long and five-eighths of an inch in width, he has provided for two bee holes one above the other, each only quarter of an inch wide. This is intended to keep off the Sphnix atropus or Death's head moth which is the chief enemy to be guarded against. Mr. Andree has had hives full of combs destroyed in a few days by this moth. As soon as the new hives are stocked we intend, as advised by Mr. Andree, to reserve the bee house for these only, and remove the two hives containing the wilder type of bee now at work to some remoter position. This will leave the tame bees undisturbed.

SOME BIBLE PLANTS OF CEYLON.

III. The Mustard Tree.

There has been much discussion as to the identity of the mustard tree (referred to as Sinapi in the Gospels) of which St. Matthew speaks in chapter iii. 31 and 32 of his Gospel: "The kingdom of heaven is like to a grain of mustard-seed which a man took and sowed in his field; which indeed is the least of all seeds: but when it is grown it is the greatest among herbs, and becometh a tree, so that the birds of the air come and lodge in the branches thereof." Again, St. Mark describes it as a tree "shooting out great branches; so that the fowls of the air lodge under the shadow of it." (Mark iv. 31.) St. Luke also speaks of the tree in chapter xiii. 19, likening the kingdom of God "to a grain of mustard-seed which a man took and cast into his garden; and it grew and waxed a great tree; and the birds of the air lodged in the branches of it."

Our Lord also refers to the smallness of the seed in Matt. xvii. 20, and Luke xvii. 6.

The mustard was then a branching tree with small seed, and could not possibly be identical with the small annual herb which produces the mustard of commerce. Dr. Royle after careful examination of the subject has found that the mustard plant of Palestine at the present day answers in every respect to the description of the sacred writers. The tree grows near Jerusalem, on the banks of the Jordan and round the sea of Tiberias. The seed is called Chardal or Khardal, the Arabic, for mustard. The tree is known to botanists as *Salvadora persica* and belongs to the order Salvadoraceae, which is considered nearly allied to the Olive family (Oleaceae). It is found in Persia, Arabia, Palestine, N. Africa, India and Ceylon. The branches of Salvadora are very numerous and spreading, with their extremities pendulous like the weeping willow. The flowers are minute; the berries smaller than a grain of pepper, smooth and red. Each fruit contains one seed which is pungent and used like mustard. The fruit has an aromatic smell, the root bark is acrid and used as a vesicant. The shoots and leaves are eaten as salad, and are also used as camel fodder. The fruit is used medicinally in various ways, and an oil is extracted from the seed. The tree is sometimes referred to as the "tooth-brush tree" from its Persian name; the wood being largely used for making tooth brushes which are supposed by the natives to strengthen the gums and to improve digestion. The wood is described as white, soft and easy to work, taking a good polish, while white ants are not liable to attack it. Weight of wood about 46 lbs. to the c. foot.

Trimen, in his Flora, says that it is found in the desert and dry regions of the Island, especially by the coast. Gardner, who evidently first collected it, makes mention in his report for 1845-6, of the large trees he met with at Elephant Pass in the Northern Province. The generic name commemorates J. Salavador, a Spanish botanist. The Tamil names for the tree are Uvay and Viyay.

There are some, however, who still incline towards the belief that it is the black mustard plant (*Sinapis nigra*) that is referred to in Scripture, pointing to the fact that this herb is found in the holy land growing as high as a horse and his rider. The following extract supports this view:

Professor Hackett tells us that crossing the plain of Akka, in Palestine, he saw before him a little grove of trees. On coming near they proved to be a grove of mustard plants. Some of the trees were full nine feet high, with a trunk two or three feet in circumference, throwing out branches on every side. He wandered whether they were strong enough for the birds to "lodge in the branches thereof." Just then a bird stopped in its flight, alighted on one of the limbs, which hardly moved beneath the weight, and began to warble forth a strain of sweet music. His "doubts were charmed away," the "least of the seeds" had actually grown into a substantial tree."

AGRICULTURAL EDUCATION.

1. Agricultural education, both theoretical and practical, should be entirely in the hands of the Department of Public Instruction. An Agricultural Department should have its own work, in assisting the agriculturist with necessary advise; the scientific Botanical department will undertake investigations and experiments and work on purely scientific lines. Where the three branches are separated more work and much better work will naturally result. In India and elsewhere, the Agricultural Department undertake general work in assisting the cultivator, the Botanical department carries on investigations, and the Educational Department undertake instruction.

2. Much benefit would arise by the establishment of a central Agricultural School on a vernacular basis as suggested by Mr. Elliott in his paper. This school should be a thoroughly equipped one, and instructions should be given there on all branches of science &c. allied to agriculture.

3. The course of studies in the school should comprise three branches:—

(*a.*) General education.
(*b.*) Sciences, bearing on agriculture.
(*c.*) Practical training.

4. As suggested by Mr. Elliott all the training, lodging and board should be provided free. Boys admitted to the school should be drawn from among the following:—

(*a.*) For training as certificated teachers for vernacular schools, the present training schools to be done away with.
(*b.*) For training such students as are nominated by Government Agents.
(*c.*) And a limited number who seek admission on their own account.

5. All students for admission should be between the ages of 15 and 18, should have passed the VII. Standard Government Examination, or should pass an Entrance test.

6. To start with, there should be abou admissions for training as teachers under the same conditions under which training students are now admitted.

Fifteen students should be nominated by Government Agents. Their selection should be entirely left in the hands of the revenue officers without imposing any conditions whatever, except those of age and preliminary educational qualification.

There are many young men in the agricultural villages who aspire to become the headman of the village, and who are wholly engaged in agricultural pursuits. Very often they are the sons of the older headmen, and they succeed to the place on the retirement of their fathers. These young men will without hesitation offer themselves as to be trained at the school, were the revenue officers to nominate them for headmanship conditionally.

Five students should be admitted annually after a competitive examination. These, when trained, will be available for service under landed proprietors, or as overseers of experimental gardens which Government Agents (as an Agricultural Department) will establish.

7. The course of studies at the Agricultural School should extend over at least two and a half years. Each year should be divided nto two terms, as the present departmentali holidays will not suit an agricultural class, which should be expected to be in training at sowing and harvesting seasons. Of the five terms thus available, more than one term or six months should be devoted to practical work.

8. The curriculum of general education should be of the same standard as that of the training schools.

The teaching of science should always cousist of an equal number of practical lessons and lectures on each subject: the following subjects among others should be taken up:—

(*a.*)	Agricultural Science	36	lessons	each term.
(*b.*)	Botany	36	,,	whole course.
(*c.*)	Chemistry	36	,,	,, ,,
(*d.*)	Physiology	36	,,	,, ,,
(*e.*)	Sanitation	36	,,	,, ,,
(*f.*)	Veterinary	36	,,	,, ,,
(*g.*)	1st aid (medical)	25	,,	,, ,,
(*h.*)	Agricultural law	25	,,	,, ,,
(*i.*)	Drawing	36	,,	each term.
(*j.*)	Mensuration	36	,,	whole course.

Practical Instruction.

(*a.*) Field.
(*b.*) Travelling.
(*c.*) Workshop.

There should be land worked in connection with the school of about fifty acres, say somewhere in the Kalutara district. This land should be used not so much as an experimental or a model farm, but primarily as a "workshop" to familiarise the students with the various operations of cultivation, harvesting, &c., drawing, levelling, irrigation, ploughing, roadmaking, lining, holing, and numerous other practical details of agricultural work which should be practised

here, and a number of students regularly told off to the farm for a month's work at a time.

After a practical acquaintance with the processes of cultivation has been established, a similar knowledge of crops should be gained on estates and gardens in an actual state of work, instead of through model farms. Travelling tours should be arranged for twice a year, and within the two and a half years' course a student should have travelled in all the important districts of the Island. In this travelling course he should make prolonged acquaintance with such cultivations as paddy, coconut, cacao, cardamoms, cinnamon, tobacco, tea, coffee, rubber, &c., and spend a number of days or weeks at selected estates. For instance, Mr. Elliott's Wallaway lands should keep a class for a two weeks to a month at work, and in the same way any coconut planter in the Veyangoda, Negombo, or Kurunegala district will welcome the travelling class to any coconut estate, while the same may be said of tobacco and other crops as well as garden products.

Workshop.—The students should acquire a knowledge of carpentry, blacksmith's work and building, sufficient for agricultural purposes. Their hands should be practised to the use of carpenters', smiths' and builders' tools, each of these branches being taken up at a different school term.

9. In the case of students who are being trained as teachers, a part of the practical work can be dispensed with and the time gained devoted to practical work in connection with the teaching profession.

10. It must be understood that no results should be expected, nor any attempt made to guage the extent of improvement resulting in the state of agriculture after a course of education as described above. All improvements should be gradual, and to force such will be unnatural and will never result in any practical good. I do not approve of experimental gardens in connection with agricultural education. It is for an Agricultural Department, or the revenue officer of the different districts to establish such gardens only in places where they think they are required.

11. There is one thing more the department of Public Instruction should do. They should not be satisfied with the mere establishment of a School of Agriculture, but the scope of such education should be extended and systematized.

A special grant should be given to all teachers of schools who train their boys for a practical course of agriculture in addition to the theoretical one now prescribed. A grant of Rs. 4 per head for first stage, Rs. 6 for second stage, and R8 for a third stage pass will be sufficient encouragement for teachers to attend to this matter. A syllabus should be drawn up, and the Agricultural Inspector appointed by the department should not only inspect the boys in their practical work, but should visit schools in different centres and organize this practical course as well as the establishment of school gardens. The Inspector in charge of agriculture or the agricultural assistant to the D.P.I. should, in addition, advise the department in connection with the central school of agriculture in all matters and take charge of some of the important travelling classes when he can find the time to do so.

12. The annual expenses for carrying out this scheme will not be much over R30,000. Of this R20,000 will include all expenses for the Agricultural School and R10,000, for providing the cost of an agricultural assistant to the Director, (who should at least be paid R5,000 a year,) and for payment of bonus on results to school teachers.

W. A. D. S.

Colombo, 28th June, 1900.

BY HIGHWAYS AND HEDGES.

The Chief Justice of Ceylon's Judgment in the *lagium* case affords amusing reading. For the benefit of the uninitiated I quote as follows from Dr. Watt:—"There are primarily three forms of the resin or narcotic (from Indian Hemp or *Canabis Sativa*), but under each there exists local modifications, special preparations from these and adulterations or imitations. The three forms are known as Ganja, Charas and Bhang. Ganja is the female flowering tops with the resinous exudations on these; Charas the resinous substance found on the leaves, young twigs, bark of the stem, and even the young fruits; Bhang, the mature leaves, and in some parts of India the fruits also, but not the twigs.

The definition of ganja as given in the local Ordinance is not a satisfactory one and does not go far enough. It would be better if all narcotic preparations from Cannabis Sativa were brought within the meaning of the Ordinance, since, as Dr. Watt informs us "from the stem, leaves, flowers, and even the fruits, a resinous extract of a powerful narcotic character may be prepared." So that it is not only the "diseased flowering tops" referred to by the Chief Justice that are capable of producing the objectionable drug.

The following further reference by Watt to these narcotics and the control of their use in India is also interesting:—"As already explained there are three forms of this poisonous drug: (*a*) ganja, the agglutinated female flowering tops and resinous exudation on these; (*b*) charas, a resinous substance found on the leaves, young twigs, and bark, and (*c*) bhang or siddhi, the mature leaves, and in some parts of India the fruits also, and even the very young twigs, but not the stems. Ganja and charas are smoked, and bhang is either used in the preparation of the green intoxicating beverage hashish, or in the manufacture of the sweet-meat known as majun (vulgarly majum). Bhang is much weaker than either ganja or charas, and by many is supposed to be much less injurious. It is sold in Bengal at from 4 to 6 or 12 annas a seer, whereas ganja and charas cost from R4 to R25 a seer. Bhang, being collected largely from the wild plant, is extensively used

all over India, the bulk of the consumption entirely escaping duty. This is mainly due to the fact that it would be impracticable to hold a man responsible for the existence of a wild plant growing within a certain radius of his hut, and it would be impossible to prohibit him gathering, from such a plant, and this daily quantity used by himself and family. This is precisely the state of affairs which prevails over a great part of India, and, indeed, on the lower slopes of the Himalaya and up to an altitude of 8,000 feet, the plant is often so plentiful as to be extensively used as bedding for cattle. The greatest difficulty exists, therefore, in regulating the consumption of bhang, but practically no such difficulty exists with regard to ganja and charas. The last mentioned narcotics can be produced only from the cultivated plant, and the consumption can therefore be regulated by law. The Excise Act provides that licensed persons may cultivate the plant, prepare the narcotics, and retail these to the consumer. The right to vend is sold by public auction, a person purchasing thereby the sole right, for one year, to all or so many of their shops in a district. Any person other than a licensed dealer, having in his possession more than a very small quantity at one time is liable to prosecution and fine. This system of farming the wholesale and retail shops exists all over India, Madras being an exception to the rule, since in South India no revenue whatever is credited to Government from these drugs.

Specimens of the fruit and leaves of a tree were sent to me early this month with an enquiry as to the use to which the parts of the tree could be put. The tree was kindly identified by the Curator of the Royal Botanical Gardens as *Polyalthia Coffecides*, known in Sinhalese as Omara and in Tamil as Nedunnarai. It is described by Trimen as an inhabitant of the dry low country forests, but extending up to 1,500 ft. It is found occurring near Kandy at Haragama and Anuradhapura. The flowers are borne from January to March and are apple-green in colour. The leaves which are shining and undulate are very characteristic, and resemble those of the coffee tree. The tree belongs to the Anona family and is rather ornamental in appearance, being hence found planted to some extent in gardens and on roadsides. The only use to which the tree is put appears to be for fibre got from the bark. Another species known as *P. langifolia* is useful in many ways to the people of India, according o Dr. Watt.

A correspondent from Matara writes:—"I send you a shrub used largely in this part of the country in dying rushes, of which mats are made, and called Welikaha. The leaf when boiled with sapan wood produces a bright red colour. Bombu or Bombi, as you know, is a timber tree which produces a bright orange colour. The leaf is mixed with matured jakwood to extract the dye which our Buddhist priests steep their robes in. Is it Symplocos speciosa, Roxb? Both the above trees grow wild but I venture to think the produce will be found marketable if only made known in Europe."

Welikaha is *Memecylon capitellatum.* (L.) (Melastomaceæ). It is also known among the Sinhalese as Dodankaha. Dr. Trimen speaks of the tree as one of the best marked species of memecylon, and easily recognized by the leaves alone. The wood is said to be hard and strong. As regard its use in dying, Trimen says that the leaves turn orange-yellow when dried and afford a yellow dye. I have observed the leaves being dried in the sun on mats near Amblangoda. This is one of the dyes mentioned in the enquiry regarding the dyeing of materials used for making baskets, mats and hats, and the possibility of improving native methods of dyeing, a matter which is receiving the attention of the Ceylon Delegate at the Paris Exhibition.

Referring to the dye of *M. capitellaltum* and other species, Dr. Watt has the following:—The leaves are employed in South India for dyeing a "delicate yellow lake." In conjunction with myrobolans and sapan-wood, they produce a deep red tinge much used for dyeing grass mats, and also good for cloth. Samples experimented with by Mr. Wardle give "a yellow colour to wool, eri silk, and bleached Indian tasar with a tin mordant, wool being dyed the deepest colour." Mr. Wardle writes: "They possess scarcely any tamin; on tasar silk without a mordant, they give a nice clear but light brown colour. There is a pretty yellow tinge on the eri silk." In another passage he adds: "This dyestuff produces good light colours, but would not be of much use in the dye-house, owing to the very small amount of colouring matter it contains." The flowers are employed by native dyers as an adjunct to chay-root for bringing out the colour in preference to alum. By themselves they produce evanescent yellow. *Symplocos spicata*, referred to by my Matara correspondent is Bombu or wal bambu. I have not heard it also called "Bombi" which is the native name of *Litsea chinensis.* The fomer belongs to Styraceæ and the latter to Lauraceæ (the cinnamom family). The wood is described by Dr. Trimen as light, white and close-grained, but liable to split, and the bark is said to afford a dye. Ferguson in his "Timber Trees" speaks of Bombu as a common tree from the coast up to 7000 ft. It is said to be a very conspicuous object when covered with its snow-white flowers. I am obliged to my correspondent for the information with reference to the use of Bombu with jakwood dye in colouring the robes of the priests of Buddha.

I have been lately struck by the tendency of much divided leaves to revert to the simple type. My observations have been limited to the leaves of a plant belonging to Araceæ which is normally much divided and consisting of as many as eight distinct segments, but which I find in various stages of reversion to the simple cordate type so common among the araceæ.

I have a few cocoa trees in my garden bearing fruit. On a tree in the same garden

I lately found a clay structure such as wasps and similar insects build, on another tree in the same garden shaped and coloured like a cocoa pod. Could this be a case of mimicry.

Mr. Weerakoon, Mudaliyar of Wellaboda Pattu, Southern Province, refers to the tendency in the paddy plant to yield no regular ear of corn, the plant being then called Beragas or Borupan (Anglice: false rush). "I have" he says "seen large patches containing such abnormal growths in the Morowak Korale and Wellaboda Pattu, sometimes 50% of the plants consisting of the "false rush." I attribute the result to inferior grain being used for sowing." The writer then goes on to ask if it could not be advisable to infuse "fresh blood" into paddy by importing a good quantity of seed paddy from India. This is what we have advised time without number, and we have imported seed from India and elsewhere on our own account in a small way. It is for Government to take it upon a large scale, and the improvement of seed in this way should form one of the duties of the reorganised School of Agriculture.

The same correspondent sends a note on "Kadupahara" which he describes as a perennial plant found growing wild in most places, but thriving luxuriantly in the up-country districts. The name is said to be derived from the ground-shaped leaves. The leaves, says our correspondent, when chopped up and prepared as a dry curry, makes a palatable dish, though the Sinhalese only use it as a vermifuge for calves. Mr. Nock, of Hakgala, is stated to have identified it as the "sow thistle," cultivated in some countries for the purpose of feeding pigs. Mr. Weerakoon recommends it as a desirable addition to our list of edible leaves. Dr. Trimen in his Flora mentions that *Sorchus asper* and *S. oleracens*, the common sow thistles of England, are commonly found as weed in cultivated ground.

ARTIFICIAL CHANGES OF PHYSICAL PROPERTIES OF SOIL.

In this paper the author considers what practical means may be employed to impart to cultivated soils the greatest possible productiveness. That the proper cultivation of the soil is of prime importance is shown by the fact that other factors important in plant growth, *e.g.*, the plant food supplied by manures, can exert their full power only when the mechanical condition of the soil is favourable. Uncultivated soils generally fail to produce maximum yields. The most favourable physical conditions exist in those soils which consist of a thorough mixture of the several principal ingredients. Thus soils in which either finely-divided (clayey) or coarsely-divided (sandy) ingredients predominate are unfavourable to the production of crops without decided changes in their properties, while soils in which the ingredients are mixed in certain proportions (medium soils) are generally productive. It is well known, for instance, that a pure humus soil, mainly on account of its physical nature, is not favourable to plant growth, but may be rendered productive by admixture with a soil deficient in humus.

It is evident that in studying the various ways of cultivating soil, not only cohesion and adhesion, but also friction of the soils with the tools and the weight of a unit volume of the soil must be considered. The force with which the particles of soil cling to each other (cohere) is of prime importance in connection with cultivation of the soil, since the ease or difficulty with which tools penetrate the soil, and hence the labour required to cultivate the soil, depends primarily upon it. The controlling influence of cohesion may be inferred from the fact that it is the main factor determining the differences between soils, although the other properties of soils should also be taken into account, since the resistance to be overcome in cultivation is always due in part to them. In general, it may be said that humus offers the least resistance to cultivation, clay the greatest, while sand stands between the two extremes.

If it be asked what practical means should be used to reduce to a minimum the labour of working soils, we should recommend a suitable change in composition of the soil as the first step. Thus, for example, mixing clay with sand diminishes both cohesion and adhesion of the soil, and renders it more easy to cultivate. It is true that by this treatment both the weight and friction of clay are increased, but, as modifications of cohesion and adhesion are more far-reaching, the increase in weight and friction may be neglected.

The improvement of the tillable properties of soils may be most perfectly attained by an increase in the proportion of humus. The working of clayey soil is by this means rendered very much less laborious, because both cohesion and adhesion, and also the weight, are diminished in proportion to the amount of humus added. For sandy soils also an increase of humus is of advantage, as it reduces friction and decreases the weight. It thus appears that manuring with materials of organic origin (stable manure, vegetable matter, straw, and peat) greatly increases the ease of cultivation, and at the same time influences most favourably the chemical properties of the soil in many different ways. Nor should the fact be overlooked that increasing the humus content promotes the tendency of the soil to assume the 'crumbly' structure, and by this means still further reduces the mechanical resistance to cultivation. Soils of crumbly structure are not only naturally more fertile, but are very much more easily worked than those having a separate grain structure. Whatever manipulations, therefore, promote the formation of the crumbly structure and tend to make such structure permanent are of great value in soil cultivation, inasmuch as they both heighten the fertility of the soil and lessen the labour required for its cultivation. This is especially true of compact, heavy soils. To obtain this crumbly structure and to preserve it, several fundamental principles must be observed. These may be summed up briefly as follows: (1) The soil must be ploughed immediately after the crop has been gathered; (2) it

ust be ploughed only when it contains a medium amount of water (about 40 per cent. of that which the soil is capable of holding); (3) the furrows must be as narrow as possible, especially at the first ploughing; (4) the land destined for tillage in spring should be exposed in roughly ploughed condition to the action of frosts during the winter; and (5) the formation of aggregates in the soil should be promoted by means of proper fertilisers. For the latter purpose humus-forming manures (stable and vegetable manure) as well as calcium hydrate (freshly slaked lime) are especially valuable. Hurtful influences, on the other hand, are exerted by such fertilisers as contain carbonates of the alkalis and soluble phosphates, inasmuch as these when applied in considerable quantities cause the soil particles to pack closely together. The same is true of materials rich in chlorides and nitrates. These salts promote the formation of crumbly structure while they remain in the soil, but when they are washed out by the rain water, they leave the soil in a puddled condition. This happens more or less with all salts which are not fixed by the soil. This can be corrected only by a careful selection and application of measures calculated to increase and preserve the percentage of humus in the soil.

From the standpoint of the agriculturist, the principal property of soils in their relation to air is permeability, for on it depends the supply of oxygen required both for normal decomposition of organic material and for the respiration of the roots. The smaller and more densely packed the soil particles, the more limited the supply of oxygen and the greater the necessity for attempting to regulate the permeability. This end is best attained by mixing a fine-grained soil with sand and by inducing a crumbly structure. If too great humidity of the soil is responsible for the lack of permeability, only thorough drainage can correct the defect. If the soil has been deprived of its permeability by washing during periods of extraordinarily heavy precipitation, the best remedies are harrowing and hoeing between the rows, and heaping up the soil around the plants. The latter is a most efficient means of increasing permeability of the soil.

Excess of water, either temporary or permanent, is hurtful to plant growth to a greater or less extent. Such a condition is a result principally of heavy precipitation on soils of high water capacity. The damage is most marked in the case of basin-shaped fields on which water from neighbouring fields accumulates, or which have an impervious subsoil at such a depth that the soil is kept in a state of saturation. The means adopted to correct this state of affairs will depend upon whether there is a permanent or only temporary excess of water. If the excess of water remains permanently or for a long period, it can be removed only by under-drainage or by the construction of ditches. The physical structure of the soil, more particularly its permeability and water capacity, determines the amount of water that may be removed by this means. The efficiency of the method consequently varies widely in different localities. A blind adherence to the common rules of drainage may in some cases reduce the water supply in the soil to a degree dangerous to plant growth. This is the case (1) in all soils of small water capacity and considerable permeability (coarse-grained, sandy soils); (2) in soils offering considerable facilities for evaporation (peat and bog earth); and (3) in all soils occupied by plants requiring considerable amount of moisture in the upper soil layer (meadows, perennial forage plants.)—*Royal Agricultural Society's Journal.*

(To be continued.)

ON THE FORESTS AND WASTE LANDS OF CEYLON.*

By A. F. Broun, Esq.,
Conservator of Forests.

The area of uncultivated land in Ceylon exceeds 20,000 of the 25,365 square miles of country contained within the Colony. The proportion of good forest in these 20,000 square miles is unfortunately small, the largest portion being taken up by scrub and by grass-covered stretches of country called *patanas*, which find their greatest developement in the hills of the Province of Uva. The scrub is partly natural, especially so on the sea coast and in the arid subzone, and partly the result of a destructive method of cultivation known as *Chena*, and which consists in clearing and burning jungle and in raising crops for two or three years on the area cultivated. Now that a careful control is exercised over this cultivation, nothing but small forest is felled; but not many years ago valuable forests were ruthlessly felled, and their ashes were utilised as manure for the crops which were raised; where such a system of cultivation has been in force, it takes years for the forest to take again a useful character. Usually a thorny scrub grows up, or as is the case in the Eastern Province, a dense growth of thick grass (*Imperata arundinacea*) springs up, as in the moist districts, the group gets covered up with *Lantana*, or, worse, because they are not soil improvers, by *Hedyotis*, *Ochlandra stridulata* or *Gleichenia linearis*.

* From the fifth volume of Trimen's Flora of Ceylon.

The patanas were probably at one time covered with trees, such as will be described later on for the Park country, but fires and grazing have destroyed the majority of these, except in sheltered places such as gullies or ravines. The trees which are to be found on the patanas are, at higher elevations, *Rhododendron arboreum*, and from 4,000 feet downwards, *Careya arboreas* known in Ceylon as 'Patana Oak,' *Phyllanthu, emblica*, *Terminalia belerica*, *T. chebula*, and *Pterocarpus marsupicum*. These are, with few exceptions, the only trees which can stand the heavy grass fires; but in the gullies, where they are more sheltered, other species, which are less robust and which are same as those found in forests at the same elevation, are able to live and to produce themselves.

In the backward state of the survey of the Island it is not yet possible to state the area of the real forests, but they cannot much exceed 5,000 square miles, although the larger area is, for the present, set aside for reservation, which includes stretches of scrub and patana englobed

within the forests. The most important belt of forest stretches from the Northern Province, mostly between the centre line of the Island and the east coast down to the Hambantota district, but important blocks are also found scattered over the rest of the Island, chiefly in the Puttalam district of the North-Western Province and in the upper hills, but also in the Kurunegala district of the North-Western Province, in the Western, Southern, and Sabaragamuwa Provinces, where are still to be found, in isolated blocks, the remains of what was at one time the extensive Singha Raja Forest.

The vegetation of the forests varies especially according to rainfall and elevation, and the forests can be classified according to the following zones and subzones:—

Dry Zones. Rainfall 35 to 70 inches. — Arid zone. Rainfall 35 to 50 in. Dry zone proper. Rainfall 50 to 70 inches.

Intermediate zone. Rainfall 70 to 80 inches.

Wet Zone. Rainfall 80 in. and more. — Lowcountry zone from sea level to 4,000 feet. Mountain zone above 4,000 feet.

The Dry Zone.—This includes about three-fifths of the island, viz., the whole of the Northern, North-Central, and Eastern Provinces, the Puttalam district and portion of the Kurunegala and Chilaw districts, the North-Western Province, the northern part of the Central Province, about two-thirds of the Province of Uva, the Hambantota district of the Southern Province, and the Kolonna Korale of the province of Sabaragamuwa. The Western Province is therefore the only one of which no portion enters in the dry zone.

The Arid Zone occupies the north-western end of the island in the Puttalam, Mannar and Jaffna districts, and the south-eastern in the Hambantota district. The characteristic trees and shrubs of this subzone are *Salvadora persica*, *Azima tetracantha*, and *Acacia eburnea* near the coast, and *Acacia planifrus* on the island of Mannar. The woody vegetation is usually shrubby and thorny, being represented by *Carissa opinosum*, *Zizyphus jujuba*, *Z. Œnoplia*, *Z. rugosa*, *Randia dumetorum*, *Flacourtia pamontchi*, &c. Further from the coast the forest vegetation is composed of the same species as of the forests of the dry zone proper, but the trees are usually smaller and the undergrowth is composed mainly of *Memecylon* and of *Stenosiphonium rulyseinaum*. The Palmyra palm (*Borassus flabelliformisi*) is found on sandy soil both in this sub-districts, especially in the Jaffna Peninsula.

The forests of the *Dry Zone proper* are the most important to the forester, not only because they are the most extensive, but also because they contain most of the valuable timber trees. The most important of these are satinwood (*Chloroxylon swietenia*) found on sandy soils, and attaining its best dimensions in the Puttalam and Batticaloa districts; Ebony (*Diospyros ebenum*), which prefers rocky, undulating ground, and which, although found occasionally in the wet, lowcountry, is almost abundant in the Northern, North-Central, and North-Western Provinces, and in the Trincomalee and Matale districts; Palu (*Mimusops kauandra*), which is found on more clayey soils from the North to the South of the Island. It attains an enormous size, and grows best, if anywhere, in the Northern Province. It is one of the iron woods of commerce. Trincomalee wood (*Berrya Ammonilla*) is found in moist but well-drained places. It extends into part of the wet zone, but the trees are usually small size. The finest trees are found in the eastern portion of the Province of Uva. Milla (*Vitex altissima*) one of the strongest of Ceylon timbers, extends also into the wet zone, where it is not uncommon; but, like the Berrya, it is a much finer tree in the dry zone, especially in the Eastern Province. The same may be said of Ranai (*Alseodaphne semecarpifolia*), although it is not so common in the wet zone as milla. The Ebenaceæ are (apart from Ebony) represented in this zone chiefly by *D. ovalifolia*, while *D. crumenata*, *D. Oocarpa*, *D. embrejopteris* and *D. montana* are also found abundant in certain localities; and *Maba buxifolia* is a very small tree which is by no means uncommon even in the arid zone. Of the Guttiferæ we have chiefly *Garcinia spicata*, *Calophyllum burmani*, and, near streams or in groves, planted before the memory of man, *Mesua ferra*. The Dipterocarps, which are so characteristic of the lowcountry wet zone are almost absent, being only represented by *Vatica obscura* in moist soils in the Eastern Province, and by *Hopea cordifolia* along streams in Southern Uva and Sabaragamuwa. Among trees which are characteristic of this zone the most common are *Polyalthia longifolia*, *P. coffæoides*, *Crateeva Roxburghii Pterospermum suberifolium*, *Sterculia fœtida*, *Azadirachta indica*, *Walsura piscidia*, *Pleurostylia Wightii*, *Sehleichera trijga*, *Nephelium longana*, *Odina Wodier*, *Cassia fistula*, *C. marginata*. *Bauhinia tomentosa*, *Acacia leucophloea*, *Acacia ferruginea*, *Gyrocarpus Jacquini*, *Eugenia jambolana*, *Barringtonia acutangula*, *Adina cordifolia*, *Canthium didegnum*, *Bassia longifolia*, *Terminalia fabra* (near streams and tanks), *Strychnos Nux vomica*, *Cordia Rothii*, *Stereospermum chelonioides*, *Euphorbia antiquoreum Sapium insigne*, *Hemicyclia sepiaria*, *Miechodon zeylanicus*, *Holoptelea integrifolia*, &c.

The most common shrubs are *Polyalthia korinti*, *Allophyllus cobbe*, *Oihna squarrosa*, *Cassia auriculata*, *Alangium Lamarchii*, *Webera corymbosa*, *Raudia dumetorum*, *Gmelina asiatica*, *Memecylon*, *Glycosmis pentaphylla*, and *Dimorphocalyx fabellus*. Creepers and climbers are not so well represented as in the moisture zones, the most abundant being *Hugonia mystax*, *Ventilago maderaspatana*, some species of *Vitis*, *Derris scandens*, *D. sinnata*, &c. The most beautiful orchids found in this zone are, without doubt, *Saccolabrium guttatrun*, which is found in the Eastern Province, and *Vanda Roxburghii* and *V. spathulata*, which are found chiefly not far from the sea. *Vanda parviflora* and *Saccolabrium Wightianum* are not uncommon, while a pretty little white ground orchid, *Habenaria pterocarpa*, is found in the rocky places. The ferns of this zone are not abundant, the *Adiantum candatum* penetrating farther into the dry districts than any other, while *Hemionitis arifolia* and *Gymnopteris quercifolia* are found in dark and moist places, while on rocks grow *Cheilanthes mysorensis*, *C. loxa* and the tiny *Ophioglossum lusitanicum*.

In the Intermediate zone trees of both the dry and the lowcountry moist zone are to be found, such as *Berrya ammonilla*, *Nephelium longana*,

Mesu ferrea, Artocarpus integrifolia. Xylopia parviflora, Albizzia stipulata, A. odoratissima, A. lebbek, &c; and there are a few species which although they are found elsewhere, can be said to be characteristic; these are *Filicium decipiens, Chickrassia tabularis,* and *Melia dubia. Terminalia belerica* attains an extraordinary size in this zone, in which are other gigantic trees like *Tetrameles nudiflora* and *Ailanthus malabarica.* Among the shrubs, *Vitex negundo* is probably the most characteristic. Another characteristic feature of this zone is the great abundance of creepers which cover the tallest trees and render forest operations extremely difficult. Some very handsome ferns grow in this zone, the most noticeable being *Aspidium decurrens, A. subtriphyllum, A. cicutarium,* and *Adiantum lumulatrun.*

The Park country of Uva can be included in this zone. It comprises the low lands of the eastern boundary of that province; and it has a quite characteristic flora, very similar to that of the Sub-Himalayan forests. The trees which are found here are found only on the patanas and occasionally elsewhere, the most noteworthy being *Anogeissus latifolia, Butea frondosa. Terminalia chebula, T. belerica, Zizyphus xylopyra, Pterocarpus marsupium, Millusa indica, Sterculia colorta, Gmelina arborea* and *Diospyros melanoxylon.* The undergrowth is, as in the Sub-Himalayan forests, mostly grass (*Imperata arundinacea*). Near water-courses the flora is that of the ordinary dry zone type.

The Wet zone includes the Western Province, the Province of Sabaragamuwa excluding the Kolonna Korale, the Galle and Matara districts of the Southern Province, the Hill districts of the Central and Uva Provinces and about one-half of the Kurunegala and Chilaw districts of the north-western Province, or, in a few words, the south-western and south-central portions of the island. It is the portion which receives the full force of the South-west monsoon, and includes the higher lands affected by the North-east monsoon. The rainfall usually ranges from 80 to 200 inches, but it exceeds even this in some places, and rumour has it that in Eratne, to the South-west of Adam's Peak, it actually does not fall far short of 400 inches.

(To be continued.)

GENERAL ITEMS.

The *Queensland Agricultural Journal* gives a correspondent the following recipe for making a concrete "milk yard":—"The concrete should be made as follows—1 part cement, 4 parts gravel (the gravel should contain naturally enough sand for the purpose), 2 parts broken metal or stone (not over 2 inches cubic): but all gravel (that is 6 parts) will do as well as if, not better than stone. Fine sand should not be used under any conditions. The floor should be kept well wetted for several days after laying down. The concrete may be laid on the surface of the ground as it is better not to break the crust."

We are informed in the same Journal that an American chemist is said to have discovered a process by which Alexandria limestone can be converted into a substance resembling wool, the threads of which are strong enough to admit of their being woven. The staple is, however, too short for the purpose. But the product has evidently a commercial value, as we are told that it is in extensive use for packing round refrigerators, boiler cases, and pipes to preserve the heat in the latter case. It is also used for deadening the sound on floors, and large quantities are being regularly shipped to the Phillippine Islands, to be used as a non-conductor in the storehouses of the American troops.

Thomas Barraclough of 20, Bucklersburg Road, London, E.C., advertises in the *Planter* (Calcutta) Fauves' Patent Rhea Fibre Extractor, stating that it produces in one operation 160 to 200 lbs. of clean fibre daily from the green stems—value £30 to £35 according to state of the market. Weight net 11 cwt., gross 14½ cwt., requires one horsepower.

We read in the *Indian Agriculturist* that Messrs. Thirkell & Co. of Fenchurch Street have written to the Curator of the Indian Section in the Imperial Institute to say that they are prepared to take all the rhea ribbons that India can produce for some years for £15 per ton, and that its offer to supply, at £40, decorticators which are capable of preparing 10 cwt. of stuff per day. Government has been asked to foster the cultivation of rhea as much as possible. In forwarding the correspondence on the subject to the Bengal Chamber of Commerce, Dr. Watt, reporter on economic products to the Government of India, shews that Messrs. Thirkell & Co. require the ribbons in the crudest form.

Some idea of the financial results achieved by the Indian Forest Department may be informed by the fact, recorded in Mr. Ribbenhop's pamphlet, "Foresty in India," that rheas in the period 1864 to 1867, the annual surplus was about fourteen lacs; it has now reached eight lacs.

In his sketch of the History of Indian Botany, Sir George King incidentally mentions that from bamboos a very large amount of forest revenue is annually derived. The sale of bamboos for the year 1896-97 amounted to no less than 110 milions of stems.

The TROPICAL AGRICULTURIST
MONTHLY.

Vol. XX. COLOMBO, SEPTEMBER 1st, 1900. No. 3.

"PIONEERS OF THE PLANTING ENTERPRISE IN CEYLON."

(Third Series.)

THOMAS DRANE, C.E.,

THE FIRST ENGINEER WHO SURVEYED AND DESIGNED A LINE FOR A LOCOMOTIVE RAILWAY BETWEEN COLOMBO AND KANDY.

THE subject of our notice was the son of Thomas and Cecilia Drane, and was born at Bromley, Middlesex, on the 7th of January, 1818. He was educated at private schools; and subsequently graduated at Cambridge University. After completing his University career at Caius College, he became an articled pupil to Mr. James Walker, the Admiralty Engineer, and President of the Institute of Civil Engineers. After completing his term of pupilage, he was selected to go out to the Island of Ceylon, in the year 1844, to make a professional Survey of the direction to be taken of the proposed line of railway from Colombo to Kandy. This, after many months of hard and arduous work, he completed in the course of the year 1845, having to penetrate a comparatively unknown tract of country through almost impassable jungle, exposed to great risks from exposure to a malarious climate, and other difficulties and dangers, which only his great physicial strength and excellent constitution enabled him successfully to accomplish. He won great credit for the admirable manner in which he succeeded in completing this task; and he had the satisfaction of learning long afterwards that his Survey and the information he afforded were of great service to the Engineers who followed him: to Capt. Moorsom, Mr. Doyne and Mr. (now Sir Guilford) Molesworth. After returning from Ceylon, (the Railway project having collapsed owing to the financial crisis in the Colony of 1846-7.) Mr. Drane was appointed second Engineer to the South-Eastern Railway, and during the time he held this appointment, he constructed that part of the main line, eight miles in length, which runs from Folkestone to Dover, including the important viaduct constructed at the town of Folkestone. He resigned this appointment in order to become the Resident Engineer of the railways in Cumberland, under the control of the Earl of Lonsdale, including the line from Whitehaven to Cockermouth; and subsequently carried on to Keswick and Penrith, in the construction of which he played a leading part. After some years he resigned this and afterwards accepted the Managing Directorship of the West Cumberland Iron Works, taking up his residence at Cockermouth, where he lived for many years, building for himself a very attractive and commodious house in the town.

In consequence of the failure of his wife's health, he was at length induced to throw up his appointment in the North of England, and he retired to Torquay, in Devonshire, where he lived quietly for the remainder of his life, and died on 31st October, 1890. Mr. Drane left an only child—a daughter. His wife still survives him.

The foregoing succinct sketch of Mr. Drane's life was kindly penned at our request in November last by his brother-in-law, Sir Frederick Young, K.C.M.G., the founder of the Royal Colonial Institute, and we publish it, with some slight additions and alterations; but we may further add a few details of the first attempt made to lay out a locomotive railway between Colombo and Kandy.

Although Mr. Drane came out in 1844, it was not till after his Survey and Estimate were completed that, towards the end of 1845, a Ceylon Railway Company was formed, and it may be of interest to put the following on record here from the original document:—

CEYLON RAILWAY COMPANY.

Provisionally Registered 20 October 1845.

Capital £1,000,000, in 20,000 Shares of £50 each.

London Provisional Committee.

Chairman.

PHILIP ANSTRUTHER Esq.
(late Colonial Secretary of Ceylon.)

Deputy Chairman.

JOHN STEWART Esq.—(late of Bombay.)
GEORGE ACKLAND Esq.
(Messrs. ACKLAND, BOYD & Co.)
W. S. BINNY Esq.
(late of the Firm of BINNY & Co. Madras).
A. CROWE, Esq.
(35 Old Broad Street.)
ROBERT CHRISTIAN Esq.
(Messrs, A. & R. CROWE & Co. Colombo).
J. G. FRITH Esq.
(Messrs. FRITH, WALLACE & Co.)
Colonel Sir F. HANKEY, G.C.M.G.
(Director of the Bank of Ceylon.)
Sir GEORGE LARPENT Bart.
(Messrs. COCKERELL & Co.)
Colonel MONTRESOR—(Ceylon Rifles),
Captain ALEXANDER NAIRNE
(Formerly of the East India Company's Service.)
LAWRENCE PHILIPS Esq.
(Messrs. L. PHILIPS & SON.)
WILLIAM SCOTT Esq.
(Messrs. SCOTT, BELL & Co.)
W. H. THOMAS Esq.
(Messrs. BOYD & THOMAS).
WILLIAM TINDALL Esq.—(34 Cornhill)
STEPHEN VERTUE, Esq.—Liverpool.
J. S. WILSON Esq.
(Late WILSON, RITCHIE & Co. Colombo.)
S. B. WORMS Esq.
(Park Crescent.)

Bankers.

Messrs. GLYN HALLIFAX & Co.
(Messrs. HANKEYS & Co.)

Solicitors.

Messrs. WILSON & HARRISON.
(1, Copthall Buildings.)

Secretary.

D. I. NOADS Esq.

TEMPORARY OFFICES No. 8.
Broad Street Buildings,—London:

CEYLON PROVISIONAL COMMITTEE.

Chairman.

Major GEORGE THOMAS PARKE,
(Deputy Commissary General.)

Deputy Chairman.

EDWARD JOSEPH DARLEY Esq., of
(Messrs. ACKLAND, BOYD & Co.

Committee:

JOHN ARMITAGE Esq.
(Messrs. ARMITAGE, SCOTT & Co.
GEORGE CRABBE Esq.
(Messrs. A. & R. CROWE & Co.)
HENRY LEWIS LAYARD Esq.
(Messrs H. L. LAYARD & Co.)
GABRIEL BENEDICT WORMS Esq.
(Rothschild Estate—Pussilawa.)

Honorary Secretary.

DAVID WILSON Esq.
(Messrs. WILSON RITCHIE & Co.)

Clerk.

Mr. J. A. LOOS.

Engineer and Surveyor.

THOMAS DRANE Esq.

Assistant Engineer and Surveyor.

C. I. WEBBE Esq.

Assistant Surveyors.

Mr. E. S. FALKNER.
„ HEW BAGSHAW.

Bankers.

The Ceylon Bank.
The Oriental Bank.

Temporary Office.

No. 24, Chatham Street, Fort, Colombo.

In the Ceylon Blue Book for 1846, the following reference was made to the Railway by the representative of the Ceylon Government:—

THE CEYLON RAILROAD.

The number of bullock carts employed on the Kandy road, although trebled within the last few years, are still found insufficient for the planters' wants; even whilst I write (May 1847) it is calculated that with all the available means of transport kept constantly at work on the main roads, it will still require a period of four months longer to bring the Coffee of 1846 from the interior to Colombo, whereas looking to the approaching unfavourable weather, the whole of it should have been long since in store here, and the greater part already shipped for Europe; many mercantile firms have still to ship two-thirds of their crops, and these two-thirds must necessarily be deteriorated by 5 to 10 per cent. in addition to the interest at 9 per cent. on the value of the produce thus detained, in addition to which as the season advances, shipping is becoming scarcer and freights rising day by day.

It was a foreshadowing of these coming embarrassments which led to the formation in 1845 of a provisional committee for the purpose of organizing a Railway Company for Ceylon.

Various lines of road have since been surveyed and a favourable one selected, along which it is stated by the Engineer of the Company, that a railway may be carried from the Coast of Colombo to the central capital at Kandy, in the heart of the Coffee districts, at a gross outlay of £800,000, including several costly bridges and an extensive viaduct. It is suggested, however, that the more expeusive portion of the work at the Kandy extremity where the line begins to ascend, should be delayed, and only those portions more easily accomplished, finished in the first instance, so as to give about 65 out of 80 miles for an outlay of about £500,000, the remainder to be completed hereafter, and in the meantime the ordinary vehicles might be employed at both ends of the line.

The whole of the scrip is said to be taken up, but it is doubted if all the holders in England would at present respond to a call, though all those who have an interest in the Colony would assuredly come forward to complete the undertaking, as they are well aware that as a certain means of conveying produce from the interior to the port of shipment, as well as keeping the Central Province always regularly supplied with the staple articles of food, and thus ensuring cheap living to the labourers on the various estates, the Railway is of the first importance to the Colony.

In his speech to the Legislative Council in August 1847, Lord Torrington made the following reference :—

Not altogether unconnected with this subject is that of a projected railway communication between Colombo and the coffee districts. I have every reason to believe that such an undertaking, to the extent in the first instance of thirty-two miles, will be not long delayed. I have received the authority of the Right Hon'ble the Secretary of State to submit for your consideration an Ordinance having for its object the facilitating this desirable undertaking, and to give its projectors such privileges and powers as cannot fail to secure the ultimate accomplishment of the end in view, with advantage to the public and to the shareholders.

As soon as I have received information that the arrangements of the Company are sufficiently matured, and the requisite proportion of the subscribed capital has been paid up, I shall not fail to submit to you such an Ordinance as may be required for the purpose.

What followed next is succinctly related by Pridham whose volumes on Ceylon were published in 1849 :—

In 1845, a Railway, with a capital of one million sterling, was projected in England by the mercantile houses connected with the colony, between Colombo and Kandy in the first instance, but with the ultimate design of the counecting other districts wherever practicable. The illimitable expansion of railway enterprise had already sustained a check, when the attension of the public was called to this undertaking, and before its plans could be thoroughly matured, and a report be received from the surveyor of its practicability—a monetary pressure had set in, and the Directors found themselves unable to obtain the full call to which the shareholders had pledged themselves. A communicatiou had already been made to the Colonial Department, which at once referred the matter for the consideration and report of the Local Government, whose reply was, as might have been expected, of a highly encouraging character.

Under these circumstanees, and in consequence of its having been discovered, that the cost of construction would very cousiderably exceed the sum originally estimated per mile, and that the Government was indisposed to accede to any proposition *immediately* involving the revenue of the colony on the capital required for the *whole* line, the Company has been compelled to suspend its intention of proceeding with the entire line for the present, and has selected a part by way of experiment. On the line thus modified, the Government has sanctioned, by ordinance, a guarantee of five per cent. per annum, along with a free grant of the land required for the railway for a term of ninety-nine years, the Government having the right of purchase after the expiration of fifty years, and the reversion of the line, without purchase, at the end of ninety-nine years. The result of this modified plan is, that the old Company has been dissolved, the capital has been reduced to one-fourth, *viz.*, £300,000, under the new Company, and the holders of shares in the former are entitled to the same number of shares in the new company, as though it had been found possible to carry the original undertaking into effect. In addition, power has been reserved to increase the capital to the original amount when requisite, and the option of the additional stock will be given to the present subscribers.

Its claims to public notice are thus set forth by its promoters. "Ceylon is subject to no volcanic action; the soil is admirably adapted for the construction of railways, and the country through which the contemplated line will pass is not liable to be flooded during the monsoons. Labour is excessively cheap in the island; and bricks, lime, and timber may be procured with facility." "The sources of revenue are a large goods traffic; considerable passenger intercourse, and the conveyance of troops and mails, &c." Under the first head, it is stated that the number of bullock bandies, with goods, passing between Colombo and Kandy, is about 79,000 annually, and the average hire about £2 10*s* each, shewing a cost for transport between Colombo and Kaudy of £197,500 per annum. The carriage of goods by these carts is tedious and uncertain, and the expense is greatly increased by reason of the extensive mortality among the cattle employed; so much so, that natives, each bearing a load of merchandise, are occasionally dispatched from Colombo to Kandy, in preference to that mode of conveyance. The cost of transport by rail will be much less, but as the traffic by this means of conveyance will greatly increase, there can be little doubt that this branch of traffic would of itself be sufficient for the remuneration of the capital invested.

The present mail coaches in Ceylon are said to shew an annual return of upwards of £7,000, but it is clear, that it is on the first source of revenue that the Company must principally depend for support in the outset.

Over the division of the line* first to be undertaken, all the traffic between Colombo and Kandy will pass; and assuming that 40,000 tons are carried

* The line selected by the surveyor, commences at the east bank of the Kalane, about three miles from Colombo, aud following for the first thirty-two miles the direction of the great military road to Kandy and Kurunaigalla, which the line crosses twice, enters the valley of the Maha-oya, which it follows for twenty-three miles, to the foot of the hill country at the Kaduganava Pass. At this point, it commences a rapid ascent to the summit on which Kandy is situated, and terminates about three miles short of that city, being a length of fuorteen miles, and making the whole length of the railway sixty-nine miles. Over the first division of thirty two miles, the country is flat, the total rise not exceeding 170 feet in the whole length, and the highest land passed over between these points, not exceeding 240 feet. Flat, however, as this part of the country is, the surface is broken in many places by short hillocks, which, though capable of being avoided in some places, will render considerable earthworks occasionally necessary, and give a class of gradients of 1 in 150 to 1 in 200. Extensive and deep cuttings should be obviated wherever possible, lest they should become torrent beds in the rainy season. The second division involves heavier gradients and works than the first, as the country becomes more broken. For seventeen miles the gradient need not exceed 1 in 150 to 1 in 200, but beyond that, they might be so steep as 1 in 100 to 1 in 50 for the remaining five miles. The total rise of country on this division is 540 feet, without any intermediate summit. The third division, forming the ascent to Kandy, is an elevation of 1,100 feet to be overcome, but the gradients may, it seems, be so arranged, as not to exceed 1 in 50, the numeous mountain ravines admitting of a lengthening of the line, so as to accomplish that object. The termination of the first division, *i.e.*, the portion to be immediately constructed, is near the point of junction between the Kurunaigalla and Kandy road, and consequently where the streams of traffic on these two great military roads meet. The termination of the second is at the commencement of the hill couury, and intersects the great military road only 13 miles from Kandy. The cost per mile, including stock, for the two first divisions of the line (which is to be single), has been estimated somewhat under £9,000 and of the third division from £21,000 to £22,000 per mile. The expense of crossing the Kalane, and entering Colombo, is avoided, as also of entering Kaudy, when the time shall arrive for completing the whole line.

up the line at 1s. per ton per mile, and 22,500 tons are brought down the line at 4d. per ton per mile, the result will be on the former £64,000, on the latter £12,000=£76,000, from which deducting £19,000 for working expenses, £57,000, or a dividend of 19 per cent. will be received.

In reference to expenditure, I may venture to observe that the Company might have safely taken credit for the moderate cost of fuel to which they will be subject, any quantity of wood being procurable at the several stations at the most trifling expense: this item in the United States stands the several companies in at one-third of the cost of the same item in Great Britain, and the relative expense would be yet further diminished in Ceylon where labour is so cheap.

Although the Company continued to issue Annual Reports in London, nothing was done in Ceylon until Sir Henry Ward took the matter up, and after a further report and survey by Capt. Moorsom in 1856-7, the Company once more came to the front and made an agreement with the Ceylon Government (passed in the Legislative Council, 22nd Jany, 1857); and sent out (in 1858) Mr. Doyne and a staff of Europeans to construct the line. The cutting of the first sod was celebrated by a banquet, 600 persons attending it, with Sir Henry Ward as President on 3rd August. But by July, 1859, Mr. Doyne reported that the work could not be done under the system adopted by the Company for £2,214,000 in place of the £1,200,000 which was expected to be the maximum. He and his two Chief Assistants threw up their posts and went to Australia, and so it came about that Mr. (now Sir) Guilford Molesworth by a new route, which had been suggested as worthy of trial by Mr. Doyne, and with Mr. Faviell as a responsible Contractor, eventually constructed the Colombo-Kandy line 1863-1867, the total cost from first to last—including money wasted by the delay and in compensation to the Company—being £1,738,483. (The Company closed its career with a 19th Report in February 1861.) And such in brief is the history of the Railway originally surveyed and estimated for by Mr. Thos. Drane, whose work as a pioneer engineer was always referred to with the greatest respect by his engineering successors who alone understood the great amount of arduous labour Mr. Drane must have undergone in performing so difficult a task as a Railway Survey between Colombo and Kandy so far back as 1844-5 and with only native assistance:

"Peace to the memory of a man of worth."

Seedless Oranges in California.—An American lady travelling in Babia some thirty years since "happened" upon some fruits of this now world-renowned variety, and got some trees home. Two of these found their way to the River-side estate in California the proprietor of which is Mr. H. Tibbetts. They were then carrying some sixteen fruits—the average annual shipment from this place has now reached 1,600,000 boxes.—*Gardeners' Chronicle.*

AGRICULTURAL EDUCATION IN GREATER BRITAIN.

PAPER READ BEFORE THE FOREIGN AND COLONIAL SECTION OF THE SOCIETY OF ARTS, ON TUESDAY FEBRUARY 27, 1900.

By R. Hedger Wallace.

(Continued from page 80.)

As regards the technical schools of the colony, agriculture, according to the report for 1899, was only taught at one institution, the students being examined in the subject under the English Science and Art regulations.

This colony further employs three dairy instructors, three fruit experts, and one poultry expert, and has a number of experimental stations, including two poultry farming stations; and the Department of Agriculture freely distributes leaflets and pamphlets of interest to agriculturists. This free distribution of information with the object of educating and assisting those settled on the land one might add is a feature common to all the colonies of the Australasian group. Before passing on from this group to the next, that is to the East Indian, I would note, so as to complete the Australasian group, that there is a botanic station in Fiji, and a technical school at Viti Levu where the native is taught the rudiments of agriculture, *i.e*, how to propagate and grow food and economic plants.

Coming to the next group, the same change in the object of the agricultural education provided, has to be noted, as was remarked when passing from Canada to the West Indies. The agricultural education provided in the East Indies, is likewise intended for the benefit of the natives of the country, and no provision is made for those who represent the planting industry. The European must, therefore, learn by experience the details of his calling as a planter. The East Indian planters in some respects, I venture to think, differ from the planters of the West Indies. They can be roughly divided into two classes or groups. There are those, for instance (generally engaged in the tea or coffe industry), who have to manage a large estate, control a large number of native labourers, and be responsible for the economic plant grown from its nursery stage, till so to speak its produce is harvested, and then, still further, have to direct control and be responsible for the manufacture of this product into a commercial commodity. On the other hand, there are those who (usually engaged in the indigo or sugar industry) have under contract, the economic plant grown for them by native tenants or proprietors, and accept no responsibility till the natives harvest the produce, and place it in their hands to be manufactured into a commercial product. The former group, obviously is more in need of a good agricultural training than than the latter, and the question naturally arises why it has not been provided? Of course I assume that it will be granted that a training in temperate cultivation under temperate conditions is not suitable and that the system of pupilage which is practically that of apprenticeship, under a manager who might be good, bad, or indifferent, is not regarded as one capable of affording the best results.

Taking the Straits Settlements as the first of the East Indian group, I would note that, according to Mr. Moore, a Malay translation of an English book on the "Principles of Agriculture" is used as a reading-book in the native schools, while in the English schools, agriculture is one of the extra subjects of the Code.

In India and its dependencies a good deal of interest has been taken lately in agricultural education by the Supereme and Provincial Goverments. I have been favoured, by the courtesy of the Under Secretary of State of the Government of India, Department

of Agriculture, with a copy of a resolution issued by the Department, which shows the progress of agricultural education in India up to 1896.

I will briefly note what has been done. In the Bombay Presidency there is, at Baroda College, an agricultural branch, and lectures on agriculture are given at the Poona College of Science by the superintendent of the Bombay Government Farms. There is also an agricultural class in connection with the High Schools at Belgaum and Naidad. The University of Bombay further offers a diploma in agriculture, but not a degree. In the Madras Presidency there is the Saidapet Agricultural College, which has been established for a number of years. In the Central Provinces there is an agricultural class at the Government Farm.

An agricultural class is also established at the Government Farm, Cawnpore, North-West Provinces. Both of the classes named are utilised by the educational department for the instruction of training School students and school-masters. The period of the agricultural course is in both places two years, but the course for schoolmasters at Nagpur is only for six months. The Allahabad University has also, so far, supported the Cawnpore farm class, in the interests of a supply of agricultural teachers as to allow a special examination on science and agriculture students who go up for the "school trial" certificate. It may be added that one of the training schools for teachers in the Bombay Presidency has on its staff an agricultural teacher who has obtained a college diploma, and gives lectures to the students in training on agriculture.

The whole question of agricultural education in India has, I believe, lately been put on a new footing entirely, through the acceptance by the supreme Government of the view that a thorough and practical education in agriculture, ending in a high-class college diploma, or in an agricultural degree, develops the intelligence of students just as well as a literary course, and that it certainly fits them as well, if not better, for duties in the land revenue and cognate services. The Madras Government has given effect to this view by making the diploma in agriculture of the same value as a B.A. degree, as a qualification for higher Government service. The supreme Government of India has emphasised this view by placing on record the following conclusion, namely, that "agricultural degrees, diplomas or certificates should be placed on the same footing as corresponding literary or scientific degrees, &c., in qualifying for admission to Government appointments, and more particularly those connected with land revenue administration."

From the resolution of the supreme Government forwarded to me I learn that this Government has impressed upon the provincial Governments and the various educational deparments the policy of "making instruction in the rudiments of agriculture part and parcel of the primary system of instruction in the country, rather than teaching it as a subject apart from the general educational programme." Perhaps the intention of the Government of India as regards agricultural education will be more fully indicated if I note three other conclusions that are recorded:—

"(1) That the practice of allowing schoolmasters either before or after appointment, to pass through a course of a few months on a Government farm is one which deserves consideration.

"(2) That a Special school course leading up to the agricultural diploma, degree, or certificate is required.

"(3) That the [agricultural] diploma should eventually be compulsory in the case of certain appointments, *e.g.*, agricultural teachers at training schools, assistants to the director of agriculture, &c.,'

Before passing from India I may add that it does not suffer from a want of agricultural text-books, there being of late years quite a respectable number published both in English and the vernacular. The Government agricultural publications are also many and of service not only to the native cultivator but to the European planter.

In Ceylon the elements of agriculture are taught as a specific subject in the Government schools, and a primer of agriculture has been published by the Director of Public Instruction. There is also a school of agriculture at Colombo which was opened in 1884, and has ten branch institutions. From this school, to which a dairy is attached, agricultural instructors are sent into remote rural districts to illustrate improved methods. The school for a number of years has also issued a monthly magazine and this along with the *Tropical Agriculturist* furnishes the agricultural literature of the colony, a colony, I may add, which has the reputation of being itself the best training ground for the tropical planter.

Our next group is the African. Here the first thing to be noted is, that following the example of the West Indies a number of Botanic stations have been established. The earliest was started in Lagos in 1888, the next being at Aburi on the Gold Coast, the rest being located at Uganda, Gambia, Sierra Leone, and in the Niger Coast Protectorate. These African stations, along with the Fiji station already mentioned, have a different mission to fulfil from those in the West Indies. They are teaching stations, in fact, they are intended to instruct natives in the rudiments of what is for them, practically, an unknown art. In the West Indies, on the other hand, they are intended to assist the peasant population to put to profitable use and art they already know and possess. In British East Africa, besides the botanic station located in it, the European cultivation introduced by the missionaries may also be regarded as of educational value to the natives. Zanibar, again, has a Director of Agriculture, and his work on the same basis may be regarded as educational. To British Central Africa the European planter has penetrated; and at Zomba there is a Scientific Department to assist in working out the problems in pioneer cultivation that incessantly arises. Passing to Mauritius, I have to refer to Mr. Moore, who states that an attempt to start agricultural schools, and to introduce the study of agriculture in the rural primary schools of this colony, fell through for want of funds.

I come now to the two self-governing colonies in South Africa. Natal has a Department of Agriculture, and employs both dairy and irrigation experts, but no school or college of agriculture has been established. Under the Natal system of school education, however, agriculture is to some degree studied. Field work on a farm or garden, for instance, is compulsory in all the native schools, and the last report of the Superintendent of Education (1898) shows that even in native girls' schools land is cultivated and garden work done by the girls. From this report I also learn that the principles of agriculture was taught in three European schools. In the Government school at Estcourt it was taught to the boys and girls in Standards VI. and VII. At the Government school at Verulam it was taught to the boys in the same standards, and in the Government school at Ixopo it was taught to the senior pupils. The examination is not colonial, but under the regulations of the English Science and Art Department. In South Africa some of the conditions differ from the other colonies, in America and Australia, for instance, native labour is available, and the native has to be taught to labour on a farm, that is, do field work, for usually he is too backward for any other kind of agricultural teaching. Again, the European farmer stands somewhat in a different position to the farmer, for example, in Australia, as he often has at his disposal, and can utilise, the labour of the natives.

Passing on to Cape Colony, I might just note that the Agent-General for the colony in London advises me that he is unable "to say precisely to what extent agriculture may be taught in the elemen-

tary schools, because many of these are not under official control." The Blue-books of the colony indicate that to some extent it is taught, and for some years it has been an optional science subject for teachers. In the Report of the Superintendent-General of Education for 1898, for instance, it is stated that not a single candidate had been presented for examination in agriculture, which Dr. Muir adds, "in view of the large total (318 as against 250 in 1897) is decidedly disappointing."

Placed under the control of the Education Department of Cape Colony are two agricultural schools —one at Elsenburg, the other at Somerest East The latter school, the Superintendent-General of Education reports, "has been allowed to linger on without alteration." These agricultural schools, I may add, were formerly three in number, and under the Department of Agricultnre, and have only lately been transferred the care of the Education Department. One of the three has, however, been given up for some time, and now it would seen that another will soon follow.

The Elsenburg School of Agriculture at Mulder's Vlei is, in a sense, a new venture, which was only opened in September, 1898; yet it represents the old Stellenbosch School of Agriculture which moved from there to this farm. The Principal, like the school, is also new, having been selected in England to start the new experiment. The school as remodelled, is intended for boys of the better class, and the entry test is the fifth standard of the ordinary school. The work done in the agricultural schools, formerly, was mainly theoretical. The school at Elsenburg is an admitted experiment to see if an institution, where practical instrution is given in farm work, gives better results than the former semi-theoretical and scientific schools. At Elsenburg, with this object in view, the students have now to devote their afternoons to practical farm work.

The Department of Agriculture at Cape Colony has a wine farm at Groot Constantia, employs experts and agricultural assistants, and issues an *Agricultural Journal*. This completes, I think, what the Cape furnishes in respect to agricultural education.

(To be continued.)

FRUIT CULTURE IN QUEENSLAND.

By ALBERT H. BENSON.

THE COMPOSITION AND APPLICATION OF MANURES.

(Continued from page 131.)

Sulphate of Ammonia.—A good sample should contain at least 20½ per cent. of nitrogen, and be worth in round figures £10 per ton. This manure is very soluble, and consequently acts with great rapidity. It is used either as a top dressing by itself or is mixed with varying proportions of phosphoric acid and potash to form a complete fertiliser. When used alone it should be applied at the rate of 1 to 2 cwt. to the acre during a period of the plant's active growth. It has a marked effect on the growth of cereals, grasses, corn, sorghum, &c.; but is apt to produce too much straw or stalk at the expense of the grain. It is therefore most valuable for the growth of green fodder or hay, but not so valuable for grain production. It is of great value in the production of vegetables when rapid growth and quick returns are desirable, but in this case it is better to use it in conjunction with soluble phosphoric acid and potash in order to produce the best results. Used by itself, it is very apt to impoverish the land, as it stimulates such a vigorous growth that the plants are apt to exhaust the soil of other available plant foods. Its use, therefore, requires judgment, followed by judicious cropping, cultivation, and the application of farm manure or a complete fertiliser.

In the case of fruit trees that have been neglected and run down, a severe pruning, followed by a good dressing of sulphate of ammonia—say, 2 to 4 lb. to the tree, according to its size—will often produce a vigorous growth provided that the roots are healthy, but care must be taken, once this growth has been forced, that the trees have sufficiency of plant food given them in the form of farm manure or a complete fertiliser to sustain and continue such growth.

Nitrate of Soda.—Is similar in its action to sulphate of ammonia, but at its present price, as compared with other sources of nitrogen, it is too dear to use. It contains a little over 15 per cent. of nitrogen, worth about £7 5s. per ton, and its cost is about £15 per ton.

Sulphate of Potash.—This fertiliser is seldom used alone—in fact, its use is only to be recommended when combined with nitrogenous and phosphatic fertilisers. A good sample should contain at least 50 per cent. of potash, and is worth 5s. 4d. per unit, or about £13 to 10s. per ton. It is probably the best form of potash to use, as the general opinion is that the best results are obtained from its use.

Muriate of Potash.—Similar in its action to sulphate of potash, and used in place of the latter. A good sample contains about 60 per cent. of potash, and is worth about £15 per ton, as the potash is considered to be less readily available, and consequently of slightly less value, when in the form of muriate than in the form of sulphate.

Kainit.—A mixture of muriate of potash, muriate of soda (common salt), and muriate of magnesia. Its value is due to the potash it contains, which in a good sample amounts to 13 per cent., worth £3 9s. per ton, whereas the price charged is not less than £4 per ton. Kainit is therefore a dear form of potash as compared with the sulphate or muriate, as not only does the potash cost more per unit but the proportion is so small that a much larger amount —from four to five times is required to produce the same result. This adds considerably to the freight and handling, and consequently renders this form of potash expensive to use.

There is one other form of potash now on the market known as "Australian potash," which contains 25 per cent. of potash and 4½ per cent. of insoluble phosphoric acid, which is worth about £7 per ton when estimated at its unit values. Its price is £6 per ton in Sydney, at which rate it is the cheapest from of potash on the market.

There are two other classes of commercial fertilisers —of which the first is superphosphate, and the other a complete or mixed fertiliser.

Superphosphate.—The manufacture and value of super or soluble phosphate was referred to in the previous part of this article, so I will only need to give its unit value, which is 5s. 4d. per unit for water soluble phosphoric acid, 4s. 6d. for citrate soluble phosphoric acid, and 2s. for insoluble. A good superphosphate contains about 17 per cent. of soluble phosphoric acid.

Complete or Mixed Fertilisers.—There are a number of manures of this type on the market, the composition and value of which are very variable, as they are made with a view of meeting the requirements of various soils and crops, both farm, garden, and orchard.

The bulk of these manures consist of a mixture of phosphatic, nitrogenous, and potash manures. The phosphatic portion is present either in the soluble or superphosphate condition or else in that of the insoluble or bone phosphate condition.

The nitrogen is present either in the form of sulphate of ammonia, or in that of blood, nipho, or other form of organic nitrogen—usually the former; and the potash is almost always present in the form of sulphate of potash. The so-called Colonial Sugar Company's manures are good examples of this type, and their composition can be relied upon, but there are others on the market equally as good.

In dealing with the question of complete or mixed fertilisers, I wish it to be clearly understood that the suggested composition of and quantity to be applied to any particular crop is not to be taken as absolutely binding on all classes of soils and under

all sorts of conditions of cropping and cultivation, but to refer to land of medium quality, well worked, in good condition, and preferably under a systematic rotation of crops. In the matter of manuring it is impossible to lay down any hard-and-fast rules, as, though we know that a certain crop will take so many pounds of nitrogen, phosphoric acid, and potash out of the soil, the mere fact of our adding this quantity of plant food to the soil will not be sufficient to secure such crop. The state of the land, heat, moisture, and many other factors have to be taken into consideration; but, at the same time, the knowledge of the essential plant foods required by individual crops, and the practical application of this knowledge, combined with sound common sense and judgment, will be found to be of great value. In the case of the application of commercial fertilisers, the agriculturist will learn as much, if not more, by careful observation of the habits of growth of various plants, and of the action of the various manures on same in his particular soil, and under the particular conditions of climate in which he is working, than he will from all the chemist can tell him of the analysis of his soil or of the plant foods extracted from it by various crops. The best results are obtained by a judicious combination of both the scientific knowledge of the chemist and the partical observation and knowledge of the agriculturist.

Composition of Mixed Fertilisers.—In estimating the value of commercial fertilisers I have taken the standard adopted by the New South Wales Department of Agriculture, viz:—

5s. 4d. per unit for water soluble phosphoric acid.
4s. 6d. per unit for citrate soluble phosphoric acid.
2s. per unit for insoluble phosphoric acid.
5s. 4d. per unit for potash.
10s. per unit for nitrogen in blood, nipho, offal, &c.
9s. 6d. per unit for sulphate of ammonia.

In the different mixtures recommended the individual fertilisers are assumed to be of the following composition, a high standard having been chosen:—

Sulphate of ammonia, containing 20½ per cent. of nitrogen, worth £10 per ton.

Nipho, containigg 12 per cent. of nitrogen, worth £6 per ton.

Dried blood, containiug 12½ per cent. of nitrogen, worth £6 5s. per ton.

Superphosphate, containing 17 per cent. of water soluble phosphoric acid, worth £4 5s. per ton.

Bone phosphate, containing 27½ per cent. of insoluble phosphoric acid, worth £2 15s. per ton.

Meatworks manure, containing 6½ per cent. of nitrogen and 14 per cent. of insoluble phosphoric acid, worth £4 13s. per ton.

Sulphate of potash, containing 50 per cent. of potash, worth £13 10s. per ton.

Buyers should always insist on knowing the analysis of any fertiliser that they purchase, and not only that, but they should insist on the seller giving them a guarantee that the fertiliser as sold is up to such analysis. Given this, it is an easy matter to compare the value of any particular fertiliser with those given above.

FOR CITRUS TREES.

Citrus fruits remove a considerable amount of plant food from the soil, as will be seen by referring to the table at the end. They require large quantities of nitrogen and potash, but only a comparatively small proportion of phosphoric acid. It is not advisable to give the trees too soluble a manure, or to apply it in too large quantities, but the fertilisers should contain plant food in both a soluble and slowly available form. The following proportions will be found to suit many orchards:—

	Cwt.
Meatworks manure, blood, and bones ..	10
Superphosphate	4
Sulphate of potash	4
Sulphate of ammonia	2
	20

This fertiliser will contain about 5¼ per cent. of nitrogen, 10 per cent. of potash, 10⅔ per cent. of phosphoric acid, of which 3⅔ per cent. is water soluble, and be worth £7 per ton. Manuring is seldom required in young citrus orchards in this colony, provided they are planted in suitable soil; but if the land is poor, then from 4 to 6 lb. per trees up to five years of age, applied in two lots, will be sufficient, but for trees in bearing the amount should range from 10 to 20 lb. per tree according to size, applied in two lots. In making the above manure, blood or nipho may be substituted for the sulphate of ammonia, but it will be apt to render the fruit more acid and somewhat thicken the skin. The best way to apply this manure is to broadcast it round the tree and to either chip, harrow, or cultivate it in; spread the manure round the feeding roots of the trees, not right round the stem. Apply in July or August, and again in January. Experience may prove that in the case of rich scrub soil of volcanic or some soils of granitic origin it is not necessary to use so much potash, in which case it may be reduced, and the nitrogen and phosphoric acid increased.

In the case of sandy soils it may also be advisable to increase the proportion of potash, but this can only be determined by the orchardist carefully noting the result of the manuring.—*Queensland Agricultural Journal*.

(To be concluded).

PLANTING IN TOBAGO.

As is well known, Cacao is just now one of the most promising and useful crops that could be grown in Tobago. It will not grow everywhere. But there can be no doubt that there are some localities in the island that suit Cacao very well. What the cultivator must do is to carefully bear in mind what the Cacao tree requires and give it the best conditions for its growth and for producing good crops. In the following pages an attempt is made to give in simple language hints in regard to choosing and planting the land, caring for the trees, gathering the crop and preparing the Cacao ready for market. It is believed that if the directions here given are fully carried out the cultivators, both large and small, will have good returns from their labour. It must, however, be remembered "Where there is little labour, there is little gain."

PLANTING.—When planting cacao the following ten points should be observed:—

1. Choose porous land, not too dry, well sheltered from the wind and, if possible, facing west.
2. Leave all bushes on the ridges for 70 feet each side.
3. Clear the land well, burning all the wood and bush, on the surface, but not in heaps.
4. Mark out the ground in parallel rows, 12 to 15 feet apart, and, at the same distance apart, place along these rows, stakes so arranged that those of one row alternate with those of the next.
5. Turn up the soil, to a depth of one foot, for three feet around each stake.
6. Plant permanent shade trees in each third hole of each third row.
7. Plant the cacao during the moist weather of June or July.
8. Plant bananas halfway between each pair of cacao trees, and tannias between the bananas.
9. Mulch around the trees, but do not disturb the roots by forking. Scratch the surface lightly with hoe or rake previous to laying on the mulching.
10. Always keep the ground clean and free from weeds.

1. Choose porous land, not too dry, well sheltered from the wind and if possible facing west.

Suitable land will generally be found on the lower and more gentle slopes of ridges, where the soil is usually loose, open, sufficiently deep and well drained. On the steeper slopes of the ridges the soil is generally

thin and poor, and accordingly useless, whilst the level lands at the bottom of larger valleys will be found very rich and capable of growing excellent cacao if properly drained. Any aspect will do, provided the land is completely sheltered from the prevailing easterly winds by belts of timber or by higher ridges. Land which is not thus protected is utterly unfitted for cacao cultivation.

2. Leave all bushes on the ridges for 70 feet each side.

As the ridge-tops are as a rule useless for the growth of cacao, it is better to leave the natural forest upon them, for the following reasons:—

(1.) These belts of timber will proctect the cacao on the lower ground from the wind.

(2.) They will assist to preserve the necessary humidity.

(3.) They will annually shed large quantities of leaves upon the lower lands, which are useful as manure or mulching for the cacao.

(4.) During heavy rains, they will prevent the water from running off the hill sides in streams sufficiently large to wash away the best soil from the cacao lands below.

3. Clear the land well, burning all the wood and bush, on the surface, but not in heaps.

Such portions of the land as are intended for cacao should be cleared of all vegetation. Some cultivators leave portions of the original forest standing for shade purposes, and meet with a good measure of success. As a general rule, however, it is better to clear the whole surface, for the following reasons:—

(1.) The trees left standing upon the ground will very rarely be in proper lines, and therefore cannot shade so perfectly as when regularly planted.

(2.) Such trees, having grown amongst a number of other high trees, will be tall and weak and therefore easily blown down.

(3.) Trees left in this way will prevent the cacao being planted symmetrically, which is of great importance to its well-being.

(4.) Many of the forest trees are totally unsuitable for shade. Only the pod-bearing or leguminous kinds should in any case be left. Others will take from the cacao the nourishment it should obtain from the soil, and starve it to death for want of food and moisture.

If the planter can afford it, it is better that the whole surface of the ground should be thoroughly well turned over and exposed to the atmosphere, in order that the soil may be sweetened. The land so cultivated can be brought into use for growth of food supplies.

Burning the timber in heaps is a bad method, because by so doing, owing to the fierceness of the fire, the wood is reduced to ashes instead of remaining in the more useful form of charcoal.

4. Mark out the ground in parallel rows 12 to 15 feet apart, and at the same distance apart place, along these rows, stakes so arranged that those of one row alternate with those of the next.

If the lands is rich, 15 feet is a good distance, if poor, 12 feet would be more suitable.

Make the rows perfectly straight, and parallel with the boundary lines; the plants should be put at equal distances from each other *in every direction.* Trees planted too close together will choke each other, whilst, on the other hand, if planted too far apart, they will fail to give the requisite support and shade to one another. Again, when the trees are planted in regular rows, it is easier to walk through the field and give attention to the plants without missing any.

5. Turn up the soil, to the depth of one foot, for three feet around each stake.

This is best done with the pick-axe some months before planting. Let the earth be thoroughly turned upside down, and afterwards mixed with good surface soil, leaf mould, or well rotted manure, if available.

6. Plant permanent shade trees in each third hole, of each third row.

There are several kinds of shade which may be used, but probably the most effectual and useful are the two "Immortelles" and the "Saman." The "Immortelles," is almost exclusively used in Trinidad. The great object of the permanent shade trees is to temper the heat of the sun, by keeping its rays off the cacao during part of the day. If shade trees are planted at every third hole when 12 feet apart, they should also be put at every third hole when 15 feet is the distance adopted, as the quality of the land will regulate the growth of the shade trees, as well as of the cacao.

Shade trees should never be planted too closely, as cacao must have sufficient light, or it cannot bear good crops. If a shade tree is too close to one cacao tree, it must be too far away from others, and the latter will accordingly suffer from having too little shade.

A common objection to the plan of using a cacao hole for the shade tree is, that one cacao tree out of every nine is lost. This is perfectly true, but if a cacao planter is unwilling to make this sacrifice, he will undoubtedly lose more than one-ninth of his crop, for the nine improperly shaded trees will yield less than the eight well shaded ones.

7. Plant cacao during the moist weather of June or July.

There are two ways of planting. You can plant cacao seeds on the spot where the tree is to permanently remain, this is called "planting at stake;" or you can plant the seeds in bamboo joints or in seed beds, in nurseries, and afterwards transplant to the permanent position. The latter operation should be very carefully performed, the greatest care being taken not to place the plants too deep in the ground, as more deaths of young plants arise from this cause than from any other. The seed when planted should be placed at a depth equal to its own thickness, below the surface.

During the moist weather which usually occurs in June and July is a good season for planting, because at this time the rains usually commence to fall regularly and generally last to the end of the year. Plants can better endure the dry season which usually extends from February to April or May, if planted at the time indicated. Planting at stake causes an increased expenditure on supervision, as a larger area of ground has to be regularly attended to than is the case when the plants are raised in nurseries. The seed sown should be selected from trees in good health and which are known to bear regular crops of first class cacao. All other seed is comparatively worthless.

8. Plant bananas at 6 to 7½ feet from every cacao tree (see section 4) and tannias between the bananas.

This means that half way between every two cacao trees there is to be a banana, and half way between every banana and cacao tree, there is to be a tannia.

These plants will afford the necessary shade and protection to the young cacao, and the value of the crop will repay a large portion of the cost of growing the cacao trees. Should there be no means of getting ground provisions to market, the produce may be used for feeding pigs.

As soon as the permanent shade is sufficiently grown all the small shade should be removed and the plantation cleaned throughout. In no case should further mixed cultivation be continued.—*Imperial Department of Agriculture of the West Indies.*

(To be concluded)

THE PLANT DOCTOR.—The Royal Horticultural Society seems rolling in wealth, or very anxious to spend what it has—a correspondent says he knows an opening, viz., to provide the sinews for war to some plant-disease man, and send him to see on the spot what disease really looks like. The postal box is apt to mislead. We certainly think the time has arrived when the Royal Horticultural Society, or someone, should give an adequate salary to a competent plant doctor whose whole time should be devoted to the work. We are only editors, and have no time for the necessary researeh and cultivation, but we are swamped with enquiries and specimens.—*Gardeners' Chronicle.*

MR. O'CONOR ON INDIAN TEA: PLANTERS AND THE CURRENCY.

The Director-General of Statistics for the Indian Government is Mr. J. E. O'Conor, C.I.E., and he follows up the Customs tables for the year 1899-1900, with a fairly elaborate Report. We quote the portions referring to our staple, which are of general interest to our planting and mercantile community. It will be observed that Mr. O'Conor attributes the falling-off in the importation of (China and Ceylon) tea into India, to the disappearance of the re-export trade through Persia, and that this is due to the great efforts of Russia to place its overland trade with Eastern Asia, that is China, on a sound footing. For the moment this overland trade has undoubtedly met with a check, the full effects of which have not yet been realised. Turning to the Exports of Tea, Mr. O'Conor, as a loyal supporter of the Government and its Currency policy, has a strong deliverance against the critics, including Mr. R. H. Elliot, but more especially directed against grumblers among the tea planters themselves, It will be well for Ceylon tea-planters, who still harp on the currency, to note what is said and how effectively the case of Brazil is dragged in as an illustration of evils avoided. Be this example apposite or not, we have long been clear that the higher rupee stopped the rapid extension of tea planting, and so put a check on the (at present) one great and universally-admitted drawback to prosperity in tea, namely *overproduction*. Do not the Ceylon planters, therefore, owe this much to the Indian Currency authorities as something to balance the other side of the account? We are pleased to see how well the average for the Calcutta Tea Sales has kept up for the past five years and that the direct export of Indian tea, to Australasia, United States and Canada, is increasing. Mr. O'Conor's remarks are as follows :—

The importations of *Tea* have, as was anticipated, again fallen away. As late as 1896-97 the importations amounted to as much as 7,875,000 lb.; in the following year, concurrently with Russian measures taken in view to the fostering of direct trade between Eastern Asia and Russia, the transit trade through Persia into Turkistan was placed under serious disabilities, and the imports of tea fell to 3,515,000 lb. In 1898-99 there was a very small recovery to 3,659,000 lb., but last year there was again a decline to 3,203,000 lb., a quantity considerably less than half the trade which existed until the new arrangements came into operation. The importations of China tea are less than a third of what they were four years ago, but besides this decline in China tea must be noted a great reduction in Ceylon tea to about half the imports of the preceding year. That is not to be regretted, so far as Ceylon tea was consumed in India, but with the reduction of the imports of Ceylon tea into India there has happened an increase in the direct imports of that tea into Russia, the arrangements referred to favouring the trade in that tea, as was observed in reviewing the trade in tea in 1898-99.

EXPORTS :—*Tea*.—The very large quantity of 175 million pounds was shipped, an increase of 17½ million pounds, being at the rate of 11 per cent, on the shipments of 1898-99. In the seven years since the closure of the mints the exports have increased by as much as 39 per cent: and although prices have not been able to maintain all along what owners of tea estates would regard as a satisfactory level in the face of the constantly increasing quantities shipped from India and Ceylon to what is, after all, a limited market—yet the industry has happily not been overtaken by the ruin and desolation which were so freely prophesied to be the consequence of placing the Indian currency system on a sound basis. Nor, happily, are there any indications that the industry is not likely to be even more solidly prosperous in the future than in the past. What a vicious currency system did in Brazil for coffee the unsound currency system of India was doing for tea. The temporary stimulus given by depreciated paper or depreciated silver led to rapid extensions of cultivation; the increasing supply led to a fall in prices; the fall in prices led to a demand for further depreciation in the currency, in order that the speculative planter might find from the taxpayers the profit which he could no longer find from consumers in an over-supplied market. In Brazil this vicious circle is still being travelled, and the issue can only be either the ruin of the planters, who are aghast at any suggestion for currency reform, or the complete and hopeless insolvency of the country. In India this road has been closed, and the capitalist will now place his money in tea with exclusive reference to the conditions of cultivation and consumption and without an eye to a depreciating currency. It is by no means improbable that in the result the near future may see a gradual restoration of the price-level, already initiated during the past year, to a level which will satisfy the producers and not restrict consumption.

PRICES IN CALCUTTA (annas and pie per pound.)

[We omit "Pekoe Fannings" and "Broken Souchong."—ED. *T.A.*]

	Orange (& broken Orange) Pekoe.	Broken Pekoe.	Pekoe	Pekoe Souchong.	Average.
1895-96 .	11 1¼	9	7 3 4-7	5 11	8 9
1896-97 .	9 11⅝	8 7¾	6 9 9-10	5 5½	8 8
1897-98 .	8 9⅜	7 5 5-7	6 0¾	4 10⅜	8 5
1898-99 .	8 1 2-5	7	5 8	4 7	8 1
1899-1900.	7 9 1-10	6 9¾	5 8¾	5 0⅜	8 4

The exports of Indian tea to the United Kingdom amounted to 154,161,492 lb., being nine-tenths of the whole quantity exported. Some portion of the tea shipped to London is of course re-exported to other countries, but it is satisfactory to note an increase in direct shipments from India to markets outside the United Kingdom, especially to Australia, Canada, and the United States.

CHEETAHS ON THE PROWL.

A very handsome specimen, of the tiger tribe, was shot just below the Hakgalla Gardens, by a well-known native huntsman. The animal had been seen prowling about the previous day, and had taken away a dog belonging to him said to be of value, so watch was kept in the neighbourhood of the animal's haunts, when in broad daylight the brute pounced upon a dog which happened to be passing a low tree overhanging a stream, when the huntsman fired, mortally wounding the cheetah, but not before his would-be quarry was slightly mauled. The carcase was brought to Nuwara Eliya where it found ready sale, Mr. Laidlaw, Agent of the National Bank, being the purchaser. The following were the dimensions ;—Length 7 ft., height 3 ft.—*Cor.*

IMPRESSIONS OF SOUTHERN INDIA.

[BY A CEYLON PLANTER.]

IRRIGATION

and ploughing are allied agricultural operations, and the Indian is as systematic in the one as in the other. With the exception of cotton, which, (as far as I could observe in a passing train) is not irrigated, every other product, even the young coconut plantation, (!) is regularly irrigated. Irrigation does not mean the free and easy letting out of water stored in tanks. No, it means the laborious and toilsome well-irrigation which is practised by the allied race of Tamils in the North of Ceylon. Agriculturists, who have given the subject of irrigation some thought and study, assert that well-irrigation is more beneficial than tank-irrigation, as the water of the former contain salts and other soluble manurial ingredients not to be found in the latter. However, the

PATIENT INDUSTRY OF THE TAMIL

was a cheering sight to one accustomed to the sloth and apathy of the Sinhalese generally. My condemnation of the Sinhalese is not sweeping. Nothing can excel the systematic toil and industry involved in tobacco cultivation (borrowed from the Tamil, I suppose) nor the attention he pays to his rice fields in the interval between ploughing and reaping. But at the best his agricultural indnstry is spasmodic, not continuous. Perhaps the fairness of his wants and the ease with which they can be met, have induced his proverbial apathy. In regard to irrigation, I noticed

TWO SYSTEMS OF RAISING WATER.

One by bullock power and other by means of the sweep or lift so familiar to the residents of old Colombo, who indulged in the luxury of baths in public bathing places. The former is a very interesting process. One side of a well is built up about three feet high. In this is fixed a beam with two curved uprights bending into the well. These support a grooved wheel in which runs the rope used in raising the water. From the top of the wall of the well a sloped embankment runs for a short distance into a scooped hollow in the ground. A large cow-hide stitched up, is used as a bucket. One end of the rope is fixed to it and the other to the yoke of a pair of oxen. These stand on the top of the slope with their back to the well and the bucket is filled. They are driven at a trot to the bottom of the slope and the bucket reaches the surface and is emptied into a trough by drawing in a piece of rope attached to the bottom of of the bucket. By pulling the reins, the bullocks are backed to the top of the slope, and the process of filling the bucket and emptying it is repeated with machine-like regularity. In the Western and other parts of Ceylon, except the North, the "lift" is worked by a single man, who dips the bucket into the well and draws it out with comparative ease, owing to the weight attached to the other end of the "lift." In India the lift is notched by having steps or indentations cut into it. On it are five or six men with long balancing poles, who move up and down it to fill the bucket and draw it up. A big cauldron takes the place of a bucket.

The freshness and the dark green of all cultivated products were a refreshing sight and in contrast with the aridity around. Water is led into the cultivated patches by means of drains. Plantain gardens, and as I said before, coconut gardens, are also watered by drains running between the rows.

PLANTAIN GARDENS

are so different to what one sees here. They are carefully tended. All the withered branches are cut and used to mulch the ground. The leaves are all dark green.

What a pity it is that no one seems interested in teaching the Indian ryot how to grow

COCONUTS.

The plants are put down six, eight or ten feet apart. From the railway one could see large trees in the villages and some only of these seemed to be bearing well. The nuts for sale at the railway stations were little larger in size than the Maldive coconut. On the lower portion of the line,

COTTON

is met with. The shrubs are two or three feet high. The great cotton district is, of course, Tinnevelly. The branch line to it diverts from the main-line at a place called Manniachi, two stations out of Tuticorin. Along the main line the centre of a cotton district is Niridunpatti, there can be seen large, stone-built cotton mills and the manager's residence on the top of an adjoining barren hill—by the way all the hills met with in the neighbourhood of the railway seemed to be barren.

The Indian ryot has not much to learn in the way of agriculture. His dry ploughing, involving as it does the thorough aëration and pulverising of the soil, the thoroughness of the operation as is seen by every bit of his land, being broken up and his systematic irrigation do not leave much to be desired. His methods are somewhat primitive and crude, but their results are satisfactory.

It will be remembered that some years ago, after the great famine, there was an attempt made at a revival of agriculture. It was argued that one of the causes of famine was defective methods of agriculture. Amateur Agriculturists condemned the Indian system as radically bad. Professor Voelcker was commissoned to study the system on the spot and to suggest improvements. He studied it and the result was that the Agent had

VERY LITTLE TO BE TAUGHT.

His conclusions were that his methods were not in agreement with those in European countries, but the conditions of both were dissimilar. His system was the result of the traditional experience of many generations and should not be lightly or hastily disturbed. Like the Prophet of old he was sent to curse, but he blessed instead. On the railway journey till Madura is reached, I did not notice any rice fields ; all was high and dry land cultivation.

THE RICE-FIELDS

are very like our own, with ridges and water. Of course, as is well-known, the Indian system of paddy cultivation is different for our sloven and wasteful system of broad-cast sowing. They sow in seed-beds and perform the laborious work of transplanting. Three-fourths of seed paddy is saved by this, a very large item in the aggregate. The benefits accruing from the mode involved in transplanting and from more room for the plants,

are the development of each individual plant into a bush and a larger yield. Weeding, too, is general.

A great deal of time was recently taken up over the deliberation of a Commission appointed to elaborate a scheme for the formation of

INDIA-RUBBER: EXTENDED CULTIVATION AND REPORTED SUBSTITUTE.

Below will be found some curious information in reference to the extended planting of rubber. Costa Rica is pronounced the best country in the world for this culture, and an estimate is furnished for an estate which is truly American in its grandeur, though it also reminds us of certain Ceylon "cinchona" estimates in the early "eighties." In short the estimate before us makes out the annual profit after seven years on 10,000 acres planted with rubber, to be 375,000 dollars, say £75,000 or £7 10s an acre. This is not too much per acre, but the risks over 10,000 acres would be considerable.—"The India-rubber World" to hand of July 1st, contains a great deal about substitutes for rubber. First, our old friend, the Rhea or Ramie plant, is to be exploited and we read:—

Patents cover the Cordner method of manufacturing artificial rubber from the Rhea fibre. The capitalization of $10,000,000 has all been underwritten for a Syndicate taking it up and no portion of it will be sold to the public for a number of months. Under the process controlled by the syndicate, a substance is produced which has the appearance, odor, and utility of crude rubber, and it is claimed that it can be manufactured at a fraction of the cost per pound of Para unwashed. The products will be manufactured in New Jersey. It costs, manufactured, as near as they can figure, 13 or 14 cents per pound, and as soon as possible they intend to discover exactly how much it is worth in all kinds of manufactured rubber goods. They do not expect it to take the place of Para rubber in elastic bands, for instance, but in many other lines where waterproof qualities, ductility, and a certain amount of resiliency are required, they believe that it will be found of great value. It is reported that Mr. Fred. Lamprough, who came over to America with Mr. W J Cordner in order to demonstrate the usefulness of the gum to the American purchasers, received a handsome fee for his services. Mr. Lamprough will be remembered as the inventor of a substitute for India rubber and Gutta percha known as "Volenite."

But this is not all. The next substitute is "Velvril" of which we are told:—

The basis of "velvril" is a drying or semi drying oil, which is nitrated by strong nitric acid. A nitro compound is formed, containing from 4 to 5 per cent of nitrogen, and this is thoroughly purified until all traces of free nitric acid are removed. In practice the oils used are linseed oil, and castor oil, but Mr. Reid states that, owing to the unstable nature of linseed oil, castor oil is preferred. The other ingredient used is nitro cellulose of a very low degree of nitration. Articles made of "velvril" materials may be placed in boiling water without losing their shape, although with the higher temperature they become somewhat more supple. By great pressure and heat combined, however, these materials can be molded into any desired shape. Mr. Reid exhibited specimens of machine belting, made of "velvril" material, such as had been running for more than two years under trying conditions, but without showing appreciable signs of wear. The fabric which forms the basis is a cotton canvas of special make. This is saturated and coated with a solution of "velvril" material, and is then folded over to the required thickness and cemented together by means of specially constructed machinery. Such belting is stated to have very great strength, is waterproof, and unaffected by oil or climatic changes. It has been found specially suitable for hot climates. The prepared canvas from which the belting is made can be used for a variety of other purposes. Trunks and portmanteaus made of it do not, like leather become moldy in a damp climate. Ground sheets of "velvril have been made for the British soldiers in camp in South Africa. It has also been used for horse covers, and, in a different mixture, for printers' blankets.

Finally there is an alleged Mexican substitute:—

"A rubber factory is in course of construction in this city for the extensive preparation of rubber from a Mexican weed by a newly discovered process. The plant is valued at $100,000 and is owned by a stock company, the principal stockholders of which are the Messrs. Soberon."

"Twentieth Century Gum" is the name given to this last new material; but the success of it as of the other substitutes has not yet been fully tested: and planters of rubber trees in Ceylon and elsewhere may take comfort in the fact that there is nothing equal to the real article.

CRUDE RUBBER AND PLANTING INTERESTS.

AN EXPERIMENT IN COSTA RICA.

The Indiana Rubber Co. (Goshen, Ind.), mentioned in the last *India Rubber World* as having been incorporated under Nevada laws, with $1,000,000 capital, were organized early in this year. They own 10,000 acres of land on the east coast of Costa Rica, purchased after four years' investigation in Central America by Lester C Singer, of Goshen, Ind., who becomes the company's assistant manager. In a letter to The *India Rubber World* Mr. Singer writes:

"I was two years in Costa Rica, and decided that country to be the best for planting rubber, for the reason that there is no dry season on the Atlantic coast of Costa Rica as there is in Nicaragua and Honduras. I have planted over 300 acres of rubber in Costa Rica, and it is doing splendidly. My system of planting is to select rich, well drained soil where there is a heavy rainfall and no decided dry season. I plant the seed in a nursery and transplant in from six months to one year. I underbrush the land and thin out the timber enough to let in the light and air, and afterwards keep the plants clear of the undergrowth. I have associated myself with the Indiana Rubber Co., whose capital stock is $1,000,000. Three hundred thousand dollars of the stock of the company will be sold at par for working capital. We expect to commence active operations soon, for which I shall return to Central America." Mr. Singer's address for a time will be in care of the United States consul, San José, Costa Rica.

The company, in their prospectus, state that their estate has a water front of seven miles along a river, which affords means of ready communication with the different districts of the plantation and with the coast. "The land is as valuable as any in Costa Rica, where land similary situated is easily sold for $100 per acre. . . Sufficient planting has been done to prove that the land is well adapted to the growth of rubber trees, chocolate, and other tropical plants. Some excellent specimens of rubber trees, which were planted by a former owner, are going on the land." Mr. Singer is referred to as "a pioneer in the planting and an expert in the culture of rubber trees. He has received the commendation of officials and others who are interested in the development of the resources of Costa Rica. His plantations have gone through the experimental stage and have proven

most excellent investments." The officers of the company are: Dr. Irvin J Becknell, president; B B Brothers, vice president; L M Latta, secretary; Luther E Bartholomew, treasurer; A S Zook, attorney; Clark Bruce, manager; L C Singer, assistant manager; and Eva Peck Bruce and Orville L Simmons trustees.

The secretary of the company, in sending a copy of their prospectus to The *India Rubber World*, writes: "In view of your article on page 206 of your issue of May 1, we beg to call your attention to the statements we make, as we believe we have in every case been conservative. Should you find any statement that is at variance with your knowledge of the rubber industry we should be glad to have you call our attention to it." The prospectus embraces the following estimate of—

EXPENSE.

Planting and bringing to production and marketing 1 acre (100 trees) at the end of 7 years ..	$40
10,000 acres will cost	$400,000
10,000 acres will produce at ½ pound per tree, in seventh year ..	500,000 pounds.
At New York price of $1 per pound, would be	$500,000
Less cost of plauting, etc., as above	400,000
Profit at end of seventh year	$100,000
The production each year after the seventh year, being 100,000 pounds at $1 per pound, will be ..	$500,000
Caring and marketing at 25 cents per pound each year ..	125,000
Aunual profit	$375,000

The *India Rubber World* cannot undertake, in the present undeveloped state of the rubber planting industry, to pass upon the merits of the estimates of planting companies. It may be proper to suggest, however, that there nowhere exists, to our knowledge, data to justify any particular calculation of the cost of planting a given area in rubber and bringing the trees to the productive age. It might be more or less than $40 an acre, and accurate statements based upon experience would be welcome by the editor. Another point is that 100 trees to the acre would seem an unnecessarily small number, as this would allow them to be planted 66 feet apart each way, and closer planting is advised by most authorities. Finally; the "New York price of $1 per pound" is misleading. This is the price of fine Para rubber, but "Centrals," which grades are obtained from the *Castilloa elastica*, the rubber tree of Costa Rica, cannot be expected to bring nearly so much money. We are informed, however, that 65 cents has now been substituted for $1 in these estimates. The yield per tree is, indeed, estimated conservatively. We shall look for the results of this experiment with much interest.

RUBBER TREES IN SALVADOR.

Writing from Santa Ana, Salvador—which is near the Pacific coast and also near the eastern boundary of Guatemala—Mr. J Hill informs The *India Rubber World*: "I have *Castilloa elastica* growing on all my farms upon the Volcan here, so that I know it will grow, but it is in very small numbers, and up to now I cannot size up its age. But I know that a pound of rubber can be had from a tree, because the men get it out and use it. These trees have grown up here and there, unnoticed and uncared for, among the shade covering coffee plantations. I intend planting some 100,000 trees this year, in order to give rubber a trial. The rubber grows wild along the coast and up to our place."

RUBBER IN THE PHILIPPINES.

A correspondent of The *India Rubber World* writes from San Francisco that a friend in Manila informs him that the plant known as the *Willoughbeia firma*—the kind of rubber plant native to the Malaysian peninsula and the Sunda islands, a creeper which grows to very large dimensions—is found growing wild in marshy sections of the island of Luzon, in the Philippines.

RUBBER PLANTING IN TRINIDAD.

In the thirteenth annual report on the royal botanic gardens of Trinidad, for the year 1899, the superintendent, John H Hart, F.L.S., gives some notes of interest on the progress under cultivation of *Castilloa elastica*, *Hevea Brasiliensis*, *Kickxia Africana*, and other rubber yielding species. One Para rubber tree has a girth, three feet above ground, of 58 inches, and is 40 feet high. Experiments to date do not promise a large yield of *latex*. One-fifth of an acre has been planted in *Kickxia* (Lagos rubber), some of the specimens being now 8 feet high, and apparently thriving in the Trinidad climate "*Castilloa* promises the best of any of the rubbers, so far, for local cultivation. A tree planted in 1885 is over 40 feet in height, and 51 inches in girth at 3 feet from the ground. It yields abundant *latex*."

THE RUBBER OUTLOOK IN EAST AFRICA

Mr. Louis Sgal, of Liverpool, who is interested in more than one company engaged in the exploitation of Indiarubber in Africa, said recently to a representative of The *India Rubber World*:—"As regards the development of Africa as a rubber-producing continent *par excellence*—I mean as a field for the investment of capital in handling rubber—a satisfactory settlement of the trouble in South Africa would no doubt beneficially affect the whole of the rubber districts in the east of Africa. If England should gain possession of the Transvaal and Orange Free State, an enormous impetus would no doubt be given to capital to Africa in railway enterprises, and it may be, in such a case, that very speedy progress would be made with the Cape to Cairo railway, which at present is not far from Portuguese East Africa. As it is, the country around the Central African lakes is improving, and the native population is getting over the disastrous effects of the failure of last year's crops. It is a strange thing that in central Africa the rubber trade should be in so few hands comparatively. Two or three of the trading companies have a few steamers plying on the rivers and up to the lakes, and although possessing only a very limited capital, they have trade over an area where there should be sufficient room for twenty more companies."

The English companies operating in Africa above referred to have no connection with the Belgian companies engaged in the Congo country, but are located further east. Good profits are reported to have been made in bartering goods of English manufacture with the natives for rubber collected by them. Mr. Sgal is of the opinion that American capital might be invested profitably in a similar way.

THE MANGABEIRA AND MANICOBA RUBBERS.

In the Brazilian state of Sao Paulo in 1899 a law was passed to encourage the cultivation of mangabeira rubber (*Hancornia speciosa*), and premiums offered for the acclimatization of other good rubber species, and for better processes of extracting the *latex*. The mangabeira tree grows native in the states of Pernambuco, Bahia, Goyaz, Espirito Santo, Sao Paulo, Minaes Geraes, and Rio de Janeiro. There are many of the trees in the last three states. A recent report from the Belgian legation at Rio de Janeiro states that attempts to grow mangabeira trees from seeds have thus far failed, the planting having been done in lands exposed to the sun. Many native trees growing on plantations in Sao Paulo have failed to yield a profit to the owners, because of having been tapped surreptitiously by the natives. The government is now distributing seeds of the manicoba or Ceara rubber tree (*Manihot Glaziovii*), and large quantities have been planted, the quality of this rubber being superior to the mangabeira. Many manicoba trees have been planted, on coffee estates, but one planter reports scarcely one of a thousand young trees surviving the attacks of ants and other

insects. The government of the state of Bahia is also encouraging the growth of manicoba, distributing a pamphlet of instructions. A discouraging report is to the effect that "lately the entire cargo of Ceara [manicoba] rubber shipped in an English steamer was refused in London, under pretext that this gum was of too inferior a quality."

RUBBER EXPEDITION TO THE SOUTH SEAS.

In pursuit of its object--the greatest possible independence of Germany in regard to the importation of tropical products from foreign countries—the colonial industrial committee, at Berlin, have decided to send a "Gutta-percha and Caoutchouc Expedition" to the South-sea colonies," for the purpose of—

1. The study of the Gutta-percha and Caoutchouc culture and exploitation, in Dutch and British Indies (Sumatra, Borneo, Java, and Straits Settlements);

2. Planting and increasing the Gutta-percha yielding *Sapotaccees*, and the caoutchouc yielding *Ficus* trees and *Apocynacæ* vines of New Guinea and the South-sea isles;

3. The sending of large quantities of seeds and plant material to New Guinea, the South-sea colonies and Kamerun, to introduce a regular culture of Gutta-percha and Caoutchouc on a large scale;

4. Transporting larger quantities of Gutta-percha leaves and bark to Germany for experimentation, to produce Gutta-percha suited for manufacture.

Rudolf Schlechter, the botanist, has signified his willingness to carry out the expedition. Herr Schlechter should be especially qualified for this important undertaking, in consequence of his rich experience gained as leader of the Caoutchouc expedition to Inhambane and West Africa; he also carried out, successfully, the expedition to West Africa in behalf of the colonial industrial committee, introducing the culture of Caoutchouc plantations in Kamerun.

The cost has been estimated at 60,000 marks, 30,000 of which have been placed at the disposition of the committee, with the proviso that it obtain the remainder from interested parties.

The Caoutchouc and cable industries have every reason to willingly and materially assist the committee to carry out its plan of sending a "Gutta-percha and Caeutchouc expedition" to the South-sea islands. An authority in our industry once said: "The Caoutchouc goods manufacturers must manifest the same interest in the agricultural side of their industry as the sugar manufacturers accord the beet culture!" The truth contained in these words stands today without a doubt, and the sharper the condition of the Caoutchouc market becomes, the nearer a possible Caoutchouc famine approaches, and the more we notice on the other side how the industries of other countries are actively employed in the cultivation of Guttapercha and Caoutchouc plantations, the more energetic should we be to transform this object to a fact indeed. It is sowing seed into the future, but some day it is bound to bear abundant fruit, and repay generously the sacrifices made.—*Die Gummi-Zeitung (Dresden).*

GREEN TEA IN THE KANGRA VALLEY.

(To the Editor, *Indian Planters' Gazette.*)

Dear Sir,—It may be of interest at the present time, when attention is being called to the advisability of making green tea instead of black in some proportions, that the system of manufacture of green tea in the Kangra Valley should be made known. It is obvious that this system has its defects, but the same should be useful as a base upon which to make experiments and improvements. There are few tea districts in India where greens are still made, but as this one district produces annually nearly two million pounds of this class of tea as against about one million pounds of black tea, it may rather be classed as a green than a black tea producing district. The whole green tea crop is purchased, I believe, locally, and exported *via* Ladakh to Central Asia, or shipped to the Persian Gulf.

In order to make green tea the leaf is allowed to "run out" considerably, four or five leaves being plucked on one shoot, the consequence is that the quality of the tea would probably be too inferior to compete with China or Japan greens in European or American markets. There is no doubt that really good green tea could be made if more care were taken as to the quality of leaf used and more attention paid to cleanliness in manufacture. The *kutcha* leaf is taken immediately from the plantation, and without any withering operation is thrown into iron, horizontally placed pans which are built over brick *chulas* fed by wood fires. Each pan takes about 12 pounds of green leaf at a time and is kept from a high temperature to red heat, the leaf being stirred and turned briskly in it for one minute for dry to seven or eight for wet leaf, some skill being required to prevent it from being scorched. Two wooden forked sticks are used to toss the leaf continually in the pan, and when it is sufficiently flaccid, it is thrown out on to a table, which is placed nearly level with the pan itself, and vigorously hand-rolled while still hot. The rolled leaf is left in balls of about six inches in diameter, but these are carried off almost immediately to be broken up again and spread thinly upon bamboo mats in the sun. Here the rolled leaf remains until the juice which has exuded from it and is upon its outer surface becomes sticky, and the leaf becomes slightly darker in appearance. It is then hand-rolled a second time (these last two processes being sometimes repeated) and the rolled leaf is made up into larger balls, which are then taken to the facing pans. These pans are built in *chulas* at an angle of 30° to 45°, two generally being placed back-to-back over one *chula*. The heat of these must not be nearly so great as that of the withering pans and not sufficient to burn the hand if quickly passed over them. One of the large balls is thrown into a pan and moved about quickly for some time until it has become heated, when it is broken up and stirred from side to side with a piece of wood until the tea has become dry and has obtained a grayish gloss. Each leaf of tea produced in this way has the appearance of a little twisted ball.

The only sorting done by the growers is to take out the dust by means of a No. 18 bamboo or wire sieve, and to hand sort the flat or Bohea leaf. The remaining bulk obtains a local price of from As. 12 to Rel-1 per *butti* (4lb.), equal to As. 3 to As. 4-3 per lb., the dust and Bohea fetching about As. 4 to 5 per *butti*, equal to As. 1 to As. 1-3 per lb.

Many of the green teas manufactured in the Kangra Valley are coloured with soapstone by which they acquire a fine silky grey appearance. Teas coloured in this way seem to be in rather greater demand than the uncoloured ones. The coating of soapstone is, I believe, supposed to preserve the teas to some extent. So-called soapstone which appears to be the same as the clay slate found in the Eastern Himalayas, can be purchased in the local bazaars. It is applied to the dried tea, about 10 lb. of the latter being put into a warmed pan with four ounces of the stone and the whole stirred backwards and forwards until the required colour has been obtained,

As in the manufacture of black tea variations of the above process are found everywhere, and I do not presume to say that the one mentioned here is better than any other. In the first withering in the pans the leaf is steamed in the moisture given off from itself, and in the case of wet leaf the steam arises in clouds from the pans so that any application for a patent for the use of steam in the withering of green leaf cannot seemingly stand. The aroma given off by the steamed leaf is quite different from any obtained in the manufacture of black tea and is an extremely pleasant one.—Yours, &c.,

Holta, 24th July. G. C. DUDGEON.

CAMPHOR-TREES IN CALIFORNIA.

According to the *New York Commercial* the camphor-tree has been grown in California for many years as a shade and ornamental tree, but no effort has been made to produce camphor commercially. At the State University some years ago a small sample of camphor was made from the twigs and foliage, and was exhibited at the fairs. The trees are widely distributed over the State of California, both along the coast and in the interior, and everywhere are much admired for their thrifty growth and natural beauty. These trees are probably nearly forty years of age, sixty feet in in height, and three feet in diameter at the base.

COFFEE AND CACAO IN THE CAMEROONS.

It appears that coffee growing has practically had to be abandoned in the German colony of the Cameroons owing to the ravages of a beetle which attacked the roots of the trees, but that cacao cultivation has succeeded admirably, and most satisfactory progress has been made by the industry. At the present moment all the southern and western slopes of the mountains are studded with plantations, on which about 4,000 labourers are employed, as against 2,000 last year—3,000 of these are natives of the colony. About 150 labourers were imported from Togoland by State aid, and a hope is expressed that labourers from that colony will by degrees take the place of the Liberian labor which has had to be imported hitherto. The labour question remains an important one, more especially in view of the late troubles in the Rio del Rey district, since the increased requirements of the plantations will demand at least 6,000 labourers for the present season. The cacao plantations produced a crop of the value of about £15,600 in 1898-99, and it is expected that this will be largely increased, although the amount is already over £9,000 more than the value of the crop brought to the market in 1895 96.—*Home and Colonial Mail.*

THE PRICKLY PEAR AS FODDER.

Poverty, one has been told, makes strange bedfellows, but that the famine should drive cattle to the prickly pear for food is a new development. We read in an Indian paper that the following instructions regarding the use of prickly pear as food for cattle have been published by the Political Agent at Kathiawar for general information under the orders of the Bombay Government:—"The instructions how to prepare the leaves are as follows:—The instruments consists of a knife, a pair of tongs, and a pincer. The tongs are intended to hold the leaf and the knife to cut it, and the pincers to pluck out the thorns. after this is done, the leaf should be washed in water, to remove any stray thorns that may be sticking to the gummy matter in the leaves, and then have the leaves cut into pieces of one inch square, and sprinkle a handful of horse-gram or chenna-gram flour mixed with a little salt over the pieces, when the cattle usually will take to it without any difficulty. But in the case of such cattle which do not take to it willingly, a few pieces may put into their mouth, and the two lips be held together, till they chew the pieces and acquire a taste for them. By this means even new cattle can be accustomed to this fodder within two or three days. An ordinary woman cooly for a payment of two annas can bring prepared leaves of about 100 lbs. which can feed three or four starving cattle to keep them alive till prosperous times occur."

BRAZIL COFFEE NOTES.

The planters in various São Paulo districts are still publishing unfavourable reports of the new crop, and are advising the holding of coffee for higher prices.

A S. Paulo telegram of the 27th ultimo says, the commercial firm of Leite Ribeiro is about to be transformed into an association composed of planters for the purpose of extending the coffee propaganda in Europe.

Naturally the rise in exchange means lower currency prices for coffee, which will be unfavourable to the planter as the costs of production will not be reduced for some time to come. We may therefore expect protests against forcing up exchange before we are many weeks older.

The negotiations between the minister of foreign affairs and the ministers of France and Italy in regard to the import duty on coffee in those countries terminated on the 27th ult. The two countries concede a reduction of twenty francs and twenty liras per one hundred kilogrammes in the duties now levied in their custom houses on Brazilian coffee while Brazil engages not to impose maximum rates on their products imported into this country. The accord can be terminated only by six months notice. Though less than what she claimed, the accord is a victory for Brazil, for she secures a reduction of about thirteen per cent on the French tariff rate without the cost of a single concession.—From the *Rio News*, July 3rd.

COCONUT CULTIVATION IN S. AFRICA.

Mr. Hulley, magistrate, Umlalazi, in his district, report to the *Natal Agricultural Journal*, says:—It is surprising that no attempt has been made to cultivate the coconut palm on the Coast lands. The reason probably is that the tree is said to take very many years to come to maturity. It would be interesting to know the age of the one on the Tongaat estate, the only one I believe in the country which I think I was told, bore fruit this year for the first time. The Dutch, when Ceylon was in their possession, compelled the villagers to plant tracts of country with the palm from Colombo southwards, and since then the Sinhalese, alive to its value, have kept opening up fresh coconut land, until now there are about 600,000 acres under cultivation. It is said that only one-third of the crop, which in good years is worth £1,000,000, is exported in the shape of coir fibre, oil, nuts, &c., the rest is used as food, and for other purposes by the people.—*Natal Mercury*, July 23.

PLANTING NOTES.

PEPPER IN INDIA.—The Coorg Correspondent of the *Madras Mail* writes :—"The planting of pepper is being attended to on a larger scale than I was aware of when writing on the last occasion. Some local ryots have gone in for it largely, I hear one man having put out 50,000 cuttings this season."

PLANTING IN TOBAGO.—The Imperial Department of Agriculture for the West Indies has lampe published some hints and suggestions for planting Cacao in Tobago. According to the preface, by Dr. Morris, these notes were prepared many years ago by Mr. Edward R Smart, and were published in a Tobago journal that no longer exists. Mr. Smart, however, being still in the island, lately offered these notes for reproduction, and they have been revised by Mr. J Hart, and issued in their present form. Other notes on other plants included in this little pamphlet were prepared by Sir Robert Llewelyn, formerly administrator of Tobago at present Administrator of the Gambia, West Africa.—*Gardeners' Chronicle*,

A HINT: WHY NOT JAFFNA MANGOES TOO?—An effort is being made (says the *Daily Mail* of July 14,) to bring the Bombay mangoes to England, and, indeed, for a few hours this week a small show of this fruit made an unwonted sight in a Bond street fruiterer's window. "But they were all snapped up as soon as the Anglo-Indians got to know of it," said Mr. George Adam, who had exhibited them. He showed our representative a letter he had received from Kathiawar, India, proposing to export Bombay mangoes to London as a regular article of commerce.

A BRAZILIAN COMMITTEE OF AGRICULTURE.—In Campinas (Brazil) a municipal committee of agriculture is about to be formed, consisting of three planters, whose duties will be : To report to the Government of the State everything of interest regarding agriculture in the municipality ; to collect information for the assistance of the district inspector of agriculture, and his guidance in estimating the probable crop ; to summon, and preside at meetings of the planters of the locality, with the same object; and to indent on the Government for seeds and "slips" for transplanting, where such are required.—*Planting Opinion*, July 28.

AGRICULTURE IN WESTERN AUSTRALIA.—We have received some copies of the monthly journal of the Department of Agriculture for Western Australia from March to July of the present year, The contents are interesting, though chiefly dealing with live-stock and farming. The regulations for analyses of soils strikes us as rather peculiar :—

The Department of Agriculture is now prepared to make analyses of soils, and furnish a full report on same for the sum of £3 13s 6d for each analysis, one half of which will be paid by the Department of Agriculture. All samples to be delivered free at the offices of the Department. West Australian Chambers, St. George's Terrace, Perth accompanied by the above-named fee.

We suppose this means that the farmer must deposit £3 13s 6d with his samples of soils ; but that he will get back not only the required analyses, but also £1 16s 9d half the fee, *pour encourager les autres* !

PARA RUBBER: GOOD PRICES.—This product seems likely to be a very good paying one for proprietors, who are able to grow it on their estates, as by the last mail an advice was received of the sale of some rubber grown and prepared on Culloden estate in the district of Kalutara at 3s 7¾d per lb. Well done !

AGRICULTURAL BULLETIN OF THE MALAY PENINSULA.—The May *Bulletin of the Gardens and Forest Departments, Straits Settlements*, contains some valuable papers upon "Native Rubbers of the Malay Peninsula," "Insect Pests," "Bee-hawk Moth Caterpillars," "Para Rubber," "Kickxia africana," and "Injurious Fungi." There is also a plate illustrating certain insects.—*Gardeners' Chronicle*.

AGRICULTURAL SHOW IN WEST AFRICA.—The exhibition recently held at Daker, West Africa, is probably the first of its kind in tropical Africa. The exhibits were chiefly native articles and products. The show was held in the public park, and to encourage the natives no entrance fee was charged. The Government of the Colony are trying to introduce the cultivation of Brazilian rubber, and they supply seeds without a charge.—*Globe*, July 20.

SUPERIORITY OF ORANGES.—A well informed writer on oranges pays the following tribute to Florida oranges : "If the Californians could only furnish us with an orange that had less skin and more juice—well, then consumers of the country would have nothing more to say. How highly these virtues in the orange are appreciated is shown in the magnificent prices paid for Florida oranges—figures about double paid for the California product."—*Planters' Monthly*.

INDIAN TURPENTINE.—The production of turpentine in India is likely before long, to become an important industry. The Punjab Government have recently sanctioned the establishment of a factory for the distillation of the crude resin, the experiments conducted in the Dehra-Doon Laboratory and in Kangra having convinced the Forest Department that production on a very considerable scale is possible. In the Kangra Valley forests alone, last season, some twelve hundred maunds of resin were collected.—*Pioneer*, Aug. 4.

JAPANESE TEA AT THE EXHIBITION.—Writing of the Japanese pavilion at the Paris Exhibition, the Paris correspondent of *Truth* says:—"The only tea drunk and sold at the pavilion is from Formosa. It tastes like strong pekoe. I cannot say I like it, but the Japs. do. They drink very weak and lukewarm. There is a kind of Formosa tea that costs three francs a cup, and is only drunk in Japan on occasions of high ceremony. The tea-house at the Exhibition is subsidised by the Imperial Government and run by two gentlemanly little Japs."

BRAZILIAN COFFEE FACTORY IN LONDON.—The new factory which has recently been opened by Motta's Brazilian Coffee Company (Limited), at 178, Goswell-road, E.C., is in all respects eminently suitable for the preparation of Motta pure coffee under the best conditions (writes a representative). Machinery and other appliances of the most modern type have been installed. There is room for the coffee trade to develop, and Motta's Brazilian Coffee Company (Limited)—whose head offices are at 116, Bishopsgate-street Without E.C.—evidently intend to do all in their power to foster the demand.—*Grocers' Journal*, July 14.

Malacca Tea : What Next ?—We gather that tea is now being cultivated and made in Malacca and an expert in Singapore declares it to be "most excellent tea in flavour and quality"—capable of holding its own against Indian tea, at a dearer price.

Bamboos.—In Madras as usual a number of experiments were made with the bamboo ; in Kistna six hundrends bamboo plants were put out in the Weld reserve and they are doing well. In South Malabar several kinds of bamboos artificially introduced on the banks of the rivers in Pokote and Mulatinnanna are doing well. Arundinaira Brandisii (the giant bamboo), planted in Ayravallikava in 18797 have now some of them a girth of twenty-two inches.—*Indian Agriculturist*, Aug. 1.

Shade Trees for Plantations.—Mr Charles Gibbon gives his brother planters the result of his prolonged experience in a very sensible way in his letter elsewhere, which is well-worth careful consideration. It used to be said that no shade could be required above 4,000 feet, for there was nearly always a canopy of cloud available. But even in Dimbula, the benefits of grevilleas among tea —if not for shade, at any rate as breakwinds and for their leaves as manure—have been appreciated.

Tea Machinery.—Messrs. Thacker, Spink & Co., Calcutta, will shortly receive an entirely original work of the first importance to planters and to all concerned in the tea industry. "Tea Machinery and Tea Factories" by A. J. Wallis-Taylor, a work concerned with the machinery and mechanical appliances required upon a tea plantation, and with the buildings and material arrangements which have to be provided for dealing with the leaf as it is taken from the plant until it is ready for transport. There are over 200 illustrations, for the most part specially drawn for the book.—*Planting Opinion*, August 4.

The Highest Point at which flowering plants have been found, according to a recent paper to the London Linnean Society, was in Tibet at 19,200 feet. Nine species recorded to 19,000 feet or higher. The plants were mostly of the order compositæ, and deep-rooting perennial herbs having a rosette of leaves close to the ground with the flowers closely nestled in the centre, are characteristic of these attitudes. In the Bolivian Andes Sir Martin Conway found two species of flowering plants at 18,700 feet and thirty-nine above 14,000 feet, the latter belonging to thirty-four general and twenty-one natural orders.—*Indian Agriculturist*, Aug. 1.

The Sea Fisheries of Malabar and South Canara with seven plates (chiefly photographs of fishing villages and boats) by Edgar Thurston, of the Madras Government Museum, is a useful *brochure* of some 166 pages with statistical appendix, in which are given abundant particulars of a great variety of fish caught, contents of stomach, hauls, sale price, &c. In one table we find the exports of salt fish from Mangalore to Colombo for seven years; and in 1898-9 a maximum export was attained in 2,635,990 lb. valued at R287,817. It is certainly very strange that Ceylon fishermen cannot retain this industry and salt enough fish for local demand. But we suppose nothing now remains of the experiment set agoing by the late Mr. Ravenscroft, Auditor-General,

Chinese Tea In Russia.—As far back a June a meeting of Russian tea dealers was held at St. Petersburg, we learn from the Allahabad journal, to consider the position of the tea trade and the probable result of the disturbances in China. It was resolved that the price of tea should be gradually increased

The "Chin Bara Tea."—We are indebted to the correspondent who brings Mr. Harcourt Skrine's enterprise in respect of "Tea for Chemists" under our notice—see elsewhere. Surely his "cold process" is more or less identical with that patented by Mr Armitage, although the latter has taken no credit for producing an article of special value to chemists who retail tea.

Mocha Tea Company.—We heartily congratulate the shareholders upon the flourishing condition of this Company and trust that the working may long continue to be such as to warrant an annual dividend of 15 per cent. The whole history of this Company (notwithstanding the purchase of fresh estates !) is a wonderful illustration of what "tea" can do under favourable circumstances and good management; but then the capitalisation per acre of tea was low to begin with.

New Markets for Tea and Coffee.—Perhaps the most interesting subject and certainly one of the most impotant, discussed at the Annual Meeting of the United Planters Association of Southern India was that entitled "New Markets":—

The Hon. Mr. Acworth's remarks about tea point to an object lesson for planters of coffee as well as tea. Some critics may urge that the enhanced demand for Ceylon and Indian teas, coming together with the expenditure of huge sums on the exploiting of old and new markets, is but a coincidence. Even if so, says the *Madras Mail*, it is a curious coincidence that Ceylon, which has spent the more freely, has made the more rapid progress. We cannot overlook the possibility that a great deal of trade that was formerly done through London now takes place among the statistics of direct trade with America, Russia and other countries. But the gross total has expanded; and it is remarkable that the expansion of this direct foreign trade has been so much greater with Colombo than with Calcutta. In both markets there are buyers representing English, American and Russian firms. There are as good opportunities for buying in Calcutta as in Colombo. We cannot, therefore, be surprised if the inference be drawn that the more rapid progress of the one, as compared with the other, is mainly due to the more liberal way in which "the wheels have been greased" in the case of Ceylon. At any rate, the suggestions that are made, based upon this inference, would appear to be worth a trial. Let India try advertising and canvassing on a scale proportionate to that of Ceylon. Let her expenditure in this direction be increased for a year or two. The results would soon show whether there was a strong probability that the growth of demand turned upon the degree of "push" applied by planters, or if we must seek some other explanation of the fact that Ceylon's superior success has been coincident with Ceylon's more liberal expenditure in efforts to make her teas known and appreciated throughout the world. There is, we fear, little chance of India adopting a quasi-voluntary cess such as this which Ceylon planters have had made compulsory upon themselves. There remains, however, another course open, the course of voluntary subscriptions to such a Fund as that of the American and Foreign Market Fund of the Indian Tea Association. This appears to be the course suggested during the proceedings of the U. P. A. S. I., and the future must largely depend upon the extent to which, and the manner in which South Indian planters follow this course,

THE INDIAN TEA ASSOCIATION (LONDON).

The report of the general committee for the year 1899-1900, presented at the meeting held on Thursday, is a record of the work performed by the Association and its able secretary, Mr. E Tye, in the interests of the Indian tea industry.

Under the heading

INDIAN TEA CROP OF 1899,

the report says, "It is interesting to note the growth of the direct shipments to outside markets in view of the increased production both in India and Ceylon, and the continued efforts which must be made to absorb as large a proportion of the crop as possible by pushing consumption in foreign countries." Under "Ocean freights," the report states that owing to the dissatisfaction felt for some time past with regard to the high rates of freight charged on tea by the Steam Conference liners, repeated representations have been addressed to the Conference asking for a reduction of one half in the present rate, but with no result. A circular has, therefore, been distributed inviting shippers to terminate the existing agreement with the Conference. The committee records that it has been successful in its efforts to reduce the warehouse charges. Under this heading an account is given of the work performed by the Association, in conjunction with the Ceylon Association in London, in securing the 10 per cent reduction that was ultimately obtained, and which represents a considerable gain to the industry. It has, however, one drawback, viz., that in the case of the building and taring charges the full reduction previously conceded has not been continued. A very interesting feature of the report is the description of the enterprising efforts being made to push Indian teas on tne Continent through the medium of the Paris Exhibition. Tea samples are being displayed, and a tea room has been established under the management of Mr. E F Langdale, who was in charge of similar work at the Health Exhibition at Earl's Court; and who, it is satisfactory to note, reports that the business is steadily improving. Samples are also being distributed, and a stall has been fitted up at which teas are sold in packets.

Reference is made to the fact that on the recommendation of Dr. Voelcker, Mr. H H Mann, B.Sc., F.I.C., was appointed as

SCIENTIFIC OFFICER TO THE ASSOCIATION,

and has submitted an interesting report on a short visit he paid to Ceylon on his way out. The Labour Bill, to which special objection has been taken by all interested in tea in Assam, who consider that no good or sufficient reason has been shown for the proposed increase of wages, was considered by a special subcommittee, and their report sent to Calcutta, and embodied in the representations laid before the Indian Government. The Bill was referred to a special committee of the council, but the consideration of same was afterwards postponed to next season. The next item of interest is an account of the one pound draft dispute, which describes the compromise ultimately effected as "entirely satisfactory to no one except the Treasury." We may here mention that the report states that the question of the revision of the Public Sale Conditions has been under discussion between representatives of sellers and buyers, but that difficulty is experienced in deciding on alterations which will satisfy both parties. Strong opposition was offered by the London Chamber of Commerce to the bills to be brought before Parliament by the dock companies regarding the imposition of extra dock charges, &c, and they requested the Association to appoint a member of their committee to represent their interests. Mr. F A Roberts, on being requested, had consented to represent the Association. The Bill was thrown out on being brought before Parliament, and a Royal Commission is being appointed to consider the whole dock question. The advisability of a Dock Trust is still engaging the attention of the London Chamber of Commerce. With regard to the increased duty on tea, the report points out that although no doubt the Chancellor of the Exchequer intended that this special tax should be paid by consumers of tea in the United Kingdom, it is felt that it will fall chiefly upon producers, who were already sufficiently hampered by the increase in the exchange. It also comments upon the injustice of tea paying 6d per lb. duty, while coffee and cocoa, which directly compete with tea, only pay 1½d and 1d per lb respectively, although the average price of all three, exoluding duty, is about 8d per lb. The committee contemplate making a representation to the Chancellor of the Exchequer with a view to the more equitable adjustment of taxation on these articles, the early removal of the war tax on tea, and a further reduction of the duty, which imposes a heavy burden on the industry.

It is satisfactory to note that

THE REGULATION OF SALES

which was in operation throughout last season worked smoothly, and that the committee intend to take the matter up again this season. As the report points out, Ceylon teas are imported more or less all the year round, and therefore practically regulate themselves, whereas Indian teas are nearly all imported within eight or nine months, and even in regard to these certain months, are heavy, others light, while tho consumption varies very little all the year round. As most importers know by now, the committee have decided to offer a bonus on green tea shipped direct from India in order to encourage planters to meet the large demand existing for it in Ameriea. As a further effort to exploit foreign markets, a circular was issued in April last inviting tea growers to support a levy for the current year on a similar scale to that raised in former years, and it is hoped that an equally good response will be made as for last year. It is proposed to apply the new levy not only to the American but to Continental markets, concerning which special inquiries are being made. Useful work has been done during the past year with regard to the joint advertising of Indian and Ceylon tea in the United States, and the committee express their obligation to Mr. Maekenzie, the Ceylon Commissioner, who has superintended the business generally. The commiitee comment upon the officiousness of the Post Office in ruling against the delivery of samples closed against inspection. As everybody knows, it is absolutely essential that the samples should be sent in hermetically sealed boxes, as they have hitherto been done, and which is not objected to in India, in order that they should reach England in a fresh condition. The Postmaster-General has been appealed to in vain, and a deputation was refused, but the committee will again address the above mentioned official as it is a matter of great importanee to the industry. Finally the committee report that upwards of £2,080 has been generously subscribed in response to the appeal of the Viceroy and Governor-General of India on behalf of the inhabitants of the famine striken districts of India, and also that £400 was subscribed in conjunetion with Ceylon for the relief of the sufferers by the fire in Ottawa. Some interesting, statistics concerning the quantities and value of the tea imported for home consumption in various Continental countries, kindly supplied by the Intelligence Branch of the Commereial Department of the Board of Trade, are attached to the report.

The annual general meeting of the Association was held yesterday. A full report of the proceedings will be given in next week's issue.—*Home and Colonial Mail*, July 27.

BAMBOO GUM: A MODERN MIRACLE.

Probably no modern discovery in natural history has been more seemingly miraculous (says "Science Siftings") than the finding of an edible gum exuding from the bamboos of Central India at a time when the people are suffering from their greatest famine. This substance is pleasantly sweet, occurs in white or brown rods about an inch long, and is found by Mr. David Hooper, of the Indian Museum at Calcutta, to consist mainly of a sugar related to, if not indentical with, cane sugar.—*Globe*, July 26.

MICA AND ITS USES.

Bengal is the chief seat of mica mining in the world. Calcutta exports more mica than all the other ports of the world put together. Its brokers have handled and sold more mica than the brokers of any other city. Its scientific men have personal acquaintance with the mines and mining men. Its merchants own the mines, and from constant dealing with the material know the best markets, and the mercantile value of any sample that could be submitted to them. Yet we find the Reporter on Economic Products ignore the valuable opinion available near at home in order to obtain a report which is erroneous, misleading, and likely to do harm. Professor Windham R Dunstan says: "The mica experts report that the samples are quite worthless, their chief defect being that they are striated or cross-grained and much cracked. *This kind of mica is only adapted for electrical purposes.*" [The italics are mine.] Cracked, striated, and cross-grained mica is wholly unsuited for electrical purposes. Any electrical engineer would have told Professor Dunstan this and I cannot conceive where he could have got this wholly incorrect information. On the strength of this report, coming from the source it does, miners, new to the business, may send home cracked cross-grained, striated mica, for electrical purposes, and find they have been "sold" since such mica is utterly worthless for dynamos. For electrical purposes the mica must be in perfectly even plates, free from buckling or corrugation. It must not be perforated or cracked in any way. In another part of this report Professor Dunstan says: "They (the plates of mica) should be roughly trimmed square or oblong, no piece to have more than five sides." This is incorrect Bengal mica is seldom, or never, cut square or oblong. It is roughly sickle-dressed to any shape the plate will give, round, zigzag, or polygonal. Again: "Care should also be exercised not to pack in the same case plates of mica varying more than one inch, in either length or breadth." Mica shipped from Calcutta varies far more than this. "Specials" are packed in the same case, and there may be anything from 36 square inches to 100 square inches. Number 1 are plates from 24 square inches to 36 square inches, and all of these go in the same case. "There is practically no sale for plates for less than *2 inches in width.*" A reference to any electrical mica dealer's price-list will show that high prices are asked for 'steeps' 1½ inch wide and 6 inches long.—*Indian Agriculturist.*

PRODUCE AND PLANTING.

TRY CHILI.—According to the latest report of the British Consul-General for Chili there should be a market for the increased supply of Indian and Ceylon teas in that Republic. The consumption of tea, the Consul-General says, appears to be on the increase if one may judge from the great number of brands advertised on all sides. Most of the tea sold is of poor quality, notwithstanding that the public are charged exorbitant prices. The import duty is one dollar per kilo, or about 8d per lb. Ceylon teas of good to fine quality, he adds, are unobtainable, and there should be a good and increasing market for them if once introduced. During 1898, which was a year in which all imports were much restricted, 639 tons of tea were imported, and although the figures for 1899 are not yet wholly procurable, they show that the imports of tea have largely increased. The value of the increase amounts to £20,000. In 1898 the British Empire sent to Chili 464 tons of tea, China coming next with 120 tons.

RUBBISH ABOUT TEA.—A correspondent calls our attention to an article on tea recently published in a paper, presumably circulating in the household, in which statements are made about tea, culled from various sources, which are really funny. We do not know whether they are intended to read as fact or fiction, but there is certainly nothing humorous in the style of the writer. After dealing most seriously with tea and the tea trade generally, a warning is given against excessive tea-drinking, and then the old story about the increase of idiocy and lunacy due to tea-drinking, especially in Ireland, is trotted out. But the gem of the collection is in the simple statement that "not long ago the papers contained an account of a woman who had died, so it was supposed from the effects of excessive tea-drinking after turning a dark green colour." Whether the poor woman turned green with envy, or tea, before or after death, or whether she drank black tea or green by the cup or by the pailful, or how long since this awful thing happened, who the coroner was, and which newspapers reported it, we offer as conundrums to those interested. The idea that tea will, if indulged in too freely, change our colour at some stage of our earthly pilgrimage is distinctly embarrassing, and if such stories were freely circulated and believed they might have some effect on the consumption.—*Home and Colonial Mail*, Aug. 3.

BRITISH NORTH BORNEO.

RAILWAY PROGRESS AND DEVELOPMENT:

200,000 ACRES OF LAND AVAILABLE FOR TOBACCO.

The 35th half-yearly meeting was held yesterday at the Cannon-street Hotel. Mr. Richard B. Martin, M.P., presided. He stated:—The tobacco industry was flourishing in four districts—Kudat, Sandakan, Lahad-Datu, and Tawao. These districts produced estate tobacco—that was tobacco grown under European supervision for export to the markets of Europe; but from Province Keppel, there was a considerable trade in native tobacco. The actual length of railway under construction was about 110 miles, and the whole of the rails were on the spot. Starting from two points on the west coast—namely Weston and Jesselton—the line ran for about 20 miles in a north-easterly direction and 58 miles in a south-westerly direction, meeting at Beaufort, on the Padas River. From Beaufort it ran almost due south-east, skirting the Padas River and the Penotal Gorge till it reached Tenom, in the interior. Within two years it was hoped that the railway would have opened up the company's territory to a point from which the interior trade could be developed and the people controlled. The sections now under construction would form the key to the vast interior of North Borneo. The line would traverse and open up some of the richest country in the territory, and with the facilities which the railway would afford a great development in the general trade of the country might be expected. By laying portable rails up the many valleys between Beaufort and Tenom, numerous artificial feeders to the main line could be formed, and timber cutters would be enabled to handle large trees and transport them both expeditiously and cheaply, without breaking bulk, to the fine harbour of Gaya, where it could be shipped from the jetty which was being built there. To the east, north and south of Tenom, the interior terminus of the railway, there was a very extensive country, where all tropical and many sub-tropical products could be grown. The whole trade of the hitherto inaccessible interior would be exclusively carried by the railway. Apart altogether from the indirect benefits which the line would confer upon the Government and the country generally, there was a fair prospect in the near future of the railway becoming in itself a profitable undertaking. The sales of land not only along the route but at the different termini would undoubtedly be considerable. In his 'Forest of the Far East,' published nearly 50 years ago, Sir Spencer St. John drew attention to

Gaya Bay, which he described as a noble harbour; and it would be difficult to conceive any place in Borneo better adapted to an important trade centre. It was practically on the high way of steamers passing between Europe and all the intervening ports, and China, as well as the Philippines and Japan. It was felt that the trade which would be developed by the 110 miles of railway terminating at Jesselton could not fail to attract the passing steamers to a port which was not only easy of access, but safe for all classes of vessels. Reverting to the subject of exports, he stated that more than one-half was under the head of tobacco. The first crop of tobacco exported in 1887 was valued at only £471, whereas the crop exported in the past year was valued at £186,454. The initial difficulties of management, climate and labour had been overcome, and the cost of the production of tobacco in Borneo compared most favourably with that of Sumatra. It was estimated that the railway would open up something like 200,000 acres of land suitable for the growth of tobacco. The telegraph system was still being extended, about 350 miles were working, and another 100 miles were in course of construction. The traffic so far had not been great, but the telegraph was invaluable to the Government, and more than paid for itself as a utilitarian and economic work.—London *Times*, Aug. 1.

SUGAR CULTIVATION IN THE STRAITS.

With reference to sugar cultivation in Perak, this form of cultivation is confined to the three coast districts of Krian, Matang and Lower Perak, which I will deal with *seriatam*:

KRIAN.—The total area of land alienated for the cultivation of sugar in this district amounts to 35,359 acres. Many applications for land for sugar cultivation were received during the year, but, owing to the proclamation of irrigation areas, in connection with the irrigation scheme for fostering the cultivation of rice, little, if any, more sugar land remains available in this district. The amount of sugar (brown and white) exported during the year was 276,689 pikuls, valued at $1,282,237. There are 26 sugar estates in Krian, of which the largest is Gula, belonging to an European Company, and comprising an area of 9,512 acres, while there is a Chinese-owned estate of 4,500 acres, and there are four other estates, also owned by Chinese, comprising an approximate area of 2,000 acres each: the total area under actual cultivation is estimated at 15,779 acres. Ten of the estates have mills worked by steam-power, and the machinery at Gula is of the best and latest description: the remaining mills are worked by buffaloes, but, in two cases, cattle will shortly be replaced by steam power. The labour force employed consists of 4,121 Chinese coolies partly working on wages and partly on a system of sub-leases, and 3,597 Indians, of whom about half are indentured immigrants, and the remainder free labourers.

MATANG.—There are 12 sugar estates in the Matang District, of which the largest comprises an area of 1,854 acres. The total area of land alienated for sugar cultivation in this district amounts to 6,500 acres, and it is unlikely that this area will be largely increased, as most of the available sugar land has been included in an irrigation area, in connection with the cultivation of rice. The cultivation of sugar in the Matang district only began in 1897, and consequently little of the produce has yet been exported: the total quantity last year amounted to 2,056 pikuls. A complete factory capable of dealing with 24,000 tons of sugar-cane is being erected on an estate owned by Sir J W Ramsden, and it is probable that most of the cane produced in Matang will be sent to this factory.

LOWER PERAK.—The cultivation of sugar-cane in Lower Perak is still in its infancy, but it is probable that, within the next few years, the area of land under this form of cultivation will be larger than that of any district in Perak, as there are vast tracts of available State land still unalienated, approximately estimated by the District Magistrate at 180,000 acres, lying between the Perak and Bernam rivers, all of which is more or less suitable for sugar cultivation. An European Company, of which Sir J. W. Ramsden is the principal shareholder, and whose local representative is Mr. John Turner, General Manager of the Penang Sugar Estates Company, has recently acquired 11,000 acres of land from the Government, and has commenced operations on a large scale, the staff consisting of three Europeans, under whom about 600 labourers, Tamils and Javanese, are now employed. Very complete machinary has been ordered, and will shortly be sent out from England, and the factory erected on this estate will probably serve as a centre to which most of the smaller planters, both European and Chinese, will send their raw produce.—*Official Report*

PROPOSED BOUNTY ON GREEN TEA.

THE INDIAN TEA ASSOCIATION.

The following circular has been issued to members by the Indian Tea Association, Royal Exchange Building, dated Calcutta, 7th August 1900:—

Dear Sir,—I am directed by the General Committe of the Indian Tea Association to address you respecting the following resolution which has been unanimously adopted by the Committee of the Association in London, viz.:—

"That 1½ anna per lb. up to a maximum of 200,000 lbs. to be manufactured this season, be allowed out of the funds of the levy (American and Foreign Market Fund) on shipments of green tea for the American market and shipped there direct from India, such funds to be distributed as a bounty at the discretion of the Calcutta Committee."

The General Committee have been asked by the London Committee to make all necessary arrangements for carrying this resolution into effect. They have considered the nature of these arrangements, and have come to the following conclusions:—(*a*) That as a first step all Tea Estates in the membership of the Association, desirous of making green tea in consideration of the bounty, be asked to furnish the Committee with four ounce samples of the teas they propose to manufacture; at the same time stating the quantity they intend to make this season. (*b*) Such samples, when received by the Committee, will be submitted to one or more experts in green tea for opinion as to their suitability for the American market. (In giving their opinion the experts will have regard to standard samples of the green teas now used in America. These samples are shortly to be received from London.) (*c*) On receiving the report of the experts on all the samples submitted to them the Committee will proceed to allot the bounty on account of those teas the samples of which are declared suitable; and will make known the allotment to those interested. (*d*) When the teas manufactured by those Companies or Estates whose samples have been accepted, have arrived in Calcutta, the Committee will require to be informed of the fact; and it will be necessary for samples of the teas to be drawn in Calcutta for submission to the experts for comparison with the original samples. (*e*) On the Committee receiving a satisfactory report from the experts upon these further samples, and also proof that the teas have been shipped to

America, the bounty will be paid. (*f*) There is no objection to the teas being sold on the Calcutta market if the producer so desires; but payment of the bounty to him can only be made on proof that the tea has been shipped to America. (*g*) It must be clearly understood that all teas upon which the bounty will be paid will be for the American market only. (*h*) The Association will not undertake, or be in any way responsible for, the shipment of the teas.

In the foregoing paragraph the Committee have, they think, embodied all the arrangements it is necessary to make at present to carry out the resolution. They would, however, remark, regarding the quality of the tea required, that anything in the nature of "dust or fannings" is, it is understood, entirely unsuited to the American market. This should be borne in mind by all Garden Managers who purpose to manufacture green teas.

The Committee propose to put the resolution into practice immediately. They therefore now invite those members of the Association who are desirous of manufacturing green teas, to favour them, if possible, by the 31st inst., with samples of the teas they propose to make, and information as to the quantity. On receiving these the further action above indicated will be taken.—Yours faithfully, W. PARSONS, Secretary.
—*The Planter*, Aug. 11th.

PEARLS FROM FISH SCALES.

FRANCE.—I have had an interview with Mr. Leuret, the manufacturer of artificial pearls from fish scales. He will go to the United States and erect works there as soon as he hears of a locality where the right kind of scales can be had in large quantities. I suggest that a suitable place might be found on the St. Lawrence River, among the Thousand Islands. Some years ago, the State or national authorities cast quantities of spawn into Lake Ontario, among which was the spawn of some salt-water fish. The latter die before maturity, as soon as the water becomes warm. Every summer, many thousands of them are cast upon the shores of the river and islands. They are called by two names—menhadden and alewives. If these were tried and found suitable, works could be built and put in operation there in a short time. The scales should be small and have a silvery sheen. The brighter they are, the higher price they will command. The scales should be removed while the fish are alive, if possible. They should be packed with slime, very little salt being used (about five grams per pound of scales). All organic matter that may cause decay should be removed and the scales left suspended in a mosquito netting until the surplus slime oozes off; then packed in a zinc can of 10 or 12 pounds capacity. Tin oxidises where zinc will not. Scales will rust tin, but not zinc. The opening in the top of the can should not be larger than half a dollar. If larger, the scales will suffer from the heat of the soldering iron. Twenty-five thousand pounds of these scales can be used per year. It is anticipated that twice that quantity may be used in a few years. The price paid will be 80 cents to $1·25 per pound, according to quality and the amount of shiny matter on the scales. The present supply is from a fish called the bleak or blay. Mr. Leuret thinks that a child twelve years old can easily remove four or five pounds of scales per day.—*United States Consul at Lyons.*

CALIFORNIA ORANGE AND LEMON CROPS.

The President of the Southern California Fruit Exchange, gives figures to the *Los Angeles Herald*, from which the following interesting review of the citrus fruit is prepared:—

	Cars.
Oranges and lemons shipped to date (end of May) since October 1st ...	13,000
Oranges yet on the trees	2,000
Lemons yet on the trees	2,000
Total Season's production ...	17,000

	Boxes.
17,000 cars of 362 boxes each ...	6,154,000
Highest previous record (1898-9) ...	5,000,000
Production last season	3,500,000

Average price obtained this year about a duplicate of that of two years ago and very satisfactory. Such is the citrus fruit industry as it stands today.

PLANTING NOTES.

INDIAN TEA COMPANIES' RESULTS.—The *Financial Times* of August 3rd has been reviewing the Indian Tea Companies and we quote as follows:—

Turning to the results attained by individual companies, we find that out of forty-three whose reports have been issued, twelve have declared dividends ranging from 10 to 15 per cent, thirteen dividends ranging from 5 to 8¾ per cent, and ten dividends ranging from 2½ to 4½ per cent, while eight have failed to make a distribution. This cannot be called a bad showing, especially when it is considered that several of the companies not making a return on Ordinary capital, are in the earlier stages of development, and may be expected later on to pay fair interest, The exhibit is rendered still more satisfactory when the large sums carried forward and placed to reserve by many companies are taken into consideration. A bird's-eye view of the main results attained by the leading concerns is given in the following table, for the statistics contained in which we are indebted to Mr. George Seton, of the Indian Tea Share Exchange:—

Company.	Ratio of expenses to receipts		Dividend.		Reserve and balance forward. 1898		1899	
	1898	1899	1898	1899	Amt.	p.c. on capital.	Amt.	p.c. on capital.
	p.c.	p.c.	p.c.	p.c.	£	p. c.	£	p. c.
Assam ...	88	89	12½	10	53,907	28·8	53,524	28·6
,, Frontier ..	82	77	4	8	461	0·2	2,837	1·0
Brahmapootra ...	74	77	15	15	28,490	24·9	25,694	22·4
Chargola ..	91	78	nil	7	4,618	3·0	4,404	2·9
Chubwa ..	92	86	6	7	10,272	9·7	10,367	9·8
Darjeeling...	78	79	5	4	4,151	3·0	4,423	3·3
Dooars ..	75	78	12½	10	51,057	22·7	50,561	22·5
Doom Dooma ..	73	70	12½	13	47,772	27·0	54,496	27·0
Empire of India ..	84	85	4¼	4¼	14,646	3·4	14,560	3·5
Jhanzi ...	92	89	5	5	15,301	17·0	15,502	16·3
Jokai ...	81	82	10	8	60,639	17 3	60,789	17·4
Jorehaut ...	84	85	11	10	35,812	35·8	35,550	35·5
Lebong ...	80	77	10	8¾	7,298	11·1	7 236	11·1
Nedeem ..	77	71	2½	4	11,941	2·9	19,040	4·7

The ratio of expenses to receipts varies, of course, with the price obtained for tea, but it will be seen that in several cases the percentage has been very considerably reduced, while the increases recorded are only slight. Comparing the dividends declared by the above fourteen companies with those for 1898, we find that four companies have increased their distributions, three have maintained them at the previous level, and six have reduced them.

ROYAL BOTANIC GARDEN, PERADENIYA.—Our Supplementary illustration shows another view in the famous Ceylon garden, which in many points rivals the garden at Buitenzorg in Java. The present director, Mr. Willis, is anxious to offer as great facilities for scientific research, and the study of economic plants as are afforded in the celebrated Javanese garden. The photograph was kindly forwarded by Mr. H. F. Macmillan, the curator. A descriptive account of the garden is given in our columns June 23rd, of the present year.—*Gardeners' Chronicle*, Aug. 4.

BRAZIL AND COFFEE.—Says Messrs. I A Rucker & Bencraft in their report of (August 2nd):—"In various papers we have read articles on the financial situation in the Brazils, and amongst them, one, a column long, in the *Times*. Three impressions remain :—1.—The enormous size of the Brazilian National Debt, viz. 1,969,077,000 milreis. 2.—The unanimous opinion amongst experts that the rise in Exchange is based on genuine improvement in revenue. 3.—Cost of production, say, of 3/5ths of the World's Coffee crop, is being rapidly and materially increased. The natural deductions from the above, our friends can draw for themselves."

GROW YOUR OWN ORANGES.—A writer in the *Gardener* advises ladies who admire foliage and have an interest in growing their own plants that they cannot do better than rear an Orange plant from a pip. Such plants are comparatively easy to rear, and although the blossom will not be so fine as that of a plant grown in heat, yet the foliage is good, and can be easily kept clean. A fine, large Orange should be chosen, having good seeds Sow five or six pips in a 6-inch pot, with good drainage, filling the pot with leaf-mould and good sandy loam. Set the pot in a warm place with a piece of glass over it. The seedlings will soon appear, and when they have made a new leaf they may be potted singly into 3-inch pots. Water sufficient to keep the soil moist is enough. A wet and sodden soil will kill the plants. If a frame or case can be used, so much the better, the chief aim being to keep the plant clean and growing. In winter the Orange must be kept free from frost and rather dry at the root. Strong shoots should be pinched back to make the plant bushy. In about four years a handsome plant fit to adorn any room will result.

PEACH.—Nothing is now more universally accepted than that the peach is an improved variety of the almond. The almond has a thin shell around the stone which splits open and exposes the stone when mature. This outer skin has simply become flesh in the peach, so that is all that gives it its specific character. It seems now clear from investigation in the history of ancient Babylon, that in their gardens—now nearly four thousand years ago—the peach was cultivated as it is now. It must have been many years before this that the peach was improved upon the almond, and this fact goes to show the great antiquity of the fruit. Possibly, gardening in some respects, at least so far as it relates to many of our cultivated fruits, was as far advanced six, or perhaps eight or ten thousand years back as it is to-day. Phœnicians, as is proved by the records, had in their gardens almonds, apricots, bananas, citrons, grapes, olives, peaches, and pomegranates; and even sugarcane was in extensive cultivation. Certainly this shows how very far advanced these nations were in garden culture these many years ago.—*Journal of the Jamaica Agricultural Society.*

MOCHA TEA COMPANY, LIMITED.

The ordinary general meeting of shareholders of the Mocha Tea Company, Ltd., was held at noon today at the registered office in Prince Street, Fort. The Hon. Mr. J N Campbell presided and the others present were Messrs. F W Bois, H G Bois, and C E Haslop. Mr. F W Bois read the notice calling the meeting, and the minutes of the meeting held on the 22nd August, 1899, were read and confirmed.

ANNUAL REPORT.

The following report of the Directors was then submitted :—

Your directors have the pleasure to submit their report and accounts for the season ending 30th June 1900.

The total quantity of Tea made on the Company's Estates was 444,030 lb which cost 28 13-100 cents per pound delivered in Colombo, including 3 65-100 cts per pound for manuring, the net average price realized being 44 89-100 cents per pound, compared with 46 87-100 cents last season.

The price of the Mocha Tea was well maintained and improved, whilst that for Glentilt, Lanka and Craighill receded owing to a largely increased yield.

The nett profit for the year (after providing R2,000 bonus to Managers, and R812·26 cost of Extension) is R81,443·82, which is equal to fully 20 per cent on the capital of the company.

From this a sum of R10,000 has been written off to Depreciation Fund and an interim dividend of 5 per cent has been paid, and it is proposed to deal with the balance amounting to R51,243·82 as follows :—

To Reserve Fund	..	R10,000
To pay a final Dividend of 10 per cent (making 15 per cent for season)	...	R40,400
To carry forward	...	R843·82

The Company's properties now consist of :—

1,046	Acres	Tea in bearing
33	do	Tea 3 years old
52	do	Grassland
92	do	Forest and fuel trees
43	do	Buildings, Rivers, Roads, etc.
1,266	Acres.	

The estimated crops for season 1900-1901 amount to 438,000 lb to cost R121,156·50 in Colombo, from which must be deducted the receipts from Glentilt Bazaars.

Mr. Giles F. Walker retires in accordance with the Articles of Association, but being eligible offers himself for re-election.

The meeting will have to elect an Auditor for season 1900-1901.

The CHAIRMAN, in moving the adoption of the report, stated that the Directors suggested a final dividend of 10 per cent, in addition to the interim dividend of five per cent, making a total of 15 per cent for the season. The Directors had further proposed to write off R10,000 to Depreciation and R10,000 to be placed to the Reserve Fund. He said he wished to call attention to certain figures which had been prepared showing the state of the company during the period of its existence —eight years. It was formed in 1892 and up to now it had paid dividends amounting to 124 per cent. That was 24 per cent over the capital. During the period of eight years, R64,000 had been placed to the reserve fund, including what was proposed to be placed to that fund now. During the same period R67,888·46 had been written off for depreciation. Including these amounts, the profits had amounted to 156½ per cent. The average annual dividend declared and paid to shareholders was 15½ per cent. Almost twelve per cent of the earnings had been written off for

depreciation, and 20 per cent had been placed to the reserve fund. The last season compared very favorably with the previous season's. The cost of the tea of

MOCHA ESTATE

was 28·55 cts. per lb, with manure, excluding manure 24·27 cts, as against 24·35 and 27·38 cts. per lb respectively for the previous year. The average sale per lb was 51·31 cts. as against 47·38 cts. the previous year. The profit per pound was 22·66 cts. as against 20 cts. the previous year. The yield had increased from 345·69 lb per acre to 374 lb. On Glentilt estate also the cost of tea had been reduced from 31 cts. per lb to 27·28 per lb, the expenditure for manuring was also reduced. Average sale price was 40·29 per lb. as against 49·95 per lb. the previous year, and the profit had been increased from 14 cents to 15·89 cents per lb. The yield had been increased from 346 lb. per acre to 496 per acre. On Lanka and Craighill estates the cost of tea had also been reduced from 28 cents per lb. to 24 cents per lb. and the average price had been increased from 48 cents per lb. to 51 cents. The total cost on the estates had been reduced from 33·67 cents to 28·91. The average sale price of Glentilt estate tea had reduced the profits, but the yield had increased from 319 to 424 lb. per acre, which made good the profits. The Company was now in possession of 1,046 acres in full bearing and 33 acres in partial bearing. The capital value of the estates, taking off the depreciation written off, &c. stood at R373 per acre, equal to about £25 sterling pe acre of tea. As a large depreciation had been written off the capital account, as well as off the cost of the machinery, &c., he thought the time would come soon when there might be no necessity to write off any further depreciation. The Chairman visited the estates lately and found them in exceedingly good condition promising good results for the future. Mr. Dunbar, who visited the estates had favorably reported them. He hoped by continued good cultivation the success already achieved might be still increased. He moved the adoption of the report.

On a question from Mr. HASLOP, regarding the debt of R10,000 for the purchase of Lanka and Craighill estates,

Mr. F W BOIS replied that in the last year's accounts, the debt was R30,000 and it was reduced to R10,000 which appeared in this year's account, but this balance had also been paid now.

Mr. HASLOP seconded the adoption of the report and the motion was carried.

DIVIDEND.

On the motion of Mr. HASLOP, seconded by Mr. H G BOIS, as attorney of Mr. Henry Bois, a final dividend of 10 per cent was declared payable forthwith.

DIRECTOR.

On the motion of Mr. HASLOP, seconded by the CHAIRMAN, the Hon. Mr. Giles F Walker, was re-elected as a Director.

AUDITOR.

On the motion of Mr. H G BOIS, seconded by Mr. HASLOP, Mr. J Guthrie was elected auditor on the usual fee of R75.

The meeting then concluded with a vote of thanks to the Chair.

HAPUGAHALANDA TEA COMPANY, LTD.

THE REPORT.

ACREAGE.

	A	R	P
Tea in full bearing ..	235	0	0
New clearings	150	0	0
Jungle &c.	369	1	3
Total Estate ..	754	1	3

Your Directors beg to submit their annual report and accounts for the twelve months ending 30th June 1900, which they trust may be considered satisfactory.

The quantity of Tea manufactured for the season (including estate and bought leaf, but exclusive of that manufactured for other estates) was 136,900 lb.

Estimating the unsold tea at a safe valuation, the net amount realised for this product has been R44,865·07, equal to an average of 32·77 cents per lb.

An interim dividend of five per cent absorbing R8,500 was paid on 31st March last, and after setting aside R3,293·58 for depreciation on buildings and machinery, the amount available for distribution (including R2,734·41 brought forward from last account) is R10,361·14. This sum the Directors recommend being dealt with as follows, viz:—

In payment of a final dividend of five per cent	R8,500 00
Leaving to be carried to next account a balance of	„ 1,861 14
	R10,361 14

In terms of the articles of Association Mr. Wm. Milne retires from the Board of Directors, but being eligible offers himself for re-election. The appointment of an Auditor for the current season will rest with the meeting. By order of the Directors,

LEWIS BROWN & Co., Agents and Secretaries.

WANARAJAH TEA COMPANY.

THE REPORT

of the directors was submitted as follows:—

DIRECTORS:—Messrs. Alex. Cantlay (Chairman), H Creasy, J W Vanderstraaten and J C Dunbar.

ACREAGE.

	Acres.	Acres.
Tea in bearing ..	1028	
1896..	12	
1898..	20	
	——	1060 in tea
Timber trees	20	
Forest	27	
Grass not available ..	27	
Total ...		1134 acres.

The Directors have the pleasure of presenting to the shareholders the report, balance sheet, and profit and loss account for the year ending 30th June, 1900.

The crop harvested amounted to 447,235 lb., against an estimate of 370,000 lb. The crop for 1899 was 336,692 lb. and the increase in crop is due to the very satisfactory results of manuring and to the favorable weather that has been experienced during the past season. 310,953 lb. have been sold in London at an average of 52 92 cents nett, and it is hoped that the balance of the crop will fetch equally good rates.

MANURE.—The area completed during season amounts to 311 acres, at a cost of R16,118·63, including application. All expenditure during the past season has been debited to crop account.

The amount at the credit of the profit and loss account is R102,906·24, including a balance brought forward of R22,621·34.

After payment of an Interim Dividend of five per cent, there remains a sum of R83,061·24 available, which the Directors recommend be applied as follows :—

To a Final Dividend of 12 per cent, making a total of 17 per cent for the year	R15,360·00
To be carried forward.. ..	37,701·24
	R83,061·24

The estimated crop for the season 1900-19 01 is 420,000 lb. of made tea, at an expenditure of R131,700, including all expenditure on young clearings not in bearing.

The Visiting Agent's reports can be seen by shareholders at the Company's office.

Messrs. H Creasy and J W Vanderstraaten retire from the board by rotation, but are eligible for re-election.

The shareholders are invited to elect an Auditor for the ensuing year.—By order of the Board,

BAKER & HALL, Agents and Secretaries.

PENRHOS ESTATES COMPNY.

THE REPORT

was as follows :—

DIRECTORS.—Messrs. W Kingsbury and E M Shattock.

The Directors have pleasure in laying before the Shareholders their Reports and Accounts for the year ended 30th June 1900.

The amount of Tea secured was 242,841 lb.—196,554 lb. on Estate account, as against an estimate of 165,000 lb, shewing an increase over last season of 38,448 lb and 46,287 lb manufactured from bought leaf, an increase over last Season of 3,373 lb. The Comparative table for the past four seasons will be found of interest :—

	Crop in lb.	Cost laid down in Colombo in cents.	Or without Manure.	Net Average Price.
1896- 97	155,625	27·52	26 31	36·42
1897- 98	145,250	26·23	25·65	39 12
1898- 99	158,106	25·41	24·05	41·03
1899-1900	196,554	23·74	22·32	37·46

These figures refer to the Estate Tea only, and the Superintendent, Mr. J E Martin, deserves every credit for the way he has carried on the working of the Estates, which are in excellent order. Prices were considerably below those of the previous two seasons, but this was due to a low market and to no fault in manufacture, and it will be noticed that the cost of production has again been very materially reduced.

The total Crop secured cost, including Manure cts. 24·58 per lb laid down in Colombo, as against cts. 26·43 the previous Season and realised a nett average price of cts, 36·96, as against cts, 40·27 in 1898/99.

Included in the proceeds of Tea is a sum of R436·26. being balance proceeds of Tea unsold at 30th June, 1899, and estimated for.

It will be noticed that a large sum has been spent during the year under review on Buildings and Machinery. This was absolutely necessary, as the Factory was really only capable of turning out some 15,000 lb. of Tea per mensem, whereas, in the busy months, 25/30,000 have to be manufactured.

An addition of 50' × 25' has been made to the factory, making it now 150' long by sections 25' to 75' broad, whilst a Turbine, a new Roller, Desiccator and Sifter have been erected and are working satisfactorily. Previous to the erection of the Turbine, considerable difficulty was experienced in getting sufficient water power during the dry months, but no further trouble is anticipated in future.

After payment of the Interest on Debentures, namely R3,030·00, the amount earned for the year (including R237·52 brought forward from last account) comes to R25,285·99 which is equal to nearly 17 per cent. on the Capital of the Company, as against 15½ per cent. last Season. Of this sum R4,500·00 was absorbed by the payment of an Interim Dividend of 3 per cent. to the 31st of December last, and the Directors recommend that the balance, namely R20,785·99, be apportioned as follows :—

By the payment of a final dividend of 7 per cent, making 10 per cent for the Year	R10,500·00
By the payment of a Bonus to the Superintendent	„ 1,000·00
By placing to Reserve Fund ..	„ 9,000·00
By carrying forward to the next account	„ 285·00

The Acreage of the Company's Estate is as follows :—

Old Tea	508 Acres
Tea over 4 years ...	25 „
Tea not in bearing ..	24 „
Forest..	51 „
Total Acreage ...	608 Acres.

In terms of the Articles of Association, Mr. E M Shattock retires from the Board of Directors but, being eligible offers himself for re-election.

It will also be necessary to appoint an Auditor for Season 1900/1901.

THE TEA CESS AND GREEN TEA.

As an old Ceylon planter, and one of the first to start tea manufacture, it was cheering to read your vigorous article headed a "Tea Cess for India." Since I have become an Indian planter for the last two years I have consistently agitated in our local Planters' Association for a "tea cess" for Southern India, and though meeting with generous support here, the proposal when laid before the U.P.A.S.I., is invariably shelved as not being feasible, and all sorts of "bugbears," such as difficulty of collecting the cess, and enormous expense that would be involved in so doing, are conjured up by the powers that run that august assembly. With the cess, there would, of course, be appointed a Committee similar to the Thirty Committee in Ceylon to administer the fund, and I take it that one Committee would represent Southern India and be centralised at 'Madras' in touch with an official or two of the Madras Government, and one at Calcutta on the same lines. That the tax would be difficult to collect, I deny ; it would be very easy to notify the authorities at each shipping port that, with every Bill of Lading for tea a "cess" receipt must be attached. If planters chose to sell over the border, say Persia, Siam, or other adjoining countries, let them do so by all means free of "cess," as that helps to relieve the strain on the London market. With the "cess" fund started, it would be, of course, most advisable to secure a well-paid energetic Secretary who would not be above pushing our interests in every way. I mention this as it is the rule among Indian papers, as far as I have seen it, to sneer at the "push" and "energy" with which Ceylon men advertise their teas. The consequence is that we get left behind in the swim. Take for instance, the Paris Exhibition. As far as "Southern India" is concerned we might just as well have never exhibited, as have done so in the poor way that we did. No information was available to this district as to private exhibits until too late to ship them, and no effort made to show up the intrinsic merits of our teas; which exist to a far larger extent than the British public are aware of. Indeed, I know it as a fact, that most, if not all, the teas made in this district for instance, have the same flavour and character as high grown Ceylons, yet we get as a

rule poor prices for want of pushing our goods by means of advertisement. Take the average British public, what do they know of Indian tea? After all these years hardly anything. They know there is a strong tea which comes from a place called "Assam," and perhaps a few people know that a fine flavoured tea comes from "Darjeeling," but other districts are practically unknown to the public, and their produce therefore is only bought by the wholesale blender for his blend. With a tea cess fund carefully administered much might be taught (not only the British public, but foreign nations) about the largest tea industry in the world.

I, for one, object to the foreign market fund and shall not continue to subscribe to it. It is a happy-go-lucky system which falls hard on individuals. For instance, take an estate of 500 acres, giving, say, on to 350 lb. per acre: it can hardly, make ends meet, while an estate of 250 acres giving say 600 lb. an acre, and making good profits, would, under the present system of an acreage taxation, pay less where it can afford to pay more. That the "cess" will be hard on all planters at first in these days of poor prices, goes without saying, but with an energetic Committee and a working Secretary, helped by Government, without more "red tape" than is necessary, I feel sure in a year or two we should find our reward in the shape of increased consumption and better prices.

Before closing this letter I will add a line in reply to A.C.'s letter to yourselves on "green tea." I do not think the method he suggests a good one, as he would start by making an inferior priced green tea, viz, an "Oolong," which is, as far as I am aware, the only kind of green tea yet made in India in any quantity. What I would suggest as a commencement, where two or three can be got to work together, is for one factory, on which there must be a steam engine, to get a steaming machine from Ceylon (the largest size only costs R650, the smaller R450, including all the information necessary for the manufacture of choice "Moyune," or pure Japan green teas) and for that factory to undertake the manufacture of a percentage of two or three neighbours' leaf, as well as a percentage of its own, bulking the teas together and shipping under one mark. For a factory equipped with *two* or *three* rollers and *two* firing machines this could easily be done without in any way interfering in the manufacture of its black tea.

It is known by actual experiment and sales that teas made on this method *do suit the American market*, and this process has been adopted lately by 8 to 12 large concerns in Ceylon, the Ceylon Tea Plantations Company showing the way. Therefore, if A. C. and his friends make their teas on this principle, they ensure themselves being put in the same class as the bulk of the Ceylon green teas, which have hitherto in a small way proved suitable to the market they are intended for.

Green teas may be divided into two classes—Oolongs or semi-green teas, which are partially fermented, and true green teas, which are wholly unfermented. These latter are the most popular class of teas in America, as shown by the fact that out of a total export of some 51,000,000 lb. of China and Japan teas to the United States, some 14,000,000 lb. are Oolongs and of the unfermented class, while over 30,000,000 lb. are of the unfermented class, which are the true green teas of commerce.

Oolongs consists of tea leaves withered either artificially or naturally by hot air, pans, or on hot plates sufficiently to enable them to be rolled; the result of this process is that the effect called by some fermentation and by others oxidisation is *partially* produced, and this effect prevents the infused leaves from being uniform in colour and causes them to vary from an olive green to alight brown.

True green teas are made of leaf which has never been fermented or oxidised, and when infused should show a *uniform* yellowish green colour, which could never be obtained had fermentation or oxidization taken place.

If, Sir, you think it advisable to cut out this discourse on green tea as savouring too much of an advertisement, do so. My only object in mentioning the above facts is to prevent men from coming to grief by sending teas not quite suitable for the American market.—H. DRUMMOND DEANE, *Stagbrook Estate, Peermaad, Travancore.* —"*Indian Gardening and Planting*," August 16.

PLANTING NOTES.

FLORIDA PINEAPPLE CROP.—E. P. Porcher, general agent of the Indian River and Lake Worth Pineapple Growers' Association, has gathered exhaustive statistics relative to the Florida pineapple crop, and from them he estimates it at 135,000 crates for the mainland. Last year's crop was about 16,000 crates which netted an average of $2.35 per crate. Another report says that the size of the fruit being extra large this year, 150,000 crates will be the minimum of the Florida pineapple crop.—*Journal of the Jamaica Agricultural Society.*

"MANURING WITH BRAINS"—is the title of pamphlet sent us by Messrs. Freudenberg & Co. (Sole agents in Ceylon for the Syndicate of Potash Works and German-Austrian Thomas Phosphate Syndicate) which takes for its motto this saying of the Marquis of Salisbury:—

"If farmers would only manure their land with brains, as the painter mixes his paints, there would be much less heard about agricultural depression."

Very useful information is given, more especially adapted, of course, to farmers in Europe; and it is shown how "potash" is not only the dominant manure for leguminous crops, for potatoes and for grain crops; but is also valuable for the prevention of Clover-Sickness, Tulip-Root and other Crop Pests.

BOMBAY MANGOES FOR LONDON.—An effort is being made to bring the Bombay mango to England, and, indeed, for a few hours a small show of this fruit recently made an unwonted sight in a Bond Street fruiterer's window. "But they were all snapped up as soon as the Anglo-Indian got to know of it," said Mr. George Adam, who had exhibited them. He showed a *Daily Mail* representative a letter he had received from Kathiawar, India, proposing to export Bombay mangoes to London as a regular article of commerce. Messrs. Adam and Company hope to import them in quantities. It was a *Daily Mail* representative who described it as of "a green colour," and then wrote: "Smell it, and visions of Eucalyptus and influenza, benzine, and motor-cars, with a distant suggestion of a half-decayed pear float across your mind. This compound fruit is the mango." Looks as if mangoes were going to be popular in London, now that a beginning has been made.—*Indian Gardening and Planting*, Aug. 16.

Correspondence.

To the Editor.

GREEN TEAS AND MR. DRUMMOND DEANE.

Stagbrook, Peermaad,
Travancore, July 28.

DEAR SIR,—In *re* your remarks *re* "Pale liquor being a desideratum for green tea" I can assure you that I am not at all "mixed" on the subject as your planting friend suggests. But there is "Pale liquor" and "Pale liquor." What I was always told to strive for was a *pale straw color*, and if you refer to Mr. Street's report and valuations published in *Tropical Agriculturist*, 21st January, 1890. you will see that I about hit the mark. I may add that the valuations in that report turned out about 2d below the prices fetched. The only interest in publishing these old valuations will be when some of the newly-made greens on my system are reported alongside of them.

But with that report and all subsequent reports I was always asked to get a *little more color into the liquor if possible* as they were a *trifle too pale* in *appearance*, though the flavour was excellent and infusion all that it should be.

This I failed to do with the "Kintyre" leaf, but with a few small experiments with "Ruanwella" leaf made by hand, I got the darker liquor, and at the same time a favourable report from America on the sample, which report unfortunately I have not preserved—as just at that time I gave up the manufacture. "Oolongs" always draw a much darker liquor more of an amber color owing to a *certain amount* of fermentation taking place when the leaf is rendered pliable for rolling by "hot air;" and though the outturn is more or less green, yet some signs of fermentation will be apparent.

I have quoted from your letter under reply, to Mr. Street, and asked him to reply to it through your paper if he will be so kind. I do not profess to be a green tea expert, but a manufacturer, who has made teas that at that time apparently satisfied the trade requirements.

If Mr. W. MacKenzie *is correct* in saying that the liquors *cannot* be *too pale* to suit the American taste, then it will be pretty certain that high grown Ceylon teas are sure to "boom";—for *pale* they will assuredly be.

I fancy only about a dozen men are at present going in for this new departure. But I feel pretty confident that if care is taken in the sorting and in get-up of the packages to suit American ideas, remunerative prices will be the result.

And it must be remembered there being no draft allowance in America, the planter has the price of a pound of tea in hand which will go a long way towards extra cost of packing the finest teas in neatly marked small hessian or mat covered packages.—I am, yours truly,

HORACE DRUMMOND DEANE.

GREEN TEAS:—THEIR COLOUR AND QUALITY: THE NEED OF EXPERT ADVICE.

Colombo, August 3.

DEAR SIR,—Mr. Deane has asked me to hand you the enclosed letter* and to reply through your columns.

The "well-known planter" referred to has made the mistake of taking Mr. W Mackenzie's remark that Green Tea liquors "cannot be too pale" too literally. Of course the liquor color may be too pale, just in the same way as it may be too dark. Mr. Deane in a recent letter to the *Observer* rightly says there is a paleness and a paleness or literally that there are degrees of paleness, *due to manufacture*, one of which would be perfection and the other degrees of faultiness and uselessness from a Green Tea point of view.

It is not necessary to refer to color from degree of elevation as this is simply a question of quality. The quality of Green Tea varies with elevation as with Black. I am not going to lay myself open to be misunderstood by entering into a description of what Green Tea should or should not be. The proper and safe medium for such description is between the individual planter and the expert *in connection with his own estate teas.* I cannot too strongly emphasize, and I would also wish you to add to the emphasis, that an enormous amount of harm may, and I fear some will, be done to the future reputation of Ceylon Greens *made without expert advice.* Although the revival of Green Tea making in Ceylon is only a few weeks old, I have had several samples sent to me which clearly indicate the *absolute necessity* of expert criticism and advice. I need hardly say that all the faults which have come under my notice can be corrected by changes in manufacture. I strongly advise Planters not to begin manufacturing bulk until their experimental manufacture is entirely approved of by an expert. They would do well to remember that the future success or otherwise of Ceylon Greens depends upon the individual excellence of their manufacture *particularly at first.*

Apologizing for having taken up so much of your valuable space, which I should not have occupied at all had not Mr. Deane asked me to reply through you,—Yours faithfully,

F. F. STREET.

RAINFALL AT TELLICHERRY, WEST COAST OF INDIA—ROADS, &c.

Tellicherry, Aug. 13.

DEAR MR. EDITOR,—In accordance with your editorial foot-note to a recent communication of mine, I have pleasure in handing you a memo of the Tellicherry rainfall from 1st January, 1899, to date, which I trust may be of interest. It is pouring as I write, and every thing is more or less damp and nasty. However, we are getting fairly good news now from the famine-affected areas; so must not grumble. The road at the top of the Tambercherry

* This is very much the preceding letter. —ED. *T.A.*

Ghât, between Calicut and South Wynaad, has been badly breached and washed away in parts, and, it is reported, may take some four or five months to repair for wheeled traffic again. This is serious for the estates in South Wynaad, the other Ghât roads being very circuitous routes to the Coast. I am sorry I am not yet in a position to send you my Annual Statistics of Exports of Coffee and Pepper from Southern India. There are still two Ports from which I have to receive information; but I should receive these any day now.—Truly yours,

RALPH TATHAM.

USEFUL AUSTRALIAN BOOKS.

Public Library, Museums, and National Gallery of Victoria, Melbourne. Aug. 8th, 1900.

Sir,—I have the honour to inform you that I have, by direction of the Trustees, this day forwarded by post for your acceptance a copy of each of the undermentioned works:—1. McAlpine—Fungus Diseases of Citrus Trees in Australia. 2. Roos—Wine-making in hot climates.—I have the honour to be, Sir, your obedient servant,

THE LIBRARIAN.

["Wine-making in hot climates" is a translation from the French and has been published by the Victorian Government for the benefit of Viticulturists whose industry is of importance in most of the Australian Colonies. The second book, is also published officially and the coloured plates are splendidly executed. This little guide may be of use to us locally in connection with the culture of orange and lime trees. We return thanks for both publications.—Ed. *T.A.*]

CHIN BARA TEA AND MR. HARCOURT SKRINE.

August 16.

Dear Sir,—I enclose an extract from the *Chemist and Druggist* which I think will interest your readers.—Yours faithfully,

CHEMIST.

TEA FOR CHEMISTS.

(Extract from the Chemist and Druggist, July 28th, 1900.)

It stands to reason that if chemists and druggists are to do business in tea, they must have an article to offer different from what their neighbour the grocer sells. We have pleasure in calling attention to an entirely new tea which is being introduced to the public through chemists. It is called the Chin Bara tea, and the process for its production has been devised by Mr. E Harcourt Skrine. Chemists may not be aware that the method of manufacturing tea adopted in Ceylon and India is intended to yield dividends to shareholders rather than the finest teas and the plucked leaf is allowed to go through a fermentation process before it is dried. Mr. Skrine finds that this is entirely unnecessary for the development of the flavour of the tea. The finest Chinese teas of old were made slowly and carefully. Mr. Skrine finds that fermentation is detrimental, in so far as it produces certain organic acids which disturb the digestion. He has therefore devised a process, and machinery for carrying it out, whereby the plucked leaves are gradually dried and rolled without undergoing fermentation; this he recalls the "cold process" to distinguish it from the other. Moreover, he takes very great care in the harvesting of the tea, and from the plucking to the final presentation of the tea, every stage of the process is supervised and expedited by a staff of skilled managers. The teas are not blended, but in the three qualities offered by the Chin Bara Chino-Ceylon Pure Tea Depôt, 5 Victoria Avenue, Bishopsgate Street, E. C., we have only the difference in the grade of leaf to recognise. The tea neither produces indigestion nor favours nervousness when taken in large quantity, so that it is just the thing for chemists to sell. It is put up in packets ready for selling, and is offered on P. A. T. A. principles for retail by chemists, whom we would recommend to apply to the Company for a copy of a pamphlet entitled "A History of Tea."

BRITISH NORTH BORNEO.

Kandy, Aug. 18.

DEAR SIR,—I send you copy of report presented at the meeting of the shareholders on 31st July by the Court of Directors of British North Borneo Co. The noticeable items are that the receipts for 1899 exceeded the expenditure by £17,372 8s 9d, and that a dividend of two per cent. to shareholders for the year was recommended :—

In 1893 the revenue was only $289.220.
In 1899 do. do. $542,919.

Very nearly double. The comparative results in the more important items of receipts are :—

	1899. $	1898. $
Farms ..	201,967	180,255
Customs ..	199,254	184,069
Land Revenue .	26,410	24,081

Comparative statement of principal exports for—

	1899. $	1898. $
Bird Nests ..	47,465	47,160
Camphor ..	39,084	37,047
Copra ..	19,161	12,840
Coffee ..	30,185	28,620
Cutch ..	146,690	267,536
Gutta ..	122,588	125,280
Hemp ..	61,803	24,590
India Rubber ..	69,777	79,600
Tobacco ..	1,862,455	1,316,660
Sundries ..	299,689	147,416
Timber ..	189,027	214,346
&c.	&c.	&c.
Total ..	$3,439,560	$2,839,844

The imports are stationary :—

—Yours truly, W. D. GIBBON.

SIR JOHN LAWES AND MANURING.

Aug. 22.

SIR,—Depend upon it, there is again some big blunder over the interpretation of Sir John Lawes' views by Mr. Talbot—or rather by the Ceylon "Times" and its correspondent. The wish is father to the thought in some quarters, in trying to get manuring checked. But those will score who keep on their way, guided by

EXPERIENCE AND SCIENCE.

THE LATEST AND BIGGEST BOOK ON "TEA."

"Tea Machinery and Tea Factories: A Descriptive Treatise on the Mechanical Appliances required in the cultivation of the Tea Plant and the Preparation of Tea for the Market. By A. J. Wallis-Tayler, C.E., Assoc. Memb. Inst. C.E. (London: Crosby Lockwood & Son; Calcutta: Thacker Spink & Co.)."

We have just received from Messrs: Thacker Spink & Co., of Calcutta, a copy of this well printed, profusely illustrated and generally handsome volume of 468 pages octavo. There are 218 diagrams and illustrations, mainly of machinery or mechanical appliances; for, although the cultivation and preparation of tea are specially dealt with, there can be no doubt this is an Engineer's book, and one based chiefly on Indian experience and modes of working. We cannot see that Mr. T. C. Owen's, or any Ceylon, tea manual or essay is referred to and we suppose Mr. Wallis-Tayler has never visited Ceylon to note the widely different and differing conditions of our tea country. Nevertheless, the volume is full of interest to all tea planters and in the section on "transport," illustrations are given of the wire rope or aërial tramway erected by Messrs. Walker Sons & Co., Limited, on the Goorookelle estate of the Galaha Co. Justice is done to the tea machinery of "Jackson" and some other patentees; but the author says nothing of certain other machines which are well-known and much appreciated in Ceylon. The book is divided into seventeen chapters, the first of which treats of the mechanical cultivation and tillage of the soil; the second of various methods of plucking or gathering the leaf; whilst the ten next succeeding chapters are devoted to descriptions of the factory and of the various machines and apparatus employed therein. The next two chapters deal with the means of transport on the plantation; one chapter is taken up with the miscellaneous machinery and apparatus used in and about tea factories; another with machines for the final handling of the tea—such as mixing, blending, or bulking machines, and packeting or parcelling machines; and in the concluding chapter of the work we have a number of tables and memoranda likely to be found useful by those engaged in the tea industry. The principal aim of the book cannot be better indicated than by quoting what Mr. Wallis-Tayler says at the conclusion of his preface;—"It should be remembered that whilst the possession of a good plant of machinery, and of a well-designed factory, will enable good tea to be made from an inferior quality of leaf, on the other hand, a good jat, suitability of soil and climate, and the most efficient possible cultivation, will be all thrown away if such means be not at hand to facilitate the preparation or manufacture of the tea from the green leaf." There is much truth in this; and altogether the volume is one that should be in the hands of all who can afford the cost which the Calcutta publishers have now fixed at the special cash price of R20 net; the previous rate being R22½.

PLANTING IN PERAK.

SUGAR.

The planting community suffers from the competition of mine-owners in the labour market, but until recently, this competition has not been severely felt, as the labour employed on plantations, excepting those owned by Chinese sugar growers, has been almost exclusively Indian, while that employed in the mines has been Chinese; recently, however, the supply of Chinese labourers has been so disproportionate to the demand, mainly owing to the quarantine restrictions imposed in connection with bubonic plague, that both Chinese planters and mine-owners have supplemented it by the employment of Indians. Judging from the demand for sugar land, and the success which has attended the majority of planters in Perak, there is every reason to predict a considerable extension of this form of cultivation in the immediate future; and the local conditions of the Federated Malay States, which are easily accessible both from India and China, and in which the labour rates are still comparatively low, should render it possible for them

to compete on advantageous terms with the great sugar-producing districts in America, the West Indies and Mauritius, which are all situated at a much greater distance from any source of cheap labour supply and which all have a local "gold" standard. It is difficult to deal with this subject without some allusion to the vexed question of currency, but it is probable, if not certain, that the most earnest advocates of bi-metallism, or of an exclusively gold standard, would admit that the depreciation in the exchange value of silver has hitherto had the effect of reducing the rates of wages and local commodities in those countries having a silver standard, as compared with those in which the standard is based on gold.

COFFEE.

Among European planters only those connected with the sugar industry have been successful, as the price of Liberian coffee, the chief agricultural product hitherto cultivated by Europeans, has been low throughout the year, although it improved towards the end, the price ranging from $16 per pikul (133 pounds) in July to $20·50 per pikul in December.

OUTTA AND RUBBER.

The attention of planters has been drawn to the great demand for gutta and rubber, and a portion of nearly all estates owned by Europeans is now being planted with trees producing rubber. The variety usually cultivated is Para *(Hevea brasiliensis)*, but considerable numbers of Rambong trees *(Ficus elastica)* are also being planted and, having regard to the insect and other pests which almost invariably attack exotic plants with special virulence, it is not unlikely that Rambong, a hardly indigenous tree, will eventually be preferred to Para, a tree imported from Brazil. Special attention was called by the Secretary of State, when forwarding copies of correspondence with the Director of the Royal Gardens at Kew, to the importance of preserving and cultivating the trees yielding Gutta Percha in the Malay Peninsula. It would appear that there are only two trees which yield the true Gutta Percha, and these are locally known as *Taban* and *Sundek;* scientifically *Dichopsis gutta* and *Payena leerii*. They are both slow-growing trees which do not come to maturity for at least 30 years, and consequently it is scarcely to be expected that they will be cultivated to any large extent by private individuals; but Gutta Percha is so valuable, in connection with submarine cables, that no effort should be spared by Government, both to preserve the young trees still remaining in our jungles, and to provide for planting others in suitable localities. Rubber, as distinguished from Gutta, is produced in all tropical countries, and there is therefore no probability of any deficiency in the supply, but true Gutta Percha is said to be confined to the Malay Peninsula and Archipelago.

COCONUTS.

A controversy was raised, or rather renewed, during the year as to the possibility of successfully cultivating sugar and coconuts in the same neighbourhood. The planter of coconuts, especially the native planters, contend that the beetles which infest their trees are mainly bred in the heaps of cane refuse connected with sugar mills. This contention, although denied by the sugar planters, probably contains a considerable substratum of truth; but, on the other hand, the Malay owners of coconut plantations pay insufficient attention to the care and cultivation of their trees, and neglect many obvious precautions against the attack of beetles. On the whole it may be said that the result of the controversy has been to shew that sugar and coconut plantations, when both are properly cared for, can be successfully cultivated in the same neighbourhood; but that, when owned by Asiatics, it is advisable that these two methods of cultivation should be kept apart. A more difficult question has been to decide between the relative claims of *padi* and sugar planters, especially in the Krian District. The same description of land is the most suitable for both these forms of cultivation; but, unfortunately, the amount of water required for the cultivation of

RICE

is entirely disproportionate to that required of sugar. It has accordingly been necessary, in order to protect Malay *padi* planters, and to ensure the permanency of sufficent land for the cultivation of rice, the one absolutely essential article of food in the far East, to proclaim irrigation areas within which the Government reserves the entire control and distribution of the supply fo water. The Agricultural Department of Western Australia has recently made enquiry as to the possibility of obtaining a regular supply of

BANANAS

from Malaya, to supplement the supplies from Ceylon and Fiji, and this may afford a new and profitable market for the "catch crops" cultivated by European as well as Native planters, while awaiting a return from their more permanent agricultural products.—*Official Report.*

STIMULATING THE GERMINATION OF TEAK SEED.

Experiments to accelerate the germination of teak seed have been undertaken in various divisions of the Bombay Presidency, and with excellent results. The teak seeds are placed in a shallow pit 1½ feet deep, which is afterwards filled with water to soak them. Subsequently the seeds are kept moist by being watered every four days. Seeds so treated show signs of germination in another five days. A second experiment was made in which the seeds were at first soaked in warm water for 24 hours, and the Divisional Forest Officer, Surat, Mr. Hodgson, writes as follows regarding the results obtained:—"I consider it would be a waste of time to grow seedlings in such a way that they take three months to appear above ground, for the seed invariably germinated in 12 to 24 hours in this Division by soaking in luke warm water, and plants show above ground in a few days."—*Indian Forester.*

TRADE IN TERMINALIA BELLERICA NUTS.

Mr. G M Ryan, Deputy Conservator of Forests, Northern Circle, Bombay, has lately issued a memorandum on the subject of Terminalia bellerica nuts in which he draws attention to a vast source of hitherto untapped wealth in the Northern Forests of Bombay; for it is difficult to believe that the matter has not already received considerable attention elsewhere. Mr. Ryan writes as follows:—"A report on the nuts of Terminalia bellerica, a tree common in all the Thana Divisions, was submitted by the Divisional Forest Officer, South Thana, in which he showed that in 1889 the value of these nuts in the English market was reported to be £7 to £8 per ton, a price even higher than that of some myrabolams. Messrs. Killick Nixon and & Co., Bombay, have agreed to undertake the shipment of a consignment of these nuts from India, to ascertain their present value in England. If they (the nuts) approaching anything like the price quoted for them in 1884, every likelihood presents itself of a new source of revenue springing up, for in addition to this Presidency, the Central Provinces also, it is found, contain Terminalia bellerica in large quantities. The annual export of the nuts under favourable conditions would, it is estimated, amount to about 1,000 tons from the Bombay Presidency alone."

As Mr. Ryan correctly implies, the Terminalia bellerica tree is common in the plains and lower hills throughout India and Burmah, and also in the Oudh sal forests; and the fruit has long been known as one of the myrabolams of com-

merce, and is exported as such. Myrabolams were recently quoted in the London market at about £4 per ton, and we shall be glad to hear of the financial results of the undertaking.—*Indian Forester.*

NALIONAL TEA UNION, LIMITED.

NOT SO PROSPEROUS.

The Directors in submitting their report and balance-sheet for the year ended Juue 30th, 1900, state that the net profits derived from the Company's trausactions for the year, after making provision for bad debts, writing off all advertising charges and losses stated in following paragraphs, amounts to £1,514 10s. 5d., inclusive of £364 10s. 10d. dividends on investments. About three years ago the Company opened a Bonus Tea Department at Manchester for the convenience of members in Lancashire and adjoining counties. This department having proved unprofitable was closed a few months ago, baving resulted in a loss during the year of £502 6s. 3d. The trading of the Continental Branch opened at Amsterdam in February, 1899, shows a loss on the year of £370 19s. 5d. This need not be a cause of discouragement, seeing that the foreign business is an entirely new departure. Owing to the reduction of the ordinary dividend for 1899, partially the result of the re-instatement of the reserve fund, many of the trading members were much dissatisfied and temporarily withdrew or reduced their purchases from the Company, which resulted in a considerable decrease in the business for the first half of the financial year. The directors are, however, pleased to report that the trade for the second half of the year, ending June 30th, shows a respectable increase on the corresponding period of 1899, but not sufficient to compensate for the set-back of the previous half year. The demand during the year has run mainly on low and cheap teas, much of which has been sold at prices which do not yield any profit, or even contribute their fair quota towards working expenses. The proportion of medium and fine teas now sold is much smaller than hitherto. The effect of the addition to the tea duty appears to have nearly disappeared in consequence of the demand for teas to retail at similar prices to those which obtained previous to its increase, thus the reduction in the average wholesale price of tea (excluding the duty), has had the effect of decreasing the already narrow margins on which the Company supplies its goods to members and customers. During the day preceding and the day on which the Budget was declared, an enormous rush took place to buy and clear tea at the then current duty rate, which transactions embraced blended and packed goods. Th Company's available duty-paid stocks were disposed of to all members and customers at the 4d rate, with the proviso that half of their orders should be taken at the new (6d) rate. This arrangement met with general approval. An interim dividend for six months on the preference shares was paid on January 1st, 1900, absorbing £500. The directors remit herewith the remaining six months' preference dividend absorbing a further £500 and leaving a balance of £514 10s 5d, subject to the payment of directors' remuneration and managing directors proportion of profits, amounting to £311 16s., but which they have agreed to reduce to £250, leaving the sum of £264 10s. 5d. to carry forward to next account. The directors regret their inability to recommend or pay any dividend on ordinary shares this year, but trust that members generally will recognise the Wisdom of giving their Company the fullest possible measure of support during the preseut year. Members will call to mind the very congested nature of the traffic and consequent growing disadvantages of the Mark Lane (Manchester) premises, which were disposed of in February. The sale resulted in a profit of £2,119 1s, 3s., after making provision for considerable alterations to the Cannon-street premises, fitting up, removal, etc. The directors recommend that the amount be dealt with thus—Add to general reserve fund, £1,500; add to reserve for depreciations £500; leaving in suspense, £119 1s. 1d ; total, £2,119 1s. 3d. Members will note that the financial years closes free of trading liabilities, against £3,151 14s. 5d. twelve months ago.—*Grocers' Journal*, Aug. 4.

PARA RUBBER IN THE STRAITS: A PROMISING OUTLOOK.

To the Editor of the *India-Rubber* and *Gutta-Percha Journal.*

Dear Sir,—I have been asked by the Committee of the United Planters' Association F. M. S. to let it be widely known that a strong feeling exists amongst planters that the time is fast approaching when we should send a representative to Para, and from thence to the different seats of the rubber industry, in order that when this country is ready to put its own rubber upon the market, we may be in full possession of all the most up-to-date methods of tapping, of obtaining the maximum output with the minimum of damage to the tree, and of curing our produce in such a manner that it will fetch as high a price as any in the markets of the world. It is already been demonstrated that we can grow Para rubber, that we can get a heavy yield, and that the quality of our produce is equal in value to the best Brazilian. These are now proved facts, and there is no doubt that if we avoid all initial mistakes when cultivating and producing on a large scale, are thoroughly coached in our business when we first make our bow to the public, and so gain straight off a reputation for quality, a very prosperous agricultural future lies before the Malay Peninsula.

I believe I am right in stating that the rubber zone is approximately confined to 15 deg. north and 5 deg. south of the Equator, and a glance at a map of the world will very soon show how exceptionally well situated we are in every respect by comparison with other rubber-producing countries. Easy transport, a labour supply that can be developed until it is sufficent for our fullest requirements, a healthy climate where the white man and the coolie alike can thrive, all these advantages are ours; and I maintain that it rests with us whether we make a suecess of the great industry which we have inaugurated here or whether by carelessness and ignorance in our initial methods we find ourselves saddled with a reputation which it may take us years to live down.

The Resident-General with characteristic sympathy, has promised the planters the assistance of an expert from Kew, and a substantial sum has been provided for that purpose on the Federal estimates; no one doubts that the result of this officer's researches will be of enormous benefit to Malayan agriculture generally, but, with respect to rubber, we believe that much additional good may be done by sending over to Para one of our own men, a thoroughly practical aud energetic planter, and, making his experience the basis of our own methods, by steadily endeavouring to improve from that point. In Selangor during the year 1898, no less than 389,500 Para rubber trees were planted and in 1899 the S. P. A. annual report shows a return of 1,600,000. Previous to 1898 a fair number were planted too. Taking 1,000,000 then as likely to arrive at maturity and with a yield of 1½ lb. per tree which we may put at 2s, or say $1 to allow for a possible fall of 50 per cent in value, we have in this State alone sufficient Para planted to give us an annual return of $1,500,000. Double this for the rest of the Malay Peninsula, and it is abundantly clear that we have already laid the foundations of what may with luck and care become an enormous trade.

It will no doubt be objected that what answers in Brazil may not by any means apply here, but surely it is folly to assume this? We know next

to nothing about our subject at present, and very soon most planters will be wanting to begin tapping on a small scale. Let us find out then as soon as possible all that there is to be learnt and apply that knowledge to suit local conditions.

It has been estimated that to send a good man to Brazil with "carte blanche" to travel as he thinks best and to extend his inquiries, if he got the opportunity, to other rubbers besides Para, will cost in all probability not less than $10,000. In these hard times this is a large sum to raise, and my object in writing is to invite public opinion upon the question. If those interested will communicate their views to the press much good may result, and when the time comes for us to take definite action, the skeleton of the scheme will already have been framed.—I am, dear sir, yours faithfully E. V. CAREY, Chairman, United Planters' Association.

SPORT IN SEISTAN, EASTERN PERSIA

REPORT BY CAPTAIN CHENEVIX-TRENCH.

The British Officer in India, Civil or Military, will go far afield for sport, and if he be particularly fond of using his smoothbore he may hereafter be tempted to try Seistau in spite of the difficulties of getting there. Taking Captain Chenevix-Trench, British Consul in that part of Eastern Persia, as our authority, we may give some description of the country and of the game birds to be found therein. Seistan, then, is a fertile plain about fifty miles square, watered by canals from the Helmand. That river forms the eastern boundary of the province and marks the local division between Persia and Afghanistan. The waters of the Helmand, instead of finding their way to the sea, spread themselves out over miles of plain and form a huge lagoon, seven or eight feet deep, called in the vernacular "Naisar." In the summer when the river is in flood, due to the melting of the snows in the far-away Koh-i-Baba, this shallow lake extends its borders for miles; but in the winter the water recedes, leaving a wide margin of grass and reeds. Then wild duck, teal and water-fowl generally come in enormous numbers from Central Asia, and the shooting would be unrivalled—if sportsmen were there. There are no boats in Seistan, but an excellent substitute is found in the native *tutin*. This is made by binding together dry reeds into a solid mass, having the shape of a pointed raft with rather a high prow. The *tutin* is pointed along and makes a very comfortable form of duck-punt. Besides the "Naisar," there are many other smaller lagoons, and all give good cover. But Seistan has other game than water-fowl. In the Report of the 1871 Boundary Commission, the following entry occurs in the diary under date February, 26th: "The land swarms with game and partridges, sand-grouse, quail, teal, duck, geese and pigeon were to be seen in every direction." Captain Trench states that the sportsman who adventures into Seistan will find villages everywhere with supplies in abundance: milk, eggs, and chickens are cheap, barley about one rupee per maund, *ata* 18 seers for a rupee. The people of the country are most friendly and are anxious to sell. Camels can be hired for transport and ponies can be bought at an average of R60 to R70 each. The Seistanis all talk Persian, very few knowing Hindustani, while Baluchis on the border speak Baluchi in addition to Persian. There is an Indian shop at Nasratabad, the chief town, and it bears the name of "Mahomed Ali Brothers," familiar enough in Quetta. This enterprising firm supplies stores and will shortly furnish soda-water also, a welcome drink in a dry land during the summer months. The enthusiastic sportsman may inquire how he is to get to Seistan: he will have to march from Quetta to Nushki and then across the desert, which Captain Webb-Ware has opened out as a caravan route. He will find rest-houses conveniently placed, and if he wishes to see a new country, which may some day rise into importance owing to its strategic position west of Afghanistan, he will take his guns and an unlimited supply of cartridges and hurry off to Quetta next winter.—*Pioneer*, August 17.

TRADE IN DRIED LEAVES AND FLOWERS.

Mr. E Rudowsky, Commission Agent, 14, Weinligstrasse, Dresden, Germany, asks us to draw the attention of our readers to the great possibilities there exist of opening up, between India and Europe, a remunerative trade in dried leaves and flowers such as are extensively used in Europe for decorative purposes. Mr. E Rudowsky, in his letter, states:—"Our selection at the present time is very limited, and the steady growing demand in Europe compels us to seek for fresh fields to make up deficiencies, and as India has plenty to offer in that direction, there is a good way of opening new and profitable makets for such produce, and thus helping the colony. To give you an idea of the possibilities of the trade, I will only mention that the so-called "Cape-flower," a small dried flower, is imported from South Africa in hundred-weights and tons, and I do not see why similar results should not be achieved gradually from India as well. Articles of this kind should be gathered with about three to four inches stem, as the case may be, so as to fasten to wreaths, bouquets, etc., well dried and packed in ten pound boxes (the limit the postal authorities carry), and sent by post. As they are light in weight a ten pound box would hold several thousand. Any dried leaves, flowers, etc., which are attractive enough to lend themselves for decorative purposes, would certainly be well appreciated here. Mr. E Rudowsky informs us that he will be glad to answer any further questions; to receive samples; and to give quotations. His address is given above. —*Indian Forester.*

RUBBER PLANTING EXPERIENCES IN NICARAGUA.

(To the Editor of the *India Rubber World.*)

In the March number of your journal appears a very erroneous article, made up, it seems, of surmises and hearsay, written by Charles D. Scott, of San Juan Del Norte, Nicaragua, in regard to rubber culture in Nicaragua. For fear that his statements may be believed by readers of your journal, I take the liberty of writing to you to contradict Mr. Scott's rash article. I am sorry he did not make a thorough search for information.

There are a number of good rubber plantations in this district. One planter is Mr. G. G. Cossitt, who gives his experience in rubber culture for the past three years, which is no hearsay or surmise, but reality. Mr. Cossitt says: "After years of exploration of Nicaragua, I decided to locate near here for rubber planting, on account of the rich land, healthy location, and proximity to market. In June, 1897, I planted my nursery of rubber seed, and in January, 1898, I began cutting the timber on the Tennessee plantation. Everything was cut clean and burnt off in April, and the rows for rubber laid off. On the 19th of May, 1898, as the rainy season began, I commenced transplanting from the nursery, and finished in July. Since then I have kept the

plantation cleaned and well cared for. At this date I have many trees from five to six inches in diameter and from 12 to 16 feet high, and two-thirds of my trees are large enough to take care of themselves with little or no more attention. These facts can be corroborated by many, or what is better by coming to the plantation and seeing for one's self."

Mr. Scott speaks of the probable short life of the trees after bleeding begins, but from my observation, there is no tree that has greater tenacity for life and can stand such rough usage. There are trees on my place that were there when I began work that are 16 to 18 inches in diameter and must have been bled for ten or twelve years and they are yet growing well. It is true that the trunks show a rough scarred appearance, but that is due to the ruthless bleeding done by the natives with the only tool used by them, "the machette." Formerly they always cut the trees down. I have been told by old men living here that rubber trees formerly grew in this vicinity that were from 4 to 6 feet in diameter.

In June, 1898, I visited a man living some miles from here to get rubber seed, and saw a tree he had planted that was eight years old and 15 inches in diameter. He had bled it for the first time during the Christmas of 1897 and got from it 5½ pounds of rubber. By a systematic way of bleeding the rubber tree, I am sure the life of a tree can be prolonged indefinitely and it will continue to increase in size and yield. From the rough manner in which the natives bleed the rubber trees of Nicaragua (the wild forest trees) they will soon be exterminated.

For my actual experience on "The Daytonia" plantation, we have trees 1½ inch in diameter and from three to four feet high, planted from seed last June. They were planted out in the open sun without any shade whatever; neither have they been shaded at any time since transplanting last September. In order to give the rubber trees all the sun possible, we have the trails running east and west, so as to catch the sun all day.

A great deal has been said, *pro* and *con*, in regard to planting rubber in the sun, but the trees grow more rapidly when planted in the sun and it is quite evident that they are more healthy and produce more rubber. Take trees planted in the shade, as a great many natives have done, and you will find them a failure. This, we have learned, by close investigation for some years back, and also from actual experience. Rubber is of very slow growth when planted in the shade, and when found in the forest you will notice that the tree has shot straight up in search for the sun.

Rubber trees planted in the sun will attain a size in diameter in two years of from 5 to 6 inches and a height of from 15 to 20 feet, while trees planted in the shade in the forest 5 inches in diameter will reach probably a height of from 40 to 50 feet and will take, as near as we can ascertain, from information gathered from all the authentic works we can secure, from twenty-five to thirty years.

The method the natives follow in tapping the rubber tree is very injurious, as they, in their ignorance and carelessness, cut clear through the bark and into the wood of the tree. This is entirely unnecessary and uncalled for, as the milky substance, or rubber, is held or contained in millions of small globular cells 1-10000 inch in diameter, and in bleeding it is entirely wrong to cut through the bark and into the wood, as no rubber milk is gotten between the bark and the wood of the tree. It is held in the minute cells in the bark and if a tree is properly tapped, by making an incision simply in the bark, it will do no injury to the tree. We would say that rubber trees are not easily killed. We find trees on "The Daytonia" plantation, volunteer trees, that have been cut nearly to pieces by the the rubber hunters and still they leave and flourish, showing that rubber is a very hardly plant and not easily killed as Mr. Scott would imply. It is a fact that there is very little known of rubber culture in Nicaragua, except on the eastern coast and near Pearl City.

As the editor of The *India Rubber World* says: "Because rubber grows in one locality, in a state, it is not an assurance that it will grow everywhere." We know there are large areas in northeastern Nicaragua that are totally unsuited for it, and even in this vicinity rubber does not do well everywhere, but altogether it is the finest locality in Nicaragua for rubber culture. In the dry zone in the interior and on the west coast of Nicaragua, it does not grow well. Rich land, good drainage, and plenty of moisture are the requisites for successful rubber culture.

GEORGE L. BITTINGER.

Pearl City, Nicaragua (Department of Zalaya), April 9th, 1900.

———

Having just returned from a two months trip in Nicaragua and Costa Rica, where I visited and inspected plantations of rubber, chocolate, coconuts, pineapples, bananas, vanilla, oranges, sugar cane, and the like, and investigated localities, soil, and cost of planting, talked with men who are working and investing heavily in them —I feel that I am in possession of correct information on this important "Rubber question" in Nicaragua. In addition to the foregoing article of George L. Bittinger, which I endorse, I will only say that I am convinced that Mr. Scott knows absolutely nothing about the "cultivation" of rubber. His little article itself is full of contradictions, one paragraph with another, and would not be worthy of attention or consideration were it not for the fact that many innocent people read your valuable journal—people who do not know, and yet who are anxious to know the facts about the culture of rubber and which is now a very profitable and staple commodity and is a product of Nicaragua.

Now I saw on the plantation of Dr. Roman, at Jinotepe, Nicaragua, not a great way from Grey, town, where Mr. Scott lives, rubber trees nine and ten years old, that had been tapped since seven years old and are as strong and healthy as though never touched; these trees are over two feet in diameter, gave an average of 5½ pounds of rubber the first tapping, which has increased nearly a pound per year since. These trees were planted at first as shade for coffee trees. I also saw a number of old rubber trees, shown me by some native rubber cutters, from which they had cut rubber every year for the last fifteen to twenty years. The treee are still healthy and big, although considerably cut up, as these native cutters are indifferent and take no care of the trees, not even sealing their uneven cuts with mud to prevent exposure to the air, sun, rain, or insects, and yet the trees thrive and yield 10 to 15 pounds at each tapping. I saw three tapped. Rubber plantations have about 200 trees per acre; figure the profits.

The rubber tree, like all other trees, requires the proper soil, care, and conditions for its growth and profitable cultivation. That it can be made as profitable in Nicaragua as anywhere in the world, there is not the shadow of doubt, of which I believe I can fully satisfy anybody by absolute proof. At present the most suitable soil and location in Nicaragua for rubber cultivation, seems to be in the region of Pearl Lagoon, where are located a number of plantations.—*India Rubber World*, June 1st.

F. D. BITTINGER, M.D.

Dayton, Ohio, May 12th, 1900.

A TEA CESS FOR INDIA.

The Editor of "Indian Gardening and Planting" deserves credit for his strenuous exertions to make the necessity for a Cess on tea in India, as in Ceylon, clear to his readers and constituents. He has had the courage to draw the attention of Indian planters to the invidious position which they occupy, and he has started an agitation for the good of the industry, while he has advocated the cess as a matter of justice rather than expediency. We hope other Calcutta editors and the press generally will follow this good example.

TEA IN THE MELBOURNE CUSTOMS.

THE P.A. SHOULD ENQUIRE AND SUGGEST REFORMS.

A former Colombo resident writing to us from a South Colony, under date July 31st, says :—"When in Melbourne at the clearing house, passing through some luggage, I was astonished at seeing the manner in which the Customs officials dealt with the tea just arrived there. There are really no facilities for dealing with tea, and I think that the Planters' Association should call attention to the matter. Each box or chest of tea was opened and the contents poured into a canvas sheet, lying on the grimy floor where all kinds of merchandise was thrown It was then taken and rolled up and placed in large scales and after taking careful note of the weight and the weight of the box or chest, it was carelessly poured back into the chest, and, of course, the chest not holding all the tea without packing, one of the attendants stepped into the chest (boots and what might adhere to them !) to give it the required pressure. A small quantity of tea, of course, is lost from every chest, but it is the practice of packing which is most obnoxious. Why should not Messrs. Davidson & Co. get the Victorian Government to invest in one of their patent packers—indeed all the Australasian Governments It would greatly facilitate their work at the Customs. One worked by hand would be the most convenient."

EXPORT DUTIES IN COLUMBIA.

The Government of Columbia has promulgated an important decree, dated April 24th by which all exporters of Produce are compelled to pay to the Government certain duties. Exporters of coffee are to pay $10 gold for every 125 kilos. Rubber and other gums, etc., are subject to an expropriation (forced loan) of thirty per cent of their value in gold.—*Chemist and Druggist.*

AMSTERDAM BARK MARKETS.—Shipments of cinchona bark from Java for the month of July are reported at 629,000 Amsterdam pounds, against 940,000 pounds in the corresponding period of last year. The total for the seven months to the end of August is 4,612,000. Amsterdam pounds, against 6,025,000 pounds in the corresponding period last year, and 6,102,000 in 1898.—*British and Colonial Druggist*, Aug. 3.

PLANTING NOTES.

SAMOA ESTATES, LD. (66,685).—Regd. July 19, with capital £50,000, in £1 shares, to adopt an agreement with N. J. Weaver and to carry on the business of cocoa, tea, coffee, sugar, fruit, tobacco, indigo and other produce planters, growers, and merchants, shippers, carriers, miners, smelters, explorers, engineers, etc.—*The Investors' Guardian*, Aug. 4.

THE TENDENCY OF RUBBER LANDS IN BRAZIL to come under private ownership and control is illustrated by the granting to a Brazilian citizen—Manoel Floriano Correa de Bulto—of a valuable concession near Manáos. The United States consul at Para reports : "The property consists of several thousand acres of rubber and cocoa land, including immense belts situated on the banks of the rio Negro, rio Japura, and rio Branco." A copy of the terms of agreement in Portuguese, has been filed in the Bureau of foreign commerce in Washington. The grant has been criticized by the *Journal do Commercio* of Manáos, as an alienation of sovereign rights.—*India Rubber World.*

FULLER'S EARTH IN THE UNITED STATES,—According to the *Chicago Chronicle*, there was recently discovered near the Ocklockonnee River, 14 miles west of the city of Tallahassee, Florida, what is believed by experts to be the most wonderfully pure vein of fuller's earth ever discovered in the world, This vein is said to yield, at the expenditure of very little labour, immense quantities of this peculiar earth, which stands the 100 test—that is to say, that it is absolutely pure, there is no waste. Nearly all the mines of this kind of earth contain, besides the valuable commodity, rock, flint, gravel, sand, &c., but this deposit is entirely free of such substances.—*British and Colonial Druggist*, Aug. 3.

THE BREAD FRUIT TREE (*Artocarpus Incisa*), the *Ficus Prolixa*, and the *Ficus Indica*, which give a sap containing the elements of indiarubber, grow abundantly in Tahiti and its dependencies. In 1850, rubber tree known under the names of *Hevea Brasiliensis*, *Hevea Guyanensis*, *Siphonia Elastica*, or *Jatropha Elastica*, was introduced into Tahiti, and the results obtained are reported to have been excellent. Nothing since, however, has since been done in the matter, although it is admitted that the production of rubber would add materially to the resources and revenues of this country. The trees most suitable to the climate of Tahiti are alleged to be *Hevea Brasiliensis* and the *Castilloa Elastica*, whose seeds are said to germinate naturally in the ground where they fall, and whose sap coagulates best in the open air.—*B. and C. Druggist.*

ELECTRICITY IN AGRICULTURE.—An association of farmers in Bavaria, according to a writer in *Feildens Magazine*, are building large electrical works to supply power for agricultural uses. The current is generated near the village of Schaftersheim, a distance of seven miles from the district of consumption, and is supplied partly by steam and partly by water power. From there it is to be sent at a pressure of 5,000 volts to the surrounding villages, where it will be employed for driving threshing machines, chaff cutters, bruising machines, &c. The motors used are very simple and compact, so that they can easily be handled by farm hands. If this experiment should prove successful, it is almost certain to be imitated in other portions of Germany, as the power used, according to the estimates, is far more economical than horse power or steam power in separate plants ; and there might be a very profitable market for such installations also in our own country.

RUBBER IN BAHIA.

H.M. Consul at Bahia, in his report for 1899, writes as follows :—

"The export of india-rubber continues to augment yearly, the value of this article exported in 1898 being £34,557, against £19,223 in 1897. A few remarks with reference to this product may be of interest. As it is well known the best rubber comes from Para, on the Amazon, the so-called seringueira. Owing, however, to the unhealthiness of the districts in which it grows, where, as a rule, rubber gatherers perish in a very short time from fever, I venture to express the opinion that it would be advisable for planters of rubber trees to turn their attention to the culture of the mangabeira and manicoba varieties, exported from Bahia. Mangabeira grows almost in any soil in that State, and flourishes in quantities in sandy districts, where absolutely nothing else can be produced. In certain zones of the interior, fertile in good rich red soil the tree yields more than four times the quantity of milk than when growing on sandy lands. This tree, besides the rubber milk, yields a most delicious fruit called Mangaba. Were it not for the difficulty in planting this variety, which requires from eight to ten years before yielding, would be the rubber tree of the future. Considering, however, all the circumstances in favour and against the foregoing varieties, the manicoba tree shows many advantages over the others to make it a commercial success. It is easily planted, either from seeds or saplings, grows in six or eight months in any kind of soil to a height of six feet, and will begin yielding a considerable quantity of milk in about three years, far more in proportion than any other rubber tree in existence. I am personally acquainted with the planter, who, on his extensive property, has, during a short time past, planted over 100,000 manicoba rubber trees, and informs me that he intends increasing his plantations to 1,000,000 trees, with the full conviction that this industry, in a few years, will show extraordinary results."—*India-Rubber Journal*, August 6.

THE PRESENT STATUS OF RUBBER PLANTING.

(FROM "THE INDIA RUBBER WORLD," MARCH 1ST.)

The utility of India-rubber is of course established. In every industry and art to which it has been applied successfully the demand is increasing, while new uses for the material are being developed all the while. These conditions obtain not only in the countries where rubber goods long have been in use, but they are becoming true of all the rest of the world. No advance in the cost of rubber checks its use. To take the United States alone, the imports of rubber have increased of late as follows :—

Year.	Pounds.	Import Value.	Average Price
1897 ..	42,159,129	$21,670,019	51·4 cents.
1898 ..	44,236,070	25,937,108	58·6 ..
1899 ..	54,408,495	34,219,019	62·9 ..

This increase of consumption exists in spite of the success attained in reclaiming rubber from worn out goods, which material is now used to the extent of many millions of pounds yearly. Chemistry has not yet availed to produce a practical substitute for rubber. So-called substitutes are in wide use, but the best of these is of value only for combination with true rubber. The supplies of natural rubber are, practically speaking, inexhaustible, but they are for the most part confined to remote countries, sparsely settled with uncivilized people, under climatic and other conditions which make them uninhabitable for white men. Doubtless the output of rubber from the Amazon or the Congo might be doubled in a year if American or European laborers could enter the forests to collect it, but this is utterly impossible.

Such conditions naturally have directed attention to the possibility of bringing rubber under cultivation, as has been done with many other products which once were found only in a wild state. Practica rubber culture in any country is yet to be developed, though the total result of experiments in many parts of the world points to success. Wherever rubber trees flourish naturally it seems reasonable to suppose that trees grown from planting the seeds will yield rubber as well as those which grow from chance. Besides, under cultivation more trees could be placed on an acre than exist usually in a square mile of forest area, so that, in the end, it may prove more economical to produce rubber on plantations than to gather it in wild lands free to all comers.

In the United States interest in rubber planting has been directed largely to southern Mexico, on account of proximity, to stable political conditions and general conditions of development there, to the salubrity of the climate, and to the fact that the isthmus of Tehuantepec is the natural habitat of a tree *(Castilloa elastica)* which yields a rubber of good quality. To-day experiments are in progress on a large scale in planting rubber in this district, with encouraging prospects on the whole, but it does not yet seem advisable for persons at a distance to invest an important part of their resources in a business the ultimate conditions of which cannot be said to be thoroughly known, without due consideration and a reasonably comprehensive study of the situation at close range. The inducements which have been held out in certain quarters to attract capital for rubber planting enterprises make the following suggestions pertinent.

A given species of rubber tree cannot thrive beyond certain limits of latitude. Thus the *Castilloa elastica* cannot withstand frost. Its growth must be confined within certain limits of altitude above the sea. It will not succeed without a certain amount of annual rainfall, certain conditions of temperature, a given degree of humility. Besides, the character of soil will affect the result. The mere fact, therefore, that the *Castilloa elastica* is found in the forests of a given State does not prove that it may be planted successfully in every locality in that State.

A fact which has largely discouraged the planting of rubber is the time required for the growth of the trees. While seven years is usually mentioned as the earliest age at which the *Castilloa elastica* may be tapped, there is rubber in the plants from their very beginning. Doubtless the longer tapping is delayed the greater will be the yearly yield, and the longer the life of the tree. At the same time conditions may exist under which rubber may be gathered at an earlier age, and the high prices might make it profitable to bleed the trees freely, even at the risk of shortening their life. It is possible that in time *Castilloa elastica* may be cultivated as an annual or biennial crop, the plants being pulled up by the roots and all the *latex* extracted by mechanical and chemical means.

All these and some other considerations point to the desirability of careful investigation of any field before investing in lands for the culture of rubber—or any other plant the success of which depends upon so many conditions. It is well not only to look into the matter personally, but to secure the advice of experts in tropical planting. While the cultivation of rubber may in the end prove a safer investment than gold mining, it is quite as important that the proper location be chosen for a plantation as for a mine.

Some estimates of the possible profits from rubber in Mexico are based upon the idea of planting the Para rubber tree *(Hevea Brasiliensis)* there. The Para tree positively cannot thrive there. The price of Para rubber is also used in the estimates, but no rubber which Mexico is capable of producing brings within 25 per cent. as much as fine Para rubber. Nor should the New York or Liverpool prices of rubber be used in estimates, without reckoning cost of transit from the plantation to New York or European markets, including also insurance and brokerage. Many

estimates are based upon an impossible yearly product. The price of land is another important item, since profitable planting may be out of the question with too great an initial outlay. Prices of land generally speaking are much higher in our new possessions in the West Indies, than in Spanish-American countries, and certainly it is far too early to speculate on the opportunities in the Philippines, besides which the *Castilloa* is not indigenous there and we must naturally look to Government experimentation to determine its adaptability to those islands. The labor supply and the cost thereof should be considered, in comparing one country with another.

No doubt it may be found practicable to plant rubber in some countries where it is not now found native, but this should be attempted cautiously. Even within such limits of latitude, altitude, climate, etc., as are found to favor the *Castilloa elastica* in Mexico it might not be possible to grow this species in another country, owing to some subtle difference in the soil, which would prevent the trees from yielding rubber, even should they grow freely. It is interesting to note that the United States government is planning a series of experiments in the West Indies and the Philippine group to demonstate to the world whether rubber can be produced in these islands.

San Juan del Norte, Nicaragua, Dec. 21, 1899.

To the Editor of the *India Rubber World*:—Your letter was duly received. I failed to reply on receipt of same, as I wished to get all the information possible regarding rubber planting. From what I have heard from several friends who have tried this business, and spent a great deal of time and money, I would not advise any one to start into the planting of rubber, at least in Nicaragua, as I am convinced that rubber is "no good." A friend of mine started three years ago and planted 12,000 rubber trees in the woods, underbrushing and thinning out the woods, the same as the natives do. They are now about as thick as a lead pencil and from two to three feet high, and he writes that it will take; at the rate of growth, a hundred years to produce anything.

If the ground is thoroughly cleaned the trees grow rapidly and will begin to produce in seven or eight years, but will it last? The rubber cannot be tapped with a bit, as the wood of the rubber tree is soft and spongy like the balsa tree; it immediately swells and fills the hole, and scarcely a drop of milk exudes. The tree must be tapped by entirely removing a piece of the bark with a sharp instrument, so as to obviate the filling of the wound by the wood swelling, and, furthermore, a small cut will only drain the milk from a very small distance on either side of it, so that to get any rubber from a rubber tree it will have to be badly mutilated, and the milk is the very life blood of the tree. Will the tree stand constant bleeding, healing, and wounding, long enough to pay the interest on the money invested for the seven or eight years one has to wait, to say nothing of the principal? I am sure not. I have been looking into this carefully, and find that after a tree has been cut three or four times, no matter how carefully, it shows signs of decay. The rainwater gets into the wound and finds its way under the bark, fermentation sets in, wood ants and beetles get in their work, and then good-by rubber tree. To plant rubber properly costs just as much in the first instance as to plant cacao, which produces a crop in the natural manner as fruit, which can be gathered without any damage to the tree; it is only a question of fertility of soil, and a little care to make the cacao tree a constant producer for an indefinite time, or comparatively so. You will probably hear from me again on this subject.—CHARLES D. SCOTT.

Apropos of the slow growth of rubber plants, Thomas Christy, of London, contributes to *The Tropical Agriculturist* some notes on planting *Castilloa elastica* in Mexico. Plants from seeds sown in the sun measured at one year 5⅜ inches in diameter, and 4 feet 2 inches high. Plants from seed sown in the forest at the same time measured only 12 to 14 inches high. Certainly the experience of the planters mentioned by Mr. Scott, does not agree with that of several correspondents of *The India Rubber World*.

A VETERAN PLANTER.

Mr. J. M. Vermont, of Province Wellesley, Penang, in writing to us about his "T.A.," refers to a paragraph in which Datu Meldrum mentioned his great age as a pioneer. Mr. Vermont writes:—"The paragraph that appeared in the *Ceylon Observer* a month or two ago with reference to myself as to my age is an error. I am entering my 74th year; but although much troubled with rheumatic gout, probably brought on by exposure in developing the three estates, I am still able to knock about, but of course not as active as in my youth."

ZANZIBAR CLOVES.

An American consular report on the trade of Zanzibar during 1899 says that the crop of cloves last year was the largest ever produced, being 8,061,259 lb. in excess of that of 1898. Notwithstanding this large crop, the Consul says that the clove plantation, particularly in Zanzibar Island, are not being cultivated in a way to keep them up to the past standard, for since the prohibition of the importation of slaves the supply of labour has diminished with increasing rapidity each year, and since the decree of 1897, granting freedom to the slaves, the labour supply has been quite inadequate to meet the demands. How this statement is reconciled with the fact that a much larger crop was gathered last year in spite of the labour-scarcity we are at a loss to understand.—*Chemist and Druggist.*

THE STATE OF AMAZONAS, BRAZIL, AND RUBBER.

CONSULAR REPORT FOR 1900.

Last year the British Consular agency in Brazil was strengthened by the appointment of a Vice-Consul at Manaos in the Amazonas. The first result of this arrangement is the presentation of a really capital report by the new Vice-Consul, Mr. Charles Lindsay Temple. This paper, which has been printed by the Foreign-office among its Consular Reports for 1900, is very interesting and instructive reading from a geographical point of view, with much graphic and descriptive merits also. It indicates the physical geography of this river-kingdom, which is the upper, or more properly speaking, the middle basin of the Amazon—the almost entire submergence of the area, when the mighty floods are out and the waters cover not so much the earth as the forest—the rapid subsidence of the all-pervading inundation, owing to the natural drainage and to the sun's rays.

One special feature is the preparation of caoutchouc or india-rubber, which is the main product of this forest-clad country. This article has always been largely used in Britain for waterproof clothing. But of late years the use for it has multiplied owing to the demand for the wheel-tyres of bicycles. Evidently the Vice-Consul has expert knowledge of all that relates to this valuable article, and this experience is embodied in the report with scientific accuracy and practical lucidity. Such an exposition must be important to those who are intercsted in this branch of trade.

Apart from this staple, there is a careful analysis of every item of export and import. Inasmuch as this vast territory of 600,000 square miles has its scanty population of 600,000 souls, largely engaged in producing certain things which the nations need across the seas, it follows that the people must largely depend on those nations for their food, their clothing, and the needs of their civilisation, though it must be admitted that this civilisation is for the most part not

very high. Thus it arises that their trade is both comprehensive and diversified. The report enters into every item of export and import, with some adequate remark upon each.

Some special facts or considerations may, however, here be noted. The dominant factor in the Amazonas trade is the indiarubber. Indeed, of the production of the world, 57,500 tons, about half, or 25,000 tons, comes from the Amazon district; of the other half, the greater portion, or 24,000 tons, comes from the East and West Africa.

The crying want will not be capital or communication—that by water being peculiarly abundant—but labour, which is, as yet, too scarce. RICHARD TEMPLE.

—*Journal of the Society of Arts*, Aug. 10th.

MAGALIESBERG TOBACCO INDUSTRY.

MR. F H HARTLEY INTERVIEWED.

ADVENTURES AND EXPERIENCES.

An interesting interview appears in the current number of the Natal *Agricultural Journal*, in the course of which Mr. F H Hartley, of Magaliesberg whose brand is so well-known to lovers of Boer tobacco, offers some remarks anent the early days of South African colonisation, and the present position of the tobacco industry in this country. *Inter alia*, he said:—"Magalie is the name of the chief who held the district when the Boers took the country. I bought my land there Vaalbank—in 1869; opened a store and soon afterwards started a mill, getting my power from the Magalie River. Since then I have spent at least £20,000 on improvements of one sort and the other. When my first mill became too small for the work I built another, and a short time ago I built the third, the best and most modern in the Transvaal at any rate. The machinery is driven by a turbine, and I can turn out really first-class flour. The Magaliesberg wheat is splendid. Everything except mealies is irrigated. The cultivation is limited to the water available on the farms. The south side of the range is much better than the north which is too hot. There they get weevil and moth into the grain much more than we do, and the rust is worse. So far as my observation goes, rust is bad according to the warmth of the nights. The Australian wheat was not up to ours in quality. The times for planting are oats in April, wheat in May, and as soon as oats are off the tobacco goes in.

Magaliesberg has had its reputation for tobacco for a long time. My father in his hunting days used to send presents of it to his Cape friends. The Voortrekkers soon discovered the suitability of the locality, and they took much intelligent care in the preparation. Nearly all the farmers in the district now cultivate it. On many of the farms Boer men, women and children work at the cultivation. Yes, the Boers, like other races, work if they can't help it. In debt? Yes nearly all. The continual subdivision of the land on the death of the parents is producing a class of Boer quite different to the original type. To convey an impression of the soil and climate to a Natal man it might be described as somewhat like the Tugela district near Colenso. The light red soil is best. Exhausted? Yes; manure is necessary everywhere. For tobacco cattle manure only is used—horse and sheep would spoil the tobacco. I cultivate about 40 acres, and there are very few, if any, who do more. In most instances the quantity is very small.

I started cutting and selling in bags in 1874 on a small scale. There was a lot of prejudice to overcome in introducing cut 'boer.' After the retrocession of the country, the Cape clapped on a duty of 2s per lb, so that limited me practically to the Transvaal, the then Free State and Natal. For a long time only Europeans who had been accustomed to cut tobacco would buy it. The Free State took hardly any; there they had never seen or heard of tobacco other than roll. They are an ultra conservative lot. You will remember what a struggle there was among farmers before the sulphur matches gave away to the safety kinds. In the Natal papers I advertised largely, and the brand became so popular among the British generally that I had to increase my plant and give up advertising. But it was annoying to be limited—I could not get the tobacco for the demand. I had to keep up the quality and competition regulated the price. The goldfields brought a big rush for cut tobacco. At first I bought from the farmers in the roll at 6d per lb, but there was such endless trouble about the moisture—nearly every farmer trying to impose upon me more water than his neighbours—that I resolved to end the constant wrangling by buying only in the leaf, and now I buy at from 3d to 9d per lb. It is necessary from business motives to buy the bad as well as the good. The good is sold in my bags under my name; the bad is cut up and sold on the Johannesberg market in bulk—with no guarantee—for what it will fetch. When ripe the plant is cut down and hung in sheds or under trees. There is not enough labour for a better way. By-the-bye, I might mention that during the British occupation the troops gained a liking for "boer" and for several years I got orders from all parts of the world, including Hongkong.

In dry seasons insects of course, are troublesome especially cut-worms. In a good season we look to get ¼ lb. per plant, and an acre should carry about 5,000 plants—that's 1,250 lb. to the acre. And rattoon or second crops produce about half as much. For, merly when the land was richer and more manured there was often a third crop. On the northern—the hotter side of the range—they still go in for third crops. The second crop was preferred by many Boers for smoking, and the first, the strongest for chewing. All genuine Boers are chewers as well as smokers. The habit, however, is growing out of fashion especially—among those who come into touch with civilisation. It might be worth mentioning that I am interested in a tobacco-growing experiment in Gazaland. I believe the country is splendid there for tobacco, coffee and other things. Tobacco will grow all the year round. There is no fever there; on the high land there the frost began this year in the middle of May.

"As to the proposals in England to settle time-expired soldiers in the Orange River Colony and the Transvaal, it is a difficult question to answer off-hand. The desirability in some respects is obvious, but to succeed in farming in any part of South Africa—putting aside racial and similar considerations—requires above all, local experience—which fact new-comers will rarely believe—and, secondly considerable capital. Farming except on the large scale of the old Boers must be mixed and to avoid disaster much and varied local knowledge is necessary. Again it must be remembered that as a farming country the Transvaal is extremely patchy, as patchy as Natal,"—*Natal Mercury*.

RUBBER PLANTING COMPANIES.

ENTERPRISE IN AMERICA.

The Mexican Coffee and Rubber Growers' Association (Philadelphia), incorporated in Delaware to acquire the property and concessions of the Grijalva Land and Coffee Co., Limited. The Grijalva properties include 100,000 acres in the districts of Mesealapa and Pichucalco, in the state of Chiapas, Mexico; about 60 miles southwest of San Juan Bautista, capital of the state of Tabasco; and front for twelve miles on the Grijalva river, navigable by the company's steamboats to Frontera, on the gulf coast.

The Palma Real Co., with a paid up capital of $1,500,000, have been incorporated under the laws of West Virginia, to acquire 68,000 acres in the

state of Vera Cruz, Mexico, to be devoted to the planting of India-rubber and other tropical products.

The Nicaragua Rubber and Agricultural Co., incorporated in Delaware, September 26, with $250,000 capital, own 8,105 acres of land in Nicaragua, purchased with a view to planting India-rubber and bananas or other fruits, on the Rio Coco, 80 miles inland from Cape Gracias. They offer to sell shares of stock, each to carry a certain amount of land planted with rubber and fruits, to be paid for in instalments.

The Isthmus Plantation Association of Mexico has been organized at Milwaukee, Wis., for the development of the lands known as the Hacienda del Corte, on the isthmus of Tehuantepec. The estate comprises 10,000 acres, and it is reported that 200,000 coffee trees and 40,000 India-rubber (*Castilloa elastica*) trees have been planted.

The Chiapas Rubber Plantation and investment Co., described as an American corporation, is mentioned in a letter from the city of Mexico as owning 12,335 acres of fine rubber lands in the Rio Michal valley, in the state of Chiapas, and having planted more than 3,000 acres in rubber.

The Government of Peru announces that concessions for rubber lands cannot be transferred without the *concessionaires* having obtained consent of the national authorities.—*India-Rubber World.*

GOLD REEFS IN BURMA.

Of the reefs with payable gold referred to in today's Government Resolution on the Geological Survey Department as discovered in Burma, the first is the Choukpazat Reef, in the Wuntho District, which has several associated veins besides a second reef half a mile to the north, and two veins of 900 yards to the north-east. Mr. Stonier finds it contains some free gold which can be extracted by simple machinery. Part of it is already being worked, the vein stone giving in all 14 dwts. of gold to the ton. The second is the reef discovered by Mr. Stonier about 14 miles north of Baumauk. It consists of quartz 9 ins. thick and where tested contains 9 dwts. of gold per ton of soil, also about 2 per cent of copper.—*Madras Mail*, Aug. 27.

COFFEE IN QUEENSLAND.

Though this, like rice, is grown upon the coast side of the main range from Cooktown to the Tweed Heads, the tendency is towards cultivation in the tropics, where plantations are now being cultivated upon a commercial scale. It has only been within the last three years that the interest shown in this product has demanded the attention of the Registrar-General from a statistical point of view, but from that time the increase in area has each year shown a fair advance. Taking the last two years for an example, it will be found that in 1897 there were 180¼ acres of productive coffee trees and 130¾ of non-productive, and in 1898, 199 acres and 233 acres respectively. The figures show an evident advance in the area planted, and the information to hand points to the statistics of the present year being yet more favourable. The imports for 1898 were 170,886 lb., and upon that basis there is room for the use of 602 acres before we overtake our consumption, which, upon the present population of 498,523, is at the rate of 456 lb. of coffee per head each year. The market in Europe, however, is good, and though we may not yet have learned how to offer our goods in the most attractive manner, the opinion expressed by the trade in London upon Queensland coffee is very favourable, and by the time we are in a position to place a fair quantity for export that method of preparing our coffee will have been attained, and we shall be able to compete with those countries wherein coffee-growing has been prosecuted for centuries. The appointment of Mr. Newport as instructor in coffee culture has given an impetus to this branch of tropical agriculture, and as he has also an intimate knowledge of what may be termed allied products, such as spices, the benefits to the farmers of the North will be greater than was anticipated. The death of Mr. E Cowley, and the exigencies of the Diseases in Plants Act at Cairns has precluded Mr. Newport, up to the present, from giving that attention to instruction he would have wished, for the reason that he was retained in Cairns to supervise the nursery, and to attend to the inspection of fruit. Arrangements have, however, now been made to release him from that detention, and his services will henceforth be at the command of the coffee-grower. A report from him upon this subject is attached herewith.

PEPPER CULTIVATION IN MALABAR.

Pepper *(Piper nigrum)* is grown in Java, Sumatra, Ceylon and other Asiatic countries, but that which comes from the Malabar coast is acknowledged to be the best. The only taluqs in Malabar in which pepper cultivation is largely carried on are Kottyam and Kurumbranad. The conditions most favourable to pepper cultivation are said to be copious rains, abundant dew in the night, and a gravelly red soil. These are found in other parts of Malabar, so it is not understood why the cultivation is chiefly confined to these two taluqs. Two varieties of pepper are produced in Malabar—the black and the white. The fruit is gathered green when intended for black pepper, but must become quite ripe for white pepper. White pepper differs from the black only in being stripped of its covering. After stripping them, the black berries are steeped in salt water, and when they have been exposed to the sun for several days the chaff is rubbed off with the hands. The process of cultivation is very simple. The vine is generally propagated by cuttings. It is usually planted at the base of trees, the most commonly used being *Murikku* (Erythrina Indica); other trees, such as the jack, cashewnut and mango-tree may also be used, but they are not in favour with the Malabar cultivators.

The first thing required for forming a pepper garden is to clear all jungle and root out all stumps of trees on the ground. This must be done by the middle of May. The *Murikku* standards, on which the vine is trained, should then be planted and about half a dozen cuttings of vine—each about 2½ feet in length—should be planted at the foot of each stem. The soil should then be turned up by digging, and the cuttings tied with a fibre on to the *Murikku* crop. The tying is necessary to facilitate the growth of the vine, which sends out small roots at every joint, which strike into the *Murikku* stem and enable the vine to climb up the prop. In three or four years the vine attains a height of six feet.

The vines begin to bear in the third or fourth year, and in four years more are in full perfection and continues so for 20 years when they die. They blossom about the month of June, and begin to bear fruit in the following two months. The gathering season is January to March. The plant requires constant rains during the blossoming season. The expenses of cultivation incidental to farming and maintaining pepper plantations are variously stated. But it may be stated approximately that a plantation of one acre will not cost more than R300 together with an annual expenditure of R10 for its upkeep. The outturns of the pepper harvest are also variously stated. The yield ranges from one to

three bharams per acre (one bharam being quivalent to 660lb.) It is stated that a single vine produces from one edangali to four edangalis of dried pepper. There is no doubt that pepper cultivation is highly remunerative, and it is a pity that it is not carried on more extensively than it is at present.—*Indian Agriculturist*, August 1.

HUNTERS THE TEAMEN, LIMITED.

MORE PROSPERITY.

The third ordinary general meeting of the shareholders in Hunters the Teamen, Limited, was held on Thursday, at the Mitre Hotel, Manchester. Mr. George Ollerenshaw, chairman and managing director, presided.

The directors reported that there was a profit on trading of £34,183 14s 1d., and after payment of all expenses a net profit of £24,964 5s. 5d., which showed an increase on the preceding year of £5,555 2s. 3d. This amount added to £2,508 2s. 1d. brought forward made a total available profit of £27,472 7s. 6d. The preference dividend for the year had been paid, and an interim dividend on the ordinary A shares at the rate of 10 per cent, per annum, and on the ordinary B shares at the rate of 7½ per cent. per annum, and £3,000 added to the reserve fund. The sum of £13,334 17s. 6d. remained available for distribution. The directors had made the payment of a dividend at the rate of 10 per cent, per annum on the A ordinary shares and interest and dividend at the rate of 10 per cent. per annum on the new issue as per agreement, and now recommended a dividend at the rate of 12½ per cent. per annum on the B ordinary shares (making 10 per cent. for the financial year on the A and B ordinary shares). It would be remembered that in March last a further issue of capital was made, viz:—20,000 A ordinary shares at 10s. premium. This premium had been added to the reserve fund. In addition to the above £3,000 and £10,000, it was further recommended that the sum of £5,000 be added to the Reserve Fund, making the same into £22,500, and the sum of £4,487 7s. 2d. be carried forward.

The Chairman moved the adoption of the report and balance sheet. He said he was again in the happy position of being able to report progress and increased profits, the result of a largely-increased turnover. The new shares had been readily taken up by existing shareholders, and application had been made to the Manchester Stock Exchange for quotation of the new shares. Gentlemen connected with the provision trades well knew that the markets during the past few months had gone dead against the retailer, and under such adverse conditions the net profit was highly gratifing. The reserve fund of £22,500 must be very agreeable news to owners of B shares, for in the ordinary course of things their shares must a year hence rank equal to A shares.

Mr. S. J. Bradwell seconded. Each year, he said, they seemed to meet under brighter auspices. Their success was not so much in an increase in the percentage of profits as in a large turnover at about the same expense.—*Grocers' Journal*, Aug. 4.

A SUGGESTION FOR MAKING GREEN TEA.

I am going to try and make green tea, but so far I have no sailing orders. I am afraid that my tea will be different from that made by others. I imagine that there must be two or three men available who know how to make green tea who could be secured as instructors. These men could be deputed to visit the different districts and instruct the managers within a given circle, and others from a wider circle could come in and attend the demonstrations. The instructor should actually make a whole break, and all concerned should make tea on the same lines and submit samples. Whatever appliances are required should be obtained beforehand, and everything prepared to make a large quantity of tea of *one quality and character*.

It would have been better to allow a bonus of 1 anna per pound, and half fee to the instructor, *i.e.*, R6,250 for 200,000 lb., or better still, R12,500 for instructors and ½ per pound bonus. The most important points in the new venture are quantity and uniformity. We have fixed the quantity at 200,000 lb. but have taken no steps to get equality of character, so that the 200,000 lb. will be split up into several sorts of tea. I do not believe that the political troubles in China will have any effect on our chances of gaining the American market; we need not hurry ourselves unduly. It will be better to get more system into our attempt even if it incurs a delay. We have not cut out China green teas in America because we have not tried to do so. If we *do* try we can do it, because our leaf is better and our labour cheaper, and because we are more honest. The plan I propose is to find instructors who have already succeeded in making suitable green tea for America.

These men will draw up a list of appliances and have them prepared by a fixed date. Iron pans, steaming cylinders, soapstone, gypsum, Prussian blue, cloth for pressing bags, tea chests of certain dimensions—in fact, anything they fancy. Each instructor would get promises of a fixed quantity of green tea to be made within a fixed circle. He would go to one central factory and *make* one invoice himself; and he would watch the manufacture of the others, and be ready to go and put matters straight if any great difference appeared in anyone's tea. The instructor's work would be done in two or three weeks, and the result would be a break of tea which could easily be matched in the future.

The individual managers would be released of all responsibility, and it really is not fair to ask any man to risk his reputation on an utterly unknown product. Those who succeed will do so *by chance*, and those who fail will be continued as fools if each one is left to mere verbal instruction. It would be wise if the proprietors to give up part of the bonus to secure expeti and experienced instructors. I feel inclined to try 2,000lb., and get R187·8·0 bonus, but I would certainly rather spend this in going to see the tea made by an expert than risk failure.

So much about instructors, but another point which is at present in dispute is the necessity of steaming apparatus. I was recently in Calcutta and had a talk with one who knows how to make green tea, and he says that steaming is done by the action of heat on the leaf. The leaf supplies its own moisture, which heat, (however applied), turns into steam.

Surely it is a mistake to apply "steam" obtained from water outside the leaf! By applying steam, a temperature of only 212 deg. can be given to the leaf, but I have read that leaf can be steamed on red hot pans; it is more than probable that temperatures over 212 deg. are required for making good green tea or Oolongs. Our Siroccos can give heat up to 350 deg., and that would make the leaf steam in about half a minute. I have never read that the Chinese or any Indian green teas in former times required a steaming apparatus.

I see an advertisement on page XIII of 9th August of your paper, stating that the cost of the *necessary* machine for steaming is R600. Would Mr. H D Deane tell us for how long *any* apparatus had been considered *necessary*. This means that the bounty of 1½ annas on 6,400 lb would have to be advanced by the intending experimenter, and most of us would like to know whether steaming by the aid of an apparatus is really *necessary*. May I suggest that steam applied to leaf will make it more moist, so that besides the cost of fuel to make the steam, more fuel will be required to dry off the added moisture. Dry heat extracts moisture from the leaf in the form of steam, and the drying is thus already commenced. A.C.—*Indian Gardening and Planting*, August 23.

A FARMER'S EVERY-DAY LIFE IN SCOTLAND.

No XI.

(By "Cosmopolite.")

AGRICULTURAL SHOWS.

The month of July is dedicated to the Agricultural Shows of Scotland, and, from the Borders to John o' Groat's, the roaring of cattle, neighing of horses and squealing of pigs awaken the many welkins of the land of the mountain and the flood. All papers, agricultural and otherwise, are crammed full of exciting prize lists of show animals, and even Chinese massacres and Boerish victories occupy but a secondary place in the news of the day. But six columns of cattle show, day by day, is a little trying, and with this "white man's burden," the agricultural newspapers have been solidly and unreadably funereal for some time past. But in the boundless monotony of farming life, we could ill spare our cattle shows, and although the judging may not be all that we could desire, perhaps it is better for us "to bear the ills we have, than fly to others that we know not of." This year the judges have been more severely dealt with than usual, some of the exhibitors even going the length of refusing the tickets awarded to them, because the judging displeased them so much, one special grievance being the fact that a first-prize ticket was actually given to a horse bred by the judge himself, and said to be about the worst in the ring. Doubtless, there is much reason in the old farmer's remark, when, having been asked why he did not exhibit any of his fine stock at the shows, he replied:

"FIRST BREED YOUR JUDGES."

A good deal depends on luck in a show ring, but the best bit of luck that can come one's way is to have the judges as personal friends, or one of them the breeder of the animal you exhibit. I once got the Champion Cup for the best Clydesdale in the show-yard, and this prize I carried off with a filly that had bad splints on the forelegs and was a shiverer; but I only let her go to the Show just to please my grieve, as I myself would never have dreamt of sending her as a likely winner. But my luck must have been in good working order that day, although the result only made me, thereafter, lose what little confidence I had in show-yard judging. I do not know if the unsatisfactory judging has been the means of driving visitors away, but the fact remains that Agricultural Shows are not so well attended, now-a-days, as formerly, and the only way to bring forward a bumper attendance is by introducing into the programme a military tournament or a Punch-and-Judy show. Last year the great attraction at one of these Shows, down south, was a prize given to the "ugliest dog in the show-yard." This novelty was so effective that the sum collected at the gate was "a record." I drew the attention of our local Agricultural Show Committee to this, and said that I thought I could put my hand on six or eight dogs, in this district, that, for ugliness, would take a deal of beating and make an exciting competition. I even advised them to go one better than this, and include the ugliest owner, so as to make a pair. Ugly people do not often have a chance to win prizes, and this would be a grand opening for them, and I think it highly probable that such a competition will be included in the programme of our next season's cattle show.

THE HOLIDAY EXCURSION SEASON

has been in full swing during the past month, and the picnic hat is gaily blooming tra-la-, so that farmers have been pestered by trippers trespassing over their parks, leaving their gates open, and making themselves an abominable nuisance in general. Trains, in consequence of the travelling crowds, have been systematically behind time, and cattle trucked for certain markets are apt to arrive after the sale is over. The trippers never think of these things,—what do they care for a hereafter, absolutely nothing?—so long as they can get their own enjoyment, let the farmers look after themselves; and this we have had to do, sometimes with very bad grace I must admit, praying all the time that the end of the picnic season might soon come, when the revellers will stay quietly at home, and swear off the fermented juices of the vine, the barley, the potato and the gooseberry.

Our cattle also are greatly disturbed by the omnibuses and char-a-bancs driving past, the rioters shouting lustily at the top of their voices, generally accompanied by an artist on an accordion, who, between the songs, drives dull care away by solemn and uncertain airs with variations. On one occasion I found my cattle, with tails erect, galloping for dear life, and then there burst on my view, driving along the road, a huge picnic party headed by a brake containing the town band, which had been commandeered for the occasion, the drum, which met with such a terrible accident on Ladysmith night, having been effectually repaired. As the party drove past me, they were letting off a song of joy of their own composition, and I plugged my ears with my fingers and hastened away to see that none of my cattle had been terrified to death by these outrageous junketers.

THE CROPS.

Had a stranger visited our district this time last year, and then come again now, he would scarcely be inclined to believe that it was the same place. Last year we were suffering from severe drought, the grass was burned up, the hay crop was almost *nil*, corn was short in the straw, and turnips were a complete failure. This year, owing to a warm and drippy season, everything is looking its very best, and, taking my own farm as a sample of the district, I never saw such a quantity of grass, I never cut a heavier crop of hay, my turnips are simply perfect, and my oats have the appearance of proving a profitable crop. I am not one of those whose cry is always a lament; when there is anything to be grateful for, I am glad to show my gratitude; and this year our crops leave nothing to be desired, except that

PRICES

may rule high when the time comes for us to sell. Beef and mutton continue at a satisfactory price, and, in this respect, the

war has helped us, and there is a prospect of prices keeping up for some time yet. The rich pasturage has caused store cattle to rise considerably in value, indeed it is difficult to get them at anything like a price that would leave a profit, but, as one must have his grass eaten down, I have been compelled, although I have no great liking for

IRISH CATTLE,

to purchase a mob of these, merely to eat down my grass, that is running wild. These cattle were bought in Limerick market on a Friday, and, the following Friday, I bought them at my nearest auction mart, so they have not been knocked about, from pillar to post, in the way that so many of these Irish cattle are treated for weeks before they are bought, and then, as a consequence, they take months to recover from the bad treatment they have endured. I trust that my mob may prove the advantage of getting this class of cattle as quickly as possible from their native wilds on to our good pastures, and that they may thrive exceedingly, and leave a handsome profit.

PLANTING NOTES.

METHOD OF MAKING WOOD FIRE-PROOF.—The latest method of making wood fire-proof is that of a Mr. Joseph L Ferrell. The timber is not steamed in a vacuum, but the fireproofing solution is forced into it by great hydraulic pressure, amounting to 1,500 lb. on the square inch for some hard woods. The solution is a secret, but is neither volatile, corrosive, nor hygroscopic, and the timber, after treatment, is kiln dried so as to leave only fine crystals in the pores. A house of this wood is uninflammable. Boxes made of it and placed in a fire of pitch-pine kept documents in them, it is stated, unscorched for 23 minutes, although the outside of the box was charred.—*Globe*, Aug. 10th.

RUBBER EXTRACTION.—We have been favoured with another letter on this subject from our esteemed confrère, Mr. A. Godefroy-Lebœnf, of Paris. He reports that the extraction of rubber from bark by a patent process has proved a success, and that a regular manufacture in this way will shortly be commenced. We trust our correspondent will keep us fully informed as to the success of this new factory, and if any of our rubber planters are enterprising enough to send us a kilo (2⅕ lb.) of any bark he would like to have experimented with, we shall see that it is sent forward and the result duly reported.

INDIAN TEA ASSOCIATION.—We are in debted to Mr. James Peter, Secretary to the Sylhet Branch of Indian tea planters, for a copy of the detailed Report of the general Committee of the Indian Tea Association for the year ended 28th February 1900,—Including list of gardens belonging to the Association corrected to the 30th June 1900, with proceedings of the Nineteenth Annual General Meeting held on the 22nd May 1900.—There is much valuable information in this volume to which we shall refer from time to time.

THE PROFITS of the Russian-American India-Rubber Co., at St. Petersburg, for the last business year are reported at 2,941,906 rubles, against 3,945,222 roubles, in the year 1898—99. The dividend will be only 35 per cent., against the customary yearly dividend of 50 per cent.—*The India Rubber World*. Aug. 1.

JAMAICA IS PURELY AGRICULTURAL.—Walking in the country and making enquiry, one soon discovers that seventy-five per cent of the people are unable to answer with any certainty the following simple questions:—"How long does it take from the time of planting for a banana, or pine apple to commence fruiting, and how long after the fruit appears does it take to ripen?" "How long does the coffee or orange take to ripen after the blossom appears?" Of those who read ninety per cent could not answer. Yet these are things that we cannot avoid seeing before us, year after year. Our young men will not take kindly to agriculture: they all want to be Clerks and Gentlemen, I hear repeatedly day by day, something sorrowfully, and frequently sneeringly. Now this is partly true, in as much as a boy who has been "educated" at an elementary school is very apt to look down on the small cultivator as beneath him, and how can he be blamed? Can he not write and read, what is the good of his education if he is to go and hoe grass? His teacher in all probability is above planting a rose in a pot, and he has unfortunately for himself and his country, never seen a white man with a spade in his hands. "Buccra" don't dig, therefore it cannot be a good thing.—*Journal of the Jamaica Agricultural Society*.

YERBA MATE TEA.—Some of our Consuls in South America refer in their last reports to the virtues ascribed to the tea made from yerba maté, a herb which takes the place to some extent of tea or coffee, and which is derived from the leaves of the *Ilex Paraguariensis*, a tree of from 12ft. to 20ft. in height. Our Consul in Paraguay says this tea is consumed by a large proportion of the populations of Brazil, the Argentine, Uruguay, Chile, and Paraguay. The leaves are gathered every two or three years and dried over a slow fire; they are then pounded in mortars in the ground, and finally packed in fresh skins and dried in the sun. The tea is made by pouring boiling water on the leaves, which serve for several infusions. The taste is bitter, but not unpleasant, and the effects are asserted to be invigorating. It is said that it would be valuable as a restorative to troops on the march and on active service, and the French Goverment have ordered a shipment of maté for the colonial troops, and some samples have also been sent to Germany for experimental purposes. An attempt is also being made to introduce it into the United States as a suitable beverage for the working classes. When analysed the tea is shown to contain caffeine and cafetannie acid in important proportions. The Consul-General at Rio also refers to the subject as one of commercial interest. It is claimed, he says, on behalf of the tea that it possesses superior stomachic properties to tea and coffee, in that, while it is refreshing and invigorating and favourable alike to mental and physical exertion, it does not disturb the nervous system. But even Brazilians are not agreed as to its merits, some alleging that by its aid the most arduous work can be done, such as forced marches of troops on short rations; others asserting that in war coffee has proved much more sustaining. However this may be, it is largely consumed in South American countries when the prices of low grade China teas are too high to admit of their shipment to South America, and it is therefore possible that it has some good qualities to recommend it.—London *Times*, Aug. 9.

THE FEDERATED MALAY STATES: PROGRESS IN EXPORTS AND PLANTING:—COFFEE, SUGAR, GUTTA, RUBBER, &c.

The Resident-General, Sir Frank Athelstane Swettenham, K C. M. G., has good reason to be proud of the continued progress and marked prosperity of the group of Malay States entrusted to his care. He has profited by observing the course of administration in India and Ceylon and taken care to avoid, as far as possible, acknowledged blunders, and to adopt any feasible improvements on the older systems of administration. The result is to make the "Federated Malay States" an object lesson to colonial administrators in the tropics, of the most interesting and useful character; and we now look forward to Sir Frank Swettenham's Administration Report from year to year, as sure to bring before us a record of good and progressive work and to contain much matter of special interest to all intelligent observers. The latest Report now before us is no exception to the rule. The revenue for 1898 (9,364,467 dollars) was the highest up to that year; but the return for 1899 is no less than 13,486,410 dollars—an increase of nearly 50 per cent! The total value of imports into the Federated States during 1899 was $33,765,073 against $27,116,446 in the previous year. The exports were valued at $54,895,139 against $35,241,003 in 1898. The *increased* value of trade was therefore $26,302,763. The tin exported was valued at $46,139,399, and beyond this, the local products exported were, Malay coffee, $530,232; sugar, $1,283,165 (nearly all from Perak); and gĕtah, $289,009, of which more than half was from Pahang. Of the four Federated States (Perak, Selangor, Negri Sembilan and Pahang) the first contributes nearly half the revenue, Selangor coming a good second; while the other two do not make together 1½ million of dollars The surplus of revenue over expenditure last year was very nearly 2 million dollars! But the Resident-General is all for progress and writes:—

I have suggested the raising of a further loan of £500,000 and the construction, at a cost of about one million sterling, of a section of about 175 miles of railway from Seremban in Negri Sembilan (the terminus of the sanctioned extensions) to Johore Bharu, whence a short crossing by ferry-steamer and the Singapore Railway would take passengers from Penang right down the Malay Peninsula to Singapore. The growing prosperity of these States, our financial position, the present price of tin and the approaching completion of the Railway construction now in hand, make the moment peculiarly favourable for an undertaking which has so much to recommend it, and would confer such manifest advantages on the Malay State of Johore and the Colony of the Straits Settlements.

Here is what the Railways have done in 1899:

The Malay open lines of Railway gave a revenue of $1,722,474 in 1899 against $1,394,720 received in the previous year. Comparatively few miles of new line were opened for traffic, but work was advanced all along the extensions. The results would have been better had it been possible to get even a fair force of labour on to the work. With tin at its present price, and immigration almost at a standstill, it is impossible to get labour for public works or planting at anything like a reasonable price.

It is very strange how development is checked by want of labour, and how difficult it seems to get the want supplied even from famine-stricken India. India and Chinese labourers are both so scarce or so much in demand that wages have doubled in a few years and even treble the old rates have to be paid. The Resident-General and his Government are, however, taking energetic measures to overcome this obstacle.—Here is an interesting paragraph on a vexed question:—

As is natural in a new country—that is, new to the rest of the world and modern methods of government—the year has been fruitful in legislation. There is no need to enumerate the Enactments passed, but we are on the eve of laying before the various State Councils some very important measures which have been under consideration for years. I allude to the Civil and Criminal Procedure Codes and the Courts Enactment. All these will probably be law before this report reaches the Secretary of State, and when brought into force, the present jury system will be abolished in favour of trial by a judge and assessors. If trial by jury is a suitable tribunal for such a mixed community as is found in these States, we are not yet ready for it, because we cannot supply the intelligent English-speaking and English-understanding jury on which its success must depend.

The working of the amended system in the States will be watched very critically we may be sure. As regards "planting," here is Sir F. Swettenham's deliverance—labour again being the trouble:—

Many Europeans have wisely planted rubber, coconuts and other products likely to do well should coffee fall to a price which would not admit of profitable cultivation. In the Negri Sembilan some of the planters have carried out the project for establishing the Coffee Curing Store to which I alluded last year. In other ways the Government is trying to second the exertions of a class whose efforts deserve encouragement. The export duty on coffee was suspended while the price fell below $19 a pikul, and steps are now being taken to establish an experimental plantation under the supervision of a thoroughly qualified Superintendent whose advice and experiments will, it is hoped, prove of great service to planters. The great difficulty is labour, and while the Government has, for the last two years been trying, not without some little success to foster immigration from India, a special appeal will be made to the Indian Government in the hope of obtaining its co-operation in our efforts to transfer some of the surplus population of that country to the Malay States.

Finally, we must close this very cursory and imperfect review of an able Report, by referring to a paragraph which at this period of "wars and rumours of wars" is of exceptional importance:—

The Regiment of Malay States Guides continues in a state of high efficiency. A large number of satisfactory recruits offered themselves for service and there was no difficulty in keeping up our full strength with men of the standard hitherto insisted upon. The Regiment maintained its reputation for good shooting and great attention was given to this part of the training. Three hundred men were offered to Her

Majesty's Government for service in South Africa but they were not required. They are ready for service there or elsewhere and when called upon will give a good account of themselves.

A regiment of Malays could not fail to be of great use, in China or even in India, should the necessity arise for its transfer; for, no people have a higher reputation than the Malays for courage and persistency as soldiers when well led.

GUTTA-PERCHA.

It is one of the strangest facts in the evolutional history of man that the discovery of the insulating qualities of gutta-percha should have been so nearly coincident with the demand for such a material, when ocean telegraphy became a pressing need. India-rubber, a similar gum in many ways, forms no reliable substitute, especially because it has been found to deteriorate in sea-water, while gutta-percha not only improves under the enormous pressure of the deep-sea waters, but appears to be absolutely imperishable: a material, indeed, of essential consideration when the cost of an ocean-cable may possibly exceed a million of money. India-rubber, too, presents many technical difficulties in its application; pure it is useless, and vulcanised the sulphur comes in as an uncertain agent. Hence, it is very doubtful, if gutta-percha had not "turned up," that ocean telegraphy would even now been practically useful. Here at once we appreciate what a debt we owe to the poking and prying investigator who saw this gum, tried it, and utilised it in other ways, and thus paved the road to the discovery of its insulating capabilities, of which he certainly never dreamt, being an untutored and unknown native Malay.

In 1843 one Jose d'Almeida, a Portuguese engineer, first sent over specimens of native-manufactured whips, knives, hats, &c., to the Royal Asiatic Society. A little later Dr. Montgomerie, a surgeon in the service of the East India Company, noted the peculiar faculty it has of softening in hot-water, and subsequent hardening in the shape then given; the idea of surgical splints was thus suggested to him. But it was not, according to some authorities, until 1848 when Prof. Faraday took the substance in hand that its higher destiny began to dawn upon the world, though it is claimed on behalf of Dr. Werner Siemens that he had suggested it as an insulating medium in 1846 to the Prussian Government. In any case it eventually proved to be precisely what was wanted, and curiously enough, though it is now approaching half a century since it began to be used, and the comparative scarcity and difficulty of supply has stimulated research in all directions for a substitute, it still remains master of the situation, since it only requires to be cleansed and purified to be available for the purpose in view. The gum is yielded by several trees of kindred species, but chiefly from Isonandra Gutta, now mainly met with in Borneo, though first recognised in Singapore. Like all native products found to be marketable in savage countries, the utmost improvidence prevailed in its collection, the trees being ruthlessly cut down and drained of their sap; and as it takes twenty-five years for a tree to attain a size capable of yielding an appreciable supply it is easy to see that even primeval forests, dotted only as they are with trees of the right description, are sure soon to be entirely depleted. In 1881 alone, the export justified the belief that no fewer than 5,000,000 trees were felled in Borneo, and as these are hewn down in the midst of younger ones without any consideration for the latter, it has been estimated that five times as many were destroyed.

Although few people can grasp the idea of the enormous number of trees which go to form wide-spread forests, the expert will gather from these figures that the waste is frightful, and would mean in time practical annihilation if it were permitted to continue. Fortunately, as in the case of the Cinchona trees which yield quinine, so soon as the value of these native products is established, and a constant demand begins to threaten extermination, the botanist lends his aid, first, by determining exactly the specie best fitted to yield the supply; secondly, by inducing its cultivation in other parts of the world which his study leads him to think are congenial. The practical collector, too, replaces the savage, and finds that a partial draught from time to time upon the tree's resources can well be borne, so that the "goose with the goden eggs" is kept alive, and becomes a perennial source of profit. The Dutch have introduced the gutta-percha plants at Buitenzorg, and the French into Cochin China; and thus, with a judicious check upon the extirpating native methods in the original forests of Borneo, Sumatra, and elsewhere, it is to be hoped that an adequate supply will be maintained and that we shall not find our transoceanic nervous system paralysed some day for the want of its proper integuments.—*Chas. T. Druery, F.L.S. V.M.H.* —*Gardeners' Chronicle.*

RAISING ORANGE-TREES FROM PIPS.

Mr. W. H. Hand, of Mount Pleasant, Penrith, asks for information as to the best method of raising orange-trees from pips. His idea is to establish a little nursery in connection with his citrus orchard from which to supply young trees to replace those that die off from *mal di goma* or any other cause.

The Fruit Expert, Mr. W. J. Allen, says:—The pips for growing orange stocks should be taken from seedling oranges, as they make the best and most vigorous trees. The pips may be allowed to remain in the oranges until the warm weather in spring, when they are taken out and planted in a bed prepared as follows:—If the land is not a nice sandy loam, cart in several loads of sand and mix it with the soil, to which add, if procurable, one bag of well-rotted sheep manure to every bed 4 feet wide by 8 feet long. Great care should be taken to get the manure, soil, and sand thoroughly mixed.

Plant the pips about 3 inches apart to a depth of three-quarters of an inch, after which mulch the top of the beds with well-rotted, dry, fine manure scattered over the top to a depth of a quarter of an inch. This should be watered with a fine rose-pot every other day unless the weather be very dry and hot, when it should receive a good sprinkling every day. The beds should be protected from the sun by using frames raised from 12 to 18 inches above the bed, and covered with hessian or light brush fastened to them, so that the beds are sheltered from the driest rays of the sun, which would possibly burn off the young plants as they show above ground. As the seedlings grow, the covers can gradually be discarded, until at length the plants are robust enough to require no further shelter. The latter part of September is a good time to plant the pips. —*Agricultural Gazette* of New South Wales.

PREPARING VIRGIN LAND FOR FRUIT-TREES.

A Correspondent at Lindfield, who is about to plant out a few trees for domestic use, asks:—

1. How deep has the virgin ground to be broken up?

2. How long before you plant should it be prepared?

3. What manure (if any) should be given to each tree?

The Fruit Expert. Mr. W. J. Allen, reports:—(1) Wherever it is possible, it is always best to break the ground to a depth of at least 15 inches—that is, loosening the subsoil, but not bringing it to the top. (2) It is always well to prepare the ground a few months before the planting season, so that it may have an opportunity of sweetening. This however, is not absolutely necessary, but is always advisable. When this

cannot be done, the desired result may be achieved by applying lime at the rate of 1 ton per acre. This dressing is essential for nearly all the land about Lindfield. The lime loosens and sweetens the soil, and the trees will thrive from the start. (3) If horse or sheep manure is obtainable, it would be well to give each tree about four shovelfuls of sheep, or double that quantity of horse, manure. This should be worked into the ground about a foot away from the young tree after it has been planted, but should not on any account be allowed to come into direct contact with the roots, otherwise it might kill the tree. The best plan, unless there are facilities for thoroughly watering the tree from time to time, would be to put any manure on the surface. The rain will wash the good of manure into the ground for the benefit of the tree, and the remainder will serve as a mulch. It will probably be necessary to have the area devoted to fruit-trees drained. If the sub-soil is sticky, and does not readily crumble when exposed to the air for a few days, draining will be essential.—*Agricultural Gazette* of New South Wales.

INDIA-RUBBER IN BOLIVIA.

(*By Manuel Vicente Ballivian.*)

The producing regions may be classified naturally according to the points from which the rubber is exported.

First Region.—Because of its importance, the region of acre occupies the first place, and in order to obtain the figures of total production shown in the general table for the republic (No. 1), we have been obliged to recur to private, but trustworthy, sources of information, such as Mr. Charles Satchell, ex-commissioner of national boundaries in the fixation of the boundary between our frontier and Brazil, in company with the chief of the Bolivian commission, Gen. Jose Manuel Pando. The quantity of 2,000 metric tons [4,409,200 pounds] annually is in complete accord with previous data communicated to us by the second of the gentlemen just named. A few days ago we read with much pleasure the report presented to the secretary general of the government, by our ex-minister in Brazil and ex-national delegate in Acre and Purus, Mr. Jose Paravicini, a document in which much information is given with reference to this important region. It is shown here that the population of this zone is practically 10,000; the number of *barracas** 100; and that the rate of taxation fixed on the export of India-rubber is 20 per cent. *ad valorem*, on an average price of 10,000 reis, or 5 bolivianos, on each kilogram. This being true, the revenue would amount to 2,000,000 bolivianos.† Owing to the rebellion in Acre, we are obliged to give, in the above-mentioned table, the tax prescribed by law, namely, 16 centavos and 12 centavos respectively, for fine gum and *sernamby* [coarse].

Acre is the official port for the exports of this region, which include a part of the rubber gathered on the upper Tahuamanu, and it is situated 4½ miles from the boundary line marked by the Bolivian-Brazilian commission. This line, however, has been disputed by engineer Cunha Gomez, but even if the present boundary should not prove exact, the one proposed by him is drawn at only 1,600 meters distant, so that this port remains in territory unquestionably Bolivian.

Second Region.—This is comprised in the zone watered by the rivers Madidi, Alto Beni, Bajo Beni, Orton, Manuripi, Tahuaman, and other lesser streams—all being rich in *seringales*. This region includes the territory known as the national delegations of Madre de Dios, Acre, and Purus, excepting that part which finds a natural and more convenient outlet in the Acre river. The export port of the second zone is Villa Bella, at which is situated a national custom house. This town is situated on the high land at the confluence of the Beni and Mamore rivers. The production indicated in the general table has been furnished to us from the official documents of the custom house mentioned.

Third Region.—This zone comprises the forests which produce rubber in the department of La Paz, or, the cantons of Challana, Songo, Mapiri, Huanay, Goroico, and a part of the province of Campolican. The outlets for this region are Puerto Perez on Lake Titicaca, and Punto and Mollendo in Peru.

Fourth Region.—The fourth region is situated in the north and east of the department of Santa Cruz de la Sierra, formed by the province of Velasco, bordering on the Brazilian state of Matto Grosso. It is in this region that the rubber is gathered along the Paragua and Verde rivers, at the most remote points, and where labor is hardest to obtain, and this is the reason for the difference in duties imposed, they being 12 and 6 centavos, respectively for fine gum and *sernamby*.*

The province of Cochabamba possesses the rubber tree in the Yuracares region; and, judging from the important discoveries recently made there, followed by petitions for concessions of *estradas*, it is probable that this region will become no less in importance as a rubber region than La Paz, for the conditions of soil and climate are identical. With public peace assured, and legislation which consults the best conditions for fostering this industry, we do not doubt that Bolivia will become one of the principal regions for the production of this important article of commerce.

La Paz, November, 1899.

The rubber movement from Bolivia will be facilitated by another steamer which has been placed on Lake Titicaca, which serves as a channel of transportation between Bolivia and Peru. The new steamer "Coya," of 550 tons, was built at Dumbarton, Scotland, and transported to Mollendo, on the Pacific coast, whence it exported the grade of rubber known as "Mollendo." It was carried from the coast in twenty-two cars up the railway, along the steep slopes of the Andes, the lake side. Then it was put together, and the boilers and engines installed. The distance traversed by the steamer is 100 miles, the journey occupying about ten hours.

EXPORTS OF RUBBER FROM BOLIVIA IN 1898.

CACAO CULTIVATION FOR INDIA.

To the Right Honourable the Secretary of State for India, Whitehall, dated Grass Mount, Forest Hill, S.E., 4th May, 1900.

"My Lord, I have the honour to submit for your Lordship's consideration the following remarks relative to the practicability of cultivating Cacao (Theobroma Cacao) in India under conditions peculiarly favourable for adoption in that country. Thus I venture to submit this proposal in view of the desire of the Government of India to develop the agricultural industries of that country, Your Lordship having recently stated in the House of Commons (*vide* the *Times*, April 4th) that the Government would do everything they could to try to vary and diversify the occupations of the Indian people."

From a report of mine on the Agricultural Products of Tolima, Colombia, issued as a Parliamentary paper by the Foreign Office, (1895) No. 379, I extract the following relative to this cultivation :—"In the South of Tolima, it is interesting to note, this cultivation is pursued on a considerable scale with great success, under the influence of irrigation. The region in question is characterised by prolonged droughts, and the application of irrigation has thus proved most advantageous. Cacao thus produced has become quite an important industry. Planters in British Colonies will be glad to learn that the plant is amenable to systematic irrigation, a condition that assures the extensive cultivation of the plant in comparatively dry regions, for excessively humid conditions of climate have been deemed indispensably requisite for the plant." Some plantations in Tolima are not irrigated, but those that are irrigated, far surpass in productiveness than the others.

The cacao planters of Tolima, who grow for and transport to Bogota and surrounding country thousands of mule loads of this article annually, have been forced by circumstances to adopt irrigation in consequence of the greatly reduced rainfall experienced during many years owing to the wholesale destruction of the forest in the district for the wide extension of pastoral husbandry. In this connection I again quote from my aforesaid Report :—"The thousands of square miles of natural pasturage on the plains and lower hills of Tolima assume during the rainy season the mossy beautiful verdure. But in the alternate season of drought the general aspect is that of a desert."

Besides being well acquainted with this culture in Tolima I have traversed hundreds of square miles of forest in another province of Colombia far distant from Tolima, throughout which I found cacao growing wild. In Colombia, under cultivation cacao flourishes from the hottest plains up to 4,000 feet above the level of the sea, hence its adaptability to a considerable range of latitude—*i.e.*, the great zone within the 25th parallels of latitude—this in the New World. Doubtless in the Old World the range would be somewhat more limited.

Plantations of cacao, in countries wherein it is largely cultivated in the ordinary way, are established under the shade of lofty trees which are planted in order to afford the requisite shade to screen the plantations from the scorching rays of the sun.

Cacao cultivation under the alternative method herein propounded, that is the irrigation method, is most beneficially influenced by this necessary condition of shade, inasmuch as a considerable amount of moisture by evaporation from the humid earth is diffused amidst the trees consequent upon the double umbrageous canopy of foliage over the land. Large plantations are thus benefitted more than small ones. Thick belts of forest trees surrounding the plantations contribute to the desired condition of humidity, as well as protecting the cacao plants from the injurious effects of strong prevailing winds.

A communication read to the Agricultural and Horticultural Society of India in 1883 states : "There is another product to which attention might be directed with advantage, namely cacao. All attempts to raise the *Theobroma Cacao* in Bengal appear to have failed : the tree attains a certain age and then dies. But there are other parts of India where the climate might be found suitable to its production."

It may not be amiss to add in this connexion, by way of indicating the facility with which cacao plants are introduced to other countries, that I introduced in 1673, under instructions from the Governor of Jamaica, Sir John Peter Grant, all the best Trinidad varieties, having visited that island for the purpose to Jamaica, where they have flourished, and where their cultivation is now carried on on a large scale. I also introduced to Colombia some of these varieties both from Trinidad and Jamaica, and this too very successfully. Furthermore, during recent years, cacao has become an important product of Ceylon.—I have, etc., (Sigd.) ROBERT THOMSON.

A NEW METHOD OF EXTRACTING RUBBER.

(SPECIALLY TRANSLATED FOR "INDIAN GARDENING.")

In the issue of the *Revue des Cultures Coloniales*, dated 5th February, to hand by last mail, the editor writes :—"A new way of extracting caoutchouc destined to transform the methods of gathering, of cultivation and preparation, has been frequently talked of in the press of late. We have asked M. Godefroy-Lebeuf, the well known colonial horticulturist, who is associated with that discovery, to be kind enough to explain its origin and consequences. The following is the letter which he has addressed to us upon the subject :—

To Monsieur Milhe-Poutingon, Editor of the *Revue des Cultures Coloniales*.—You have asked me for information on the extraction of caoutchouc from bark. You have an absolute right to do so, for it is, thanks to you, that I have been able to obtain, through the intervention of M. Le Cesne, the first elements of our researches. I say "our" for as soon as I was in possession of samples, I communicated them to all who interested themselves in the question. At first I anticipated that the solution of the problem would be effected by the employment of chemical processes, and naturally I engaged my searchers in following that view. We were far from suspecting that the method of extraction was very much more simple than we had foreseen. By means of the distribution of samples a scrap of bark fell, by the help of M. Wehry, into the hands of M. M. A. and V.. of the Museum. While these gentlemen were triturating the mass they found that the pounding eliminated easily a great proportion of impurities ; they pushed their researches deeper, obtained a little mass of gum mixed with bark, ascertained that the gum gathered itself together, and that the particles of caoutchouc agglomerated they continued the mechanical action and obtained at last caoutchouc sensibly more fit for use than the average of the gums which we receive from Africa.

"These gentlemen wished to associate us in their discovery, and it is thus that the Arnaud Godefroy-Lebeuf, Verneuil and Whery patents were taken out.

"Our process is remarkable in the sense that it permits the extraction of cautchouc from the smallest scraps of wood, twigs and bark which contain it.

"In spite of the rough instruments, which I use, whenever you wish it I engage to extract from plants of less than six months, nay of less than three months from sowing, an appreciable quantity of caoutchouc and appreciable to such a point that I ask myself if the annual culture of caoutchouc plants will not be industrially possible. The bark must have been dried as a necessary preliminary ; with green or fresh material I could not affirm anything.

"Note that our processes are based upon the *Landolphias* and *Hancornias*, I believe without having experimented, that they may be applied to the *Ficus*, *Willoughbeia*, *Urceola*, *Parameria*, *Mascarenhasia Crygtostegia*, and to all plants which contain fibres of caoutchouc in the dry state.

"And now, here is what we base our process upon. The caoutchouc coagulates in the tissues of the plants in proportion as they dry, in such a way that a parcel of bark and roots is nothing but a parcel of very impure caoutchouc. It is a question of eliminating the impurities.

"Take a scrap of bark of Thol, *Landolphia Hendeloti*, dry it. When dry, take a mortar and pound the bark for a minute. This done pass the whole through a fine sieve. You remove 10 per cent. of dust, rub in your hands the broken scrap, there will come out more dust. Repeat the operation five or six times and you will obtain a "malga" composed of fibres of caoutchouc mixed with particles of bark.

"When you have pounded it enough you place the 'malga' in hot water, boiling in the strictest sense, but only during a few minutes and you pass the whole through a sieve, which will allow the particles of bark to pass with the water so saturated with tannin that this product alone, perhaps, will pay the expenses of extraction.

"You again pound the little mass which remains in the sieve; the splashes resulting from the action of the pestle fix themselves on the sides of the mortar and may be removed by washing ; after some operation you obtain a mass of caoutchouc still impure, but of which the impurities do not reach 10 per cent. of the weight of the gum. With a little patience one finishes by getting rid of all. In order to refine the gum we pass it between cylinders abundantly moistened and we obtain perfect caoutchouc. This is a laboratory experiment which I will make under the eyes of your readers if they ask it of me; the treatment by the ton per day necessitates apparatus which we shall see produced shortly.

"The *Landolphia Hendelotii* give easily 6, 7, 10, 15 per cent. of their weight dry (bark); I take but 7 per cent. as an average. In this way 10,000 kilos of bark would give 700 kilos of caoutchouc. I estimate the price of bark at 100 francs per ton on the spot, the expenses of extraction at 70 francs per 70 kilos ; we obtain then 70 kilos for 170 francs. Our process is applicable everywhere, it requires but primitive appliances for small operations and if one does not wish to push the cleansing to the end.

"As for the mode of operating with creepers which grew again when cut, here is the experiment which I invite planters to make.

"Let them divide their concession into 10 equal lots, cut and treat by our process all the creepers which grow in lot No. 1 from the first year, and renew the operation in the following years in the other lots. They will thus have ten cuttings, which will give them such results that they will not hesitate to take care of their creepers and increase them.

"I engage to obtain in a single treatment of the richest creeper ten times more gum than could be obtained by tappings. Note that we do not only treat creepers which are fit for tapping, but the feeblest, since the plants of a few months give already an appreciable part of gum.

"When *Landolphia* is dealt with, the manipulation is hard enough, the fibrous bark not breaking without protest ; but with *Hancornia speciosa*, it is easy. That bark does not contain more than 5 or 6 per cent. of caoutchouc ; that at least, is what I have obtained by primitive process ; but the bark is very friable reducing to powder almost instantly under the pestle. The gum disengages with very small effort.

"I cannot find a better comparison as regards the process than with the extraction of gold from quartz. Gold exists in all parts in the quartz as caoutchouc exists in the dry plant where it is coagulated. Break the quartz, break the bark, eliminate and separate the gold and the caoutchouc ; there, in two words, is all the operation."—*Indian Gardening.*

PRODUCE AND PLANTING.

THE TEA TRADE OF RUSSIA.—Through the Foreign Office, the Board of Trade have received a copy of a despatch from the British Commercial Agent at St. Petersburg, in reference to tea. It states that the consumption of Ceylon teas is increasing in Russia. Much tea comes to Odessa, though mostly in transit to Moscow, where it pays duty. Some 7 500,000 funts (1 funt equals 14½ oz) of tea were cleared at Odessa last year, much more than in 1898, thus showing that Odessa is gradually becoming a big tea market at the expense of Moscow, which hitherto monopolised all the tea trade of Russia. Moscow, as the great tea distributing centre of Russia, is much concerned by present events in China. According to local papers, big tea firms are buying up all supplies possible. Large quantities of black tea are en route, partly by the Volunteer Fleet steamers, "Kherson" and "Yaroslav" the former from Colombo, the latter from Singapore. Private telegrams say the stocking of reserves at Hangkow is impossible, as also the Kiakhta route while two companies decline insuring. Large stocks have been brought up, but without facilities as yet for shipment. The St Petersburg dealers, it is said, have met together to consider the advisability of raising prices for retail sale, and rumours say they are inviting the co-operation of Moscow firms. Haukow and Foochow, especially the former, are the chief markets for Russia's purchase of tea Of 1,511,000 poods of Bohea imported into Russia in 1898 over 1,000,000 came via Odessa. The remainder, as also almost all brick and cake tea, for the preparation of which Russian firms have constructed special establishments at Hankow, Kiau-Chang, and Foochow, came overland via Irkutsk. 1,106,000 poods of brick tea and 34,200 of cake tea were imported by this route in 1898. The present disturbances affect the most important point of the tea transport routes to Russia. According to the *Commercial and Industrial Gazette* of St. Petersburg the amount of tea exported from China to Russia in 1899 was in piculs (1 picul equals 133 lb) as follows:

	Black.	Green.	Brick, &c.	Total
Via Odessa ..	189,751	5,698	—	195,449
Via Kiakhta ..	197,143	—	340,628	537,771
To Russian Manchuria ..	29,357	29,030	78,266	133,653

THE EFFECT OF CHEAP TEA.—Tea growers have considered that their lot, when compared with the distributor, is not exactly a happy one, and they have looked with envy upon the profits of the large tea dealing firms. But these latter have their ups and downs. At a recent meeting of the National Tea Union, which has not had a successful year, and consequently could not pay a dividend on its ordinary shares, Mr. A. J. Slaney, the managing director, in the course of his speech on the directors' report, said ; "The last three years, including the one just closed to June 30th, have been trying years for the tea trade in particular. With the exception of a few concerns, whose efforts have been mainly directed towards the exploitation of their proprietary lines without the slightest thought or care for the interests of the retailer, I do not think many wholesale firms in our trade have done really well. That which affects us so much is the extraordinary craze for cheapness, and English ladies seem nearly all tarred with the same brush, delighting to boast what beautiful tea they buy at 1s 2d, 1s 4d, and 1s 6d per lb retail. Well, with a sixpenny duty to come off, carriage, manipulation, packing, &c., the margin is very small indeed when a really good article is supplied,

The worst feature has been the increasing tendency of prices downwards, with just this plain fact that we have at times more work for a less turnover, with of course diminished margins becoming beautifully less, until in many cases they almost entirely disappear. The public are certainly getting the best of it, for neither the grocers' nor the wholesalers' profits on tea are what they were some years ago. Naturally we expect to do a shade better out of medium and fine goods, but with dwindling proportions of this kind the position becomes more difficult from a profit-making point of view. To show how fine our trade is cut I may state that a single eighth of a penny more per lb all round would go a long way towards paying a handsome dividend on our shares. As an example take the teas we are selling today at 1s, 1s 1d, and 1s 2d, duty and carriage paid. It often happens that there is barely a half-penny per pound between the cost at the docks, to which duty has to be added, and the price at which the stuff is sold duty and carriage paid to all parts. When you remember that rent, rates, wages, &c., have to be paid, and when a large and increasing proportion of the output is in stuff on which a gross margin of about ½d per lb. only is obtainable, with a decreasing proportion of such grades as might yield us a gross profit, say, of ¾d to 1d per lb, you may realise why our margin for division today is so much smaller than hitherto,"

VENEZUELAN COCOA.—The British Consul at Caracas states that as the prices of cocoa are at present very good it has caused agriculturists to continue extending their plantations, and it is thought that in a short time cocoa will take an equal place with coffee in importance as an article of export. A proof of this is that, notwithstanding the many drawbacks to agriculture, the amount of cocoa exported in 1899 showed an increase. —*Home & Colonial Mail*, August 17th.

THE TEA PLANTERS OF ASSAM AND THEIR AGRICULTURAL CHEMISTS:

THE GREAT QUESTION:—HOW TO MAKE TEA PAY!

THE *Indian Planters' Gazette*, of August 18th, tells us that,—

Mr. H Mann, B.SC., F.I.C., Agricultural Chemist, who has been appointed Scientific Officer for the tea districts, has made a short preliminary trip to Assam, Cachar, and Sylhet, in order to get some idea of the districts and of his line of work. He is now touring through Darjeeling, the Terai, and the Dooars. As the result of his visit to the tea districts in the Assam Valley, Mr. Mann has suggested to the Calcutta Committee that he should devote attention in the near future to an extended investigation of typical soils from each of the Assam districts, to a study of "Blister Blight," of "Thread Blight," and possibly also of "Red Rust," and to an attempt to discover methods for placing the so-called "fermentation" of a tea under better control.

The study of blights and of soils is of importance and of scientific interest, but what planters and all interested in non-paying gardens want to know is,—How can tea be made to pay? Why cannot tea of good quality be made the season through? It is an established fact that at certain periods teas of excellent quality are manufactured, which, do what we will, we cannot turn out at any other times during the season. Why is this? There must be some reason for this phenomenon. What we want to know is how to make good quality teas, the season through from start to finish. A knowledge of the life history, etc., of blights will not help us. A study of the chemical process of oxidation, or so-called fermentation, would lead to more valuable information in the direction indicated. If Mr. Mann will discover the reasons for our not uniformly obtaining the, so much to be desired and coveted, bright, new copper colour to our rolled leaf, he will indeed have performed a signal service to planters. We want to know to what this colour is due, and how we can always obtain it throughout the season. Tea with infused leaf of this colour is bound to be *good*. Why cannot we always obtain it? There must be reasons,—what are they?

REMOTENESS OF THE RUBBER COUNTRY.

Writing of a trip up the Amazon, by steamer, to Manaos, Frank Leslie Rockwood, in the Lewiston (Me.) *Journal*, mentions meeting another steamer which "had been away from Para for one year, up one of these unexplored rivers, and had not been heard from. There were rumors that the Indians had got her, but here she was, loaded with rubber, and full of wild, half naked passengers, just returning from a successful trip. They could tell experiences that would seem improbable in the present day, but this great Amazon river and its branches will not be explored for fifty years yet, as some fighting has to be done to see it all." It is not strange, in view of the assertions made by this correspondent, that the English shareholders in Amazon shipping lines do not get larger dividends. He mentions a profitable local trade along the river, all the profits of which are pocketed by the officers of the steamers, "who get rich out of it." It is such conditions as are here suggested that have the most important bearing upon making rubber an expensive commodity.—The *India Rubber World*, August 1st.

PLANTING NOTES.

A CAMPHOR TIP.—The *Evening News* is advising its readers who are putting away their clothes to buy what camphor they need at once, as events in the Far East are likely to lead to much higher prices. The information, however, is a trifle late, and is only another instance of where the *irresponsible adviser* shows his incorrect knowledge.

PROTECTING YOUNG TREES.—To protect young trees from ants and borers it is recommended to wrap the tumps with tarred paper. Dig away the earth so that the tarred paper may be put well below the surface. Fold the paper about the trunk and tie tightly round the middle and bottom. This prevents the entrance of insects to lay eggs under the bark. When the paper is in place put back the earth above it, and tie the top of the paper closely to the tree.—*Journal of the Jamaica Agricultural Society.*

THE VALUE OF NUTS.—It is said that the Nut trees of the world alone could, if necessity arose, provide food all the year round for a total population three times greater than the present. It has been pointed out to the Washington Department of Agriculture that Brazil Nuts around Para grow in such profusion that thousands of tons of them are wasted every year; with Coconuts it is the same in many centres.—*Journal of Horticulture*, August 16th.

COFFEE CROP SITUATION.—The Brazilians have furnished four crops from July 1, 1896, to June 30,1900, averaging 9,200,000 bags, against the four previous crops, averaging 5,000,000 bags. Production for four years has so largely overtaken consumption and the visible and invisible supplies are so heavy everywhere that in order to obtain and secure higher values there must be something in the way of a crop failure, and it is by no means a question of eight or nine or to 10 million bags.—So say Messrs. W H CROSSMAN & BRO, of New York.

COST OF PLANTING RUBBER.

(To the Editor of the *India Rubber World*:)
In your issue of July 1, under the heading of "An Experiment in Costa Rica," you state that "nowhere exist to our knowledge, data to justify any particular calculation of the cost of planting and bringing to a productive age rubber trees. It might be more or less than $40 per acre." I will give you figures from actual experience. Planting trees fifteen feet apart each way or 196 to the acre, the cost of planting would be per acre:

	$
Underbrushing land	2
Thinning out timber	4
Transplanting	2
Costs of plants from nursery	1
Total	9

To bring the trees to a productive age, viz. eight years old, all that will be required is to keep out the undergrowth. To this, I think, all who understand anything of the nature of the growth of rubber will agree. This cleaning will not be as much work as the first underbrushing, as the growth will not be as heavy at first. But, allowing it to cost the same as the first underbrushing, or $2 per acre, there will be one cleaning the first year, six months after planting; and after that two cleanings a year for four years, then one cleaning per year for two years, a total of seven years, bringing the trees to their eighth year, when there will be a product of one to three pounds of rubber per tree, from which expenses can be paid.

The total cost cost of planting and bringing trees to production is, per acre:

	$
Planting	2
First year, one cleaning	2
Second year, two cleanings	4
Third year, two cleanings	4
Fourth year, two cleanings	4
Fifth year, two cleanings	4
Sixth year, one cleaning	2
Seventh year, one cleaning	2
Total for planting and bringing to production	31

My reason for cleaning but once the sixth and seventh years is, that the trees are so large that the light undergrowth will have no effect, if the cleaning is done once a year. Believing that this will be of value to you with reference to the cost of producing rubber, I remain, yours very truly,

ASSISTANT MANAGER, The Indiana Rubber Co.
Goshen, Ind., 21st July, 1900.

A BISHOP ON DIGGING.—After distributing the prizes to the successful scholars of the Hampton Grammar School on Wednesday, the Bishop of London said he always thought it would be a good thing that every boy should have some definite manual work. He was not sure that digging would not be a good thing—digging hard for one hour. Our first parents had to perform that very primitive pursuit. It was one that had to be done in the primary tussle with Nature, in which, after all, we were engaged, and which civilisation had produced. Everyone ought to know what hard manual labour meant, and he should be glad to see its application take a place side by side with the more highly developed curriculum of which we were so proud.—*Journal of Horticulture*, August 16th.

ST. HELIER'S TEA COMPANY, LIMITED.

The eighth annual ordinary general meeting of the shareholders of the St. Helier's Tea Company, Limited, was held today in the office of Messrs. Bois Bros. & Company, agents and secretaries, when the following report by the directors was submitted:—

ACREAGE.

250 acres in bearing.	
29 do	planted in 1896.
34 do	do 1898.
313 acres.	
114 do	Jungle, &c.
Total	427 acres.

The Directors have now the pleasure to submit their Eighth Annual Report to the 30th June last, which they trust will be considered fairly satisfactory by the Shareholders.

The crop, which was estimated at 95,000 lb. of made tea to the 30th June, has turned out 108,110 lb., but has realised an average price of 35·29 cents per lb. only, as against 38·69 last year.

The cost of the tea in Colombo, exclusive of the sum of R2,667·53 expended on Capital Account, works out at 24·65 cents per lb., as against 25·56 cents per lb. last season.

The balance at credit of Profit and Loss Account, after writing off the sum of R1,572·64 for depreciation of buildings and machinery, but including the sum of R705·42 brought forward from last year, amounts to R2,784·10: and out of this sum the Directors recommend that a final dividend of 5½ per cent be declared, absorbing R2,750 00, leaving the sum of R34·10 to be carried forward to next year.

Mr. W Sandys Thomas retires from the board by rotation, but being eligible offers himself for re-election.

The Shareholders will have to elect an Auditor for season 1900-01.

There were present: Messrs. W Sandys Thomas (Chairman), Stanley Bois, W Cross Buchanan, (by his attorney, W Sandys Thomas) Percy Bois, H C Buchanan, Miss S J Buchanan and Miss M A Buchanan, (by their attorney (Mr. Stanley Bois).

The report was adopted, and a final dividend of 5½ per cent declared, making eight per cent for the year.

Mr. Sandys Thomas was re-elected Director.
Mr. O T MacDermott was re-elected Auditor.

SOUTH AMERICA when it comes to be systematically opened up by the great capitalists of the world, as will surely happen in this century,— says *Bradstreets*'—and the union of the fluvial systems of the Amazon and the Orinoco, will absorb the attention of the world's best colonists and engineers. A great empire is destined to grow up in that continent, and from the Andes down to the Atlantic and the Caribbean Sea will be witnessed the most tremendous activity. A rich soil, great grazing plains and gold mines of immense resources will be exploited by a new breed of men, the result of an interminglingof the hardiest emigrants from old Europe and North America. South America is a continent that will not be long neglected by the empire-makers of civilisation.

TEA *versus* COCONUTS IN CEYLON.

ERRONEOUS VIEWS CORRECTED; ROOM FOR EXTENSION OF PALM PLANTING.

A correspondent inquires whether we noted an editorial paragraph in the columns of our evening contemporary, a week or two ago, setting up Tea against Coconuts. We had marked the paragraph for comment, but the pressure of other important matters caused us to lose sight of it. After all, what the local "Times" says cannot mislead those who are interested in either product, or in both (as a growing number of planters are); for there is no antagonism between the two. The idea of rivalry in a bad sense is a creature of a disordered imagination—just as was some years ago the attempt to set up Ceylon Tea against Indian Tea, when, really, as British-grown Teas they had a common destiny, namely to oust the China product from its pre-eminence which they have so largely done—though it is equally a morbid imagination which would regard our commercial success as the true origin of the Boxer movement—a *casus belli*, in fact!

Tea and Coconuts are, without doubt, the most important products of the Island; and on them mainly, if not wholly, depends its prosperity. But European and Native alike grow both products, manufacture them, and deal in them; and the success of one in no wise depends on the failure of the other. Where our contemporary of the "Times" got the confused, if not wrong, idea that "some have gone so far as to hint that the various products of the coconut palm were as large in amount as the total value of estate produce," we cannot divine. We presume he means that his "men in buckram" had asserted, or implied, that the total *value* of all palm produce exported was equal to the value of the Tea sent out of the Island; for, of course, one cannot compare the *amount*, or quantity, of one with the value of the other, any more than one is justified in speaking of Coconuts as if they were not estate produce. We have certainly not come across any one who claims equality of value for Coconut and Tea *exports*; and yet our contemporary offers a comparison between the value of the *exports* only of the respective products! We have seen it stated, and we have asserted ourselves over and over again, that one great difference between the two products is this: that, whereas, practically, all the Tea we grow—save at most 1½ per cent—is sent out of the Island and appears in the Export Tables,—only about *one half* of the produce of the Coconut palm (we doubt if so much,) is shipped beyond seas. Even then, however, we are not aware that it has been claimed that the total value of produce of the palm is equal to that of the tea produced in the Island. Apart from other considerations, the latter is valued as a manufactured article, while much of the former is sent away, and most of it is consumed locally, in a raw state. Whether the snuffing-out of Tea or the snuffing-out of Coconuts—may the Fates forfend either blight!—would be the greater calamity to the country and the people, is an academic question which we see no advantage in discussing.

Can it be that our contemporary was thinking of what Governor Ridgeway said when he opened the Legislative Session of 1898, and recalled only a very hazy idea of the comparison then instituted between the chief Island products and the object of the comparison? His Excellency, whether rightly or wrongly, deprecated the pessimistic views then held by some about the position and prospects of Tea; he asserted his own confidence in it: and then compared the condition of trade in 1897 with that of 1877, to show that the Island was far more dependent on Coffee in 1877 than it is now on Tea. When Coffee was at its highest value, was the reasoning, it stood in the Export Tables at 81 per cent of the total value of our exports, while Coconut produce was then valued at less than 4 per cent. The value of Tea exported in 1897 was but 56 per cent; while the products of the Coconut palm had risen to 15½ per cent; and in the interval the total trade had risen from 1,234 to 1,831 lakhs, of which exports represented 611 and 850 lakhs, respectively. The object of the comparison was not to magnify Coconuts at the expense of Tea, but to show that the Island is less dependent for its present and prospective prosperity on one product then, than it was in the days of Coffee—surely an undeniable fact, and a very desirable one at the same time, as it is not only in respect of "eggs" that the concentration of all one's hopes on one object is unwise. It may be mentioned that, although the exports of Tea have increased by 15 million lb. since 1897; yet, owing to the fall in price and the increase of other exports (Plumbago especially), Tea only counts in value for about 52 per cent of the total value of Exports (by the Customs) in 1899; Plumbago counting for 22 per cent; Coconut produce between 14 and 15 per cent; Cinnamon nearly 3; Cacao scarcely 2; Coffee not quite 1½ per cent (what a falling-off for the old king!); Cardamoms and Cinchona together scarcely 1 per cent, and all the rest about 4 per cent.

One other point, however: the Customs valuation of produce is by no means conclusive. It is at best a rough-and-ready estimate; but Coconut products are at a disadvantage in last year's statistics. As we pointed out in a review of the Chamber of Commerce Export Tables soon after their publication in January, there was a falling-off in 1899, as compared with the previous year, in Oil, Copra and Nuts, which represented about 59 million Coconuts or a deficiency in value of about 1¾ million rupees. This was due to the two droughts of last year, which, indeed, told on the crops of this year, as well. But there is evidence of a recovery beginning now; and as we have no present apprehension of over-production in Palm products, we have no hesitation in saying that we welcome the extension and development of the Coconut Industry far more readily than that of Tea,

THE PHYSICAL PROPERTIE OF SOIL.*

The investigation of the physical properties of the soil, its so called mechanical analysis into particles of various grades of fineness, upon which depends to a large extent the amenability of the soil to cultivation and its power of supplying water to crops, has of late years received greater attention than the chemical methods of examining the soil. Whether too much was expected from the chemist, or whether the method itself was essentially at fault, certainly the old way of determining the gross proportion of the principal elements of plant nutrition—nitrogen, potash, phosphoric acid, lime—present in the soil, has often failed to yield information of practical value to the cultivator; hence the German investigators, led by Professor Orth, of Berlin, in analytical matters, and by Professor Wollny, of Vienna, as regards soil physics, have been more and more concentrating their attention on the physical side of the question. The example of the Germans has been followed and extended by the younger school of American investigators in the various agricultural experiment stations that are so liberally scattered over the United States, with the result that the experimental work carried out in the laboratory and in the field on this subject by Hilgard, Osborne, King, Whitney, and others, probably by this time exceeds in amount the whole of the continental work. In England, but little research of the kind has been done, hence the late Sibthorpean Professor has thought it well to prepare—first, for a lecture course at Oxford, and now in book form—a summary of the more important recent investigations, chiefly American, on the physics of the soil, with the view of inducing our younger agricultural teachers to pay a little more attention to questions of cultivation, and a little less to artificial manures. Professor Warrington's book cannot fail to be of service to the serious student of agriculture; it brings together a mass of information that was scattered through scientific periodicals of various dates and countries, whereas hitherto the only place where the English reader could find any general view of the subject was in that excellent little book *The Soil*, published by Professor King, of Wisconsiu, in 1895.

Soil physics, with which the book before us deals is briefly the study of the laws of tilth, of the acts of husbandry as affecting the texture and water contest of the soil; and as Professor Warington maintains at the outset, this question of tillage and management of the land is of far greater practical importance than manuring. Every farmer or gardener is well aware that one mis-timed cultivation may easily ruin all chance of getting a satisfactory crop; indeed, on some soils a single ill-judged operation may throw the land into a bad state that can never be rectified during the whole rotation, until the land goes down to grass again.

The only question is, whether the soil physicist will be able to provide much more practical assistance to the cultivator than the chemist has in the past, and we think Professor Warrington rather exaggerates in its turn the value of a physical analysis of a soil; in the present state of our knowledge we doubt if more can be predicted from it than information of the most general kind, which any experienced man would gain by merely walking over and handling the land on one or two occasions.

Professor Warington in this connection draws attention to some of Hilgard's examinations of Mississippi soils, and Whitney's of Maryland soils; mechanical analyses are given of land suitable for market garden work, Tobacco, Wheat, and grass, and of these he says: "With these differences in physical constitution, the agricultural value of soils, and their suitability for the growth of different crops plainly connected. We could hardly have a better illustration of the great influence of physical structure and of the extent to which this can be revealed by the methods of mechanical analysis." The example given hardly bears out this opinion, the classification (market-garden land, Tobacco, Wheat, and grass-land) is of a very general kind; neither here, nor in any other American work, is there a correlation of the soil analyses with those subtle but real differences in the working of particular soils which the cultivator learns by experience; indeed, we question if the American farmer is sufficiently practised in the finer arts of tillage and management of land to supply the analyst with the information necessary for the interpretation of the experimental results. Such classification as soil analysis gives may be of service to the pioneer opening up new districts, or introducing more specialised crops in what has been a roughly cultivated region; but in a country like ours, where there exists a body of actual experience about the behaviour of almost every individual field, the soil physicist has still to learn from, and not to teach, the cultivator.

Our own experience would tend to show that the problems of soil-texture are too complex to be solved by a consideration alone of the sizes of soil particles. We have found, for example, that soil samples from almost contiguous fields on a well-marked tract of land that possessed special cultural characteristics, yet would vary by more than cent. per cent. in their proportions of sand and clay, although there were no differences in the behaviour of the land to tally with these variations in mechanical composition.

The first chapter of Professor Warington's book is devoted to a consideration of the methods of mechanical analysis. On the whole, he appears to give the preference to the process of grading the soil particles by means of water running at various speeds, which has been brought to the greatest refinement of Hilgard; and Schlœsing's decantation method, which is practised in France and Belgium, is dismissed as crude. But, as Petermann has pointed out in his book on the Analyses of Belgian Soils,* the alkaline solution employed in Schlœsing's method ensures that the material estimated as "clay" shall correspond very fairly in its chemical nature to pure clay, i.e., hydrated silicate of alumina, and with this our experience agrees; whereas the "clay" separated by the other methods is much more largely mixed with sand particles of excessive fineness. Of course, Hilgard's method is of great refiuement in grading the particles of sand. It may be questioned, however, if this refinement is not something of a snare, tempting the observer to consider his work more accurate than is possible from the nature of the material; for our observations seem to show that in a country like Eugland, of a markedly undulating surface, that has long been under cultivation, the mechanical composition of the soil varies enormously, even from field to field on the same type of land.

Chapters II. and III. deal with the relation of the soil to water, the movements of water within the soil as affected by cultural operations like ploughing, hoeing, mulching, and rolling—this is the part of the book that will particularly appeal to the gardener, for here he will find explained the principles that underlie much of his practice in the management of the land, and a proper appreciation of these principles cannot but quicken his observation when at work, and his powers of dealing with a novel situation. The discussion is plentifully illustrated by accounts of actual experiments, mostly carried out in America, and very skilfully devised to illuminate the point at issue; while, as he reads, the thoughtful gardener or farmer will be able to supply a running comment from his own experience.

The last chapter of the book deals with the movement of salts in the soil, with the composition of drainage waters, and the loss of plant food that thereby results, and particularly with the sterility arising from the accumulation of saline residues in

* Lectures on some of the Physical Properties of Soil. By Professor R. Warington (Oxford, Clarendon Press, 1900.

* Recherches de Chimie, &c., Appliquees á l'Agriculture (Bruxelles), 1898.

or near the surface, when the percolation of rain-water through the soil is exceeded by evaporation at the surface. Under such conditions the soluble parts of the soil unused by plants. such as the sulphates of soda and magnesia and common salt, may accumulate to such an extent as to form a white incrustation on the surface that renders the land wholly or partially sterile; this occurs, for instance, in the white alkali soils of America, and again in other hot countries where irrigation is carelessly practised without under-drainage. The phenomenon on a small scale is not unknown to gardeners. Plants kept in pots for some time without a change of soil, and watered regularly with spring or well-water, gather up a hurtful excess of saline matter; and we have seen on a greenhouse Rose-border a characteristic saline efflorescence due to "white alkali" from the water used. The remedy is in all cases the same—to wash the salts out of the soil into the subsoil by increasing the amount of percolation through the soil. Professor Warington might have found an interesting illustration of the point in Sir Alfred Milner's book on Egypt, where he shows how the English irrigatiou engineers found many of the lands had been rendered sterile, because only the old irrigation canals bringing the Nile water to the fields were in use, while the canals at a lower level, which should have returned to the Nile the water that had percolated through the soil, had been allowed to decay. When, however, the drainage canals were restored, and the lands well drowned to wash out the saline matter that had accumulated by evaporation, the fertility returned.

In conclusion, we have to thank Professor Warington for a very instructive book on a little-known subject, that cannot but be fruitful both of thought and of suggestion to the agricultural teachers to whom it is commended, and also to the gardener and farmer. We cannot, however, help wishing that the book were something else—it is after all a compilation that might have been drawn up by another man. What the younger generation of agricultural investigators and teachers would have accepted from the Sibthorpian Professor with even fuller gratitude, would have been a little more criticism and suggestion of fruitful lines of research. The energy of the American researchers in accumulating results is not always tempered by wisdom, sometimes the wood cannot be seen for the trees, and instead of a wholesale commendation of their work, we should have preferred an ampler measure of the judgment and long experience of Professor Warington himself. *A. D. H.—The Gardeners' Chronicle.*

MANURES:

Being a Lecture delivered by Mr. A. P. Hanson, (Agricultural Teacher, Jamaica.)

If there be a subject the study of which the Agriculturist can neglect without doing material harm to himself, it is not the study of manures. In an island like ours whose wealth is only in the soil, and whose population is rapidly increasing, the prudent man looks forward to the time when there will be little or no maiden land to be cultivated, and the success of the Agriculturist will depend entirely upon his skill to accumulate and apply manure. Even now our small land owners are crying out. After one or two years' cultivation of a plot of ground they abandon this latter, which with careful tillage and the application of manure, would yield far more than the badly tilled, so called "strong land," and save the planter the money paid as rent. Only to say this, however, will not bring about the desired effect upon our people. They want to know how to come in possession of manure, but this is not far to seek. The scientist if asked, will tell us of special manures such as sulphate of ammonia, nitrate of soda, &c., but they are far beyond the reach of the ordinary planter, nor does he need be anxious about them, for he has always immediately around him many things that can be turned to valuable fertilizers if only properly treated. Let us look for example, at nature's method, which is always exemplary. Here is a luxurious growth of trees and shrubs. Unlike our cultivated plant, these remain on the same plot of ground for years in succession, and, instead of diminishing, acquire increased vigour and luxuriance every season. They never cry out as our cultivated plants seem to do that the soil is poor. The reason for this can be easily explained. Instead of being removed to some remote place, the leaves, flowers, fruits, &c., of the plants of natural growth fall back upon the soil, decay, and return to it the elements of which it was robbed. In this way the fertility of the soil is constantly kept up. On the contrary, when we cultivate our plants we reap not only the crops, but the leaves, stems, and sometimes even the roots of the cultivated plants, in this way the soil is year after year robbed of its fertilizing elements, and in course of time must become impoverished. The planter should remove from the field nothing but what he requires for home consumption or the market. He should plough into the soil all the leaves, stems, and roots of the plants cultivated, and of the weeds that grow. Besides these latter if permitted to remain will deprive the cultivated plants of their food. If seeds are permitted to seed in the field, this will cause increased labour. If these points are carefully attended to, such a course of procedure will give longevity to the producing power of the soil. In addition to these, we have numerous other substances that can be most effectively employed as manures. Every planter should always be making a compost heap upon and into which he should cast sweepings from the house, the kitchen, and the yard; also hair, blood and bones of the animals that might be killed, rags, the litter from the stable, the goat-pen, the stye, the rabbit-pen, the fowl-house, night soil, dead fowls, and all things that will decay. It is by diut of such carefulness that we can always be in possession of manure to a greater or less degree, manure cheaply got, but of great value. Another instance that comes within the reach of every one, and which claims special attention as a fertilizer is wood ash. Ashes may be collected in large quantities in every home. It contains potash which is required by every plant, and enjoyed by all as a luxury. Therefore, waste not the ashes. but give it to the plants. The common salt also is a valuable fertilizer. But it may be said that they cannot afford to use this as a fertilizer. The elements in it which makes it valuable as such are soda and chloriue. Well, both these are to be found in the ashes above spoken of. It will do well, however, to pour sea water into the holes dug for the purpose before planting the cuconut or sugar cane. In respect to the application of manure to the soil, it must be uuderstood that the parts of the manure used up by the plants must assume a liquid form. The plants cannot take solid bits of food as we do, and water is a great influeuce in dissolving the plant food. When we put sugar in a glass and pour water upon it the sugar seemingly disappears, and the only evidence of its presence are the colour and taste of the water. When we drink this coloured water we drink iu the sugar too. This is similar to what goes on among plants. Water is necessary to euable them to take up and assimilate food. I scarce need state also that the plants send out their roots in search of food below the surface of the ground, aud that before the water can penetrate the earth to bring about the desired result the soil must be properly tilled. Tilled as a rule to the depth of about eighteeu inches, unless the soil before reaching that depth be of such a nature that it will yield no support to the plants. When this ploughing has been accomplished lay over the soil the manure collected, aud bestow a kind of secondary tillage so as to ensure the manure getting mixed with the soil. When there are plants such as bananas, already in the field, the manure need not

be heaped np around the stem of the plant, as the trunk is entirely unable to absorb the manure from without. One way by means of which we oan make the most of the good work wrought upon the soil by manure is by not putting in the same kind of plant every year. All men do not like the same kind of food—all plants do not take up the same kind of plant-food from the soil. If some do, it is done in a varied extent. Again, some are deep feeders and gather up the food from the lower layers of the soil called the sub soil. Others draw from the upper layers called the surface soil, and are called surface feeders. These facts must lead us to see that certain elements in the soil may be left untouched by certain plants. We therefore see the necessity for what is called rotation crops. For example, if yon plant yams on a certain plot of ground this year, do not plant yonr yams on that plot next year, but vary by planting corn, say, next year; then in the third year plant sweet potatoes, and in the fourth year plant peas. Return to yams the following year and retrace yonr steps, under favourable circumstances you are certain to have very satisfactory results. When you have done these things, leave your fields to nature, and she will do the rest—*Journal of of the Jamaica Agricultural Society.*

ARROW-ROOT CULTIVATION.

The cultivation of Arrow-root is, by no means such a difficult thing as may be imagined. It is grown much like the common potato and, after it has once been put into the ground, is in need of no special care: like potatoes it should be sown on soil composed of a due admixture of sand and loam. It will grow well on land where the surface soil is open, sandy and light and not moist at all, although it will thrive better on moist land, the tubers yielding, however, a less qnantity of flour, than when they have been raised on dry ground. Whether roots or tubers, or whether shoots be used, the great thing is to select light open soil, and to break it up thoroughly before planting the shoots or laying down the roots or tubers, so that the new root or tuber may be allowed free and unchecked scope for the fullest development. The earth should then be made up into beds and the shoots or roots or tubers, two in each hole, should be put down at intervals of 12 to 18 inches apart, when they are covered over with leaves to prevent the earth from drying np—these leaves, when decayed, serving as manure and hindering the growth of weeds. Unless in a great failnre or rain, the land sown does not need watering. The sowing should be made in the rainy season, or not later than October or even November. In proportion to the depth to which the ground is dug up and the soil is stirred the tubers become large. No further care is then needed beyond frequent weeding and keeping the roots clean and sweet. Though the crop does not specially call for manuring, it will derive some benefit from a dressing of rotten old dung and leaf mould. The soil is not to be disturbed after the planting till the tubers are fit to be dug up, that is some eight to ten months after. It should be borne in mind that the cultivation slightly varies, when tubers or roots are used. In this case, the roots or tubers are sown on a separate piece of ground, and when the shoots come out they are to be transplanted to the beds specially prepared, and set down at the distances indicated above. Care should be taken to water the roots or tubers till the shoots come out, and to protect them from too much exposure to the heat of the sun. As the plant grows, the roots of each should be earthed up so as to allow of their fuller and freer development. In order to secure tubers of large size and in greater quantities, the flowers should be cut off just as they appear on the plant. When about six months old, the stems and the leaves of the plants not allowed to flower, will be strong and green; while plants that have flowered become yellow and show signs of decay. It has been found that plants which had been stripped of flowers produced, on an equal space of ground, about thrice the weight of large turbers as compared with the plants that had flowered, which yielded a small number of middling sized tubers with a great number of smaller size.

As to the simplest process for converting the arrow-root into the finest flour, the roots should first be stripped of the scaly leaves by washing them in water. When sufficiently clean they should be reduced to powder by the use of graters or, more easily still, by pounding them in a mortar. Sufficient water should be poured over the powder to convert it into a liquid; and after this liquid has been thoroughly stirred up, it should be filtered through a rough cloth, in which the threads are set apart, into another vessel which should be kept nnshaken till the powder settles down at the bottom. The stale water should then be poured out and the powder should be stirred up again with fresh water and passed through the process of filtration through a finer cloth. The washing and filtering should be repeated till the water comes out perfectly free from the slightest tinge of any color. When the powder is finally settled, the water should be thrown away, and the sediment dried in the sun on clean white paper.

While drying, the powder should be constantly broken up to prevent it from forming into lumps and to reduce it to a state of perfect fineness.—*Planter.*

GROWING SWEET POTATOES.

A Virginian farmer, in the *American Agriculturist*, gives the following advice on growing sweet potatoes: —To begin with, soil free from stone seems essential, and a clay loam the best. The field is well ploughed and the soil turned up in high ridges, far enough apart to be worked by a one-horse cultivator. I leave the field for a couple of days or so, for the soil to become warm and well dried out.

Perhaps you buy the plants. I make a square of boards, a foot and a half to two feet deep, in a sunny place, and fill with mast (dried pine needles, tea-tree leaves or forest oak needles would serve the same purpose), slightly mixed with dry clay loam, for a depth sufficient for the seed potatoes to be placed on end. I placed them close together and over all put a covering of mast. If mast is unobtainable, a lot of finely cut straw will do, being careful that it is not put on too thickly. The sun is allowed to shine in a while, then towards night a muslin cover is put on. This is wholly or partly removed at times, but must remain on over night.

The potatoes are given an occasional light sprinkling, unless native uses her watering pot on them.

It will not be long before crips, tender, green leaves will peep through the mast, which must lie thin and light. When sprouts are from 5 to 8 inches long, one can readily pull them, one at time, by hand through the mast, pulling only such as are of proper length for planting from day to day.

When ready to plant, a quantity of the sprouts are supposed to be large enough two or three days after the ridging. One person begins at the end of the row, and with a gardener's trowel quickly makes little openings 18 inches apart on top of the ridge. He does this in an even manner, and another follows with bucket or apron full of the slips and drops one, stem end down, in each little whole. Next the one who used the trowel comes along with a bucket of tempered water, and a small dipper, and puts a small quantity of water in each hole with the plant, while the man who dropped the slips follows closely behind, and with one quick movement of both hands firms down the soil around each slip. It has been quick work, and the rows look even and handsome The dipper of water keeps the slip fresh until it starts its rootlets. One may look over a large patch and scarcely see a lost plant. During the season, the cultivator goes through twice. Weeds are not very prolific then, and the plants got ahead rapidly. —*Agricultural Gazette.*

THE MARTYRDOM OF GARDENING.

Much has been written of the pleasures associated with the pursuit of gardening; but its penalties have been almost entirely ignored. Nothing can damp the enthusiasm of its advocates; there is no sorrow associated therewith that their remembrance can recall. It was Socrates, we think, who wrote of double blessedness: "If you marry, you will repent it; and if you do not, you will repent it;" and the same advice may be given to those about to enter earnestly upon the horticultural life. It is a great responsibility to have charge of a large and (potentially) beautiful garden, which has many visitors during the season of flowers and fruit; who, though they may not be too critical in your immediate presence, may yet be very emphatically so, when, disappointed with what they came to contemplate, they have retired from your view. They came, perhaps, with great expectations, for whose existence you were partly responsible, and which, saddening to relate, have not been fulfilled. But they do not consider that you are hardly to blame for the "washed-out" condition of your earthly paradise in a season such as this. Nature, like that memorable creation of Dickens, viz., Captain Cuttle's landlady, Mrs. McStinger, has her great washing-days, somewhat trying to her constitution; and her subjects, like the humble captain, have to suffer the consequences. After a visitation such as we have recently experienced of the annual "Lammas floods," accompanied, in all probability, by fierce south-easterly winds, you go into your garden of an early autumn morning, and you find that your Roses, in a literal as well as a metaphorical sense, have "gone to the wall." Many of your finest climbers, suddenly succumbing to the pressure of the storm, and the weight and violence of the rain, have been blown to the ground. The entire blooms of your garden, Roses, Lilies, Sweet Peas, Violas, Irises, Delphiniums, Gladioli, and Carnations, have been utterly destroyed; and nothing remains to their fond cultivator, whose gaze only yesterday was riveted by their beauty, but to remove them from the parent plants as speedily and effectively as lies within his power. Even this, as most of us know from experience, is a serious operation, or at least a very tedious and irritating one; making immense demands upon the divine faculty of patience, while at the same time it makes havoc of the fair elemeut of hope. But Hope, as the optimistic poet has sung, "springs enternal in the human breast;" and though a thousand magnificent flowers have been swept to desolation on the wings of the shower-laden, remorseless blasts, as many buds, full of embryonic life and potential loveliness, remain. Bnt what of that, if these are destined by Nature to endure a similarly crucial experience, as soon as they have spread their silken petals to the air, and dedicated their beauty to the sun?

To preserve a garden in all its possible integrity and symmetry, under such atmospheric conditions as we have endeavoured to describe, is a perfect impossibility; in many instances you feel almost paralysed by the sad destruction of your treasures which the elements have wrought. Nature, so long your sympathetic friend, and gentle inspirer, is now your enmey; in her amiable moments, she had looked like the innocent flowers she was preparing to destroy; but the surpent of deceit was lurking invisibly there. The great Wordsworth, indeed, has asserted of Nature (in all probability when he was experiencing on a calm evening her benignant influence during his famous visit to the regions of Tintern Abbey), that "she never did betray the heart that loved her"; and there can be no question that she usually, though not always, gives warning before she strikes. But what of all this, when she strikes so very hard? Her fairest creations of the gardens, and of the fields; the golden corn that is ruthlessly swept by her autumnal floods, and levelled to the ground; her loftiest trees, which are prematurely divested of their large and lustrous leaves; the fair fruits that are severed, unripened, from the pendulous boughs; the flowers that too early anticipate their decay; receive for the most part no mercy from Nature when she is suddenly seized with such impetuous moods.

But even Nature, with all her unconscious cruelty, can repent; though often for the horticulturist her repentance comes too late. And then we experience the full significance of those Aruoldian words—

"Sad Patience, too near neighbour to Despair!"—*Gardeners' Chronicle.*

RAISING TOMATO PLANTS.

In an answer to a correspondent who desires information how to raise 100,000 tomato plants for a canning factory, the *American Agriculturist* says: "If planted in rows 5 feet apart and 3 feet in the rows, which is about the proper distance, it will require about 3,000 plants per acre. One ounce of tomato seed contains from 8,000 to 11,000 seeds, but of course it is not safe to count upon the growing of every seed, and producing a good, healthy plant. Truck farmers generally sow about ¼ lb. of seed per acre to be planted. For early fruiting it is necessary to sow the seed in hotbeds or greenhouses and transplant the young plants from time to time as they become too crowded. But as for canning purposes extreme earliness is not of prime importance, the seed may be sown in the open ground in a warm and sheltered border where the young plants may be covered with hay or some other light material in case of late frosts Some large growers have been quite successful with planting the seeds direct in the field, but this is only practicable on light and warm soil."—*Agricultural Gazette.*

HORTICULTURAL TEACHING IN GERMANY.—Herr L. Wittmack, in a paper contributed by him to the *Official Catalogue of the German Section of the Paris Exhibition*, mentions the measures taken in Germany with regard to horticultural training. The science, he says, is highly developed. The most advanced teaching emanates from three institutions: the Royal School of Horticulture at Wildpark, near Potsdam, established for seventy-five years, and shortly to be transferred to Dahlem, near Berlin, in the vicinity of the new Botanic Garden; the Royal Institute of Pomology at Proskau, near Oppeln (Silesia); and the Royal School of Pomology and Viticulture at Geisenheimsur-le-Rhin. The kingdom of Wurtemburg has, since 1860, possessed a private institution, the Pomological Institute of Reuthingen; and Saxony, since 1892, has maintained a School of Advanced Horticulture in Dresden. At Koestritz is an establishment for general instruction. Elementary schools of gardening are sometimes in connection with, sometimes independent of, higher-grade schools; they are maintained by different confederate states, or by the governments of the provinces. Prussia includes twenty-three, Bavaria five, Saxony two, Würtemburg four, the Grand Duchy of Baden, Saxe Weimar, and the Grand Duchy of Hesse, each one. In all these establishments instruction is given in the culture and utilisation of fruits and vegetables, &c.; moreover, instructors continue this course of training in different towns. In certain cities, such as Berlin and Leipzic, are schools of gardening for young men, who do practical work in the day; in other cases, again, in Berlin for instance, there are gardeners who themselves make arrangements for obtaining courses of instruction; often apprentices and youths attend the popular courses for the adults. In some localities they teach gardening and the cultivation of fruit-trees to children in the gardens attached to their schools.—*Gardeners' Chronicle.*

TROPICAL PLANTS IN QUEENSLAND.

ANNUAL REPORT FOR THE STATE NURSERY, KAMERUNGA.

SIR,—I have the honour to submit the Annual Report for the year ending 30th June, 1899.

SUGAR-CANE.—During March I noted that some insect appeared to be attacking and damaging the cane in two out of the three fields under this product. I at once reported the matter and sent specimens to the Department, and Mr. Tyrou proclaimed them to be the cane-borer. Upon this the instructions of the Department were prompt to destroy the two fields of cane in which it had been found, and to search the other fields carefully. The two fields of cane, therefore, have been destroyed, but hitherto no borer has been observed in the third field, though a sharp watch is being kept.

CITRUS FAMILY.—Fruit fly seems to be especially bad this year, and allows no fruit of the orange or lemon trees to ripen; a few only of the rough-coated lemon have escaped. Bark-splitting is bad among the citrus trees, and the scale *Lecanium longum* is to be found on some of the orange-trees.

BANANAS.—The exports from the district remain good, though fruit fly and a species of rust are giving trouble in the vicinity of the Baron River. A supply of good Cavendish banana suckers, free from disease, will be kept for distribution. The new Guinea varieties have, I understand, been lately transplanted, together with the *Musa textilis*, to a new piece of ground. They have not borne yet this year.

COCOA.—*Theobroma cacao.*—One of the old trees bore three pods early in the year, from which seed was obtained. There being no demand for seed just then, these were raised in the bush-house, where no difficulty was experienced in germinating them. There should be a fair supply of seed this coming season, the heavy rains having been all in favour of the cocoa-trees.

The effect of an attempt at pruning these trees, some time back, has been apparently to stunt their growth. Pruning is not generally resorted to, and considerably more moisture in the soil and humus is necessary for a satisfactory growth than is to be had in the present locality of the cocoa-trees in the Nursery.

MANGOSTEEN.—Two trees in the bush-house have attained a height of 5 feet and 4 feet respectively, while those in the open vary from 18 inches to 2 feet. This is a slow-growing tree, but thrives best under much the same conditions as cocoa, needing a heavy moist soil rather than a light dry one. The fruit, if it can be successfully grown, will probably prove both popular and profitable. Its flavour and delicacy are unsurpassed, and the fruit, having a thick rind or skin, will travel well in cases or even sacks for journeys of a week or so.

PEPPER.—*Piper nigrum.*—Pepper in its natural state grows on the stems of large and rough-barked trees in dense scrub land. It would probably grow readily in scrub lands in this vicinity, but it must have shade. The pepper in this Nursery being out in the open, and having only a small stick some 5 feet high to cling to, is not growing under sufficiently suitable conditions for satisfactory results to be expected. The plants seem to take to the soil and climatic conditions readily, however, and the growth seems as strong and healthy as could be expected. Planted under more favourable conditions, its culture would probably prove very successful.

CLOVES AND NUTMEGS.—The soil in this Nursery is not suitable for these spices. Better and more satisfactory results might be obtained by growing these trees on the borders of unfelled scrub, where a certain amount of shade, humus, and leaf-mould would be obtained. Such districts as the Lower Russell, Daintree, and Bloomfield would appear to more nearly approach the conditions of their natural habitat.

VANILLA.—This orchid seems to grow readily in this district. I have met with it in several places other than these gardens. The bean is particularly valuable when properly cured, though it is easy to spoil its value by improper methods of drying and sweating. I have not seen any vines in bearing yet; those in the Nursery are suffering from the attack of the green arboreal ants which eat away the stem close to the ground. The plant does not necessarily die when the stem is served, but derives its nourishment from the small short roots it puts out into the bark of the trees it grows on. It will, however, endeavour to get new roots into the ground, and will send down long succulent shoots, which would form new connections with the soil if not in their turn attacked by the ants. While putting all its energy into forming root, however, it is natural that it will not bear to the same extent as a healthy plant, and possibly will not bear at all.

Probably artificial fertilization will have to be resorted to, and unless the question has already been gone into, there will be room for some interesting entomological experiments.

The Plumeria or Pagoda tree-shade for the vanilla orchids in the nursery is insufficient, especially just now, when it is shedding its leaves. The trees are not tall enough or of large enough girth to give sufficient support, nor do they deposit sufficient leaf to form mulch that can retain the moisture. Some of the vanilla plants are already very near to the tops of the trees they have been set to grow upon. The bark of this shade-tree, moreover, does not give sufficient hold for the vanilla, but gives way here and there, allowing the orchid to hang in festoons, to its own detriment.

DIVI DIVI (*Cæsalpinia coriaria*).—These trees are growing well and bearing heavily. The crop is now beginning to come in. Cultivation is reduced to a minimum with this, and judging by the quantity of pods on each tree, it should prove a paying crop. Its bulk will, however, be its disadvantage, and will be a serious expense if any great amount of transport is necessary.

COFFEE (*C arabica* and *C. liberica*).—The field of coffee that had been planted here, and was, I am given to understand, some three years or more old, was rooted out by the late overseer. The few trees that have been left along the roadside are poor specimens, being neither of a good class, nor in any way cultivated, pruned, handled, or topped. The few berries on the trees are small, and quite unfit for seed. The plants in the bush-house are of a mixed variety, and are one and all too old and stunted to make good plants for distribution. I have had to refuse applicants for both plants and seed—a state of affairs that I hope may be remedied by next planting season.

As I am dealing with this subject separately in another place I will say no more on coffee culture here.

CEARA RUBBER (*Manihot Glaziovii*).—This tree has taken to the district and soil. In the nursery it has been become almost a weed. The large trees that are bearing seed scatter it about and it germinates readily, even in the middle of footpaths if left long enough. Section III., field 1, has been planted up with several hundreds of these trees about 6 feet apart, as well as a portion of field 3 of section III., and in a few years, when these trees are large enough to be tapped, they should prove a fair test of its economic value. There are any number of plants and cuttings available for distribution.

PARA RUBBER (*Hevea brazilienis*) is not doing so well as the Ceara. It appears to be considerably more delicate and to suffer during dry weather and hot winds. The plants are hardly big enough or old enough to judge of its possibilities yet.

ASSAM RUBBER (*Ficus elastica*).—This thrives well here and is a most handsome plant. It will, however, be a very long time before there is sufficient stem to tap.

FIBRE PLANTS.—*Agave rigida* grows well and is to be had here in quantity. Nearly all of the old plants are now flowering. *Musa textilis* has taken to its new quarters and is making new suckers rapidly. Ramie needs much more rain and moisture than it gets in this nursery. It is small and stunted. I have seen it grow luxuriantly in swampy ground. *Fourcroya gigantea*: the mother plants have flowered and are dying away, giving place to innumerable young seedlings.

PALMS.—These useful trees seem to grow well in this district. There are many handsome varieties in the gardens. *Phœnix rupicola* looks well and germinates from seed readily, but is difficult to transplant if allowed to grow too long in the seed-beds. *Elœis guineaensis* seed has been germinated after repeated failures. The palm is prolific and plenty of seed is available. I hope to be able to germinate in quantity and have plants for distribution soon.

TEOSINTE (*Euchlæna luxurians*).—The few plants grown here have not been very successful. Most of the seed seems to have been taken by cockatoos, which are troublesome. There being only enough seed for replanting, none has been available for distribution.

KAFIR CORN (*Sorghum*).—This useful grain, known as "white cholum" in India, does not seem to have been raised during the past year. It is usefnl as food for man and beast, and supplies abundant fodder. It is broken or crushed, or boiled, and used as a substitute for rice. Is fattening food for cattle and horses in this state. There are several varieties, of which this is one of the best though small. It produces a large quantity of stalk and leaf, which is popular fodder for draught cattle in the East Indies.

PAWPAW.—The continued heavy rains in March had disastrous effects on our Pawpaw trees, killing many off by rotting the roots. Some would have recovered had not the wind blown them down before new roots could be made. Several good trees were lost, including the branching variety. There are several varieties not in the Nursery, however. Three distinct varieties are known in Southern India, besides a Chinese variety, apart from the branching variety here. The Singapore Pawpaw is not especially large, but turns a golden yellow when ripe, and has a fine flavonr. The Chinese is a long pointed fruit, and is a dark green colour when ripe. This would probably travel better than most. The male tree is not a necessity in a garden, though there is nothing lost by retaining one should a number come up from the seed. The *Papaya carica* may be dicœcious, monœcions, and even hermaphrodite. I hope to be able to deal with this interesting fruit tree later on by itself.

JACK FRUIT (*Artocarpus intergrifolia.*)—The only tree of this useful fruit in the Nursery shows signs of a past crop, but none of a further crop this year. The tree is rather slow-growing, but the timber is hard and good. It is of a dark yellow, and is useful in making furniture. The tree is prolific. I have had over seventy fruit on one tree, averaging 35 to 40 lb. each, some fruit being 65 to 70 lb. each. The fruit has a strong but not unpleasant smell, though many object to it. Once the taste is acquired, the fruit becomes very popular. The seeds make an excellent vegetable, and are a good substitute for potatoes when boiled. When dried and ground the seeds or nuts give a wholesome meal. The nuts roasted are not unlike English chestnuts. The fruit, seeds, pulp, skin, and all except the rough outer covering are readily eaten by cattle, and pigs are specially fond of them and fatten on them.

Of the plants and seeds received during the year a few rooted cuttings of *Piper methysticum* are still in the bush-house. Before planting out I would await the result of my suggestion to open up a piece of new scrub land in which plants of this nature may be experimented with under conditions more readily approaching their natural habit.

Many of the plants subsequently mentioned in the list as being received would appear to have succumbed, as no trace of them can be found

PARA RUBBER.—Of the 260 plants received some sixty odd have been planted out in the Nursery, and a few distributed. A good many seem to have died out.

CANDLE TREE.—The seed sent up has germinated freely, and there is any quantity of seedlings available for distribution.

DURIAN (*Durio zibethinus*).—All the seed of this tree have failed to germinate. This is possibly owing to the seed having either dried in transit, or to being kept too moist in the seed-bed. The seed is somewhat difficult to germinate, and should be planted as soon as possible from the ripe fruit I trust some more will be obtained shortly for experimental purposes.

CEARA RUBBER is germinating freely, but the African rubber (*Kickxia africana*) is not as yet showing any signs of germination.

IMPROVEMENTS.—Nothing of the nature of permanent improvement has been carried out this year. Ordinary wear and tear has had to be remedied, and small repairs were necessary to the dwelling-house and bathroom, after the departure of the late occupants. These have been effected, and the house has been repainted. The office and outbuildings, that also need painting, are now being done.

The advisability of purchasing, for the use of the labourers employed, the humpy that was erected in the adjoining paddock by one of the labourers at his own expense is under consideration.

PUMP, BOILER, AND MACHINERY.—As the late overseer remarked in his last report, it was found necessary to thoroughly overhaul this plant. The floods in March had done some damage by washing away the corrugated iron shed over the pump, and breaking off the foot-valve of the suction-pipe and washing it down stream. The boiler had not been tested or examined, apparently for five years or so. This was done, and the shed replaced by a smaller and more substantial one. The foot-valve is presumably buried under some of the new sandbank in the bed of the river. A thorough search having failed to discover it, it was replaced.

The pump itself had to have new packing supplied for the pistons, and this has been fitted up, and now works well, but the injector mechanism on the boiler is now found to be worn, and not working properly. As the pump was not working, and could not be worked, when it was examined for repairs, this injector irregularity could not be tested. It is a constant source of trouble, and if a small donkey pump could be supplied for filling the boiler, as is, I understand, in use at the Mackay State Nursery, it would save a great amount of time, trouble, and labour.

The plant, as now situated, is inconvenient and awkward. The engine-house is near the house of the man in charge, but the pump is down on the bank of the stream some 100 yards off, and the water supply some fifty or sixty yards further off again. Whenever the river is in flood the pump is submerged, and the piping and foot-valve bent, damaged, or (as in this case) broken off and lost. This is gradually spoiling the pumping engine, and is a constant expense. I would therefore suggest that at the end of this dry season the pump be removed to a site alongside the engine-house, and three spears be sunk from there. This would cost only some £35 to £40, save subsequent expense in repairs, be above flood-mark, and enable the pump to do more work.

I would suggest that a piece of scrub land adjoining the present enclosure in the nursery reserve be opened up for the purpose of experimenting with such products as Vanilla, Pepper (three varieties), Cardamoms, Nutmegs, Cloves, Cocoa, Mangosteens, &c., &c.; all of which need more or less shade and constant moisture, mulch, and humus.

The opening up of such a block, say 5 acres in extent, would not necessarily be an expensive undertaking, for all the plants and trees mentioned (each an industry in itself, if proved capable of being grown under existing climatic conditions) it is necessary to have the larger scrub trees standing. The clearing would therefore be reduced to a minimum, and amount to little more than a brushing of the scrub.

The Pepper family and Cardamoms need dense shade, and but little more clearing would be necessary for the larger spice trees, and would give them many of the conditions essential to their successful culture, and also supply them with surroundings and soils infinitely nearer to those obtaining in their natural habitat.

Each of these products I hope to deal with in the course of the year, and to record my experience of them in Departmental *Journal* from time to time.

HOWARD NEWPORT.

—*Queensland Department of Agriculture.*

PLANTING NOTES.

PEACHES IN GEORGIA, U. S. A.—The Hale Peach Orchard in Georgia has, we are informed, about 300,000 trees; one block of 60,000 Alberts is the heaviest loaded of all. The proprietor, Mr. Hale, estimates that 8,000 car-loads of Peaches will be shipped out of Georgia this year.—*Gardeners' Chronicle.*

THE MULBERY IN LOMBARDY.—By way of Milan we have news to the effect that the immature condition of the Mulberry foliage in Lombardy has greatly interfered with the success of the silk industry in that section of Italy. The frequent and serious variations in atmospheric conditions have been all against cocoon raising by the silkworm, and the decrease in production is placed at some ten per cent. So much for the inter-dependence of commerce and vegetation.—*Gardeners' Chronicle.*

SOOT.—From a paragraph in our valued contemporary, the *Revue de l'Horticulture Belge* for August, we learn that a dressing of soot is fatal to the Phylloxera, and beneficial to the Vine. We have seen no Phylloxera now for some years in our vineries; but should it occur again, we shall hope to try the effect of the soot, as if efficacious, it would save much trouble and expense. The plan adopted is to dig in around each stock in winter time 1½ litre of soot (say 2 pints). Our contemporary speaks of the root-form of the insect. Whether a dusting over the foliage with soot would be equally efficacious is not tarted.—*Gardeners' Chronicle.*

TOMATO DISEASES—There are various diseases, all of which have been repeatedly described and figured in our columns: 1, the leaf-rust, Cladosporium fulvum, chiefly attacks the leaves, which look as if dusted with brown powder; 2, the Tomato-rot, which is identical with the Potato disease; 3, the Black-rot, attacking the fruit chiefly, but not entirely—it often forms circular patches around the style; 4, the sleeping disease, attacking the leaves which become flaccid and droop. Bordeaux Mixture, or potassium sulphide ½ oz. to a gallon of water sprayed on the plants will be of service, if carried out effectively at an early stage of growth, but spraying will have no effect on No. 4. All these diseases are greatly favoured by growing so many plants of the same species in the same house. Under such circumstances the disease is certain to spread from one plant to another, hence the necessity of up-rooting and burning all affected plants. As even now many people seem not to know of the Bordeaux Mixture, we add the proportion: copper sulphate 4 lb., lime unslaked 3 lb., water 40 gallons, Place the copper sulphate in a coarse-sacking bag, and suspend it in 6 gallons of cold water, in a wooden tub with no iron about it. Slake the lime and add it to the copper solution gradully. Stir freely with a wooden stick, and add the remainder of the water' then let it settle. It is best to use more rather than less lime, so that the foliage may not be injured by the spraying It is as well to try the effect on the leaves before using it extensively, as then the mixture can be diluted if necessary. Two or three applications at intervals are better than a strong dose at one time. Less troublesome to make, and in some cases equally effectual, is a mixture consisting of liver-of-sulphur oz., water 10 gallons.—*Ibid.*

Tea.—China furnished little over 48 per cent. of the total supply; Japan, over 41 per cent. This shows that Ceylon and India have a great field for work if they would supplant China and Japan teas by machine-made tea.—*American Grocer*, Aug. 8.

FISH MANURE.—A Tellicherry correspondent writes :—"The shoals of sardine fish had failed to appear on the Malabar Coast for the last three years consecutively and consequently the coffee planters were in utter disappointment in procuring the fish manure, which is manufactured only of this species of fish. Now I am glad to mention that the shoals have just appeared on the Coast and there is every sign of a continuance of their appearance. I hope this will be a welcome news to coffee planters as they attach much importance to this manure."—*Pioneer.*

EARTH NUTS, PEA-NUTS (ARACHIS HYPOGEA).—From an American jounal we have the information that the last crop of this edible nut was reckoned at between four and four-and-a-half million bushels. This is quite a favourite article of consumption in the United States, and would be more so here were heat applied to driven off the oily contents—as is the case, we believe, in the States. Mr. Theodore Wood, a number of the Executive Council of New Guinea, says that Pea-nuts are likely to prove a great success in that part of the world, certain portions of the "Possession" being eminently adapted for their culivation. Samples sent to Brisbane would appear to be quite equal to the best of anywhere else. As far as can be judged at present, the class of land in British New Guinea upon which the Pea-nut will thrive should yield at least four tons to the acre, and in favourable seasons the planter may be expected to take two crops per annum. The cost of cultivation is very small, the labourer being easily satisfied with a very trifling remuneration.—*Gardeners' Chronicle.*

COMMERCIAL CULTIVATION OF PLANTS UNDER GLASS. —It is estimated that the retail value of cut flowers sold in the States annually is $12,500,000, the estimated apportionment of this sum being for—

Roses..	$6,000,000
Carnations	4,000.000
Violets..	750,000
Chrysanthemums	500,000
Miscellaneous flowers, including Lilies, &c.	1,250.000

Estimating the average retail value of Roses, Carnations, and Violets at $6, $4 and $1 per hundred, respectively, the total number of each sold annually based on the above values, would be, of—

Roses..	100,000,000
Carnations	100,000,000
Violets	75,000,000
	275,000,000

The retail value of the plants sold is placed at $10,000,000. Taking the plant trade as a whole, and the country in the aggregate, the average-sized pot used is estimated to be 3 inches, and the average retail price 10 cents per pots. This means that there are no less than 100,000,000 plants sold every year. To handle this bussiness in entirely requires probably an average of not less than one man for every 1,500 square feet of glass, or 15,000 men in all. Fifteen hundred square feet of glass per man may seem like a low estimate, and such is the fact when considering commercial establishments of any size. The larger the area of glass, other things being equal, the more square feet one man can handle. As a matter of fact, some of the large Rose-growing establishments do not use more than one man for each 10,000 square feet. Large Carnation establishments will run about the same as Roses; while Violets, owing to the great amount of work involved in cleaning the plants and picking the flowers, average higher. It is the many thousand small establishmets that increase the amount of labour required.—*American Gardening.*

TIGER SHOOTING IN THE MALNI FORESTS, C. P. INDIA.

At the foot of the Satpuras, not far from the mountain homes of Mahadeo, lies the Malni Forest Reserve. In the good old days, to the keen shikari, there could have been no fairer country, both for scenery, climate and "sport." In those days, the Malni Reserve lay on the borders of an interminable expanse of forest-country, open and park-like, crossed by many small streams, running swiftly in their rocky beds. Low hills, covered with a pleasing mixture of teak and large feathery bamboos, were dotted about at frequent intervals, and in the near distance range upon range of mountains rose high, one above the other. In all this vast extent of country there were but few small scattered villages; but, on the other hand, it was the home of the aboriginal gond, a race which, alas, is fast disappearing with the advance of cultivation and so called civilisation; and it has already lost, at least in those parts, all its manly, noble characteristics. In those days every man could have prided himself on being a simple, truthful, unsophisticated man of the woods, a true lover of the jungle, a real sportsman. In addition, each village had its recognised shikari, or leader of the hunt: but the leader of them all, the recognised and accepted king, was Telu. He was, perhaps, the last of the real unadulterated aboriginal gonds of the old school.

A BORN SHIKARI,

a perfect tracker, a polished jungle gentleman. He was long, lanky and venerable in appearance. Clothed in his black, wrinkled, epidermis; a piece of string round his waist; a "chakwak" (pipe) worn behind the ear! with his long flowing matted locks—nothing could ruffle his temper, or his keenness after shikar. Alas, poor man, he died, so the legend goes, many years ago, a victim to the ire of the Deo, over some little neglected shikar offering.

The gonds, however, did not hold undisturbed possession of these wilds. There were many other denizens of the jungle; and the bison, the sambhar, the cheetah, the smaller deer, the black bear, the tiger and the panther were all to be found here. My first year in India was drawing to a close when I found myself posted to the Malni Reserve. During the whole of the year, my one and only ambition had been to shoot a tiger: and in the vain endeavour to get one I had tried every expedient that mortal youth could dream of—stalking, beating, bribing, praying, cursing, sitting up by day and by night, everything had been tried in vain. I had in fact begun to think that tigers were a fraud and a dillusion, except as regards their pug-marks. But the Malni Reserve soon raised my hopes. Not only were pug-marks plentiful enough, but my gond friends, who had got over their natural shyness, and with whom I very soon got on the best of terms, assured me of easy success, and told me many a startling tale. Not only this, but the good sport I had with other beasts—my first sambhar, my two bears, my panther—soon raised my fallen hopes.

It was under these circumstances that Telu and the little band of shikaris I had collected together, came to me one day with the news that a tiger was creating much havoc among the cattle at the village of Malni, which gave its name to the Reserve; and they urged me to proceed to the place as soon as possible. Accordingly, Telu and his little court, with a herd of young buffaloes went on ahead to prepare the way, and I myself soon followed.

In those days, Malni was a small Gond village, though perhaps larger than most, situated some short distance from the river of that name; and the strip of broken ground between the village and the river was covered with scrub jungle, fairly dense in places, with a few large trees; the whole interseeted by numerous small, moist, shady streamlets and nalas. On arrival the reports I received were so excellent that I soon determined

TO GET THAT TIGER,

and I am afraid it would have required many, very many, reminders from my superior officer before I could have been got to budge. Moreover, postal arrangements were very defective. However the luck was with us, for the very first morning after my arrival Telu came rushing into camp with the news that one of the young buffaloes had been killed during the night, and its carcass dragged away into the jungle—always a most auspicious sign. Messengers were immediately sent off to bring up as many beaters as they could from the surrounding scattered small villages. Meanwhile, Telu and myself did a track round the area in which the tiger was supposed to be slumbering after its gorge. The tiger had killed in the patch of jungle between the village and the river, and so the matter was comparatively easy. The River Ma ni on one side the viliage and fields on the other, and a nice sandy path above and below; and the results of our investigations were most satisfactory. The tiger was there, so Telu assured me.

The next operation was the tying up of the machan, and more particularly chosing the right tree to have it on. Personally, I knew nothing about it, and so hard to trust to Telu; and we chose a spot with a small open space in front, and a small strip of growth on the left.

Eventually the beaters arrived. I was seated on my tree, the stops were duly arranged on the right and left of me, and the beat began. For volume of noise, mingled with queer weird local sounds the beating of the tom-tom and the ubiquitous kerosine tin, it would be impossible to beat a throng of aboriginal gonds. And so the beat came merrily along, and I was ready to jump out of my skin with very excitement. Suddenly, a grunt and a growl was heard—and then a huge beast is seen by me to be moving through the patch of scrub, away on my left, some 200 yards away. At the same time, the group of stops on my left start coughing and hammering.

Mad with excitement I loose off my rifle in the direction of the tigress. Bang goes my right barrel, bang the left: and by the time the smoke has cleared away, there is no sign left of the tigress. However, no sooner have I had time to reload my rifle, then the tigress appears in the open, start in front of me. She is apparently looking straight at me, and about 80 yards away. This is too much for me, and whizz goes the bullet from the right-hand barrel. Over rolls the tigress, kicking like a shot rabbit, and bang goes the second bullet, and the smoke clears away for me to see

THE TIGRESS BOLTING

back towards the beaters. Much excited, I had hardly time to reload when away on my right, across the open space a small

young tiger dashed past and then a second. I at once imagined that they must have stopped on the edge of the jungle, and to get a better view I proceed to scramble higher up the tree. As I am scrambling up out dashes a third young brute and stops immediately under my tree. Balancing myself as best I could, I fire, only to see the cub dash on into the jungle.

Eventually the beaters come up; I descend from my machan, and a consultation is held. There is no doubt that the tigress is badly wounded—a pool of blood where she fell, and blood clearly shows the direction she has taken. But, alas, the three cubs have gone off unscathed.

In the excitement of the moment I at once determined to track the wounded tigress, and away we start, the plucky gonds only too keen to follow. The blood, however, soon stops, and matters are proceeding somewhat unsatisfactorily, when one of the shikaris suggests that the tigress must have made for water, and he assures us (as far as I am able to understand), that he can take us to the very spot. Accordingly, we give up tracking and proceed straight for the suggested haven of rest. As we get near the spot, men climb up trees to look ahead, while the rest wander about somewhat aimlessly. Suddenly one of the men from the top of a tree remarks, in a very casual tone of voice—

"THERE LIES THE TIGER."

Immediately we all come rushing up,—convinced that we should see the fallen monarch dead as mutton. We are all crowding round a little bush growing out of a small nalla, when suddenly a terrorizing "uph-uph" resounds at our very feet, and out springs the tigress. We did not stop to inquire, away we scattered in all directions and scrambled up the nearest trees; whilst the tigress fortunately for us, kept to the nalla and disappeared. That was enough for me, at least for that evening. Besides, it was getting dark. And so we wended our weary way home, sick at heart that no trophy had been bagged. However we were soon holding councils of war; and the valiant Telu's proposals that a company of buffaloes should be brought in to our assistance next day were unanimously carried, and all arrangements duly completed. Meanwhile, I spent a restless night, dreaming of tigers and cursing my bad luck.

Next day the beaters and a herd of buffaloes arrived, and away we started. All Central Indian portsmen will have learnt the value of the jungle-reared buffalo in tracking wounded carnivora. Accustomed, as they are, to live in the densest jungle, they are quite prepared to meet the onslaughts of any tiger, and promptly forming into line, heads down, they will charge straight at any tiger they may meet. Accordingly, on this particular morning, it was decided that I should sit on a selected tree and that the beaters should drive the buffaloes through the jungle, and thus beat the wounded animal out. I had not sat up very long, and the comparatively silent beat had only been going on for a very short time, when away, in the distance, down below me, some considerable distance away, I saw a huge tiger bound across a small open space. I at once got to the ready and waited patiently, shortly to be rewarded by

THE TIGER APPEARING;

and there he stood, a few yards from me, looking back in the direction of the beaters; but alas his body was covered by a clump of trees, on one side his huge head projected, on the other his tail. No, it was impossible to fire, and meanwhile I shook with excitement and fear that the tiger would see me and bolt. However, after an age of suspense, the tiger stepped forward quietly and slowly, and his body being exposed I fired. Down he dropped without a move, save a wag or two of his tail. But I was not going to lose him this time, and before he could ever think of coming to life again, three more bullets were duly lodged into him.

Soon the beaters came up and there were great rejoicings; but this was not the wounded tigress. It was a fine male, 10 feet 5 inches, and never a wound had he received before. The question of the wounded tigress, therefore, still remained to be solved. Accordingly, we proceeded to track through the jungle, the shikaris leading the way, tracking down the dry nalla beds, the buffaloes being driven through the thicker bits of jungle. After a time we came to a small underground nalla, a kind of a small winding cave, which opened out into the bigger nalla down which we had been tracking. The trackers stopped, and after some little further examination arrived at the conclusion that the wounded tigress had retired into the little cave. But there were doubts expressed, and so in the hopes of further developments arising I took up a position behind a tree at some little distance from the month of the cavern and fired a charge of shot into it. At once

A DEEP, LOW, GROWL

came out from the cave, and away every one fled to take refuge up the nearest trees, whilst I stood at attention. But nothing further happened and similar charges of shot only succeeded in bringing forth low grumbling growls. Consequently, other steps had to be taken. On creeping up to the mouth of the hole and cautiously peering in, it was impossible to see anything of our friend, as the small cave at once wound round to the right. It was, therefore decided to try the effects of a prog. Accordingly, I stood at attention on the banks of the nalla just over the hole, whilst two of the braver gonds, armed with a long bamboo, proceeded to push this into the hole. Suddenly, a loud roar. Away they all bolted, fully expecting that the tigress would bound out in her wrath, but no tiger appeared. Again and again were those tactics followed; but save for a growl there was no apparent result. Braver and braver grew the proggers, and the tigress, in her anger, would gnaw the end of the bamboo, but she refused to show herself. Owing to the winding nature of the hole it was impossible to get at her, and so the bamboo was given up in despair. During these antics we had noticed that a small tiny crack in the ground led down from the bank into the hole, and peering down it, a small portion of the tigress could be seen. In fact, its tail, as it afterwards turned out. Accordingly, I had sent for kerosine, but only a single bottle was forthcoming. This we lighted and poured down the hole, with the result that the tigress' tail was badly singed; but still she refused to show herself. And so the day passed and darkness was coming on, so that all further plans of operation had to be postponed. Moreover the shikaris assured me that the tigress must be at the point of death, otherwise she would never have endured such treatment. We contented ourselves, therefore, with blocking up the mouth of the cave loosely with branches, and then wended our way home, fully confident that next day we would merely have to dig her out. And all arrangements were made to obtain the necessary implements from a distant depôt.

Next morning, armed with spades and pickaxes, we again set out; but as soon as we reached the hole, the shikaris, after examining the place, pulled out a few hairs and exclaimed, "The tigress has got out during the night;" and sure enough there were the pug-marks going down the nalla towards the Malni River. Here was a serious predicament. A council of war was hastily summoned, and as a result the buffaloes were again sent for, whilst we waited in patience. After a few hours the buffaloes arrived, and the order for an advance was given. The shikaris and myself tracked down the nalla, the buffaloes were driven through the jungle on either bank, followed by the beaters. And so we tracked down the nalla, until we came to the river where it was found that the tigress had turned back into a dense bit of jungle a little higher up. But she had not drunk water in the river, and this was considered a good sign by the shikaris, who took it to mean that she must indeed have been very bad. On the edge of the river we again formed up into line, the buffaloes on this occasion leading, and we all followed. Suddenly, after having proceeded a short distance, the buffaloes made a mad dash forward, snorting vigorously; something yellow was seen to dash past in front of the buffaloes and jump down into a small nalla a little to our left, whilst all the beaters and shikaris disappeared up trees. Meanwhile, goaded on by my friends, who were safely ensconced on the tops of trees, I crept quietly up to the edge of the nalla and peered over. There, round the nearest bend to the nalla, I could just make out

THE TIGERS' TAIL,

and little else; however, I came to the present, and taking careful aim at the root thereof, discharged both barrels in rapid succession, and then gracefully retired at the double. After a short time, having reloaded, I again advanced cautiously at the ready, but just as I crept up to the edge of the nalla and peered over, there was the tigress a couple of yards off, staring me in the face, and she at once opened her mouth, making a hideous face; but like a flash of lightning I fired and the tigress sprang a few feet into the air, and fell on the same spot; again I fired and over she fell. But my blood was up; hastily reloading, I fired again and again, and assurance was indeed made doubly sure. It was now getting dark, so the tigress was hastily swung on to a pole, flaming torches were lighted, and our entry into camp was indeed a sight for the gods. My first tiger, and a tigress besides, and no end of tamasha! On the first day the tigress had been hit a little to the right side of her chest, and it had all festered very badly.

And now for the moral. When I began writing this account of how I shot my first tiger, I had certainly meant to draw a moral for the benefit of our young shikaris. I should have felt that I had not written in vain if I could impress upon them the folly of at once following up a wounded tiger on foot; the folly of losing one's head and firing at a dangerous animal at long ranges, especially when it is coming straight towards one; the folly of ruining a valuable skin by firing a quantity of lead into the carcass of the dead animal. But after all, does my story really bear out these excellent precepts? Had I followed them, how much never-to-be-forgotten excitement should I not have missed? And, apparently, as long as the luck is with one and the gods are favourable, all will end well. After all, youth may indeed rush in where extension-wallahs fear to tread. FELIS CHAUS.

THE CEYLON PLUMBAGO TRADE.

The following is the substance of a letter addressed by Mr. T. Stretch, of Messrs. Darley & Butler, London, to our evening contemporary:—

"The present position of the plumbago trade seems to be exciting a more than usual interest in the article, and has led to some writing which is not instructive but misleading, and which may therefore do harm in some quarters. What is the actual position?

1. For many years London was the great distributing market for plumbago as well as for most of the produce of the East. Then considerable stocks were held here, and the Continental and, to a large extent, the American trade was supplied from this source. In consequence prices were governed chiefly by the supply on this market. This has long ceased to be the case, and, owing to facilities of communication and the enterprise of Agents and Merchants on the Continent and elsewere, a more direct means of doing the business has been evolved. Instead of London, Colombo has become the distributing centre; stocks in London have for some years dwindled to a quite inappreciable quantity, and prices are ruled by the supplies available in Colombo. The transfer of the trade from London accounts for the fact that few Brokers now thoroughly know plumbago. Those who now handle it know it well, and are honourable and trustworthy men.

2. The method of transacting business has altered to meet the altered conditions. Whereas formerly a user on the Continent sent an order to his London Agent on a sample of plumbago actually in stock, under the later system he sends his order on a standard sample supplied to him by an Agent either representing a shipper direct or the shipper's Agent in London, who transmits the order to Colombo where the plumbago is bought. This is a simple enough matter on the face of it: but the satisfactory completion of the contract depends upon the shipper delivering to the buyer a quality equal to the standard on which he bought. A consumer knows what he can use best in his special manufacture, and it does not suit him to receive inferior plumbago even if he pays for it less than his contract price. This is the great difficulty and it can only be overcome (1) by the shipper being exact in buying to match the standard, and (2) by the dealer who sells to him being loyal to his engagement and delivering the quality he has sold. Supposing these conditions fulfilled, there can be no better way for mine, owners and dealers in Ceylon of carrying the business through. The chief market is at their hand, and the orders in that market are the proper gauge of the demand from all the world.

3. It has been alleged that present prices of plumbago are low, and it is sought to show that this is in consequence not of oversupply but of the method in which pumbago is brought and sold. It is not the fact, however, that prices are low. Taking ordinary lumps as the representative grade, reference to the statistics will show that the price in Colombo in the years 1891 to 1896 ranged from R125-130 per ton for common to R240-260 for good. There was hardly any variation in these six years, though in 1894 the price of common fell to R100,

In 1897 the rise in prices began, which culminated last year, when they advanced to R400 for common and to R1,125 for good. The above quotations are taken on the last day of each year. On the 30th June last, common was quoted R350, and good R700—a considerable fall, but still leaving prices high. The rise that took place was clearly traceable in its causes, and was based on nothing newer than the laws of supply and demand. During a long period of depressed trade, especially marked on the United States of America, manufacturers became habituated to the system of buying as they wanted supplies. Most of them did not buy for stock, for prices altered little. When the trade began to improve, they did not believe that prices would continue to rise—no one anywhere dreamed of such activity as has been witnessed in the last two years chiefly caused by the movement of trade in the U S. after the last Presidential election. When they awoke to the fact that prices were really rising all wanted to buy at once, and the rise became a succession of leaps and bounds. It is natural that there should be a re-action. It is the regular course. All markets stocked; high prices checking trade; buyers holding off; producers accumulating stocks and unable to sell; prices, what can be obtained and quite uncertain. This condition will in turn change, and as surplus stocks are used up, a stable market will once more exist, but what prices will rule when that time comes it would be unwise to prophesy The statement of such patent facts and elementary principles demands an apology, but it seems called for by the ignorance of all such principles shown in the writing referred to.

4. To sum up the position then, it appears:—

(*a*) That London is not now the distributing centre, but that Colombo is.

(*b*) That the system of business is now based on standards, the accurate matching of which requires judgment, knowledge and honesty,

(*c*) That prices are not low at present, and, judging by experience of the past may go lower.

And finally, that they are governed, as they always will be, by the laws of supply and demand, and the invariable rule that, after a period of inflation, there must come a time of depression. How long the latter will last will depend much on producers, who will have to adapt themselves to the demand. If they do not do so now, many will perforce have to do so later, when it becomes unprofitable to work their mines. In the meantime, the only advice that can be given them is: Don't believe in any fancy or interested schemes for overriding natural laws. Such schemes always recoil on their inventors bringing loss where gain was promised."

The strange part is that while he was about it Mr. Stretch entered into no explanation of the causes of the enormous expansion of the plumbago trade during the past few years. It is not simply that the price rose rapidly and to an unprecedented pitch, (from which it has since fallen):—that may be accounted for in the way Mr. Stretch points out; but the far stranger experience is the simultaneous enormous increase in exports. Usually, one would expect prices to fall with an addition of 50 per cent to exports; but that was not the case during most of 1899. Here are the figures for the past four years:—

EXPORTS FROM CEYLON.

	Cwt.		Cwt.
1896 ..	340,491	1898 ..	473,075
1897 ..	357,257	1899 ..	616,385

We suppose it is true that increased activity in regard to "armaments" in Europe and America, accounts for the disposal of well-nigh 14,000 tons above the average export, during part of 1898 and in 1899? But then we infer there is no slackening of armaments even now and yet the shipments of our valuable mineral this year have greatly fallen off—only 243,190 cwt. to 3rd of Sept. against 412,178 to same date last year. After all, this may mean that heavy stocks were laid in last year; but if so, was it not a little foolish of the buyers to be in such a hurry to store up so much beyond current requirements and so raise the price so greatly?

THE PROSPECTS OF CEYLON TEA IN AMERICA,
LOCAL MANUFACTURE OF "GREEN" TEA.

We learn that the attitude of the large United States' tea importers towards Ceylon "greens" is that of determined hostility. They resented the introduction of our "blacks"; but they have four times as much interest in "greens," and it is thought that Ceylon dealers must work through the tea-packet houses at first.

We have received copies of advertisements of Ceylon tea, published by two tea houses in Boston which are not subsidised by the Ceylon Commissioner. They have both been forced to push or hold "Ceylons," by the action of a subsidised Firm. One of the former, it seems, refused some time ago to sell Ceylon packets. But they have been obliged to advertise our teas, because a rival was making such vigorous efforts. This is what advertising does all the world over:—it makes an article known; householders inquire for it; grocers must have it; and importers then have to look out for it.

In this connection, we may refer to the local manufacture of "green" tea and Mr. F. F. Street's very practical letter of which we had no time to make mention yesterday. It is clear there is to be no "rush" into the making of "green" tea, as was feared by the American Commissioner and some London dealers. These gave two million lb. as the quantity which, if well made and satisfactory, might be taken off in twelve months; but we see that our evening contemporary thinks one million lb. an outside estimate for Ceylon "green" tea shipments in 1901. If so, there will certainly be no special pressure and the American importers may well restrain their hostile attitude for a few years, say till about 1903, when perhaps we may get up to four or five million lb. in shipments of "green" teas.

HOW TO MAKE GREEN TEAS: IMPROVED METHODS ADVOCATED.

To the Editor.

Sept. 3.

Dear Sir,—At the request of Mr. H D Deane, and in the interests of those making green teas, I desire to draw attention to that part of Mr. Deane's printed letter, "How to manufacture green tea," which gives a "gloss" or "glaze" to the leaf, as I consider it improves the leaf appearance of the teas treated and in no way detrimentally

affects the liquor, and will, I think, improve the keeping properties of the leaf so treated.

China green teas, which are highly glazed, are very good keeping teas, much more so than blacks.

Although I should deprecate following Chinese methods in many respects, I think Ceylon planters cannot do better than follow them in the matter of glazing the leaf, especially as Ceylon greens are inclined to be *dull dead* and unattractive in leaf appearance, without the glaze.

The following is the extract referred to:—"When you final fire for packing, I recommend that when the *Sirocco trays are spread* to put them in a '*steam cupboard*,' (particulars can be had from Messrs. Brown & Co., Limited.) and turn on steam for 30 seconds, before firing; this will give the tea a *fine gloss* or to take the *juice of some of the tea you are rolling*, and water each tray when spread with it, seeing that all the tea on the tray is moistened with it. *This latter process* is best done *in a wooden tray or box*, and the *juice mixed in with the hand sufficient to make it all damp* (every grain) but *not wet*, then spread on the trays and fire at 190 to 200, and you will have the 'glazed' tea which some American dealers prefer."

To which Mr. Deane has since added the following post-script in copy sent to me:—

"A good plan, indeed the better, is to use one roll of steamed green leaf on the day of final firing for glazing only, to do this steam the leaf and squeeze out most of the water before starting roller, *then put on the weights* and roll till there is no juice left, collecting the juice in buckets. You will get sufficient to do over 1,000 lb. of tea and the juice will be thicker and the glaze more pronounced and the twist tightened."

"Of course the leaf in the roller after this can only be fired and mixed in with the fannings."

As this glaze can be applied to different degree,s I would suggest planters to send samples to me in order to ascertain whether the *degree of glaze* applied is as it should be.

While on the subject of green tea, I might mention that I deprecate describing Ceylon green tea as Chinas are graded, viz. "Hyson," &c., far better grade as per Mr. Deane's letter or as suggested by Messrs. Larkin, viz. Ceylon black tea gradings with the prefix green, to which I would add, *avoid* the word "Broken," as brokenness, in green tea, condemns; thus we have "O.P.," "P," "P.S.," "Souchong," &c., all *leafy* grades.

Apologising for taking up so much of your valuable space.—Yours faithfully,

F. F. STREET.

GREEN TEA MANUFACTURE IN CEYLON.

Writing to a Madras paper ("Planting Opinion") Mr. Drummond Deane gives the following list of proprietors or Agents in Ceylon as using his patent process:—

Ceylon Tea Plantations	... 2
Eastern Produce and Estates	... 2
Maskeliya Tea Co.	... 1
A E Wright, Esq.	... 1
E Rosling, Esq., Chairman, Ceylon Planters' Association, Hon. J N Campbell, Ceylon Planters' M. L. C.	... 1
C P Hayley, Esq.	... 1
Messrs. Geo. Steuart & Co.	... 2

and several more are on order.

This makes ten factories so far in all. Mr. Deane adds:—

"So far no one in India has tried my method, I suppose, on the principle "that nothing good can come out of Ceylon." I hope shortly to have permission from London to go in for "green Teas" myself, but "London Agents" don't like teas going to America naturally, and there's the *rub*, when one is financed from London."

The *Indian Planters' Gazette* of August 25th, says:—"Letters from planters in the tea districts point to the fact that the green tea manufacturing mania has not caught on in Bengal and Assam. With the exception of one or two faddists, no one gives it even so much as a thought."

CEYLON TEA IN AMERICA.

The total imports, exports, and net imports of tea for the fiscal year ending June 30th, 1900, were as follows:

Imports from—	Pounds.
China	40,867,290
Japan	35,189,623
East Indies	4,455,450
United Kingdom	2,444,400
British North America ..	1,352,616
Other Asia and Oceanica ..	302,636
Other countries	231,476
Total	84,843,491
Exports	1,539,869
Net imports	83,303,622

HINTS TO HAY GROWERS.—The hay-growing experiments by Sir John Lawes at Rothamsted Park have had interesting results. On land which has had no manure for forty-five years the weight of hay secured is 12¼ cwt. per acre; the plot receiving a mineral manure has given 27 cwt. per acre; while the plot receiving a mixture of minerals and ammonium salts has yielded 38 cwt.; and the plot receiving minerals and nitrate of soda has given 49½ cwt. The heaviest manured plot produced 60½ cwt. per acre, while the same plot on a portion of the land which has received a dressing of chalk in addition to other manures gave 65¼ cwt. per acre.—*Journal of Horticulture*, August 16th.

Vol. XII.] SEPTEMBER, 1900. [No. 3.

THE BRANDING OF CATTLE.

IT would seem impossible to exactly define where "firing" as a panacea for the ailments of dumb animals ends and branding as a cruel practice begins. In this island the native cattle doctor very frequently resorts to "firing"; indeed his surgery is almost entirely confined to the hot iron, to the neglect of the knife.

I would divide this subject into (1) Therapeutic branding, (2) Branding for identification, (3) Branding for artistic effect, (4) Branding for concealment of theft.

(1.) There are many ailments of the lower animals in which the use of the firing iron is advisable and even imperative. For instance, cattle have sometimes to be fied (*a*) round the eyes in cases of eye disease, (*b*) on the cheek for opening parotic ducts or for inflammation of these ducts, (*c*) round the root of the horns in cases of caries of the horn, (*d*) on the neck for dislocation, which, however, is generally incurable, (*e*) on the shoulder for lameness in that region, (*f*) round the knee joint for inflammation, spavin, rheumatism &c., (*g*) round the fetlocks for sprain, rheumatism, &c., (*h*) about the suffraginous bones for boney exostosis, (*i*) in the region of the loins for weakness or for sprain of the psoe muscles (a rare complication in cattle), (*j*) point of the hip for fracture, (*k*) on the round bone for dislocation, (*l*) on the hock for spavin, rheumatism, &c., (*m*) hind fetlock and suffraginous bones for the same causes as in the case of the foreleg. Firing is sometimes done on the chest in place of setoning, but though both these forms of treatment have their advocates, they might well be replaced by the use of liniments or mild blisters which serve the same object, viz., to act as counter-irritants. Again, for the same reason the left flank is sometimes fired by the natives in cases of hoven or impaction of the rumen, but here also the practice might advisedly be dispensed with. The same might be said with regard to firing round the genital organs in cases of evertion. Firing is sometimes done round tumours and abcesses instead of opening them or externally applying some preparation to dissipate them ; in this case, too, the practice of firing is not to be recommended. There should be no excuse for firing on the cannon bone as cattle do not suffer from splints.

It will thus be seen that the entire body is liable to be fired for various complaints ; but it must be carefully borne in mind that no firing should be done in more than one place at one time. I might here refer to the empirical treatment of horses where blistering has been done at one time from the withers to the coronets in the forelegs, and in some instances also on the loins and both the

hinds. It is not only the branding of cattle by ignorant villagers, but treatment of and operation on animals generally by empirics and ignorant people as well, that call for suppression. What should be done as regards the branding of cattle is that every owner of stock must be required to possess a certificate to the effect that his animals, if branded, have been fired on therapeutic grounds,—and the certificates must be signed by a qualified Veterinary Surgeon or recognised (but better still *licensed*) vederala.

A. CHINNIAH,
Veterinary Surgeon,

Greatest amount of rainfall in any 24 hours on the 23rd July, 1·56 inches.

Recorded by Mr. C. DRIEBERG.

PRACTICAL HINTS TO HORSE-OWNERS.

By A. CHINNIAH, O.S.V.C.

CHAPTER II. (*Contd.*)—FOOD AND FEEDING.

Guinea Grass is much liked by horses and is to be preferred to other cultivated grasses. It is easily cultivated, but during very dry and hot weather it requires to be irrigated or watered. The cultivation of this grass is carried on more or less throughout the island, but principally in the hill district. The percentage of moisture is less than in water grass, but it is proportionately rich in woody fibre, which is a necessary auxiliary to digestion.

Mr. Guthie of the Department of Agriculture, Sydney, made the following analysis of Guinea grass when rather dry :—

Water	...	11·26 per cent
Ether Extract (fats, &c.)		10·65 „
Albuminoids	...	11·37 „
Carbohydrates	...	40·54 „
Woody fibre	...	26·08 „
Ash	...	9·50 „
		100·00 „

Nutrient value = 53½. Nutrient ratio = 1 to 4

Panicum Molle (Mauritius or water grass).—This is a common grass in Ceylon and largely used for feeding cattle and horses. The percentage of water is great and hence the nutrient ratio is lower. During the rainy season most of the lowlands under this grass become flooded, and for that reason one has to be careful in the use of the grass, as it is believed that through feeding of horses on grass cut off flooded lands the parasitic worm known as Filaria oculi finds its way into the eye through the digestive organ. This grass has got to be dried a little before it is given to horses, as it is apt to cause colic if given very wet. Hence in rainy weather particular care has to be taken in feeding with water grass.

Jungle Grass.—Many horses in Colombo are fed on what are known as "jungle grasses." These grasses being very fine are preferred by most horses to cultivated grass. Wild grass is no doubt more nutritious than cultivated grasses, but, as it has a large quantity of roots to which a good deal of earthy matter adheres and is got rid of with difficulty, the grass has to be used with care.

I might here refer to lucerne (*Medicago sativa*) though it does not fall within the grass family (*gramineæ*). Lucerne belongs to the order leguminosœ on which the herbivora depend for their nitrogenous ingredients. It is cultivated in India for feeding horses, but it is not known among horse-owners in Ceylon. Those who can afford it feed their horses on lucerne in place of hay from Australia. There is no reason why lucerne should not thrive in Ceylon, and be used, especially in the hills, for feeding horses; as Mr. Nock of the Hakgala Gardens has shewn that it grows and yields well in the Nuwara Eliya district. Experiments with lucerne at the School of Agriculture, Colombo, proved that it can be grown even in the hottter parts, but that it requires to be irrigated or watered in dry seasons.

POULTRY FEEDING.

The following notes on the subject of feeding poultry published in the *Fancier's Gazette* will repay perusal by those who are poultry fanciers:—

The kinds of grain which are richest in nitrogenous matter are known as leguminous, *i.e.*, beans, peas and lentils. These, however, are not very easy of digestion, and it would not do to attempt to feed poultry entirely on them, but limited quantities of pea meal and bean meal given in the soft food will prove very useful where an extra large quantity of nitrogenous matter is required. But, generally speaking, there is nothing like oats as a general food, both for chickens and for laying hens, as they are especially rich in nitrogenous matter, contain a fair percentage of minerals, and are lowest in the heat forming scale in comparison with barley and wheat and Indian corn. Indian corn is much more freely used in poultry keeping than it ought to be, because it is lowest in the scale of nitrogenous, and highest in that of heat forming. Let us, therefore, apply this information to the three main points.

Chicken Rearing.—Here we want to produce as large a frame as we can; the secret of success in rearing young stock being to grow a frame capable of bearing a heavy weight of meat when the

time comes for fattening. If we give too much fattening food to chickens when they are growing, the tendency is for them not to develop in frame as they otherwise would. The best foods, therefore, for chickens are oatmeal, with a little pea-meal and a percentage also of lean meat. This latter must be varied according to the circumstances under which they are raised. Chickens which are kept in the country, and have access to a wood or copse where they can obtain plenty of insect life, will need very little, and can be fed almost entirely on oatmeal, whereas those which are kept in town will need to have this want supplied by the addition of lean or fibrine meat. On the whole excellent results would be obtained by feeding little chickens alternately on biscuit meal, with meat at one time and groats or coarse oatmeal the next. As they grow, of course, the food can be changed, and they can have whole oats instead of groats, and a more liberal percentage of lean meat in proportion. Lean meat contains roughly about 25 per cent of albuminoids.

Laying Poultry.—For the production of eggs poultry also need a large percentage of nitrogenous matter, as this is required for the formation of the egg; they also need a little extra supply of mineral matter. Now oats are always fairly rich in mineral matter, whilst meat fibre and fish are rich in albuminoids; therefore, it will be found that on the average a somewhat similar diet to that recommended for chickens will suit the laying hen. In actual practice I have found that poultry will lay better upon oats than upon any other corn.

The Fattening Fowl.—Here we do not need to give frame-growing foods at all. What is wanted is to increase the amount of flesh and fat. This can be brought about by giving a surfeit, and by preventing exercise, which tends to the distribution of heat and prevents the accumulation of fresh bodily substance. Fatty, starchy and sugary foods are recommended for fattening purposes. Thus fat meat residues, Indian meal, potatoes, rice and cow's milk are amongst the best foods for fattening purposes. Many people of experience recommend oatmeal to be given with milk for fattening purposes, and that is excellent. Oatmeal contains if anything more fat forming matter than Indian meal, and is to be preferred to that on account of its effect upon the colour of the fat. I ought to point out that oatmeal, too, not only contains a considerably higher percentage of albuminoid and fibrine matter than Indian meal, thus being suitable for all the three purposes which have been enumerated, but it does not contain so high a percentage of starchy or heat giving matter, and thus is more easy of digestion than is Indian meal. Oats possess a much higher value as a general poultry food than they are reputed to possess by a very large percentage of the poultry-keepers of my acquaintance. If poultry-keepers would use whole oats more freely than Indian corn and wheat as an evening food for their stock they would obtain better results.

STABLE MANURE AND FRUIT TREES.

The Fruit Grower gives some wholesome advise regarding the indiscriminate use of stable manure in fruit cultivation, which growers would do well to take to heart. We reproduce below the pith of the article under reference:—

Where fruit trees are fed heavily with stable manure they can never be depended upon to produce the best fruits in abundance, and the more that is fed to them, the more insipid and watery will the fruits be. Though nitrogen is necessary, it is only necessary in proper proportion and in conjunction with other elements needed to produce the best results. The tree will not grow without nitrogen, but that is no reason why it should be fed to the trees in excess or in unequal proportions to the other elements. Still it must not be forgotten that often the trees in those soils which contain the largest proportion of nitrogen give fruits which are more watery, and the skins of which are only partially coloured, when contrasted with the fruits grown on the soils containing less nitrogenous materials. So long as the wood growth of the tree is ample each year, remember that the soil contains enough nitrogen and does not need any more fed to it. Lime and potash work wonders in the orchard, and there is no doubt in our mind that were our plantations dressed with applications of lime, muriate of potash and superphosphate, they would yield far better fruits and crops than they are in the habit of doing under the present out-of-date system. We warn our readers against the free use of stable manure in fruit culture, or rather, we repeat our warning—for this journal stands out as the only one in which this idea has been persistently advocated—for we are sure that the dosing of fruit trees with nitrogenous material is a gross error, and if the land is made over-rich, with the organic substance stable manure contains, there can be but one result, and that is an increase of wood growth at the expense of fruit. The dung feeders are simply ruining their fruit trees every year that they nauseate the soil with this foul-smelling compound. They are starving their fruit trees really, inducing weak and diseased growth, and in due course the trees will become producers of third-grade fruits, which are a source of annoyance to dealers and of loss to the producers. Here our views are in striking contrast to those of our contemporaries. They advocate the digging of a big hole, into the bottom of which large supplies of dung must be shot, and after covering this with soil they set the roots over this bolus. They argue that in time the roots will reach the manure, and that it will furnish the tree with ample plant food for many years to come. The argument, to our mind, is not convincing. We say, use no manure when planting, and particularly no stable manure. Feed in due course with surface feeding, and thus induce the roots to spread out near the surface. That is the way to secure plentiful crops of large fruits.

CEYLON TIMBERS AS COMPARED WITH ENGISH TIMBERS.

The July number of the *Imperial Institute Journal* contains an interesting report by Professor Unwin, F.R.S., on Ceylon Timbers. We presume the report is based on tests applied to the collection that was sent to the Ceylon section of the Imperial Institute some 8 or 9 years ago. If

so, and considering the age of the specimens (which we think should be noted) the report is a most favourable one for Ceylon timbers. We quote as follows from the report :—

The precise combination of qualities required in a timber for special purposes, including facility of working, uniformity of structure and freedom from defects, appearance, durability, and other qualities, is not to be determined from mechanical tests alone. Further, the results of mechanical tests of the same timber vary with the locality in which the timber is grown, the conditions of felling and seasoning and other circumstances, to a greater extent than is commonly supposed. In some 2,000 tests of different logs of long leaf pine made for the Government of the United States, which had all been selected by the forest officers and subjected to the same treatment, it was found that the crushing strength varied from 2·04 to 4·40 tons per square inch ; the co-efficient of transverse strength from 1·90 to 7·25 tons per square inch ; and the heaviness from 28 to 65 lbs. per cubic foot. Hence very definite deductions from any set of tests on a limited number of logs must be subject to correction.

For European timbers I take the following values as representing fairly what is accepted as the averages of such results as are trustworthy :—

EUROPEAN TIMBERS.

Name of Timber.	Heaviness in pounds per c. foot.	Crushing strength, pounds per S. inch.	Transverse strength, pounds per S. inch.	$\frac{fc}{w}$	$\frac{fb}{w}$
	w.	*fc*	*fb*		
Oak	52	10,000	12,000	193	230
Elm	34	10,300	8,000	320	235
Ash	47	9,000	13,000	191	277
Red Pine	37	8,300	8,300	157	224

Broadly speaking the strength of timber increases with its heaviness. The most valuable timbers for structural purposes are those which have considerable strength without excessive weight. The pine timbers so largely used are not only easy to work, but they have good strength in proportion to their heaviness. In the above table the strengths have been divided by the weights per cub. foot and the results are given in the last two columns. Compared in this way, Elm is superior to Oak, and even red pine is not much inferior.

TABLE OF CEYLON TIMBERS.

Name of Timber.	Heaviness in pounds per cubic foot.	Crushing strength, pounds per square inch.	Transverse strength, pounds, per square inch.	$\frac{fc}{w}$	$\frac{fb}{w}$
	w.	*fc*	*fb*		
LIGHT TIMBERS. UNDER 42 lb. per c. ft.					
Sapu ...	41·4	3,490	7,820	84	188
Vinakku ..	40·4	4,290	9,510	106	234
Lunumidella ...	20·4	3,200	5,720	157	280
Walukina ..	32·4	6,100	9,010	188	280
MEDIUM TIMBERS. 42 to 60 lb. per c. ft.					
Panakka ...	54·9	9,200	12,960	167	236
Dawata ..	47·3	5,920	10,820	125	228
Jak ..	43·4	7,550	6,840	174	157
Del ..	48·1	6,500	9,310	135	193
Suriyamara ...	57·0	9,300	14,600	163	256
Ilanthai ..	48·9	6,170	7,790	126	159
Mendora ..	59·7	5,810	13,710	98	230
Ubberiya ...	56·7	7,620	10,090	139	178
Tawenna ..	46·1	7,660	8,070	166	175
Margosa ..	47·3	6,640	11,480	140	244
Halmilla ...	49·9	7,630	15,450	153	310
Suriya ..	50·3	6,230	11,660	124	233
HEAVY TIMBERS. Over 60 lb. c. ft.					
Gurukina ..	62·6	5,350	8,740	86	140
Satinwood ...	64·3	7,500	13,780	116	214
Milla ...	60·9	6,630	14,760	109	242
Ranai ..	63·3	5,800	10,570	92	167
Chomuntiri ..	75·5	6,530	14,490	86	192
Nedun ..	70·8	8,700	16,040	125	226

Taking the light woods, it is clear that as regards strength in proportion to weight, Lunumidella and Walukina stand best. The remarkably light wood, Lunumidella, is not absolutely as strong as red pine, but in proportion to its weight it is even a better timber. Walukina is weaker than ash, and about the same strength as red pine.

Of the medium woods, Halmilla is strongest in proportion to its weight, and Suriyamara stands next. Ubberiya, which Mr. Stone thinks well of, is somewhat weaker than oak, but it has a greater transverse strength than elm. Tawenna has nearly the same mechanical properties as Ubberiya. Suriyamara is somewhat stronger than either of these.

The heavy timbers do not give very high results. Satinwood has greater transverse strength than oak, but the strength in proportion to weight is not so good. Milla and Chomuntiri have a little greater transverse strength, but their crushing resistance is low. Nedun is the heaviest, and, for cross breaking, the strongest timber. But its constants obtained by dividing the strength by the weight are not so good as those of European timbers.

I know no tests of the shearing resistance of European timbers along the fibre which are trustworthy. But the following results of tests at Watertown Arsenal may be used for comparison with the tests of Ceylon timbers.

	Shearing Strength. Lb. per sq. in.
Ash — —	458 to 700
Red oak — —	726 to 999
Yellow pine —	286 to 415
Spruce — —	253 to 374

SHEARING STRENGTH OF CEYLON TIMBERS.

Name of Timber.	Shearing Strength along fibres. Lb. per sq. in. *fs*	$\frac{fs}{w}$

Milla	—	—	1,004	16
Ranai	—	—	925	15
Chomuntiri	—	—	1,333	18
Nedun	—	—	1,486	21

In a few cases the shearing resistance is rather low for light-wood timbers. In most instances, however, it is as high as, or higher than, that of timbers commonly used. Amongst the medium timbers there are seven which have greater shearing resistance than American oak. The figures in the last column show the relative values of the timbers as regards shearing strength.

[The following are the botanical names of the timbers referred to :—

Sapu, Michelia champaca
Vinakku, Pterospermum suberifolium
Lunumidella, Melia dubia
Walukina, Calophyllum bracteatum
Panakka, Pleurostylia Wightii
Dawata, Carallia integerrima
Jak, Artocarpus integrifolia
Del, Artocarpus noblis
Suriyamara, Albizzia orodatissima
Ilanthai, Zizyphus jujuba
Mendora, Vatica Roxburghiana
Ubberiya, Carallia calycina
Tawenna, Cryptocarya membranacea
Margosa, Azadirachta indica
Halmilla, Berrya Ammonilla
Suriya, Thespesia populnea
Gurukina, Calophyllum Burmanni
Satinwood, Chloroxylon Swietenia
Milla, Vitex altissima
Ranai, Persea semecarpifolia
Chomuntiri, Heritiera littoralis
Nedun, Pericopsis Mooniana.—ED. A.M.]

RESOLUTIONS OF THE INTERNATIONAL CONGRESS OF VETERINARY SURGEONS, 1899.

For the following Resolutions respecting the diseases of stock and their prevention (agreed to at the 7th International Congress of Veterinary Surgeons, held at Baden-Baden, July, 1899,) we are indebted to the *Cape Agricultural Gazette*:—

I.—PREVENTIVE MEASURES AGAINST THE SPREAD OF EPIZOOTICS IN CONSEQUENCE OF INTERNATIONAL CATTLE TRADE.

The Seventh International Veterinary Congress considers an effective fight against epizootics, in the interests of the individual States as well as of the public economical welfare, both useful and desirable. The means to be employed are a uniform application of scientific principles and an efficient regulation of the veterinary department, of the intelligence department respecting epizootics, and of international cattle trade.

But the Congress, considering the difference in the economical development and the conditions of traffic as well as the dissimilitude of veterinary organization in the separate countries, does not think the moment has yet come for laying down definite principles of an international agreement.

II.—THE PREVENTON OF FOOT AND MOUTH DISEASE.

It is in the interest of an effectual prevention of Foot and Mouth Disease :

(1) by all and every means to prosecute the scentific investigation of this disease ;

(2) to exclude the infected district from free traffic ;

(3) to submit the traffic in cattle for sale to a strict veterinary police control in such a way, that the cattle of cattle-traders should be placed under the inspection of the police before sale ;

(4) that buttermilk and all other remnants of milk should not be supplied habitually from the co-operative dairies until they have first been submitted to such a temperature as shall insure the extinction of infectious matter ;

(5) that the authorities should be required to order in certain cases the slaughter of animals, the proprietors receiving compensation for the resulting loss ;

(6) to regulate in the whole country, as far as possible, the initiation, the continuation and the completion of the needful veterinary police rules, whereby special weight is to be laid upon the strict carrying out of the separation and disinfection of the clothes of the attendants, etc.

III.—THE NEWEST SUGGESTIONS FOR AN EFFECTUL MEAT INSPECTION.

(1) The Congress desires to draw the attention of the Governments of the States officially represented to the necessity of the general introduction of compulsory inspection of meat.

(2) None other than certificated veterinary surgeons can be summoned as professional men to inspect meat. In places where it is still impossible to establish a regular veterinary service, lay inspectors with limited powers may be provisionally appointed. These must be trained for their profession as much as possible by veterinary surgeons in the larger slaughter houses, be examined by the State, and constantly be controlled in the exercise of their function by veterinary surgeons. Only veterinary surgeons should be appointed as professional inspectors of meat and as the directors of slaughter houses and cattle sheds.

(3) Instruction in meat inspection at the veterinary colleges must be improved and

extended. Meat inspection should be made as far as possible the object of practical examination for a veterinary diploma.

This examination too must take place for the obtaining of the diploma as a veterinary surgeon. Moreover, it is required in this case, that the candidate has worked at least 8 weeks in the meat inspection of a large public slaughter house, standing under regular veterinary supervision.

(4) As a matter of principle, all inspection of meat must be founded on sure scientific bases and experimental rules, which should be agreed upon by an international understanding.

(5) Inspection must be extended to all kinds of butcher's meat and be introduced everywhere. It must include all beasts for the butcher and every kind of meat that serves for human food and public use, whether it be destined for human food and public use, whether it be destined for public sale or private consumption.

(6) The efficiency of meat inspection is only perfect in those places where public slaughter houses exist together with compulsory slaughter. On that account, their erection in as many communes as possible is advisable.

(7) It is necessary for the inspection of fresh slaughtered meat coming from outside:

(*a*) that the flesh of cattle and horses should be brought in at least in quarters, that of swine only in halves, and that of all other animals in an undivided state: and further,

(*b*) that the most important intestines should be in natural connection with the meat.

Fresh meat introduced from foreign countries is subject to the same requirement.

Preserved meat from foreign countries can only be imported if it is kept in a trustworthy, sanitarily unsuspicious manner, and its harmlessness can be affirmed with certainty.

(8) Meat authorized for consumption after inspection must be marked in a proper manner (stamping, leading, etc.).

(9) Meat proved to be harmless but of inferior quality must be sold under declaration at certain places ("Freibänke") under the supervision of the authorities.

(10) The introduction of a universal and compulsory insurance for slaughter cattle under State control is urgently required in the interest of meat inspection and the stamping out of cattle diseases.

(11) The results of meat inspection should be collected for scientific and economical purposes in statistics arranged on a definite plan, in which international uniformity should be aimed at.

ARTIFICIAL CHANGES OF PHYSICAL PROPERTIES OF SOIL.

(*Continued.*)

Thus, while the methods noted are effective in removing the hurtful excess of water, they may bring about a condition of dryness which in most cases, especially where rain is scarce, and in time of drought is unfavourable to growth of maximum crops. To do away with this difficulty, which militates against the best interests of rational tillage of land, such means of regulations ought to be adopted as will either cause the water to drain off more slowly, or allow of complete stoppage of all flow temporarily. The former can be attained only imperfectly, because in the end all the water not held by the soil is removed; in the latter case, however, with proper care the moisture may be thoroughly utilized in accordance with the nature of the soil and the requirements of the crops. Drainage cannot be controlled effectively with open ditches, but it may very readily be done in case of under drains by calculating the diameter of the drain pipe on the basis of the quantity of water that percolates through hard, heavy soil. According to the experiments of the author, this amounts to 0·0008 cubic meters, or 0·8 litre per second and hectare (=0·56 pint per second per acre). With this as a basis, and starting with the smallest feasible diameter of pipe (4 cm, or 1·6 in.), the drainage system may be so constructed that part of the moisture may be kept in the soil for a long time. This, however, hardly answers the purpose, since the humidity of the soil, especially during the period of plant growth, cannot be fully controlled. Hence it is recommended that open ditches be provided with board dams and drains with flood gates, by means of which the flow of water may be interrupted either partly or entirely, as the occasion may require. This method is simple and easily applied in all ordinary forms of drainage. The higher portions of a dangerously moist field should be reserved for grains and hoed crops, while the lower parts are used for crops which possess a high power of evaporation (such as meadows). Even in this case, however, the plants will suffer, if the moisture in the soil exceeds 70 to 80 per cent. of saturation. The temporary pools which form on very fine grained soils during heavy rains must be removed either by direct withdrawal of the water (water furrows), or by such means as will bring about a diminution of the water capacity; in other words, an increase in permeability or an increase of evaporation from the soil. In the first case effort must be directed principally toward producing a crumbly structure through cultivation and manuring, as suggested above, since by this means the water-holding capacity of the soil is reduced and percolation promoted. On extremely fine-grained soils (clay soils, black-earth), which in their unmodified condition offer the greatest resistance to the passage of water and become thoroughly moist only with the greatest difficulty, this process is indispensable in order that the precipitation may be of any use at all to plants. A favourable modification of

the water capacity and penetrability of such soils may also be brought about by admixture of soils of opposite physical characteristics, as, for instance, coarser grained soil (sand). By this means stiff soils are rendered more easy to cultivate, and are more readily changed into a condition of separate grain structure.

Enlarging the surface of evaporation, as is done in ridge and hill culture, is another means of preventing harmful accumulation of water in soils. By this means, also, a portion of the rain water is removed from the reach of the plants by flowing into the furrows between the rows.

Close planting also assists to some extent in reducing the moisture in the soil by increasing the amount of water drawn from the soil by the crop.

It is a mistake to allow wet soils to lie fallow, especially in wet seasons, because the conditions in fallow soils are much less favourable to evaporation than in cultivated soil. Allowing soils to lie fallow, however, is not harmful; on the contrary, it may be useful if the soil during a previous long drought has become dry to a considerable depth.

Lack of moisture in a soil may be corrected either by direct application of water (irrigation) or by increasing the absorptive power of the soil. Irrigation is to be recommended in all cases in which the water supplied by precipitation is insufficient for the production of maximum crops. The point at which irrigation becomes necessary varies in different localities and is determined by the energy of evaporation, the water-holding power of the soil, and the distribution of precipitation. In the warmer climates we may assume, as a rule, that when precipitation is less than 24 to 28 in. irrigation is required for maximum crops, while in colder localities in which evaporation is less rapid and crops smaller, on account of the low temperature, the limit may be placed at about 16 in.

With regard to the treatment of soils which have little water capacity, great permeability, and favourable conditions for evaporation, the aim should be mainly to keep the ground water at a proper level, or, if this is not possible, to increase the water capacity of the soil.

The latter may be accomplished by admixture of fine-grained, earthy materials (clay, loam and marl), or by increasing the percentage of humus through liberal applications of manures of organic origin (stable manure, peat, &c). Another, though less effective, means is rolling the soil, provided it be followed at the beginning of dry weather, by harrowing, hoeing, &c. to reduce evaporation.

For soils of small water capacity such operations as limit evaporation as far as possible are generally recommended. Too frequent ploughing of the soil should be avoided, and ploughed land should be harrowed as soon as dry weather sets in, to reduce the surface of evaporation as much as possible. If the soil becomes too hard, as may happen as a result of violent rains or of rolling, loosening of the surface (harrowing, hoeing) is of great advantage in reducing evaporation and thus retaining moisture in the soil.

Furthermore, hill or ridge culture is to be avoided, since in this case evaporation is greater than in level culture. Close planting should not be practised for the same reason. Allowing the soil to lie fallow may result in the storage of moisture in the soil, but it is recommended only when the soil is dry to a considerable depth. Finally, mulching or covering the soil with a layer of dead vegetable matter (stable manure, straw, &c.) reduces evaporation from the soil for a time at least.

CLINICAL NOTES.

By A. CHINNIAH, G.B.V.C.

I performed successful operations on three dogs suffering from cancer of the penis. In all three cases castration was performed in addition to the ablation of the cancerous growth from the parts. The following letter from Colonel Webster testifies to the fact that my mode of operation has been attended with successful results :—

Berwick House, Cinnamon Gardens,
4th August, 1900.

I have much pleasure in stating that Veterinary Surgeon A. Chinniah was called in to attend my dog, which was suffering from cancer, on the 2nd June, 1899, and after performing an operation—removing the immediate cause of the disease on the 8th September of the same year—was able to perform a further operation resulting in the cure of the dog.

(Signed) H. G. WEBSTER, Lieut.-Col.

CULTIVATION OF THE ARECANUT IN BOMBAY DISTRICT.

(A Note by Mr. J. W. Mollison, Deputy Director of Agriculture, Poona.)

The palm is a native of Cochin-China, Malayan peninsula and Islands. It is cultivated throughout tropical India, but does not thrive at any great distance away from the sea.

Betel palms, cardamoms, and pepper are the chief crops grown in the garden lands of Kánara. In old-established gardens there may be a few jak-fruit and coconut trees, also plantains, limes, coffee bushes, and pineapples. These gardens are chiefly found in Sirsi and Sidádpur taluks and in the whole Collectorate extend to some 17,000 acres. They generally occupy the bottom lands of narrow valleys. The most favourable situations are in valleys which have the slopes on both sides fairly extensive, moderately steep, and covered with forest growth. The forest growth gives beneficial shade and shelter, and supplies the gardens with branchwood, leaves, and litter for manure and other purposes. The garden land extends usually in a narrow strip along the course of any particular valley and is subdivided according to ownership. Bottom land which is open and cleared appears to be more suitable for rice beds than for spice gardens. Some garden occupants also own rice lands, but most commonly they only cultivate garden land. An owner may own three or four acres, sometimes more, often less. All garden owners are Haviks—a shrewd and hardworking,

well-behaved class among the Brahmins. They are supposed to have come originally from Mysore. Their methods of cultivation are almost identical in all gardens, and presumably are ancient in origin. The methods adopted are successful in practice, and although they appear at first sight extraordinarily antiquated to a casual onlooker, they may, like other time-honoured Indian practices, be found on full enquiry the most suitable for the existing natural conditions of the district. The Haviks are well-to-do, as evidenced by their commodious well-built houses, which in many cases are roofed with Mangalore tiles.

The narrow strips of spice gardens follow the course of the old nálas which drained the valleys before the gardens existed. When the gardens of any particular valley were first formed, the bed of the nála was levelled and also the bottom land along its course. Since that time the slopes on either side have been gradually cut away and many of the old gardens are now bounded laterally by almost perpendicular cuttings 10′—20′ in height. These cuttings present a complete barrier against trespass by man or beast and shelter the gardens from storm and wind. The occupants' house and buildings are close to the garden, above the cuttings, usually in a cosy fairly dry situation. A garden is entered by descending a steep narrow pathway or by rude steps which lead to a plank-bridge over a ditch at the bottom. The rainfall of the district is heavy, and the positions of the gardens are such that much drainage water must pass through them. Drainage is thoroughly arranged for by main ditches cut along the course of the garden strips and by cross minor ditches which carry water to the main drainage channels. The main channels are bridged here and there as required by long slabs of stone or by three or four pieces of palm-stem placed side by side. The heavy rainfall and the flood of drainage water in the monsoon undoubtedly wash much of the garden land away, and more particularly so if the soil is not of a particular kind. The most suitable soil is called locally kagdali. This is a yellowish-red or reddish-brown earth which usually exists in deep beds as the side cuttings of the garden show. In these cuttings rock of a soft nature sometimes obtrudes a few feet below the surface, but more often the whole depth of cutting is soil-like in character, and appears in layers which vary somewhat in consistence. There are no definite lines of demarcation between layers; but near the original surface generally there is sometimes a gritty or gravelly section which is considered inferior. Further down there is a layer which presents a shaly appearance which deceives the eye. At first sight it appears hard, durable or rocky, but a piece can easily be broken off by the hand, and if squeezed or rubbed crumbles into an impalpable powder which feels moist and soapy. This soil material as seen in the cutting has a peculiar metallic lustre, but when crumbled is simply a fine argillaceous yellow earth extremely retentive of moisture, and which under pressure becomes consolidated, so that running water does not readily remove it. It is easy to understand that a soil of this class is suitable for a spice garden. It does not matter much whether the soil is naturally fertile or not, because the yield of the crops grown is mostly affected by the quantity and quality of manure directly applied. As regards the soil the chief point is that it must be of such consistence that it can withstand the denuding effect of flood water and be so retentive of moisture that little or no irrigation is required in the fair season. In many gardens irrigation is not required even in the hot weather. At this time a trickling stream fed from natural springs may be seen running along the main channels or a perennial nála passes by the main channels through the garden. The soil is thus kept continuously moist. In such garden ferns and mosses in great profusion and variety grow along the drainage channels. In other gardens not so favourably situated a little irrigation may be required in March, April, and May, and this is arranged for from a tank or tanks usually built of stone and not very capacious, which tap the waters of natural springs.

In laying out a garden, the soil is first levelled and then the drainage channels are made. The main channels are about four feet deep and four or five feet wide at the top with sides having an easy slope to the bottom. The minor cross channels are one foot wide and about 18 inches to 2 feet deep. These channels are exactly parallel. They are distant from each other 12 to 15 feet. The space between is called bharan. The bharan has a rounded surface. It is highest in the middle, thus rain water drains freely to the channels. A pathway runs along the middle of each bharan, or rather by usage the middle of each bharan becomes a pathway. On each side of the pathway, in old-established gardens, a line of alternate betel palms and cardamoms is found with pepper plants trained on the stems of the palms. The palms are 6 to 8 feet apart in the rows. It takes, however, many years of patient labour before the garden gets to this stage. When a new garden is made the bharans are thoroughly dug and weeded. Plantains are planted along the water-courses. They give some direct return for expenditure incurred, but the object in planting them is to provide shade for the betel palms. When the plantations afford sufficient shade, pits 2½ to 3 ft. square and 2½ ft. deep are made. Leaf manure and pieces of plantain are put in the bottom of the pits and then excavated soil partly filled in. The young palm trees four or five feet high and three or four years old are planted in these pits, and sufficient of the excavated earth put round and pressed on the roots to keep the plants straight.

(To be continued.)

ON THE FORESTS AND WASTE LANDS OF CEYLON.

By A. F. Broun, Esq.,

Conservator of Forests.

The lowcountry wet-zone is the country *par excellence* of the Dipterocarps. In the Chilaw and Kurunegala districts, and in the Northern portion of the Colombo district, they are represented only by *Dipterocarpus zeylanicus*,

but further South and East they increase in number and species until, in many cases, they form almost the entire forest. No doubt, several new species will have to be added, and even since the first volume of Trimen's Flora has been published fresh discoveries have been made, a case in point being the *Stemonoporus (? Vatica) Lewisi*, which was found by Mr. F. Lewis of the Forest Department at about 1,000 ft. altitude above Pelmadulla. The curious almost wingless fruit of *Shorea lissophylla* was also found near the Bentota river in the Western Province. The forests of this zone, where they have been saved, are to the eye the most magnificent of the whole island, the trees often reaching a height of 100 feet to the first branch. On this account the trees are often difficult to identify, and it is probable that many are still unnamed, especially as it is not always possible to hit on new species at the time when they are in flower or fruit. The most beautiful of these forests is probably the forest of the Hiuidun Pattu, in the Southern Province; in it the most important Dipterocarps are *Dipterocarpus hispidus*, which in the South almost replaces *D. zeylanicus*, *D. glandulosus*, *Shorea oblongifolia*, *Doona trapezifolia*, which extends up to about 3,000 ft. above sea level, *D. cordifolia*, *D. macrophylla*, *D. congestiflora*, which produces a valuable timber, *Hopea discolor* and *Vatica affinis*.

Vatica Roxburghiana is found near streams and in lands subject to inundation in the Western Province and in Sabaragamuwa, while *Vateria acuminata*, which also loves the neighbourhood of water, is found on more rocky ground. The Dipterocarps which are able to ascend to an elevation of 4,000 ft. are *Doona zeylanica* and *D. Gardneri*, and *Stemonoporus Gardneri*, which has been found up to nearly 5,000 feet.

Amoug the natural orders, which are also widely represented, are the Guttiferœ, the Ebenaceœ, and the Sapotaceœ. The first-named is represented chiefly by the ironwood *Mesua ferrea* and *M. Thwaitesii*, by *Calophyllum spectabile*, *C. Burmanni*, which extends into the dry country, *C. bracteatum*, *C. tomentosum*, *Garcinia cambogia*, *G. morella*, (the gamboge tree), *G. terpnophylla*, and *G. echmocarpa*, which latter grows up to 6,000 ft. elevation. The Ebenaceœ are particularly abundant in the forests of the Adam's Peak Range, and in the Pasdun and Hiuidun Korales.

Ebony, as has already been mentioned, is fouud in small quantities in this zone, but the most important tree of this family, which is unfortunately almost extinct, the Coromandel or Calamander wood of commerce, *Diospyros quaesita*, is still found here and there in the Pasdun Korale and in the Hinidun Pattu. Attempts have been made for several years to obtain the fruit in order to propagate the species artificially, but, although rewards have been offered, none has been obtained.

The other most noticeable trees of this family are described by Mr. F. Lewis, who has made a special study of them. In the wet forests, extendiug from the moun tain known as the Haycock into the Sabaraga muwa Province, the most noticeable example of the Ebenaceæ are *Diospyros posia*, *D. Gardneri*, *D. insignis*, and *D. Thwaitesii*. The first of these is found up to 3,000 ft. altitude, while the last, though endemic, is restricted to the areas of high raiufall. *D. pruriens* is found very sparingly in the wet forests towards Adam's Peak, and in one place in the Western Province. A remarkable species, possibly a form *D. Ebenum*, locally known as 'Kallu kiria,' occurs at the foot of the Rakwana hills, and is conspicuous by its black lace-like heart-wood, but little is known of its flowers or fruit. One of the most common, but valueless, of the order is *D. insignis*, which extends up to 2,000 feet altitude in the West of Ceylou.

The Sapotaceœ are also well represented, especially in parts of the Matara district. The most important are *Chrysophyllum Roxburghii*, *Isonandra lanceolata*, *Bassia fulva*, *B. neriifolia*, which lines the banks of rivers, *Palaquium petiolare*, *P. grande*, which extends into the mountain zone, and *Mimusops Elengi* which is also found in the dry zone. Among the more noteworthy trees belonging to other natural orders, the following are characteristic of this zone:— *Dillenia retusa*, *Wormia triquetra*, *Cullenia excelsa*, *Elæocarpus serratus*, *Kokoona zeylanica*, *Canarium zeylanicum*, *C. brunneum*, *Lasinthera apicalis*, *Pometia eximia*, *Canpnosperma zeylanicum*, which in places forms almost pure forest, *Pericopsis Mooniana* near water-courses, *Adenanthera pavonina*, *A. bicolor*, *Pygeum zeylanicum*, *Carallia integerrima*, *C. calycina*, especially in the Galle district, *Anisophyllea zeylanica*, *Homalium zeylanicum*, *Symplocos spicata*, the three Myristicas (*M. laurifolia*, *M. Horsfieldia* and *M. Iriya*). Various species of Cinnamomum and Litsea are also abundant; and, among the Euphorbiaceæ, *Bridelia retusa*, *B. Moonii*, *Aporosa latifolia*, *A. Lindleyana*, *Ostodes zeylanica*, *Chætocarpus castanocarpus*, and *Macaranga tomentosa* are the most common; while among Urticaceœ there are numerous figs, *Artocarpus integrifolia*, *A nobilis*, and *Trema orientalis*. Among the shrubs which characterise this zone may be mentioned *Humboldtia laurifolia*, *Maesa indica*, *Agrostis tachys longifolia*, *A. Hookeri*, *Ixora coccinea*, *Ardisia Moonii*, &c.

Most of the palms of Ceylon are found in the zone. The most important by far is *Caryota urens*, the toddy and sugar of which provide many jungle people with means of existence. The Talipot palm (*Corypha umbraculifera*) found in several forests, especially in the Kurunegala district, and is noteworthy for the enormous panicle of flowers which the male tree produces, and for its leaves, which are used for umbrellas, fans, mats, &c. The *Nipa fruticans* is characteristic of brackish waters, while several species of Calamus, with the help of their hooked tendrils, climb to the summits of the highest trees.

Among the characteristic climbers may be mentioned *Coscinium fenestratum*, *Ancistrocladus Vahlii*, *Entada scandens*, *Acacia concinna*, *Strychnos cinnamomifolia*.

The most beautiful orchid of this zone is the *Dendrobium macarthiæ*; and amoug the most interesting ferns may be meutioned *Gleichenia linearis*, which covers large extents of country, *Blechnum orientale* and *Nephrolepis exaltata* which, after the first-named, are the most

common, *Cyathæa sinuata*, which is only found in the Southern Province, *C. Walkerii*, the tree fern of the lowcountry, *Thamnopteris Nidus*, the so-called Bird's-nest fern found growing generally on trees, *Asplenium rutæfolium*, *Diplazium lanceum*, *D. Schkuhrii*, *Aspidium Thwaitesii*, *Lastræa deparioides*, *Niphobolus Gardneri*, *Pleopeltis pteropus* (var. *minor*), *Tœnites blechnoides* (in the Matara District), *Drymoglossum heterophyllum*. *Stenochloena palustris*; *Polybotrya appendiculata*, *Gymnopteris variabilis*, *G. contaminans*, *G. subcrenata*, *G. quercifolia*, *Acrostichum aureum* (generally not far from the sea in swampy places), *Schizœa digitata*, *Angiopteris evecta*, *Ophioglossum pendulum*, and *Helminthostachys zeylanica*. *Botrychium daucifolium* and *Oleandra musæfolia* extend into the mountain zone.

The forests of this zone are of by no means so large in extent as those of the dry zone; they usually occur in isolated blocks, covering ridges and separated by stretches of chena or by paddy fields. The most important blocks are the forests that in former days formed part of the extensive Sinharaja forest; they are situated in the Galle district of the Southern Province, the Pasdun Korale of the Western Province, and the Kukulu Korala of the Province of Sabaragamuwa. The lower forests of the Adam's Peak range also belong to this zone.

GENERAL ITEMS.

A bulletin of the Kansas Agricultural College advises that dairy cows should be always fed after milking, and never just before or while milking. One reason given for this advice is that there are odours from the feed that may be absorbed by the milk direct, or if there are volatile matters in the food they will taint the milk, while if the food is given after milking, these volatile matters are worked out before the next milking. A cow properly trained will give more milk when she devotes her whole attention to giving milk than when she is fed during milking time.

A correspondent to the *Cape Agricultural Journal* offers the following advice for treating fowl cholera which many will be glad to have:—Take one large tablespoonful of Little's Dip and mix it with *three gallons of soft water*, and in the mixture soak some wheat, lock up the fowls, and give them the wheat to eat and some of the same water to drink. Three or four days of this treatment will stop the epidemic. The treatment, it is said, has been always found successful.

The same journal states that one pound of bisulphide of carbon will destroy all the insect life in 100 bushels of grain in a bin, or will be effective in 1,000 cubic feet of space. It forms a dense gas, heavier than the atmosphere, and consequently it not only permeates the grain but finds its way into all the crevices in which the insects breed. To preserve grain for sowing the best plan is to keep it in an iron tank or tin lined box, if it can be made airtight, and place on the top a piece of cotton saturated with bisulphide of carbon, then close it down, taking care not to let the fumes come in contact with a light. The grain can be left like this till required for sowing and will be perfectly safe from weevils and the germinating power in no way injured.

One of the latest remedies for ants is gasoline. Pour about half a pint into the ant hill and set it on fire. The gasoline will instantly spread throughout the ant hill, and as the heat on the surface increases the gas will generate from the utmost recesses and the fire destroy the ants. Half a pint will burn from three to eight hours and kill every ant in the largest nest and all that attempt to enter it from without.

The following recipe, from a Sydney paper, is said to be a certain remedy against rats, mice and cockroaches:—Take 1 lb. of flour, 2 tablespoonfuls of oatmeal, 4 to 6 oz. of plaster of Paris; mix. dry and place in pans or plates on the floor, in cupboards, &c. Securely cover up all other food in the house and take care that children and pet animals do not have access to the mixture. A correspondent says that he tried the mixture in an old store and killed 600 rats in three nights!

The TROPICAL AGRICULTURIST
MONTHLY.

Vol. XX. COLOMBO, OCTOBER 1ST, 1900. No. 4.

PLUCKING, PRUNING AND PREPARATION OF TEA.

THE "*CEYLON OBSERVER*" PAMPHLET OF 1897 ON THE ABOVE SUBJECT.

(By "1874.")

HAVE gone through this pamphlet again with much interest. I am at present going in for the subject of Pruning and referred to it to try and get some authority for my views. The pamphlet consists of opinions from 84 planters and comments on the letters by the editor. It contains a great mass of information. It would enable a proprietor, visiting his estates, who had no special knowledge of tea, to put shrewd questions to his managers, and ask them to give reasons for the line of action they had adopted. I think that it was unfortunate that the questions were put so as to show the influence of the three P's of the heading, on the fall in prices.

The 6th and 7th questions on the list are for "any other causes *apart* from Overproduction." Surely the range of prices depends *entirely* on the relation between demand and supply. In 1876 my manager made some "blackened" red leaf and got 10 annas for it. The red leaf was blackened by being steeped in ink. The ink was made by boiling hard tea leaves in iron pans. Yet we got 10 annas and the stuff could only be called *tea* because it appeared to be tea. Would it be too much to ask you to re-open the ballot, as applied to each question in turn, and leaving out its relation to average prices?

I should like to start the question of "Pruning." From your pamphlet I see that the general opinion says that "cutting down" reduces the value of the made tea, until the bushes have begun to get well covered. Some planters condemn cutting down but a large number say that it is necessary at intervals. This is the very point I wish to question. Letter No. 13 from "Hantane" says: "(3) Severe pruning, I have no experience of. I don't prune severely but often, every 12 months or so. The estate is old, the soil poor, but it is liberally manured and pruners are kept at work steadily all the year round. The result as far as I can yet judge has been wholly beneficial, no falling-off in the teas, and good plucking averages all the year round." That was three years ago; it would be interesting to know whether the same system has been carried on up to date. There is only one alternative for cutting down or cutting back and that is to cut out all old and useless wood each time the bush is pruned. The planter quoted above, does not say for how long he has refrained from cutting down, and so his support loses nearly all its value for my contention that "cutting down" *can* be entirely dispensed with if the bush is pruned properly each time it undergoes the knife. By "properly" I mean that all the good yielding branches shall be cut back as far as is judged necessary, but all old branches which have ceased to yield should be removed from the bush so that new branches may take their place. I can say that I have cut down only five acres within the last 10 years. I regret having done so, and I can go on indefinitely without cutting down, because I remove the useless wood each time the bushes are pruned. The test of the fitness of a branch to remain is that it shall have some decent new red wood on it. If it has not grown new wood about three-eighths of an inch in diameter since the last pruning, it has to be cut out or cut back. This work is done by a special gang of men who follow the ordinary pruners. The bush having been pruned is open to inspection. Each branch shows at a glance what it has done in the way of growth. If *all* the branches are bad, only one or two are removed and the rest given another chance, and they generally respond,

and soon begin to grow new wood if they are not heavily plucked too soon after pruning.

Letter No. 15 by "Custos Pamperio Horti" is very strong against hard pruning, and contrasts tea pruning with that of coffee, much to the disadvantage of the former. Did it strike him that the immediate effect of injurious pruning is to give a larger crop of tea leaf, whereas the opposite result would come about with coffee bushes. If the manager has pruned year by year "for leaf" *i.e.* lightly, the yield gradually gets less; the only remedy is to "cut down." But in coffee as soon as a branch or leading stem, (or whatever it was called) ceased to yield it was cut out, and *the rest* of the bush treated in a decent manner. Tea is not treated in this way because it will respond immediately to the knife, whereas to cut down a coffee garden means the loss of the crop for that year.

Letter No. 16 by "W. I. G." says:—"Tea is not nearly so severely pruned as it was a few years ago." Letter No 17 by "Incog" says:—"Tea occasionally requires heavy pruning but this is much overdone.' Letter No. 19 by "G. H. G." says:—"I have often been told by those who have had experience that flavour is greatly lost by cutting down old bushes to 12 to 15 inches after they have reached too great a height after successive prunings. I have never heard that such bushes ever regain their original flavour." Letter No. 27 by "S." says:—"Neither does severe pruning affect the quality, only shortens the life of the bush". I agree here because I believe that each cutting down reduces the vigour of the bush, and that this accounts for the many played out estates which have been abandoned. Letter No. 33 by "J. J." says:—"I am against severe pruning, medium is what I do, cutting down once in 6 years or so." The point of the matter is that discriminate pruning costs money year by year, and to save this expense, the bushes are cut down periodically. It cost little to cut down the bush. The relative cost would be as follows:—(1) cutting down every 6th year @ R2 per acre. 6 cuttings out of old wood @ R2 per acre=R12. Take a garden of 1,000 acres—cutting down cost R2,000, cutting out costs R12,000. Here is a palpable gain in solid coin. But what has the saving cost? First of all one or two invoices of thoroughly bad tea, say 1,000 maunds of tea @ R2 below average value. This means R10,000. Then a reduced outturn for a few years until the bush has re-grown to its full sizes which may be put down at anything up to R30,000. The deceptive part of cutting down is that a portion only of the estate is cut down each year and so no idea of the actual loss either in quality or yield can be formed. In some rare cases a manager advises, or is advised, to cut down the bulk of the estate and *then* follows one memorable year of bad quality and short yield, but still no lesson is learned from this. It is only hoped that the next cutting-down may be long deferred, or done regularly on a fixed proportion of the estate, so that the directors and shareholders shall not *notice* it. If you will not pay the estate extra R2 or R3 per acre per annum to have good pruning done, you will have to pay for it in steady loss, and eventually will lose the whole estate. Money saved on pruning is spent in digging the grave of the estate.

Letter No. 37 by "L." says—"(Severe pruning) is rarely resorted to: one case I know, when this was done, gave very beneficial results, both as regards yield, and at the same time quality was maintained. I hardly think that this refers to cutting down." "L." probably means a thorough cleaning out of the bush leaving all the thick branches. It is quite impossible that cutting the bushes down to stumps can give the same yield as if those bushes had been properly pruned and had not been reduced to such a state of overgrowth that they refused to yield. Cutting down a bush which has ceased to yield will cause it to yield *some* leaf. But judicious pruning will prevent the bush from *ever* getting into a non-yielding state. There *will* be a succession of new branches, if the old ones are removed as soon as they get too old to yield vigorously." Letter No. 45 by "M." says:—"Severe low pruning (necessitated by too close plucking and injudicious modes of pruning) have much to do with the falling off of quality." This is my own view. "Cutting down is necessitated by injudicious modes of pruning." I cannot agree that close plucking is the cause of it unless it has been done too soon after pruning. Give the bush time to grow enough leaf to carry on its proper work, and after that you can take all that appears if you have enough labour to do so. Letter No. 18 by "G." says:—"I believe that a high bush gives a better quality of tea than a bush pruned down low." The system I advocate will keep the bushes at one constant level. Letter No. 50 by "D." says—"Fields of hide bound bushes here and there are treated in this fashion. Severely pruned old coffee-land tea gets more frequent touches of this treatment as the growth generally is more mangy of this class of tea, and more subject to the growth of lichens and other pests." I do not agree with "D." that lichens are one of the pests. Moss on a tea branch means (I think) that the branch has ceased to grow, and to expand. If hard plucking deprived the branch of its leaf, there is not enough sap returned to make new growth of wood. The lichens find a surface (like a rock) which is undisturbed and promptly grow on it. Do you find moss on vigorous branches? If not it is *not* a disease but a sign that some other agency is killing that branch. It is a *sign* that the branch should be removed, because it has stopped expanding.

Letter No. 53 by "L." says—"Excessive cutting down (a pernicious system fortunately fast dying out) reduces the quality and the quantity for many months." "L." is convinced of the necessity of judicious pruning. The whole of this letter might be printed here with benefit. Letter No. 66 by "Old Dimbula":—"I have seen ten year old tea cut down to 9 inches or a foot. The reason given was to get good strong healthy growth." Well, it took three years to grow the size the trees were when pruned; the pluckings all that time have been a loss and the trees have not such good stems as they had previous to the heavy pruning. The trees should be pruned and not merely cut down, and this can't be done under R9 to R10 per acre. Here we have strong support to what I urge as the proper way to treat the bushes. I gave R2 extra per acre as the cost of the thinning out. "Old Dimbula give R9 to R10 as the cost of pruning and thinning out combined, so perhaps I should allow R40 per acre for cleaning out; but even this figure makes no practical difference in the loss from cutting down as compared with the gain of *money* saved by cutting down. I think that I have a good show of hands against "cutting down," but some say that it is necessary. I want to prove that it is *not* necessary. It can't be obviated by judicious pruning, which certainly costs more each year, and I think it *necessary* to have the cleaning out done separately. This entails more expenditure and more supervision, and I think that the *future* good of the bushes has been disregarded for these two reasons. Both Managers and Proprietors concur *because* there is less expenditure and less trouble, and because the enormous harm done by careless pruning is not apparent until the time comes when the bush *must* be cut down; and even then the harm is not noticed because the cost (*i.e.*, the loss) is spread over 5 to 10 years, by treating only portions of the gardens *each* year. If you really want to know the harm done, you must cut down the *whole* estate; the amount of loss having been ascertained, can be divided by 5 or 10, and you will then know whether judicious pruning is advisable, *i.e.*, is the *extra* cost of good pruning equal to the loss from cutting down divided by 5 or 10. The range of 5 to 10 is given for difference in climate, soil, jât of plant, &c. But even here the calculation must not stop. At the end of 5 or 10 years you must *again* cut down the whole estate. You will then find that the loss in yield is greater. And the third time of cutting down will prove

conclusively that it is a great mistake. "Only," your managers have said: "It *must* be done." I want to prove it need *not* be done. If any of the 84 planters who wrote in 1897 will take up this subject, they should not only say whether cutting down is or is not advisable, but they should state what method should be adopted to *prevent* the necessity. My system of pruning is as follows:—First year half the garden is pruned to pencil size, *i.e.*, all wood under three-eighths of an inch is cut out; new wood over that size is left about one to three inches in length; the rest of the garden is left unpruned. The second year this plot is left unpruned. The third year it is pruned lightly, merely cut across about three inches over last pruning. The fourth year it is left unpruned. The fifth year it is again pruned to pencil size. And so on, but at each pruning, when the bush is fully exposed, old wood is cut out, if found not to have made good growth during the two years from the last pruning." I have found this plan to answer for ten years, and as far as I can see it will answer for ever. After pruning I pluck for six months to a standard of two feet—nothing below that level is taken, so that the small bushes can have a chance of growing and the sides of the big bushes are allowed to extend. This growth below two-foot level supplies roots with all they require in the way of leaf to return sap for the wood. I fancy that a root cannot grow in size until it has got sap *returned from the leaves*. And if it cannot grow in size it cannot grow in length and go and fetch food from farther off or deeper down. Supposing the roots to have exhausted the soil, you will not get them to give fresh growth even if you cut the bushes down. If we come to examine the causes of the supposed necessity for cutting down, I think it will be found in the desire for getting the greatest immediate return without consideriug the future benefit of the estate. It takes a long time to seriously injure the tea bushes, and probably no one manager has ever watched the decadence of an estate, and ascribed it to the harm done by "cutting down." Nor as far as I know has any estate escaped from cutting down for a period of 20 years. If there *is* such an estate it could be used to back up my theory. If a discussion and expression of opinion can be re-started, it would be well to find out whether present-day planters acknowledge or deny that the tea bush *can* renew itself indefinitely from suckers thrown out direct from the roots. My theory is that suckers are not formed until the roots become too much for the upper growth. By judicious pruning and allowing sufficient leaf to the bush, it will grow roots in proportion to the growth above ground; when some of the branches get too old and hide-bound to allow the sap to pass freely, a sucker is formed to take up the surplus sap. The old branches should then be removed so that all the sap can go to nourish the suckers and supply good leaf from it.

But when a bush is cut down the roots do all they can to send out new shoots through the old channels. The roots are much too large for the new plant, and they cannot grow in size because there is not enough growth of leaf left by the pluckers to supply them *all* with sap. Some of them die out or become dormant, and come into use again when the bush has increased sufficiently in size and has enough leaf left on it to send down the sap.

Of course an excessive yield would sooner exhaust the soil, but no one would object to exhanst the soil by this channel, and he would have enough money to restore enough to the soil to maintain the yield of leaf. I think that the time has come to settle the question because the *permanence* of an estate has become one of prime importance. In former times when dividends were larger and easier to get the future was disregarded. It has probably become an accepted belief that every estate *must* deteriorate, but I deny it emphatically, and it will certainly add to the value of an estate if it can be proved that its yielding life *can* be indefinitely prolonged by judicious treatment, and that when the yield falls off from actual exhaustion of the soil it can be kept up by replacing the wanting constituents. There are many trees whose life under suitable conditions runs to thousands of years.

Tea is not old enough yet to state definitely that a bush *must* die within a stated period. It seems to have the power of reproducing itself indefinitely, and I think that this power should be used, and that the growth should not be forced by cutting down. This matter of cutting down tea is entirely one to be guided by the proprietors.

The planter may persuade the proprietor that cutting down is necessary, but he does not explain that this step will cause only immediate yield at the cost of the future efficieny of the estate. The proprietor, not knowing better, consents. He finds that the yield improves for a time, but again falls off. This recurs until the estate cannot respond; it is sold, and that is the end of it.

Machinery *must* wear out, and money is written off year by year for depreciation; equally tea bushes *must* wear out unless money is given year by year for more careful pruning, and they can be made to renew themselves year by year.

AGRICULTURAL EDUCATION IN GREATER BRITAIN.

PAPER READ BEFORE THE FOREIGN AND COLONIAL SECTION OF THE SOCIETY OF ARTS, ON TUESDAY, FEBRUARY 27, 1900.

By R. Hedger Wallace.

(*Continued from page 152.*)

As regards the rest of the African Continent, there only remains for me to mention that practical agriculture is taught in the Mission schools at the Gold Coast. Boys from the Government schools are also trained at a model farm. There is, further, on the West Coast, a scheme of agricultural instruction formulated, covering three years, by which, beginning with a year's work at a local Botanic Station, a selected pupil then proceeds for a year's work in Jamaica, and finishes his final year at Kew Gardens.

Coming nearer home, at Malta agriculture is not taught in the primary schools, but the Third Reading Book contains short lessons on Agriculture. Beyond this, agricultural education does not seem to receive any support. Cyprus also does not seem to have made any provision for affording instruction in agriculture. The aid may be given indirectly, however, for in 1896 Mr. Gennadius, who was formerly Agricultural Adviser to the Greek Government, was appointed Director of Agriculture in this colony.

In making this survey, I have now journeyed right round the world, following the common flag of Greater Britain. Our position in this country is, however, a peculiar one, in respect to agricultural education and many other things, for we are both a great Colonial Power and, at the same time, an assertive Free Trade nation. This, therefore, invalidates any useful comparison being made between ourselves and other nations, and such I do not intend to make. A witty writer has said that our population is brought up "upon grammar and ready-made goods." In Greater Britain these "ready-mades" of whatever nature are not so easily obtainable as here, for it must be borne in mind that in young countries the division of labour is not so complete as in the older ones, and, therefore, every man, in some slight degree, is a jack-of-all-trades. The two golden rules of colonial life being that a man should be prepared and willing to do anything; and, if you want a thing done, do it yourself.

I think it will be admitted that even the little information I have been able to present in this

paper regarding the work accomplished in Greater Britain, indicates that the value of agricultural education is universally recognised in the Empire. Its aim in the self-governing Colonies is to benifit the Imperial rate, and in the rest of Greater Britain to benefit the native race. The agriculturist in the self-governing Colonies, I would add, has, besides all the facilities for gaiuing knowledge that has already been enumerated the command of services of a large body of scientific men acting as chemists, botanists, vegetable pathologists, bacteriologists, entomologists, &c., in connection with departments of agriculture. Some of the Colonies in this respect are even better equipped than the Mother Country.

I have already stated that those who go abroad to Greater Britain with the intention of engageing in some from of soil cultivation, directly or indirectly, can be arbitrarily divided into two classes—planters and farmers.

As regards the first named, from the survey made it would seem, generally speaking, that agricultural education in Greater Britain is intended almost exclusively for the natives, the planter directs rather than for himself. The question thus arises that seeing that planters commonly cultivate tropical and subtropical plants under similar climatic conditions, is a suitable technical training and experieuce obtainable at home? Further, would the training of an English agricultural school be of any general service to a planter? These questions are undoubtedly open to a good deal of discussion. The second group is the farming class and again practically the same questions can be formulated. Those who go abroad with the intention of farming fiud their way into one or other of our self-governing colonies, and they may be arbitrarily sub-divided into two divisions, *i.e.*, those who already have some experience of farm operations and practical farm work, and those who have not. Seeiug, then, that in Greater Britain to-day there exists nine agricultural colleges and schools, and that they all make instruction in practical work a distinctive feature of their curriculum, the question is, would both the divisions of settlers just differentiated equally benefit if they studied at these institutions? Two reasons, I think, might be advanced why agricultural institutions, giving practically equal time to class-work and field work, are so nniversal in Greater Britain. The first is that those who have been settled on the land had themselves previously no experience of farm life, and would have welcomed such an opportunity had it been obtainable in their time, and now they judge of others needs by that of their own in the past. The second reason is that the majority of the pupils who do attend these institution are addmittedly drawn from towns.

Dropping now all arbitrary defferentiation the question here again arises, can a training or education for farm life in Greater Britain be obtained at home? Colonial authorities state emphatically that it cannot. To give one illustration in support of this statement, I may say that I find in "The Government Handbook of Victoria" it is stated, with respect to agricultural education, that "there are institutions in England which profess to give an agricultural education fitting young men for colonial life, but the training obtained under such circumstances must be very defective. The knowledge of colonial conditions must be wholly theoretical, and the time spent in such institutions is likely to be almost entirely lost." Here is an authoritative statement, but, of course, it must be borne in mind, and due allowance be made for the fact that the Governmet in question, like other Colonial Governments, have colleges of their own into which they naturally desire to attract intending settlers. Undoubtedly the practice of Canadian, Australian, and South African farming is not as ours, but then the principles are the same. It matters then little whether it be studied in this country or in some other part of the Empire. The institutions of this country are very naturally better fitted for training English farmers than colonial settlers, and the students attending them are not far removed from the influence of home. In the Colonies, on the other hand, and at the colleges there, the youth would he better trained for colonial life, but of course he would have to undergo an early eeparation from home and friends and all these two words imply. As to which is the best course to follow, anthorities differ.

The agriculture of this country is the result of centuries of experience and progress, and has become definite and specialised, but in the colonies agriculture is passing through the experimental stage only. The secret of success in such a stage of agriculture lies in what should also be the watch word of the colonial farmer adaptability. The colonial settler is called upon to apply in a variety of ways, and to adapt to a hundred purposes whatever knowledge he possesses of observed facts, and common or general principles. Here again another question arises which could well be debated, *i.e.*—would an English training give a settler that hardiness, keenness, alertness, handiness, and general long-headedness necessary for action under the inclusive term of adaptability?

I have endeavoured to avoid, as far as possible, interpolating into this paper my personal opinion or views. My aim has been to show the amount of good work that has been planned, and also accomplished, in Greater Britain, in furtherance of the interests of agricultural education. If I have even partially succeeded in doing this, I venture to think two conclusions can be safely arrived at.

First, that throughout Greater Britsin, irrespective of climatic, racial, and political divisions, there is a universal movement to give all interested in the culture of land every opportunity, facility, and assistance possible to improve themselves, their art and craft, and the land and its produce.

Secondly, that the purely educational or teaching facilities in agriculture offered by other portions of the Empire, where the general agricultural conditions are somewhat akin to our own, are not only so distributed as to cover fairly the area in question, but are also equal in educational valne to any of the agricultural training or teaching institutions in this or the other countries of Europe.

These two conclusions I venture to think might be regarded as the logical sequence to the survey made, and facts recorded in this paper.

FRUIT CULTURE IN QUEENSLAND.

By Albert H. Benson.

THE COMPOSITION AND APPLICATION OF MANURES.

(Continued from page 154.)

FOR BANANAS.

All banana-growers know that this fruit thrives best in rich scrub land that is rich in humus and nitrogen; hence any manure that is applied should contain these elements. Farm manure is especially adopted for this crop on account of the large quantity of organic matter it contains, and when it can be obtained in qnantity it is the best manurial agent that can be applied. If followed by commercial fertilisers, its beneficial effects are considerably increased. The banana is a strong quick-growing plant; hence it is necessary that the plant food supplied to it shall be such that it is in a readily available condition. This necessitates the use of quick-acting fertilisers, but they should be combined with a proportion of slower acting ones, so that the effects may be more lasting.

Where bananas are planted in old land it is advisable to apply the fertiliser at the time of planting, mixing it thoroughly with the soil that is placed

in the hole that is dug for the plant, so that the young plant will have a sufficiency of plant food from the start, and therefore make a rapid growth. Subseqnent manurings should be applied broadcast ronnd the plants or, in the case of old plantations, over the whole of the ground, so as not to confine the roots to one particular spot, and then chipped, harrowed, or cultivated in. The best time to apply such fertiliser is in early spring before the summer growth starts, as it will then be available for use when growth takes place.

Mix as follows:—

	cwt.
Superphosphate	6
Meatworks manure	6
Nipho	6
Sulphate of potash	2
	20

This will contain—5½ per cent. of nitrogen, 5 per cent. of potash, 9⅓ per cent. of phosphoric acid, of which 5 per cent. is water soluble, and be worth £5 16s. per ton.

The first application to the young plants when planting should he at the rate of 4 lb. per plant, and subsequent manurings should not be less than 10 cwt. per acre.

If wished, 2 cwt. of the nipho can be replaced by 2 cwt. of sulphate of ammonia. This will increase the percentage of nitrogen by, ·8 per cent. and the cost by 9s. per ton.

FOR PINES.

For pines no manure is equal to good farm manure, or well prepared compost. If the farm manure used contains a considerable proportion of sawdust, as is often the case when it is obtained from town livery or 'bus stables, it should be allowed to become thoroughly fermented before it is applied as this will tend to remove any deleterious properties of the sawdust. Where a commercial fertiliser is required, the plant food contained therein should be in a readily available form; and this has been especially noticeable at Redland Bay Experiment Orchard, where the application of superphosphate and sulphate of ammonia—particularly the latter—has produced very rapid and marked results. Where the land is impoverished it is advisable to apply, the manure previous to setting out the plants, which will then make a good start, but in rich land this is not necessary. The best way to apply the manure in this case is to take out a trench with the plough where the line of plants is to be planted; spread the manure in this trench and thoroughly mix it with the soil by running a Planet Jr. cultivator with only two narrow teeth up and down the trench, the plants being then set and the earth drawn round them. If commercial fertilisers are applied without being thoroughly mixed with the soil in this or similar manner, they are apt to burn the young plants should dry weather follow the planting. In any case, unless well mixed there will be more likelihood of loss, and the plants are not so well able to obtain it as it is in one spot instead of being evenly distributed.

In applying commercial fertilisers to older plants, especially when same are grown into a thick mass, I strongly advise their being composted as previously described instead of being applied direct will supply both plant food and humus as well as cover for the surface roots, which is apt to be washed off by heavy rain.

The fertilisers should be made as follows:—

	cwt.
Superphosphate	9
Meatworks manure	5
Sulphate of ammonia	4
Sulphate of potash	2
	20

This will contain 5½ per cent. of nitrogen, 5 per cent of potash, 11 per cent. of phosphoric acid of which 7½ per cent. is water soluble, and is worth £6 12s. per ton.

Proportionate amonnts of dried blood or nipho can be nsed in the place of the snlphate of ammonia the proportion of superphosphate being reduced ac, cordingly. This will reduce the price of the mannre- but at the same time reduce the proportion o, soluble phosphoric acid. For pines in full bearing at least half a ton to the acre should he applied if no farm manure is used; less in proportion to the quantity of farm manure applied.

FOR STONE FRUITS.

Use a similar manure to that recommended for citrus, but reduce the nitrogen and increase the phosphoric acid and potash.

FOR STRAWBERRIES.

As the strawberry is a quick growing crop in this colony, and, as a rule, the plants only occupy the ground a few months, quick-acting fertilisers are essential. Well rotted farm manure dug into the ground sometime previous to planting is an excellent preparation for the crop, but when the soil is at all poor the following fertiliser should be placed in shallow furrows and well mixed with the soil as previously described in the case of pines, the plants set out and the soil drawn round them. The composition of the fertiliser is as follows:—

	cwt.
Superphosphate	10
Sulphate of ammonia . ..	5
Sulphate of potash	5
	20

This will contain 5 per cent. of nitrogen, 12½ per cent. of potash, 8½ per cent. of phosphoric acid, all water soluble; and is worth £8 2s. 6d. per ton.

From 4 to 6 cwt. to the acre, according to the richness of the soil, is a snfficient dressing. This manure will also suit Cape gooseberries and tomatoes.

FOR VEGETABLES OTHER THAN PULSES.

In order to produce good vegetables they must be grown quickly, thus the application of quick-acting manures is required. This will be obtained by the following mixture;—

	Cwt.
Superphosphate	14
Sulphate of ammonia	5
Potash	1
	20

This will contain 5 per cent. of nitrogen, 2½ per cent. of potash, 12 per cent. of phosphoric acid—all water soluble, and is worth £6 5s. 6d. per ton.

Apply from 4 to 6 cwt. to the acre. Instead of using all superphosphate, half bone phosphate and half superphosphate can he used. This will reduce the price 7s. 6d. per ton, and will render the manure more lasting.

In applying commercial fertilisers to vegetables, it is best to mix them thoroughly with the soil before planting, but, if wished, they can be used as a top dressing, taking care to distribute them evenly, and not to allow them to cover the leaves of the plants, as if so they will be very apt to scorch or burn them.

FOR OATS, BARLEY, CORN, OR SORGHUM, WHEN USED FOR FODDER.

A quick-acting manure is required, which should be applied at the same time that the seed is sown, and harrowed in the case of broadcast crops. If the corn or sorghum is sown in drills, the manure should be applied as recommended in the case of planting pines. It can be made as follows;—

	cwt.
Superphosphate	10
Bone phosphate	5
Sulphate of ammonia	4
Sulphate of potash	1
	20

This will contain 4 per cent. of nitrogen, 2½ per cent. of potash, 15½ per cent. of phosphoric acid, of which 8½ per cent. is water soluble, and is worth £5 14s. 3d. per ton. Apply from 4 to 5 cwt. to the acre.

FOR BEANS, PEAS, COW PEAS, AND OTHER PULSES.

No nitrogen is required by these plants unless the soil is absolutely deficient in this plant food, and then it is advisable to give a little to start the plants till they are sufficiently strong to provide their own nitrogen. These plants require a considerable proportion of potash, so that in all soils that are deficient in this respect, a fertiliser rich in potash must be used. For an average soil the following will be found to answer:

	cwt.
Bone phosphate	10
Superphosphate	6
Sulphate of potash	4
	20

This will contain 8 per cent of potash, 18¾ per cent of phosphoric acid, of which 5 per cent. is water soluble, and is worth £5 12s. per ton.

From 5 to 6 cwt. to the acre, mixed thoroughly with the soil before planting, should be a fair dressing in soils of average quality.

The following table, which has been obtained from a number of European and American sources, gives the total amount of ash removed from the soil by 1,000 lb. of the following fruit—farm and garden crops, as well as the composition of the ash, showing the relative proportions of phosphoric acid, potash, and nitrogen. In the case of the nitrogen, the amounts given represent not only that contained in the ash, but also that contained in the albuminous matter of the fruit or plant.

As previously stated, the mere fact that a given crop takes so much out of any given soil cannot be considered accurate under all conditions, but is at the best only an approximation. At the same time, it is of value, as indicating the particular plant foods which are required by different crops; and when this knowledge is combined with the experience gained by the practical application of manures and commercial fertilisers, it will be found to be of great assistance to all agriculturists.

* Complete analysis not given.

GREEN TEA MADE BY "OLD CHA."

Sir,—I am now in a position to give you the result of the attempt (and so far the only attempt) made to manufacture green tea by my method, which though nothing to boast of, is, in my opinion, fairly satisfactory, considering the somewhat difficult and unfavourable conditions under which the trial was made.

I do not feel at liberty to mention names, but here is the report for what it is worth:—

	Colombo value.
No. 1.—Well-twisted O. P. leaf, uncoloured liquor, fine quality, pungent, but too light in colour ..	50 cts.
No. 2.—Pekoe leaf, liquor fine quality but rather too thin and pale in cup	35 ,,
No. 3.—Souchong leaf, pungent ..	30 ,,
No. 4.—Flat, flaky, fanning liquor, fine quality and pungent ..	27 ,,

These teas were made in a desiccator, a drier I had never used before, and I was rather afraid of the effects of the powerful fan. It was also my first attempt to make green tea for several years. The tea was not final-fired, nor was any care taken to make it look nice; but for these circumstances, the valuation might have been a trifle higher.

I see you head my letter in your issue of the 13th—"The Panning Process." This is a mistake. I do not use a pan, but use a sirocco or other modern drier instead. As I find these do the work quite as well, and as they get through the work much quicker, they are cheaper than the pan, which, though good enough in former days, is far too slow and expensive to suit present-day planters and present prices.

The proposal to glaze our teas, as desscribed by Mr. Street in a recent issue, is undoubtedly a good one, and should be adopted. It is really a different way of facing the teas, *and a much better way*, and would doubtless enhance its value in any market; but I think 210° far too high a temperature for final-firing Such a temperature would, I fear, reduce the strength and pungency of the liquor.

I have certainly seen black tea lose its strength and pungency by being final-fired at a very high temperature, but I forget now what that temperature was. By the old (Chinese) method, final-firing was a very slow process, occupying from 6 to 12 hours. The dhools were often left on for the night, the fires having been carefully covered with a thick layer of ashes—to prevent the temperature rising—and, seeing the tea could be left on 12 hours without being burnt, it is clear the temperature could never have been above 150—probably less, and I believe this to be the reason why China tea keeps better than ours. Anyhow, I should say 170 to 180 is the highest at which it would be safe to final-fire teas, whether black or green, and I believe this would be found to do the glazing quite as well as 210, though it might take a few minutes longer.—Yours, &c.,

OLD CHA.

—Local "Times."

THE RUBBER INDUSTRY OF THE AMAZON VALLEY.

A very important factor, from the merchant's point of view, in the rubber trade, is the loss of weight that is constantly taking place in raw rubber. This loss is extremely variable, and a consignee has to place the greatest faith in the consignor that the invoiced weight of rubber has really been shipped as more or less shortage invariably takes place. Moreover, the shrinkage in weight is so variable that no exact figures can be quoted by which it may be calculated. The cause being the evaporation of the water contained, it varies according to the quality, being greater in the case of the porous "Sernamby" than in the firmer "Fine" rubber. The longer rubber is kept and the larger the pieces the less it loses in weight. Dry "Scrtao" rubber coming from distant parts, whence shipments are only made once a year, will lose only about 1 per cent. between the estates and Manaos; whereas newly-made rubber coming from close at hand will lose as much as 10 per cent. As the means of communication get more rapid, and the rubber reaches Manaos sooner after being manufactured, the tendency to lose in weight becomes larger. Between Manaos and foreign markets a loss of 4 per cent. may be taken as an approximation of the average loss of weight.

A machine, designed on the principal of a cream separator, to separate the caoutchouc from the watery part has been tried, but has not proved successful as regards the latex of the *hevea*, though good results have been stated to have been attained with the latex of the "castilloa."

Another means of separating the caoutchouc is to add chemical re-agents which cause the latex to coagulate. Of these acetic acid and corrosive sublimate have being found to give the best results. The latter owing to its antiseptic properties would appear particularly suitable. A solution of alum is used to a small extent in the State of Matto Grosso, to prepare rubber from the latex of the *hevea*.

The following analysis of the latex of the *Hevea Braziliensis* is given by Seeligman:—

	Analysis. Per cent.
Caoutchouc	32
Nitrogenous matter	2·3
Salts	9·7
Resinous matter	traces
Water	55 to 56

The rubber having been prepared, it is shipped from the estates in "balls" or "pellets" to merchants in Manaos, and by them sold to one or other of the export merchants in the same condition as received. By the export merchant it is cut up into small pieces, the "Fine" separated from the "Entrefine," and then packed in wooden cases, each case holding about 170 or 160 kilos. It is then shipped to Europe or the United States, as the case may be. Owing to the loss of weight already mentioned, each merchant is obliged to have his own store, as no warehouseman could give a receipt for a quantity of produce the weight of which is constantly varying. For the same reason rubber is rarely sold by auction.

The commercial system by means of which the working of rubber estates is effected is somewhat complicated. Goods are in the first place imported from abroad by one class of merchants named "Importadores." In Manaos and Para most of these are at present Portuguese houses. They usually buy on ninety days' credit. The goods are then sold on the Manaos market to another class of merchants named "Aviadores," who generally buy on a twelve months' credit. These "Aviadores" then ship the goods up-country to the estate owners. The "Aviador" business is chiefly in the hands of Brazilian and Portuguese firms. The estate owners then barter these goods to the men working their estates, who are not so much labourers as small tenants, the rubber trees being leased to them for the rubber which they extract, paying them any difference that may remain to their credit, over and above the value of the goods supplied to them, in cash. This rubber is then shipped by the estate owners to the "Aviadores" in payment of the goods that have been consigned to them. The "Aviadores," on receipt of the rubber, sell it without delay to avoid loss in weight, to one of the exporting firms, receiving payment at once, in cash. With this the "Aviadores" pay the "Importadores." The exporting houses cut, pack, and ship the rubber drawing against shipments, generally on London credits, at ninety days' sight, and selling their bills to bankers at Para. Shipping documents have generally to accompany the draft, and in case of shipments to the United States, a certified Consular invoice. Manaos being without telegraphic communication, and consequently without foreign banks, the exporting houses which buy rubber on this market are obliged to keep a supply of cash in hand to pay for rubber bought, which as has been already stated, has to be paid for at once in cash. Such is the so-called "Aviador" system, and so far it has been found to answer better than other methods of doing business. Suggestions have been made whereby it is proposed to eliminate some of these middlemen, and to bring the consumer into closer contact with the producer. In order to study this question it is necessary to consider the conditions under which the rubber estates are at present being explored and worked.

The *Hevea Braziliensis* is, as has already been stated, scattered through the Amazonian forests. In some places it is much more frequently met with than in others. Nothing but actual exploration and trial will enable the most experienced person to form any reliable opinion as to the value of a block of forest. The manner in which explorations are conducted is as follows:—An individual who enjoys a certain amount of credit in Manaos charters a small launch and freights her with a cargo of food, clothing, and implements necessary. He then proceeds to search in the low-class hotels and boarding-houses at Manaos and Para, or perhaps he may even go to the State of Ceara, whence the labouring classes are chiefly recruited, for a number of men with whom he intends to work his estate. These he engages, not on wages, but on the condition that he will barter his goods for the rubber they extract. Most of these labourers draw a considerable advance before they can be persuaded to go up-country. With this cargo and crew he proceeds to the district where he intends to work. Having arrived at a place which he considers promising, he despatches some of the most practised labourers, or "seringueiros," as they are here named, to explore the forest, find the rubber trees and open the paths between them. With the remainder he builds a store, known as the "Barracao," in which he stores his goods, and which becomes a rendezvous or nucleus for the colony. The men all this time are living at their own expense, the price of supplies given to them being debited to their account, to be paid for in rubber later on. The forest having been explored, the trees located and connected by paths, known as "Estradas," the men select which they are going to work. Each "Estrada" makes a loop, visiting generally some 100 or 150 trees, and returning to the starting point, generally on the bank of a river or stream navigable for canoes. Each man builds his own small hut, or "Baraca," where he lives and from which he works the two "Estradas" which he has selected. From time to time he pays visits to the central store to obtain goods, and deliver the rubber he has collected. This the owner of the store, or the "patron," as he is termed, buys from him at a price, generally fixed by the "patron" himself, and credits him with the amount as a set-off against the goods that have been supplied to him. As the "seringueiros" can, as a rule, neither read nor write, the opportunities of an unscrupulous "patron" are great. At the end of the season, that is to say, in January, most of these men return to Manaos. A fresh lot is generally taken up by the "patron" each year.

The labourer or "seringueiro" spends his day much as follows: Rising from his hammock just before day-break he takes a cup of black coffee. He then proceeds to tap the trees in one of the "Estradas," affixing at the same time the cups to catch the latex as it exudes. The necessary cups are placed at the foot of each tree at the time that the "Estrada" is being opened. By 9 a.m. he has tapped the trees and is back in his hut. He then proceeds to cook and eat a scanty meal. At about 11 a m. he again visits the trees, taking with him a vessel into which he pours the contents of the cups. By 1 p m. he is again in his hut. He then proceeds to smoke the latex he has collected during the day. The latex cannot be left standing over night, as fermentation sets in and "entrefine" rubber is the result. It is almost invariably, therefore, smoked each day as collected. By 2 p.m. or 2-30 p.m. he has generally finished his day's work, and can spend the rest of his time in idling, hunting, or fishing as he pleases. On the following day he rests the "Estrada" which he worked the day before, and works the other. An active man sometimes works four "Estradas" two each day. Such men are known to produce as much as one ton of rubber in the season. It is on such performances as these that calculations quoted in prospectuses of rubber companies distributed in the United Kingdom seem to be based. They are, however, quite erroneous when applied generally. In a good place an average man will make as much as 4 kilos. of rubber in a day, but it must be remembered that he does not work all the year round, and that he loses many days when it is raining or when he thinks it is going to rain. Any excuse is good enough to prevent a "seringueiro" from going into his "Estrada."

The season during which the "Estradas" are worked lasts from August till the beginning of January. During the remaining months of the year there is generally too much water in the forest to allow the "seringueiros" to enter the "Estradas."

When considering the question as to whether British companies have here a good opportunity for the investment of capital, the following points should be borne in mind. Rubber is brought down to Manaos at the present day from beyond Iquitos, in Peru, and from beyond Orton, on the River Beni, in Bolivia, and goods are shipped to there from Mansos. A glance at the map will show how remote are these places. It is reasonable to suppose that natives of the country, who well understand the matter, would not go and explore so far afield if workable forests existed nearer home. The fact of their doing so points to the probability that most of the forest worth obtaining in the neighbourhood of Manaos has already been taken up. Of course, this does not mean that a company could not purchase already opened up estates, in good condition, and do good business with them. But again certain difficulties to be encountered should be remembered. The greatest of these is the quantity and quality of the available labour supply. A company would have to work on a large scale and have a well-ordered system. The labourers to be found in Manaos are an extremely independent, not to say unruly class, and although the comparative rarity of crime up-country speaks well for their conduct on the whole, yet they are so unused to obey any sort of discipline that it would be very hard to work with an organised estate, especially as these is practically no legal authority outside the towns, and every man's will is, up-country, a law unto himself.

For the individual enterprise of that class of men which has done so much in opening up other tropical countries, men of resource and adaptability who prefer a rough life, there is probably a good field in Amazonas. Beginning, as they naturally would, on a small scale, and extending their business, they could probably do well. When the way has been opened by these, and a class thus created who really understand the business, there will be more opportunities for companies to work with success. It must be remembered that at the present time rubber export merchants have many difficulties to contend with. There is considerable competition in their business, and there are the unending and baffling variations in exchange. A company that owned rubber forests on a large scale could avoid exchange transactions almost entirely. The necessary goods imported would be paid for in London by the results of the sales of the rubber produced. Moreover, once a rubber estate is in good working order, it should be possible to make very certain calculations as to its annual yield. Taking these points into consideration, it would appear that the natural extension of the rubber merchant's business will be in the direction of securing the actual forests and lands in order to control the supply. No doubt means will be found eventually to overcome the difficulties stated above.

Owing to the recuperative power of the tree it is improbable that the available supply of rubber from the Amazon valley will be exhausted in the near future. Also the enormous area over which the estates extend makes it unlikely that unexpected events should occur by which the industry as a whole would be damaged, although, no doubt, local checks may be expected from time to time to occur For the same reason, and owing to the scarcity of labour, it is improbable that any very sudden increase or decrease of the annual production will occur. The tendency is at present for a slight increase of the total production each year.

The best district in Amazonas is commonly reputed to be that of the River Acre and the headwaters of the Purus.

Two British companies are at present established in the Amazon valley—namely, the Para Rubber Estates, Ltd., and Amazonas Rubber Estates, Ltd. The former have an already opened estate in the islands near Para, whilst the latter are breaking in virgin forest on the headwaters of the River Teffe. in the State of Amazonas.

Beside these, a Belgian company named "La Bresilienne" is working an estate near Para, whilst a French company, the "Camptoir Colonial Français," is working some estates on the River Javary. Several other French, German, and Belgian companies are said to be about to be organised for the same purpose.

Caucho is a vegetable product similar to rubber in many of its qualities, but inferior to it in usefulness. It is obtained by tapping trees much in the same way as rubber. The tree from which it is obtained is a variety of the "Castilloa." This tree prefers drier parts of the forest than the *hevea*.

Owing to the fact that the laticiferous system is not connected throughout the tree, it is not possible to drain all the latex by tapping only a small area of the bark, as is the case with the *hevea*. The tree has, therefore, to be cut down in order that the whole tree, including the branches and twigs, may be tapped. The roots also, which often project above the ground, are tapped. I am told that it takes as much as 15 days for the whole of the latex to exude from the tree. The latex is collected first in small cups placed to receive it, and subsequently is poured into a suitable vessel, or sometimes into a trough cut in the tree itself or into a hole made in the ground. A small quantity of soap solution is added to it to produce a more rapid coagulation. The juice of a creeper named "vitelha" is generally added for the same purpose. When the latex has coagulated, which takes some days, the mass is taken out, and caucho "slabs" are thus formed. Caucho "balls" are made by rolling up strips of the coagulated latex that has exuded from cracks in the bark. By common accounts an average caucho tree will yield from 30 lb. to 40 lb. of caucho, including the scraps.

Owing to the fact that the trees are cut down and destroyed, the collectors, or "caucheros," as they are called, are constantly moving about to discover fresh trees. Whereas at one time nearly all the caucho came from Peru, it is now more extensively worked on the Javary. During 1899 a large amount was

also received from the Purus. The actual work of exploring and tapping caucho trees is still done chiefly by Peruvians, even in Brazil, the Brazilians preferring to work the *hevea*.—*India-Rubber and Gutta-Percha Trades' Journal.*

Of late years the enormous consumption of rubber in the manufacture of bicycle tyres has created a very great demand. The supply not being able to cope with this demand the price has steadily increased, and considerable attention is now being paid to the production of rubber all over the world. So great is the demand at present that although the supply from the Amazon Valley alone has increased from 8,635 tons in 1880, to 25,370 tons in 1899, the approximate price of 2s. 6d. per pound in 1889 increased to 4s. 6d. per pound in 1899. The British Vice-Consul at Manaos states that the total world's supply to-day is about 120,000,000 to 130,000,000 lbs. valued at about £15,000,000. At the present time laticiferous plants yielding "caoutchouc" or "rubber" are being worked for commercial purposes in Brazil, Bolivia, Central America, East and West Africa, whence come the chief supplies, while Guiana, the Eastern Archipelago, Madagascar, India, and Ceylon contribute a small quantity to the general stock. More than half the total supply is exported from the Amazon district. In Brazil several kinds of laticiferous trees exist from which rubber is manufactured. In the State of Ceara, the *Manihot Glaziovii*, locally known as the Manigoba, is fairly extensively worked, and considerable attention is being paid to its cultivation. In the State of Maranho the *Hancornia speciosa* or Mangabeira is beginning to give results. These trees, however, are unimportant compared to the *Hevea Braziliensis* or Seringueira, to which the Amazon Valley owes its present prosperity. The *Hevea Braziliensis* is found scattered through the forests that clothe the banks of the Amazon River and its tributaries. It does not strike the eye among the innumerable varieties of trees to be met with in the Amazonian forests, and is often difficult to detect. A peculiar glistening of the trifoliate leaves and the whiteness of the bark serves as a guide to the practised eye. The tree grows to the height of 70 to 100 feet, and as a rule, when full grown, a girth of from 5 to 7 feet at a height of one yard from the ground. The tree flowers in January; the seeds are ripe and begin to fall in March in the case of old trees, and in May in the case of young trees The seeds are contained in a hard shell, three or four in each shell, which hang by a short stalk from the upper and outer branches. When ripe the shell explodes, often with a loud report, scattering the seeds to a considerable distance. For this reason it is difficult to procure seeds. There are for practical purposes three distinct varieties of the "seringueira" to be met with in the forest. These are locally known as the seringueiras "casca vermelha" (red bark), "barriguda" (bellied), and "casca preta" (black bark). The first of these, the "casca vermelha," grows in the higher parts of the forest which are seldom or never flooded. The latex which it yields is scanty, thick, and will not run. It is therefore of little value. The second of these the "barriguda" so named because the trunk increases very rapidly in thickness towards the base, grows in those parts which are almost constantly flooded, named "igapos." It yields plentifully a thin, watery latex, which is of little value. The third variety, the "casca preta," grows in those parts where a certain amount of drainage exists, and which form a intermediary zone between the permanently flooded parts and the high land. It is this variety which yields the latex from which the rubber of commerce is manufactured. The "latex," or as it is commonly known, the "milk" of the tree, is a milky juice contained in special tubes running amongst the other tissues of the plant. These tubes, in the case of the hevea, are connected, forming what is known as the "laticiferous system." The latex is quite different from what is called the "sap," and probably does not play any part in the nutrition of the tree. According to some authorities it forms a reserve of water to be drawn upon in cases of drought. The actual extraction of latex cannot kill the tree, and the common statement that the trees are "bled" to death is a mistake. As a matter of fact, though trees, exhausted, inasmuch as they will not yield any more latex are common—actually dead trees, killed by overtapping are rarely met with. The latex as it exudes from the bark is of a dazzling whiteness, resembling milk, which it also resembles in composition, inasmuch as it consists of an emulsion in which "caoutchouc" takes the place of the better in the ordinary milk. The fluid part of the latex consists of water with very small quantities of albuminous matter, organic acids and phosphates in solution. The extraction of the latex, or as it is usually called the "tapping" of the tree is effected by making an incision in the bark of the tree. From this incision the latex flows for about three or four hours, after that it stops flowing of its own accord. The incision should not penetrate beyond the bark, which is generally about ⅛-inch thick, into the wood of the tree, and for this reason a very small axe, which rapidly thickens wedge like from the cutting edge, is used, the shape of the instrument preventing its entering too deep. The axe is generally about ¾-inch wide. The custom is to strike with it a backhanded blow upwards, thus making an oblique cut in the bark. It is probable that a better method would be to use a chisel and mallet and make a V shaped incision. Recent experiments at Henaratgoda have shown the advantage of this shaped incision. The incision having been made, a small tin cup, of a capacity of about four ounces, is affixed just below it to receive the latex as it flows. This is effected by pressing the edge of the cup, which is sharp, into the bark, until it gets a sufficient hold to remain firm. By this method, however, a second wound is made in the bark, which is injurious. No better method has yet been suggested. In some places a winding groove is cut in the bark of the tree, and by means of a clay breastwork the milk is conducted into a vessel placed at the foot to receive it. This method is found, however, to be very exhausting to the tree, and is falling into disuse. The usual mode of tapping is to make an incision with the axe at the height of some six or seven feet from the ground; on a level with that incision and at a distance of some eight inches a second cut is made, and so on round the tree. On the next day incisions are made just below these, and so on day by day, until they reach the ground. Incisions are then made on the same plan, beginning as before from the top and working downwards between the former rows. A tree that will carry seven cups eight inches apart is considered a large one and although trees that will carry eight or nine cups are to be met with, the average do not carry more than four or five. The latex having been obtained and collected, the caoutchouc, or rubber known to commerce, may be obtained from it in various ways. The only method, however, that has met with practical success is that of evaporation, by which the watery portion of the latex is driven off, and solid caoutchouc remains. The object to be secured is that as little water as possible shall remain in the caoutchouc, the putrefaction of the caoutchouc owing to the presence of these matters being extremely detrimental to its elastic properties, and therefore to its market value. In the Amazon district the method followed is to light a fire upon the ground, and to invert over it a specially-constructed, funnel-shaped chimney. From the narrow end of this funnel, which is open, the smoke and heated gases pour out in concentrated form. The fuel used for the fire consists, as a rule, of chips from any hardwood tree that grows handy to the labourer's hut, The nuts of the "Urucury palm" (*Attalea excelsa*) are sometimes used, their smoke containing a trace of acetic acid, and creosote being

found particularly effective in curing the rubber and preventing putrefaction. It is, however, a mistake to suppose that all over or even a large proportion of the rubber coming from the Amazon district is cured in this way. It is, on the contrary, very rarely that the rubber cutter will be at the trouble to collect these nuts, he nearly always prefers to use wood chips, which give him less trouble to procure. The fire having been made, and a large stream of hot smoke pouring out of the chimney, the operator seats himself on a small stool by the side of it. The latex is contained in a basin placed at hand. In his right hand he holds a paddle-shaped piece of wood, in his left hand a small calabash. Dipping the calabash into the basin of latex he pours a small quantity over the paddle, which he then revolves in the smoke issuing from the chimney. That having dried in a layer over the paddle, he repeats the operation. In the course of time a "ball" or "biscuit" of solid rubber is thus formed. In some parts where it is the custom to manufacture very large balls or pellets, an arrangement is made by means of a pivot to rotate the ball over the chimney. The wooden core is withdrawn through a slit made in the "biscuit," or simply drawn out in the case of the pellet. The latex of a tree named "macaranduba" (*Mimusops elata*), and more often that of a tree named locally "amapa" is sometimes used to adulterate that of the *hevea*. In both cases the adulteration is extremely prejudicial to the quality of the rubber produced. Three distinct qualites of rubber are manufactured in the Amazon district, namely, "fine," "entrefine" and "sernamby" respectively. "Fine" rubber has been well smoked, and is free from putrefaction. "Entrefine" rubber has been either burnt while been smoked, or has been insufficiently smoked, and has therefore putrefied. It is due to carelessness on the part of workmen, which it should be possible to avoid. "Sernamby" is the "negro-head" of commerce, and consists of scraps mixed with dirt, or strips peeled off the bark of the tree, and mixed with impurities of all sorts.—*Journal of the Society of Arts.*

DISTANCE IN PLANTING.

We are often asked, at what distance should Nutmegs, Rubber trees, Cacao trees, Mango trees, &c. &c., be planted. Now it is absolutely impossible to lay down any hard and fast rule as to what distance trees should be planted apart, for the matter hinges on many contingencies, which if unknown will lead to erroneous conclusions. If Rubber trees are to be planted, let us first ask what is required, or what is to be aimed at or produced. It is evident that we do not want a low straggling tree, but one having a straight trunk free from branches. The best koown method of producing such trees is to plant thickly. It is very false economy to plant thinly with the view of saving cost of plants and planting, for unless trees are thickly planted there is no hope of getting them to make straight stems without a lot of pruning; and even with this well done, they will not be as good or as shapely as they will by nature's pruning. This is a well known fact among foresters and the amateur cannot err in planting too close—as it is always in his power to cut out, if his plants are at any time crowding each other, but on the converse, he cannot put in a plant to supply vacancies without it suffering from the overgrowth of those already established. It is easier to cut out therefore than to supply, and a better and more seientific practice. A recent writer in the Queensland Agricultural Journal, one of the leading periodicals of the day in its special subjects says:—

"That the trees are allowed to grow thickly together, that they may be drawn up to a suitable height before the forests are thinned, and then, by the time the rotation period has arrived they expand laterally, and form fine thick boles." They have in fact made "height growth." The term "height growth" in forestry is derived from the German, but the principle has long been known and adopted by all who are sufficiently acquainted with the leading principles of Forestry. An example may be made with low growing plants to illustrate the subject. If plants are planted closely, it will be found that they grow much taller than when planted singly on the open, because they are nature pruned, that is to say nature does not allow side branches to develop and straight clean stems result. In a Rubber plantation it is of the first necessity to have as large number of clean straight stems on as small an area as possible, and this result can be attained by close planting.

Planting must however be regulated by the quality of the soil on which the plantation is to be made, for it is clear that, what would be close planting for a rich soil would be wide planting for a poor one, and therefore the richer the soil the wider apart may the trees be successfully planted. The nutmeg does not require to have a straight stem, but rather a spreading top, which should be well exposed to light and air. Nevertheless to plant the nutmeg at too great a distance, is a mistake; for unless the ground is well covered over with foliage, too much evaporation goes on in dry seasons, and the trees suffer. It is better therefore to manage to plant your trees to cover in the ground by their branches meeting above as soon as possible within reason, allowing each tree a spread according to the richness of the soil.

With Cacao I am decidedly of opinion that closer planting, than is generally practised, would be beneficial. If a Cacao Estate is examined it will be found that the best bearing portions are those which best cover the ground, and the worst portions, are those where the trees are too thinly planted to do so.

In some cases this cannot be avoided, as the planter cannot fully prove the nature of his soil, until he plants his trees, and it is generally more convenient to plant all the trees at the same distance. Where, however, the soil is known to be poor, it will be distinctly to his advantage to plant more thickly and get the ground covered at once. Too thick planting on the other hand is as great a mistake as the converse, and on rich soils examples are easily found where the trees have not sufficient room to expand their branches in accordance with the amount of nutriment available.

This is however much more easily remedied than too thin planting, for the judicious pruner will first of all give room by cutting away gradually, for a season or two, the branches from those trees which he marks for removal, and then, in the end will remove them to make room for more vigorous brethren.

With the Mango, the same arguments may be applied. With it we require branches and the stem is of little consequence but it is highly important that the branches should have all the light and air possible to induce flowering and fruiting, and therefore the mango may be planted in isolated positions with great advantage.

It is very important in making plantations of any kind to get the trees to all "come away together" —(*i.e.*) to get them well started and not to allow blanks to occur, and the cultivator will do well to maintain regular supplies especially during the first two years.

In making plantations of Rubber where the trees are planted close together, with the view of securing straight, clean stems, it should always be the aim to surround the plantation with a belt of trees of bushy habit, to act as a wind break; for it is clear, that where a forest of clean stems exist open to the wind, evaporation would be almost as great as in the open, and that high winds would be liable to do considerable damage, which might be avoided by this simple means. It is well to remember therefore that it is better in most cases where timber or stem is required, to plant thickly; while where fruit is required from the smaller branches, these may profitably be planted in more exposed situations.—*Trinidad Bulletin.*

BASIC SLAG TO INSURE BEST, QUICK, AND PROFITABLE RETURNS.

(Extract from an Essay by Professor Dr. P. Wagner, P.C. Director of the Government Research Station, Darmstadt.)

I have said already that to a soil distinctly poor in Phosphoric acid more of this ingredient should be restored than is being removed by the crop. This application of a Phosphoric acid manure should be continued until the Phosphoric acid has become laid up as a store, for use in the soil ensuring quick and profitable returns. Only then will it suffice to return to the soil the same amount of Phosphoric acid by means of cattle manure or artificial Phosphoric acid fertilizers as is removed by the crop.

As the most suitable Phosphate to increase the fertility of the soil, I have recommended BASIC SLAG, and I would draw attention to a previous contribution of mine in which I proved the superiority of Basic slag over Superphosphate. I would point out that quick and satisfactory effects can only be looked for from the application of Basic slag rich in Phosphoric acid readily available to the plant, *i.e.*, Phosphoric acid soluble in Citric acid. Below I give results obtained by the application of Basic slag with a low percentage of Phosphoric acid soluble in Citric acid and Slag, most of the Phosphoric acid of which was soluble in Citric acid. It will be perceived that the efficacy of the Basic slag increases in proportion to the solubility in Citric acid of the Phosphoric acid in the Slag. The trials were made in three rows side by side :—

Phosphoric acid.		Amount of yield	Increase in yield over unmanured plot.
0·5 gr.	Superphosphate	541·2 gr.	397·2 gr.
0·5 ,,	Basic slag No. 1. 89% soluble in Citric acid.	503·1 ,,	359·1 ,,
0·5 ,,	Basic slag No. 2. 82% soluble.	464·7 ,,	320·7 ,,
0·5 ,,	Basic slag No. 3. 65% soluble.	416·7 ,,	272·7 ,,
0·5 ,,	Basic slag No. 4. 39% soluble.	306·9 ,,	162·9 ,,
0·5 ,,	Basic slag No. 5. 36% soluble.	281·1 ,,	137·1 ,,
1·0 ,,	Phosphate meal prep. 2% soluble	159·0 ,,	15·0 ,,
No manure		144·0 ,,	0·0 ,,

The prepared Phosphate meal hardly had an effect upon the yield worth mentioning. Basic slag No. 1, 89% of the Phosphoric acid of which were soluble in Citric, acid very nearly equalled in effect the increase in yield derived from the application of Superphosphate. But Basic slag No. 5, of which only 36% of the Phosphoric acid was soluble in Citric acid, had only one-third of the effect of Superphosphate. As the quality of Basic slag offered by the trade varies to a great extent, it is not to be wondered at that the results obtained by the application of Basic slag have often differed. *It is most satisfactory that the difference in quality and the value of the various Slags as to their manurial effects is now becoming more and more widely known.* It is also a matter of satisfaction that almost all Thomas's Phosphate Works now use Quartzose for dissolving the hot fluid of the Slag, *and that farmers are now beginning to lay stress upon a fair percentage of the Phosphoric acid in Basic slag being guaranteed as soluble in Citric acid.*

PLANTING IN TOBAGO.

(*Continued from page* 155.)

9. Mulch around the trees, but do not disturb the roots by forking. Scratch the surface gently with a hoe or rake previous to laying on the mulching.

To "*mulch*," is to place upon the ground, near to the trees, vegetable matter which will gradually afford food to the roots and check the evaporation of water from the ground. Dried or wet grass, leaves &c. usually called "*trash*," should be laid six to nine inches deep about each tree, leaving a space of six inches clear just around the stem. A few heavy stones may be placed on the mulching, if necessary, to keep it in place, but this is seldom required except in windy districts, and there, cacao should not be planted. The trash or mulch will keep the ground perfectly moist through the dry weather, and enable the cacao plant to pass successfully through the dry season. Mulching should therefore be done previous to the dry weather setting in, but if any quantity is left undecomposed when moist weather again prevails, it should be raked into wind rows and allowed to rot, and then evenly spread over the whole surface.

10. Always keep the ground clean and free from weeds.

The ground should be kept clean and free from weeds, or they will overgrow the young cacao plants and rob them of their nutriment. Frequent hoeings should be made, but the greatest care should be exercised not to cut too deep with the hoe, or the roots may be injured. It is best to weed by hand immediately around the stem of the trees.

PRUNING.—Let the cacao tree grow freely during its young state, and allow the young branches to spread until neighbouring trees meet; but keep them in form and well balanced, by pinching out the points of the shoots, from time to time, as found desirable. Allow the tree to form its head, but remove all weak branches with a sharp knife, and never allow any part of the tree to get too thick, or the free circulation of the air will be prevented. All branches which are decayed or diseased in any way should be at once removed. No attempt should be made to limit the trees to a certain height. The larger the tree, the more fruit it can bear. Shoots called "*robbers*" or "*thieves*" when occurring out of place, should be removed; but when they arise where a branch is required, they may be used with the greatest safety and economy, as for example to rejuvenate stunted trees, and to replace diseased or broken branches, which have had to be removed.

In pruning, use a sharp knife. No special directions can be laid down how to use it. A good pruner is "made not born," and the best written instructions are but a poor substitute for practical teaching. The general principles which should guide everyone who is cultivating cacao are:—Prune little and prune often. Never cut large branches away at one time.

Cut close and clean, so that no water may lodge in the wounds. Never leave stumps or spurs to rot out. Cover all large wounds with tar or paint.

PICKING CACAO.

The first point to settle is, when the pod is ripe. It should be ripe but not over-ripe. The colour should be fully attained, whether red or yellow. If the beans shake easily about, the pod is probably over-ripe. When picking Cacao always cut the pod with a sharp knife.

Never pull or tear the pod off by hand. If you do, you injure the tree, and it will not bear from the same place next year. It is better not to break or open the pods amongst the Cacao trees, nor allow open shells to lie about. The shells should be buried as soon as possible. They will thus enrich the land and probably prevent disease from spreading in the locality.

CURING CACAO.

The following brief account is taken from "Notes on Curing Cacao for Small Settlers" prepared by Mr. W. Cradwick, and published in the Jamaica Bulletin 1896, p. 15:—

The best vessel in which a small cultivator can ferment Cacao is an ordinary flour barrel. To prepare this for the reception of cacao beans, first bore about a dozen holes, each half an inch in diameter, in the bottom of the barrel, then place about ten inches of banana trash in the bottom of the barrel. Line the sides also thickly with trash, and have a sufficient quantity on hand to cover the beans when placed in the barrel. When the barrel is ready break the whole of the pods and place the beans in the barrel, covering with the banana trash. The beans must be left to ferment for two days, then remove one-third of the beans and lay them in a heap on the floor and mix them thoroughly. Remove the balance of the beans and mix them also, but do not put the two heaps together. After placing fresh trash in the barrel, put the beans which were at the top back into the bottom of the barrel and those which were at the bottom, place at the top. Cover with trash in the same way as before and leave for two more days, when the beans should be treated in exactly the same way as before. They should then be left for two more days, when they are to be taken out and washed thoroughly. On the day the beans are finally removed from the barrel the work should be commenced very early in the morning, so as to get all the sun possible on the first day, for the beans mildew very quickly. They should be washed immediately they are taken out of the barrel as this helps to keep them plump.

The proper amount of Cacao to ferment in one barrel is the quantity of beans obtained from 1,000 ordinary sized pods. If many more than this number are put into one barrel, the fermentation is too great and the beans turn black.

If a less quantity, say below 700 pods, are to be fermented, the green trash and more of it must be used, and a weight not exceeding 28 lb. placed on the top, which helps the fermentation.

When the Cacao is being dried, it is not advisable to expose it after the first two days to the extreme heat of the mid-day sun; it is better to take it in about 9 o'clock, and then put it out again between three and four o'clock.

Disease.—If any pods are observed which have commenced to become black or rotten, either at the top or the bottom, they should at once be carefully collected and destroyed. It has been found that this rotting is caused by a highly infectious disease, and that it is liable to spread if rotten shells are left on the field, or rotten pods allowed to remain on the trees.

II. SHORT NOTES ON OTHER PLANTS.

Orange.—The cultivation of the orange is very simple, for when once the plants are fairly in growth, all that is necessary is to keep them free from weeds and well watered. The orange delights in alluvial soil, but, if well watered and manured, will thrive almost anywhere. The plants should be placed about 25 feet apart in well-prepared sites. The future positions of the plants having been marked off at the required distances, holes should be dug out about 18 inches deep and 2 feet wide. The soil, which has been taken out of the holes, when freed from roots and stones, should be returned to them, but, if of a poor nature, should be enriched with good rotten manure. When the soil thus treated has settled down, one plant should be placed in the centre of each site and well watered. They will bear fruit in about 6 years. Whenever possible "grafted" or "budded" trees should be planted in preference to trees raised from seeds. Grafted or budded trees bear in 3 or 4 years, and they can be depended upon to produce first-class fruit.

Shaddocks and Grape Fruit.—These require the same treatment as oranges.

Mango.—The mango thrives best in rich, deep, well-drained soil, and should be given a rather dry, open situation. The plants should be carefully set, at not less than 30 feet apart, in holes prepared in the same way as recommended for the orange. The only pruning they require is the cutting out of weak and straggling growth. The size and flavour of the fruit are much improved by high cultivation. The best kinds only should be planted. Seedlings cannot be relied upon to come true from the parent, and, accordingly, it is better to pay more for a known grafted variety, such as "*Julie*," "*Peters*" or "*Dirine*," than to grow a tree from seed, only to find after years of waiting that it produces fruit of a worthless character. Mangoes generally bear fruit in about 5 or 6 years. These remarks concerning seedlings apply to other fruits as well as to the mango.

Star Apple.—This tree thrives under the same conditions as the mango, and should be given the same amount of room.

Bread Fruit.—As this tree attains to a large size, the plants should be placed 40 or 50 feet apart, in rich, well-drained soil, care being taken not to injure the roots or leaves. The sites should be prepared in the same way as recommended for the other fruits. They will probably bear in 4 or 5 years.

Pine Apple.—The pine apple succeeds best if cultivated in a well-drained, rich, fibrous, loamy soil, of such a nature that it will not become compact by frequent waterings. The more light and air the pine-apple gets, the better it will thrive, and, therefore, it is advisable that the plants should be set 3 feet apart every way. The ground, after being well dug all over, should be thrown up into low ridges, three feet apart, and the suckers (3 or 4 of the bottom leaves having been previously taken off each, so as to enable them to throw out roots more freely,) should be planted very firmly on the ridges, also 3 feet apart. The suckers on the second ridge should not be planted opposite those on the first, but alternate with them, thus giving each plant much more room. When the plants are in active growth, they should be mulched with manure, stable manure being preferable, as it affords ammonia, which is favourable to their growth. If really fine results are desired, the plants should, after they begin to show their fruit, but before it begins to ripen, be watered with moderately weak, liquid manure, made from horse, sheep or pig dung; as soon, however, as ripening commences they should be kept dry. Under the above treatment, they should fruit in about 12 months.

White Yam.—White yams thrive best in a rich, loamy soil, in a warm, sunny situation, protected from high winds. They should be planted six feet apart, on hills prepared in the following manner:—The ground after being freed from weeds, should be deeply dug, and then about 3 or 4 bushes of soil should be scraped up in a heap, where a plant is required. A piece of yam, or preferably a yam head, weighing from one to two pounds, should be placed in the centre of each hill and covered by about two inches of soil. When they have made from 12 to 18 inches growth, stakes, 10 or 12 feet long, should be struck in for them to twine around, (one in the centre of each hill.) Beyond being kept free from weeds they will require no further care until ready for digging, which is usually in from 9 to 12 months' time.—*Imperial Department of Agriculture for the West Indies.*

SWEET CASSAVA.

(*Manihot utilissima*)

The following results have been recently been obtained by Professor Carmody as the result of an Examination of Sweet Cassava (Jamaica variety) grown at the Experiment Station St. Clair.

SAMPLE SWEET CASSAVA, GROWN AT ST. CLAIR.

Prussic Acid .. .. 0·17

This is fully in accord with the result obtained by Francis, published in Analyst for 1877, in which, the mean of fifteen samples was found to be H. C. N, ·0168 or 1·175 grains per lb. Dr. Taylor fixes the poisonous dose of Prussic acid at one grain, but at the same time reports the death of a healthy woman who died in twenty minutes from a dose equivalent to 9-10 of a grain of Anhydrous prussic acid. It appears therefore that the root is distinctly poisonous in its raw state, and that it is rendered harmless by cooking, for some of the roots were eaten by myself and four members of my family on the day it was dug up, without inconvenience. It would be convenient to know how much of the poison is in the skin of the root and how much among the starchy fibres; how much is dispersed by boiling or roasting, and how much is left in the substance when reduced to an eatable state. In countries where *Cassava* is the staple article of food; cases of poisoning by it are seldom heard of, but the poison found in the root by the Professor and the cases of reputed poisoning which have occurred, appear to show that a full examination of our product is necessary for the safety of consumers and we believe that work on these points is in hand under Professor Carmody's direction and will soon be forthcoming. Fowls eat the fresh roots without poisonous results following.—*Trinidad Bulletin.*

TOBACCO AS AN INSECTICIDE.

In answer to Mr. W. Lawlor of Sunnyside, Tenterfield, who asks for advice as to the most effective way of using tobacco (ordinary dried leaf) for insect pests, the Entomologist, Mr. W. W. Froggatt, says; It can be used in the two following ways:—For aphis, the roots of the affected trees are bared, and the tobacco, ground to powder, is dusted well over the roots and ground about them. A ring of tobacco dust is put round the trunk of the tree just below the surface. The earth is then thrown back, and when rain comes the nicotine is washed out of the tobacco, and gets spread over the roots, killing all black or woolly aphides with which it comes in contact.

Secondly, as a wash: 1 lb. of waste tobacco will make about for gallons of wash, and ½ lb. of soap is added to make it more adhesive. The leaf can be steeped in cold water over night, and the soap boiled up and added; but most orchardists boil up the leaf and soap together, straining the resulting liquor and applying it hot. Tobacco is a contact poison, and is the best known remedy for soft-bodied things like aphides, but it does not affect scale insects very much, when they are full grown and protected by their shelly outer covering. If tobacco wash could be sprayed on to the larvæ of scale insects it would destroy them wholesale.—*The Agricultural Gazette of New South Wales.*

TOBACCO CURING

A year or so ago I ventured to recommend to our Himalayan planters' attention the Sumatra variety of tobacco plant, on the grounds that it grew remarkably well in good soils in the hills, and had proved itself exceptionally hardy, producing during the monsoon season a very fine plant with beautifully fine texture leaves. Of this there is not the slightest doubt, provided the soil is good, the rainfall not too heavy, and the soil does not come waterlogged. I find, however from correspondence and notes in various planting journals on this side, as distinguished from Madras, that the trouble is that of manufacture. This likewise I found out for myself, for although I had no difficulty in getting a fine plant, and none in hanging and ripening the leaf, yet when it came to the necessary fermenting a difficulty at once presented itself more especially as to the extent and degree of the ferment,

I am strongly of opinion there are thousands of acres of admirable tobacco lands in the hills, and that the Himalayan regions should certainly during the monsoon produce a very superior tobacco, more especially as after the rains the weather is perfectly ideal for curing operations, collecting, and so forth.

Some time ago I saw a writer put forth the assertion that Gauhanti could produce tobacco fully equal to that of Havannah. If there is anything in this assertion it is high time the planters of those parts woke up to the fact that tobacco of the quality produced in Havannah would fetch money and plenty of it to insure the business being highly profitable. This apart, however, increasing quantities of both Java and Sumatra tobacco are no doubt being bought for the covering leaf of Indian-made cigars, for, however much the makers may puff Indian cigars, their first and chief recommendation, without Sumatra and Java covering leaf, is simply cheapness.

The time was when the British public went to China for the sum total of its tea, but India has totally altered that state of things; and why it should not produce all the tobacco it requires for its own consumption and some for export to boot is a thing I do not understand. Here is a country with a perfectly marvellous range of climatic conditions and soils, and yet quantities of Java and Sumatra tobacco are imported, and American-grown tobacco is no doubt being increasingly imported into this country.

Coming to the subject of curing, I have before me the latest revised edition of the Bulletins on the tobacco industry in the United States, bearing date 1898, in which are set forth the methods practised in many parts of the United States by one of the chiefs of the United States Agricultural Department.

It may be stated at once that of the fermenting processes "very little is known about the chemical changes that occur in these processes." Again, there is a strong feeling among the more intelligent planters that more information is needed upon the changes which take place in order that these may be carefully controlled. After a careful perusal of the American publication I have no difficulty in forming the conclusion that you can no more make a good tea-maker from book reading than you can a tobacco-curer. It has to be systematically learnt from observation. Indeed it is stated that even an expert cannot lay down written instructions that will be certain to guide the operator aright. For the information, however, of planters, it may be stated that the farmers or planters of the States in a very large measure sell the tobacco uncured; turning it over to the manufacturer for curing. In this case the *modus operandi* is briefly as follows:—The crop is planted in rows of 3½ to 4 feet apart and 18 to 24 inches from plant to plant, it is topped from fifteen to eighteen leaves, and suckers taken off from time to time, that is, as I understand, in this case the side shoots and any emanating from the ground around the main plant. In cutting the plants a general average is struck, and the plants cut when the middle leaves are ripe. The plants at cutting time are laid on the ground to wilt for an hour or two, and turned if necessary to prevent scorching, and it is material the day of cutting be a fine dry one. After wilting sufficient the plants are attached to laths and slung up in the withering barn, which is quite tight but provided with ventilators for ventilation until the tobacco is thoroughly wilted. When thoroughly dried, which is at the outside in two months, it is taken down; the leaves stripped from

the stalks and piled in heaps. It is explained that it is taken down during a warm damp spell. Supposing the damp spell did not occur, I apprehend it could be produced by injecting hot vapour into the barn or shed. The heaps are then covered over with sacks or cloth to keep them in "order" which means a moist condition in which the leaves will not break. The leaves are then packed in boxes lined with strong tough paper, which is also tightly wrapped over the top before closing. In this state a great deal is sold to the curing or manufacturing establishments. Some growers, it is added, carefully sort the leaves and get 3 cents a lb. more for it. Here it will be seen is no question of fermenting for the grower, that being done by others

In the matter of fermenting there appear several methods, of which the following is the first. The sweating is done in wooden cases holding 300 lbs. of tobacco. About half an inch blank is left between the boards to allow moisture to escape. The boxes are then filled with leaves packed with thick ends outwards; they are then tightly pressed down to exclude air as much as possible and the top is screwed on the box. The boxes are piled up in the warehouse, and there left all through the winter and the following summer; being merely changed in order once or twice, *i e*, the bottom box is placed at top and all the boxes turned upside down. This, in brief, is apparently the simplest method of all. It is added that the warehouse temperature is kept pretty uniform during the winter and sometimes the tobacco is overcured, and sometimes undercured. "Nothing in point of fact is done save to maintain the temperature of the room moderately uniform."

In Florida, however, where the Cuba and Sumatra kinds are somewhat extensively grown, the process is entirely different. To begin with, the leaves are gathered as they ripen and not all at once; this for the Sumatra kind; the Cuba plant is cut as already described. When dried, as in the case of other kinds, the leaves are piled for the ferment, and this may be done on the floor or in bins. The room is then kept very moist, and the temperature also very high by artificial means, as may be gathered from the following:—"The temperature of the room is kept quite high and the vapour from the bulk which is being worked over is very pungent and almost overpowering. There is a strong odour of ammonia which makes it difficult to breathe." The bulk is watched incessantly and as the temperature rises the tobacco piles are torn down and rebuilt, each hand of tobacco being shaken out to cool it, prevent sticking and dry it somewhat. Before the sweat is completed the piles are pulled down in similar fashion eight or ten times. The exact time when they should be pulled down and rebuilt depends entirely on the rise of temperature and the condition of the tobacco, which can only be determined by the operator, but the temperature of the pile is allowed to rise gradually until it occasionally reaches 180 F., this representing the maximum, from which the pile slowly recedes until the temperature of the room is reached, and this temperature of 180 F. must be reached gradually.

For the wrapper leaf, the temperature should not go too far, but for the filler, the further it goes and the more intense the action the stronger and finer will be the tobacco, if well done. When the process is completed the leaves are very carefully sorted into grades and packed into either bales or "Carottes" (cylindrical rolls). The fillers, that is, the leaves reserved for the interior of cigars, are frequently re-sweated in order to bring out the fullest quality and also *petuned*. What may be the scientific meaning of *petuned* (the word itself) I am unable to say, or what language it is derived from, "but sophistication" will fit the case very well, as the following shows:—"The essential part of the *petuning* liquid is a thick infusion of tobacco stems of the finest quality obtainable. To this is added molasses, cider, Jamaica rum or sour wine." Other matter is also added, but is a secret of the Cuban makers which they are unwilling to divulge.

After this the bales are piled in the warehouse, and the temperature of the room kept rather cool, and there the tobacco should remain at least two years, "and the longer it is left to age the better it becomes." Other modified methods there are, but it would appear much depends on the ferment, and pulling the piles to pieces the moment there is any danger of over-fermentation: and likewise preventing a too rapid fermentation. In every case the leaves would appear to be bulked to a considerable extent either on the floor, in bins, or hogsheads; and when the tobacco has run the course of the ferment it is so far complete.

In the case, however, of the celebrated Virginia tobaccos, the modification is so considerable as to constitute another method. The leaves are taken straight away to the barns and hung up. These barns have flues running through them, and the moment the leaves are hung quite fresh, the fires are lit up and heat gradually increased without check day or night until it reaches 80 or 90 degrees and maintained at that until the leaves turn a bright yellow, which is in the course of from 18 to 36 hours, and requires very close watching for the correct colour. After this stage is reached the temperature is increased hourly five to 10 degrees until it reaches 115 to 120° at which it is held until complete cure of leaf is effected, after which the temperature is slowly run to 160-175° for the purpose of curing the stalks.

TYPES OF TOBACCO EXPORTED.

The United States export an immense lot of tobacco to many countries: among them I find the following (the observations appear to me not altogether devoid of a species of humour):

1. "The German type is a very fat heavy-bodied leaf, strong, tough, and elastic . . . a fat leaf is always demanded."
2. "The Italian type is a little lighter in colour than the German, very smooth and silky, not so fat, but of good length.
3. "The Austrian type is slightly lighter in colour than the Italian, but the two types grade into each other so that no sharp lines can be drawn."
4. "The French type of tobacco is lighter in colour . . . thinner of body, not so fat; has little elasticity, and in most ways is a poorer grade of leaf than the three types just described."
5. "The Spanish trade takes a large quantity of nondescript and low-grade leaf and lugs of all types, colours, and textures, very little good leaf is called for."

Lastly come our gallant Jack Tars, thus:—"The heaviest type of tobacco goes to England for use in Navy Plug. Sailors require stimulants, and the heaviest of tobaccos carrying a high per cent. of nicotine are used in Navy Plug." NICOTIANA. —*Pioneer*, Sep. 15.

CHILE PEPPER CULTURE.

Mr. J. B. Neff, of Anaheim, California, discourses on Chile pepper culture, in the *California Cultivator*, on the basis of his own experience as a successful producer of hot stuff.

How Plants are grown.—A hot bed is made by excavating about 16 inches deep; fill in to within 4 inches of the top with damp stable manure, tramping down very solidly. Spread about 4 inches of sandy loam over the manure. The seed is sown quite thickly over the loam, and then about ½ inch of loose, sandy soil placed evenly over it, and all kept damp. When the plants have two or three leaves, thin to 1½ inches apart each way. The plants must be watered while in the hotbed by sprinkling. Great care should be taken to protect from frost.

Soil and Preparation.—Rich, sandy soil is the best for the Chile pepper. It should be ploughed deeply, and be put in a state of thorough cultivation. Ridges should be made 3 feet apart, and the plants set 2½ feet apart on the ridges. All plants must be on

a water line, and to get this the ridges should be made, water run down the furrows, and the plants placed about 2 inches above the water mark. This insures every plant receiving water when irrigated. Plant as soon as danger from frost is past.

Cultivation.—Frequent cultivation is necessary until the plants get too large to allow of a cultivator and horse passing between the rows. All weeds must he pulled out. When the plants are set as before noted, all the ridge will be on one side. This must be worked down with a cultivator, and then a plough used to throw earth on either side of the furrow, so that the plants will he midway on the ridge.

Irrigation.—While the plants are small water will be needed about once in twenty days, but as they get larger it will he needed as often as once a week, though only in small quantities. The plant seem to have no deep roots, consequently the surface soil must be kept damp.

Picking.—The field should be gone over about once a week after the peppers begin to ripen, all that are fully ripe being taken off. Great care must be exercised to pick all the stem with the pepper. They should he allowed to lie in the sun one day after being picked in order to toughen the stems and prevent them breaking during the process of curing.

Stringing.—The common method is to cut strings of strong, smooth twine 8½ feet long. Draw this through a needle about 10 inches long, which is often made of a bicycle spoke. Peppers having any breaks r blemishes must be thrown away, as they would decay before drying properly. Of course, where an evaporator is used these can he saved. After the strings are full and tied they are hung on nails driven into a rough pole or other framework standing about 6 feet from the ground, and left until dry; or if shelter is available they may be moved before becoming fully dry and hung closely together under such shelter, but where there is a free circulation of air.

Evaporating.—Many growers prefer evaporating instead of drying. The evaporators used are of various designs and sizes, but they should he large enough when the peppers are dried on strings to hold not less than 500 strings. The usual plan is to have a furnace with several turns of 8 to 10 inch pipe in the basement, the peppers being placed in the second storey over a very open floor and with good ventilation. The temperature must be kept at 110 degrees Fahr., and in this way the house can be refilled about every four days.

Yield and Price.—Both of these, of course, vary with the season, soil, and water-supply. Two hundred and fifty strings of 5 lb. each is called a paying crop, but with all conditions favourable, including a late, warm season, as high as 400 strings, or even 2,400 lb. per acre, of dried peppers may be grown. Prices range from 35 to 75 cents. per string if sun-dried, and 7½ to 12½ cents. per lb. if evaporated.—*Planting Opinion.*

A DOUBLE TRAGEDY.

Down from a twig on a Northern Spy tree
A canker-worm swung in security;
He'd eaten all season since first he was hatched,
As a ravenous glutton he couldn't be matched.
He slipped inch by inch to the grass-covered ground,
Where he thought safe concealment mightly surely be found
In which he could pupate till autumn set in;
But a hen came that way and she gathered him in.
Gathered—gathered—gathered—she gathered him in.
She gathered him in, and his final rest
Was there, in there, in her well-filled chest;
And she strolled around in search for more,
For it tasted better than aught before.
But I thought of her end, her final act,
When the farmer'd slice with a carver's tact,
And remark, as each piece made him look less thin,
"I gather her in, I gather her in,
Gather—gather—gather—I gather her in."
—*American Agriculturist.*

TEA IN THE PARIS EXHIBITION.

Tea is well represented at the Paris Exhibition, and vigorous efforts have been made by various sections of producers to bring their produce under the notice of visitors, says a correspondent of the *Grocer*. China is, as might be expected, in the background, and although there is a fair representation of the ordinary products of that country and a good Chinese pavilion, tea by itself does not receive any special or adequate representation. Close to each other in the Colonial portion of the Exhibition, near the Trocadero, Japan, India, and Ceylon all have pavilions for the supply of cups of tea to visitors at moderate charges, and there is some interest in contrasting the different ways in which the teas of each have been put before those likely to wish to make use of them.

As might be looked for with a land which has recently and most rapidly adopted the civilisation of the West, Japan is well forward in methods for attracting attention to its products. The beautiful pavilion is surrounded by a garden in the Japanese style, planted by gardeners brought over from the Imperial gardens in Tokio, in which there is a pagoda (an exact representation of one of the celebrated temples in Japan), and some striking and interesting specimens of Japanese art, architecture, and industry. There is a separate tea-house, the operations of which are conducted under the organisation of the Guild of Tea Merchants of Japan. The fabric is of light woodwork framing peculiar to Japanese houses, and the garden is surrounded by woodwork railings, the whole being dainty and characteristic. The method of serving the tea is much the same as in the pavilions of the other producing countries, but it is somewhat suggestive of the Oriental wisdom and shrewdness generally associated with the wily Mongolian. The menu presented to visitors affords a much greater range of selection, as well as variety in price, than do those of the Indian and Ceylon pavilions. The card itself is well got up, printed in French on one side and English on the other. It offers a choice of the black tea and the green tea of Japan, also of the Oolong of Formosa, and for the small sum of 50 centimes a daintily-served cup of tea, with cakes, can he obtained. For 1 fr. the same is supplied, with the addition of a small souvenir present and a packet of tea, to he taken home. The latter is Japan tea of most excellent quality, and, if one is partial to a drink of the kind, is likely to impress favourably. Of course it is absolutely different in character from the black tea of India and Ceylon; in fact, the difference between the infused liquor of an ordinary Japan tea, as contrasted with black teas such as are drunk in England, is greater than that between ordinary tea and coffee. With the sample of tea is given some literature on the subject, printed in French on Japanese paper.

On the first floor of the tea pavilion there is a saloon reserved for the service of ceremonial tea, in the style followed in Japan. An afternoon call there is a serious thing, requiring ample time, and of the latter a large part is occupied in serving tea elaborately. The tea used for this is of a particularly fine and delicate character, being apparently little more than the dust which covers the golden tips on the points of the young leaves. It was said to be worth 30 fr. or 40 fr. per lb, and was of a very small make, the size being something like the very smallest and most powdery dust, and the colour deep green. A Japanese lady in attendance makes and serves this, and visitors take their seats on a dais, cross-legged in Japanese fashion, while the lady from Japan sits in the middle with an assortment of brushes, dusters, and tea-cloths round about her, so as to produce an absolute cleanliness in all the utensils. Each part of the process is conducted with the utmost care, and when the tea is finally prepared for drinking, it is passed round in a peculiarly formal manner, with elaborate bows on both sides, and has to be drunk out of a basin in a fashion which one must see to understand.

The Indian pavilion is part of the general exhibition given in the Indian Palace. The building is a very beautiful and characterisitic one, but there was grave delay in its completion and in the opening of some sections of it. That portion set apart for the sale of cups of tea is comparatively limited, and is not particularly well situated for attracting attention, but it is very daintily fitted up. The table service as to the cups, pots, &c., used is excellent. The tea is made in the best possible manner, and the tea supplied for consumption, while still remaining pure Indian, is not obtrusively pungent in its character, and very well suited to impress favourably those who already like tea and may want to contrast the tea of one place of origin with that of another.

The Indian tea-room has the advantage of having a number of beautiful trees actually growing in it. Those in charge endeavoured to buy up the right to cut them down, which the Exhibition authorities would not sell, and it is fortunate they did not do so, as in the height of summer they give a grateful shade and add much to the pretty effect of the place. The tea is served by waitresses speaking several languages, who are very beautifully dressed in costumes which, although not strictly having any relationship to India, are Oriental in their general character, and of a design and in a style which suggests that they might have been furnished by Liberty & Co. All are dressed alike, but the costumes appear to be varied from day to day. Although the tariff was somewhat higher than in the Japan tea-room, excellent value was given in the quality of the tea and of the biscuits, &c., supplied, and this exhibit might be considered a very fair bid on the part of the Indian tea people to popularise their produce among the visitors to the Exhibition. A considerable number of those seemed to appreciate the advantages of an afternoon cup of tea, but it was not very clear whether they were French people experimenting in what to them was a novelty, or visitors from other lands who were merely following "their custom of an afternoon."

Closely adjoining—in fact, practically part of the same block of buildings as the Indian Palace—is that of Ceylon, by no means so beautiful in its design and execution or in the wealth of characteristic detail, yet serving its purpose as a shelter for the representation of the products and industries of the island. In this instance the pavilion for serving cups of tea is right outside, in a separate building, with large accommodation in the way of al fresco tables and chairs, much in the style of any ordinary French cafe. A few Cingalese men, with their characteristic tortoise-shell combs in their hair, and dressed in the usual white cotton costume of Ceylon native servants, assist in supplying the tea; but the waiting is mostly done by waitressess, who might be those of an "A. B. C." shop in London. The trade being done is at times very large, and every seat seems occupied. A small orchestra plays in one corner to attract people, and this seems to answer its purpose very successfully.

The tea supplied on the occasion of my visit to the Ceylon pavilion was neither so good in itself, so well made, nor so daintily served as the competing pavilions, and the value given for money was inferior to that in either of the other two, but that appeared to be of little consequence. Ceylon tea has been so well advertised, not only throughout the Exhibition, but throughout Paris in general, and the situation (being at a point where many footways meet and cross) being a very desirable one, there is no necessity to give more to the customers than they expect. A very large trade was being done, and apparently many of the visitors were French people, and numbers had frequently to be turned away.

Ceylon tea generally throughout the Exhibition was being exceedingly well pushed in the restaurants, the Ceylon Commissioners having made contracts with most of them to supply pure Ceylon tea, and a neighbouring restaurant (with a familiar English name) had actually gone the length of cutting under the rates charged at the tea pavilion to attract people into their place for cups of Ceylon afternoon tea.

In Paris generally tea has certainly been more in evidence during this Exhibition than ever before, several well-known English concerns having opened depots, and a large number of places having been induced specially to push certain Ceylon teas that were being exhibited.—*Indian Gardening and Planting.*

PLANTING NOTES.

Productions of the Jewish Colonies in Palestine at the Paris Exhibition.—We are informed by Mr. S. Eldod, manager and director of the Palestine Wine and Trading Company, Limited, whose business premises are at 11, Bevis Marks, City, that the Jewish colonies in Palestine have obtained at the Paris Universal Exhibition of 1900, a Gold Medal for their wines and Grape-brandy, and a Silver Medal for fruit-trees and fruits.—*Gardeners' Chronicle.*

Cooking of Vegetable-Marrows.—As the season of Vegetable-Marrows is now with us, here are two very good modes of cooking them, sent us by Dr. E. Bonavia:—"*(a).* 'Young Marrow Parmesan Fashion.—Take as many very young Marrows as you require, cut each in four, lengthwise; stew them with butter, without water, adding salt, till they are quite soft; place them on a hot dish, and powder them rather thickly with grated Permesan cheese. In the same saucepan put a large spoonful of good stock or gravy; mix in the pure of two or three large tomatos; pour this sauce on the Marrows, and serve. *(b).* Young Marrow, Milanese Fashion.—Cut the number required in halves, lengthwise; half boil them in water and salt; remove the interior of each half, chop it up, and squeeze it in a clean rag to remove the water; then fry a chopped Onion in butter, adding the squeezed pulp, thickened with a little flour, and add a tablespoonful of cream, if handy; season with pepper, salt, nutmeg, and grated Parmesan. The whole should be as thick as porridge. When cold, bind the whole with a whipped egg or two. Fill the Marrow-shells with this stuffing; sprinkle over them some grated Parmesan, and bake to a light brown. N.B.—A variation of this is the addition of minced-meat and Sultana-raisins to the stuffing."—*Ibid.*

Fruit in Ceylon.—The attempts which have been made in the past to cultivate fruit on a large scale in Ceylon have not been of so encouraging a nature that hopes may be entertained that we shall see Orange orchards and fields of Pines filling our markets with a cheap and abundant supply of two of the best fruits Europeans can eat in the East. Oranges remain scarce and dear, which might in the gardens of the village around Colombo alone be grown without trouble and in abundance to fill all the requirements of Colombo, and the constanly increasing number of steamers and ships putting into our harbour. It is possible that the attempts which have been made in the past to cultivate Oranges on a large scale resulted in a failure on account of the class of plants chosen not being best suited to this climate, and whilst it is most desirable that better strains should be introduced, the Oranges which are in small supply in Colombo are not by any means undesirable in quality, but the quantity first requires attention. The Pines usually offered for sale in Colombo are of a very poor description, yet what Ceylon can do in the shape of Pine growing is shown by the delicious fruit to be secured by paying an increased figure. We are rather sanguine that were a start made by encouraging villagers round Colombo to plant the best strain of fruit trees, the results would very amply repay the time and money expended.—"Times of Ceylon."

THE CAMBRIDGE EXPEDITION TO THE MALDIVE AND LACCADIVE ISLANDS.

The last of the three scientific expeditions which have left the University of Cambridge during the past two years for work in various British dependencies has recently returned. It may be remembered that in April, 1899, an expedition left for the purpose of investigating the formation of coral reefs in Ceylon, the Maldives and Laccadives, under the charge of Mr. Stanley Gardiner, Balfour Student of the University.

After several weeks in Ceylon, three months were spent in the island of Minikoi, the most southern of the Laccadive Islands, the lighthouse of which is usually seen by travellers to the East about a day and a half before reaching Colombo. This island has obtained a very unenviable notoriety on account of the large number of wrecks on its reefs, the last of which were the steamship "Thrunscoe," which went ashore shortly before the expedition arrived, and the yacht "Tolna," belonging to Count Festetics, at the beginning of this year. It has long been proposed to erect a signal station on the island, as it lies in the direct route from the Red Sea to Colombo, Australia, and the Far East. From this point Mr. Gardiner cannot see that there would be any difficulty in communicating by means of Marconi's apparatus with Southern India, or, better, with a station on one of the higher mountains of Ceylon.

The members of the expedition took up their residence in a native bungalow, which they had erected close to the lighthouse, and from this centre carried on work of a very varied nature. The natives were not friendly to the English, on account of the disputes which have arisen after the various wrecks on the island though they were in no way actively hostile. The population numbers about 2,500 adults, of whom less than 900 are men, the greater number of the native males being absent on voyages. Many of them are employed on board the various English steamers which sail from Calcutta. The thorough survey of the island and its reefs made by the expedition revealed the interesting fact that the island had been recently elevated to a height of about twenty-five feet. Considerable attention was also paid to the currents round the reefs, which were found to be very varied, and large collections of the land and marine fauna were obtained.

In October Mr. Gardiner, accompanied by Mr. Forster Cooper, proceeded to the Maldive Islands, where they were very kindly received by the Sultan, who is locally known as the Sultan of the 12,000 Lands. The group was found in a ferment owing to a recent change of Grand Vizier and the removal of Mr. Nusserwanjee Dadabhoy by her Majesty's ship "Marathon." Owing to these causes considerable opposition was shown throughout to the work of the expedition by different Ministers and nobles. The Sultan, however, lent a schooner of about 18 tons, and did everything in his power to assist the work, despatching a Royal proclamation to every part of his dominions.

The group, it may not be generally known, is about 500 miles long, and consists of a perfect maze of small islands and reefs. It has passed successively into the hands of the Portuguese, Dutch, French and English, the old treaty of friendship and alliance with the Dutch being renewed yearly with the Governor of Ceylon by mutual presents of local produce to the value of about £20. Owing to disputes arising out of the wreck of a German vessel, a second treaty has, however, lately been made in respect to salvage. The people are Mahomedans of mixed Cingalese, Arab, and Malay stock, and the Sultan claims to have been given his title at Damascus by a former Caliph. All trade has to be carried on at Male, the Sultan's island, except in Maldivian vessels, and a small fleet of schooners is run by various Bombay merchants in Colombo. Rice is the principal import, no grain having been in recent years grown; and coconuts and dried fish, a kind of "Bombay duck," are given in exchange. Steamboats seldom visit the island on account of the strong currrents and numerous reefs, which are constantly growing up or being washed away. Indeed, the navigation of steel ships is practically impossible except in bright sunny weather. A good instance of this was seen on the occasion of the visit of her Majesty's ship "Marathon" in 1899, when, in passing out of Male atoll, she stuck for some time on a reef, which was supposed to have at least seven or eight fathoms of water over it. A hurried survey of the group was made in 1836, but the people at that time were in a very disturbed state and few islands were visited. Since then practically no Europeans, except a few wrecked sailors, have visited any part of the group except the Male atoll, and nothing was known of the internal affairs or government of the many islands.

The expedition visited over 300 islands in every part of the group except the most northern atoll of Tiladummati, partly in the Sultan's schooner and partly in the steamship "Ileafaee," which was for some time chartered. At all the islands the members of the expedition went freely among the people, talked to them, and heard their legends and grievances. In everything their proceedings were the objects of the greatest curiosity, thousands of people who had never seen a white man before visiting their vessel. As far as possible observations were carried out, in particular on the currents of the group, and numerous soundings of the greatest interest were made. The positions of islands and reefs in the atolls were fixed, and all the latter were thoroughly dredged. Large collections, too, were made of the land and reef fauna.

On the whole, the work of the expedition, though the white members suffered severely from Maldive fever, was of a very satisfactory character. The government, mode of life, wants and relationships of the people have been investigated, and specimens of nearly all articles of native manufacture obtained. With regard to the reefs, it is hoped that these investigations will set many scientific points at rest in respect to their formation in the Indian Ocean. The collections, too, should once for all determine the possibility of there having been at one time in this region a large island, which has been repeatedly called into existence to explain the present distribution of animals and plants. It is hoped to communicate some of the results of the expedition to the meeting of the British Association at Bradford in September.—London *Times*, Aug. 18.

JIPIJAPA OR PANAMA HATS.

Ecuador is the real home of the hats wrongly designated under the name of "Panama," and according to the *Recueil Consulaire Belge* this industry afterwards extended to Peru and other countries, even to Yucaton in Mexico. Everywhere in Latin America the hat is known under the name of "Jipijapa" in honour of the city

where its manufacture was first started. It is only in Europe or outside of the producing countries that this hat receives the name of a city which does not make it. The finest hats are made in Jipijapa and at Montecristi, in the province of Manabi (Ecuador), this industry being one of the greatest resources of the country, The *toquilla* or leaf of a small plant is used for this purpose. It grows abundantly in the country the leaves coming up in the shape of a fan. The plant is the *Carludovica palmata*. There are jipijapas of all qualities, from those costing a few pence to those worth several pounds. The merit of these last, really marvels of fineness, consists as much in the scarcity of the straw as in the difficulty of the weaving, and therefore it is exceptional to find these hats on the general market. The hats of current sale cost a few shillings, the finest not exceeding from £5 to £6 in price. In buying a Panama it is necessary to ascertain two things—that the straw is whole and that it is not stiffened. It is not easy to recognise this first condition. In order to make two from one, the weavers split the straw with such perfection that unless a person is accustomed to such examinations it is almost impossible for him to distinguish the difference. Of equal fineness the hat made from whole straw is worth three or four times the one manufactured from the straw that has been split. The second condition is easily recognised for the hats are stiffened to make the straw firmer and white. Good *toquilla* is white and stiff enough not to need any gum, and only ordinary Panamas are stiffened.—*Journal of the Society of Arts*, Aug. 17.

COLOPHONY AND TURPENTINE.

The Forest Department have recently erected a distillery at Nurpur, Punjab, for the manufacture of rosin and turpentine from the crude oleo-resin which exudes from the *Pinus longifolia*, a tree which occurs plentifully in the Western Himalayas and less so in the Eastern. The trees are tapped by cutting wounds in the main trunk and suspending small earthenware cups for the reception of the exuding resin, the wounds being extended when they cease to flow. The samples produced in the factory are very good, the turpentine being quite colourless and the rosin being pale and clear. The Forest Department possesses, of course, a decided advantage in having no difficulty about trees to tap, but arrangements might be made for the tapping of forest trees on payment of a fee to the department. The business must be a lucrative one, as the department has furnished their factory with copper plant at a considerable expense.—*Indian Planters' Gazette*, Aug. 25.

THE COFFEE CROP IN COORG.

An estimate of the coffee crop in Coorg for 1900 has been received from the local Administration, and the figures are appended, with the estimates of 1899 for comparison :—

	1899.	1900.
	Tons.	Tons.
Estimated yield (1½ cwt. an acre for Europeans in 1899 and 2 cwt. in 1900)	2,089	2,751
Estimated yield (¾ cwt. an acre for natives in 1899 and ½ cwt. in 1900)	683	1,120
Total ..	2,772	3,871
	cwt.	cwt.
Estimated average yield per acre of ordinarily well cultivated coffee in full bearing ..	2	2¾
	Tons.	Tons.
Export of coffee taken from the toll gate returns	4,134	2,366
Average annual export of coffee in the ten preceding years ...	3,228	3,326

Taking the average crop to be about 5,100 tons the estimate of 3,871 tons for the present season represents about 76 per cent of the average against 53·3 per cent in 1899.—*Indian Gardening and Planting.*

TEA :—THEA OR CHA.

WHAT CHINESE DRS. SAY.

"The Chinese physicians say that upon the mountain Tiengo grow above one hundred sorts of simples all of very sovereign virtues. But, amongst all others, China is famous for a herb called Thea or Cha, and whereof the natives and other neighbouring people make their drink called Thea or Cha, taking its name from the herb. Of all the places in China this herb grows fastest, and in greatest abundance, in the province of Nanking, near to the city of Lucheu, and indeed the same is only found in China, Siam, and in the island of Japan. The leaves thereof are very like unto those of Sumack, and that this is a sort of Sumack none need to doubt. However, it springs not wild, but by manuring; is no tree nor herb, but a bush or shrub, which they plant upon little hills three feet asunder, and grow as high as a Rosetree, the branches whereof are full of flowers and thin leaves of a dark green colour, which, though they differ not in shape, yet they are of several sizes, for upon one shrub are at least of five several degrees in bigness. The first and biggest grow upon the lowermost sprigs; next to them follow those of the next size, and are lesser than the first, and so by degrees grow all the other sorts. But so much as these leaves decrease upward in bigness so much the more the increase in price, for a pound of dried leaves of the first bigness is worth five Dutch shillings, that of the second bigness is worth fifty shillings, but that of the third five guilders, that of the fourth fifteen, and that of the fifth and last bigness fifty. Yea, sometimes one hundred and fifty guilders a pound if well prepared. Upon the branches grow small green buds, which produce little flowers with white leaves, yellow within, and in bigness, fashion, and colour very like the flower of Sweet Briar, but different from it in smell. After that the flowers are shed, there remains a husk which contains a blackish seed, which, being sown in the ground, brings forth the third year new bushes, from whose leaves is gathered every year a rich harvest, and that in such places where it rains and snows as it does in Europe, so that it is probable enough that there might be bushes raised from that seed if it were sown in some shady fruitful European soil. It is full of spreading roots, which run but shallow in the ground, and are good for nothing; but the leaves they gather every day, and, drying them in the shade, preserve them for their drink Thea, which they use instead of beer, not only at tables, but upon all visits and entertainments, and, which is more, whosoever has anything to dispatch in the palaces of the Grandees is presented as soon as he is seated with a cup of this liquor, which is always drunk, or rather supped off hot, according to the fashion of the ancient Romans, who esteemed more of warm than cold water. If at any time this liquor proves bitter to the taste they mingle a little sugar with it, and drink it to drive away drowsiness. But such especially find the benefit in drinking thereof who have overcharged their stomachs with eating, or discomposed their brains with too much strong drink, for it is a very great drier of gross humours and dispels vapours, occasioning sleep. It strengthens the memory, but increases gall if drunk in too great a quantity. In brief, they extol the virtues of this drink infinitely, and attribute their not having the stone or gout to this, as they term it, most noble drink, which we may believe the rather because in all our journey forward and backward we saw nobody afflicted with these distempers. There is a very great difference in the manner of preparing and using this liquor between the Chinese and those of Japan, for the Japonners beat the leaves to a powder, and mingle it with boiling water in a cup, which they afterwards drink off, but the Chinese put the leaves whole into a pot of

boiling water, which, having lain in steep for some time, they sip off hot, without swallowing down any of the leaves, but only the quintessence thereof extracted. Others prepare it with milk and a little salt mingled with the water, which is not so well approved; but, however prepared, it is not only drunk in China and other parts of India but is much used likewise in divers other countries, and the general consent of all people that they find much goed by it enhances the price, and makes the same to be sold here at a very dear rate.—*Extract from an Embassy from the East-India Company of the United Provinces to the Grand Tartar Cham, Emperour of China, 1669. . . . English . . . by J Ogilbt, Esq., Master of his Majestic's Revels in London."—Gardeners Chronicle.*

SHELLAC.

There seems to be no reasou why the *Coccid, Tachardia lacca* should not be artifically propagated. Were plantations of the trees upon which lac is formed, among which are *Butea frondosa, Zizyphus xylopyra, Mimosa* sp., *Erythrina* sp. and *Croton lacciferа*, made in suitable localities, there is every likelihood that the artificial protection of the eggs and the careful distribution of the same would lead to the increased production and facility of collection of lac. Exactly as one of the wax insects, *Ericerus pela*, which is closely allied to *T. lacca*, and has the same habits and transformations, is cultivated in China, so might this species he worked to advantage in India. More difficulty is indeed attached to the rearing of the wax insect in China than would be found in the case of the lac insect. The Chinese in the district of Szechuen, where the wax insect produces best, collect the eggs from what is supposed to he a more healthy district for their oviposition, *viz.*, the region of Been-Chaug. The producers carry the eggs over mountainous country to the more suitable district for wax production, the distance between the places occupying about a fortnight to cover. The eggs are then tied up in small hags and suspended from the twigs of the evergreens, on to which the newly-latched larvæ swarm and subsequently produce a coating of wax in the same manner that the lac insect produces lac. Both the gum lac and the dye made by the insects are marketable products.—*Indian Planters' Gazette*, Aug. 25.

AGRICULTURE AND CHINA MATTING.

(*From an ex-Ceylon resident.*)

Manila, Aug. 17.

The Civil Commissioners take over power here from General Macarthur, the Military Governor, next month, and one of them will start an Agricultural Department, but I am afraid they will be long in starting Experimental Gardens.

You will see by the paper I am sending that the Government have selected a site for a Sanitarium on the Benguet hills. It will be reached by rail from Manila to Dagupan (across Luzon) and a small hill railway is to be made from Dagupan up the hills. I am afraid it will be two years before this line is made, as everything is done very slowly. Manila is improved since the American occupation, but there is plenty of room for more improvements, especially in the roads. Bad road metal is put down and rollers are unknown.

A SANITARIUM FOR LUZON.

Luzon is to have a Sanitarium. It will be located up in the life giving mountains of Benguet at a place called Bogio, about 45 miles from Dagupan to which place it will be united by a mountain railroad, and all this will be done as soon as possiblo and within a year. Messrs, Wright and Worcester of the Civil Commission journeyed north to locato a suitable site for a Sanitarium. These gentlemen returned to Manila last Friday, filled full with praise for the Benguet country. In selecting Bogio for the proposed sanitarium, the commission had three very important matters in view, the first of which was, of course, a health resort. A place where, during the most oppressive months of the Luzon year, Americans and Europeans could go and rest and recuperate. For this purpose the place chosen is admirably situated. It is high in the mountains and contains an abundance of the purest, freshest water, the nights and days are cool, the scenery superb and inspiring. Besides the motives of health, the establishment of a summer resort here and the building of a railroad from Dagupan will be the means of opening up a wonderfully rich region, and will in this way prove a good political move, while from a military point of view such a step would be invaluable.—*Manila Times*, August 16th.

CHINA MATTING MANUFACTURING CO.

PROSPECTUS.

Capital, $1,000,000 (Hongkong Currency) divided into 50,000 shares of $20 each, of which $5 is payable on application and $5 on allotment. Head office Hongkong. This Company has been formed for the purpose of making by power-looms straw matting of the same description as that now produced by hand-looms in the neighbourhood of Canton (China.) The export of Matting from China to the United States has of late years become a most important trade, having risen in the last 10 years as follows:—from 179,472 rolls shipped in 1889-1890 to 370,170 rolls shipped in 1898-1899 but, as usual, the quality of the goods has fallen away with the increased demand, while prompt delivery to contract time has become increasingly difficult.

Many attempts have been made to devise looms which could be worked by steam to take the place of the crude hand looms used by the Chinese and Japanese, but success has only been attained by a loom which became the property of the Kobe Manufacturing Co., and which has since been brought to a high state of perfection by further inventions and improvements.

The promoters of this company, having experimented with a small trial plant of 50 of these power looms and introduced various further improvements suggested by their knowledge of the Matting trade and requirements of the market in the United States, are now satisfied that Matting made by such machinery must supersede that made by hand looms and have accordingly entered into an agreement with the Kobe Manufacturing Co, to acquire all the rights to the invention.

While experimenting with 50 looms, some 10,000 rolls were made and shipped and the reports on the later and better made shipments were all of a highly favourable and encouraging nature, the evenness of the fabric and the great improvement on the old hand-loom matting, especially as regards the selvage or edge, being particularly praised and commented on. One great difficulty was to get the machines to turn over the straw so as to produce a clean surface at the edges of the Matting. This difficulty was overcome some few months ago, and the looms can now, in the opinion of experts, turn out a perfect fabric. As each power loom can produce about 30 yards a day as against 6 yards produced by hand-loom, the saving in the time is obvious, while the advantage of being able to rely upon punctual delivery will be a great boon to dealers at home who at present have to put up with much delay and loss of time in getting their goods. The advantage is still more obvious to-day in view of the political unrest all over China and the great probability of the present troubles in the North spreading to the South, in which case the matting industry in the districts around Canton is likely to suffer to such an extent that it may take years to recover, matting being entirely dependent upon the labor of the peasant class when not en-

gaged in their ordinary farm work. It it proposed to erect a Factory capable of running 450 looms producing about 100,000 rolls per annum, of which it is estimated, at the prices recently obtained in the United States for the Matting sent there for sale, there would be a net profit of a least $1½ per roll, or say $150,000. In course of time further experience and economies will undoubtedly improve upon these figures. The promoters of this Company have, as before stated, experimented with 50 looms and having acquired from the Kobe manufacturing Company all the rights to the invention will transfer the same to the new company together with fifty looms and other machinery, stock in trade, good will, etc., for $350,000 (Hongkong currency), which amount will be taken by the Kobe Manufacturing Company and the promoters in shares. The capital of the company, as far as can be roughly estimated, will be laid out in the following manner:—Land, buildings and machinery, $470,000; working capital, $180,000; Kobe Manufacturing Company and promoters for rights, good-will and sundry machinery, including engine and 50 looms, $350,000 taken in shares.—Total, $1,000,000. —*Manila Times* Aug. 16.

ADDITIONS TO THE ZOO.

At the monthly meeting yesterday of the Zoological Society of London at the offices in Hanover Square, Dr. Henry Woodward, F.R.S., vice-president, in the chair, it was reported that there had been 137 additions to the society's menagerie during July. Among them special attention was directed to a fine pair of tigers (Felis Tigris) from Mysore, India, presented by H.H. the Maharani Regent of Mysore; to a sharp-nosed badger (Meles leptorhynchus), from China, representing a species which had not been in the society's collections since 1873; and to a young female brindled gnu (Connochœtes taurina), born in the society's gardens, being the first instance of this species breeding in the society's menagerie. It was also announced that the Right Hon. Cecil J Rhodes had presented to the menagerie a lioness which had arrived on the 11th inst. in the steamer Saxon, of the Union Castle Company, and that the company had kindly brought it from the Cape freight free.—*Globe*, Aug. 17.

GOLD CRAZE IN MADAGASCAR.

Paris, Aug. 17.—The discovery of gold in the Malagasy provinces of Imerina and Ambositra has generated a veritable craze in all sections of the population, irrespective of race or colour. All ties of business, family, and long residence in the capital and other centres are being uprooted, and there is a universal rush for the new El Dorado. The fever of speculation has already been productive of much misery. There is no doubt that there are gold deposits, but most of those found hitherto prove to have been almost exhausted by natives before the French Conquest. The gold region extends about 100 miles south of Antananarivo.—*Daily Express.*

CAPRIFICATION OF FIGS.

The process of caprification or cross-pollenisation of Smyrna Figs is performed chiefly by women and children; it consists in gathering the Profichi, and suspending them in the branches of the Smyrna tree, says *California Fruit Grower*. In the Meander orchards it is customary to string the hard Profichi on the ends of rushes, which are pushed horizontally through the sides of the Fig; if the Profichi are plentiful two are strung on each end of the rush, which is then thrown up into the Smyrna tree and caught among the branches. The fig wasp, on emerging from the Profichi, enters the Figs nearest to hand, not discerning any external difference between the young Smyrna Figs and the young Mammoni, which it would enter if still in the caprifig tree. But once inside the fig wasp discovers that something is wrong, for, instead of finding short-styled gall flowers in which it could lay its eggs, there are only female flowers with long styles, which are entirely unfitted to receive the eggs: insect is unable to escape, and in darting about in vain efforts to find some gall flowers, the pollen with which it was so freely dusted in emerging from the Profichi is rubbed into the receptive stigmas of the female flowers. The little wasp finally dies in the Fig without having been able to provide for the production of its kind, and on cutting open a Smyrna Fig shortly after caprification one can usually find the dead insect.

The quantity of caprifigs needed to caprificate a Fig tree varies with the size of the tree. In Smyrna some thirty Figs are required to caprificate a large full-grown, edible Fig tree.

TRADE IN BORNEO.

The report of Mr. Consul Keyser on the trade in Borneo has just been received. With regard to Brunei, it appears that there is a good opening for the collection and cultivation of rubber and gutta-percha, but the Chinese have practically killed the trade and driven the natives out of their country.

Sarawak, which is governed by Rajah Sir Charles Brooke, is, however, progressing rapidly, and the exports of rubber and gutta-percha from this district are increasing every year, as the following figures show

The reports being as follows:—

	1898	1899
Gutta-percha ...	513,200 lb.	1,362,267 lb.
India-rubber ...	515,333 lb.	664,133 lb.

These, with rattans, form the chief articles of of export.—*Indiarubber Journal*, Aug. 20.

LINSEED OIL-CAKE.

This product has long been known to gardeners in the country as a valuable manure for fruit trees, especially for vines and peaches; but its use has not been as general as its valuable properties warrant. Mixed with lime it has a wonderful effect on fruit trees. Judging from the reports on experiments carried out on the several Government experimental farms by the application of linseed cake to certain cereal crops, the conclusion to be drawn is that it is one of the best fertilising agents we have. As a cattle food and even for horses, its value is fully recognised in England and Scotland and hundreds of tons of it are imported annually from India by Scotch farmers, who are better acquainted with its valuable properties than the Indian *ryots*. As with bone-meal so with linseed oil-cake. Those out of India think more of it than the Indians, with the result that, instead of being utilised in this country for the manuring and fertilisation of crops, these valuable substances are being sent out of the country. It is a striking commentary on the peculiar conditions obtaining in India, that the people do not recognise the value of their own indigenous products, and allow foreigners to exploit them to their own advantage. Messrs. Barry and Co., Calcutta, are the Managing Agents of the Gourepore Co, Ld., and will be glad to furnish particulars as to the linseed oil-cake manufactured by the latter.—*Indian Gardening and Planting*, Aug. 30.

CEYLON TIMBERS.

Amongst tropical timbers there are some peculiar to Ceylon which occupy the first rank in importance, some even being unequalled in beauty and commercial value, *e.g.*, Calamander and Ebony. The Timber Expert for the Imperial Institute has recently made an examination of samples of Ceylon timbers and has pointed out in several cases the probability of certain kinds gaining increased favour in the timber market, more especially with cabinet makers. Some of the samples, however, at his disposal were from uncertain sources and of doubtful species; whilst with many the age of the trees from which they were obtained could not be determined. Obviously, the latter character is of vital importance in estimating the value of timbers. The age of trees grown in temperate climates can generally be distinguished by the number of rings to be seen in a transverse section of the stem, each ring indicating a definite period of growth, owing to one season of activity being followed by one of rest in the same year. In Ceylon, however, where the vegetation is generally evergreen and therefore comparatively uniform in rates of growth throughout the year, the idea of "annual rings" can no longer be relied upon as indicating the exact age of a particular tree.

The rates at which trees grow, and therefore the seasonal rings in their stems, are, to a great extent, controlled by climatic conditions; and since Ceylon, above all places, offers such a great variation in this respect, it is more than probable that if sections of trees from different parts of the island were examined, certain conclusions could be arrived at which would be capable of general application. The only way in which reliable information can be obtained on the point in question is by examining as many trees as possible, of known age. The knowledge thus gained can then be applied in solving the age of timbers about which no record of planting has been made.

In this connection we learn that Mr. Herbert Wright, the Scientific Assistant at Peradeniya Gardens, is giving special attention to the subject of annular rings and planters when felling any trees (in the hill or lowcountry—in the Puttalam and South Batticaloa districts, where coconut clearings are being made) would do well to forward to him thin sections of the same, about three inches in thickness. Mr. Wright, more particularly, wants sections of trees "of known age." Such, however, can only refer to timber trees planted on estates or around bungalows, and chiefly of imported —Australian, Indian or Japanese—trees. We have never heard of any planter trying to grow the cabinet-wood-yielding trees of the island, more especially Ebony and Calamander? If we are wrong, our good friends, Mr. W. H. Wright and Mr. Wm. Jardine, will correct us. Indeed, Calamander is nearly extinct in the Crown forests in the island. Here is what Dr. Trimen says in his "Flora":—

Diospyros quaesita:

Forests of the moist low country below 1,000 ft.; rare, Singhe Raja Forest; Hiniduma; Potapitiya, Kukul Korale; Karawita Kande; Ratnapura; Dotalankanda, Pasdun Korale. Fl. April. Endemic. This affords the finest of the variegated woods known as Calamander. The tree is much sought after, and, from being destroyed in many places, is becoming more and more scarce. Thunberg in 1777 first discovered 'Calaminder' wood to be produced by a species of *Diospyros* (see his 'Travels,' vol. iv.).

The shape and large size of the fruit afford a ready means of determining this species, and the venation of the large leaves is also characteristic.

And from the current "Agricultural Magazine" we extract a passage out of a report by Mr. A. F. Broun, Conservator of Forests:—

Ebony, as has already been mentioned, is found in small quantities in this zone, but the most important tree of this family, which is unfortunately almost extinct, the Coromandel or Calamander wood of commerce, *Diospyros quaesita*, is still found here and there in the Pasdun Korale and in the Hinidun Pattu. Attempts have been made for several years to obtain the fruit in order to propagate the species artificially, but, although rewards have been offered, none has been obtained.

Still another extract we take from the late Wm. Ferguson's pamphlet on "Ceylon timber trees":—

I recollect reading in 1849, a very interesting account by Mendis Modliar of the mode of procuring Calamander Wood, and the fact that the variegated part so much in request is an *accidental* product of the tree, some trees producing none of it, some near the lower part of the trunk, whilst in others it is found only near the middle of the trees, and generally not in luxuriant trees growing in rich soil, but in those growing in dry rocky ground. These remarks apply to several of the trees producing *variegated* or *ornamental* woods, such as the Tamarind, in which the beautiful Calamander-like wood is found only in very old trees, and generally in the heart of the lower part of the trunk, or in the roots; and the differences of soil, climate and situation have such an effect on the timber of the same species of tree, that unless these facts are taken into account respecting the specimens used as tests, the tables of streugth, weight per cubic foot, specific gravity, &c., &c., are not to be depended upon. Again the times of felling, mode of seasoning, &c., should also be taken into account.

Nitrogen and Electricity.—Tesla says it will yet be feasible to procure nitrogen from the air in a form suitable for fertilising purposes by means of electricity. By transmitting electric power great distances without wires, Tesla also thinks that power will be made so cheap that it will pay to pump water for irrigating lands that cannot be otherwise utilised. Yet such a source of cheap nitrogen would be no more remarkable and not as practicable as the method by which every intelligent farmer now extracts nitrogen from the air instead of paying for it. Leguminous crops have the power to extract nitrogen from the soil's atmosphere by means of nitrifying organism or bacteria. These crops will thrive on poor land if dressed with a little potash and phosphoric acid, and then if ploughed under (in whole or in part), the nitrogen thus obtained is added to the soil's supply of plant food. The wonderful function of bacteria is just beginning to be realised in agriculture as in other industries. In this and other ways Nature will help intelligence as applied to farming, more readily and efficiently than to idly wait some transcendant discovery for the artificial extraction of atmospheric nitrogen.—*American Agriculturist.*

THE WALAWE ESTATES COMPANY.

RICE GROWING.

The *Government Gazette* contains the memorandum and articles of Association of this Company formed to take on lease and thereafter purchase or otherwise acquire the Walawe estate at Ambalantota, and prepare, manufacture, treat, and make marketable paddy, rice, tea, copperah, oil, and (or) other crops or produce.

The nominal capital of the Company is one hundred and twenty-five thousand rupees, divided into 205 preference shares of R100 each, bearing a cumulative preferential dividend at the rate of eight per cent. per annum, and also ranking in priority to the ordinary shares for return of capital upon a winding up of the Company and 225 ordinary shares of R100 each, the remaining 595 shares of R100 each to be issued hereafter in such manner as the Company may direct, with power to increase or reduce the capital. After the payment of the cumulative preferential dividend at the rate of eight per cent. per annum, and a cumulative dividend on the ordinary shares at the rate of eight per cent. per annum, the balance profits of any year which the Directors may recommend for division shall be divided and paid as to two-thirds to the preference and ordinary shareholders *pari passu*, and as to one-third to Edward Elliott so long as he shall be Manager of the Company, and upon the retirement of the said Edward Elliott from the management the balance profits shall be divided between the preference and ordinary shareholders *pari passu*. The signatories are :—H Creasy, Colombo, G H Alston, A Thomson, G W Carlyon, W Henry Figg, Whittall & Co. and *per pro.* E B Creasy, R E Shaw.

NYASSALAND COFFEE COMPANY.

THE ANNUAL REPORT OF DIRECTORS.

Directors :—Messrs. W P Metcalfe, Chairman; Geo. Kent Deaker, H Creasy and W Shakspeare.

ACREAGE.

10	acres	coffee	planted	Dec. 1895.
240	do	do	do	1896—Feb. 1897.
383	do	do	do	1896—Feb. 1898.
633	acres	under	cultivation.	
2,843	acres	reserve.		
Total 3,476	acres.			

The Directors beg to submit the accounts closing the year 1899, the period under review covering six months only.

Superintendence.—During the six months Mr. G N Barclay was in charge of the estate.

Progress of Works.—The ordinary routine work of the estate was partially carried out, but possibly owing to Mr. Barclay's unfortunate illness, the weeding, from latest reports received, would appear to have suffered from lack of supervision, Mr. Robins being absent on furlough.

Crop for 1900.—The issue of this report has been delayed in the hope that full information would have ere this been received, but the Directors regret that no details have yet come to hand as to the outturn. The accounts to the end of April show 42 bushels parchment coffee secured as the result of first pickings.

Financial Position.—To the 31st December, 1899, the Company was indebted to Messrs. Carson & Co. to the extent of R8,500, and they have continued to finance the Company during the present year. It has not yet been found practicable to conclude the arrangements foreshadowed in the last Director's report.

Directors.—Mr. W P Metcalfe retires by rotation but is eligible for re-election.

Auditor.—The appointment of an Auditor for the current year rests with the meeting.

DOOMOO TEA COMPANY.

THE DIRECTORS' REPORT.

Directors :—Messrs. W Kingsbury, F W Bois, W D Gibbon.

Your Directors beg to submit their Report and Accounts for the season ending 30th June 1900,

The tea received from the two estates aggregated 242,790 lb. against an estimate of 220,0 0 lb. and the price realized was 46·57 cents per pound against 42·83 cents per pound the previous season. The cost of production was however reduced by almost 4 cents a pound the resulting profit being 13·88 cents per pound against 12·22 cents.

The Doomoo Factory has been removed and re-erected at Verellapatna as a withering shed, and the whole of the Company's Tea is now manufactured on the latter Estate, this having been considered advisable owing to the rapidly increasing cost of firewood.

The amount available to deal with is R37,264·92 and your Directors recommend that R2,500 he passed to Depreciation account R5,000 to Reserve account that a Dividend of 7 per cent for the year be paid forthwith and the balance of R1,764·92 be carried to next account.

The Directors would also ask the shareholders to sanction the payment of a bonus of R500 to Mr. Mason for his efficient and economical working.

The estimate for the current season is 245,000 lb. Tea on an expenditure of R71,205—which includes a sum of R3,000 for a new bungalow which is necessary on Verellapatna.

The acreage of the two estates is as follows viz :—

Doomoo ...	210	acres	Tea	6 years old and upwards.
	3	,,	,,	4 ,, ,,
	6	,,	,,	under 2 years.
	219			
	22	,,	Timber.	
	58	,,	Chena and Patna.	
	299	acres.		
Verellapatna	345	acres	Tea	5 years old and upwards.
	120	,,		4 ,, ,,
	35	,,		3 ,, ,,
	24	,,		2 ,, ,,
	524			
	10	acres	Grass.	
	154	,,	Chena and Patna.	
	688	acres.		

In accordance with the Articles of Association Mr. F W Bois retires from the Board, but being eligible officers himself for re-election.

It will also be necessary to appoint an Auditor for season 1900—1901.

Nyassaland Coffee Company.—We regret to see that this enterprising Company is to be no exception to the usual experience of pioneers. But it seems to us cultivation has been forced on a little too rapidly : 663 acres of coffee would be a really big charge even in Ceylon : how much more in a new and like B. C. Africa. We think it a pity the Directors did not confine themselves to 400 acres as a maximum, until they had got profitable returns and proved the plantation to be a success. Then the weeding probably would not have fallen into arrear, while the financial position would have been distinctly better. However, we have no doubt all has been done with the best intentions and no Directors can guard against the illness of their Superintendents

PRODUCE AND PLANTING.

Russian Customs Tariff on Produce.—The Board of Trade have received, through the Foreign Office, a copy of a Russian Imperial Ukase, dated July 21, stating that the Russian Government have decided to increase temporarily the duties on articles comprised in certain sections of the Russian Customs tariff on their importation into Russia from European countries. The conventional tariffs existing in conformity with the treaties between Russia and other States will not be affected by the present Ukase, which was to come into force from July 23 (August 5)—*i.e.*, the date of its promulgation. In the list of articles liable to increase there is no mention of tea, but there is an increase of 50 per cent upon roasted coffee, cocoa, and spices, an increase of 30 per cent upon raw coffee, and 20 per cent upon ground cocoa.

———

The Tea Trade of Canton.—An interesting report on the trade of Canton for the year 1899 by Mr. Scott, the British Consul, has just been issued through the Foreign Office. In his report Mr. Scott says: "The returns of tea given in the Customs returns convey no idea of the real quantities exported. In the case of tea, the information is positively misleading, as the figures show an actual decrease, while I am informed that there was really an increase of about 1,000,000 lb. as compared with 1898, which year, however, was the worst year, as regards the quantity exported, on record. The total amount exported to London is stated to have been 5,250,000 lb. This was all junk-borne to Hongkong for transhipment. The 1,130,214 lb. which appear in the Customs returns was none of it destined for the United Kingdom, practically the whole being consumed in China itself. The improvement in the trade last year is held to be temporary only, the whole course of the trade having a downward tendency year by year, and is gradually but surely diminishing. The requirements for the 1900 season are said to be only 4,000,000 lb. The result of the trade in 1899 is said to have been profitable to the producer, and more ground has been put under cultivation, but the increased quantity thus produced will all be required for consumption on the spot and for export to other parts of China."—*Home and Colonial Mail*, Aug. 24.

PLANTING NOTES.

American Maize in the Punjab.—A trial is to be made in the Punjab as well as in other parts of India of samples of American maize recently received from the Rev. R Winsor, Secretary to the American Board of Commissioners for Foreign Missions.—*Pioneer.*

A "Tea Cess" for India.—Mr. G. L. Acworth, Chairman of the United Planters' Association of Southern India, alleges that the planters are not so much to blame as the Indian Government for the non-establishment of a "Cess" on tea (for advertising purposes) such as is so successfully collected and utilised in Ceylon. If that be the case, we think it would be well if the Viceroy were approached, and if this could be done through the Ceylon Government or His Excellency Sir West Ridgeway personally, a successful issue might be anticipated. If the Planters' Association prepared a brief statement of how the Cess has been worked in Ceylon and what has been done with the money, and requested our Government to lay it before the chief Indian authorities—or the Viceroy himself—with the hope that a similar Cess (as prayed for by the Indian planters?) might be sanctioned for India, we cannot see how a refusal could be given.

Colvillea Racemosa.—This is one of the most beautiful trees we have received from Madagascar, and like the Flamboyant (*Poinciana regia*) it belongs to the great *Leguminosoe* Order. It was introduced into this country many years ago, and is almost naturalised here. It attains to a height of some forty feet: has beautiful fern-like foliage, not unlike that of *P. Regia*. When in flower, as it is now, it is a grand object with its long racemes of glowing orange-scarlet flowers, rising from the upper axils of the leaves. From two to five racemes, about fourteen inches long, come out at each terminal axil. When properly grown and a little care taken of it, the tree grows into a handsome shape. It is easy of culture, and is propagated from seed, which it bears freely. The tree is well worth a place in any garden. —*Indian Gardening and Planting*, Sept. 6.

The "Plumbago" Puzzle.—A correspondent to our contemporary puts the mystery surrounding the plumbago trade "in a nutshell," when he says:—

"Whatever the cause was for the rise beginning in 1897, and going on till nearly end or middle of 1899, the fact must remain that people wanted plumbago for specific purposes, and not to lay it down on the chance of it being useful some day. Whatever the stuff is used for, it must be—one would think—for the class of things whose manufacture or output is expanding and not contracting, and yet we see 242,000 cwt. selling at vastly inferior prices in 1900 to 400,000 cwt. in 1899 (export to 30th August for the two years)."

To say that the desire to lay in stocks, caused the great rush and increase in price, notwithstanding 50 per cent more of shipments during 1899, is absurd on the face of it; while increased activity in armaments seems only a partial explanation.

Rubbishy Teas in the Colombo Market.—We have repeatedly urged self-respecting tea planters—the vast body of the community in fact—to take action through their Association with reference to stuff which is a disgrace to the name of "tea" put up for sale in the local market. Again and again has such "Ceylon tea" been condemned as "unfit for human food" at the Melbourne Customs; and though London is not so strict, there can be no doubt of the injury done to our good name from such shipments. We are glad to see that Mr. F. F. Street is supporting our view of the need of a paid "expert" at the local Customs to stop the export of *trash*, such as is never seen from even China or Java. Surely factory sweepings or spoilt tea, if they have to be sold at all (in place of being put in the manure heap) can be disposed of to coolies or tambies? Here is an extract from Mr. Street's latest circular:—

"Quality.—Generally the selection has not been good, catalogues containing a large proportion of tea more or less spoilt in manufacture. Many of these rubbishy teas can only bring discredit on the industry, as the worst get into native buyers' hands, who sell them, at large profits, in our Harbour, to passengers calling here. Quotations of from 10 to 20 cents must leave loss to the estate. We desire to draw the 'Thirty Committee's attention to this subject, as it is an evil that has existed for many years. It seems rather absurd that planters should require protection against themselves, but that such protection is needed, in the interests of the industry, is manifest to everyone connected with the trade."

Malacca Rubber at Kew.—Specimens of gutta and rubbers from Malacca have been very favorably reported upon at Kew, with prices ranging as high as 2s 10d per lb (for *getah greep jantan*). The neglected child of the Colony may yet recover some of her pristine prosperity with such favorable results.—*Perak Pioneer*, Sept. 5.

A Rich Russian Rubber Company.—The profits of the Russian-American India Rubber Company, at St. Petersburg, for the last business year are reported at 2,941,906 rubles, against 3,945,222 rubles, in the year 1898 99. The dividend will be only 35 per cent., against the customary yearly dividend on 50 per cent.—*The India Rubber World*, August 1st.

The Sustaining Power of Bananas.—One of the most courageous marches ever taken, was that of Colonel Willcocks to Kumasi. We hear that during the march from Kumasi the whole party lived on Bananas. On one occasion they even waded shoulder high through a river for two hours. Does anyone want a higher test of endurance on a vegetable diet than this?—*Journal of Horticulture*, August 16th.

Tea Prospects at Home.—There have been growls over the heavy London stocks of Ceylon tea at the end of August. But it is pointed out that, notwithstanding big arrivals, they are not heavier than at the end of July, and that August's deliveries have, therefore, been very satisfactory. It is from the present date onwards that the stocks should gradually decline, and we hope to see a considerable difference at the end of September and of October.

Timber Transport.—The Cochin Durbar have secured the services of Mr. Haffield, an engineer, to prepare a scheme for the construction of a tramway to convey timber from the Sircar forest to the backwater, and for the deepening of canals to float the logs down expeditiously. At present it takes a little over a year for the timber to reach the Sircar Depôt at Ernacolum, after considerable difficulty and expense; but when the scheme is completed there will be a saving of money and time. The scheme is estimated to cost two lakhs of rupees.—*Pioneer*.

A New Fruit.—In this thirsty season the raiser of a new fruit is a public benefactor. "The Mahdi" is not a pleasant name, but we do not doubt Messrs. Veitch's new hybrid of the raspberry and the common blackberry is not the less sweet for it. Perhaps they will send samples to the newspapers, as the Kentish gentleman did with the tobacco he had raised, which led to lively expectations of a new industry for distressed agriculturists in Southern England and Ireland. It is not the first time this hybrid has been heard of. In fact, it has been something of a sea-serpent in its generous appearances. But this time there is no mistake about it. Its origin is known and it is duly certificated. We hope it may become as popular and as plentiful as blackberries. Too little enterprise is shown in the cultivation of new fruits in England. There is the Rocky Mountains berry (*Rubus deliciosus*), for instance, which well merits attention, and would thrive in many soils. The worst of these delicate soft fruits is they must be lightly handled and quickly despatched. And then the growers assert that railway freights are exorbitant, if not prohibitive.—*Egyptian Gazette*, Aug. 23.

A New Assam Line on the metre gauge system has been proposed. It will run along the foot of the Khasi Hills to Jherria, thence westwards to Mao-iong, Jatab Tilah and Dwara Bazaar. Including sidings, the length of the line will be thirty miles, and it is estimated that the cost will be R15 lakhs. It is expected that the gross earnings will amount to R1,50,000 a year, and the working expenses are estimated at 53 per cent so that the return on the capital outlay will be 4·67 per cent.—*Pioneer*.

Criticising Tea Companies.—We give elsewhere an extract from the latest *Investors' Review* in which the Editor, Mr. Wilson, is engaged in the (to him) congenial occupation of pitching into the financial methods of the promoters of certain big Tea and Plantation Companies. There is, no doubt, another side to the picture which he presents if the Directors cared to come forward with it.

The Late Sir John Lawes.—"I am afraid," writes a correspondent, "the Tea controversy proved too great a shock for the veteran Scientist of Rothamsted. It was bad enough to be misunderstood and misrepresented by his neighbour, G. A. Talbot; but that his newspaper echo here of manurial heresies, should ask whether the great student and advocate of scientific agriculture had ever seen a tea bush, must have been too much for the octogenarian. R I.P."

The Trees of Mexico—the vegetation of the *tierra caliente* has often been described and compared with that of Ceylon, says a correspondent of the *Speaker*; but upon the great Mexican plateau also the trees, where they exist, are splendid and always contrive to group themselves well. Foremost, I think, comes the ash—a glorified ash, handsomer than ours, graceful as well as massive and of the richest green; but the characteristic tree is the pepper-tree, or, as it is commonly called, the Peru, for it is not indigenous to this country but was introduced years ago by a Viceroy from Peru. It is of a most brilliant green and covered with bunches of coral-like berries. At a distance this tree rather resembles our willow, while the willows, in protest as it were, have taken unto themselves the shape of poplars. No enumeration, however, would be complete without special mention of a species of cypress which, though of no great height, attains a gigantic size. Its bulk must be measured by the ground it covers, for its branches spread out in all directions. The Ahuete-huete, the finest specimen at Tule, has a trunk 40ft in diameter. The ubiquitous prickly pear and cactus hedges give our Mexican scenery a character essentially its own—the prickly pear has always been Mexican, it was the Aztec emblem and is still stamped upon the ponderous Mexican dollar. To complete and vary my picture, Mexican landscapes are blessed by the richest diversity of beautiful skies and the cloud effects are quite unrivalled in spite of the dry climate—or rather, perhaps, because of it: such extraordinary brilliance may be due to the dryness of the air:—

"Largior hic campos aether, et numine vestit
Purpureo."

The sky seems "larger" here than anywhere else. I mean that one seems to see more cloud-pictures all round, and not only towards or away from the sun. Our atmospheric brilliance, too, seems to fit the Virgilian "purple,"

PRODUCTION OF TEA IN INDIA.

OFFICIAL STATISTICS.

[The two tables appended state the facts regarding the production of tea, the first in abstract for the fifteen years 1885 to 1899, the second in detail for the two years 1898 and 1899. It should be noted, however, that the figures, for which the Government are dependent upon the planting community, are imperfect and defective, planters sometimes withholding information.]

AREA.

The area under tea in India at the end of 1899 extended over 516,732 acres, nearly two-thirds (64·1 per cent) being in the valleys of the Brahmaputra and Surma, which contain as much as 331,151 acres—namely, 198,673 in Assam (the Brahmaputra valley) and 132,478 in Cachar and Sylhet (the Surma valley). In extent of cultivation Bengal comes next, the area under tea being 132,923 acres, or 25·7 per cent of the whole, and about the same as in the Surma valley.

The production of tea is therefore, to the extent of nine-tenths of the whole area, limited to the two provinces of Assam and Bengal.

The other tenth is divided between Northern and Southern India, thus :—

Northern India.	Acres.	Southern India.	Acres.
North-Western Provinces	7,854	Madras ..	10,164
Punjab ..	10,135	Travancore and Cochin ..	23,115
Total ...	17,989	Total ..	33,279

The principal localities in each province where tea is grown are these :—

In Assam.	Acres.	In the North-Western Provinces.	Acres.
Surma Valley:			
Cachar ...	60,542	Kamaun ...	2,846
Sylhet ..	71,936	Dehra Dun ..	5,008
Brahmaputra Valley:		In the Punjab.	
Sibsagar ...	76,797		
Lakhimpur ..	63,444		
Darrang ..	41,469	Kangra ..	10,135
Nowgong ...	12,520		
Kamrup ...	3,818		
In Bengal.		In Southern India.	
Darjeeling ...	50,673		
Jalpaiguri ...	74,121	Nilgiris ..	7,321
Chittagong ...	4,663	Malabar ..	2,398
Ranchi & Hazaribagh	3,366	Travancore ..	23,103

There is a small area of 1,390 acres in Upper Burma, but in this province the leaf which is produced is not made into tea, but is pickled to be eaten by the Burmans, and the area and production may therefore be left out of account,

There are also a few small areas in Goalpara, the Khasi and Jaintia, hills, the Chittagong hill tracts, Simla and Cochin.

Tea cultivation in India has been mainly concentrated in tracts where a heavy rainfall and a humid and equable climate permit of repeated flushes and pluckings of the leaf. In the valleys of the Brahmaputra and Surma the yield averages about 448 lb. to the acre, and in Bengal about 406 lb., the yield in Jalpaiguri (the Duars) being 533 lb., and in Darjeeling about 281 lb. In Travancore the average yield is stated at 644 lb. per acre, a figure that must be taken under reserve. In the North-Western Provinces the yield per acre is 297 lb. Elsewhere the yield is much lower.

The area under tea has expanded from year to year without a pause during the fifteen years comprised in the statistics appended. In 1885 the area was about 284,000 acres; in 1899 it had increased to 516,732 acres, the increase being in the ratio of 82 per cent.

The number of acres added to the tea-growing area each year has been :—

	Acres.		Acres.
1886 ..	14,294	1893 ..	20,970
1887 ..	14,584	1894 ..	4,688
1888 ..	11,524	1895 ..	15,190
1889 ..	9,374	1896 ...	17,563
1890 ..	11,126	1897 ..	36,838
1891 ..	17,610	1898 ...	31,561
1892 ..	12,432	1899 ..	15,052

The average addition in the last five years (23,241 acres) was much larger than the average addition (13,365 acres) in the five preceding years.

The plantations vary greatly in size. In Assam, where the industry is mainly carried on by Europeans with ample capital, where fusions of estates have been in progress for some years in view to economy of management, and where most plantations have large unplanted areas attached to them, the area of a plantation averages as much as 1,266 acres. In Bengal the average area of a plantation is 727 acres; in the North-Western Provinces the average falls to 119 acres, while in the Punjab, where natives grow tea extensively in the Kangra valley, there are only about four acres to each plantation. In Madras the average is about 86 acres.

PRODUCTION.

The quantity of tea produced has increased in the past fifteen years in much greater ratio than the area under cultivation, for, while the area has increased by 82 per cent, the increase in production has been 161 per cent. In 1899 the production in Assam, where the season was favourable in most of the districts, increased by more than 18 million pounds, and in Bengal by more than 4 million pounds.

Representing the area and production in 1885 by 100 in each case, the ratio of increase in each compared with that year is stated below, the actual increase of production each year over the production of the preceding year being also stated:—

	Area.	Quantity produced.	Actual increase annually in lb.
1885 ..	100	100	..
1886 ...	105	115	10,899,835
1887 ...	110	129	9,826,270
1888 ..	114	139	7,540,462
1889 ..	117	149	7,250,331
1890 ..	121	156	4,993,531
1891 ..	127	173	11,831,496
1892 ..	132	170	—1,873,628
1893 ..	139	185	10,253,626
1894 ..	141	188	2,465,144
1895 ..	146	200	8,694,783
1896 ..	152	219	13,018,227
1897 ..	165	215	—2,643,846
1898 ..	177	228	9,296,746
1899 ..	182	261	23,445,966

PERSONS EMPLOYED.

The number of persons employed in the tea industry in 1899 is returned at 558,001 (permanently) and 96,615 (temporarily), or altogether about two-thirds of a million people (654,616 persons), which would work out to about 1·27 persons to the acre.

EXPORTS AND CONSUMPTION.

The tea produced in India is exported, mainly to the United Kingdom, to the extent of about 97 per cent of the average production. The sub-

joined figures give approximately the quantity of tea consumed in India, the figures representing the average of the last five years:—

		lb.
Indian tea	Produced ..	160,643,992
	Exported ..	155,474,416
	Left in India ..	*5,169,576*
Foreign tea	Imported ..	6,210,615
	Re-exported ..	3,487,630
	Left in India ..	*2,722,985*

Thus approximately 8 million pounds were left in India on the average of which 5·17 millions Indian and 2·72 millions foreign, the bulk of the foreign tea being Chinese, though a substantial quantity consists of Ceylon tea. More than a million pounds are purchased annually for the British Army, and a larger quantity must be consumed by the European and Eurasian civil population, and by natives who, in some of the larger towns, are adopting the tea drinking habit.

The principal markets for Indian tea are stated hereunder, with the quantity exported (in lb) to each country in the last five years:—

By Sea:—				
1895-96.	1896-97.	1897-98.	1898-99.	1899-1900.
United Kingdom.				
123,947,369	135,456,884	137,655,857	139,245,995	154,161,492
Australia.				
6,774,652	6,155,895	6,792,654	6,306,135	8,362,797

Other trans-frontier countries.				
6,048	13,664	18,144	23,968	25,312

PRICES

The prices of tea in Calcutta fluctuate greatly. Taking the price in March 1873 to be represented by 100, it appears that until 1885 the level was well above that point, varying from 110 to 148. In that year, coincidently with the great fall in exchange and in general prices, the level fell to 90, and a low level was maintained in the following years until 1895 when there was a rise again to a high level. In 1897 prices again fell and they have remained at a low level since, as the consequence of the extremely rapid increase of production in India and Ceylon.

These figures all represent the course of prices of fine Pekoe in January of each year as given by the Bengal Chamber of Commerce. The level for each year from 1873 is stated below:

1873	..	100	1887	..	77
1874	..	123	1888	..	84
1875	..	123	1889	..	77
1876	..	136	1890	..	63
1877	..	148	1891	..	81
1878	..	135	1892	..	71
1879	..	129	1893	..	87
1880	..	126	1894	..	52
1881	..	135	1895	..	97
1882	..	126	1896	...	84
1883	..	110	1897	...	64
1884	..	116	1898	..	61
1885	..	90	1899	..	58
1886	..	90	1900	...	64

In the Statistical Department the average prices of the various descriptions of tea sold at the public sales held in Calcutta during the tea season have been computed for some years past. From these accounts the figures below are taken, being the prices in annas and pies per pound of the three descriptions which form the largest proportion of the tea sold and the variations in the prices, the average price of 1885 being represented by 100:

	Broken Pekoe.			Pekoe.			Pekoe Souchong.		
	Price As.	Pie.	Variation	Price As.	Pie.	Variation	Price As.	Pie.	Variation
1888	10	3	109	8	1	100	6	3	109
1889	9	9	95	7	5	92	5	7	89
1890	8	10¾	87	7	2	89	5	8½	91
1891	8	7½	85	7	0½	87	5	3⅓	84
1892	11	3¼	110	8	9	108	6	5¼	103
1893	9	2 4-5	90	7	2⅖	90	5	4 4-5	87
1894	11	8	114	9	4 4-5	116	7	2 5-7	116

1899	6	9¾	66	5	8¾	71	5	0⅗	81

J. E. O'Conor,
Aug. 14, 1900. Director-General of Statistics.

CEYLON TREES: SECTIONS WANTED.

We are glad to learn from Mr. Herbert Wright (Scientific Assistant at Peradeniya) that he does not want Calamander or Ebony in particular, and that it does not matter whether the trees are native or otherwise. Mr. Wright wants sections of *any* tree, of *known age*, providing it has been subject, throughout its life, to a Ceylon climate. For instance, a section of stem of Cacao, Erythrina, Bombax, Grevillea, etc., would,—providing the age was known,—afford data on which to base general conclusions. The greater the variety of specimens forwarded, the better it will be. This being the case, we feel sure that not a few planters and others will endeavour to oblige Mr. Wright. Sections of Grevillea from Upper (or Lower) Dimbula, to compare with sections of the same tree grown at 2,000, 3,000 and even 4,000 feet lower down, could not fail to be of interest. Of course, Hakgalla Gardens, New Galway, Nuwara Eliya and Uva, as well as the Western districts, can give a variety of tree sections, of Grevilleas, Eucalypti, and Acacias; while any planter uprooting or cutting down an old cacao tree should not forget Mr. Wright.

West Indian Lime Juice.—Mr Algernon E Aspinall, secretary of the West India Committee, Billiter Square Buildings, writes to the *Times*:—"The attention of the West India Committee has been called to the fact that at the present time lemon juice is being largely mixed with lime juice in this country, and the compound is being sold as 'lime juice,' to the detriment of the buyer and of those British West Indian colonies, such as Montserrat and Dominica, where the lime fruit is extensively grown. The West India Committee, therefore, confidently appeals to the British public to further the interests of those colonies by insisting upon 'pure West Indian lime juice' and 'cordials' being sold in bottles marked as such or so described in the invoices. By this precaution every buyer will secure for himself the benefit of the Merchandise Marks Act (1887), which forbids any false trade description, and thus secures the buyers in obtaining the goods they have asked for."—*British and Colonial Druggist*, Aug. 24,

TEA PLANTING AND EXTENSIONS IN NORTHERN INDIA.

Some weeks back a Ceylon Visiting Agent expressed the opinion that only the visit of a practical man to the Assam and other Tea Districts in the North could give us reliable information as to the actual condition and prospects of the Tea Industry as a whole. We supplemented this opinion by expressing surprise that some of the planting journals in Calcutta or elsewhere did not take the trouble to get exact and full information. On this, our contemporary of the "Indian Planters' Gazette" thinks we have not been reading his columns, inasmuch as they have contained full reports of the working of the principal Indian Tea Companies and reviews of the Government Blue Books. But we have to tell our contemporary that, all these we have read and yet we are not satisfied. We get all the Official Reports direct and treat them only as affording approximate information, just as the reports of the "*principal*" Tea Companies can only amount to "approximate" and not complete information. Is there not room for an enterprising young journalist in Calcutta to do what we did in Ceylon when we laid the foundation of exact planting statistics, namely to visit each of the tea districts in person and compile information on the spot which could then be maintained by means of circulars at intervals. In a few months, we hope to be able to tell the world not only the exact acreage planted with tea in Ceylon; but the area planted under 6, 4 and 2 years old—the extent of fields (if any) just cleared and the prospect as to any farther extensions. It is no doubt a big order to ask all this for India with its 480,000 or more acres of tea; but then Ceylon counts up to not far short of 400,000 acres. We are aware that Messrs. Thacker, Spink & Co.'s Directory gives the cultivated acreage of each estate; but there is nothing to shew how much is young tea or newly planted and still less what extensions are in prospect. The Tea Association in its annual estimate deals with young and old tea; but there is surely room for a Calcutta journalist or a planting correspondent to run round the districts and compile a very valuable statement, meantime writing letters by the way which, we think, would give our contemporary of the *Indian Planters' Gazette* great prestige and advantage if they appeared in his columns.

IMPORTS OF MANURES INTO CEYLON.

We have been asked to obtain for planting information the figures showing the importation of Manures for 1899 (the whole year) and for the first six months each of 1899 and of 1900; and while we give the former from the Annual Report, for the latter we are indebted to the courtesy of the Principal Collector of Customs. It will be seen that the past half-year shows no increase as regards saltpetre refuse or sulphate of potash, but sulphate of ammonia shows a rise of 109 tons. In bone dust there is a comparative decrease; but it is difficult to compare other items seeing that this year so much is put under the heading of "other manures." Taking the totals of value, the comparison for the six month periods is as follows:—January June 1899:—R526,703; January-June 1900:—R701,516—showing a big rise.

Imports:	1899. Quantity. Tons cwt. qr. lb.	Value. R c.
Manure, Bone ...	3,635 19 0 0 ...	235,223 7
Patent Manure ...	— ..	—
Rape Cake Manure	100 0 0 0 ..	4,498 0
Refuse of Saltpetre	304 13 1 19 ...	68,480 27

A NEW GUTTAPERCHA.

INTERESTING DISCOVERY AT ZANZIBAR.

An interesting discovery has recently been made in Zanzibar. According to our consul there, the fruit of a tree which grows principally at Dunga will, on being tapped with a knife, produce a white fluid which when placed in boiling water, co-agulates into a substance closely resembling gutta-percha; this in the process of cooling becomes hard, but can on its previous soft state be moulded into any required shape. The fruit somewhat resembles a peach in shape, but is of the size of a small melon. It is not improbable, he adds, that it will prove to be an inferior order of Guttapercha.—*Globe*, Aug. 31.

THE INDIAN TEA CROP 1900-1:

TO TOTAL 182 MILLION LB.

The Secretary, Indian Tea Association, under date, 8th September, has issued the following particulars with respect to the present season's crop of Indian tea, *viz.*:—

	Manufactured to 15th Aug. 1900.	Balance to be made to end of season 1900.	Total.
	lb.	lb.	lb.
Assam ...	31,194,240	35,156,456	66,350,696
Cachar ...	13,025,338	14,343,489	27,368,827
Sylhet ...	14,607,380	18,473,260	33,080,640
Darjeeling ...	4,758,269	3,084,690	7,842,959
Terai ...	1,392,028	1,150,720	2,542,748
Dooars ...	10,491,623	12,448,690	22,940,313
Chota Nagpore ...	76,960	80,000	156,960
Chittagong ...	391,041	483,345	874,386
Kangra Valley ...	1,600,000	1,300,000	2,900,000
Dehra Dun ...	886,845	732,500	1,619,345
To this total of			165,676,874
must be added:—			
1. Kumaon (Estimate)			300,000
2. Gardens from which no returns have been received, including private and native gardens (Estimate)			16,168,000
Total			182,144,874

Shipments to America, the Colonies, and other Ports are estimated at 23,000,000 lb., and local and trans-frontier consumption at 7,250,000 lb. There will, therefore, remain on this basis about 151,894,874 lb. for export to Great Britain. As the statistics from Travancore and other districts in Southern India have not been received to date they will be issued separately.

As a means of comparing with the above, we give the Indian tea exports for the past three seasons:—

	Twelve months, 1st April to 31st March.		
	1897-98.	1898-99.	1899-1900.
	lb.	lb.	lb.
To United Kingdom ...	137,655,857	139,245,995	154,161,492
To Russia ...	689,271	500,889	467,451
„ Canada ..	593,532	1,044,256	1,932,943
„ United States ...	929,704	1,413,624	2,744,854
„ China ...	565,274	883,307	1,248,857
„ Persia ...	1,464,394	3,456,791	1,953,900
„ Turkey in Asia ...	1,336,970	2,598,281	2,149,414
„ Australia	6,792,654	6,306,135	8,362,797
„ Other Countries ...	1,424,161	2,021,394	2,016,419
Total ...	151,451,817	157,470,672	175,038,127

We believe our own Planters' Association Committee will very shortly issue a revised estimate for the Ceylon crop or export for 1900; but there is no chance, we fear, of its being lower than the original estimate of 138,000,000 lb. Already we have about reached the 100 millions, and we suppose we are bound to exceed 140 by the end of the year. The practical question then is how is the aggregate of the Indian and Ceylon Tea exports—or 325,000,000 lb. at the very least, allowing for South India—to be disposed of? Much depends on Russia and America and on the course of affairs in China.

BEET SUGAR CROPS OF THE WORLD.

Writing on the 16th June, Mr. F. O. Licht reports uneven weather in Germany, warmth alternating with fosts and snows, followed by copious rains. Work of hoeing has been somewhat delayed, and is slightly behind, but the beets have sprouted well, and now look strong and healthy. It is estimated the beet area of Europe will increase this year by 209,000 hectares.

"Our preliminary estimate of the European beet sugar production, will compared with the preceeding campaigns as follows:—

	1899-00.	1897-99.	1807-98.	1896-97.
Germany	1,790,000	1,721.718	1,852,857	1,836,536
Australia	1,120,000	1,051,290	831,667	934,007
France	970,000	830,132	821,235	752,081
Russia	900,000	776,066	738,715	728,667
Belgium	300,000	244,017	265,397	288.009
Holland	180,000	149,763	125,658	174,206
Other countries	275,000	209,115	196,245	202,990
Total	5,535,000	4,982,101	4,831,774	4,916,586

"Thus the campaign of 1899/00 is giving hopes of a surplus of about 553,000 tons against its predecessor."—*Sugar Journal and Tropical Cultivator.* Aug. 15.

INDIAN TEA ASSOCIATION.

INTERESTING TEA ITEMS.

The following is an abstract of the proceedings of a meeting of the General Committee held on the 4th instant.

Present:—Mr. H C Begg (Chairman); and Messrs. R H A Gresson, W Holder, G Kingsley, A Troeher, and T Traill,

Letters of 27th July and 3rd and 9th August from Mr. Ernest Tye, Secretary, Indian Tea Association, London, came up for final consideration after previous circulation. The chief matters dealt with in these letters were:—

(*a*) Bonded Warehouse Charges.—In the letter of 29th July it was stated that the London Committee had informed the Secretary of the Tea Clearing House Committee that the concessions made were not wholly satisfactory. Particular objection had been taken to the withdrawal of the reduction in the bulking and taring charge which bad been made on the 23rd January.

(*b*) Paris Exhibition.—In his letter of 3rd August Mr. Tye stated that the Indian tea stall was well patronised for the tea in packets; and that orders were daily received from all parts of France for quantities varying from 1 lb. to 5 kilos. The majority of these orders were from former visitors to the Exhibition who had left Paris. The Association Contractor, Mr. Langdale, considered the result of the efferts which had been made was most encouraging; and he thought that further progress would best be attained by the establishment of sale depots. He hoped to have two hundred of these in working order in different parts of Paris before the close of the Exhibition in November.

(*c*) The Proposed Bounty on Green Teas.—This matter was referred to in the letter of 3rd August, from which it appeared that further samples of green teas suitable for America would be shortly sent out from London. These samples would be in addition to those to be received from Chicago.

The Committee had in the meantime received samples of the green teas which some of the gardens in the Association were prepared to manufacture in consideration of the bounty. It was decided to submit these samples at once to the experts, and to ask for their opinion upon them. As the standard samples had not arrived, the experts were to be instructed that while they might definitely accept any samples which they might deem suitable, none were to be definitely rejected at present. An offer made by a

member of the Committee to place before the experts certain standard samples which had been received from America, was accepted with thanks. The Committee had also previously taken steps in the direction of procuring samples of Ceylon green teas.

(*d*) Tea in South Africa.—In his letter, dated 9th August, Mr. Tye stated that the Committee in Loudon were inclined at present to leave the sale of Indian tea in South Africa to the ordinary course of trade.—*Indian Gardening and Planting*, Sept. 6.

FOR AGRICULTURE AND SETTLEMENT.

AUSTRALIA V. SOUTH AFRICA.

Now that there is a prospect of a termination of the war in South Africa, and that it appears clearly to be the intention of the British Government to place the Orange Free State and the Transvaal under British rule, the Australian nomadic instinct has begun once more to assert itself. From Victoria and New South Wales there appears to be a large exodus of adventurous spirits to the new colonies (for the Orange Free State has already been formally annexed by Great Britain under the name of the Orange River Colony), where they hope to better their condition either as mechanics, farmers, miners, or labourers. As it was in the early alluvial mining days in the various colonies of Australasia, when, if a report were spread that a new rich alluvial goldfield had been discovered, immediately hundreds of men abandoned claims, where they were doing moderately well, and rushed away on horseback, on foot in drays, and even pushing wheelbarrows to the new Eldorado, not pausing to consider distance climate, supply of provisions, &c., so it seems that today the Australian worker is inflamed with a desire to seek better fortune in our new colonies.

Before the mania for emigration to South Africa takes hold on the Queensland miner, farmer and others, we should like them to pause and give heed to what is said by those who have been in that country for many years

Let us consider the Orange River Colony, the area of which is 50,000 square miles. Like the adjoiniug parts of the central plateau, it is, says Mr. A H Keane in the lastest work on the Boer States, essentially a steppe (plain) land, level or undulating, covered for the most part with herbage, somewhat dry and in places even bare. Hence it is mainly a vast grazing ground, affording pastnre to millions of merino and Cape sheep, goats, cattle, and horses, but so *ill-adapted for tillage* that scarcely one-hundredth part of the whole area is nnder cultivation. The rich agricultural tracts are mainly confined to the banks of the Caledon River, where the land nuder wheat is increasing, and where the vine and fruit trees also thrive.

But elsewhere, and especially towards the south-western frontier, the country presents an extremely dreary and even desolate aspect, and this character is maintained on both sides of the Orange River below the Caledon confluence. Thus, the extensive tract stretching from Kimberley for 150 miles across the river towards the De Aar railway junction *may* possibly contain vast underground treasures, but on the surface has little to show except a monotonous succession of rugged, waterless, and almost treeless plains, dotted with boulders, and here and there relieved by the so-called kopjes, weather-worn knolls or hills, seldom rising more than 600 or 700 feet above the surrounding land.

These kopjes are admirably adapted for defence, and, when manned, form a serics of small citadels, and so were eminently suited to the peculiar style of warfare of the Boers. All the waters of the Orange River Colony flow into the Orange River, and are so carried to the Atlantic. But the tributaries of that river are something like many of our Queensland rivers inland. They look well on a map, but the thirsty traveller often finds them mere beds of sand.

Now a word about the Transvaal. This republic has an estimated area of 119,000 suquare miles. A high range of mountains from 5,000 to 6,000 feet high runs along its eastern boundary, and there are numerous central and south-western "rands" or hills, which, except in the cases of isolated peaks do not rise more than a few hundred feet above the tableland. This tableland, consisting of rolling downs, represents almost the whole of the Transvaal. The Limpopo or Crocodile River forms the northern boundary, and here the land falls to about from 2,000 to 2,500 feet above sea-level. This portion of the country, the Limpopo Valley, is extremely unhealthy, fevers of the African type being very prevalent. The country bordering the river is well-wooded, and affords splendid cover for the big game which has as yet escaped the bullets of the Boer and European hunters. The dreaded tzetze fly is also much in evideuce here. Amongst the wild beasts may be mentioned the lion, leopard, hippopotamus, rhinoceros, and crocodiles. Along the whole course of the Limpopo there is a stretch of country 40 miles wide, rendered uninhabitable to settlers, owing to the ravages of the tzetze fly amongst horse and other stock.

The great want of the two countries is water and rain, and the Western squatters of Queensland know too well by bitter experience what this meaus. It means that cultivation is impossible, and it means that watered and grass country must be available to which the starved-out flocks and herds of waterless regions can be driven to find sustenance. Without irrigation, agriculture must continue to hold a very subordinate place in the industries of both the Orange River and Transvaal colonies. Of minerals, there are vast deposits in the Transvaal; amongst them, gold ranks first. Next come copper, iron, lead, saltpetre, sulphur, coal, and diamonds. Only 5,000 or 6,000 acres of gold concessions have as yet been worked, so it would seem there is room for the prospector. Silver, copper, and lead have not been worked for the past six years.

Now touching the climate. Owing to the position of the great mountain ranges, the rains occur much as they do in our own colony. The country east of the range gets the greatest raiufall, and this becomes a more and more vanishing quantity as one travels towards the west. The soil is naturally fertile on the plateau south of the Zambesi, but is mostly parched in dry seasons. Tree growth is confined to willows, wild figs, and iron-wood, which grow in the neighbourhood of "spruits" or river valleys and "kloofs" or deep gorges.

Where cultivation can be carried on, good crops of cereals are raised, and tobacco, the vine, and Enropean fruits succeed well. There are as yet only 50,000 acres of this immense territory under cultivation. Can the Queensland farmer find it profitable to enter on farming pursuits there? From what we have written about the climate, the rainfall, the sandy river-beds, wild beasts, the tzetze fly, to which must be added locusts and horse-sickness, the reply would obviously appear to be, "Certainly not."

For the sake of comparison, let us draw a picture of the first establishment of a farm in Queensland.

In the first place, the farmer has a choice of land from an area of over 600,000 square miles. He can elect to live in a tropical, semi-tropical, temperate, or cold part of this enormous territory. Nearly the whole of the coast lands are well wooded; whilst inland, in addition to vast rolling plains of exceptional richness, there are forests of maguificent timber to which the settler can help himself for the purpose of building, fencing, &c. From the coast to many miles inland he is certain of sufficient rainfall for his crops. The climate is very salubrious, fevers being rarely contracted in the bush, and they are rapidly disappearing before the axes and fires of the settlers. For 300 or 400 miles inland from coast there is a plentiful supply of water, either in rivers, creeks, or lagoons. Everywhere, crops are produced all the year round: everywhere, almost, there is either a market close at hand or a railway line to take the farmers' produce to it. These railways extend in

all directions--north, west, and south—from the various coastal cities. The settler, having selected his land, can camp on it with his family in a tent in perfect safety. There are no wild beasts for him to fear. If his fire goes out at night, no prowling lion or hungry leopard springs upon him in the dark; no band of savages takes advantage of his defenceless condition to murder and plunder him. He can safely set to work, build his house of the bush timber, fence his land with the material at his hand, and set to work with the almost certainty of taking off his first crop within six months. No elephants or monkeys are here to trample down and carry off his corn or sugar-cane, or dig up his sweet potatoes for him. Here, he has perfect peace, a life of labour, but also a life full of comfort and enjoyment. He has no hordes of natives to do his work for him, and so does not yield himself up to a life of voluptuous idleness, a result which invariably happens in countries with a vast native population, as in parts of Asia, Africa, the Indies, and South Sea Islands. Here the farmer is able to work with his family and his farm hands, and it is only in the sugar districts that a certain amount of reliable black labour is necessary, although such labour is anything but what is called cheap labour.

Then take the question of roads and markets. The Queensland farmers are in almost every district in touch with a railway line. There are many large coastal cities, many large inland cities and towns in Queensland alone, where a good market exists for all the produce they can supply. In addition to these, they have the southern markets which can take largo quantities of produce. How does the case stand in South Africa? There are few railways, few roads and few markets. The distances between these market towns are enormous, unless in the older settlements in Cape Colony; and old settlers in Queensland will remember how, in the old days, the only means of carrying wool and other produce to the few towns on the coast were the lumbering bullock-dray or horse-wagon. Weeks and even months were spent in such travelling. Now, a glance at the map of the two South African colonies will show what long distances would have to be travelled by farmers settling, say, in thewestern portion of the Transvaal or in the central and north-eastern districts of the Orange River Colony. Still greater difficulties of transit must be encountered by settlers in Bechuanaland or in Rhodesia, where there are scarcely any market towns except Buluwayo and Salisbury in the latter, and Mafeking and Taungs in the former. Such being the outlook for transport and markets, how can the Australian farmer hope to better himself by pioneering in such a country even with land at from 1s to 4s per acre?

With minerals the same objections arise: want of water and want of railways. Why go to South Africa to prospect, when such magnificent fields as the Etheridge and many other auriferous districts of Queensland in the midst of white settlement, with good roads, timber, and good land together with a fair rainfall, lie open to the prospector, and are capable of supporting large mining populations, and affording many openings for remunerative subsidiary industries?

No, we should recommend our Queensland farmers and miners, mechanics and labourers, to remember that it is "distance that lends enchantment to the view," and to also remember that not one of our colonies offers such excellent prospects to agricultural and mining settlers as does this splendid colony of Queensland with its excellent climate its just laws, its British institutions, its freedom, for all, its illimitable agricultural lands, its forests, rivers and mines, its roads, railways, telegraphs, and its numerous cities and towns. Most of these advantages are yet in the womb of the future in the two South African colonies, and an immense amount of pioneering work will have to be done by the Australian who elects to abandon his comfortable home for the unsettled portions of the new colonies.—*Queensland Agricultural Journal.* Aug 1.

A GIANT ELEPHANT'S TUSK.

A gigantic elephant's tusk comes from the interior of German East Africa. A native was the fortunate hunter who bagged this trophy, and it is said that the fellow tusk was only a trifle smaller. The big tusk weighs 241 pounds. The two tusks were brought by way of Bagamoyo to Zanzibar, where an American acquired them at a fancy price. Some idea can be formed of the gigantic size of the elephant, when we reflect that it carried about with it an appendage of well-nigh five cwt in tusks! Sad to relate, elephants of this size are becoming rarer every day. The merciless war of extermination carried on for years against the elephant by ivory hunters has been only too successful. Where once immense herds were to be seen, you may now travel for hundreds of miles in the vain search for those forest monsters. They tend to retire further and further from the coast in quest of solitudes as yet uninvaded by man. Perhaps the recent regulations made at the Foreign Office Conference in London may help to improve matters.—*Home paper*, Aug. 24.

ARRIVAL IN CEYLON OF A KEW BOTANIST:

FOR EXPERIMENTAL GARDENS, MALAYA.

Amongst the passengers who arrived here recently by the steamer "Hakata Maru," was Mr. Stanley Arden, a recent Kew student, who has been appointed Superintendent of Government Experimental Plantations in the Malay Federated States. Mr. Arden, in accordance with official instructions, broke his journey here for the purpose of visiting the Botanic Gardens and obtaining a general knowledge of Ceylon products and the conditions under which they are cultivated.

At Peradeniya he was met by Mr. Macmillan, a brother Kewite, and while there, he made arrangements for visiting certain estates and government rubber plantations. Mr. Arden, being educated at Stockport Technical College, has had the usual training and a successful career at Kew. In 1896 he was the winner of the Hertfordshire County Council's Scholarship. Mr. Arden left Kew in April last and has been qualifying himself in special directions for his new work. As experiments in rubber cultivation are intended to take up his chief attention at first, he went to Cambridge to study, under Professor Marshall Ward, with his assistants, Messrs. Biffen and Parkin, the most approved scientific methods of treating rubber latices for coagulation, and to acquaint himself with the principles of Biffen's patent coagulating machine.

Mr. Arden is much struck with what he has seen of the vegetation of the tropics, more especially with the wealth and beauty of the Peradeniya Gardens, the extensive undulating green lawns of which he considers are particularly grand. Most of the trees and shrubs, however, are familiar to him through his acquaintance with them at Kew, but here many of them appear in an incredibly altered form. We wish Mr. Arden a successful career in his new sphere of work, and will watch with interest the results of his experiments, and hope to include the same from time to time in our *Tropical Agriculturist.*

THE CEYLON PLUMBAGO INDUSTRY.

We have read with interest the various letters which have recently appeared in the columns of the local papers regarding the position of our one commercial mineral of importance, plumbago. At first a gradual but latterly a sudden and enormous rise in values, has been followed by a no less sudden collapse; and it is no doubt the duty of all interested in the industry to consider very carefully the present state of so important an article of export from this Colony. With this object in view, let us see what figures there are to help us. A reference to the export returns gives the following plumbago as exported, in tons, to different countries:—

In.	To U.K.	America.	Continent.	Elsewhere.	Total.
1893 ..	5,059	8,192	3,469	160	16,880
1894 ..	7,518	5,104	4,257	97	16,976
1895 ..	6,113	7,489	3,074	70	16,746
1896 ..	5,767	7,813	3,235	149	17,024
1897 ..	7,983	4,440	5,333	106	17,862
1898 ..	8,025	9,385	6,164	79	23,653
1899 ..	9,296	15,027	6,378	118	30,819

The Ceylon Chamber of Commerce values are given as follows per ton:—

Date.	Highest price large Lump.	Highest price for O. Lump.	Highest price for Chips.	Highest price for Dust.
	R.	R.	R.	R.
7th Jan. 1895 ..	300	280	170	95
15th do. 1896 ..	330	290	140	90
5th do. 1897 ...	310	260	120	90
11th do. 1898 ..	365	345	220	145
5th July 1898 ...	600	560	370	200
10th Jan. 1899 ...	700	650	500	300
4th July 1899 ..	1,000	950	650	500
9th Jan. 1900 ..	1,000	1,050	800	550
3rd Sept. 1900 ...	700	600	450	300

From these figures it will be noticed that, until early in 1898, no movement of great importance took place either as regards increase in exports or rise in prices. There can be little doubt now that the plumbago required by crucible-makers and others, had been bought so sparingly towards the close of 1897, that when a special demand set in at that time for the article, there was practically none found on the spot unsold, either in London, New York or the Continent. Consequently, orders came out to Ceylon from buyers in Europe and America, who hitherto had generally got all their supplies from the older and larger importers there, and the latter apparently having nothing to spare had to decline business. This led to a much larger and much more widely distributed demand in Colombo, and with keen competition to fulfil orders on hand, prices advanced rapidly.

The advance in prices in Ceylon was stimulated not only (1) by keen competition to get plumbago to fulfil legitimate orders; but (2) the excitement which follows an unusually large demand, combined with rapid advance in prices, led to numerous purchases being made with the sole object of such being turned over locally at a profit. Then again (3) dealers who had made forward contracts with the older and more regular exporters, found the market had gone dead against their being able to fulfil such contracts without serious loss and this led to orders at higher rates being given by exporters to enable them, if possible, to fulfil their engagements in Europe and America. The local Law Courts have given us some confirmation of this state of things. The high prices, however, led to an inevitably large output, and the exports for 1899 reached 30,819 tons against 17,862 tons in 1877. With such a great increase in export, prices could not be kept up and it only required a few large buyers to suddenly hold off the market, in order to lead to the inevitable collapse.

What is of most importance now, however, is, not what has taken place in the past, but what is to be the future of plumbago; and our reason for glancing over the past is solely that this may enable us to bring some light to bear on the future. The exports for the year 1900 (1st January to 10th September) aggregate 12,573 tons, and we would ask our readers to carefully compare these figures with the corresponding periods of 1897-1899. These are:—

1897	.. 12,160 tons.
1898	.. 16,988 ,,
1899	.. 21,944 ,,
1900	.. 12,573 ,,

—showing that for the year 1900 there has been a falling-off of 9,374 tons compared with the year 1899, and a falling-off of 4,415 tons compared with the year 1898. In short our exports have already gone back to those of the year 1897—before the great rise in prices commenced. The demand for crucibles must, of course, continue, and crucible-makers must continue to buy plumbago, and therefore it may be safely affirmed that prices of plumbago are not going back to those ruling in 1895-97. But plumbago, even at present prices, must show good returns to most of the pit-owners. Surely, if during the year 1897, plumbago could be purchased in quantity and sold at from R280 to R365 for high-grade lumps,—high-grade lumps at R600 to R700 in the year 1900 should show a handsome profit for the pit; while all other qualities are in proportion. It is easy to get people who will say that labour has gone up, and so it has; also that "this," "that" and "the other" have gone up in price, and that it will not pay owners now to work most of their mines. It will require some very clear statistical statements to be put before us, before we can accept that view, or be convinced that pitowners of local experience will not continue to find plumbago mining a very profitable invest- ment, if values remain at or near those now current.

Of course there are pits and *pits*, and no doubt the recent boom led to wild speculation in plumbago land and to the rapid opening up of some mines which will probably never pay. Then again it has yet to be made clear to those interested, what the cost is of opening up and keeping free from water mines in the very low country, compared with the cost of such as are to be found on the hillsides in the Kurunegala and other higher plumbago districts. On one property in Maskeliya 150 tons of

plumbago have been taken out in the present year without interfering with the tea. Mining under European supervision has been going on for a few years back, and there are now mining experts available at our doors for advice. The output of plumbago will, no doubt, continue to be ample for current requirements, and if average prices remain even near those now reported as current, the industry, in our opinion, must continue to be a flourishing one, at any rate, for experienced pit-owners.

In this connection, we take over elsewhere from our contemporary, the letter of a Philpot Lane Firm who are, apparently, anxious to establish a London mart for plumbago on a new system as detailed. Even if there were no objection, and only decided advantages in this plan, we consider the day is past for such a proposal. "All the world" interested in plumbago may now be said to have come to, or to be represented, in Colombo and the fully-established direct trade with America and the Continent of Europe cannot be interfered with. The true mart, therefore, for Plumbago, with abundance of competition. is in Colombo itself.

GREEN TEAS IN CEYLON.

Extracts from Minutes of proceedings of a meeting held at the Victoria Commemoration Buildings, Kandy, on Saturday, the 15th day of September, 1900.

Ceylon Green Teas.—Submitted correspondence from various applicants for grants. Intimated that payments had been made as under :—

July 1900	9,168 lb	Brunswick Green Teas	R916·80
do	25,000 lb	Ceylon Green Teas per Whittall & Co.	2,500·00
Aug. 1900	3,518 lb	Nahakettia Green Teas	351·80
do	1,2020 lb	Ceylon Green Teas per Whittall & Co.	1,202·00
do	10,090 lb	Brunswick Green Teas	1,009·00
do	6,990 lb	Tillyrie Green Teas	696·00
do	10,225 lb	Ceylon Green Teas per Whittall & Co.	1,022·50
do	2,367 lb	Nahakettia Green Teas	236 70
Sept. 1900	3,645 lb	Dewalakande do	364·50
do	10,120 lb	Brunswick Green Teas	1,012·00
Add total as per previous statement	181,144		18,114·40
	274,257 lb.		R27,425·70

Leaving the balance of R2,574·30 still available at date.

Read Minutes of Proceedings of a meeting of the Sub-Committee of the "Thirty Committee" appointed to confer with the Colombo Experts, with a view to establishing a Standard for Ceylon Green Teas held at Colombo, on Monday, the 13th August, at half-past seven o'clock in the morning also Minutes of Proceedings of a meeting held at Colombo on Tuesday, the 28th August at 3 p.m. to fix upon a Standard for Ceylon Green Teas. Resolved :—"That the Report be adopted as follows.

(1) That in Green Teas each grade must be restricted to 5 per cent siftings when sifted through a sieve of No. 30 Mesh. (2) That the grades be Young Hyson (Broken Pekoe and Orange Pekee) Hyson (Pekoe) Hyson No. 2 (Pekoe Souchong and Souchong) (3) That up to 10 per cent of leafy siftings as a separate grade be allowed for cess in each invoice not more than half of which shall pass through a No. 30 sieve. (4) That the sample of Hyson No. 2 submitted be approved as a Standard. Subject to (a) the tea having the absolutely true green character and containing no fermented leaf (b) cloudy or brown liquor must not be passed. (5) That the question be again brought up for consideration two months hence. (6) That before payment of the grant under the new scheme there shall be filed with the Secretary an invoice (form to be supplied on application). (7) That the sanction of the Governor in Executive Council be applied for to an appropriation of of R20,000 as desired and determined by the Committee for the purpose of payments under the grant and new scheme above ment oned.

PLANTING NOTES.

Poultry: Prevention and Treatment of Fleas, Lice, and Mites.—Infestation is always worst in dirty and neglected runs and roosts, and such are a standing danger to more cleanly neighbours. Cleanliness and freedom will always put these pests under a disadvantage, not only cleanliness of the nests, walls, and floor, but also of the ceilings and perches. To suppress these pests the houses should be cleaned down at least twice a year with a wash made of hot lime and soft soap, the ceilings, walls, and nests having a good coating; the wash should be fairly liquid so as to run into every crack and crevice. Early spring and autumn are the times for these applications. The perches are best treated with boiling water and soft soap, or with an emulsion of kerosene. It is important that houses should be well built, with as few cracks and crevices as possible, for in such harbours these pests congregate and may escape from any wash used.—*Proceedings of the Agricultural Society.*

Elephant Hunting in Siam.—The kraal is only a couple of a hundred yards from the river, and there is a funnel-shaped enclosure extending from the North Gate to the ford. Into this the animals are slowly led—for they must now be kept very quiet. One leader and then another passes through the narrow gateway, followed by some confiding friends. The decoys stand near by way of encouragement to those in the rear, which are imperceptibly crowded forward. A few get restless, but before long they are all safely in, and the trained elephants slip out through the other gate. Then it is that the wild ones realise that they have been trapped, and, madly eager to get out, trumpet, bellow, and groan; creating, as a local paper truly said, "a scene of such confusion that no two people saw it alike." The walls now swarm with spectators, who amuse themselves by watching the bewildered beasts, some of which seem to resent their imprisonment, while others are indifferent, and others again engage in settling private quarrels, or roaring defiance at the gallery. One inquisitive youngster, that was destined for a civilised and useful life, tried to squeeze between the piles of the refuge, and got jammed across the ribs—the thickest part of his body. His efforts to get free attracted his friends, who watched him while he struggled and bellowed. One big fellow tried to push him back, but failed; then there was a pause, during which one could almost see them thinking; and another, having apparently worked it out in his mind, tried from behind. and, fairly lifting him, off his legs, pushed him through, amid shouts of applause from the crowd. —*From "Elephant Hunting in Siam," in the "Cornhill Magazine" for September.*

PINE HILL ESTATES COMPANY.

THE REPORT.

The report of Directors was as follows:—

ACREAGE:

Tea in bearing	...	279½	acres
Young tea 1898	..	31	,,
do 1899	..	65	,,
Cardamons	...	1½	,,
Jungle and Patna	..	9	,,
Fuel and Grass	...	11	,,
Waste Land	...	1½	,,
Scrub (disputed)	...	18	
		416½	acres

The Directors have the pleasure to submit their seventh annual report.

The amount at credit of profit and loss account including R190·77 brought forward from last year's account is R10,804·67, out of which an interim dividend of 3 per cent was paid on 29th January amounting to R6,262·20

The Directors now propose to pay a final dividend of 2 per cent making 5 per cent for the year which will absorb 4,174·80

And to carry forward to next season 367·67

R10,804·67

The low prices ruling for the last six months are responsible for there not being a larger amount of profit available for distribution.

The crop of Tea realised from the estates was 131,947 lb., and from bought leaf 60,602 lb. as against estimates of 110,000 lb. and 40,000 lb. respectively. The estate tea showed an increase of 17 per cent on the previous season owing to a very favourable year. The net price realised was 38·96 cts. per lb. against 40·76 cts. last year.

The estimate of crop for the current year is 125,000 lb. from the estates and 50,000 lb. from bought leaf, or 175,000 lb. in all.

Factory.—The factory has now been completed, but the original estimate for the cost of the improvements was found insufficient, and it has been considerably exceeded.

The new clearing has unfortunately not been successful owing to unfavourable weather, and the expenditure on it has been heavy. It is hoped, however that the steps which have been taken to supply all vacancies will result in a good field of tea being secured.

According to the articles of Association Mr. Robert E Prance retires from the Board of Directors, but, being eligible, offers himself for re-election.

An Auditor for season 1900-1901 will have to be appointed.

KANDY AGRI-HORTICULTURAL AND KANDYAN ART EXHIBITION.

At the meeting of the Committee held last month, the following gentlemen were elected to form an Executive Committee:—Messrs. J H De Saram, L Creasy, J B Carruthers, T C Huxley, H F McMillan, E Beven, E Webb, Diwa Nilame, and Chief Interpreter, Kandy Kachcheri. The following sections for Exhibition were approved of and the details of awards have been left to the Executive Committee.

Section 1.—Flowering plants in pots, cut flowers in boxes, stands or glasses, ferns and orchids in pots, foliage plants in pots.

Section 2.—Fruits, vegetables, vegetable products.

Section 3.—Food products.

Section 4.—Cattle, poultry, dairy produce (butter, cheese, cream, and eggs.)

Section 5.—Preserved fruits, pickles, sweet meats, bread.

Section 6, *Art-work, &c.*—Gold and silver jewellery, brass and iron work, pottery, lacquer work, models, masks, musical instruments, mats, baskets and fans, ivory and wood-carving, photographs.

Section 7, *Natural History.*—Collections of birds, butterflies, insects, shells, eggs, sporting trophies.

Section 8, *Miscellaneous.*—Fireworks, decorations.

Section 9. Oil machinery, machinery for the manipulation of Green Tea.

CACAO HOLDINGS UNDER SIXTY ACRES IN CEYLON.

Extracts from Minutes of proceedings of a meeting of the Cacao Committee of the Planters' Association of Ceylon held at the Victoria Commemoration Buildings, Kandy, on Friday, the 14th September, 1900, at eleven o'clock (11 a.m.) in the morning:—

CACAO HOLDINGS UNDER 60 ACRES.

Mr. Chas. Gibbon read the annexed abstract of Returns received through the courtesy of Government of Cacao Holdings under 60 acres. Resolved:—"That the thanks of the Cacao Committee be conveyed to Government, for the Returns furnished of Cacao holdings under 60 acres."

GRAFTING CACAO.

Resolved:—"That the attention of the Director, Royal Botanic Garden, be again drawn to the questions of grafting of Cacao, and also to Mr. Hart's remarks under date Trinidad, 13th September, 1898 (copy annexed) with special reference to the following sentence with a request that he will favour the Com-

mittee with his observations thereon:—"The course pursued has been to inarch a branch of a desired variety upon a well grown and healthy seedling, and the result has been that the union has taken place very freely, and there can be little doubt that in future any desired kind or variety can be perpetuated by this means."'

MR. HART'S REMARKS, UNDER DATE, TRINIDAD, 13TH SEPTEMBER 1898, REFERRED TO:—

TRINIDAD, 13th Sept. 1898.—It has on no more than one occasion been asked whether it is possible to graft Theobroma cacao and hitherto I have not been in a position to reply in the affirmative. I have now to report for the information of the Society that experiments have been carried out at the Royal Botanic Gardens, by inarching several varieties of cacao upon young seedlings with all the success that could be desired; and I hope that the grafted plants will be sufficiently hardened to be shown at the next meeting of the Society. The course pursued has been to inarch a branch of a desired variety, upon a well grown and healthy seedling, and the result has been that the union has taken place very freely, and there can be little doubt that in future any desired kind or variety can be perpetuated by this means.

I desire to point out the opening this process will afford for the extensive planting of any desired variety or kind, and that it will enable the planter to put samples of cacao upon the market with less variation in size and quality of the bean than has hitherto been possible.

I also desire to point out, that it may be possible, as it is with apples and pears in a temperate climate—by grafting weaker growing varieties upon kinds having a larger amount of vegetative vigour—to increase the yield of such kinds as that known as "Criollo," to as much as that of the more commonly productive varieties.

It will also be possible to maintain perfectly true, any kind which may have arisen from seed, on any plantation, and to preserve indefinitely any particular kind that may be desired. We have yet to prove, however, how the grafted plants will thrive, but judging from grafted plants of other kinds I see no reason to anticipate that there will be any difficulty under this head. I recommend the practice as well worth the attention of planters who have on their estates single trees, which are noted for the quality of the bean and the quality they produce.

CACAO DISEASE.

I have been requested by a successful and prominent planter, to bring up before the Society the question of disease among cacao trees in Trinidad for discussion. This gentleman has forwarded to me several specimens of (so called) diseased cacao, but after a careful and lengthy microscopical examination, I have not been able to say that the pod have been destroyed by disease. I am free to confess, however, that there is possibility of disease arising in any culture, and therefore in cacao; but I must reprehend as strongly as possible the spreading of views that we have disease of certain kinds until it has been fully proved that such do exist, as it is calculated to do an immense amount of harm to the cacao industry. A strict watch, however, should be kept for anything which appears to be of a pernicious character, and planters would, I think, do well to forward affected specimens to me, to be transmitted to mycological authorities, if necessary. So far, I may say, I have not found anything of a pernicious character; and I should be glad to hear my idea confirmed, that at present there is little cause for alarm.

(Signed) J. H. HART F.L.S.,

A FARMERS' EVERY-DAY LIFE.

NO. XII.

(By an ex-Ceylon Planter.)

AGRICULTURE

is still the chief industry of the country, although less attention is paid to its necessities that to any other; and now that we have got a member who does all in his power to help us, I think it would be very poor form indeed to try to oust him from his seat. He has fought well in the interest of the fishing population, and in return for that they have set up a herring-curer in opposition to him. Let it be so; but although I voted against him when he gained his seat, I hope to record my vote in his favour on the next occasion. He has championed the cause of farmers, and we are much in need of a few like him, seated in the House, for at present, I doubt if there are more than half a dozen legislators to defend the backbone of the country. Our member can honestly say that he has always worked for the good of the greatest number, a thing that but few can pride themseves on, for it often happens that, when one makes enquiries as to what number the average parliamentarian has worked for, it generally turns out to be *number one.* Successful farmers who have the ability have seldom the leisure to stand for their country, whilst there are any number of carpet-baggers stalking round, whose only qualifications for a seat in the House are the gift of the gab and no stake in the country whatever. I do not care what party is in power, so long as the best interests of our tight little island are properly attended to; and in the case of rural matters, I think that party feeling should be sunk altogether, and both sides of the House should strive to keep in a prosperous and flourishing condition that industry which, on its becoming unhealthy, has signalled the downfall of all the great nation of the past.

TILLAGE AND PASTURAGE

may be said to have begun with the creation of the world. Egypt, shortly after the days of Noah, became celebrated for agriculture. The first art learned by any rising nation was that of cultivating the soil. The ancient Romans were born agriculturists, and their most celebrated commanders were taken from the plough. To be a good farmer was accounted the greatest praise, and the very Senators cultivated their own ground themselves. With the decay of agriculture came the downfall of Rome, as will come the downfall of Britain, for when recruits can no longer be raised in our agricultural districts, and the nation has to depend for its fighters on the scum of the cities, in whom strength of body is about on a par with strength of mind, then will come the beginning of the end of our Empire, and legislators will remember, when too late, that they stamped out the greatest industry of the country, by encouraging the importation of cheap and nasty food from abroad, destroying the physical powers of the nation, and that courage which a conciousness of strength produces.

I have written, on a previous occasion, of the great rise in

THE PRICE OF COALS

during the past few months, the fears of a coal famine during the coming winter, and the national dread lest our mines prove to be almost exhausted. No sooner had I arranged for an extra supply of peats and firewood, as a set-off against the impending coal famine, than a writer to the Press,—one of those

great thinking men, trong on statistics,—springs on the nation the gratifying news that there are still 180,000,000,000 tons of coal in the mines of Britain, and that, at the present rate of consumption, the supply will last 500 years. That news has pleased me not a little: 500 years' supply will last my time, and, as posterity has never done anything for me, it can look after itself for all that I care. In the meantime the vision of myself and family, during the coming winter, seated round the place where a fire should have been, has been dispelled.

We have had a terribly trying time for

HAY-MAKING;

for weeks the rain has rained every day, and it has only been by fits and starts that the hay crop has been secured. It is an exceptionally good crop, however, and, as everything else, has been benefitted by the rain, we have no cause of complaint. I have had to endure much worse than this, when, in the middle of crop on the old coffee estate, the monsoon broke, and the rain poured down for weeks on end. The coolies, shivering with the cold, could scarcely pick the *palam*, which dropped and was washed down the drains. But when the season came to a close, and the estimate had been more than secured, the miserable time of picking was forgotten, and the warm rays of the sun dispelled from the minds of the coolies the recollection of the cold, wet and shivering season they had lately endured.

The abundance of grass has raised the price of

STORE STOCK

considerably, and the first of the lamb sales has gone off with a rise of from 5s to 8s a head on last year's prices. Let tea planters try to imagine what this means to grazers, by comparing these prices with the prices of their own staple. Supposing that a tea crop had sold, last year, at an average of 8d per lb., the planter would, no doubt, have been greatly pleased; but, supposing that the war in China, or some other cause had raised the price of the same crop to 1s per lb. this year, a princely fortune would appear tobe dawning on the proprietor. Such then has been the experience of the sheep farmer this year.

The cry out about

FINGER-AND-TOE DISEASE.

in turnips, which is usually heard at this season of the year, is ringing over the whole land, but the wailers never seem to think that they are themselves responsible for this most terrible disease. Perhaps, in the course of another generation, farmers will have learned to avoid, as they would the plague, manuring, with superphosphate, their turnip break, and will have given up that most deadly style of cropping known as the "five course shift." My land, which lies in grass for eight or nine years, has no sign of canker now. Indeed, I never saw a finer crop of turnips than that which I have this year, here or anywhere else. My next neighbour, who has followed my lead, told me the other day, that he has a field in turnips, this year, which had lain in grass for seven years, and he never had finer and sounder roots in his life. Another of his fields, however, which had only been in grass for three years, is now rotten from top to bottom. It takes a long time to drive a new idea into a farmer's head, but it gets there in course of time, and I hope yet to see this example bearing good fruit.—"*Cosmopolite.*"

TWO MAHOGANY LOGS FETCH £1,536.

Two logs of African mahogany were sold for the unprecedented amount of £1,536 the otherday at the auction sale of Messrs. Edward Chaloner and Co., at Liverpool. These logs formed one tree, and were bought to be cut into veneers to decorate the palatial residences of certain American merchant princes. The veneers are used in place of wall-papers, and, being beautifully figured, give a superb effect. The prices realised for the two logs were respectively 10s 3d and 7s 3d per superficial foot.—*Daily Express*, Aug. 27.

"CEYLON HANDBOOK AND DIRECTORY."

A new edition of this work has been in hand for some months back and a great deal of preliminary work has been done. The circular of estates and other Directory information was issued last month: and we invite suggestions from friends and others interested as to "improvements,"—"what to leave out of the bulky volume," and as to anything that is still wanted We have already received several communications on the subject, and we are bound to say they chiefly embody requests for "*more.*" We have promised in fact to try and give each *plantation's* TELEGRAPH as well as POST station: to show at a glance, the estates belonging to the several Limited Companies, or big individual proprietors; to give a list of all GRANT-IN-AID and PRIVATE Roads (always provided in these cases that the planters concerned are ready to co-operate). These are but a few of the "planting" improvements. In the bulk of the book there will be considerable changes, and although we are hoping to compress the volume a good deal (in regard to Agricultural information and Trade Statistics, etc.) we do not think anything specially required for reference will be omitted, while much that is new and useful will be found, added in. But to secure a really useful Book of Reference and Directory, there must be co-operation all round and every proprietor or manager should see that a return is filled up for *his* estate and sent in as per the Supplement issued last month while, as usual, we feel sure the Mercantile and Trading community of Colombo will do all that is required. From officials—heads of departments especially,—we always receive, and are sure still to receive, all the help we can require to make a volume which is in universal request as correct and complete as possible.

THE ANNUAL CROP OF MUSHROOMS in France is valued at £400,000, and there are 60 wholesale firms in Paris dealing exclusively in them. In the Department of the Seine, it appears, there are some 3,000 caves in which mushrooms are grown, and about 300 persons are employed in their culture.—*Home paper.*

Correspondence.

To the Editor.

EXTRACTION OF RUBBER.

Etablissement d'Horticulture, Paris, leSme August, 1900.

DEAR SIR,—The system of extraction of India-rubber from the bark is now in full working order. Manufacture will be established before the end of October near Paris, and the Company asks for barks from all parts of the world for trial. Landolphia Hendelotii has proved till now to be the best producer of rubber mechanically extracted from the bark, as it is the most suitable for dry and sandy soils where no other plant will grow, so this plant should be a fortune on rich soils; but, many other plants such as Landolphia Kirkii, Vahea Madagascarensis Hancornia and a few Ficus are also good producers of rubber from the bark.

Apocynaceous plants seem, therefore, better designed for that purpose, and I believe it will be interesting for Ceylon growers to have their attention called to plants of this family, such as Cryptostegia, Beaumontii, Chonemorpha and others.

Chonemorpha macrophylla is a good producer of excellent rubber, but I have never received bark from old plants; but only from tender stems a few months old. In each sample rubber is found in the central part of the stem (moelle), but I believe it is the same in many plants when these are young. If you cut a stem of Chonemorpha in small pieces three inches long and let the milk coagulate in the open air, you will find a little piece of rubber large enough to repay the extraction by this very simple way; but I do not know if Chonemorpha is a quick-growing plant. I have only seen small plants in our houses.

I want bark of any producer of rubber and better of any lactiferous plant, for I have received bark of plants reported bad producers which have proved good for our system of extracting the rubber. People say this plant is not good, the rubber does not flow; but perhaps it is so much the better for our system because the rubber coagulated in the bark will be easily extracted mechanically. Where the latex flows easily in the rainy season, the bark is poor; where the latex does no flow in the dry season, the bark is rich: so much I can say actnally.

I want only one kilo of each sort of bark, taken as much as possible on plants of known age. Where the stem is too small to permit to bring out the bark, kindly send one kilo of these stems; and believe me to be, your most obliged servant,

A. GODEFROY-LEBEUF.

CEYLON TEA IN NEW ZEALAND.

Dunedin, 13th Aug.

DEAR SIR,—I send you a Dunedin *Star* and some printed matter. When read, you will see the Tea Blenders here wish to kill the trade in "Pure Tea." Will you kindly criticise their action and the reports inserted by *Star's* Special Reporter as my own and Mr. ———'s opinions. I may state Mr. ——— did a lot of damage three years ago by issuing a circular "Poison in the cup; Tea in lead packets." He makes a hit at cooly labour and coolies handling Tea.—Yours faithfully,

GEO. T. K. MACKENZIE.

TEA IN PACKETS IN NEW ZEALAND.

A petition was presented to Parliament today from tea merchants, timber merchants, manufacturers, tinsmiths and printers asking that a higher duty be imposed on teas imported in packages and boxes than upon those imported in bulk. The petition states that large quantities of teas are imported into New Zealand which have been packed outside the colony in packets and that coolie and other cheap labor is exclusively employed in preparing the packets and boxes in which the teas so imported are packed, and also in packing the teas. Tea merchants in New Zealand, they say, are placed at a disadvantage as compared with foreign tea dealers who can obtain labor for packing at nominal rates, and who contribute nothing to the Income Tax or the revenue of the colony and do not aid in the development of its resources If all teas were imported in bulk and packed in New Zealand large quantities of timber, paper and other material grown and manufactured in the colony would be utilised in the making of packets, boxes and cases and the industry would afford employment to large numbers of tinsmiths, carpenters and other artisans, and also young people. The petitioners therefore pray that an additional duty, say ½d per lb, be imposed on teas imported in packets and boxes weighing less than 30lb. net,

On the subject of the petition asking Parliament to place a higher duty on tea imported in packages and boxes than upon those imported in bulk we have interviewed Mr George M'Kenzie, of the Hondai-Lanka Tea Company, and he condemns the petition root and branch saying:

The Ceylon people are the only ones who put up tea in lead packets. These teas guaranteed pure, are sent to all parts of the world. The effectiveness of the guarantee cannot be questioned. All the packets put up in Ceylon are sealed lead packets. That sealing cannot be done here. The work is so fine that the ordinary plumber cannot do it. it was tried in London and failed. The lead packets put up here are not sealed. A blender can so blend as to get any profit he chooses, whereas the dealer who supplies lead teas does not interfere with the packets—he sells them as he gets them. All who import pure tea from Ceylon get about 1d per lb less profit if sold in sealed lead packets, because the sealed tea packet costs 1½d. and to put up the same tea in paper costs only ¼d per lb. The large proportion of tea sold as pure Ceylon is generally made up of cheap Chinese, Fiji, or Java tea, which can be bought at a much lower price. It is well known that many thousands of chests of Chinese tea were destroyed on the wharf by the Customs, about four years ago. It was not allowed to be landed at Melbourne, and then was condemned in Dunedin. Fifteen thousand chests of the same, condemned in New York last year, were sent to Canada, and from there to England, and the owners could not get it in anywhere on account of its adulteration. I think it would be unwise to facilitate the putting-up of teas in New Zealand. You can buy tea siftings and dust for 2d per lb landed here, and this is the material used for adulteration purposes. If there were no lead packets the business would be entirely in the hands of two or three people, who could give any value they chose. The presence of the packet teas in the market compels the putters-up to maintain the standard. Some of those who were asked have refused to sign the petition, and some in the trade were not asked. I understand that only two or three Dunedin merchants signed it. As for the so-called encouragement of labour, two boys would put up in packets all the tea imported monthly in lead; one printer would turn out 5,000 or 6,00

labels in a couple of hours; the paper used cannot be made here; and there is a very small amount of timber used in making the boxes, for they are sent backward and forward and used again.

THE OTHER SIDE.

Having obtained Mr. M'Kenzie's statement, we deemed it a fair thing to interview Mr. N Harper Bell, who supports the petition, and his views of tea subject were thus expressed:—

The justice of the petition involves three questions—

1st. Whether it is better to have the tea packed locally or by coolie labor.

2nd. Whether there is any injustice to existing importers or to the public in prohibitory duty on the coolie article.

3. Whether the lead packages adopted in Ceylon are superior to the local methods of packing.

1. The tea at the gardens is graded, bulked, put into chests or half chests, and despatched to Colombo. There it is auctioned, and, according to the instructions of Home or colonial buyers, either despatched in original packages or repacked into small lead packets and boxes of from ½lb and 1lb packets to 5lb and 10lb boxes.

As originally purchased, it is extremely exceptional for a tea to combine all the qualities for which the consumer looks, and consequently, as much blending takes place in preparing the teas for the small packages in Colombo as in any other part of the world where such packing is done. The tea to be so blended is necessarily exposed, and in the hot, humid climate of Ceylon it naturally loses its aroma and fragrance at an infinitely higher rate than in a temperate climate such as New Zealand. It is even affirmed that a sample of tea left exposed one night on the liquoring table will be quite mouldy on the following morning. The handling and mixing are done by coolie labor under circumstances of climate, etc., which are, to say the least, not conducive to an improvement in the qualities of the tea. It can readily be seen, therefore, that if blending must take place, it is better that it should be done in New Zealand than in Ceylon. Blending is so absolutely a necessity that without it a very large proportion of the teas of the world would be unsuitable for general consumption. One tea possesses strength without sufficient flavor; another tea has most delicious flavor without the strength necessary for an agreeable liquor. Few original samples of tea, therefore, would meet with the approval of the public palate, which varies very much in different countries, or even districts. The expert blender in New Zealand, having a more certain criterion of the taste of his colony, has a great advantage in this respect alone. On all these grounds, therefore, the advantage to the public rests with the locally-packed article.

2. No injustice is apparently inflicted upon the present importer of coolie-packed teas if the extra duty be imposed, as the stock argument of such a dealer is invariably that tea is only locally packed for the sake of extra profit. In this regard it may be pointed out that inferior teas can be and are grown in all tea countries, but as the expenses of freight, duty, etc., etc., are equally heavy, no matter what the quality, the inducement to add rubbishy cheap teas to a blend is infinitely greater to a Colombo merchant than to a New Zealand one. Further, the argument that teas are only blended in the colony for the sake of mixing cheap rubbishy China tea, etc., with it is an insult to the public, who, in my opinion (after an experience of some sixteen years), are the best judges of a good cup of tea.

3. The question of the best way of packing tea in small quantities is one involving a certain amount of trade dispute. Most people are agreed that the lead package in vogue with the Ceylon packers is superior to paper as regards the retention of the finer distinctions of quality and flavor of the tea, but many people prefer the paper as offering less chances of lead or muriatic acid poisoning. The tin package gradually finding favor in this colony when made by the blocking process, entirely obviating the use of solder, possesses an advantage over the lead package in all ways, and quite overcomes the objection to the paper bag, the paste of which may be as prejudicial as the solder used with the lead wrapper. I has the additional advantage of being absolutely air-tight. Personally I have packed the Bell Tea in such tins from its inception, and although a more expensive way of packing the evident superiority of the method has met with public commendation.

THE DUTY ON TEA.

TO THE EDITOR.

Sir,—I see by last night's *Star* that the tea blenders have petitioned Parliament to stop by means of a forbidable duty tea in Ceylon sealed packets, their chief argument being that the work is done cheaper in Ceylon, and therefore in favor of the importer of such packets. This is not the case. It costs 1½d to pack tea in sealed lead packets and boxes, and the same tea would be packed in paper for ¼d to three-eighths of a penny, besides being well blended with dust, fannings, cheap China, and other inferior teas for extra profit, and then put in a paper packet bearing the words "pure Ceylon tea" to mislead the public.

Tea packed in paper will not keep. From the day it is removed from the lead-lined chest in which it came from Ceylon, India, or China till it is used it is losing in strength and flavor. Believe me, but for the extra cost, no tea would be sold in paper bags.—I am, etc., Ex-Planter.

August 9.

A COMPLIMENT TO THE "TROPICAL AGRICULTURIST."

Exposition Universelle, Paris, 1900,

Ceylon Section, Trocadero, Aug. 20.

Sir,—I enclose the card of a Mons. Henry de Varigny—a gentleman connected with *Le Temps*—who wishes to have future issues of the "Tropical Agriculturist" for review in his paper. I shall be glad if you will write to him and say whether or not you are disposed to accede to his request.—Yours truly, W. E. DAVIDSON,

Delegate for the Ceylon Government at the Paris Exhibition.

Monsieur de Varigny is a remarkably-gifted man. He writes also for the French *Nature* and an Agricultural Review.—W.E.D.

[*Le Temps* being the leading paper in Paris, we take this as a special compliment—and agree to send on the *T.A.*—Ed. *T.A.*]

THE RIPENING OF BANANAS.

Galle, Aug. 28.

Dear Sir,—Anent the "fearsome story" about the ripening of bananas taken over from the *Westminster Budget*, the Sinhalese process of forcing on the yellow colour is certainly less objectionable. The plantain bunches are buried in the ground, and then fumigated till the ripening process is complete. Plantains treated in this manner have a very disagreeable taste.—Yours faithfully, A.

FRUIT-GROWING IN LOWER AMBAGAMUWA.

Ambagamuwa, Sept. 5.

Dear Sir,—I think it may surprise a good many that lowcountry fruits can be successfully grown at this elevation. On this estate, when I came to permanently take up my residence in 1889, I planted the following fruit trees :—Mangosteens 12 plants, 9 now growing, 2 bearing ; Ceylon plums (Uguressa), planted ½ dozen, 2 growing and in full bearing ; lovi-lovi, 2 planted, 1 in full bearing ; rambutans, 2 dozen planted, about 1 dozen growing, 4 in bearing ; num-num, 2 planted, one alive and in bearing ; billingberries, 2 planted, both growing and in bearing ; breadfruit, 4 planted, all growing and bearing profusely ; loquats, 4 planted, 3 growing and in bearing ; jamboos and rose apples, 2 of each in bearing ; oranges and mandarin oranges, a good many, all in bearing. I have even successfully grown peaches, two are thriving, one in bearing. Limes growing almost wild, cropping very heavily. Soursops on this estate and pomeloes or shaddocks go to feed even the coolies. Coconuts I planted about 300 and have about 160 growing luxuriantly ; two trees have borne this year. Thus you will see, sir, that Ceylon fruit, with care, can be successfully grown anywhere in Ceylon, save and except, I suppose, over an elevation of about 3,500 feet. Even this I would question.

I am sending you 1 mangosteen, 1 loquat, 1 num-num and some Ceylon plums and rambutans, the fruit now in season at this "packum." You will, perhaps, find the fruit not quite of such a flavour as the same fruit grown in the lowcountry, but I think you will say "They are not so bad." Your contemporaries would do well to copy this letter for the benefit of their readers.—Yours truly,

ADAM.

[The fruit sent to us look very well-grown, indeed, and are not without flavour, some being very good, the mangosteen and plums especially. This goes to show that every estate in the country ought to have a fruit garden of some kind ; for, undoubtedly, there are fruit-trees suited to each elevation from Colombo up to New Galway, where Mr. Kellow has done so much ; and to Nuwara Eliya, where Mr. John Cotton's growth of plums and strawberries is quite wonderful.—Ed. *T.A.*]

RUBBER IN SOUTH AMERICA AND IN CEYLON, &C.

September 9th.

Dear Sir,—I enclose an extract from *The Field* of 21st July last. The last sentence of the extract appears worthy of correction.—Yours faithfully, PLANTER.

[The extract is as follows :—

The recent Consular Report on the great interior district of Brazil known as the State of Amazonas, presents itself rather as a description of the country from the pen of an observant traveller than as the list of exports and imports which constitutes the usual contribution to literature of Her Majesty's representative in foreign lands. Ten or twelve pages are devoted to an account of the rubber industry alone. Of late, the enormous consumption of this article in the manufacture of bicycle tyres has created an ever-increasing demand, and although the supply from the Amazon valley has trebled in the last ten years, the former average price of 2s 6d. per pound has now increased to as much as 4s 6d. The total world's output is from 120 to 130 million pounds, of the value of fifteen million sterling, and of this the Amazons supply not much less than half, though the crop obtained from East and West Africa is not far behind. A little comes from Malaysia, Madagascar, and Mauritius, and still less—some 500 tons—from India and Ceylon, but South America is not only first in quantity, but in quality. The low-lying land chiefly affected by the rubber-yielding trees is completely submerged in the rainy season, which lasts from January to July, so that collecting is only possible during the last five months of the year. The trees yielding the latex are the *Manihot Glaziovii*, chiefly worked in Ceara, *Hancornia speciosa* the mangabeira of the natives, which is beginning to give results in Maranhao, and *Hevea brasiliensis*. The latter, however, is infinitely the most important, the bulk of the caoutchouc being obtained from it. It is, nevertheless, by no means common in the forests, an average of one tree only to every two acres being good ground. The yield of each tree when worked under satisfactory conditions is not more than from 2 lb. to 3 lb., but though a rest is from time to time necessary, the latex may be drawn for many years without causing the trees to perish, as has been generally supposed. It is therefore improbable that the available supply of rubber will be exhausted in the near future, and, owing to the enormous area over which the tree is found, much of which still remains to be exploited, it is unlikely that the industry will fall off. At the same time, however, attempts to cultivate the tree from seed in Africa and Ceylon have not hitherto been successful.

We take to ourselves blame for not correcting *The Field* long ago. It is quite a mistake to say that the experiments in Ceylon to grow rubber trees (Para especially) from seed have not been successful. Only the other day a small consignment of Para rubber taken from trees in Ceylon realized in London 3s 7¾d a lb. and we hope to see the export increasing year by year now.—Ed. *T.A.*]

TEA FREIGHT TO AUSTRALIA.

Colombo, Sept. 17.

Dear Sir,—The accompanying letter, addressed to the Vice-Chairman of the Chamber of Commerce, should be of general interest to both growers and dealers in Tea, and I send it to you for publication should you care to insert it.—I am, dear sir, yours faithfully,

H. WALTHEW.

R50 PER TON FREIGHT TO AUSTRALIA FOR TEA.

Colombo, Sept, 17, 1900.

To the Vice-Chairman, The Ceylon Chamber of Commerce, Colombo.

Dear Sir,—There has practically been a tacit contract between shippers to Australia and the mail steamers that freight should be paid and received at R40 per ton, and although all shippers know the rate to be excessive, they have paid it without a murmur or agitation, feeling that the advantages of a regular mail service compensated largely for this exorbitant charge. Shippers have borne without serious protest the curtailment of space to a point which has practically starved the Australian Markets and permitted other growths (to the incalculable injury of the Ceylon Tea Industry) to find a Market in Australia which they never would have done, if freight space had been plentiful at a time when Australia was starving for the produce of our Island. The mail steamers,

during the past four months, have ignored the wants of our trade, or perhaps more correctly speaking, they have not made arrangements to fulfil the requirements of the Tea Trade, notwithstanding the fact that they have to call in at Colombo for coal and passengers, and will always find ready for them 300 tons of cargo at £2 13s 4d, netting £800; practically sufficient to pay their coal bill to take them down to Australia

The R40 per ton freight which is charged to shippers to Australia equals about 4¾ cents per lb. calculated on the basis of 850 lb., being the average nett weight of a ton of 50 c-ft. of Tea. This is as much as is paid on tea to any port in the British Empire inland and transhipped either at New York or London as far west as Ontario in Canada, or as Far East via Hongkong and the Pacific as British Columbia, and is 25 per cent more than is paid to Australia from Calcutta.

As the Australian Colonies are the principal outlet of teas sold in Colombo, the buyer here has to deduct the extra price of freight which he is paying from the price he pays to the planter, and so the whole industry suffers through shippers having to pay to the mail steamers running to Australia, this excessive rate of 4¾ cents per pound.

We have now arrived at a point when Ceylon tea is so well-known and so well-liked in Australia that the trade requires more freight space to carry the produce of the Island to the Australian markets, and our nominal friends, the Ring of ship owners, whom the trade have been supporting at the above mentioned rate of R40 per ton for so many years, now turns like the proverbial viper and advances its rates 25 per cent or 1¼ cent per lb.

The tea trade of Ceylon is no doubt capable of bearing this blow with fortitude, feeling that the mail steamers are only buying at their own expense the means of bringing in outside steamers to compete with them at a much lower rate of freight, thus helping to break the iniquitous monopoly which has been saddled on the trade of the Island. But the question goes deeper than the question of breaking a monopoly; it is the question now of the Steamer Agents having broken a tacit contract. Speaking for my firm, I should be very pleased to see a much heavier rate of freight imposed for the next month or two upon all tea to Australia, as I happen to have shipped my quantum for a little time at R50 per ton, but the point of the sudden demand upon all Australian shippers, to pay R50 per ton is the absence of consideration for the traders who have supported the mail companies. Many merchants in the Fort have calculated their orders upon a R40 per ton basis, and they have bought to ship at R40 per ton freight. If they suddenly without warning or notice, are called upon to pay R50 they themselves have to bear the loss of R10 per ton. If the mail companies wish to charge shippers R50 per ton, then it is only just and fair that they should give the shippers due notice of their intention. If this had been a port where the freight rate to Australia fluctuated according to the law of supply and demand, no fault could be found with the mail companies in their present action, but however large the space offering here and however small the amount of cargo obtainable no mail steamer breaks the rule of their "Ring."

There has been many a time of depression in tea which could have been relieved, had a steamer come in with empty space and offered same at a low rate. But the "Ring" which manages the mail steamers have no consideration for the industry of the island or her traders: they feel that they have a monopoly, and can take extravagant liberties with the trade as is the nature of mono-polists.

I think the time has come when the Chamber of Commerce should enter a serious protest against the monopoly and against the arbitrary raising of rates without notice, and I think that I am not going wide of the mark, when I make the statement that if a body of shippers were to hang together, a Line of steamers could be chartered, to call in here monthly to carry the tea export of this island to Australia at 35s, thus saving ¼d per lb. on the present rate of R40 per ton.

If the ship-owners maintain this rate of R50 per ton, planters from next Wednesday's sale onwards will note a fall in the value they obtain of one to two cents per lb.

I should like this letter to be put before the Committee and with your approval I should like to publish it.—Yours faithfully, H. WALTHEW.

THE SALE OF PLUMBAGO.

(To the Editor "Times of Ceylon.")

Sir,—We have been much interested in the editorial and comments on the subject of plumbago, which have arisen from our original letter to you on the subject. It would appear from suggestions that have reached us, that if a definite *modus operandi* were formulated by which the producers could deal with the consuming centres *direct*, they would be glad to avail themselves of such a system. There are two suggestions we notice, made you which present possible difficulties to be overcome:—

(*a*) That the article requires preparation after it leaves the producers' hands before it can be used.

(*b*) That the non-success of the produce-consumer principle in tea may apply also to plumbago.

The former could be obviated by handing the rough plumbago to one of the Colombo curing firms who undertake to prepare at a fixed rate, or, if the output of the mine was sufficient, it would pay to erect a curing shed and do the work there. We have heard of a firm of curers who, after curing a parcel sent to them for cleaning, refused to allow the mine-owner to ship his plumbago himself, instead of selling it to them as he had been previously accustomed to do. The owner very properly resented such high-handed treatment and started curing himself. Producers, however, should have no difficulty in finding curers to do this work at fixed charge. The reasons of the failure to sell teas direct to the consumer are so obvious, that it is hardly necessary to deal with them in detail. The sale of plumbago, however, is on different lines. The main point to be remembered is that, in tea, the average consumer is a private individual, who buys a pound at a shop within a few yards of his house. In plumbago, the consumer is a large manufacturer who can buy 50 tons at a time. The factory may be situated in the interior of Europe or the United States, and may require a certain time in which to pay for its purchases. To sell to it would, therefore, necessitate an organization which is prepared to take charge of the shipments of plumbago on arrival, deliver it to the factory door, and if necessary, to wait till the factory settling day for payment. If this could be done the producer would be getting the utmost value for his article, as he would be getting *the actual price the consumer pays*. To arrive at this we make the following proposal to those interested in the sale of plumbago:—We are prepared to organise a six-weekly auction sale in London of all the plumbago sent to us for realization. In good time, prior to the sale, we will, as is the custom with the Government sales of ebony, forward to every consumer in all parts of the world, catalogues and samples of the different parcels. We will offer to these latter to take their limits for purchasing in auction, and should they secure the parcel, forward the goods to their port, giving them the necessary facilities for payment. It would not be advisable to hold sales at a less interval than six weeks, as sufficient time would not elapse between the receipt of samples by the manufacturer and the date of sale to allow him to *write* fully as to his requirements; and orders cabled by him would not lend themselves to full and complete instructions regarding his needs for any special quality or quantity. This

will afford the consumer every inducement to purchase through us, as he will see exactly what he is going to buy—an important point—and know that he is buying at first hand—a condition under which, it is interesting to note, he is often prepared, from a sentimental point of view to bid more freely than if he thinks he is paying somebody else a profit. The concentration of bidding thus obtained should show favourable results for producers. We would credit the producer with the actual price thus obtained, forwarding official voucher if necessary. For doing this, that is, circularising prior to sale, selling, shipping to buyer, and, if necessary, giving the latter credit, we would make an inclusive charge to producer of 5 per cent, paying out of this any brokerages or agents' commission we may incur for the better sale of the goods. The above, we think, would offer a means by which the producer should get better prices for his staple than by any other method. But, if we are to make this successful, it is absolutely essential that we have the confidence and support of the producers. It would be of no use our endeavouring to concentrate all the buying of plumbago into one channel, if sales are at the same time being encouraged elsewhere. The assortment which we offer for sale must be sufficiently varied and tempting to compel the buyers in all parts to come and bid up in the sale for their requirements, and the sale would then come to be regarded as the recognised channel of supply. If the producers of plumbago in your island would only take the trouble to investigate the present *modus operandi* of disposing of their consignments, we feel sure they would be anxious to at once effect a radical and sweeping change. The market is largely controlled by one or two brokers, whose interest it is to befriend the manufacturer to the detriment of the unfortunate consignor whose goods *must* be sold. There is no proper organisation or concentration of the buying element, as in tea, and we *know* of many cases where plumbago owned by natives and others has been sold much below its value, merely from the fact that buyers on the Connent and in the States have not been thoroughly advised before the sale.

We shall be glad to receive communications from any producer on this important subject, and give them any information they may require.—Yours, &c.,

CHAPMAN, ANTHONY & CO.

15, Philpot Lane, E C, London, 24th Aug., 1900.

Coconut Planting and Native Enterprise.—We are interested to learn of the success of a retired native gentleman in the cultivation of a coconut property of rather more than 100 acres in extent. When it was acquired by him, over three years ago, it was bearing an annual crop of 73,000 nuts. By judicious and liberal manuring the present proprietor, who is dealing with his soil in a bold and enterprising manner, has succeeded in raising the crop to 123,000 nuts per annum —but hitherto he has consistently allowed his expenditure to exceed his income. He spent more than R5,000 last year on the cultivation of the estate and next year expects the income exactly to cover his expenses. Subsequently, he expects to reap a handsome profit and is fully confident that the yield in a few years more will reach the high figure of 600,000 nuts. The planter in question, as may be guessed, is a gentleman of original ideas and fond of experimental work. We shall watch with interest the results of the present experiment in the "high cultivation" with our great palm staple. Old Mr. Lamont has said there is scarcely a limit to what the coconut tree will utilise of manure and that for every rupee spent on fertilisers, *two* at least should be got back.

ARBORICULTURAL OPERATIONS IN INDIA.

We have received a copy of the Report on the Arboricultural Operations in the N.-W. Provinces and Oudh, for the year ending March 31st, 1900, of which Mr. W. H. Moreland, Director of Land Records and Agriculture, is the author.

We learn from the Report that 2,213 of the total 2,919 miles of metalled roads, and 4,872 out of 23,220 miles of unmetalled roads, have now been provided with avenues of trees. In 1898 special instructions, intended to encourage the planting of trees by private individuals were issued by Government; but these were issued too late for results to be apparent in the figures for last year, though the Report mentions several instances where private persons have started avenues from one to four miles long. It is expected that arboriculture can be materially extended in this way, through the personal influence of the District Officer. It would appear that it is possible to maintain nurseries in that special expenditure, namely by putting them in charge of road coolies and those in charge of road bungalows.

As regards supervision, operations on Provincial roads remain in charge of officers of the P. W. D., while those on local roads are, as a rule, supervised by officials of the District Staff representing the executive of the District Boards.

The financial results of last year show the aggregate receipts as R84,988 or R500 in excess of the previous year's income: on the other hand the expenditure rose by nearly R8,000, and amounted to R89,196. The Provincial roads show a handsome profit, while there is a deficit on the roads managed by the District Board. This result is due to the administration of the former being closer, while the established avenues are considerably larger; so that while there is little expenditure, there is at the same time an income drawn from them.

TEA CULTIVATION IN INDIA.

The Director-General of Statistics publishes a paper in which he shows all India to have 516,732 acres under tea; but Mr. O'Conor confesses that his figures are imperfect and defective, information being withheld in some cases. We shall give the details later; but meantime we may mention that 33,279 acres of tea are put down for Travancore and the Madras Presidency, and it is estimated that in all India 15,052 additional acres of tea were planted in 1899; 31,561 in 1898, and 36,838 in 1897—thus showing how the higher rupee checked extension. It is stated that last year gave a wonderful increase (23½ million lb.) in production, but this is not borne out by the exports? Mr. O'Conor gives the consumption of tea in India on the average of five years at 5,169,000 lb. of Indian tea and 2,723,000 lb. of foreign tea (chiefly Ceylon). Of course, this could be largely increased if once the millions of India (as in China) took to drinking tea.

SCENT FARMING.

London, Aug. 30.

I heard the other day from someone who ought to know that there is a great opening for "scent farmers" and "growers of sweet herbs." I can believe that this branch of agriculture would be especially pleasing to female gardeners, for it conjures up at once a dream of fragrant perfume, and certainly the cult of sweet lavender and the tending of the modest rosemary should be more attractive than cutting cabbages and digging potatoes. All that is required is pluck and a small amount of capital to start a scent farm. Land, of course, is the principal difficulty. For the raising of lavender the soil must be of deep, sandy loam, if possible overlying chalk. An acre of lavender in good condition is calculated to yield £50 in a season. English lavender is the sweetest in the world and the demand for it is great. It is hardy and needs but little cultivation. There is a typical scent farm at Wallington, near Croydon, and there is no question of its financial success. For miles round the Crystal Palace and the Epsom Downs are fields of blue lavender. The cultivation of rosemary too and of the more plebian peppermint is an occupation with money in it, and I cannot help thinking that it is work essentially fitted for gentlewomen and it might succeed the violet growing. I am told also that a dairy farm managed by ladies would prove most financially successful at any of our crowded seaside resorts. Milk, eggs, and poultry are not to be had for love or money by visitors, most of the country people being pledged and bound to send their produce to London direct. Kitchen garden produce, we all know is most difficult to be obtained at crowded seaside places. I really believe a very lucrative business might be done by ladies able to supply farm produce, vegetables, fruit and flowers to visitors at any of our rising seaside resorts.

A SCOTCH FLOWER SHOW.

I was much pleased by a visit I paid the other day to a country flower show in a remote village amongst the Scotch hills. Such potatoes! such beans, leeks and onions! I never looked on before above ground. Carnations of every shade of colour and of enormous size were stuck in ginger-beer bottles, with a circle of paper round each separate bloom. Deep purple and variegated pansies were displayed on white cards. Bridle bouquets made up of pure white flowers, even baskets for table decoration, were all there, artistically spread out upon the schoolroom tables and desks. But what pleased me more than any of these most creditable exhibits from the gardens of the cottagers were the collections of seeds and fruits made by the boys of the village and the pretty bouquets or "boggies" of wild flowers gathered and arranged by the little girls attending the school. In one boy's collection of wild fruits and seeds 100 different varieties were found, all neatly arranged upon a square sheet of green moss, fir cones, wild raspberries, bilberries, acorns, beech nuts, chestnuts, etc., all collected and carefully arranged by the boy (the first prize winner) himself. I am told that the village schoolmaster (who is somewhat of a botanist) encourages his pupils to employ their leisure hours in searching the neighbouring woods and moors for these botanical specimens, and is most kind in assisting them to name and arrange their treasure trove. What an intelligent and enlightened schoolmaster for an obscure country village in the hills amidst the sheep and the heather! Would that there were more such in our rural villages and hamlets to influence so wisely and intelligently the tastes and pursuits of the rising generation—the youngsters of our country cottage homes.

I forgot to say that rows and rows of competing scones, oatcake, butter, cookies, and home-made jam reposed upon shelves all round the room. I felt so much inclined to test personally the virtues of these fresh and tempting exhibits. I was told that a very handsome prize had been offered at a neighbouring village for the largest collection of queen wasps, and that over 500 had been produced by one small boy. A perfect terror amongst wasps that boy must have been.

PENELOPE.

FORESTRY IN BRITISH INDIA.

BY B. RIBBENTROP, C.I.E., INSPECTOR-GENERAL OF FORESTS, TO THE GOVERNMENT OF INDIA.

A copy of this valuable work has come to us. Its object is explained in a prefatory note:—

The end of my career in the Indian Forest Service is drawing near. It has extended over thirty-years, and though I was not in the country when regular forest conservancy was first introduced under the auspices of Mr. (now Sir Dietrich) Brandis, I arrived when it was still quite a small sapling, and I have seen it grow to the mighty tree it is at present, under the wide-spreading shadow of which I have grown old. This is my excuse for preparing a general description of the forests and a resume of the introduction and growth of forestry in the British Indian Empire, to the publication of which I have obtained the consent of Government. I am, however, solely responsible for the matter, the form, and the opinions expressed.

The contents are as follows:—

Physical possibilities of India as a forest-growing country; Evergreen Forests; Deciduous Forests; Dry Forests; Alpine Forests: Littoral and Tidal Forests of Burma and Bengal; Riparian Forests; Zones in which no forests grow; Influence of man on the Indian forests; Influence of forests on the climatic conditions of a country; Local influence of forests on the fertility of the country; Early forests policy after British occupation; First attempts at forest administration; The dawn of Forestry in India; Present forest administration and its development; Organization of the Forest Department and its growth; Proprietary status of forests in India; Forest laws; Constitution of State Forest property; Further progress of constitution of Reserved forests under modern legislation; Forest Settlements; Demarcation; Forest Surveys; Working-plans; Communications and buildings; General protection; Protection from fire; Grazing and browsing; Sylviculture; Arboriculture; Works of improvement of existing forest growth; Exploitation and outturn; Minor forest produce; Financial results of Forest Administration; Technical education; Indian forest literature; Forest Administration in Native States. Appendices.—(i) Chart of the average annual rainfall of India (mentioned at page 6). (ii) Map showing the description of distribution of Forest lands under Government control on 30th June 1899 (mentioned at page 123). (iii) Map showing the advance made in Forest Surveys up to 30th June 1899 (mentioned at page 130). (iv). Map showing the advance made in Working Plans up to 30th June 1899 (mentioned at page 139).

The maps are well-executed and very interesting,

THE CONGO STATE AND COMPETITION: DESTRUCTION OF RUBBER.

A very favourite argument used by the admirers *qui and meme* of the Congo State consists in the oft-repeated statement that the country is being developed and is becoming prosperous by the introduction of fresh capital, &c. If by ruining acres of valuable rubber-producing forest land, by depopulating entire districts with fire and sword, by causing thousands of natives in Congo State territory to cross the river into French territory, in order to get quick returns, development is secured, then the country is being developed—not otherwise. Does the circumstance that since 1892 rubber in increasing quantities has been exported and many new rubber-exporting companies formed, prove that the country is becoming prosperous? Let us see. In 1897, 1,662,380 kilos of rubber were exported from the Congo State. Out of these 1,662,380 kilos of rubber *no fewer than 1,071,499 kilos came from the Domaine Privé!* Out of the 1,071,499 kilos, the *Domaine Privé* "taxes" accounted for 721,541, the balance of 349,958 being supplied by the two companies, Société Anversoise du Congo and Abir, in both of whom the Congo State, as already shown, is interested to the extent of one-half the shares. Deducting the output of the *Domaine Privé* from the quantity of rubber exported, there remains 590,881 kilos to represent private enterprise. A further examination reveals the fact that one singe company, the Société Anonyme Belge du Haut Congo, the absolute genuineness of which, as a strictly private company without State participation in profits, operating *outside* the *Domaine Privé*, is doubtful (see footnote, Article III.) exported 458,862 kilos out of the 590,881 kilos remaining. So that all the other companies put together merely succeeded in shipping home in 1897 a paltry 142 tons, reckoning 1,000 kilos to the ton! Does this indicate prosperity? Take ivory. In 1897 the Congo State exported to Belgium 289,117 kilos of ivory. Out of this total the *Domaine Privé* produced 198,326 kilos! The export of other products is insignificant. The facts speak for themselves. There is nothing in the remotest degree approaching a genuine increase of prosperity in the Congo State. Private enterprise in three-fourths of the territories is simply non-existent, and even in the nominally Free Trade zone the legimate barter transactions of independent traders are hampered at every turn by the proceedings of the official taxgatherers, who use coercive measures to compel the natives to pay in taxes the products of the forest which they would otherwise exchange against European goods. The increasing magnitude of the rubber exports from the Congo State since 1892 is due therefore not to legitimate commerce, but to slave labour. Remove that slave labour and the bubble of "prosperity" is pricked.—*Speaker*, Sept. 1.

THE LAST LONDON CINNAMON SALES.

The third quarterly cinnamon sales for the year, held in London on 27th August, appear to have gone off very satisfactorily for sellers. When noticing the May sales the following month, we suggested an explanation for the drop that was then recorded, in the heavy catalogue, and the trade disturbance caused by the South African war; and we expressed the hope that, unless our exports continued to advance, there would be a recovery from the slight falling off. As it turned out, there has been no diminution in our cinnamon exports—quilled bark being in excess of the quantity sent away last year, and the shortage as compared with 1897 and 1898 being more than made up by the increased output of chips; and yet the prices show a good advance, with a brisk demand.

Although the report we append speaks of a moderate supply, it will be seen that the quantity catalogued was in excess of that brought to hammer in August last year, and yet—what very seldom happens—almost the whole quantity was knocked down to bidders—all but 8 bales out of 1,141! And how this happened, with an advance in prices of from 1d to 4d—surely a most exceptional experience—is told in a very business-like way in what follows. At the commencement of the sale, it looked as if the easier prices of last May were to rule again; but a brisk competition soon established itself; and prices were forced up almost irrespective of grades. We are not told what excited the unlooked-for competition; but the caution should be noted that this ignoring of qualities and grades is not an experience to be calculated on, as it did not express any particular feeling in the spice market. Probably some broker put in a bid for a mark of which another had long a monopoly, and that led to fancy prices; for it is well-known that some of the best marks are almost invariably bought for Spanish Firms; and Spain has evidently recovered sufficiently from the debilitating war to be able to resume trade on the old lines.

Even more satisfactory than the advance in prices of plantation spice, is the neglect of "wild bark. The former was due to some exceptional local condition; the latter indicates the continued resolution of the trade, as expressed at previous auctions, to have nothing to do with spurious bark. If exporters have not already learnt the lesson that it cannot possibly pay them to send stuff for which no one bids, or which fetches 1d a lb., they will soon be convinced of the futility, and that will help to maintain prices for honest spice.—We quote as follows from Messrs. Forbes, Forbes & Co.'s Report on September auctions:—

London, August 23.—*Cinnamon.* At the quarterly auctions held yesterday the supply was moderate, viz:—1,141 bales Plantation quill, against 1,202 bales at the previous sales, and 959 bales at this period last year. We are pleased to report an exceptionally brisk demand, and the clearance of all but eight bales.

The "worked" cinnamon comprised 305 bales, and the "unworked" 836 bales. The "unworked" quill chiefly sold at about ½ to 1d per

lb. dearer; firsts 9½ to 1s 1d; seconds 9½d to 11d; thirds 9½d to 11d; and fourths 8d to 9d per lb. A few lots of native growth sold at 2d to 7d per lb. for fifths to firsts.

The sale of the "worked" cinnamon was very exceptional, and for most of the marks the increase in price ranged from 1d up to 4d per lb. The opening bids for the leading mark. were cautiously made, and it appeared that easier prices were likely to be established.

As the lots progressed, a strong spirit of competition set in between two or three of the leading buyers, with the result that prices were forced in some cases 2d to 4d per lb. firsts, seconds and thirds occasionally being practically bought at nearly the same price. Some lots sold at exceptionally high prices; these, however, must not be taken as representing true market value, and such prices are not likely to be obtained again.

Firsts realized 1s 1d to 1s 8d; Seconds 10½d to 1s 7d; Thirds 9½ to 1s 7d; Fourths 8½d to 1s 1d per lb.

About 1,300 Bales wild Ceylon were quite neglected and all bought in. Of low chips and bark, some 1900 bags offered and were nearly all, withdrawd for lack of bids, a few bags Bark being sold at 1d. Chips 3d and Quillings &c. 6½ to 10d per lb.

Stocks of Ceylon 2,544 bales; Wild 2,581 bales; Chips 5,205 bags; and Wild Bark, &c. 8,037 bales.

Next Auctions 26th November.

Forbes, Forbes and Co., ltd.

CEYLON IMPORT DUTY ON TEA.

Ceylon imposes a 25 cents import duty on all foreign teas coming into the Island. The abolition of this altogether unjustifiable duty has all along been opposed by Ceylon planters. The *Ceylon Observer* suggests that the Planters' Association should move the Imperial Customs officials to fix a proper tea standard so as to exclude rubbishy and worse teas. The unfortunate part of the business is that Ceylon alone dees not suffer, our produce likewise gets a bad name. People in Australia and other parts of the world are not, generally, sufficiently well versed in geography to distinguish between Ceylon and Indian teas—to them they are one and the same. We think that all the Tea Associations (London, Indian and Ceylon) should take cognisauce of the matter, and, working in unison, adopt measures to move Her Majesty's Customs to fix some proper standard at all ports, so as to prevent the shipping of rubbishy teas, and worse, from the countries of production. We have never been able to understand the action of the Crown colony imposing a 25 cents import duty on our produce considering that its teas are admitted free into this country. The tax is undoubtedly detrimental to the best commercial interests of the Colombo port, as, were it not for this prohibitive duty, Southern Indian tea at least would be shipped for sale to that mart. Some time ago we suggested Indian teas being shipped to Colombo and there blended and sold, making that place the great Indo-Ceylon mart for all Indian and Ceylon teas. The suggestion, for obvious reasons, met with no favour. and our fellow-planters in the Island were dead against it, for it of course meant the abolition of the 25 cents import duty. We trust that they will now see that the retention of the tax is opposed to their best interests. A fixed and proper tea standard by Her Majesty's Customs would do away with all necessity for the duty, and its abolition would lead to a great expansion of business in Colombo; which would greatly benefit the Island in very many more ways than one.—*Indian Planters' Gazette*, Sept. 8.

BOOK RIFLES FOR SMALL GAME IN CEYLON.

(*To the Editor of "The Asian."*)

Sir,—In a recent issue of your valuable journal I noticed a most interesting article by your constant correspondent, "Fleur-de-lys." He brought to the notice of sportsmen a branch of sport few realise the existence of—myself amongst the number—*viz*, the excellent rook rifle practice to be had at small game of which there is an abundance in the low country of Ceylon, and which offer absolutely no sport with the gun. In the tank country flamingoes and the larger kind of water birds, inland jackal, big squirrels, hares and pigeon of various kinds are very plentiful, and afford splendid tests of skill with the small-bore rifle, while there would be no fun in shooting them with a shot gun. It is only done when shooting for "the pot" and when there is no danger of disturbing better game. The great objection, in Ceylon at any rate, is the necessity of taking an extra rifle for two reasons, *viz.*, (1) the wrong weapon is sure to be handed to you by the wretched 'trackers" (?) we have to employ; (2) the great trouble of having to keep an extra gun clean—this is no small consideration out here as our servants are quite incapable of keeping firearms clean, more especially small-bores, which they soon succeed in chocking; if you value the weapon you must clean it yourself. However, your correspondent suggests the use of a weapon which is adapted to shoot with a reduced charge. With this end in view I have been experimenting with a breech adaptor and the miniature cartridges in a Martini-Metford ·303 by Rigby. I may be unfortunate with the ammunition, but the accuracy with these cartridges has been most disappointing. What diagrams would your correspondent (who is undoubtedly an expert) think possible at 50 and 100 yds.? Has he, or any of your readers, had any experience with the latest American rifle, the Savage, which Messrs. Westly Richards have taken up the agency of? This rifle has a most taking appearance, being hammerless with a self-contained magazine (6 shot). It shoots a nickel soft-nosed bullet with very much the same velocity and force of the British ·303, and it also has a miniature cartridge which is claimed to shoot with great precision up to 100 yds. The price is also most reasonable, *viz.*, about £4-0 0. Any information on this subject from any of your readers will greatly oblige others as well as—M. L. W.—Madukelle (Ceylon), 30th August, 1900. —*Asian*, Sept. 11th. [The above initials will be recognised at once as those of a well-known young Knuckles planter and sportsman.—Ed. *C. O.*]

Short Crop of Cacao in Central America.—Up to the present time the shortage of cacao from the Machala and Santa Rosa districts exceeds 10,000 bags says a Guayaquil correspondent of the *B. T. Journal*, of July 15. This represents an average value of a quarter of a million sterling, or one-fifth of the exports. Not only does this alone cause a despondent feeling in commercial circles, but the civil war in Colombia along the Ecuadorian frontier also has a bad effect on trade. The export tables of coffee, rubber, hides, and vegetable ivory or tagua show that there exists a considerable amount of excessive trading as well as speculation.

AN INDIAN TEA CESS AND THE CEYLON TEA DUTY.

It is very gratifying to us to see both the Indian and local press now so generally taking up subjects which, for a long time, we urged almost as one crying in the wilderness. We refer to the need of pressing on the Indian Tea planters and also the Government, in season and out of season, the need for establishing a Cess Fund for advertising their tea in new countries, after the pattern set in Ceylon; and secondly the need for abolishing the unwise, inequitable and anomalous import duty on tea in Ceylon. It is well-known that its existence has already cost Colombo much business not only in the handling of the teas of Travancore and other South Indian districts; but also in the manufacture of brick tea for Russia, during the recent crisis—an industry which, if once started, might have led to great and rapid developments in regard to one of our most promising customers. The bugbear held up now as ever, is that, if the duty be abolished, inferior China and Java teas will come here to be blended with Ceylon. But can *any* tea imported be inferior to some that is already sold in the Colombo market?—and why should a blending business be relegated to London, America, or the Colonies, if it can be done in Colombo? No one can be so ignorant as to suppose that Ceylon tea will not still continue in Mincing Lane as elsewhere to be bought on its merits, or that any buyer or dealer can be deceived by manipulation or blending in Colombo. The cry for "Pure Ceylon" tea is of very little value in these days when veritable rubbish is sold at Colombo sales. There must now be the guarantee that it is "good" as well as "pure" tea and such guarantee can be as readily given when Colombo is a free port for tea, as at this moment. If the attention of the Viceroy in Council is called to this Ceylon tea duty, its abolition will assuredly be requested more forcibly than politely. Far better on every account, not to wait for such an invitation or request.

A TEA CESS FOR INDIA.

I have read with much interest your articles on a "Tea Cess for India." It is a great satisfaction to us here in South India to find you using your powerful influence with the object of inducing the Indian Tea Association to make a second appeal to the Government of India to place a small compulsory tax on the export of tea. The feeling of my own Association (and I believe it is the same with others in South India, though I cannot speak with authority for those Associations) is, that a compulsory cess should long since have been imposed: that the small contribution hitherto raised in India for the Foreign Market Fund is a blot on the spirit of enterprise and the dignity of the Indian tea planter, and that a tax on the same lines as that raised in Ceylon would not merely be no hardship, but would be refunded to us over and over again by the certain increased consumption of our produce. In addition to this we down here, who are so near Ceylon and are so closely in touch with those in the islands, feel very bitterly, that we are talking a mean advantage of the liberality and public spirit of our brother planters across the water, and with very small cost to ourselves are reaping what they have sown. It is hopeless to expect the Indian Tea Association to move further in this matter, if they are going to wait for a "fair show of unanimity" from the Indian tea planters. That we shall never get. What we want is a good majority. I think you are wrong in stating that by "unanimous consent" the Ceylon "growers placed the matter in the hands of their Government. Was it not because the growers were not unanimous, that an influential majority placed the matter in the hands of their Government? In all communities, particularly in those so large and so varied as that of the tea planters, you will always find a certain proportion, on whom persuasion and argument are thrown away. In such cases the opinions and wishes of the greater and more influential number should be considered. Surely this is a social law? I am glad to see from your issue of the 16th August, that those standing out from the present Fund in Northern India do not amount to more than 35 per cent., and a part of those standing out would (I understand) not disapprove of a compulsory cess. Might not then the minority, which would be still smaller were Southern India added to the poll, be disregarded?

GRANVILLE L. ACWORTH.

Peermaad *via* Periakulam, Sept. 1st, 1900.

—*Indian Gardening and Planting*, Sept. 13.

"THE TALE OF A TUSKER"

is given in *Macmillan's Magazine* for September in a paper signed "A. D. G-G." We make a few quotations. The paper opens:—

Most shooting stories tell of success, of some good bag, or of the gain of a particular head; for a change, here is a tale of defeat. This is the account taken from my journal, of a long day after elephants, a most interesting and exciting day, to which I look back as among the very best of all my sporting time. Then I was a comparative novice at big game. The country was Ceylon, and the month January. For arms, I had a ·450 express, while the big rifle (a ten-bore) was carried by Hena, a Cingalese, who was an indifferent hunter, plucky enough, but quite ignorant of woodcraft. . . . All at once Hena bent and peered into the foliage to the left, where I saw a few leaves gently shaking. "*Alliah* (an elephant)," he whispered, and then clutching my arm in his excitement, "*Eta, eta, eta alliah* (a tusker elephant), and suddenly I saw among the leaves a long and shining tusk. Without the slightest warning we had walked straight up to a tusker. Now in Ceylon tuskers are extremely rare, so rare that few sportsmen ever see one. I can think of half a dozen people who have shot one, but I know nobody who can claim two. It was difficult to make the elephant out in the half-light of the dense cover, but he was not of great size, probably something over eight feet high. He was broadside on, perfectly motionless: and as I loaded and cocked the ten-bore, more noiselessly than I had ever done before, as I crept cautiously towards the animal and paused when he made a quiet pace forward, as I halted within ten yards to wait an opportunity to

fire, confident in my two or three previous triumphs, I never doubted of success. The foliage was so thick about him that I could not see his head distinctly, but his quiet advance, for he took now and then a slow step onwards, promised soon to bring him into a gap near me about a yard broad. Into this, accordingly, I crept and crouched down, six or seven yards from where I thought he would pass. For full five minutes I waited. The elephant was quiet, evidently dozing, but now and then he would swing his trunk against the thin stems on either side, causing a shiver and rustle of their foliage. I could hear the deep rumble of his inside, and the great breaths that once or twice bust up from his lungs; I could see his forefeet distinctly, but no vital spot. Then he came forward and stopped, the brute, at the very edge of the gap, his brain covered by a thickish sapling, his forehead and trunk in full view. Not daring to stir I waited, for an age as it seemed, noting every wrinkle of the loosely-hanging trunk, every blink of the half-closed eye, every stain and blemish of the tusks; the left one, the nearer, stood two feet beyond the lip and was broken sharply at the end; the other was a foot longer. I do not know how long the animal stood there, but at last round he swung into the gap towards me and as I hurriedly raised the rifle and pulled the trigger he was towering above me barely five yards off. I was too close to him and felt my aim had been too high; his advance had taken me by surprise.

But a two-ounce bullet hits hard and this one knocked the tusker over like a nine pin, as the tremendous crash of branch and sapling plainly told, a torn-off twig hitting my shoulder. The smoke hung very dense, and I did not like to advance, but a shrill trumpeting and continued crashing showed that the beast was struggling to his feet and when I plucked up courage and went forward, he was on his legs, his feet far apart, his body swaying drunkenly from side to side, his head buried in the branches. Of course I ought now to have fired at his heart, but I was a beginner and did not, trusting to the common rule in Ceylon which bids one fire only at the brain. Already he began to make some staggering sort of way forward. He got back into the gap but never exposed his head; his pace quickened into a run, and then wildly trumpeting, he rushed headlong forward, crashing, smashing, rending, straight through the thick and cumbered forest. My dash in pursuit hindered at every step by the chaos of destruction in his wake, was hopeless; the bushes closed behind his tail and I saw him no more.

Then come five pages of jungle description, in following the elephant, being benighted and in getting back to the hut :—

I have had the luck to know a little of many jungles, and they are all delightful; from the muddy fastnesses of the Sunderbunds and its mysterious waterways arched in with palms, to the glowing autumn pinewoods of the Himalayas; from the vast grass coverts of the Terai to rocky bamboo-clad hills and upland teak-forests, black, burned and leafless in the Central Indian summer. But for Ceylon I keep an extra warm corner in my heart, poor though its trophies mostly are. There first I shot big game; there first I saw the jungle and drank in and made my own its spirit. Sad would I be to think that spirit could ever leave me or that I am never again to follow through the forest some one or other of its greater denizens, and to be there, more truly than it is possible elsewhere, my own master owing allegiance to no man.

CHEAP TEA FOR INDIAN VILLAGES.

I am absolutely ignorant with regard to the tea trade, but I have read a good deal lately about the "booming" of Indian teas, and it seems to me that one opening which might be made use of is neglected, so I venture, very humbly, to point it out. I mean the sale of cheap tea, or tea dust, among the poorer class of natives in agricultural districts. These districts are often malarious, and officials who have to do a good deal of camping find that their servants keep free from fever if supplied with tea while they are out. I happened to live for a short time in a small station in Behar where fever was very prevalent among the natives. My servants considered "a little tea" a remedy for all ills, and the demands on my tea-caddy were so great, that at last I procured a quantity of tea dust at four annas a pound from a garden in Darjeeling, and told my servants that they might have as much of it as they liked at that price, paying the freight myself. The whole supply, 10 lb., was gone in a day, and I could have got rid of four times the amount for many of my neighbours' servants were anxious to buy it too. The cheapest tea to be had in the station was adulterated tea-dust, sold by the local Whiteley at seven annas a pound! Since then I have always kept a supply of dust for my servants, they appreciate it greatly, and buy it most willingly at 4 annas a pound. Most of them, I believe, drink tea at least once a day, and they declare that it keeps them in good health. Whether this is really so I do not know, but they certainly keep very well, although this place has a bad name for fever, and once when the supply of dust ran out, and it was some time before a fresh lot arrived, so many began to ail that I was obliged to get them some more expensive tea from the nearest station. I believe the native *pesaris*, or druggists, sell a dreadful compound which they *call* tea, and I know of one enterprising servant, in a particularly malarious district, who buys cheap tea dust, through a relative working on some tea garden, and sells it to the villagers at 8 annas a pound.

Every large village has a *bazaar* once or twice a week, and I have no doubt that cheap tea would find a ready sale on these occasions, or it could be disposed of by employing men to take it round from village to village, like the native pedlars or *soudagars* who sell cloth and other cheap articles.—Tea.—*Indian Gardening and Planting* Sept. 6.

GREEN TEA IN THE NORTH-WEST HIMALAYAS.

In a recent number of *Indian Gardening and Planting*, a correspondent of yours remarked that he was unaware that green tea had ever been extensively manufactured in India. That he is in error as to the above, the following facts will shew. Up to about ten or twelve years ago, the districts of Dehra Dun, Kangra and Kumaon, in the North-West Himalayas, confined their attention solely to green teas, which were all exported at very profitable rates to Kabul and Central Asia. We found the manufacture simple as well as remunerative, as the cost per pound was far less than that of black tea. The qualities preferred were Young Hyson, Hyson, and Gunpowder, all of which had, however, to be entirely free of dust or broken tea, which sold separately at something above cost price. In speaking of my own district, the Dun, I remember the time when Central Asian merchants visited the gardens early in each year, and cheerfully advanced large sums to secure the whole season's crop; and later on, after the rains, they used to return with their own camels and carts and buy up all the tea, for cash down, that the gardens could produce: in fact the demand generally exceeded the supply. The tea was simply packed in gunny bags, lined with some thin cloth within. Each bag con-

tained about a maund more or less, and the packing cost on an average seven annas per bag. When I mention that the cash price paid at the factory before delivery amounted to anything between As. 12 to R1·4 per lb., it will be realised how profitable the manufacture of green tea was at that time.

But those halcyon days of prosperity came to an untimely end, and in the beginning of the "nineties" this profitable business wholly vanished. Its destruction may be assigned to three causes, viz., first, the prohibitive customs duties levied by the Russian Government in Central Asia; second, the suicidal fiscal policy of the Amir of Kabul; and last, but not least, the apathy, and I may say the pusillanimity, of the Indian Government, in not vigorously supporting the planters of Northern India. Unanimous representations were made by the districts above-mentioned, with a view to having these disabilities removed if possible, and a strong deputation waited on Sir James Lyall, the then Lieutenant-Governor of the Punjab. Though we were well received, and given every opportunity of thoroughly explaining the ruinous situation, we could not help feeling disappointed at the official *laissez faire* attitude adopted towards the whole tea industry. And it was apparent to us that the Indian Government had evidently not yet emerged from the destructive thraldom of the "masterly inactivity" school; and as a consequence the unfortunate deputation broke up without having obtained any tangible results from the powers that be. Subsequently I had the honour of a personal interview with the then Viceroy, Lord Lansdowne, who though showing the greatest sympathy with the planting community in its distress, he yet professed his inability to do anything for the industry in the direction desired. It is a noticeable fact that just about that period, both the Kabul and Russian Governments treated the Indian Government as a wholly negligible quantity in politics, and we were far too weak and vacillating in our policy to resent such derogatory treatment, and claim an equitable reciprocity in trade.

Be the cause what it may, once again nothing was done to help the struggling planters in these parts. In despair I offered to proceed to Kabul myself, and personally represent matters to the Amir from the non-official trader's point of view. Fortunately this proposal found favour, and I was accorded permission to accompany Lord Roberts' mission to the Amir. However, the mission, as everybody knows, did not proceed to Kabul, for political reasons, and once more an opportunity was lost of obtaining some redress. As a last resort I applied to be allowed to address His Highness the Amir direct by letter. This request was granted with the proviso that I should first submit my communication to the Government at Simla for approval. The letter was considered satisfactory, and was graciously translated into courtly Persian, and returned to me to forward on to Kabul. That was many years ago, but in spite of proverbial Oriental politeness, His Highness has not to this day had the courtesy to acknowledge a respectful and important petition, concerning the trade interests of so many of his own subjects, as well as those of the Indian Government. Some months after the despatch of my letter, I heard from private sources, that the Amir had declared his firm intention not to be guided in any way by the Indian Government in matters concerning the internal trade of his kingdom; and we were therefore sacrificed to the whim of an unenlightened potentate, and the ineptitude of our own rulers.

The above ends the lamentable history of a once flourishing trade in Northern India. The green tea market having been destroyed through the machinations and neglect of others, we were perforce obliged to turn to the manufacture of black tea, but with nothing like as profitable results. The wisest course now, in my opinion, would be to revert again to green tea, if not altogether, at any rate to a considerable extent; and to make it this time especially for the American consumer. From the fact that the Central Asian, and subsequently the Bombay traders, have pronounced our green teas as very similar to the same qualities from China and Japan, I feel convinced that the hill gardens of Northern India are capable of producing a commodity that would compete on more than favourable terms against China and Japan teas in the American market. But I cannot say I feel very sanguine that any such business-like step will be generally undertaken in these days of official neglect and regrettable drift and disunion among those connected with tea. When planters show so little cohesion and community of interests, and Government show such marked opposition and discouragement to all private enterprise, no decided improvement can logically be expected, in the tea industry of Northern India.—J B Leslie Rogers.

BRICK TEA FROM LONDON TO RUSSIA: INDIAN TEA AND THE PARIS EXHIBITION.

TEA COMMISSIONERS NOT OF MUCH USE IN NEW COUNTRIES!

(*From a prominent London merchant writing to the Calcutta "Planter."*)

For several years back a large shipment of brick tea in baskets has been sent annually from China to London for re-shipment from there to Siberia through the Kara Sea. This route has proved rather unfortunate and is, I think, now entirely abandoned. One year, tea to the extent of 4,000 tons was on board the P. & O. steamer "Aden" which became a total loss on the island of Socotra. Last year's shipment was despatched in a fleet of 3 or 4 light draft steamers bound for the Yenisei River, one of which was totally wrecked somewhere about the White Sea, and the others being unable to get through had to return to London, where the tea was re-warehoused. It lay in bond here all winter, and sometime last spring it was re-shipped, a statement being made that it was going Overland from Vladivostok. I query the route as the Siberian Railway is so incomplete, and I question whether the tea may ever reach its destination owing to the disturbed conditions in the north of China, but anyhow I am told those who tried to work this service do not intend to re-open it. At present there is litigation involving a very serious amount of money in the London courts, the owners of the tea claiming to be refunded by the steamer people who had made the contract to carry the tea to Siberia, the amount of the cost that it is now entailing upon them for sending it through by the other route.

If you happen to see the London *Grocer* for Saturday 18th Aug. there is a page there on "Tea in the Paris Exhibition" *contributed by me. The *Grocer* has excised certain references to Japan tea which I think it would have been well to print, but they were cutting the article down to the limit of a page. You will see that I have endeavoured to deal fairly with the representation, of tea by each of the countries, and that I take a much more favourable view of what the Indian people have done as compared with the others than some of your correspondents have expressed.

Of course the Indian planters lack the energy of the Ceylon man and do not advertise themselves so thoroughly, but all practical tea experts regard

* This article has been already reproduced in the *Tropical Agriculturist*.—Ed. *T.A.*

Indian tea as a much more satisfactory article than Ceylon tea and appreciate it accordingly, as you can see from the higher price which they have to pay for it. I think a great deal of nonsense is being talked and written about producing green teas and about the lack of missionaries to open up foreign markets. The ordinary trader is a much better missionary than any special commissioner, and I do not think the latter have ever achieved much wherever they have gone. They have simply upset the ordinary distributive methods, which to my mind work in almost an automatic manner, blenders making use as they go along of the tea from which they can get the best value. This is how Indian and Ceylon teas have made progress gradually in all black-tea-drinking countries, merely displacing China tea, but it is a totally different thing to displace green.

Please note that I have not written this for publication over my own name, but you can make what use you like of the statements I give you, and I will accept responsibility for any of them.

TEA IN TRIPOLI.

Tripolitania.—Tea is now supplied by England in very large quantities, most of which are re-exported to the interior of Africa. Formerly several Hamburg firms used to sell tea here also, but for some years past they have had to withdraw from the market as they could not compete with English prices and conditions. The most current qualities are green teas ranging in price from 1.90 frs. to 2.20 frs. per kilo. c.a.f. Tripoli.—*M. Ernest Labi, Belgian Consul at Tripoli.—British Trade Journal*, Sept. 1st.

PLANTING NOTES.

Manganese Mining in Central India.—A Syndicate, with extensive Manganese ore rights, has, it is stated, approached the Bengal Nagpur Railway Company with a proposal for the connection of their workings by a 2ft. 6in. gauge mineral siding to the Tharsa station, a distance of ten miles. In addition to the ore traffic, the proposed branch would serve the large pilgrim traffic to Ramtek in the Central Provinces.—*Pioneer*, Sept. 15.

The Passion Fruit.—A London horticultural journal states that shipments of passion fruit packed in the shredded bark of the tea tree have arrived in London in an excellent state of preservation. The same organ refers to the great possibilities there are in shipping dried fruits from Australia, not only to England, but to other parts of the world. The dried fruits of Mildura have made a good impression, and demonstrated the possibility of a profitable trade being carried on, provided all the primary conditions of careful curing and packing are scrupulously and undeviatingly fulfilled.—*Indian Gardening and Planting*, Sept. 6.

Gas Lime.—The usefulness of gas lime for land is becoming better known every year, and the proper time to apply it is directly the corn crops are carted home. But it must not, says a contemporary, be put on "seed" fields, because if applied fresh and in quantity, it kills all vegetable life. Albeit when it has lost its sulphur which it does in a few months, it is no longer injurious to plant life, but succors it, and acts as a potent fertiliser. It acts most usefully when fresh in killing all kinds of creature pests in the soil, which are very destructive to crops in many fields. Tipula grubs, slugs, and wire-worms are the worst pests, but gas lime kills them when applied properly—that is, in sufficient quantity and quite fresh.—*Journal of Horticulture*.

Egg-Preserving in Westralia.—The Department of Agriculture intends to have a thorough test made of the various modes of preserving eggs, and for this purpose a large stock of eggs will be obtained and treated with different preparations at the Government refrigerating works. The eggs will not be tested until the next Producers' Conference.—*Westralian paper*, Sept. 5.

Flower Farming in the United States.—There were in the United States last year no fewer than 9,000 farms on which flowers for cutting were grown under glass for sale, the total areas actually under glass aggregating 22,500,000 square feet. The Department of Agriculture at Washington estimates that the retail value of the cut flowers sold from these flower farms annually is no less than £2,500,000 apportioned as follows:—

	Number of cut flowers	Value per 100	Total value £
Roses ...	100,000,000	24s	1,200,000
Carnations ..	100,000,000	16s	800,000
Violets ..	75,000,000	4s	150,000
Chrysanthemums	——	——	100,000
Miscellaneous flowers, Lilies, &c.	——	——	250,000
	Total ...		£2,500,000

In addition to this it is further estimated that the retail value of the plants sold from these flower farms is £2,000,000, and the number about 100,000,000. The total retail value of the annual output is thus £4,500,000 or just 4s for each square foot of glass. On the average one man is required for every 1,500 feet of glass, making 15,000 employed in the industry in all. The State of New York comes first in connection with this industry, having 4,500,000 square feet of glass; Illinois is second with 4,250,0 0 square feet; and Pennsylvania third, with 4,000,000 square feet. The amount of capital invested in the industry over the entire country is over £2,250,000 and it is estimated that this sum is actually received by the growers each year for the plants and flowers sold.—*Journal of Horticulture.*

The Consolidated Tea and Lands Coy., Ld., has a good deal of tea and coconuts in Ceylon, and in every sense the proceedings at the annual meeting is of local interest. Sir John Muir's speech deserves attention: he strongly condemns the Indian Government for its "rupee" policy and rightly enough shows the advantage gained by China and Japan; but to be quite frank Sir John should have added that the higher rupee put an end to his own policy of further large planting extensions, and that this stoppage was greatly to the benefit of the tea industry, generally. It appears that the Directors and Agents are to always make up any balance required for a 7 per cent dividend out of their fees and commissions. This time they give up half, showing that the total fixed for Directors and Agents in Calcutta, Colombo and London is under £7,000 per annum or the equivalent of about 5s per planted acre. Sir John rightly takes credit for the Company's holding and further planting of cinchona in Southern India—and why not in Ceylon, as well as coconuts? Altogether this Company is a very large and important one and it will be seen that it tries to push Indian and Ceylon teas in America on its own account.

EILA TEA COMPANY OF CEYLON, LD.

REPORT

The Directors submit their Report and Accounts for the year ending 30th June, 1900.

The crop on Eila Estate was 256,403 lb (exclusive of 21,335 lb made from bought leaf) against an estimate of 241,000 lb, and on Kanangama 106,570 lb against 150,000 lb estimated.

The total amount of tea manufactured was 384,313 lb and the cost of production, including the purchase of 85,320 lb of green tea leaf was 22·76 cts. per lb.

The average price of tea after estimating the value of that unsold was 30·38 cts. per lb as against 33·11 cts. for last season.

During the year a further instalment £500 was repaid to the Standard Life Assnrance Company on accounnt of their Loan of £7,000

The Directors regret that while there is an increased profit this season from Eila, the young clearings on which estate are now coming on well and give good promise for the future, there has been little or no profit from Kanangama; this is due partly to the drought in the earlier months of this year which reduced the yield for the season and partly to bad management by the Superintendent, and the Directors have reluctantly been compelled to make new arrangements for the working of the estate.

The net profit for the past season after writing off depreciation on buildings and machinery is	R12,468·84
to which must be added the balance from last season	2,907 49
making in all	R15,376·33
Out of this the Directors propose to pay a dividend of 5 per cent absorbing	R15,000·00
and to carry forward	376·33
	R15,376·33

The estimate for the current season provides for a crop of 416,500 lb. Tea at a cost of R90,680·45.

The estates of the Company at this date consist of:—

Eila—564 acres Tea 5 years old.
62 „ „ 4 „
90 „ „ 3 „
240 „ Forest.
956 Acres.

Kanangama—215 acres Tea 5 years old and upwards.
108 „ China and Patna.
323 Acres.

During the year Mr. Stanley Bois was elected to the Board of Directors in place of Mr. Percy Bois, who has left the Island.

Mr. F W Bois retires in accordance with the articles of Association, but being eligible offers himself for re-election.

The shareholders will have to appoint an Auditor for season 1900—1901.

PUTUPULA TEA ESTATE CO., LTD.

REPORT.

ACREAGE.

Tea in full bearing ..	421	
Do partial ..	33	
Do two years old and under	7	
		461
Do Coffee and Para Rubber		21
Forest, Grass, Wasteland &c.		217
		699

The Directors beg to submit to the Shareholders the accounts for the year ended 30th June, 1900.

The crops secured amounted to 182,749 lb. of made Tea against an estimate of 185,000 lb. or 12,449 lb, in excess of last season's crop.

The nett average price realized was 33·09 cents per lb., costing to produce 24·58 cents f.o.b., including the purchase and application of manure to 180 acres costing R6,248·21. The cost per lb. on manuring was 3·42 cents.

The yield works out a little over 400 lb. per acre calculated on all but 7 acres of Tea under two years old.

The clearing and planting of 11 acres with Para Rubber was carried out costing R318·04. This expenditure, it is expected, can be reimbursed by the sale of Para seeds and plants, 20,000 of the latter now being in nurseries.

During the past season the withering accommodation has been extended by raising the roof of the Factory and adding another storey, the extra space thus acquired, measuring abont 33,300 sq. ft., will be of great assistance in coping with the increased yield resulting from manuring operations. The total cost, R5,972·32, which includes the erection of a new weighing platform and stair case, is being carried forward and will be charged in the present season's working account under capital expenditure.

The yield for the present season is estimated at 190,000 lb. at an outlay of R45,713, which includes the treatment of 140 acres with artificial manure to cost about R5,460. The profit for the year amounts to R12,713·50 which the Directors recommend should be applied as follows:—

6 per cent Dividend ..	R12,000·00
Bonus to Superintendent ..	500·00
Balance carried forward ..	213·50
	R12,713·50

In terms of the Articles of Association Mr. W. B. Kingsbury retires from the Board of Directors, and being eligible, offers himself for re-election.

The appointment of an Auditor for the current year rests with the Meeting.

PLANTING ON THE ANNAMALAIS, S. INDIA.

COFFEE—TEA—CARDAMOMS.

We are pleased to see Mr. E. J. Martin, formerly of the Kelani Valley, looking so well after his spell of hard work in opening land and pioneering on the Annamalais. If Sir Arthur Havelock has done nothing else for the Madras Presidency, during his five years of administration, he has at least developed a new and promising Planting District in the Presidency and induced several reliable Ceylon planters to bring their capital and experience to the Annamalais. Altogether some 20,000 to 25,000 acres of forest-land have been taken up, and out of this, as much as 3,500 acres, Mr. Martin estimates, have been opened and planted with coffee, cardamoms and tea. Sir John Muir (or one of his Companies) has 6,000 acres and has opened chiefly in coffee and cardamoms. Mr. O. A. Bannatine, formerly of Maskeliya, is one of four partners who have taken up 2,500 acres and he has opened some hundreds. Mr. Martin himself has 1,500 acres with 400 opened—300 or so in tea and 100 in cardamoms. The latter product may be said to be indigenous and a good deal of income has been made last year from gathering cardamoms in the jungle. Mr. Martin speaks well of the labour supply, though not many workers can be got, during crop time in the ricefields in the lowcountry. As for transport, Coimbatore is 45 miles off; but another station 20 miles nearer will soon have the railway, and Governor Havelock, true to his promise, is giving the district a

cart-road right into the estates, the trace being now cut through Mr. Martin's property. This for a district only three years old is exceedingly good and the Annamalai planters altogether will have cause to regret the retirement of Sir Arthur Havelock who has taken a warm personal interest in their advancement,—an advancement, however, which brings benefit to the whole community.

All the products grown look very promising. Mr. Martin's elevation is about 3,500 feet with magnificent outlooks to the Travancore Hills. The climate is hotter than in Ceylon at the same altitude and the rainfall (which is much above the average this year) though plentiful, is not well distributed, rendering some months about April rather unhealthy. Nevertheless, we could only congratulate Mr. Martin on looking so "fit" after his hard work as pioneer, and we added that he ought to have had a dozen or score of paying "creepers" to benefit by what can so rarely be got now, real jungle work in clearing and planting, away from railways and roads with few or no luxuries. Such an experience it is that makes the contented planter—contented when eventually he sees all in order, and the cart-road within hailing distance. We may add that the terms for these Annamalai lands are 50 cents a year per acre rent and one rupee on land planted and in bearing, the lease being for 30 years with the privilege of renewal for another 30 years on the same terms. The Madras Government do not intend to give out any more land beyond the 25,000 acres; but there are some blocks which were taken up by Ceylon men who have never touched them. These we suppose, or rather their leases, are probably available for sale or transfer, if the claims have not expired. Meantime we congratulate Messrs. Martin and Bannatine and other Ceylon friends on their good prospects and trust they may have the due reward of their labour.

TEA IN SOUTH CAROLINA, UNITED STATES.

We are indebted to several home correspondents for cuttings from the London *Times* and other papers respecting tea-growing in Carolina, as if it were an important matter to us in Ceylon. But with labour at a dollar a day, no tea industry can ever grow to much in the Southern States.

Plantation Doctors in California.—In the long ago there were doctors for the "coloured pussons" held in bondage on Southern plantations; now it is the plants cultivated that are treated by doctors—or their equivalent; for we find, according to the report of the Californian State Board of Horticulture, that inspectors are required to make plants of infected orchards, showing the exact location of each infested tree; and as a result of the careful work of the inspectors, great success has attended their efforts. Twenty-eight orchards in Riverside County, which in 1897 had a total infection of 1609 trees, had in 1899 only 433, a reduction of over 73 per cent.—*Gardeners' Chronicle*, Sept. 8.

BRITISH ASSOCIATION AT BRADFORD.

BOTANICAL SECTION.

Mr. J Parkins read a paper on "Fungi found in Ceylon growing upon Scale-Insects."

GERMAN EAST AFRICA: PROGRESS IN DEVELOPMENT.

The Foreign Office has just issued encyclopædia report by Mr. Vice-Consul Dundas on German East Africa from 1892 to 1899. It opens with a description of the boundaries, position, and size of the territory, its lakes, rivers, climates, history from the most ancient times, population, administration, public health (including the hospital accommodation), posts and telegraphs, agriculture, industry, lighthouses, shipping, roads, transport, imports and exports, schools, troops, the military expeditions, the various divisions, with details as to the condition of each, and much other information of a similar kind. Under the head of population, some remarks occur on the two classes of Bant tribes, known as the elder and the younger, which should prove of interest to ethnologists. The imports and exports increase year by year, and in 1898 amounted to £581,013 for imports and £212,399 for exports. Cotton goods amount to nearly half the imports, foodstuffs and other provisions coming next in importance; while the main exports are ivory, rubber, copra, copal, sesame, and coffee. The export of ivory, however, appears to be decreasing, as Congo ivory now goes by the West Coast, while that from Uganda is exported by Mombasa. Zanzibar has a preponderating share in both the import and export trade. On the whole, Mr. Dundas says that the general impression left on the traveller in the region is that the German Government has thrown its heart into the thorough development of East Africa. "No stone has been left unturned, no opportunity missed, to make the most of everything to be found in the territory, which undoubtedly possesses many natural and rich resources. The Government loses no time in ascertaining the natural wealth of the country, and no money is spared in making experiments. The planter and farmer are not behindhand in their endeavours, and are content to spend their money freely in hopes of getting a large return later on. Some have obtained very reasonable results. The British trader does not appear to have thought it worth his while to try his fortune in this the largest of German colonies. The cause is probably not far to seek. He no doubt would not be satisfied to have small results at first, and therefore seeks out some other place. He also expects to have everything his own way. His prospectuses, price lists, inquiries must all be in his mother tongue, regardless of the fact that those to whom he sends them are foreigners, and perhaps not conversant with the English language. The largest foreign community is, of course, the Indian. They appear to be in a flourishing state, although complaints are made as regards taxation. This grievance is in reality quite unfounded. Zanzibar and Mombasa, both so close at hand, spoil the Indian and native as regards taxation. They fail to understand the difference which must necessarily prevail here regarding taxation, and they cannot discriminate between rates and taxes. The East Indian traders must bear in mind that, though somewhat more heavily taxed than in India, they make more than in India. Moreover, the want of knowledge of the German language and Govern-

ment system is a great disadvantage to them. They have been too prone to expect the same conditions of life under German rule that they were accustomed to in India and Zanzibar."—London *Times*, Aug. 27.

SIR JOHN LAWES AND SCIENTIFIC AGRICULTURE: THE FIRST EXPERIMENTAL STATION AND RESULTS.

In 1842 a patent taken out for treating mineral phosphates with sulphuric acid marked the beginning of the manufacture of artificial manures, an industry which has since attained enormous dimensions. In 1843 a young chemist, Dr, (now Sir) J Henry Gilbert, a former pupil of Liebig, became associated with Mr. Lawes, and the foundation of the Rothamsted Agricultural Experiment Station dates from that year. With the exception of the station founded by Boussingault at Bechelbronn in Alsace, the Rothamsted station is older than any other, for the earliest German station (Möckern) was not founded till 1852, whilst the first of the American stations (Middletown, Connecticut) dates only from 1875.

The plot upon which wheat has been continuously grown, year after year, for more than 50 years without manure of any kind, the land merely being kept free from weeds, is in the highest degree remarkable, for it has given over the whole period an average yield of between 13 and 14 bushels o dressed grain per acre, which is more than the annual average yield of the crop as grown in the United States and several other leading wheat countries. The manurial experiments upon the mixed herbage of permanent meadow, carried out over a long series of years, have yielded results of the highest practical value, and in particular they have shown what a dominant factor is the character of the season in determining the size and the quality of the crop. The field experiments in general have demonstrated how essential are nitrogenous manures for cereal crops, potash manures for leguminous crops and phosphate manures for turnips and swedes. The relative values of sulphate of ammonia and nitrate of soda as sources of nitrogen, the composition of rain and drainage waters, he utilization of town sewage, and the manufacture of silage are other lines of inquiry which in turn received attention. The publication in 1861 of the classical memoir on the sources of the nitrogen of vegetation marked an epoch in the history of plant physiology. The question as to whether plants assimilate free or uncombined nitrogen was answered unreservedly in the negative, and for more than a quarter of a century this was regarded as a cardinal doctrine, if so it may be termed, of physiological faith. But, as our knowledge of micro-organisms advanced, the position taken up with so much confidence had to be reviewed, and in 1891 it was admitted, in a Rothamsted paper dealing with the sources of the nitrogen of our leguminous crops, that considerable fixation of free nitrogen may—and does—take place. In his brochure on "Fertility," published in 1881, Sir John Lawes stereotyped the views which he had enunciated 20 years previously, and thereby added much to the difficulty of modifying his opinions at a subsequent date. The 70 pages of this masterly pamphlet all pointed to one conclusion—that the soil is a mine and not a laboratory. The author wrote:—"If the evidence of the Rothamsted experiments up to the present time has not established beyond all cavil that practically the source of the whole of the nitrogen in our crops is the store within the soil itself, and the nitrogenous manures brought upon it, there can be little doubt that in the course of their future progress they will afford conclusive evidence on this point." Nevertheless, ten years subsequent to the publication of these words conclusive evidence came from Rothamsted itself which pointed in quite the opposite direction. It is a matter of regret that if Sir John Lawes did not find an opportunity of rewriting his essay on "Fertility" in the light of the fuller knowledge since attained of the micro-organisms of the soil.—London *Times* Sept. 1.

THE ACME TEA CHEST.

A planter having complained of the weight of the tea chest on inspection in our office, we are able to give the following information:—"About 17 lb. are the tares of the acme veneers complete against say 26 lb. for momies including hoops, lead, nails, etc. If your planting friend refers to gross weights then: A size of chest when filled with Souchongs, Pekoe Souchongs, or Pekoes comes in well under the 129 lb. limit of London warehouses, and B size (smaller) suits, in the same way, for B.P., etc."

PLANTING NOTES.

The Coffee Crop in Nicaragua for this season is estimated, by both Government and planters, at fully 150,000 bags, as against 75,000 bags for the last season; the export duty on which will amount to 300,000 pesos, or sufficient to pay the interest on the foreign debt of $1,400,000 and leave a handsome surplus of $40,000 or $50,000 gold.—*British Trade Journal.*

The Nyassaland Agri-Horticultural Society's Committee held a meeting on Thursday evening when they made some important changes in the published list of classes to which they wish attention drawn. Also to the additional notice at the end of the advertisement. Next week the prize list, which is a very good one (over £130) will be published in full.—*Central African Times*, August 18.

Basic Slag on Clay Soils.—A writer in a weekly contemporary praises in generous terms the beneficial effects of basic slag on the stiff weald clays of Sussex. The use of this phosphatic manure on the Uckfield College and neighbouring pastures has been productive of extraordinary results, grass land that a few years ago was scarcely deserving of the name having been rendered productive and fertile by the prudent application of this substance. The basic slag answered well alone, but it was most effectual when employed with sulphate of ammonia, the weight of yield being increased by the addition of two cwt per acre of nitrogenous dressing, while the quality of the herbage was of a better order than when nitrate of soda was the accompanying substance. The writer relates a striking instance of an incredible farmer in proximity to the college being brought a convert to the virtues of basic slag through practical demonstration of its effects. After much persuasion he was induced to dress part of a grass field with the manure, and so clear and tangible was the result that he is now an extensive user and a strong advocate of the material. For clay soils there seems to be no more serviceable artificial manure than basic slag.—*Journal of Horticulture and Cottage Gardener*, Sept. 6.

Pruning oftentimes is entered upon with the impartiality of Mrs. Squeers, when that estimable being dispensed her brimstone and treacle, "if they didn't need it then, they might at some other time." No pruning at all would be better in the end than this, but it would be vastly better than either, were trees properly pruned at planting, and yearly cared for to keep them in the right way.—*Queensland Country Life*, Aug. 23.

The Parsley-leaved Bramble.—Any time from the end of October onwards to March is suitable for planting this useful Bramble, provided the weather be suitable for the operation. Perhaps early in November is as good a time as any. It is done the same as planting Raspberries. Fertile yet rather porous soil is best, as the plants do not become established quickly in cold heavy land. This Bramble is good for covering walls or fences, or it may be trained in the form of arches over walks, or in any other convenient manner desired. When it commences bearing all that is necessary is to cut the portions out and retain the best of the young growths, is in growing Raspberries.—F.—*Journal of Horticulture and Cottage Gardener*, Sept. 6.

How Water Ascends in Plants.—At one time there was considerable difference of opinion as to the course pursued by the sap of trees in ascending from the roots, and that followed by the food materials elaborated in the leaves when being transferred to the various portions of the tree in which their process of growth was in progress. It has now been established that all the moisture required by the tree or plant for its existence and growth is taken up by the roots, and that the water so absorbed is conveyed to the higher regions through the medium of the woody part of the stem. On the other hand the food material elaborated by the leaves are conveyed to the various parts of the plant system by the bast tissues which immediately underlie the bark, and are ranged around the outside of the wood.—*Journal of Horticulture.*

Trade of British New Guinea.—The annual report of British New Guinea for the year ending June 30th, 1899, shows that the exports of indiarubber for that year were £1,935, against £3,683 in the previous year. Of sandalwood £2,920 worth were exported, a decrease of £20 on the previous year. The report goes on to say that the decrease in indiarubber is probably partly due to the most accessible country near the coast having been more or less worked out. At present, also, it is next to impossible to prevent the destruction of the trees in new country. Apparently the export of sandalwood may increase during the coming year, as the price has risen. The industry is now carried on in a more systematic fashion than it used to be.—*British and Colonial Druggist*, Aug. 24.

Sir John Lawes, says the London *Times* —was one of the greatest benefactors of agriculture—perhaps the greatest—the world has seen. His originality in experimental research and his inflexibility of purpose, coupled with a genius of no ordinary kind, enabled him to discover grand truths which have had a profound influence upon the progress of agriculture. Happily, through the munificence of their founder, the Rothamsted experiments do not cease at his death. By a trust deed, executed in 1889, Sir John Lawes set apart a sum of £100,000, together with the laboratory and certain areas of land, for the prosecution of the investigations in perpetuity. The unique feature of the work at Rothamsted—its long unbroken continuity—will thus be characteristic of it in an ever-increasing degree.

Various Essences and Perfumes can be obtained, says the last annual report of the Government of Cyprus, from the aromatic herbs growing in the State forests, and experiments are being made to ascertain whether they can be produced on a commercial scale to yield a fair profit. There is a small Government garden at Nicosia from which plants are distributed so far as means will allow; but there are no botanical stations.—*B. and C. Druggist*, Aug 24.

Planting in Nyassaland.—Our correspondent, Mr. Henry Brown, formerly of Matale and Dimbula, fairly takes our breath away by his enumeration of all the good things to be enjoyed, and produced, in his adopted land; and yet who ever heard of any one making money in Nyassaland—and can Mr. Brown tell us of half-a dozen men who have stood and enjoyed the climate as long as he has himself with his exceptionally strong constitution? It is, however, extremely interesting to read about the growth of so many old and new products—chillies and fruit among the rest.

Ceylon Tea in New Zealand.—We direct attention to a letter on another page from Mr. G T K Mackenzie of Dunedin, who has taken a leading part in pushing the sale of pure Ceylon tea in New Zealand. It will be observed that he complains of a move on the part of certain local dealers to get an import tax placed on packet teas imported from Ceylon and yet the same agitators are so inconsistent as to say that such Ceylon packets are far inferior to their own, inasmuch as our "coolie" labourers who pack, cannot be depended on for cleanliness. Now Mr B.—or who ever he is who urges this argument - shows the crassest ignorance of Ceylon conditions, inasmuch as every factory and store manager here is most particular about all the workers in tea,—whether firing, sorting or packing—being specially tidy and clean. If the New Zealand authorities are so ill-advised as to tax our packets of pure tea, it will be to the distinct disadvantage of their own people, and moreover it may lead to a disagreeable reprisal one of these days.

Dearer Quinine.—By the last advance of cinchona bark at the Amsterdam auctions, which nowadays are the means through which the world obtains almost the whole of its quinine, the price of bark has reached the highest point touched in recent years, ever since, in fact, Holland and Java became what they are. Quinine has advanced in consequence though it has not yet reached the price to which it attained last year. This is mainly due to the fact that specnlators are not so weak and "heady" a body as they were twelve months ago The "small" men got severely bitten in many cases then, and have left the article alone since. The result has been beneficial to the quinine market, which today occupies a sounder position. It is, as we show in an editorial note, a cause for congratulation that, after six months of consistent high prices, quinine is cheaper than it was after one sudden leap on the part of bark to a less height than it now occupies. Another healthy sign is that the London stocks of quinine have been reduced during the last two months after a long period of increase. Speculators are still commendably cautious, and makers, though eager buyers of barks at the high rates, keep their price of quinine in close touch with that of cinchona. The outlook is thus very promising, especially as the autumn demand is near at hand.—*B. & C. Druggist*, Aug. 31.

TEA AND THIBET: "GREEN" *vs.* BRICK TEA.

In the absence of any practical experiment it is, of course, impossible to say how great a measure of success would attend an attempt to create a demand for Indian tea in Thibet, but it should most certainly be made. Although the proposal to manufacture green tea for the American market has fallen rather flat with Assam and Bengal planters, a proposal to manufacture brick tea would probably meet with some response. The tea refuse, etc., which Messrs. Barlow & Co. offer to dispose of, would not in any way affect brick tea manufacture, as the latter would be made from prunings, etc. It would, of course, take some time for the commodity to establish a market for itself, and for it to do so at all would doubtless prove a matter of much difficulty, but as the tea would be manufactured from material, which at present is not utilised at all, planters in Assam and Bengal would find it to their advantage to make it. Mr. A Dalgleish pointed out in 1881 that the Thibetan market was "capable of taking all the surplus tea for which, in the home market, there is no demand," and, further stated that it was one which "we can supply without increase of production, and at the same time without withdrawing a single pound of the tea which can find a sale in the London market." There were at the time opponents to the scheme propounded by Mr. Dalgleish, who thought it better to look for a market to America and the English Colonies rather than to Thibet, but this, we think, was due to a misapprehension of Mr. Dalgleish's plans. The trade in brick tea with Thibet would not be in preference to, but in addition to, extension in other directions. The Thibet market and the others are entirely distinct, and the kind of tea required for the former is an altogether different article to that required by the home and foreign markets, and would not in any way interfere with our export trade with other countries.—*Indian Planters' Gazette*, Sept. 15.

CHEAP BANANAS:

EFFECT OF THE NEW WEST INDIAN MAIL SERVICE.

Bristol is to be the port. and London the chief market for the new West Indian service, which Messrs. Elder, Dempster and Company are inaugurating immediately after Christmas next. The new service is to carry mails and merchandise as well as passengers. It is to help the West Indies to forget the iniquities of a foreign sugar bounty system, and it is to place West Indian fruits and other products on the English markets to an extent never before attempted. The start with, the English consumer will be invited, on tempting terms, to dispose of 500 tons of bananas a fortnight.

Steamers will arrive at Avonmouth and discharge direct on to the railway alongside. Two hours later the boat trains will be at Paddington, or, if needs be, Midland trains can be loaded by the waterside and sent without loss of time to the heart of England. The Bristol Dock authorities have been bestirring themselves to cope with the new traffic. Along the Avonmouth quayside a passenger station and fruit store are to be provided, as well as other necessary accommodation, at a cost of £16,000. The Bristol Chamber of Commerce has established a West Indian section, and the section is sending out a Commissioner who is going to arrange forthwith for an exhibition in Jamaica or Bristol manufactures.

It is under a ten years' contract with the Crown Agents for the Colonies that Elder, Dampster and Co. are establishing the new service, the Government paying a yearly subsidy of £40,000. For the first three years the steamers employed must have a carrying capacity of not less than 3,000 tons, accommodation for fifty-five passengers, and be capable of a speed of 15 knots an hour; and another stipulation is that every boat shall bring over 20,000 bunches of bananas (equal to 500 tons.) After three years have elapsed boats capable of carrying 5,000 tons cargo and 150 passengers will be placed on the service.

The first steamer dispatched from Bristol will be the "Port Royal," which will leave on Jan. 16th She is one of four steamers being specially constructed for the line, and has accommodation for one hundred first-class passengers, fifty second-class passengers and 5,000 tons cargo. It is reckoned that she will do the trip to Jamaica in eleven or twelve days, and it is likely that Mr. and Mrs. Chamberlain will be amongst the party travelling by her in January. At all events they have expressed a wish to be with the first passengers by the new service. The service to Jamaica will be fortnightly to begin with; later it may be weekly; and one of its special features will be low fares to boys and girls sent from the West Indies for education in England.

The large quantities of fruit that each steamer will bring to England will be conveyed in holds specially adapted. In each hold the temperature will be kept uniformly low. Bananas will be ranged in rows or "streets," and all that science and experience can suggest to achieve the best results will be done. Experts have already left for the West Indies to make arrangements for the collection and shipment of fruit, and an expenditure of £30,000 will be incurred on account of cooling machinery. It is evident that in Jamaica big things are expected of the new service, for the report is that already land there has gone up ten per cent in value.—*Daily Chronicle*, Aug, 31.

SCIENCE AND TEA PLANTING

In your issue of 19th July, page 45, Mr. Stebbing asks me how I propose to carry out the natural desire to make tea "pay." He refers to my letter in yours of 28th June and in that I said that what we want to know is how to make an unprofitable garden pay and how to improve the tea of that garden and the way to do so is to get such a garden and improve it.

I contend that an experimental garden would be of greater value than a scientist. Of course if the scientist could be employed *on* that garden it would become of greater value.

Mr. Stebbing says that my views are not shared by the bulk of planters, but I note (in yours of 16th August, page 110) that Mr. H. J. Lawrie, in his speech, has almost repeated what I said about Mr. Bamber and the value of another scientific investigator. If Mr. Mann could be placed in charge of a tea garden, with an experienced assistant to teach him the rudiments of tea planting, there is no doubt that he would do great things. He would then investigate tea pests, and the question of "fermentation" from their proper base, *i.e.*, in regard to "profit,"

He could try all the proposed remedies for pests, and he could try all the latest discoveries in tea-making, such as red lights for the colouring room, or the refrigerating process. I see that Mr. Stebbing agrees generally with the proposal for an experimental garden, and I fancy that he imagines that I am running down the scientific officer himself. I do not doubt that Mr. Bamber, for instance, did *some* good for tea planting, but he made no discoveries, and has done little more than compile an encyclopœdia of existing knowledge, and in my opinion Mr Mann will accomplish no more unless he is fixed to one place and investigates improvements which are practicable and profitable. Supposing that the garden he takes over has been making 6 anna tea for the last five years and a yield of four maunds per acre ; he will try all sorts of manures, giving their costs and the results in increased yield ; and he would try various methods of manufacture, and keep records of results. He might, if he pleased, analyse the soil before manuring and tell us that he returned so much per acre of what was wanting, but that information alone, without the facts as to increased yield and cost of manuring, would be of no interest or use to tea planters. The decadence of every moriband tea estate can be placed to the faults of the proprietors. As a rule, they grudge funds for absolute necessities ; they imagine that money cut off from the expenditure means so much more profit. What we want is an experimental garden which will show the proprietors that a certain course of action ought to result in a certain profit, and they will *then* find money for the necessary improvements.

A large number of estates pay handsomely, and it may be asked why these should subscribe to show the way to their less fortunate brethren. There is nothing more certain than that tea planting is a progressive industry. Every manager should look ahead. He should find out what he should do if his tea goes down one or two annas per pound. I would not mind betting that within six years Assam tea will go down two annas per pound, and that the tea of other districts will remain at the present figure. How many Assam planters reckon on a loss of two annas per pound ? If this does happen they *must* make more tea per acre and the experimental garden will show them how to do it. The decadence of Assam averages is hardly a part of the heading of this letter, but as I have mentioned it I may as well give my reasons. Assam tea prices are not given for their value for drinking, but only because of their ability to bolster up weaker teas. Every improvement in the weaker teas will thus decrease the value of the "strengthening" Assams. The weaker teas will have to improve to keep their present prices, and they *will* improve ; each year sees improved machinery and process. Whatever happens, even the best estate *must* look ahead and be prepared to increase its yield if necessary ; the necessary knowledge can be acquired and stored up by the experimental garden. I would bar all catch crops, we want to know how to make "*tea*" pay. Universal improvement will not reduce the value of our teas, in fact, it is only by steady and marked improvement in the quality of our tea *as a whole* that we shall be able to extend our markets and oust the Mongolians Mr. Lawrie said that every pice that we can spare should be used in opening out new markets, but improved quality of tea will be a great factor in doing so. Is it too late to have both the scientific officer *and* the experimental garden? The cheapest way would be to lease a garden which does not pay, for a period of five years ; the same could be done five years hence in another district.

The great difficulty in experiments is keeping accurate records, and a scientific man would of course have been trained to keep records.

I should imagine that some of the larger companies would be glad to lease out say 200 acres of their worst tea, and allow the scientist to investigate the manufacture of their teas. The vendors of manures would give their goods free of cost as an advertisement. New tea machinery would also be given free of cost till proved of value.

I agree with Mr. Stebbing as to the possibilities of catch crops, but they must be kept severely apart from tea science. Catch crops will only enable bad gardens to hang on longer, and swamp our market for the sake of a small profit from other crops.—A.C.—*Indian Gardening and Planting.*

PLANTING NOTES.

Orchid Fibre.—Orchids are famous for beauty and general attractiveness, but it is not generally known that they have a place in the arts that ministers to the physical wants of man. But in some parts of the tropics, where Orchids abound, a very delicate fibre is prepared by the natives which they use in the preparation of the many ornaments these races prepare for trade with the paler races of men.—*Journal of Horticulture.*

Phenomenal Sale of African Mahogany.—On the 24th ult., at the auction sale of Messrs. Edward Chaloner & Co., at Liverpool, two logs of African mahogany were sold for the unprecedented amount of 1,536*l*. These logs formed one tree, and were bought for the purpose of being cut into veneers for the decoration of the palatial residences of some of the merchant princes of the United States of America. The veneers are used in the place of wall paper, and, being beautifully figured, give a superb effect. The prices realized for the two logs were respectively 10s 3d and 7s 3d per superficial foot, which is a record for African mahogany logs in the rough state, as imported.—*British Trade Journal*, Sept. 1.

The Glut of Fruit.—With the present enormous fruit crop, especially Plums and Damsons, it is devoutly to be hoped that means are being taken to preserve it whole, or as jam, so that the cultivators will not be losers by the bounty of Providence. Such bulky goods at the present onerous freight rates charged by the railways often cost more in transit charges than they sell for, but preserved on the spot, or in the vicinity of the fruit orchards, their bulk is considerably reduced and their distribution as preserves made lighter and much less costly. We hear this year of Cherries and Plums left to rot on the ground, and it will doubtless happen that much of the Damson crop will be a loss to the growers because of low price and high railway rates, unless something be forthwith undertaken to turn the fruit into a marketable commodity.—*Gardeners' Chronicle*, Sept. 8.

A Substitute for Turf on Lawns.—In *Die Gartenwelt* for Augnst 25 last, we remarked that a correspondent recommends as a substitute for grass in dry places under trees, and in any place where grass does not succeed, or mowing is not desirable, Veronica repens (erroneously called V. alpina). V. repens is but little known in gardens, but it is a plant worthy of being highly recommended. The plants form a regular, green, fresh-looking carpet, and possesses the desirable attribute of not suffering in unfavourable weather. The plant is covered in the spring with innumerable whitish flowers, so that the lawn looks then as if covered with fresh-fallen snow. The plant is propagated by division after the flowering is over in April, much in the same manner as Violets and Chamomile are treated, and the plantlets set out at 6 inches asunder in well-tilled soil, being copiously afforded water at the start. In four or five weeks the plants will have grown together. Although the plant endures uninjured every sort of weather, it is advisable in time of drought to sprinkle overhead freely once a day.—*Ibid.*

MUCH ADO ABOUT COIR.

[How time and money are wasted at the Imperial Institute.—Ed. *T.A.*]

It is recorded in the abstract of the proceedings at the thirty-first meeting, on the 11th April, 1899, of the Indian Section Sub-Committee of the Imperial Institute, Sir Stenart Clive Bayley, K.C.S.I., in the chair, that Sir George Birdwood, one of the members of the Committee, reported that enquiries had been made by firms anxious to import coir fibre into the United Kingdom direct from India as to the best means of obtaining supplies, and also the amount of our coir fibre available for this purpose, and that the information asked for had been obtained and communicated at once to the enquirers. Yet, towards the close of last year Sir Frederick Abel, Bart, K.C.B., D.C.L., &c., the Honorary Secretary and Director of the Institute, was moved to place himself in epistolary communication, by what is departmentally described as the "flying seal,"—whatever that may mean—with Dr. George Watt, C.I.E., Reporter in Calcutta on Economic Products to the Government of India, on the subject of coir. His letter is not given in the Annual Report of the Institute, which was presented to both Houses of Parliament by the Secretary of State for India, on behalf of the section, last month, nor is even an abstract of it offered. Whether the Institute had it in mind to improve its slender finances by

A LITTLE DABBLE IN COIR YARN,

or whether the Director only thought of ascertaining where he could secure, on exceptionally favourable terms, the means for covering the floors of the long, and generally empty corridors of the Institute with coir matting, is thus left to the imagination. Be this as it may, the Reporter immediately placed himself in communication with various members of the mercantile community of Calcutta.

Thus it was that he was informed by Messrs. Bathgate Pim & Co., that they "handle that article to some extent," but they were of opinion that coir "of better quality at a cheaper price is to be obtained in Ceylon than in Calcutta." They determined, therefore, to send on the Reporter's letter to their firm in Colombo. In due course the Ceylon firm informed him that it would be glad "to undertake to supply annually the 300 to 400 tons of coir desired by the Imperial Institute authorities. As we are uncertain as to what form of coir is wanted, we are sending to you, under separate cover, samples of the products of the coconut husk, viz.: mattress fibre, first and second quality, bristle fibre, coir yarn, and coir dust. Please indicate which of these products is required by the Imperial Institute authorities." Messrs. McLeod and Co., of Calcutta, stated that they were large shippers of coir, and that they would be obliged if the Reporter would favour them with full particulars of his requirements in order that they might be in a position to follow up the matter. Messrs. Blackwood Blackwood & Co. wrote that they were in a position to do business in coir, and would be pleased to learn if tenders for the supply of the article were required, and what quality was needed. Messrs. Ullmann Hirschtorn & Co. similarly expressed a wish to have details, together with a sample of the coir required. Messrs. Simpson & Co. said that they would be much obliged to the Reporter if he would favour them with the name and address of the officer in charge of the Institute to enable them to address him direct on the subject of coir. Messrs. F. Munjie & Co. wrote:—"Referring to your enquiry regarding any merchants in Calcutta who might be able and willing to undertake the supply of coir, we beg to state that we are able and willing to do the same, whether coir, coir fibre, or coir yarn, up to any quantity that you may desire, and all qualities, as we are thoroughly conversant with this class of business, and shall be glad to wait upon you with our samples and quotations on receipt of your reply mentioning the class of goods you require." Finally, the Inspector-General of Jails reported that his Department was prepared to supply coir fibre to the Institute and he asked for a statement of conditions and other particulars.

But it seems at last to have dawned on the Reporter that he had not addressed to his enquiries

TO THE BEST QUARTER,

for he was informed by the Bombay Chamber of Commerce that there were shippers of coir on the Malabar Coast, notably Messrs. Volkart Brothers, of Cochin and Tellicherry, and Messrs. Peirce Leslie & Co., of Cochin and Calicut. The Chamber then remarked that the latter "have their firm in London (2 Lime Street Square), and if the Director of the Scientific Department of the Imperial Institute will communicate with them he will no doubt obtain all possible information regarding the article." In other words, the Director could have obtained all the information that he needed on the subject of the supply of coir by trotting down from Kensington to the City, or writing a few lines to some well-informed commercial acquaintance in Mincing Lane, who would probably have placed himself at once in telephonic, or personal communication with Messrs. Peirce Leslie & Co., or some other firm of experts round the corner. The Collector of Malabar was referred to by the Madras Board of Revenue, and he said that Messrs. Peirce Leslie & Co. were willing to give the information that was desired. Meanwhile, however, the Deputy Collector at Cochin had referred to Messrs Aspinall & Co., Messrs. Grieve & Company, Messrs. Peirce Leslie & Co., Messrs Volkart Brothers, Messrs Ramachandra Mahadeva & Co., Mr Dharsey Khetser, Mr Gulaveney, Mr Kassein Haji Ibraim, Mr Kadam Kandi, and Mr Moidin Kutli, all of Cochin, about procuring "brush and mat fibre," and the majority of these merchants said that they were willing to undertake the supply of the required quality and quantity of fibre. Messrs Peirce Leslie & Co. remarked that they were unable to give the information regarding the quality of fibre wanted by the Director in the absence of sample, but they suggested that the shipment of fibre can be made from Cochin to London direct to save the heavy cost of sending it to Madras.

The Collector of South Canara was also referred to by the Board of Revenue, and he placed himself in communication with Messrs Peirce Leslie and Co. at Mangalore, who informed him that the supply of "coir fibre in this District is small in comparison with the quantity obtainable in the Malabar District, and we do not think any firm here could ship to Europe at a price that would compete with shipments

FROM COCHIN AND CALICUT.

Our firm at these latter ports, we may mention, ship annually large quantities of coir fibre and yarn to Europe, and if Mr G W R Curtis would communicate with our London office, through whom all our business in Europe is worked, they would be pleased to give him all information, and to submit him samples with quotations of the various qualities usually exported from the Malabar Coast". Thereupon the Collector reported to the Board that there are two of the European firms at Mangalore who "do not wish to enter into the business of supplying coir or coconut fibre to Mr. G. W. R. Curtis, while the remaining firm, Messrs Peirce Leslie & Co., say that their London office would be pleased to give Mr Curtis all the information that he would require, and submit to him samples with quotations of the various qualities usually exported from the Malabar Coast. I do not think that any native firm would undertake the business." The record throws no light, sad to say, on the domicile, occupation, or needs of Mr. Curtis. But there is reason to suppose that he is one of the exceedingly few individuals who yielded in the year under notice to the temptation of making an enquiry of the Indian Section of the Imperial Institute about an Indian product that is thoroughly well understood in "the Lane," since some 152,800 tons of coir of the value of 2¾ crores of

rupees, or about £1,850,000, were shipped from India —mostly from the Malabar Coast—in the ten years ending 1897-98, the greater portion of which was "handled" in London.

The Report omits to state what was the outcome

OF ALL THE CORRESPONDENCE

that was caused by the Director's enquiry. Perhaps the subject is still under the consideration of the Indian Section, which is so badly off for something of a really useful nature to do. But the episode serves to show once again, that the "economic products" of India can be studied far better in the business haunts, of those who trade largely in them than at the Institute, whose motto might well be "Great cry but little wool." The suggestion would not perhaps commend itself to Mr. J R Royle, C.I.E., the Secretary and Curator of the Indian Section, who draws a salary of £500 a year. For, on the 24th October last, at a meeting of the Sub-Committee, a letter was read from him, in which he drew "attention to the fact that the present term of his appointment would expire on the 31st March, 1900, and asking whether it would be renewed, and if some addition to his salary could not be recommended." The Sub-Committee thereupon drafted a letter to the Secretary of State for India, in which it may, or may not have asked for enhancement of the salary. But as no more than £500 is budgeted for in the estimate of expenditure for 1900-1901 it may be concluded that Lord George Hamilton, while approving of the rentention of the services of Mr. Royle, regretted his inability to sanction an increase in conformity with the wishes of the present incumbent of the Curator's office. To most people who study the Report of the Sub-Committee it will probably appear that a salary of £500 does not err on the side of illiberality, for it means an expenditure by India of R625 per mensem, for which there is very little in the way of benefit to India to show.—*Madras Mail.*

RICE.

CHANGES IN THE VARIETY HANDLED ON THE PACIFIC COAST.

Within the last year or two, says the *San Francisco Grocer and Country Merchant*, a great change has come over the position of rice in this market. Up till that time the chief description sold here to white people was the Hawaiian product, which, under the reciprocity treaty came in free of duty; but since then the imports of this variety fell off, until it has almost completely disappeared, and is no longer a factor in the trade. The cultivation of rice in the islands appear to have largely give way to that of sugar cane and the more profitable articles; and the increase of the local population has not only consumed all that was raised there, but has called for extensive shipments of Louisiana rice from this market, as well as of other descriptions from China and Japan. Their normal parity, in fact, has been and is above ours; under which circumstances evidently they can send us little or no rice.

As the Island supply became exhausted, domestic consumption turned to the Japanese article or to that from Louisiana, according to which was the cheaper. Of late this has been the Louisiana article, as crops have been abundant there and prices low, while on the other hand values in the Orient, owing to the Indian famine, have been abnormally high. Jobbers have naturally given all possible encouragement to the Louisiana article, as, owing to the great varieties of it that are always on offer, it affords a much better chance of a profit than the foreign descriptions that come only in standard grades, and are consequently sold for the slimmest sort of a margin. The off grads of foreign would not be worth the freight here and the import duty; and consequently they are consumed at home, where, in fact, they constitute the staple diet of the people. The wonder is that jobbers do not follow the same policy with regard to sugar, instead of co-operating with the Trust to restrict the sale to limited varieties at fixed prices.

The changes that have taken place in the character of the staple consumed on the Pacific Coast have naturally given rise to a good deal of substitution and misrepresentation, which, when once stated, is apt to become by force of competition, more or less general. Louisiana was first substituted for Island, and now Louisiana, Japan, or rice grown in Lonisiana from Japan seed, is being substituted for the genuine imported article. In many cases it is difficult, except for an expert to distinguish on sight, the one from the other, but on cooking the difference is quite manifest since the seed article does not cook dry and free like the imported, but comes out more or less gluey or mushy, so that the Japanese at least cannot be deceived by it; and it would be well for our readers to take note of this fact.

Another substitution that is now being tried is a mixture of a large proportion of low-grade Louisiana with China mixed for the genuine China mixed, the market value of which is always known to a nicety, and which consequently generally sells very close to cost. A practised eye will, by comparison, at least, readily detect the difference in this case by the size and appearance of the grain. The name "China mixed" unfortunately ends itself too easily to this sort of substitution, and should never have been adopted. It is in reality not China rice at all, but rice grown by Chinamen in Siam and shipped here via Hong Kong, thus covering up its origin.

While on the subject of rice it may be opportune to caution our less experienced readers against receiving any old and weevily stock in their warehouses and thereby infecting their goods, which very readily occurs. This, of course, is not likely to be sent them from any responsible source, as it is, in fact, tantamount to a crime. Fortunately, however, it is easy of detection, for if sacks containing weevily rice are left for half an hour in the sun the weevils will appear on the outside, and this is the test that consignments are subjected to by jobbers before receiving them into their warehouses. Even the exposure during the trip from the wharf, depot or warehouse is frequently sufficient to bring these animals to the surface; and goods infected in this way should never, on any account, be taken to account. The same applies to beans.

PEA NUTS OR EARTH NUTS FOR POULTRY.—In most of the coastal districts it is comparatively easy to obtain good crops of these "nuts." For poultry, according to an American authority, pea nuts are a food that can scarcely be excelled. In the experience of the authority quoted, they are far more satisfactory than maize, wheat, or oats for laying hens, as well as for growing chicks. Hens and chicks do not get so fat on them as upon grain. As a dainty to throw into the feeding yards, a few plants, nuts and all, come in very handy.—*Agricultural Gazette of New South Wales.*

Correspondence.

To the Editor.

THE DEATH OF SIR JOHN LAWES.

Analytical Laboratory 79 Mark Lane, London, E. C., September 6th, 1900.

SIR,—I send you a cutting from last Saturday's *Times* containing an appreciative memoir of the late Sir John Lawes whose death is very sincerely regretted by all those interested in agriculture who have read the numerous papers published during the past fifty years in connection with the well-known experimental plots at Rothamsted.

I have had the honor and pleasure of paying several visits to the well kept farm and the particular objects of the various experimental plots have been personally explained to me by Sir John Lawes, whose genial manner and kind hospitality always added so much to the pleasure of a visit to Rothamsted.

The writer in *The Times* in his reference to the absorption of free nitrogen from the atmosphere by leguminous plants, gives the impression that the more recent theory is, that these plants, CAN absorb free nitrogen *themselves* whereas the fact still remains as true now as it was when first enunciated by Sir John Lawes in 1861 and repeated in his essay on "Fertility" in 1881, that leguminous plants can only absorb nitrogen indirectly through the agency of bacteria, by which the primary work of fixation of the free nitrogen from the atmosphere is performed.

It may be useful to point this out as otherwise a wrong impression might be gathered from a perusal of this otherwise very correct memoir.

JOHN HUGHES.

[For the greater part of the notice in *The Times* see page 273.—ED. *T.A.*]

Re IMPORT DUTY ON TEA.

Hewaheta, Sept. 22.

SIR,—I would not abolish the import duty on tea, but would suggest that it be reduced to 25 cents per 100 lb. By so doing sufficient funds would be available to enable Government to appoint Tea Inspectors, whose duty it would be to inspect all tea coming into the Island and all tea leaving the island. Direct garden shipments might be passed without inspection, as the countries to which they go have their own inspectors.

Blends of pure Ceylon might be so stamped by the inspectors and blends of China and Indian and Ceylon stencilled in large letters across the packages.

If possible, a standard of quality should be fixed: it is not only the red leaf—for, excepting its bad appearance, it often draws a very good liquor—but some teas sold by public auction lately in Colombo consisting of whole invoices were objectionable: the dry leaf, bad in colour and smell; infused leaf, black and nasty, and liquors loathsome to the palate. Would some enterprising man get such teas analysed, possibly a standard in leaf might be fixed and a standard of liquor based on chemical analysis. Should the Tea Inspector think any teas not up to this standard of liquor he might hand samples to the Public Analyst. If Colombo became the centre of the tea industry—and I see no reason why it should not—what a grand thing for Colombo; and, as we should always be the nearest producers to the central market, I see no reason why we should not reap some advantage. The question of blending China tea with Ceylon applies just as much now, as it would if the blending were done in Colombo, except that the Government Inspectors here would have more hold than when the blending was done all over the world.

If any confusion arose *re* the import duty on Tea being mixed up with the Tea Cess, doubtless some arrangement could be come to with Government *re* division of duty, but I am inclined to think in a very few years the revenue from the import duty of 25 cents per 100 lb. would be far in excess of the cost of collecting and payment of inspectors, and Government might see its way to hand over any balance to the "Thirty Committee" for exploiting tea in foreign countries.—Yours, &c., E. T.

P.S.—Would the nominal duty of 25 cents per 100 lb. stand in the way of houses making Colombo their headquarters? I hope not.

E. T.

RUBBER PLANTING IN TOBAGO, WEST INDIES.

Richmond, Tobago, Aug. 28.

DEAR SIR,—The cultivation of rubber, particularly the Castilloa elastica, is more than likely to prove very successful in this island.

I recently sent to London a sample, weighing 21 lb., of rubber obtained from Castilloa trees I planted on this estate eight to nine years ago. It was valued at 3s 6d per lb. by Messrs. Lewis and Peat, who report that this rubber would have a ready sale at that price.

I cannot yet say what the yield of rubber per tree is here, as the experiments I made in tapping were carried out just after an exceptionally dry season; and being anxious not to run the risk of spoiling the coming seed crop, I only tapped the trees very lightly. But from a tree tapped lightly on three different occasions at a week's interval, I obtained a half-lb. of rubber.

The Castilloa does remarkably well here. One tree eight years old measures five feet in girth at three feet from the ground, and another of the same age measures four feet and ten inches.

The Louis d'Or rubber plantation, started here two years ago, is progressing exceedingly well under the able management of Mr. T. Orde. The estate has now 160 acres of Castilloa and 40 acres of Ceara rubber. There are several other estates in the island now being planted up with cacao, rubber, nutmegs and coffee, all of which thrive well in the Windward and Northern Districts.

I find that cacao bears very well under the shade of Castilloa. Nine years ago I planted an acre of rubber and cacao together—the rubbers at 24 feet apart, cacao at 12 feet—and so far I have noticed very little, if any, difference in the bearing of these cacao trees and those under the shade of the "Bois immortelles." Finding this the case I planted last year 15 acres in the same manner, and there is every reason to expect that in another eight or nine years, they will give a gross return of about £30 per acre. Coffee also bears very well under the Castilloa,

A question of great importance to rubber planters is whether a paying quantity of rubber can be got from either one year-old seedlings or saplings three to four years old. If it proves that this can be obtained, of course, close planting would be carried out, followed by a quick return. Can you give me any information on this point?

Last year I sent to England the bark of a four-year old Castilloa tree to be experimented upon. The dry bark weighed three lb. all but one oz., and it gave 4½ oz. of rubber. As this was the result of a laboratory experiment, I cannot say if the process, applied on a large scale, would make close planting profitable or not.

Another matter of great importance is to ascertain the quickest and most effective method of tapping the trees. I hope that Mr. Willis will, before long, publish details of the experiments carried on at the Gardens since the issue of his circular of June, 1899.—I am, dear sir, yours truly,

M. SHORT.

RUSSIAN TEA TRADE.

Kandy, 26th Sept.

Sir.—I herein enclose copy of letter and accompanying despatches received from Government on the subject of the effect of the Chinese Crisis on the Russian Tea Trade.—I am, sir, yours faithfully,

A. PHILIP,

Secretary, Planters' Association of Ceylon.

Colonial Secretary's Office, Colombo, 25th September, 1900.

Sir,—I am directed by His Excellency the Governor to forward to you for the information of the Planters' Association, the enclosed copy of a despatch from the Secretary of State for the Colonies, together with copies of the despatches from Her Majesty's Ambassador at St. Petersburg on the subject of the effect of the Chinese Crisis on the Russian Tea Trade.—I am, sir, your obedient servant,

(Signed) A. G. Clayton, for Colonial Secretary.

Secretary, Planters' Association of Ceylon.

(Copy No. 146. Commercial.)

St. Petersburg, 8th August, 1900.

My Lord,—With reference to my despatch No. 134 of the 26th ultimo I have the honour to transmit to your lordship herewith a further report which has been addressed to me by Mr. Cooke on the subject of the Crisis in China and the Tea Trade.—I have &c.,

(Signed) Charles S. Scott.

The Marquess of Salisbury, K.G., &c.

THE CHINESE CRISIS AND THE TEA TRADE.

The *Commercial and Industrial Gazette* of St. Peterburg, commenting on the nominal opening of the great Nijni-Novgorod Fair (July 15 to 28) with reference to the prospect of the tea trade states as follows:—The Chinese Crisis came on just when the first and principal crop at Hangkow was brought up and ready for despatch for Russia. The question is: was it safely sent away? The two routes are by sea from Hankow to Odessa, and via Siberia overland. The latter direction is either (1) by water to Liantsen and thence by land to Kaljan and through the Mongolian steppe to Kiatakor (2) along the Amur, and in this case, from Hankow by sea to Vladivostock or to Nikolaevsk. According to Moscow tea dealers, up to June 8 to 21, 1900, the purchases made were 648,955 half-chests of the first crop against) 609,052 in 1899) of which 590,306 were bought by Russian firms, or 35,552 more than last year. The first crop is the all important one in the tea trade, 2nd and 3rd crops being comparatively insignificant. This first crop being safely brought in at Hangkow, and Russia having solid supplies over from last year, though mostly of the inferior 2nd and 3rd crops, there need not as yet at least be any sensible disturbance in the international market. The whole question is how much has been despatched from Hangkow and in what direction? The disturbances became serious just as the ordinary despatch from Hangkow should have begun. Thanks to the crisis and to the shallowness and other difficulties of navigation on the Amur, the oversea route alone remained. But here too the Volunteer Fleet steamers were taken by the Government and difficulties arose in finding others. All that is known at present is that the Steamship "Kherson" (Volunteer Fleet) has arrived with tea at Odessa, as also the Steamship "Odessa," while the "Yaroslav' (Volunteer Fleet) bas passed Port Said with tea for Odessa. The English Steamship "Drumgard" chartered by the Volunteer Fleet, has left Hangkow with tea as also the "Siam" of the East Asiatic Company, the latter with 70,000 half-chests, originally destined for Siberia. More black tea was bought up at Hangkow this year than last, and bought up earlier, so the stocks there are larger. Ceylon and London teas (the latter both Chinese and Ceylon) are in greater stocks than last year, and now probably rapidly increasing. Some 30,000 chests of brick tea were sent in the spring from London to Vladivostock, after failing last year to reach Siberia via the Obi and Yenisei route. On July 1 to 14, 1900, there were 114,192 half-chests in Moscow Customs Depôts, against 66,908 in 1899. In general there is considerable doubt and hesitation in the market, all awaiting events, though some have raised prices. Prices in Siberia have risen considerably and promise to continue rising. Much depends on what trade is done at Nijni Novgorod market now opening.

(Signed) Henry Cooke.

PLANTING NOTES.

Ratwatte Cocoa Coy.—We have to thank Messrs. Geo, Steuart & Co., (agents and secretaries) for a copy of the directors' report which was to have been submitted at the annual meeting in Kandy this afternoon. It is published on another page, and shows that, while no dividend is recommended, a profit of R5,320 has been made on the crop-bearing portion of the estate and that the prospects both for tea and cocoa for the coming season, are good.

Baked Land.—A good many people who experience great difficulty in working land that bakes readily after rain may be interested in the following advice issued by the Texas Agricultural Experiment Station:—"There are several things which can be done to improve your land, the choice of which one, or of a combination of two or more, will depend upon your local surroundings. Subsoil ploughing will prove of benefit. If you combine with this a considerable quantity of lime, say at the rate of one-half ton per acre, it will perhaps prove more beneficial than anything else that you could do. But as this may be too expensive you may find it necessary to try this: Deep ploughing, eight to ten inches, and the application at the same time of large quantities of swamp muck, barnyard manure or any fertiliser rich in vegetable mould. Green manuring, that is ploughing under a green crop of any kind of forage or luxuriant growth, is a practice method of great value. Wood ashes in large quantities, two or three tons to the acre, will prove very beneficial. This is perhaps the only remedy which would prove of any value so late in the season as it is now. The deep ploughing and heavy dressings of manure should be done not later than midwinter."—*New South Wales Agricultural Gazette*

COFFEE AND PEPPER FROM WESTERN INDIA.

We call attention to the annual Report of Mr. R. Tatham of Messrs. Arbuthnot & Co., Tellicherry, giving the year's exports of the two staple products, coffee and pepper. It will be seen that apart from 127,331 cwt. of plantation coffee, no less than 81,000 cwt. are said to be native coffee; while 168,000 cwt. pepper are declared to be of a value exceeding 6,300,000 rupees!—and the planters, Mr. Tatham says, are more and more growing pepper as a bye-product to coffee. This is just what we have wanted the tea planters of Kelani Valley and other similar districts to take up. If they cannot do much in rubber or cinchona, they should do a great deal in pepper; for Kegalla was a famous pepper-growing district 150 years ago, as also the upper portions of the Matara division of the Southern Province. We would therefore press more and more for a revival of the pepper-growing industry, among the lowcountry planters of Ceylon.

PLANTING IN B. C. AFRICA: COFFEE, &c. IN NYASSALAND.

(By an ex-Ceylon planter.)

Mlanji, B. C. Africa, Aug. 16.

This is supposed to be a country void of comforts, and inhabited by savages; at least anybody reading the books written by most travellers would arrive at that conclusion. I myself came here expecting to have to rough it and prepared to do so, even to the same extent as the savage races whom I expected to have to civilize.

Now I find I was mistaken and that every comfort that the most fastidious appetite could desire is here; also dwelling-houses not to be despised by the most ambitious orientals—brick houses with windows and doors of excellent finish; and wattle-and-daub bungalows which would put some of the Ceylon planters' P.D. houses in the shade.

To enumerate some of the

VARIOUS PRODUCTS

we have in cultivation, as well as the fruits, vegetables, and grains we luxuriate in, might surprise some of your readers. Of Ceara rubber we have growing trees 12 feet high, with a diameter of one foot at only three or four years' age. This rubber is being planted pretty extensively as boundary trees, and amongst the coffee on some estates. It may do better than it did in Ceylon, as the climate here is more like that of the home of the Ceara tree. At all events the tree seems to be a deeper feeder here, and does no harm to coffee planted along with it, as it did in Ceylon.

CACAO.

I only know of one plant in the country, and Mr. J W Moir, of Lauderdale, is the owner. This plant was imported about five or six years ago, and is now only about four feet high, and measures three or four feet across the branches,—not a promising specimen by any means, especially to any one who has seen the growth of cacao in Dumbara and Matale. My opinion is that our climate in Nyassaland is not suited for cacao, unless near the rivers and lakes at a lower elevation, but there the rainfall is much less—25 to 30 in. We have too great extremes of heat and cold. We get frost in June and July and in October and November dry heat, reaching 96° to 100° in the shade, which neither

COFFEE NOR CACAO

likes. Shade may mitigate those evils, but I doubt if the rainfall is sufficient for cacao even with shade, but I may be wrong; at all events, it does not thrive here.

CARDAMOMS

should suit our climate well. We have none here that I know of. I brought some seed with me from Ceylon, and gave them to the African Lakes Co.'s Gardener to plant, but I do not think he ever got them to grow; at least I have not heard of any in the country. We have growing wild here any amount of *Amomum meleguetta*, Grains of Paradise, which produce a seed that was much sought after in days of old, and largely exported from the west coast, but now superseded by Malabar and Mysore cardamoms. I gathered and sent home to my London agents over half a ton of seed a few years ago, but they could not find a purchaser for the consignment, and it was destroyed in bond. The undergrowth of our forests in the wetter parts of this country is composed of this variety of cardamoms, with two other sorts nearly allied to this. Ginger grows well here, and is cultivated by the natives, along with Turmeric, as a condiment.

TOBACCO

of an excellent quality can be and is grown here; the soil and climate seem to suit the weed. And when grown from a fine variety seed is of excellent quality. I have made cigars equal in flavour to the best Havana, but to get the nigger to manufacture a couple of cheroots of the same quality would baffle an expert's patience and perseverance—nothing but machinery will keep the kaffir uniform.

FIBRES.

Fibres, we have galore in the bush, *Sanseviera* of two kinds grow wild. We have a variety of China grass, as well as the real, imported variety. A number of trees supply bark of which the natives make excellent rope, as also two "Momba" trees, from which the bark cloth to cover the savage is made, as well as excellent cordage and binders for housebuilding, etc.

Aloes are common all over the country, and one or two indigenous varieties are found in the bush. We have some excellent timber trees here, Mahogany trees, 150 ft. high, and 20 to 30 ft. in circumference. African teak and a variety of legnamsuti, as well as many other valuable cabinet woods are plentiful.

AUSTRALIAN GUMS

grow well, blue and red gums thrive splendidly. Robusta trees I have growing over 100 ft. high, and 5 ft. in circumference, at 6 years' age—I have plants from the seed of those trees 8 and 10 ft. high at 18 months age. White ants do an awful amount of damage to gums, causing the death of many plants, and even well-grown trees. Annatto trees of enormous dimensions are here, and they bear very large crops of seed, but I never thought it worth while extending their cultivation as the price of the article is so

low. I have one Pepper vine doing well. Vanilla and Kola plants were introduced, but they died before reaching maturity. Wild Pepper, both the vine and the tree varieties, are to be found in the forests.

CINCHONA.

Ledgeriana and a good hybrid were introduced by somebody and are to be found on some estates, but they are not cultivated to any extent. I have often thought of putting in a nursery of Ledgeriana, as it seems to grow well, and now the price is better, there is encouragement for attention to this valuable tree.

I remember the days when the Dimbula planters used to value Cinchona Succirubra trees at so many rupees each, and calculate their fortunes by the number of growing trees, and their age;—quinine was then selling at a guinea per ounce. I went in for planting cinchona with the rush, but found when my trees were fit for harvesting that the bark, when delivered in Colombo, did not pay.

CHILLIES.

Some time ago I saw a letter in the *Observer* from somebody in Rakwana, enquiring about the cultivation of chillies. I have 100 odd acres planted between the lines of coffee as a catch crop; they are now three years old and lots are beginning to die off after continuous cropping for two years. After the first crop I cut them down and dug them in as manure to the coffee; they grew up again quickly, and I have now nearly finished a second crop. I intend to uproot and dig them in altogether in the course of a few months more, as the coffee has now closed in upon them and they have served me well, having more than paid for the opening of the coffee-clearing. I could not pick half the crop for want of labour; but I should say each tree gave more than 1 lb. of dry chillies, and the price I got was from 37s 6d to 56s 6d per cwt. The variety I have planted is the common bird's-eye used by the Ceylon cooly and found growing on most estates wild in Ceylon. This kind, if of good quality, bright and clean, always meets with a ready sale. I have tried other varieties, and Capsicums, but there is a very limited demand and uncertain market for any kind, except the very pungent bird's-eye chillies. Chillies take about eight months before they begin to bear fruit.

I might give your readers a list of our

FRUITS

to shew them that we are not wanting for delicacies for the table:—Soursop, oranges, bullock's-heart, pomegranate, loquats, guavas, red China, pink-hearted and gooseberry varieties; papaws, peaches, plums, figs are here, all in bearing for the past two or three years. Apples, pears, and cherries are growing on one or two estates. Pine-apples, raspberries and Cape gooseberries are common everywhere, the latter a weed like tomatoes on estates. Flowers—shoe-flower, convolvulus, roses of different kinds, amaranthus, nasturtiums, caliopsis, geraniums—are in profusion in most little garden plots in front of bungalows,

FOOD SUPPLIES.

By way of food supplies we can boast of the cheapest if not the choicest in the world. English potatoes 1d per lb.; sweet potatoes 3d per bushel; cabbages 1d to 2d each; village fowls 2d each; rice 1d per lb.; pumpkins and cucumbers about 6d per basket; beans in great variety, Indian corn and millet, all at 1s per load of about 60 lb.; eggs 3d per dozen; plantains and bananas in great variety, 3d per bunch.

Store prices for imported goods are:—Flour 6d; sugar 6d; tea 2s 6d; jams 1s; butter 3s per lb.; and other articles in proportion. Cassava and arrowroot are grown everywhere, and are as cheap as other native products. We can always get fairly good curries made here; the only thing we do miss is the coconut. Breadfruit I have never seen here. We have no jaks either; I had some plants once growing about 2 ft. high, but they were eaten by white ants.

HENRY BROWN.

COFFEE PLANTING IN B. C. AFRICA.

[TO EDITOR "CENTRAL AFRICAN TIMES."]

Dear Sir,—As I have already stated I shall only be too glad to visit any plantation where berries are in a state of growth, with Mr. Henry Brown or any other planter, so as to convince me that we are troubled with much worse enemies whether borer or "drought which do the maximum amount of damage to our coffee," and I should like to see "some old estates where no bug is to be found which have 80 to 90 per cent spotted and light berry caused by these enemies."—I am, &c.,

KENNETH CAMERON.

Namasi, August 9th.

Dear Mr. Editor,—The first time I observed coffee in this district really affected by drought was in 1896, when the thermometer registered 98 degrees Far. (at some stations over 100 degrees was registered I believe). The coffee drooped, the leaves and bark shrivelled up, the natural healthy flow of sap was checked, fissures were laid open in the bark of the trees, and canker set in on fifty to seventy per cent of my coffee trees after which bastard and barren wood was very visible.

Dr. Macvicar paid me a visit after another dry season, 1897, when my coffee also suffered from drought and in the course of conversation one day asked me if I had anything I would like examined with the microscope. I suggested the sap of coffee trees in the shade and in the open. He first went to work on the leaves and bark from a number of trees in the open. When the sap from those trees was examined it was found to contain brown spots which proved beyond a doubt that the sap cells were damaged and the sap diseased. When the sap of the bark or leaves of the shaded trees was examined it was found to be perfectly natural and of a light green colour.

The above observations, I think, prove beyond a doubt that our coffee is damaged by excessive heat and the fact is well-known that coffee will not do well where the shade temperature reaches ninety degrees without shade and heavy shade too.

I have tried heavy pruning and cutting down both as a remedy for sunstroke and canker in coffee, but when the trees are damaged into the ground as is often the case, it is as bad as canker in the flesh of a human being and had better be abandoned to the inevitable. Roadside shade trees are frequently cut down on the plains in India for sunstroke and canker.

—Yours, &c., H. B.

Mlanje, 1st August.—*Central African Times.*

PROPAGATION OF MANGOES BY BUDDING.

The following interesting paragraph occurs in Mr. Gollan's report on the Saharanpore Botanical Gardens for 1889-1900:—In paragraph 88 of the last annual report it was noted that the mango was said to be successfully propagated in Jamaica by budding. With a view of testing this assertion a series of experiments were conducted last summer. The first trials were made about the beginning of April and were repeated at intervals of a fortnight until the end of August. No difficulty was experienced during the whole period covered by the experiment in finding clean and apparently well developed buds, nor was there any difficulty in finding stocks with bark that would rise readily, but only one of the various lots of buddings which were made proved a success. In the successful case the buds were inserted on the stocks on the 4th July and they began to shoot out in about a month after the date of insertion. In every trial a dozen plants were operated on, and as eight plants out of the dozen budded on the 4th July were successful, this is a fair percentage when comparisons are made with other kinds of trees which are not easily budded. On the 20th of the same month, and on two dates in August, a dozen plants were in each instance operated on, but not a single success was met with, nor on any of the dates on which budding was tried prior to the 4th July. The budded plants now stand with shoots from 12 to 15 inches long, and by July next, or within the year from date of budding, they will be quite fit to plant out to where they may be intended to be grown. I am not yet prepared to say that the method is an improvement on the universal system of propagating the mango under grafting by approach, but as it is intended to have a more extended trial made in July next, I have to give a definite opinion on this point in the next annual report.—*Gardening and Planting*, Sept. 13.

Cocoa in Dutch Guinea.—The cocoa crop in 1899 exceeded that of the previous year by about 50 per cent; prices have shown an upward tendency. The total crop for the year was 3,969,945 kilos. The following are the amounts exported during the past five years:—

Year.	Quantity. Kilos.
1895	4,456,338
1896	3,302,567
1897	3,584,715
1898	2,830,414
1899	3,859,980

THE

AGRICULTURAL MAGAZINE,

COLOMBO.

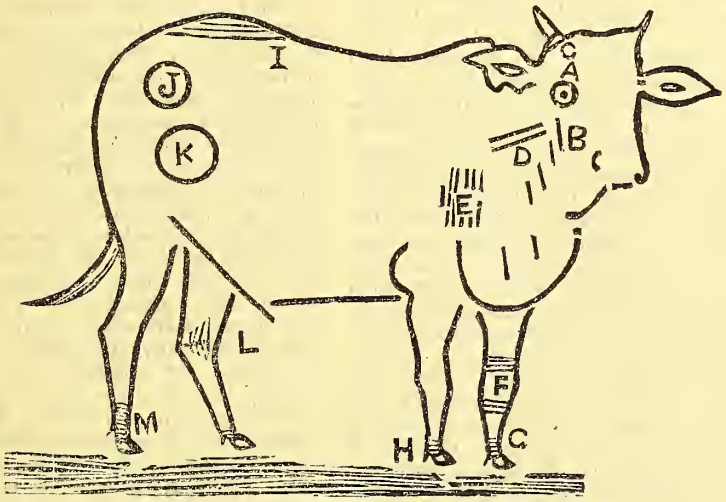
Added as a Supplement Monthly to the "TROPICAL AGRICULTURIST."

The following pages include the Contents of the *Agricultural Magazine* for October:—

Vol. XII.] OCTOBER, 1900. [No. 4.

THE BRANDING OF CATTLE.

(Continued from last number.)



A. Round eye.
B. On cheek.
C. Round root of horn.
D. On neck.
E. On shoulder.
F. Round knee.
G. Round fetlock.
H. About suffraginous bones.
I. Loins
J. Point of hip.
K. On round bone.
L. On hock.
M. Hind fetlock, suffraginous bones and coronet.

The common method of branding cattle in this country—by which a great part of the body is covered with letters, figures, designs and diagrams—tends, so to speak, to deaden the skin, so that its physiological functions are seriously interfered with. What our village cattle keepers have to be taught is that it is not the immoderate use of the firing iron, or even of drugs, that induce's cattle to develope and put on flesh, or impart strength to them; but that it is the food and the care bestowed on them. I shall now go on to consider the second division of my subject, viz., branding for identification. In Ceylon there is no system adopted by cattle-owners, nor are there any regulations specified by the State, in regard to branding for identification. As a rule, the letters branded for identification are of unnecessarily large size, and it is not uncommonly the case that the initials of the owner's name practically cover the entire side of the animal's body. In some countries there are special regulations as to the places where branding for identification might be done. I am inclined to think that the best places for marking is the croop or the thigh, and that no letters need occupy more than three square inches. I have heard it suggested that animals should be branded ou the neck, close behind the ear, as this does least injury to the hides. But I am not inclined to sanction this, particularly when the branding is done by the ordinary village hand, as the spot indicated is too delicate—I almost said vital—to be subjected to the action of a hot-iron, particularly when this instrument is carelessly handled. I quite see the force of the remark that hides are damaged by branding, but at the same time I cannot abandon my recommendation made from a veterinary point of view to suit commercial ideas. I would, however, avail myself of these ideas to enforce my objection against indiscriminate and immoderate use of the firing iron, since the more it is used the greater is the damage done to hides and the lower the prices they fetch. Many other devices have been conceived for superceding the firing iron in marking for identification, such as ear-marking, tatooing, and branding with chemical solutions, but when we consider the circumstances of the mass of the Island population, it is not to be hoped that any of these devices can either be recommended or enforced. I do not think that branding with the hot iron could be superceded as a convenient and satisfactory method of marking for identification, but what is necessary is that such branding should be limited by certain regulations, which should be enforced through the ordinary administrative channels, so that while the cattle-owner marks his cattle in a manner and to a degree sufficient for purposes of identification he does not cause unnecessary suffering to the beast, nor damage the prospective value of its hide.

A. CHINNIAH.

(To be concluded.)

[*Erratum.*—For "opening parotid," in line 19 of the first part appearing in the September number, read "open parotid."]

Greatest amount of rainfall in any 24 hours on the 1st Sept., 3·87 inches.

Recorded by Mr. C. Drieberg.

OCCASIONAL NOTES.

A correspondent, who is evidently interested in tropical drug plants, for which we know there is some enquiry from Europe, sends us a list of plants and asks us for the Sinhalese names. We give below a note on each of the plants named: 1. *Michelia champaca*, Champak, Sapu. 2. Sweet Basil, *Ocinium basilicum*, Suvandatala. 3. *Tinosporae*. There are three indigenous species of Tinospora: *T. malabarica*. var. Tomentosa, Bukinda, Walkinda; *T. crispa*, Tittakinda; *T. cordifolia*, Rasakinda. 4. *Wrightia antidysenterica*, now *Hollarrhena antidysenterica* is Kenchi a Conessi bark of commerce. It is not indigenous and has no native name. A close ally is *Hollarrhena mitis*, Kiriwalla or Kirimawara, is found native, and the bark is much used medicinally for fever and dysentry. Dr. Trimen states that the bark is sold under the name of "Kalinda." 5. *Emblica officinalis*, now *Phyllanthus emblica*, the *Emblic myrobalan*, Nelli. 6. *Saraca indica*, Diyatalmal or Diyaratambala. 7. *Abroma augusta*, "abrome," not indigenous and no native name. 8. *Nigella indica*, now Nigella sativa, small fennel or black cummin, Kaluduru. 9. *Trapa bispinosa*, Ikiliya. 10. Aloes, the drug is the product chiefly of *Aloe vulgaris*, not indigenous, no native name. 11. Neem, Margosa or Kohomba, *Azadirachta indica*. 12. Sepalika, this is the native name of *Nyctanthes arbortristis*.

A correspondent signing himself Robert Thompsou has addressed a letter to the Secretary of State for India on the subject of Cacao Cultivation, which from the writer's experience of cacao he is led to believe will succeed in certain parts of the Empire. Mr. Thompson has seeu cacao grown successfully under irrigation ou vast areas where the rainfall is very meagre, and he is sanguine that the same can be done in parts of India if the trees are grown under "shade." Refering to past

failures in the attempt to establish cacao gardens in India, Mr. Thompson says that notwithstanding the abortive attempts referred to, there can be little doubt that in Southern India numerous sites could be selected for the establishment of plantations of this important product.

There is perhaps no plant more peculiar in its relation to soil, temperature, rainfall, aspect and such natural conditions than is cacao, as witness the very restricted area in Ceylon in which cacao flourishes. However, we sincerely hope Mr. Thompson is right in his conjecture, which coming from a man of his experience is worthy the notice of the Imperial authorities, and we thrust that a fair trial will be given by the Indian government to cacao culture under the conditions indicated by the writer in question.

The Superintendent of the Calcutta Botanic Gardens, referring to Rhea, mentions in his report that a machine which is said to meet all requirements, and which certainly meets the needs of Rhea growers better than any hitherto offered, has now been put upon the market, and its advent appears likely to give a fresh inpetus to rhea cultivation. It is a pity the machine in question is not more definitely referred to, for there are a number of people in Ceylon possessing stocks of rhea, who would be glad to have further particulars.

Dr. Reginald Ashe, the Superintendent of the Jail at Mymensing, has lately used with much success, in the treatment of diarrhœa and dysentery, flour made from the plantain. Any variety of plantain, he informs the *Indian Medical Gazette*, will do, but the *kutch kala (musa sapientum)* from its size is the best to use. The plantains are cut just before ripening, they are skinned with a sharp wooden knife, so as to avoid blackening, then cut into thin slices, sun dried, pounded in a mortar, and sifted through muslin. The fine powder or flour should be stored in air-tight glass bottles. The issue is 2 oz. for each meal, cooked in a brass vessel with a little water. *Dahi*, or butter milk, can afterwards be added. The taste of the plantain powder is slightly astringent, but fruity and palatable.

In the last published report on the Department of Agriculture, Bombay, the following occurs under the head of Agricultural Education :—As a step towards reviving the agricultural classes which were languishing for want of students, the scholarships attached to the classes have been reduced in number and raised in value. The University have recently agreed to the conversion of the diploma in Agriculture into a degree, and Government have also been pleased to direct that the licentiates of Agriculture should have a preferential claim to District Inspectorships of Agriculture before other officials of the Revenue Department or those of the Survey Department who do not know English, and that they should also be placed on the same footing as licentiates of Civil Engineering for admission to the Forest Department, provided they undergo the special course of training in forest subjects and pass the same tests in those subjects.

The same report, under the head of cattle disease, gives the following interesting statement showing the percentage of deaths from Rinderpest and Foot and Mouth disease in the Bombay Presidency. Rinderpest—attacks 1,220, percentage of deaths 68·85; Foot and Mouth disease—attacks 2,679, percentage of deaths 4·23. It is remarked that this shows a decease in the number of attacks as well as in the percentage of deaths.

PROFESSOR ROBERT WALLACE.

After a considerable interval of time we have had the pleasure of hearing from the Professor of Agriculture at Edinburgh University, who has always taken a keen interest in Tropical Agriculture, while he has already visited Ceylon three times in the course of his travels to India and the Australian Colonies. Professor Wallace, who is possessed of remarkable energy and great power of observation, has made it a point of studying the agriculture of the British possessions on the spot. His first visit was to Canada, and later on he traversed India, Australia, and the Cape, dealing with the agriculture of each of these countries in a book or pamphlet, or a course of lectures. In the letter received by last mail, he writes :—

"I am now busy writing my new Indian lectures, and find the work most interesting. Of course I include Ceylon in my new course, and anything of importance you think should be noted, I shall be glad if you will let me know. I may go out again some day to Australia, so there is a more or less remote chance of my looking in upon you. My brother from Egypt (where he is Director of Agriculture) who is staying here (Thornhill, Dumfriesshire) has just returned after a trip 'round the world,' but went by Japan instead of your way."

Professor Wallace encloses a syllabus (issued as a supplement to the *Edinburgh University Calendar*) of the new course: The Garton lectures on Colonial and Indian Agriculture. The course is dealt with in the following manner: Section 1. (Session 1900-1901, 20 lectures) India and Ceylon, Egypt, South Africa. Section 2. (Session 1901-1902, 20 lectures). The Dominion of Canada, Australasia, the smaller Crown Colonies (West Indian Islands, British Guiana, the Straits Settlements, Ugauda, and other African Continental possessions and Islands; Islands in the South Atlantic and Pacific Oceans.) The agriculture of India and Ceylon is treated of, under the following heads, which are again divided into a large number of subheads: Introduction, Tillage Implements, Cultivation of Crops, Irrigation, Manures and Live Stock. As showing the interest which the Professor still takes in the East, we reproduce, on another page, a letter written by him to the *Scotsman* on the subject of Indian Forestry. Query: Is the Ceylon Forest Department more considerate of the Forest rights of the natives?

CEYLON TIMBERS.

Still another Report on the specimens of timber sent from Ceylon to the Imperial Institute has reached us. We have already referred to the Report of Professor Unwin; the present report is by Mr. Herbert Stone, F.L.S., one of the expert referees of the Imperial Institute.

Mr. Stone, at the outset of his report, states—and gives good reasons to support the statement—that there is but a poor chance of our Colonial timbers competing with English woods, unless they present some peculiar merits. The exceptions are those timbers which in some way resemble English staple timbers and which will pass under the same name. Three examples are Suriya-Mara (*Albizzia odoratissima*) Halmilla (*Berrya ammonilla*) and Lunumidella (*Melia dubia*). These, if imported respectively as "Ceylon rosewood," "Ceylon Satinwood" and "Ceylon Cedar," would, it is expected, with the help of assiduous advertisement, readily be bought on trial, and probably be adopted for many purposes. Unless such a plan (which Mr. Stone hastens to assure us, is no deception, from a trade point of view) is adopted, only one out of the nineteen specimens of Ceylon woods examined has any chance of gaining a footing in England.

Mr. Stone writes short but interesting notes on the following timbers:—

Michelia champaca, Sapu, S; Sanpakam, T.
Pleurostylia Wightii, Piyari, S; Panakka, T.
Calophyllum Burmanii, Gurukina, S; Chiru-punnai, T.
Pterospermum suberifolium, Velanga, S; Toddi, Vinnaku, T.
Vitex altissmia, Milla, Milila, or Sapu-milila, S. Mailai Kata-manaku, T.
Zizyphus jujuba, Masan, Maha-debara, S; Ilanthai, T.
Vatica Roxburghiana, Mendora, S.
Carallia calycina, Ubberiya, S.
Cryptocarya membranacea, Tawenna, S.
Carallia integerrima, Dawata, S.
Azadriachta indica, Kohomba, S; Vempu, T.
Melia dubia, Lunumidella, S; Malai-Vempu, Patiri, T.
Alseodaphne (*Persea*) *semicarpifolia*, Wewarani, S. Ranai, Yavaranai, T.
Heritiera littoralis, Etuna, S; Chomuntiri, T.
Thespesia populnea, Suriya, S; Pu-varasu, T.
Berrya ammonilla, Halmilla, S; Chamandale, Male Kuda-munakku, T.
Albizzia odoratissima, Suriya-Mara, S; Karuvakai, T.
Preicopsis mooniana, Nedun, S.

Presumably it is the same collection, consisting of twenty-two specimens, which was submitted both toProfessor Unwin and Mr. Stone for report. Of these twenty-two, the present report deals with nineteen, those not dealt with being *Calophyllum bracteatum*, Walukina, S., *Artocarpus integrifolia*, Kos, S., Pila T., and *Artocarpus nobilis*, Del, Waldel, S. Why such common building timbers as the two latter have been left out is not stated. It is a pity that a number of errors in nomenclature has crept into both Professor Unwin's and Mr. Stone's reports—particularly as regards native names. To give an instance, one specimen is referred to as Vuinaka and is said to have been marked Vincol. In order to identify the wood the specimen was sent to Kew, but the name could not have been found in its corrupted form in any of the lists. It is most probable, however, that the wood referred to was *Pterospermum suberifolium*, and we so give it in the above list in which we have inserted all the Sinhalese and Tamil names as well. Again, one or two errors are likely to lead to great confusion,—for instance, Tawenna is given as *Dicopsis petiolaris* (now *Palaquium petiolare*, order Sapotaceae) instead of *Cryptocarya membranacea*, order Lauraceae). It is doubtful therefore which is the correct name of the specimen at the Imperial Institute, whether the Sinhalese or the botanical one.

As might be expected from his general remarks with reference to Ceylon timbers, Mr. Stone has not much to say in his notes in praise of our woods except in the cases already mentioned. Regarding Ubberiya, he says "this wood is the most beautiful of the series, resembling remarkably the most beautiful wainscoat oak in every direction of the grain. Apart from the reddish tinge, there are very few persons, even in the trade, who would not pronounce the wood to be oak." But even this beautiful wood has its drawbacks, since it does not darken with age, nor preserve its colour when polished.

In the note on Lunumidella, which, as stated above, Mr. Stone selected as a marketable timber, we read "to obtain the best effect of the grain, Lunumidella must be cut in the direction of the radius, *i.e.*, quartered, as the beautiful satin lustre does not appear in the tangential section." This is a hint—if the fact is not already known—which local timbermen and builders should take note of. The lightness of Lunumidella is said to be remarkable, and for this quality alone, says Mr. Stone, it should have a future before it. Suriya-mara, referred to as "the sweet-scented *mimosa*," (a name by the way we have never heard it called by) is perhaps best spoken of in the report. The timber is said to be a 'genuine rosewood," the wood "extremely hard, even harder than Ebony." (Indian rosewoods are the product of *Dalbergia latifolia* and *D. sissoides.*) It is recommended that Suriya-mara should be allowed to season for at least two years before shipment, as the logs examined were found to be quite wet, though it is surmised that they must have been felled not less than eighteen months previously. This would lead us to suppose that the wood specimens reported on must have been a late contribution from Ceylon to the Imperial Institute collection, and not part of the original consignment of samples made some 8 or 9 years ago. Of Nedun, which is considered one of our best furniture woods, Mr. Stone has, strangely enough, very little to say in commendation.

We cannot help thinking that to be able to report to the best advantage, the timber expert should, in addition to the application of technical tests, examine timber not merely by means of hand or block specimens of doubtful age, but in the mass and even *in situ* before making deductions which are intended to have a practical and commercial bearing.* If, however, Mr. Stone has been the means of introducing three of our Ceylon woods to the notice of English timber dealers, we, and all who are interested in the development of the Island's resources, will have occasion to be grateful to him; but then it is a question whether the Island can spare, for purposes of export, any appreciable quantity of the three timbers which are said to have a future before them.

CLINICAL NOTES.

VASECTOMY.

On the 25th of August last I performed this operation on an Arab horse "Anthony." Instead of amputating the whole cord, I removed only about two inches of the *vas deferens*, more by way of experiment than for any other reason. I am glad to say that the operation was attended with no bad results, but in fact was as successful as could be desired, as the animal was able to be ridden on the 12th day after the operation.

The following was the *modus operandi*:—The animal was thrown down and secured in the usual way, but no chloroform was used. I began by making an antero-lateral section, with proper antiseptic treatment, on the off side of the scrotum along the line of the cord, and carefully dissected and took out the *vas deferens*, which was eventually severed and a piece about two inches in length removed. I fastened the wound with catgut ligature and covered it with antiseptic cotton wool and painted it over with colodion. The incision on the near side was postero-lateral, and made close to the groin. As a result there was slight bleeding from the scrotum. This wound was treated similarly to the first. The first wound was an exposed one and required to be protected from flies, but that on the near side did not give this trouble, though from its peculiar position it caused an awkward gait in the animal till it was perfectly healed. I however prefer the antero-lateral to the portero-lateral section.

The advantages of this operation over ordinary castration are: (1) It preserves the testicles, as a natural appendage of the horse. (2) It is less painful and cruel as no nerve is burnt, cut, or twisted. (3) The healing is quick, and in this, particular care was effected in what I consider to be the minimum time. (4) There is no liability to tetanus. (5) There is less chance of the growth of a schirrous cord. (6) There is little or no bleeding. (7) There is economy in the preservation of tissues which in the ordinary operation are cut or mutilated. Perhaps the only objection that could be brought against this operation is that it is apt to cause perplexity to the breeder, and even mislead him, as the presence of the testicles is apt to deceive him into the belief that an animal so operated on is still a stallion. A new term would be required for such horses, for the term gelding would not correctly describe them.

A. CHINNIAH,
Veterinary Surgeon

[*Erratum.*—In August number, under Clinical Notes, for "bracheal" read "median."]

THE GRAFTING OF THE MANGO.

In Ceylon we only hear of grafted mangoes in the Northern Province where this system of propagation was taught the Jaffna Tamils by Mr. Dyke, a past Government Agent, whose name is still associated in the North with many useful measures for the improvement of Agriculture and Horticulture.

In the Bombay Presidency the common method of grafting in vogue is that known as inarching or grafting by approach. It differs from graft, ing in that the scion is not removed from the parent until they are both firmly adherent. The operation is thus described in Dr. Nicholl's Tropical Agriculture: A branch of the parent having been selected about the same size as the stock, the bark and a portion of the wood are pared away to the extent of two or three inches, and they are then bound fast together, the bark of the wounds being accurately fitted, and grafting wax applied over all. It is usual to make tongues in the stock and the scion, so that one may fit into the other, but this is not really necessary, although it helps to prevent movement, which is always fatal to union.

On a visit to India some years ago the writer saw this method of propagating the mango extensively practised in the neighbourhood of Bombay. It would appear, however, that there is another method of grafting even simpler and more sure than inarching, which we think is worth a trial by all growers of the mango in Ceylon. Mr. Horace Knight, writing to the *Queensland Agricultural Journal*, says that after long and close observation and numerous experiments, he has arrived at the conclusion that no other tree is simpler to graft according to this new method, and that the work can be done at any time, though it is best done when there is an upward flow of sap. He then goes on to describe the process which he has adopted and finds so successful, namely, that in which the bark only is used without any adhering wood. The process is in fact more akin to budding than to true grafting, since the grafts are simply pieces of bark, which though they have no growth on them, contain dormant eyes or buds. The size of the pieces of bark may vary according to the size of the trunk or branch on which they are to be grafted, but the most convenient proportional dimensions are said to be length twice the breadth, and if the pieces are taken off from places where rings occur, there will as a rule be found two or three latent buds in the pieces. The bark may be taken off either old or young trees, but the older bark is more easily removed and handier to trim into shape. In carrying out this method of grafting the first thing to be done is to cut out the section for inserting upon the host. Should the edges of the piece cut out be bruised or torn, cut the injured parts away till sound healthy bark only remains. Now press the piece firmly over the spot on the host where the piece is intended to grow, and make a clean cut into the bark of the host all round the piece and of the shape of the piece. Next take out the bark on the host which has been cut into and put the prepared section in its place. Do not make it fit so tightly that it has to be squeezed in, but make it a nice fit. Now bind it on with ordinary candle cotton, or other convenient material, with just sufficient pressure to make it touch the underlying tissues of the host, avoiding, if possible, binding over the buds. Clay or grafting wax is not required, as is commonly supposed, to keep out air and so effect a union. It may happen that the prepared piece of bark is thicker

than the bark of the host; but even in such a case if carefully applied and tied on, union will follow. If the weather be hot and dry the leafage above the graft may be left for shade, but should be ringbarked 6 or 8 inches above the graft. In two or three weeks' time the upper growth of the host may be removed by cutting at the point where it was ringbarked. If at the same time the buds on the graft are found to have started into growth, the binding may be removed. All young shoots except those on the graft must be rubbed off as soon as they appear. In favourable weather on the other hand the host could be deprived of its leaves and the majority of its branches. At this stage, the tree, being highly impregnated with sap, will take kindly to the piece of foreign bark that is inserted into its own bark and bring about union without delay.

MYRISTICA KINO.

Agricultural Ledger, No. 5, of 1900, deals with Kino obtained from the so-called wild nutmegs (Myristica, sp.) Kino, as obtained from the barks of trees, is of two kinds: Malabar Kino, which is the best, is got from *Pterocarpus marsupium*. This tree, which is indigenous to Ceylon, is known by the Sinhalese as Gamalu, and in Tamil as Venkai. Trimen, in his Flora, records the fact that a red gum-resin exudes from the bark and is used medicinally, also that it affords a fine timber, very hard and heavy, dark reddish brown, durable and containing a red resin. The other kind, called Bengal Kino, is the product of *Butea frondosa*, also indigenous to the Island, and known in Sinhalese and Tamil respectively as Gaskela and Parasu. Dr. Trimen says of it: "A dark red astringent juice exudes from the bark, which hardens into a brittle ruby-coloured resinous-looking gum, the Bengal kino of commerce." The wood is described as soft, light, and not durable.

These gums are used largely in medicine as astringents, the former having been for long an official drug in the British and American pharmacopœias.

Some four years ago Dr. Edward Schaer, Professor of Pharmacology in Strasburg wrote a paper on a new kino from Myristica, after examination of an extract handed to him by Dr. Warburg of Berlin who had received it from the Director of Kew. The specimen was obtained from *Myristica malabarica*, and was like the official kino in appearance.

Professor Schaer succeeded in obtaining from Buitenzorg further specimens of products of other wild nutmeg trees. In each of these he found a crystalline deposit which distinguished them from the kino from other sources. This deposit was determined as *Calcium tartrate*—a conclusion of some interest in vegetable physiology as inorganic crystals peculiar to plants have hitherto been traced to *Calcium oxalate*, sulphate, phosphate and carbonate.

Dr. Schaer summed up the result of his investigation as follows:—The dried juice of several Asiatic species of Myristica (*e.g.*, *M. malabarica*, *M. fragrans*) as regards appearance and physical qualities, show but little difference from Malabar Kino. 2. This substance which may be termed "*Myristica kino*" agrees in the chemical reactions due to their constituents in all important points, with the kino of *Pterocarpus marsupium*. It can therefore be stated that drugs of a very similar character, and partly of close resemblance to official kino, are to be found in the families Leguminosæ (*Butea*, *Pterocarpus*, *Milletia*), Saxafragaceæ (*Ceropetalum*), Myrtaceæ (*Eucalyptus*, *Angophora*) and Myristicaceæ.

3. Myristica Kino differs as far as can be observed, from the *Pterocarpus kino*, and probably also from Butea and Eucalyptus kino, by containing in the crude state of the inspissated fresh juice, smaller or larger amounts of a distinctly crystalline calcuim salt, viz., calcium tartrate, suspended in, and depositing from the liquid juice. By this characteristic admixture it can be easily distinguished from the official kino and probably also from other kinds of commerce."

There is no doubt that the property of secreting this so-called "Kino" is possessed by nearly all species of Myristica; indeed, Kurz in his "Forest Flora of British India," remarks that one of the features of this genus is that the bark "abounds in an acrid juice which is viscid and stains red." *M. longifolia* is said by Dr. Watt to exude a red resin, while *M. gibbosa* and *M. Kingii* (both Indian trees) also yield gum resins which can be evaporated into a kino-like substance, particularly the former, of which it is said that the evaporation of the clear juice gave a kino which was almost indistinguishable from commercial specimens of Malabar kino.

In Ceylon we have four indigenous species of Myristica. *M. horsfieldia*, the Sinhalese "Ruk' is well-known for its wood which is used for boat-making (the flowers of which have the characteristic odour of sandalwood); *M. irya*, Sin. Irya; *M. zeylanica*, and *M. laurifolia*.

This-last is the familiar "Malabodde" or "wild nutmeg" of Ceylon, the arilled fruits of which are very like the true spice fruit. The wood of this tree is light and sometimes used for tea-boxes, while Dr. Trimen mentions that an orange-red astringent gum exudes from the bark. Mr. T. F. Bourdillon, Conservator of Forests for Travancore also refers to *M. laurifolia* as secreting "a thin red juice" from its stem.

The report on Myristica Kino concludes thus: "If the fresh juice could be collected in any quantity from the wild nutmeg trees of India, and evaporated to dryness without much delay, the residue would be an admirable substitute for commercial kino." At present, however, there is no call for Kino from the new sources indicated, as there is enough of the commercial article produced by the forests of the west coast of India. Still it has been shown that such new supplies will be always available to be drawn upon whenever necessary.

CULTIVATION OF THE ARECANUT IN BOMBAY DISTRICT.

[A note by Mr. J. W. Mollison, Deputy Director of Agriculture, Poona.]

(*Continued.*)

The palms are raised in seed-beds and are once transplanted before they are planted out permanently. The first seed-bed is carefully prepared, the soil is dug, broken fine and mixed with leafmould. Fully matured nuts from old trees are specially selected for planting. These are planted about 9 inches apart, in April. The seed-bed should be kept thoroughly moist. The shoots appear in June. The seedlings are transplanted in October into any moist place in the garden or along the water-courses about 2 feet apart and remain thus until permanently transplanted. This permanent transplantation is usually done towards the end of the rains. In the following March the trees are manured with leaf manure and the manure is covered with fresh cut branchwood which is partially withered, but which retains the leaves. The object of placing a layer of small branches above the manure is to break the force of heavy rain. The rain soaks through the brushwood, moistens the manure, but does not carry it away as would be the case if it were uncovered or covered with soil or in any other ordinary way.

The betel-trees are manured as described every second year and come into bearing in ten years or so. The plantains are maintained for some years after the betel-palms are permanently planted, but in time are removed and the cardamoms are planted between the palms and on the stems of the latter pepper vines are trained.

The *bharan* gets more or less washed away during each monsoon and the channels more or less damaged. This to some extent is prevented if plantain leaves, dried grass, and other available rubbish is put on the surface. But despite any precautions, the *bharan* is more or less denuded. The earth from the pathway is therefore removed to repair the drainage channels, &c., and new Kogodali earth is brought in, in headloads from the cuttings which border the gardens and placed along the centre of the *bharans*. This renewal is necessary at least every third year. It is an expensive operation, but the excavation from the cuttings is done in a systematic manner, the area of the garden can be gradually extended. The trees in the first plantation of betel-palms generally stand wide apart, but as they grow other young trees are planted between them. A nursery is always maintained to provide young trees for this purpose and to replace those which die from time to time.

Betel-trees are known to fruit for thirty or forty years, and there is a popular belief that they sometimes propagate much longer. On an average each tree has two bunches of fruit, sometimes three or four. But two good bunches yield as much as three or four inferior ones. The size of the bunches depends upon the manure used and upon the rainfall. A good bunch gives 200 to 300 nuts, and a specially good one about 400. with unfavourable rain or cloudy weather in April or May, many of the young nuts fall off and a smaller number of nuts on each bunch reach maturity. The trees produce flowers in March and April and the nuts are ripe in November or December, but to some extent the trees produce flowers and fruit out of season. Immediately below each bunch there is a frond, or leaf. It, with its sheath, remains attached to the tree for about two months after the inflorescense comes. Then these leaves fall to the ground. A few additional leaves fall during the monsoon. The sheaths of the leaves are a valuable product in the garden economy, they are used to provide hoods for protecting the bunches of betel nuts from the rain. If not protected the nuts rot. Two sheaths are used to make one hood.

The sheaths are skewered together to form a hood by means of thin pieces of split bamboo in a manner which is easy to demonstrate, but difficult to describe in writing. The hood is made adjustable in a very ingenious manner: and when it is bound round the bunch with thongs of plantain bast, it efficiently wards off rain.

The hoods are made and tied on by professionals who come from Mysore territory and below the ghats. A good workman can make 250 hoods per day and is paid Rs. 2 per 1000. This operation and tying them on carts at contract rates Rs. 10 to Rs. 12 per 1000 bunches and 2 meals per day, the men do not ascend and descend each tree, when once they have climbed up, they by means of slight exertion swing the tree and deftly catch hold of another and rarely descend to the ground for hours. The expert climbers who gather the fruit by cutting the bunches from the stem, getting Rs. 4 per 1000 bunches and three meals per day. Some garden owners or their regular servants are experts in making hoods, in adjusting them, and in climbing the trees. It is extremely interesting to note the manner in which the work is done. The climbing in the fair season looks extremely simple and easy to an onlooker, but in the monsoon with falling rain the tall smooth stems are slippery and the ascending process is much more difficult. The climber first ties his feet together round the insteps with strongbands, stripped from the sheath and leaves of the betel palm: this helps him to grip the stem with his feet. He carries with him strung round the neck a wooden rest on which to sit when he gets to the top. This rest is shaped like a two armed pick, and through a hole which corresponds to the shaft hole of a pick, a rope is passed and spliced, so that it is endless, when the fruit is reached the rest is unstrung and attached to the tree. The double end of the rope is passed round the stem and is long enough to pass over the two prongs of the rest, and when drawn tight secures the rest to the tree. It does not slip down, because the circumference of the stem increases downwards and the rings in the tree offer obstruction

to sliding and slipping. The operator sits resting one thigh on each wing of the rest and one hand at least is comparatively free to fix the hood over the bunch of nuts or to sever the bunch, when ripe, from the stem. The bunches when ripe are lowered to the ground by being slung to a rope over which they ride. Any one who has seen a bunch of betel-nuts can easily determine how the bunches are placed on the rope. They rapidly slide down and are caught by a man who holds the end of the rope at the ground. The stretched rope is held inclined at a considerable length from the tree.

(*To be Concluded.*)

ON THE FORESTS AND WASTE LANDS OF CEYLON.

By A. F. Broun, Esq.,
Conservator of Forests.

(*Concluded.*)

The Mountain Zone.—The forests of this zone form the cap of the island. It is from them that all the most important rivers take their rise, and for the preservation of water supply it is therefore necessary that they be preserved. The highest summits of the island, unless they are too rocky for tree growth, are covered with trees which form a continuous sheet from Pedro Peak to Hakgala, from thence to Totapela, and in a curved line to Kirigalpotta and Adam's Peak. The forests are found on both sides of the ridges, but the tea estates of Bogawantalawa and Maskeliya have encroached far up the slopes. It is not improbable that to these clearings is due to the silting up of the lower reaches of the Kelaniganga, and the consequent frequent inundations which are a plague in the low-country. A wise rule now prevails to allow no sale of Crown lands above 5,000 feet, and there are not many of these left between 4,000 and 5,000 feet. The general character of the forests of the mountain zone is the same as that of the dry country; the trees are flat topped, not generally very tall, and the undergrowth is not unlike in general appearance, the most characteristic are several species of *Eugenia, Calophyllum Walkerii, Michelia nilagirica, Gordonia zeylanica, Elaeocarpus obovatus, E. glandulifer, Meliosma pungens, Litsea* (5 species), *Rhododendron arboreum*, &c.

The undergrowth consists, especially above 5,000 feet, mostly of the numerous species of Strobilanthes which flower and die down every twelve years, and some of which reach a height of 20 feet and a girth of trunk of 12 inches. During the flowering time the forest is a blaze of colour, and swarms of bees, attracted to the flowers, produce abundance of honey, which has a peculiar flavour. When the seed ripens, thousands of jungle fowl suddenly appear wandering up from the low-country for the food, which they obtain abundantly.

Besides these plants, there are also large quantities of the little hill Bamboo (Arundinaria), species of *Coleus, Hedyotis*, and ferns, of which the most noticeable and characteristic is the handsome tree fern *Alsophila crinita*, which is found in moist places, in gullies, or on the face of moist rocky precipices. The stem of this occasionally attains a length of 40 feet. Among others the most interesting are *Lomaria Patersoni, Lastroea Beddomii, Leptogramme Totta, Osmunda javanica* (in sunny places near streams), *Diacalpe aspidioides, Doodia dives*, and *Marsupta fraxinea*, the last being only found in the lower portion of zone, replacing *Angiopteris evecta*, which it closely resembles. The moisture in the atmosphere causes the branches and trunk of trees to be covered with epiphytic plants, such as numerous mosses, ferns, of which some *Hymenophyllums* closely resemble the mosses, and orchids, the most beautiful of which latter are *Dendrobium aureum, Cologyne odoratissima*, and *Eria bicolor*, and creeping plants such as *Piper, Medinilla fuchsioides*, &c. In this zone are found the strange *Balanaphoras*, which are found at higher elevations only within the tropics.

European genera are found mostly in this zone, but, on the whole, they occur chiefly in well-lit localities, or in patanas, and, excepting *Rhododendron arboreum*, the majority are shrubs or herbaceous plants, such are *Berberis, Cardamine, Viola, Hypericum, Rubus, Viburnum, Anaphalis, Lobelia, Campanula, Gentiana, Pedicularis, Drosera*, &c. Exceptions to this rule are *Impatiens*, of which there are numerous species, some extremely handsome, *Vaccinium* and *Ilex*, which all grow under shade.

This concludes my sketchof the forest flora of Ceylon. It is a very incomplete one, but with a wealth of species to choose from, it is difficult not to omit a number of characteristic ones. To this may be attributed any glaring omissions, as well as to the fact that the writer of this notice can in no way lay any claim to being considered anything botanically but an amateur.

INDIAN FORESTRY.

University, Edinburgh, August, 1900.

Sir,—The reference to Indian Forestry made in the London letter of your issue of 30th July opens a subject that should receive more notice at this time in view of its bearing upon famine in India. The following quotation conveys a world of meaning to the initiated:—"Lord Elgin corrected the one mistake of the Department, which carried out too stringently the rules for minor produce. Now the forest pastures and brushwood are thrown open to the people to preserve their cattle in time of famine, and the old jealousy between the district and the forest officers has ceased."

In the published account of my visit to India in 1887, while pointing out the great benefits to India of forest conservancy and urging its enormous extension on more rational lines, I was able to point to more than one mistake of the Department and also to give several excellent reasons why such mistakes were possible. I believed then, as now, "that the best interests of the Empire must suffer if the main object of the efforts of the Forest Department is reduced to the growth of forest trees." It is probably a little premature to assert that the Forest Depart-

ment has made but "one mistake" when it took about forty years to discover the mistake in question and to have it rectified. People must not jump to the conclusion that we have adopted the wisest course in connection with the whole forest area of India by following the German plan of management and thereby entirely discarding the natural condition of annual purification by fire under which all the great forests of India have been grown during past generations. Probably time may show even from a forestry point of view that it would have been better not to have had our eggs all in one basket. There are many weighty reasons from the agricultural standpoint (now that the culivator has had restored to him some of the privileges of which Government, while ill-advised, saw fit to deprive him) why certain forest areas as of old should be regularly purged by fire. The position is fully discussed in the chapter of Forestry in *Indian Agriculture;* and the late Dr. Cleghorn, who kindly read the proofs of that chapter, without assuming any responsibility for the statements it contains, declared that, if my views proved to be correct, very important changes might require to be made in the system of forest management in India. After a lapse of ten years one of the most important changes asked for has been given effect to. Whether other necessary alterations will be made and how long it may take for their accomplishment remain to be seen.

It was specially gratifying to see General Michael, writing on 2nd August, emphasise the credit due to the late Dr. Cleghorn for the very important part which he played in the establishment of scientific forestry in India, but no one mentioned the fact that General Michael himself may be justly described as the pioneer of Indian Forestry. The forestal condition of India to-day might have been in a sorry plight, indeed, but for the grasp which the then Lieutenant Michael, from the time of his appointment as a forest officer in 1848, took of the situation in Madras, and the great success which he achieved in saving what remained of the ancient forests of Southern India, which were being rapidly and wastefully destroyed. There is no gainsaying the fact that the so-called "benighted Presidency" gave origin to the Imperial Forestry Department for all India, which with all its defects has achieved so much, and General Michael (1848 to 1855), followed by Dr. Cleghorn in 1856, were the instruments used in the preliminary work which led to its formation and to the appointment of Sir (then Mr.) D. Brandis as Inspector-General in 1864. It is a significant fact that largely owing to the judicious way forest conservancy was introduced in Madras the absence of friction between the forest officers and the people has been a conspicuous feature of the forest management in that Presidency. The so-called "old jealousies" to which your correspondent refers were experienced further north, where forest conservation was introduced more on the cast-iron German system (now happily begun to be relaxed), which did not sufficiently respect and adjust itself to the interests of the agricultural community, and to which it was my painful duty to refer in writing in 1898, "that much of the valuable time of the Forestry Department is taken up in fighting the Agricultural Department."—I am, &c.

Robert Wallace.

August 15th, 1900.

ARTIFICIAL CHANGES OF PHYSICAL PROPERTIES OF SOIL.

(Continued).

Keeping in mind the great influence directly and indirectly exerted by the temperature of the soil upon the growth of plants, the practical agriculturist will endeavour to find means to modify the temperature according to the necessitics of the plants. In colder climates, naturally efforts must be made to promote a rise in temperature, while in warmer regions it will often be necessary to proceed in the opposite direction. In what ways and to what extent the temperature of the soil may be influenced is briefly discussed below.

In the cultivation of plants which furnish products of high market value, such as vines, fruit trees, &c., and which require a rather high temperature, artificial changes in exposure or inclination (producing south-west, south or south-east exposure, or inclining the plane of growth more directly towards the south) may be of considerable benefit especially in cold climates. The method will, however, be productive of good results only when the soil contains sufficient moisture, because only in that case is the high temperature beneficial, and the increase in yeild sufficient to justify the outlay required to make the change. This method need not be restricted to hilly lands but can be applied to level soils. Roof-like elevations may be constructed with broad surfaces facing towards the south and rather narrow exposures towards the uorth. The former may be planted with crops that require considerable warmth, the latter may be renewed for grass or such other foliage as requires less heat. This method is not adopted to extensive field culture of crops furnishing products of comparatively low market value, both on account of the very unequal growth of the plants on the two opposite inclinations, and because the benefit derived even under favourable circumstances would not justify the outlay.

On hilly land in hot climates a reduction of temperature of the soil may be necessary on steep inclines facing the south, south-east or south-west, because under such conditions, not taking into account the fact that the moisture is generally insufficient for maximum crops, the temperature of the soil frequently exceeds the limits for the perfect development of plants. In such cases the construction of terraces offers special advantages, since by their means the temperature of the soil may be lowered and the moisture in the soil regulated in accordance with the needs of the plant. Another common method of altering the exposure of the soil consists in the construction of beds, running through the whole length of the field and separated from each other by furrows. The effect of this arrangement is to bring about a more rapid removal of water from surfaces of high water capacity, but, leaving out of account the fact that

this result may be accomplished by simple means (water furrows), the process in question has the disadvantage of producing unequal heating of two oppositely inclined surfaces, resulting in unequal growth of the plants on the two sides. For this reason bed culture is not suited to fields that are to be planted with only one kind of crop. In such cases level cultivation which secures a higher and more uniform temperature is decidedly preferable.

If, however, this method is followed the bed should run north and south if the field permits since the difference in temperature between the east and west slopes is far less marked than that of slopes facing north and south. In other words, the disadvantages of unequal heating is least with beds running north and south, an excellent means of raising the temperature of the soil in the cultivation of plants in ridges or in hills. Soils so cultivated have a higher average temperature during the growing season than those cultivated level. The effect is of longer duration in ridge culture than in hill culture, because in the former the ridges are constructed before seed time, while in the latter the hills are made in the more advanced stages of growth of plants. For this reason ridge culture is especially suited to plants which require a considerable amount of heat (maize, sunflower, beets, &c.,) in climates unfavourable, as regards temperature, to the growth of these plants. However, this is true only for regions in which the weather in spring is not too cold, for the plants growing on the top of the ridges are, on account of their exposed position, more easily injured by late frosts in spring than those planted on the level soil and hilled up later.

As a general rule, both these methods are mainly adopted to such soils as have little capacity for collecting and retaining heat (clayey and calcareous soil), and which are also apt to collect excessive quantities of water. It is evident that the increase of temperature due to ridge or hill culture is of no advantage on soils of little water capacity and great permeability (sand) when precipitation is scanty. Under such conditions level culture is to be preferred. It should be remembered when ridge or hill culture is used that ridges running north and south are of higher and more uniform temperature than those running east and west. Regulation of the store of water is the soil is another means of modifying the temperature. If the soil is wet elevation of temperature is brought about by removal of the excess of moisture.

The proper means to this end are direct removal of water, lowering water capacity, and increasing permeability of the soil as already explained. That the desired result may be obtained by these means has been proved by various experiments. Another means of changing conditions of temperature in soils is intermixture with soils of opposite properties as regards heat. Admixture of sand with clay or earth rich in clay and limestone results under natural conditions in an average increase in the temperature of the soil, while the opposite process produces a lowering of the temprature of the soil. By thoroughly intermixing sand and humus a soil results which collects heat more rapidly and to a greater depth than is done by either separately. Increase of humus in mineral soils as, for instance, by the liberal application of manures of organic origin prevents extremes of temperature.

The TROPICAL AGRICULTURIST

MONTHLY.

XX. COLOMBO, NOVEMBER 1ST, 1900. No. 5.

NATIVE AGRICULTURE IN CEYLON.

ROPOSALS for Instruction of Natives in Improved Modes of Cultivation and the Introduction of Suitable New Products by E. Elliott, late Government Agent. Southern Province.

PRECIS OF PROPOSALS.

(1.) Separate European interests and leave them in hands of Director, Botanic Gardens and staff. §1-2.

(2.) Continue care of native interests in Public Instruction Department. § 3, 4, 9-10,

(3). Natives ready to follow example and adopt new process or products, if shewn to pay (instance given). § 5.

(4.) Duty of Government to shew the way by planting model market gardens, in villages throughout the Island, and working them by trained gardeners. § 6-7.

(5.) These men to be ignorant of English and to be drawn from the districts to which they will return after training, and required to open gardens on certain terms of remuneration for a limited period. § 8, 13, 14, 15, 16, 17, 18.

(6.) Training to be done at Government expense at Agricultural School, but all instruction to be given in Vernacular, and supplemented by a year's practical work on a farm on a line of rail not far from Colombo. § 9, 1[illegible].

(7.) Produce of farm to be sold at a stall in the public market, and it is believed it would be self-supporting after first year, as all the labour is to be supplied by students. § 12.

(8.) Seeds of all kinds to be provided at Agricultural School, and given freely to the gardeners.

(9.) Instruction to include breeding of poultry making of butter, and ghee, diseases of cattle and castration, &c.

(10.) Instruction in Paddy to be confined to cultivation of experimental plots at the central farm, to test suitability of seeds, manures, &c. Subsequent distribution to be through Government Agents or gardeners, but no cost of cultivation to be chargeable to Government. Other proposals for encouragement of the extension of paddy cultivation.

(11.) Cost of Scheme; immediate outlay to be raised from R10,000, (present cost of Agricultural School) to R20,000 and ultimately to R30,000 exclusive of cost of providing farm and buildings.

The Commission which has recently reported on the proposed department of agriculture has undoubtedly failed to enunciate a practical scheme, and this I think is largely due to its not recognising at the very outset that what is suitable and probably required in the interests of agriculture as carried on by Europeans and other capitalists on a large scale, is not wanted for the humbler native cultivator of praedial products,

As regards what may be called European agriculture, it seems as if its requirements had been already fairly met by the recent additions of a Chemist, a Mycologist, and an Entomologist, and it may be left to Government in consultation with the Planters' Association to consider if this should be turned into a department with the Director of the Royal Botanic Gardens as the recognised head, which he now is to all practical purposes I believe.

As regards native agriculturists, the interference of these scientists is not required and is indeed to be deprecated, though their services would doubtless be available to advise in special cases, such for instance as an invasion of insects or extraordinary pests.

The object of this paper is to put forward a moderate scheme exclusively dealing with the interests of native cultivators working on a small scale.

The first fact to recognise is that native cultivators are ready to adopt improved methods and new products if they see that there is money in them. As instances of this I may recall that the native owners of small gardens freely bought hand pulpers when they found the *coffee* thus prepared fetched a higher price. In *sugar*, when a cattle mill for expressing the juice was provided at a moderate price, it was freely adopted by the cane growers in the Southern Province. *Citronella*, which was first grown by Europeans, was freely taken up, and thousands of acres in the Southern Province were cultivated with this product, and the oil extracted with the aid of steam and modern apparatus. When there was a demand for European *vegetables* in Galle for the French steamers, the agent of that line supplied seeds, and very large quantities of lettuce, chives, beet-root, tomatoes and other similar products were grown in the neighbourhood of Galle; but these have disappeared since the demand ceased.

The motto therefore for those desirous of improving and extending the scope of native agriculture should be *via per exemplum*. In the absence of the European element in most rural districts, the example should be set by Government—by the institution of model gardens—and their gradual multiplication all over the Island,—which would be more or less objects for imitation and centres for the distribution of improved seeds and new varieties. [The cultivation of paddy may be excluded from the scope of the general scheme and be dealt with seperately in the mode I will presently deal with.] In fact what is required in the first instance is the improvement of the cultivation of fruits and vegetables in villages and the substitution of regular vegetable gardens for the spasmodic crops now raised in chenas. Collateral branches requiring attention also are the improvement of the breed of fowls, dairy products, treatment of cattle including castration. To provide for the necessary instructors, or supervising agency for these model gardens, it will be necessary to gradually train a number of persons drawn from the localities to be served, and as they are qualified to return them to their own neighbourhoods throughout the country, beginning with gardens at the Agencies and Assistant Agencies with at least one smaller garden in each headman's division.

The training and controlling agency, with ramifications all over the Island for extension, is already available in the Educational Department, with which the Government Agents, their assistants and headmen are closely in touch and already work amicably.

A former Director was the first to take up the question and induce Government to give some measure of support. Any retrogression is due to the appointment of a gentleman who was a schoolmaster and took small interest in the subject. The position is now filled by a Civilian who has prior to his appointment paid some attention to the question, and as his tenure of office is likely to last for some years, there is a guarantee of a continuity of administration, which justifies adhesion to the existing arrangements in preference to a new departure.

Besides retaining the Director as the controlling authority I would adhere to the Agricultural School (subject to the modifications I will detail) as the mechanism for teaching a certain amount of theoretical knowledge (during the first year) and supplementing it with a working farm of some size on a line of railway, but as close as possible to Colombo, for practical work during the second year of the course. The farm should be rather a large market garden, at which vegetables of all kinds, country as well as introduced, should be cultivated by the students themselves according to the very best method, and the training should be such as to make them good practical working gardeners, conversant with European modes of Horticulture, as well as breeding of poultry, treatment of cattle (including ability to castrate). All agricultural work and attention to cattle should be done by the students, and no cooly labour allowed. A garden so worked should show fair profits, and should supply an existing demand for vegetables, green meats and good fruit in time.

The next consideration is, having your trained man, how to keep him in his village. The best safeguard for this is to look on a knowledge of English as a disqualification for admission to the Agricultural School, and to have all instruction at it conveyed in Sinhalese (Tamil can follow later after the wants of the majority in the Island have been fairly met). I would draw the first students from young vernacular schoolmasters and the most intelligent pupils in vernacular schools who have passed in the highest standard—a few from each district—and put them through a two years' course as already indicated. I would at first restrict the number of admissions to 20 a year, say for 5 years, and to induce the proper class to come up for instruction I would make it perfectly free, including cost of travelling to and from their homes, only excluding personal clothing. I believe a sum of R15 per head per mensem would cover this item. The knowledge now required on entrance and the further education given in general subjects at the school are fatal to the chances of those now trained at some cost adhering to an agricultural course: and to raise the standard would still further reduce the chances. If there is a demand for a higher course from those prepared to pay *moderately* for it, such students would be I think very few and familiar with Sinhalese colloquially, and would therefore benefit by the oral and practical instruction given, and be competent to supplement this by reading text books in English and some private tuition in the more advanced branches. To such a class Government might offer a scholarship yearly to proceed to one of the Indian Colleges for an extended course of education, and from them would be drawn the future teachers of the school.

My scheme proposes eventually to have

1. Provincial gardens at G. A. Stations.
2. District gardens at A. G. A. Stations.
3. Village gardens in Principal Headmen's Divisions
4. School gardens.

If suitable men are available I would make an immediate beginning with the 1st and 2nd class. Sites of moderate size are doubtless available or can be procured on moderate terms. Each garden should be allowed one cooly for a few months, after which the garden should be self-supporting by the sale of produce, and a regular account kept of receipts and expenditure. The gardens should be under the immediate control of the G. A.'s and A. G. A.'s of the stations. As funds accumulated improved breeds of fowls should be procured and the eggs sold or given away free (with the authority of the Agent) to villagers willing to undertake the rearing of poultry. Young cocks should also be distributed in like manner. Each gardener should be competent to castrate cattle and be required to do it free of charge. Dairies &c. might follow in time at the larger stations or where grazing is available.

As these stations are filled and the first purely vernacular gardeners trained under this system become available, one should be attached to each principal headman who should be required to find him a proper site for a garden, in which he should be expected to raise vegetables, fruits &c., in the mode he has been taught, digging up the soil, properly manuring, &c., giving information and setting an example and supplying seed to his neighbours. He should also be required to visit a certain number of schools in his neighbourhood and teach the scholars for say an hour twice a week, and induce them to start small plots round the school, the master being instructed to co-operate.

I look to this preliminary teaching to develope a taste for gardening, &c., and a useful guide to the selection of scholars for the Colombo school. The men should receive a small salary for the first year say of R15, to be reduced to R10 in the 2nd year, and R6 in the third payable half-yearly on production of a certificate to be granted by an Inspector or some other authority to be appointed by the Director that the payee is keeping up a proper garden. The produce of course he would be at liberty to sell and keep the proceeds. After a few years it would he possible to reduce the remuneration to a small grant or a more substantial prize for the best garden in a given area, &c. There would he then a margin for increasing the number without entailing a larger aggregate outlay. For certificated school-masters who have gone through the Colombo Agents, of course the Director would possibly secure re-employment as school-masters,-and they should receive some additional remuneration on condition of keeping up a good garden, stock of poultry, and being ready or willing to castrate bulls *free* on application. I note Mr. Willis in his memo. [p. 7) speaks of the necessity of having gardens, but he connects with it a higher standard of education which is beyond all requirements, at all events at present. He also yearns for a better class of student, sons of wealthy native landowners. Such men invariably acquire a knowledge of English, are attracted to the towns, are not likely to take to a rural life and would only go to the Agricultural School for the general education he very properly deprecates.

My students would be drawn from the sort of landed population who are likely *not* to be spoiled by a temporary residence in Colombo, and are pretty sure to return to their villages.

To assist the Director in this branch and to secure an officer who will devote his whole attention to the working of the scheme, I would utilize the services of Mr. Drieberg (with suitable additional remuneration) as assistant for Agriculture and Inspector of Experimental Gardens. These he should personally visit and see how the gardens are working and give them instructions. He should, however, remain Principal of the School, but be relieved of personal tuition or lecturing, and also supervise the Model Farm visiting it very frequently.

I would suggest the D. P. I office might be housed at the Agricultural School. It would keep the Director more in touch with this branch of his duties and obviate the necessity of Mr. Drieberg's absence while attending an office in the Fort.

At the Central Farm special attention should be paid to country vegetables for the production of good seed for distribution to the rural gardens, as well as to the importation of seed of other vegetables which can be grown in the Island. There is a great demand in all parts for vegetables which is now met very imperfectly. Seeds of all kinds should also be cultivated for sale to the public atmoderate rates.

Paddy Cultivation should also receive a great deal of attention at the central farm, and an area of 25 acres be kept continually under tillage, but this should be largely of an experimental nature to test suitability of new kinds of imported seed, their periods of growth, ratio of return, &c., also the value of various kinds of manure. The discovery of a plough which will turn up the soil to a sufficient depth but can be worked by the ordinary cattle is a matter that should receive attention. Other points on which research is desirable will suggest themselves to the Superintendent, and he will be in a position to give advice and information based on *practical* experience, which Mr. Drieberg is not able to do at present. The labour for this experimental cultivation will, of course, be supplied by the students, and they will thus become generally familiar with the trials, and the results: it is to be hoped they will carry away some useful ideas, and give them a trial in their villages. By way of encouragement students should be informed when leaving that they could at any time obtain the loan of an improved plough and a gift of good seed if they see their way to utilizing them.

More expenditure in pushing the actual experimental cultivation of paddy in all villages I would not advice. Except perhaps the advantages of deeper ploughing there is little or nothing the native cultivators as a whole are not aware of, and when they do not work in the best known native methods it is due to poverty or other disability. One, for instance, is the difficulty of getting cattle and in some districts even good seed paddy is the want not in their power to rectify. When in the Batticaloa district recently heard a good deal of the paddy was not worth milling, it gave so small an outturn of rice which in the Hambantota district is as a rule 50 per cent. In such cases Government should step in and make a present of say 1,000 bushels of paddy. Again, where good seed has been introduced by some energetic Assistant Agent, it has got so hybridised as to lose its original productiveness and the knowledge where it came from is lost, or if known it is not easy to get a further supply.

As regards cattle it is worthy of consideration if Government should make advances on the security of the holdings to landowners to purchase buffaloes as is I believe done in India, repayment being spread over a number of years. There is at present I understand great scarcity of cattle all along the South-east coast of Ceylon, while there is a surplus in the western side

Connected with this is the question of pasturage for cattle which has been much restricted since the prohibition of chenas, and is becoming serious both in the more settled districts and where cultivation is being extended in the more outlying parts.

But these are points which may be considered and dealt with apart from the scheme I have formulated:—

Estimate of Cost.

Asst. to Director, and Inspector ..	R4,000		
Teachers and Instructors ..	4,000		
Keep of 40 students at R200 ..	8,000		
			R16,000
6 Provincial gardeners.. ..	2,000		
10 District do	2,400		
45 Village do	4,400*		
Allowance to certified teachers ...	600		
Prizes of R50 each for the best-kept village gardens over 2 years in existence	1,000		
			10,400
			26,400
Contingencies			3,60
Total Estimated Cost of Scheme when in full working			R30,000

Each village gardener should be entitled to a lease at a rental of 25 cents an acre, of two acres of suitable Crown land for the purpose of cultivation of praedial products (excluding coconuts) so long as he keeps up a proper market garden. With this inducement and after 2 years' training and 3 years,' endowment, while making a start in his own village, besides eligibility for promotion as a district gardener, and the possibilities of substantial prizes for the best-kept garden, as well as others at district shows which should be held regularly—with all these encouragements, there is every hope, if not certainty, of most of these men keeping to the trade and working on the lines they have been taught. Thus in time there will be a large number of Government market gardens even in the most out-of-the-way parts of the Island more or less of an example and a source of advice and assistance, by issue of seed and otherwise, to the villagers.—E. ELLIOTT, October, 1900.

[Mr. Elliott, in the above paper, draws a distinction between Planting and Native Agriculture: the former

* 15 at R180, 15 at R120 and 15 at R60

he considers, can be served from Peradeniya; the latter by a reformed Agricultural School to be continued under the Department of Public Instruction. Our objection to this course is that it would not secure the personal interest, attention and responsibility of the Provincial and District revenue officers and their headmen, without which we are hopeless of any real permanent progress being made in the improvement of native agriculture.—*Editor, Tropical Agriculturist.*]

THE FIRST PUBLIC SALE OF GREEN TEA IN COLOMBO.

FULL PRICES REALISED.

FINE GREEN TEAS FROM A KALUTARA ESTATE.

At the public sale of tea, on 10th Oct. last an event which is certainly worth noting took place. It was the first auction at which green teas were sold in Colombo, and the result must surely be regarded as eminently satisfactory. Two estates invoices were offered—one of high-grown tea and the other of low grown—and there was, curiously enough, very little difference in the prices paid for each. The breaks were divided into Young Hyson, Hyson No. 1, and Hyson No. 2, and the following were the prices paid for the high-grown invoice, sold by Messrs. Forbes & Walker:—

LABOOKELLIE GREAT TEAS

1,575 lbs...Young Hyson..52 cts.
1,260 lbs..Hyson No. 1..42 cts.
3,920 lbs..Hyson No. 2..37 cts.

These prices must be considered good, though Labookellie, being an estate at a considerable elevation, is accustomed to get excellent prices for its teas; and no doubt, when the Superintendent has had more experience in the manufacture of green teas, he will turn out a very much better sample than even these.

The second estate offering green teas, was Arapolakanda, the property of the Eastern Produce and Estates Co., in Kalutara, and, inasmuch as the prices paid for its invoice of green teas was almost as good as that given for Labookellie, green teas, the Superintendent of the estate who made the tea has to be congratulated on the result. As the estate referred to offered an invoice of black teas in the same sale, we are able to make a very effectual comparison, of the prices realised for the one and for the other. They compare as follows;—

ARAPOLAKANDA.

Green Teas		*Black Teas*	
lbs.	cts.	lbs.	cts.
1,710	Young Hyson..50	3,780	Broken Pekoe..39
1,360	Hyson No. 1 ..41	2,400	Pekoe ..34
852	Hyson No. 2 ..37	540	Pekoe Souchong28

We think our readers will agree with us that this result is one of which all of us in Ceylon can heartily congratulate ourselves. It clearly demonstrates that even leaf from Ceylon low-country estates can be made into excellent green tea, and that prices can be paid in the open market as high as, if not higher than, those commanded by black teas.

We may state that some of this teas were purchased by Mr. Tokmakoff to be sent to Russia; others we believe are destined for Canada.

We may say that the leaf of the Arapolakande tea had a better appearence than the other, whilst its liquor was more pungent and had more of the true green tea flavour, which is the more remarkable as it is a low-country tea, and it was thought that leaf from such estates could not be made into the best green tea.—Local "Times."

RUBBER IN RHODESIA.

We have received an interesting little pamphlet upon the rubber industry in the British South Africa Company's territories. The writer is Mr. Philip Lyttleton Gell, one of the directors of the Chartered Company, and although the information at the disposal of the writer is admittedly imperfect, he gives facts which clearly show that there is an extensive field for the development of the rubber trade in the extensive territory controlled by the Chartered Company.

In the introductory notice Mr. Gell has arrived at certain conclusions which he briefly states under eight headings, which are as follow: (1) All the rubber should contribute to the revenue; (2) all wild rubber should be regarded as a capital asset of the company; (3) immediate legislation is necessary to regulate the industry and protect it from extirpation; (4) no monopoly should be granted, although outsiders wishing to collect rubber must obtain the local licence; (5) the duty of, say, 3d per lb. should be levied upon all traded rubber; (6) all licences to be available only within the district specified; (7) a department of forestry should be established; (8) encouragement should be given to the investment of capital in the systematic cultivation of rubber.

In the course of the pamphlet the writer deals with the sources of rubber, extensive tracts of north-east and north-west Rhodesia producing natural rubber of high commercial standing, whilst it is indigenous in abundance in the southern part of the country. The native methods of extraction are, as usual, very destructive and the methods of preparation faulty, but it is believed that the various rubber species can be introduced and cultivated, and the rubber latex collected under proper management.

The chief indigenous rubber belongs to the Landolphia species, which flourishes in the Mweru districts.

Dealing with the regulations enforced in other countries, he says that in the Congo State the industry is largely worked by the Government. Concessions for extracting rubber within fixed areas and for limited periods are also granted, but the lessees are bound to plant a certain number of new trees each year, bearing a fixed proportion to the weight of rubber extracted. Amongst other restrictions the felling of rubber trees is forbidden, and for the infringement of this and other regulations, penalties of from 100f. to 10,000f. and imprisonment may be imposed, employers, directors of companies and State agents being liable for the payment of fines incurred by their servants. Export duties on rubber are fixed at 10 per cent. by treaty with France and Portugal. There is apparently an additional duty of 50 centimes per kilo. fixed in February, 1898, and a fee of £200 is charged for every licence to establish an India-rubber warehouse. Natives who hold licences to collect rubber apparently have the option of compounding for their fees by paying one-fifth of the rubber collected to the State.

In Lourenço Marques a monopoly of the production and trade in rubber for twenty-five years has been granted over the unoccupied State lands. The concessionaires pay a rent of 200,000 reis (equal to £44 7s 11d) per annum, and undertake to plant 20,000 trees in two years. They further pay a duty of 50 reis (equal to 2·65d) per kilo, for seven years; rising to 75 reis (equal to 4d) per kilo. for the remaining eighteen years. They are exempt from all other imposts. They have the option of retaining the land at the same rent at the expiration of the monopoly, which, however, does not restrain the cultivation of rubber on private property and its export by private persons.

The Mozambique Company forbids any individual to purchase rubber from natives, or to extract it through agents, without a special annual licence, extending only from February 1st to August 31st, which costs £3 per annum. 30 reis (equal to 1.6d) per kilo. must be paid before rubber can leave the district in which it is collected, and a receipt for the tax must always accompany the goods. Every person purchasing rubber or collect-

ing it must keep books showing the amount received daily, and report it once a month to the district official.

RESTRICTIONS IN BRITISH POSSESSIONS.

The system in Lagos is based upon a theory that the ownership of forests is vested in the local tribes, under their "native authorities," that is, chiefs. Within districts under the control of such "native authorities," no person may collect rubber without a licence, for which he pays £5 to the "native authorities" and 2s. for each load of rubber. No tree of less girth than 3 ft. at a distance of 3 ft. from the ground may be tapped. It may not be tapped more than once in eighteen months, and only in the manner prescribed by the "native authorities." The preservation of the protecting timber is also provided for. No tree of a girth less than 9 ft. at a point 10 ft. from the ground may be felled, and a similar tree must be planted in the nearest suitable spot within seven days. A permit must be obtained from the "native authorities" for all trees felled, and a fee of 5s a tree must be paid. This system, Mr. Gell understands, proves ineffectual.

The British Central Africa Protectorate has not yet established any adequate system for preserving the rubber industry and deriving substantial revenue from it. The protectorate does, however, forbid the destructive traffic in root-rubber and rubber obtained by boiling bark, and it levies a 5 per cent transit duty on rubber for the maintenance of roads, which produces about 1½d a lb.—*India-rubber Journal*, Sept. 17.

A report on the rubber industry of the British South Africa Company's Territories has been prepared for the company by Mr. Littleton Gell, and the following particulars extracted from it are taken from the *Board of Trade Journal*:—

It is now ascertained that extensive tracts in North-West and North-East Rhodesia produce natural rubber of high commercial value, while in Southern Rhodesia indigenous rubber is reported in abundance in the Sabi Valley and along the Zambesi. There is also good ground for believing that various foreign species of a yet more valuable character can be gradually established throughout the territory, and there are certain kinds which may be expected to thrive even in the drier climate of the Southern Rhodesia plateau.

On the other hand, the native methods of extraction are very destructive, and in the absence of protective regulations the opening of markets will not inevitably tend to the rapid extirpation of indigenous rubber trees. Further, the existing methods of preparation are faultly, and impair the market value of South African rubber.

The indigenous rubber, which (so far as official information goes) has at present been identified in the British South African territories, belongs chiefly to the class of gigantic creepers scattered amongst other growths.

Passing on to the administrative aspects of the rubber industry, the elementary principle which emerges is this—that the indigenous rubber must be regarded from the first as State property (as in the Congo, Lorengo Marques, and Mozambique territory), and should not be abandoned to private exploitation. It represents an exhaustible accumulation of natural capital, to which neither the nomadic natives nor the casual adventurer has any proprietary claim, but which should be husbanded, and, if possible, increased to sustain the immense expenses of developing a new territory. The native, who extracts it, and the trader, who exports it, must, of course, receive an adequate inducement for their services. But in the indigenous stage the rubber industry does not require any outlay on plant or large capital. It is not speculative; the settlement of the country diminishes the trader's risks. Transport is comparatively cheap for an article highly valuable in proportion to its bulk. No expensive management is involved. Accordingly, whatever profit there may be after the native and trader has been reasonably remunerated should be retained.

The problems which present themselves may be conveniently dealt with in the following order:—

1. The measures necessary to preserve the existing sources of rubber.
2. The methods of obtaining a revenue from the industry.
3. The future development and expansion of the industry, including the suppression of detrimental methods of extraction and preparation.
4. The policy towards purposals of exploration.

The systems established for the protection of the rubber industry in other territories have been of the following types;—*(a)* Forests, including rubber trees, are reserved as State property; they are directly administered, and the rubber is collected by a forest department. *(b.)* The forests are retained as State property, but private enterprise is permitted over specified areas under terminable leases and strict conditions. *(c.)* Tracts of forest are transferred to private or joint stock ownership, and the development is left to individual action under some degree of legislative regulation. *(d.)* Forests are abandoned to the first comer, subject to more or less effective regulations as to methods of extracting or trading rubber; this appears to be the usual British principle outside India, and the least wise of any.

The regulations existing in other African territories afford some useful suggestions, though speaking generally, they appear to be very imperfectly enforced. Penalties of from 100 francs to 10,000 francs and imprisonment of ten days to six months may be imposed, employers, directors of companies, and State agents being liable for the payment of fines incurred by their servants.*

There will probably be no hesitation in recommending that immediate regulations should be framed for North-West, North-East, and Southern Rhodesia for the protection of wild rubber which should embody certain well ascertained principles, *i. e.*:—*(a.)* A minimum age and girth should be established, below which a tree must not be tapped; the exact measurements must be adapted to different species and localities, so that legislation should only establish the principle empowering our officials to promulgate the precise regulations for each district, after reports have been received as to the nature of the rubber plants there prevailing. *(b.)* The intervals at which trees may be tapped should also be regulated. Subject to local modifications, it would be safe to forbid tapping the same trees, or the same area, in two successive years. *(c.)* A general regulation will be required that rubber may only be collected by tapping, that no tree may be cut down, and no roots grubbed up and boiled; on the other hand, to avoid unreasonable rigidity, or to deal with exceptional conditions, a local official should be empowered to modify this regulation.† *(d.)* A general regulation is desirable providing for the plantation of young rubber trees in forest land by persons extracting rubber, in some propotion to be fixed by the local official, and a small reward for every tree planted should be paid.‡

---

* Export duties on rubber are fixed at 10 per cent. by Treaty with France and Portugal. There is apparently an additional duty of 50 centimes per kilo, fixed in February, 1898, and a fee of £200 is charged for every license to establish an india-rubber warehouse. Natives who hold licenses to collect rubber, apparently have the option of compounding for their fees by paying one-fifth of the rubber collected to the State

† Root rubber is reported in North-West Rhodesia as a special product of the country. Unless it differs from other rubbers extracted from roots the process is not to be enconraged.

‡ In Indian forest districts the systematic plantation of any trees which it is desired to establish is secured

If in special districts the extraction of root rubber is permitted, the rate of replantation must be high—not less than two to one. (*e.*) The forest trees which provide the indispensable shade must also be protected from destruction. (*f.*) Powers should be taken to forbid absolutely the extraction or sale of rubber in a district for a fixed period; as a penalty for breach of regulations, or merely as a protective matter.

As regards the future development of the industry, the important points are as follows:—(*a.*) The steady replanting of indigenous trees, and the preservation of the shade trees in forest areas (*b.*) Improved methods of extraction and preparation. (*c.*) The introduction of superior species in cultivated areas. (*d.*) The formation of a small forestry department, a member of which would have special experience of rubber.

SOME QUESTIONS ON CACAO.

SIR,—Will you kindly allow me elbow room in this column to ask—

(*a*) If anyone in the Island knows what Mr. Arden actually meant by "topping" cacao? Mr. Gibbon alludes to it as "very unusual."

(*b*) If, however, "topping" is merely what is more commonly known as "suckering" (*i. e.* ridding the tree of young shoots upwards from the stem in order to promote crop, and decrease height), is not this system of "topping" rather the rule than the exception.

(*c*) And what is the allusion to the "topping" of shade trees?

(*d*) And if Mr. Arden was "presumptious" to comment on an "absence of light and air," why have most cacao planters exemplified the justice of the verdict by increasing the intervals between their shade trees?

(*e*) And is it not probable that Mr. Arden's remark on this head had as much, if not more, to do with the distance at which cacao itself has been planted in the past?

(*f*) And why does one gentleman talk about "topping cacao," and another about "cacao topping itself"?

(*g*) And why should it be supposed that "suckering (*i.e.* forcing) a tree strengthens it?

(*h*) And if "suckering" strengthens a tree why was it considered "not wise to remove them all" (the "suckers"?)

(*i*) And if "suckering" weakens a tree why should Caraccas be considered doomed? Has it not always been "suckered" (weakened) systematically, until its health has become such that, when the canker came, it was unable to resist it? Has it, therefore, had a fair chance?

(*j*) And has it been satisfactorily demonstrated that Forestero is such a far more hardy variety than the "red"?

(*k*) And is there anyone who can say that "suckering" Forastero will not eventually reduce it to the present anæmic condition of Caraccas?

(*l*) And why is it planters consider Forastero a "stingy cropper" in comparison with Caraccas, when the former (a tree many sizes larger than the "red" variety), is rarely planted at greater distance than the "red"?

(*m*) If Forastero at 12 ft. by 12 ft. gives 2 cwts. per acre, what will Forastero at 24 ft. by 24 ft. give per acre?

(*n*) Until someone is in a position to answer this question from practical experience, what sort of justice is that meted out to Forastero

(*o*) And is not the complaint of "stinginess" probably owing to the fact that the free cropping Forastero varieties have been saddled with the "stinginess" of other Forastero varieties and which have no (colloquial) distinctive name? It is not possible that planters have been too "sweeping" in their statements when they have compared the cropping capacity of the highly-cultivated Caraccas with that of the numerous varieties of Forastero from time to time imported into the Island, and between which scarcely any trouble is taken to disinguish?

Well, Sir, this is a long list. The truth is when I first began asking questions I had no notion my ignorance was so great.—Yours, etc., POD.

MR. J. B. CARRUTHER'S ANSWERS.

PUCKERING—PRUNING—ANEMIA—VARIETY—EXPERIMENTS.

On referring 'Pod's' queries to Mr. J. B. Carruthers, he has kindly jotted down some partial answers to the questions asked, which he considers are of interest as shewing a desire to get an accurate knowledge of cacao, and as such he welcome them. He takes the queries in the alphabetical order thus;—

"PODS" QUERIES,

a. to *f.* Mr. Arden's remarks must be considered only in relation to the cacao estate he saw and the methods carried out there.

"Topping" probably means pruning the higbest vertical branches.

g. & *h.*—"Suckering"—*i. e.* cutting off "suckers" is not "forcing"—it gives the impression of strengthening the tree, because the nutrition taken up by the root has less branches to support and consequently those that remain are strengthened.

i—Pruning for fruit is only necessary when a tree produces long, unbranching shoots which shows no flower buds, suckers in cacao produce flower buds and fruit after one year's growth. Nature should not be interfered with unless an increase in the yield can be obtained.

j.—There is much evidence that Forastero is hardier. Exact experiments would, however, give a moreabsolutely trustworthy proof.

k—"Anæmia" is a disease of the blood in animals with a circulatory system, and in plant life there is no analogous system and therefore no disease which has any similarity to "anæmia."

l.—Do planters consider Forastero a "stingy cropper?" The largest tree in Ceylon are red cacao (Caraccas), but they are older in most cases than the Forastero.

m—Such an experiment would undoubtedly give knowledge of great importance to planters.

o.—No experiments of an accurate kind have been made to show the relative fruit-producing qualities of the two varieties, and all opinions are only based npon local observations often not very correctly made, and the deductions obtained not very carefully or legically worked out.—Local "Times."

RAMIE FIBRE AS A SUBSTITUTE FOR COTTON.—Mr. D. Edward Badclyffe, Regent's Park, writes that Lancashire is threatened in connection with the cotton industry with a serious loss, and he asks why this country does not profit by its lessons. When the last great famine took place during the American war Great Britain, he says, was shown the folly of relying on one country for it supplies. "We have," he adds, "a vast territory in which we could grow Ramie, which is a fibre far superior to cotton. It will grow where cotton grows, and where it will not. The possibilities of this plant are enormous. It grows wild in India and many other of our possessions. It will make anything that can be made by flax, cotton, wool, or silk. If our Colonies would turn their attention to Ramie growing, the possibility of a vast industry being crippled for the want of snpplies would be a thing of the past."—*Journal of Horticulture.*

---

by paying the natives trifling rewards for sowing seeds' distributed to them during the last season before they migrate from exhausted clearings to take up fresh ground. Small further payments are annually made for three or four years as a reward for weeding, &c., until the new trees can protect themselves. This system has proved effectual and cheap.

ARTICHOKES.

I have been asked to give information about Artiebokes, the different kinds of which are often confused. The Jerusalem Artichoke is the first and best known. This is an entirely distinct vegetable from the globe or crown artichoke, being cultivated solely for its tuberous roots, which somewhat resemble those of the potato, while the edible portion of the crown or true artichoke is the receptacle of the unexpanded flower heads. It is somewhat unfortunate that the name of Artichoke should have been applied to both the above, and still more so that it should have been also adopted in the case of the comparatively new Chinese artichoke (so-called)—*Stachys tuberifera*, a totally distinct plant.

The true "Jerusalem" artichoke is really a species of sunflower *(Helianthus tuberosus)*, a native of the American prairies, the word "Jerusalem" being merely a corruption of the Italian "girasole," or sunflower. It grows, in good ground, to a height of 8 ft. or 10 ft.. and, though it seldom flowers, it usually affords, under even ordiuary culture, a heavy crop of useful tubers. Its nutritive value is very nearly the same as that of the potato, slightly—though very slightly—inferior; but the plant being more hardy and easily cultivated, succeeding in any odd corner or shady plot, fully compensates for this. The peculiar sooty flavour of the tubers, when cooked, though liked by some, is objected to by others. The proper time for planting the seed tubers is from November to March. The sets, consisting of the smaller but fairly well shaped tubers, should be planted in much the same manner as potatoes, that is, in furrows about three feet apart, placing them one foot asunder. Though the Jerusalem artichoke will grow freely and produce more or less good crops in poor, shallow or shady ground, yet it enjoys a fairly sunny and moderately sheltered spot, with well-worked and liberally manured soil. The tubers being perfectly hardy may be left in the ground until required for use, but it is just as well to lift and store them in a cool place in case the soil should become so hard as to prevent their being dug in the open. When selecting tubers for seed, those of moderate size and a nice, smooth shape should be chosen, as being more likely to produce tubers of the same character. There is a new, white-skinned variety which is claimed to be a great improvement on the type, but it is scarcely as prolific as the other.

2.—The Chinesese Artichoke.—This is a totally distinct species, bearing a large number of knotted-looking roots of good flavour. It should be planted in drills or furrows like those for potatoes but rather closer. It is very prolific, but the roots are small.

3. The Globe, or Crown Artichoke.—This is likewise a distinct plant from the foregoing. It is a strong-growing, perennial herbaceous plant *(Cynara scolymus)*, with handsome foliage, but cultivated for the sake of fleshy flower receptacles or heads, which are boilded till tender, and eaten with melted butter, toast, etc.

The plant are increased by means of division, as a rule, though seed of two or three varieties is now obtainable, and where a large stock has to be raisecl in a short time, this is an excellent method. When the new growth commences, any old plants may be either lifted bodily, and divided into pieces, with one, two, or three good crowns or growths apiece; or some of the outer suckers (rooted) may be separated and planted out in a properly prepared quarter. Salt and nitrate of soda are among the best of fertilisers or stimulants for this plant.—*Jamaica Agricultural Journal.*

MANUFACTURE OF COCOA.

The selected cocoa beans are first cleaned from the dust and attached particles which have come from various sources during the fremeutation of the seeds.

The machines for cleaning the beaus are very ingenious aud effective, removing from the seed coat every trace of foreign matter. The cleaned seeds are next roasted in the most careful manner, every precaution being taken to secure a uniform effect through the whole mass. During the roasting the seeds change colour somewhat, and become more or lees modified in taste. In under-roasted seeds the flavour is not fully developed, while in over-roasted seeds the pleasant taste is likely to become greatly impaired, or it may even be wholly replaced by a bitter and harsh flavour. These relations of colour and taste to the roasting of the seeds make this portion of the manufacture one of the most delicate processes from beginning to end. By the roasting, the shell becomes more readily detachable, and its complete removal is the next step. The crushing of the seeds into small fragmeuts is easily accomplished; and this is followed by a thorough winnowing, by which the lighter shells are carried away by themselves, leaving the clean fragments of the roasted seeds ready for further manipulation. Among the fragments can be detected minute and very tough bits of tissue. These bits are the hardened germs, or rather portions of the germs, and these are separated from the rest by an apparatus of much simplicity and efficiency. The cleaned shells are usually placed at once in packages for transportation. They are extensively used for the domestic preparatiou of a wholesome and very low-priced drink. This beverage contains a fair proportion of the active principle of the chocolate seeds themselves, and the flavour is suggestive of chocolate. The cleaned fragments constitute the so-called "cocoa nibs" of some foreign markets, and in this state they are used for the preparation of a simple decoction. But in this form they require to be boiled a long time for the development of flavour, and it is, therefore, better to have them treated beforehand in order to reduce the time of boiling; and this is all the more necessary, since during the long boiling a part of the more delicate aroma peculiar to chocolate seeds is apt to be dissipated. In the preparation of chocolate, the fragments are ground by a complioated mechanism until they attain the greatest degree of fineness, and constitute a perfectly homogeneous mass or paste. If it is to be a plain chocolate it goes directly into the moulds for shaping it. The moulding is a noisy but interesting operation. The chocolate cannot be pressed into moulds, because it sticks to the presser; it is, therefore, shaken in. A plastic lump of the proper weight is placed in a shallow mould. A number of these moulds are put in a wooden tray, placed upon a table, which is shaken automatically, causing the metal moulds to jump up and down in a very lively manner, aud making as much clatter as a regiment of cavalry crossing a bridge. Every step of the process has to be watched with the most assiduous care. When the plastic mass has been shaken into the mould so as to be perfectly uniform in shape and size, the pans are removed to the cooling-room. If the chocolate is to be sweetened, a definite amount of the purest sugar, previously pulverized, is added before the moulding, and the whole ground and commingled. If it is to be a vanilla chocolate. the finest quality of Mexican Vanilla beans (which are superior to those gone elsewhere) are blended with the semi-fluid mass, and formed in moulds, as already described. The variations in the process are innumerable, many of them comparatively unimportant when taken singly; but to secure the best results it is important that each of these slight changes should be made at just the right time and in the right way. The manufacture of breakfast cocoa is based upon two important factors—first, the removal of a definite portion of the cocoa-oil from the roasted seeds; and second, increasing the miscibility of the powder so as to secure the greatest practicable degree of fineness. The method of manufacture is substantially as follows:—The ground fragments of roasted seeds are subjected to hydraulic pressure, by which a certain amount of the fat is eliminated. The pressed mass is, in the most successful process, treated mechanically in such a manner as to divide and sub-divide the minute

particle until they are capable of pressing through a sieve having several thousand meshes to the square inch. But such pulverization as this would, under ordinary circumstances, reduce the mass to a dull and unattractive powder. In the process devised by the owner of the best cocoa manufacture, this high degree of fineness is secured without any loss of brilliancy in the powder—the color being of the bright red which is not only attractive in appearance, when conjoined with the natural chocolate odour and flavour is characteristic of absolutely pure cocoa of the highest grade.—*Jamica Agricultural Journal.*

FLAX CULTURE.

The cultivation of flax for fibre purposes would doubtless yield a profitable return in many parts of this colony, and it is equally certain that on dairy farms where a large quantity of skim or separated milk is available for feeding calves and pigs the growing of flax seed for mixing with the milk would pay the farmer handsomely. The cultivation of this crop is simple and inexpensive, and for stock feeding purposes at least, it is one of the most useful products that can be raised. It is not necessary, nor is it desirable, that the soil on which flax is grown should be very rich. On the contrary, excessive luxuriance of growth is injurious, and generally results in the crop being "laid," which renders it comparatively worthless either for fibre or seed. The best soil is a sound dry, deep loam, with a clay subsoil. By good and careful cultivation, however, flax may be grown on various soil, but the class of soil just mentioned will be found to give the best results. In the preparation of the soil for the crop one of the points of greatest importance is that the land should be thoroughly cleaned of weeds, and made into a fine state of tilth of a moderate depth. The soil to a depth of three or four inches cannot be too fine. If the autumn cultivation has been carefully carried out a good harrowing in spring will generally effect perfect pulverisation of the soil. Following the last harrowing it is necessary to roll thoroughly, in order to secure an even surface and consolidate the land, which may be broken up again with a short-toothed or brush-harrow before sowing, drawn up and down in the direction in which the land had been ploughed. The seed best adapted for the generality of soils is Riga, although both Dutch and American varieties may be used with equal success in certain localities. In purchasing seed a point should be made in seeing that it is plump, shining, and heavy, and of the best brands, from a reputable merchant. It should be seen that it is free from the seeds of weeds; this will save a great amount of trouble afterwards when the crop is growing. Home grown seed is usually the most reliable, and we would, therefore, recommend every farmer to only sow each year as much foreign seed as would produce a sufficient quantity for his flax crop the following season. The produce of seed averages about 12 bushels to the acre, so that the seed saved of one statute acre would sow about six. In growing flax for fibre, it is better to sow thick than thin, as with thick sowing the stems grow tall and straight, with only one or two seed capsules at the top, and the fibre is found greatly superior in fineness and length to that produced from thinly sown, flax. The latter usually grows coarse and branchy, and produces a large quantity of seed, but very inferior quality of fibre. It is not advisable to grow flax more frequently on land than once in three or four years. It does well, as a rule, after a grain crop, but in America and and the Argentine, the usual practice is to sow flax on the sod on newly broken up land. In those countries it is held that the crop is more beneficial to new land than a bare-fallow, as it materially assists in pulverising the sod, and from the shade it affords helps to retain the moisture in the subsoil. There is every reason to believe that this practice would be equally successful in the wheat-growing districts of New South Wales. It is true that flax is a somewhat exhausting crop on the fertility, but this may be more than compensated for in the better condition the soil is left after it, compared with the pulverising effects of a bare fallow, and the system is, at any rate, worthy of a trial. The flax crop is not easily drouthed if it gets a fair start, and covers the ground fully before the dry weather sets in. Its roots penetrate much deeper than the wheat plant, and it will succeed almost anywhere with a rainfall averaging 20 inches and upwards per annum.—*Sydney Herald.*

Ramie Fibre as a Substitute for Cotton.—Mr. D. Edward Radclyffe, Regent's Park, writes that Lancashire is threatened in connection with the cotton industry with a serious loss, and he asks why this country does not profit by its lessons. When the last great famine took place during the American war Great Britain, he says, was shown the folly of relying on one country for its supplies. "We have," he adds, "a vast territory in which we could grow Ramie, which is a fibre far superior to cotton. It will grow where cotton grows, and where it will not. The possibilities of this plant are enormous. It grows wild in India and many other of our possessions. It will make anything that can be made by flax, cotton, wool, or silk. If our Colonies would turn their attention to Ramie growing, the possibility of a vast industry being crippled for the want of supplies would be a thing of the past."—*Journal of Horticulture.*

Cocoa in the Philippines.—The Cocoa plant grows in great abundance in the Philippine Islands, and it is stated that there is a good opening for the manufacturers of chocolate products of all kinds in the islands. The Cocoa plant in the Philippines is more like a shrub or bush, being about 10 feet in height, than the plant in South America, which averages about 25 feet in height, and forms quite a tree. The reason for the bushes not growing taller is to be found in the lack of proper cultivation, as the farmers of the islands give little attention to their farms. The large planters have as yet done little to develop the Cocoa industry, though their other crops are large and often well cultivated The Cocoa plant grows near the protected towns, and will furnish two crops a year without cultivation. In the mountains tons of Cocoa go to waste every year. The leaves at certain periods of the year have a deep, rich, green appearance, while the flowers take on different colours and are most striking. The fruit is a large pod, oval in shape, which contains the beans from which the chocolate is manufactured. If, says an authority, modern methods of working the product were introduced, much of the waste occurring through primitive appliances could be avoided, and the profits be large.—*Journal of Horticulture.*

The Lac Industry of Assam.—A recent report of the Assistant-Director of Agriculture in Assam deals in detail with the lac industry there. Lac occurs in its natural state in various parts of the forests of Assam, as well as of Burma, but chiefly in parts of the Khasi and Garo hills, and the export in recent years has averaged 16,000 maunds, or something over 500 tons, but in some of the forests, owing to the ravages of the Kolaazar epidemic and depopulation, the production is declining. The production in Manipur is not sufficient for the local needs, and quantities of lac are sent there from the Kubo Valley of Assam. In Assam the lac is usually collected twice a year, first in May and June, and then in October and November. The first is mainly used for seed purposes, while the second forms the export. A few days after the collection, pieces of of stick lac containing living insects are tied on to the branches of the trees on which the next crop is to be grown. The usual plan is to place the lac in small bamboo baskets and tie these on the twigs of the trees. The insects soon crawl out, and spread over the young branches, on which they promptly begin to feed, and secrete the resin. This is allowed to go on for about six months, when the lac is collected; but if the secretion has been defective or insufficient the insects remain undisturbed for another six months.—*Gardeners' Chronicle.*

CINCHONA CULTIVATION IN SOUTH INDIA.

We take the following extracts, on practical cultivation from the annual administration report on the Government cinchona department, Nilgiris for the year 1899-1900.

The total expenditure on factory account amounted to R1,17,092—13—11 under the following principal heads :—

	Rs.	A.	P.
Purchase of 207,258 lb. bark	67,069	9	8
,, of new machinery	4,211	14	5
Cost of chemicals and cost of manufacturing and distributing alkaloids	45,811	5	10
Total ..	117,092	13	11

General Condition—*(a) Dodabetta.*—Notwithstanding the exceptional dryness of the season this estate continues to look well. With the exception of a few patches where the soil is inferior, the older trees look healthy and vigorous, and the trees on the small plots of new land planted in 1897 and 1898 have made very good growth. Further experience confirms the opinion expressed in the last Administration Report that the local seed has not deteriorated, for the seedlings raised from seed taken from the estate trees and planted in new land in 1898 have come on quite as well as those raised from seed received from Jamaica. The estate was well cultivated during the year. In addition to the ordinary weeding and forking, 14,328 renovation pits were made and 3,380 yards of deep drains were dug in plots which required drainage. A damp sub-soil is well known to be a fruitful source of injury to cinchona and the beneficial effect of the deep drains was well marked ; 113·35 acres of the estate were pruned and the yield of dry bark from this operation was 71,640 lb. or 632 lb. per acre. The trees had not been prnned for many years and the yield of bark from the thicker branches and from extra stems was consequently high. It is a well known fact that cinchona trees, whose stems are shaded from the direct rays of the sun, yield a higher percentage of alkaloid in their bark than trees whose stems are freely exposed; and in order to prove whether it will pay to protect the stems of old trees, a plot of 6 acres in an exposed position was selected and the stems of the trees were closely covered with grass. The trees being large, the cost of the work was high, amounting, as it did, to R58-2-10 per acre; but the effect of the grassing on the appearence of the trees was most beneficial. The bark will be analysed when the trees have been under the protection of the covering for two years, and it will then be possible to show whether this mode of increasing the alkaloidal value of the bark is profitable or not. An increased yield of 941 units, when the value of the unit is one anna, would cover the cost of an annual covering of grass, but as the covering will probably last for several years, and as the quantity of bark on each acre is at least 4,000 lb., a very small increase in the richness of the bark would repay the cost of the work. An increased yield of snlphate of quinine in the bark of 50 per cent. would give 2,000 units more per acre and an increase of 25 per cent. would give 1,000 units per acre.

The total expenditure on Dodabetta for the year was R15,211-10-5 or R47 1-8 per acre; the crop obtained was 80,248 lb. and the cost of eaoh pound of bark was therefore R3-0-39.

(b) Nedivattam.—Although this estato suffered moro from the drought than Dodabetta, still the amount of actual damage done by the failure of the rains was not large. When it is noted that out of the 151 days from the 1st of November to the 31st March there were only 5 days on which rain fell, and when it is known that the cinchona tree thrives best in a climate where the rainfall is well distributed throughout the yoar, it is remarkable that the old and yonng trees on the Nedivattam estate withstood the drought as well as they did. The coppice plots showed no signs of being affected by the drought, but many of the oldest trees as well as younger trees standing on old ground with a south-west exposure suffered from the want of moisture and lost a good deal of their foliage. Dying trees to the number of 6,837 were cut down and yielded 33,488 lb. of bark. The estate was weeded as usual and was well dug before the dry weather ; 30,500 renovation pits were made in plots 28 and 10 and were filled in with weeds ; 33,500 eucalyptus plants were put out in plots 22, 27 and 32 and vacancies in the proceeding year's fuel plantings were supplied. A large number of these plants, however, succumbed to the drought. The total expenditure on the estate was R14,189-14-1 or R45-0-10 per acre. The crop obtained was 33,488 lb. and the cost of each ponnd of bark was therefore As.6-9·55.

(c) Hooker.—The old portion of this estate which consists of 145·33 acres of cinchona, 48·24 acres of fuel trees and 9·93 acres lying fallow, cannot be said to be in a satisfactory condition. It was found necessary during the year to coppice 10,588 sickly and dying trees which yielded 26,543lb. of dry bark, and it is to be feared that this process of the elimination of the unfit will have to be repeated year by year nntil the old land is entirely cleared. In the Administration Report for 1896-97 it was pointed out that there were only 10·59 acres growing a first crop of cinchona, while the remaining area was growing a second crop. The trees on the 10·59 acres are looking well and their growth on the whole is very good, but the second planting on old land has never been satisfactory. This land, which was originally rather poor grass land with a bad exposure, has now been under cinchona for 31 to 34 years and it is not surprising that under these conditions the trees fail to attain their maximum growth The total expenditure on the old Hooker estate was R4,927-2-7, or R25-7-3 per acre, and the cost of the crop of bark was As. 2-11·64.

The No. 1 extension of 80 acres of forest land which was planted in the southwest monsoon of 1898 has come on very well. The young plants suffered very little from the drought and their growth has been most satisfactory. The plants were only from 3 to 4 inches high when they were put out. Many of them are new over 6 feet high, and the tallest of 50 plants that have been selected for quarterly measurements was 6 feet 10 inches at the end of the year. A comparison of the growth of these plants with the measnrements of plants recorded by the late Mr. McIvor in the early days of the cinchona enterprise is of particnlar interest as it shows that under favourable conditions the present growth of cinchona plants raised from local seed and from seed received from Jamaica is quite as vigorous as was the case with the plants and seed received direct from South America.

The No. 2 extension of 80 acres was planted during the year, and although the south-west monsoon was a failure the plants have grown well and promise to do as well as, if not better than, those on the No. 1 extension.

A commencement was made with the felling and nurseries for the No. 3 extension which will be planted during 1900-1901.

IV—Manure —On the Dodabetta estat 17·9 acres were manured with cattle and stable manure and 41·73 acres were treated with lime at the rate of 7½ cwts. per acre. The lime was spread over the ground and lightly forked in at a total cost per acre of R18-4-5. The effect on the trees was. decidedly beneficial. An experiment was made on 1 acre with a mixture of fish, snperphosphate, Thomas' phosphate, sulphate of iron and potash. The total cost of the manuro and its application was R185-6-4. The effect so far has been a very marked improvement in the appearance and growth of the trees. The bark will be analysed after the manure has been down for two years. The plots referred to in the last Administration Report were inter-coppiced with the result that the trees manured with the mixture of bonemeal, white castor poonac, nitrate of soda and nitrate of potash gave 4·75 per

cent. sulphate of quinine and 1·18 per cent. febrifuge, while the plot treated with bone meal, white castor poonac, superphosphate and nitrate of potash gave 5·18 per cent. sulphate of quinine and 1·25 per cent. febrifuge. At Nedivattam plots 10,14, 28 and 29 were manured with cattle manure and at Hooker the plots thus treated were Nos. 1, 2, 7, 8 and 14.

V.—Nurseries.—At Dodabetta the measures referred to in the last Administration Report to eradicate the nematode worms which were damaging the plants in the nurseries have proved tolerably successful, but it cannot be said that the evil has been entirely remedied. At Nedivattam and Hooker the growth and condition of the plants in the nurseries have been quite satisfactory and there has been no sign of any disease. At Nedivattam succirubra seed has been put down to ensure a good supply of strong seedlings on which officinalis and Ledger will ultimately be grafted. Fourteen pounds of officinalis seed taken from trees, some of which analysed from 9 to 10 per cent. sulphate of quinine, were received from Mr. Van Leersum, the Director of the Government Cinchona Plantations in Java. This seed has been put down in the nurseries at Nedivattam and Hooker and has germinated well. Mr. Van Leersum also forwarded a Wardian case containing 50 grafts of Ledger, officinalis and hybrids on succirubra stocks, but owing to the delay caused by the landing of the case at Colombo instead of at Madras, only 15 of the plants were alive when they reached the estate, and of these 15, only four successful grafts are growing the growth in the remaining eleven being confined to the succirubra stock. Mr. VanLeersum's kindness and liberality merit the warmest acknowledgement and it is greatly to be regretted that after all the care and trouble he bestowed upon the grafts, they should have been so neglected on the voyage and then detained at Colombo instead of being landed at Madras.

Crop.—The total quantity of bark harvested on the three estates during the year was 140,279 lb. or 38,972 more than in 1898-99. The crop which consisted of 19,458 lb. red bark and 120,821 lb. crown and hybrid barks was obtained by the coppicing of sickly trees and by thinnings and prunings. On the Dodabetta estate 1,920 sickly trees were coppiced and yielded 8,608 lb. of dry bark and 113·35 acres were pruned and gave 71,640 lb. of bark or 632 lb. per acre. The trees coppiced at Nedivattam numbered 6,837 and yielded 33,488 lb. of dry bark and the number coppiced at Hooker was 10,588, the yield being 26,543 lb. A magnifolia tree at Nedivattam which had to be coppiced, because of illhealth, yielded the large total of 120 lb. of dry bark. This tree was about 34 years old and was one of the best grown trees on the estate. The amount of bark purchased from private growers was 207,258 lb., and 16,553 lb. were harvested from a plot of land in the Bikkatti village on the Kundahs. This land having reverted to Government, the Collector of the Nilgiris offered the cinchona trees that were on it to this department. The trees were accordingly coppiced and the bark was sent to the factory. The cost of harvesting and transport from the Kundahs was 6·24 pies per lb. of dry bark and the expenditure incurred was charged to the Dodabetta estate. In estimating the cost of the year's crop, the sum expended on the harvesting and transport of the Bikkati bark, viz., R538, has been deducted from the total spent on Head office and old plantations. The result, viz., R48,941-2-9, represents the cost of the 140,279 lb. of estate bark or As. 5-6·98 per lb. From statement No. 7 it will be seen that at the commencement of the year the stock of bark amounted to 286,579 lb. and at the close of the year there was a balance of 305,822 lb.

Factory.—The total quantity of bark worked up during the year was 344,312 lb. consisting of 318,881 lb. crown and hybrid barks and 25,431 lb. red bark, and the alkaloids extracted amount to 14,803 lb. consisting of 10,188 lb. sulphate of quinine and 4,615 lb. febrifuge. The output was thus less than in 1898-99, but it was considered sufficient to make about 10,000 lb. of quinine during the year under review, whereas during the preceding year an effort was made to show how much quinine could be made in the factory in one year with the present machinery. Unless the demand for quinine increase largely an output of 10,000 lb. of quinine annually will be quite sufficient to meet all requirements. The boilers which had worked well for years, broke down in June and their condition was reported on by the Inspector of Steam Boilers in July. The smaller boiler was reported to be worn out and not worth repairing and the larger boiler was repaired in accordance with the Inspector's directions. Sanction was given in G. O., No. 2885, Revenue, dated 11th August 1899, for the purchase of a new boiler which will be put up during the current year, and in G. O., No. 626, Revenue, dated 18th September 1899, a new disintegrator, a centrifugal machine and new boiling and crystallizing pans were sanctioned. The disintegrator which arrived at the end of the past financial year will be put up at once and the other machinery will be installed during the current year. The quantity of bark purchased from private growers during the year was 207,258 lb. and the price paid was R67,069-9-8, or As. 5-2·13 per pound against As. 3-2·9 per pound paid in 1899-99. The quality of the purchased bark was about the same in the two years and the higher price per pound paid during the year under review was due to the rise in the price of bark in the London market.

The statement given above which includes all factory and manufacturing charges as well as the actual cost of all the bark used does not include the item of R4,211-14-5 for new machinery and plant, as this is not a legitimate charge against the factory for the year. This item appears in the stock statement as an addition to the value of stock, and it is intended in future to wrote off 10 per cent. of the value of plant and machinery and debit it to the factory. This has not been done in the present instance as the new machinery has not been erected and the cost of the existing stock of old machinery has been debited in full in former years, so that there is no necessity to write off any sum for its depreciation. The following table shows the cost of the 14,803 lb. of alkaloids manufactured during the year, compared with the cost of the 19,841 lb. of alkaloids made in the preceeding year :—

	1899-1900.		
	Crown and hybrid barks.	Red bark.	Crown, hybrid and red barks.
	RS. A. P.	RS. A. P.	RS. A. P.
Cost of each pound of alkaloid in the bark.	6 14 6	9 3 2	7 1 1
Cost of manufacture etc., per pound.....	2 8 3	1 9 0	2 7 2
Total cost per pound....	9 6 9	10 12 2	9 8 3

	1898-99.		
	RS A. P.	RS. A. P.	RS. A. P.
Cost of each pound of alkaloid in the bark.	4 4 2	8 1 5	5 7 1
Cost of manufacture etc., per pound	2 7 11	1 4 0	2 4 6
Total cost per pound...	7 6 1	9 5 5	7 11 7

It will be seen from the above that the increased cost of the alkaloids made during the year under review was chiefly due to the higher cost of the bark that was used. The cost of manufacture and distribution per pound of alkaloid extracted from all the bark used was R2-7-2 against R2-4-6 in the preceding year. The increase of As. 2-8 per lb. is due to the fact that a larger proportion of quinine-yielding barks was worked up during the year. The proportions of quinine barks and red barks used were 92·7 per cent. and 7·3 per cent., respectively, against 81 per cent. and 19 per cent. in the preceding year. The cost of the manufacture of the alkaloids

from the red barks was As. 5 per lb. higher than in the preceding year. The explanation is that a much smaller quantity of red bark was worked up during the year, and the cost of the labour was proportionately higher. The crown and hybrid barks averaged 3·19 per cent. sulphate of quinine and 1·11 per cent. febrifuge against 3·37 per cent. sulphate of quinine and 1·01 per cent. febrifuge in the preceding year and the red barks averaged 4·19 per cent. febrifuge against 3·94 per cent. the year before. The percentage of total alkaloids from all the barks worked up was 4·299 per cent. against 4·297 in 1898-1899.

The total cost of the alkaloids from the quinine barks including packing and distribution was R1,29,390-3-9 or R9-6-9 per lb., but as the febrifuge from the crown barks is a bye-product in the manufacture of quinine, it may be considered that the 10,188 lb. of quinine cost R1,29,390-3-9 or R12-11-2 per lb. and the 4,615 lb. of febrifuge from the crowns and red barks cost R11,493-8-7 or R2-7-10 per lb. These valuations have been adopted in the stock statement (No. 11).

The following table gives the outturn of quinine and febrifuge since the commencement of manufacture at Nedivattam :—

	Outturn of alkaloids.					
	Crown and hybrid barks.	Red barks.	Total bark.	Sulphate of quinine.	Febrifuge.	Total alkaloids.
	LB.	LB.	LB.	LB.	LB.	LB.

1899-1900	318,881	25,431	344,312	10,188	4,615	14,803

Quinine.—At the close of last year the stock on hand was 11,591½ lb. and during the year under review 10,188 lb. were manufactured, making a total of 21,779½ lb. The issues during the year amounted to 7,378½ lb. and there remained a balance in store at the end of the year of 14,400 14-16 lb. The amount of quinine issued exceeded the total of any previous year, and the increase, as compared with last year, is due to the fact that, under the orders of the Government of India quinine is supplied by this department to all provinces, except Bengal Pnujab and Assam. The number of hospitals and dispensaries supplied direct with quinine was 650 against 396 last year, and the number of 5-grain powders sent out was 1,127,785 against, 1,018,532 in 1898-99.

Febrifuge.—At the close of last year the stock on hand was 11,274½ lb. The quantity manufactured during the year was 4,615, making a total of 15,889-8. The issues were 2,676½, leaving a balance in store of 13,213 lb.

Miscellaneous.—*(a) Issues of quinine packets to Collectors.*—During the year 400 packets of 102 5-grain powders were issued to Collectors for sale, and the amount realized by the sale of powders by Revenue officials was R764-12-0

(b) Sale of quinine at Post offices.—It was noted in the last Administration report that, owing to the raising of the price of the powders from 2 pies to 3 pies, there had been a falling off in the sales at post offices. During the year under review, however, the number of packets sold was 5,501 and the number sent out as permanent advances was 936·44. The corresponding figures for 1898-99 were 4,766·14 and 279·48 and it is expected that the return to the original price of 2 pies per 5-grain powder during 1900-1901 will result in a further increase in the sales. A special report on this subject and on the sales by Revenue officials will be submitted to Government on the 1st September.

(c) Deputation of the Director to Java.—In accordance with G.O., No, 1394, Revenue, dated 17th April 1899 the Director visited Java in May 1899 and and on his return journey paid a visit to the Bengal Government Cinchona Plantations near Darjeeling. A special report on Cinchona in Java was snbmitted to Government and was reviewed in G.O., No. 608, Revenue, of the 8th September. The success which has been obtained by the Java Cinchona planters was shown to be due to the care taken to grow the richest possible bark. The climatic conditions in Java are undonbtedly more favourable than in India; bnt, on the other hand, the Dutch planter is more heavily taxed than the planter in this country. If the principal of selection based on analysis is followed, and if cinchona are grown on suitable soil, and well cultivated, sthe cinchona industry in Southern India might be revived with a very good prospect of success.

(d) Subordinate Staff.—Messrs. H. V. Ryan and E. Collins, the Superintendents of the Dodabetta and Nedivattam estates and Mr. D. Campbell, the Manager, of the Head office, have done very good work during the year. The work of the office has been largely increased, owing to quinine being supplied to other provinces including Native States, and as there has been no increase in the establishment, the work has at times been very heavy.

(Signed) W M. STANDEN,
Director,

TANNING IN INDIA.

The *Indian Mechanic* says: At the present time tanning might almost be said to rank among the decadent indnstries of India, although it is but a few years since the prosperity of Indian tanners became quasi-proverbial. The enormons export trade in tanned skins and hides that was done by Madras a few years ago, was a trade that yielded large profits. Now, however, not only are profits reduced

but in many instances tanners have incurred heavy losses, output has been reduced, and the whole trade has lost grouud. Not only this. Some 10 years ago factories were opened in Calcutta for the purpose of drying skins and hides, and the dried articles began to be largely exported to the United States of America, where they underwent the tanning processes. The reason for this was not merely that American tanning produced better leather, but also rhat it was both more expeditious and cheaper. More recently a "pickling" process has been resorted to in Madras in place of tanning; and pickled skins are now being exported in lieu of tanned skins. Not that shipments of the latter have been stopped entirely. The pickled article has only partially taken the place of the tanned, but unless some considerable improvements are made in the process of tanning resorted to in Southern India, it appears probable that every year will see an increased proportion of the skins and hides of the country exported in an untanned state, so that they may undergo in America or England the cheaper and more expeditious processes of tanuing than are in vogue there.

Circumstances such as those briefly alluded to, lend additional interest to any practical suggestions for the improvement of local tanning or for the introduction of new tanning agents. We are led, therefore, to call attention to the latest number of the *Agricultural Ledger* (No. 9 of 1899) wherein the merits of Tari or Tari pods as a tanning agent are discussed. Hitherto Tari appears to have been regarded chiefly as a dye-producer, but in the publication under notice a report on an analysis of the pods by Professor Wyndham R. Dunstan, M.A., F.R.S., Director of the Scientific Department, Imperial Institute, London, calls attention to the valuable properties of the plant as a tanning agent. In some localities in India, the Tari pods are already used for tanning purposes, but the properties of the plant do not appear to be generally-known, and its cultivation is perhaps not as extended as it should be. Professor Dunstan, after distinguishing between *Cæsalpinia digyna* (Tari or Teri) and *Cæsalpinia coriaria* (Divi-divi) remarks upon the analysis of the pod cases of the former. The pods, it may be remarked, hold two thick-shelled peas which contain oil, but very little tanning matter. The seeds are removed, the pod-case is then ground alone. It is easily powdered, and from the powder water readily dissolves the tanning constituents, furnishing a liquid which is of a light or dark brown colour, according to its strength, Professor Dunstan recently analysed three samples of Divi-divi pods, with the result that the poorest showed 19·73 per cent. of tanning matter, the best 32·79 per cent., the average about 30 per cent. When he came to analyse the powdered pod-cases of the Teri, he arrived at a percentage of over 50 per cent. of tanning matter, and in one instance (a sample from Assam) the percentage was nearly 60. Commenting on this, Professor Dunstan remarks that is clear that the tanning value of Teri is greater than that of the South American Divi-divi. Moreover, in the case of Divi-divi the usual plan is to prepare for the use of the tanner and "extract" of the material, but the pod-cases of the Teri are so rich in tanning that the material could be used direct by the tanner without the previous preparation of an extract, "which, as is well-known is a disadvantageous process, since it always leads to a considerable enhancement in colour," With the view of obtaining a practical opinion as to the tanning value of this Teri powder, a sample was furnished to a well-known tanning expert, who reports that he is much impressed with the results obtained. They compare very favourably with those contained by the best Divi-divi, whilst the aqueous liquor from *C. digyna* did not appear to undergo the injurious fermentation that is the difficulty in the use of *C. coriaria*. Professor Dunstan gives in tabular form the results of the analysis of three specimens of the powdered pod-cases of *C. digyna*, derived from Burma and Assam (though he erroneously refers to one of the Burma samples as from Bombay). The table is as follows:—

I. I. No.	Serial No.	Whence received.	Moisture per cent.	Tanning matter in material dried at 110 per cent.	Total soluble matter per cent.	Non-tanning matter per cent.	Ash per cent.
		CÆSALPINIA DIGYNA.					
		Pegu Circle.					
6,921	6,258	Bombay....	11·07	53·82	61·95	14·08	3·28
		Eastern Circle.					
6,372	4,887	Burma.. ..	10·93	53·86	62·83	14·86	3·76
9,293	10,795	Assam.....	11·40	59·89	65·80	12·73	1·84

The sample from Assam is the richest in tannin. No sample was sent from Madras, and we are not aware to what extent, if any, the plant is available in the Southern Presidency.

Mr. David Hooper, in an introduction to Professor Dunstan's report in the *Agricultural Ledger*, briefly sketches the history of Teri-pods, hut makes no allusion to it as growing in Madras. The earliest samples tested were from Chittagong, where the plant was growing wild. Mr. John Tail, of Kidderpore, tanned a skin exclusively with the pods, and the process of tanning extended over four days. He remarked:—"The leather I conceive to be of a very superior quality, possessing not only an equality in softness with that tanned with Divi-divi (*Cæsalpinia coriaria*), but surpassing it in colour and appearance, and is consequently capable of being used far more extensively for tanning purposes, especially when a bright colour is required, than the Divi-divi." Some years ago, Messrs. Cammiade Brothers, of Madras, wrote to the Reporter on Economic Products, Calcutta:—"The pods of *Cæsalpinia digyna* are said to yield leather as white as snow. If that report is correct, this tannin ought to cut out all others in Madras, provided it can he grown cheaply." Mr. Evans, Chemist, of the Tanners' Laboratory, Bristol, has reported upon the pods:—

"They yield about 33 per cent. of tannic acid, which is in some measure like that of the babul (*Acacia arabica*) pods, which gives a cream-coloured precipitate; but this unites with gelatine in the form of a precipitate as white as driven snow, and its reactions with other chemicals give divers colours, which will make it equally attractive to the dyer. In saying this much, we can say with satisfaction as a chemist that it is almost perfect; what may be its behaviour in the tannery remains to be proved."

Enough has been said to show that the merits of Teri as a tanning agent are considerable. As to the plant itself, a report from Prome describes it as a thorny scandent shrub growing on low ground and near streams in forest without bamboo. From Toungoo we learn that the tree is never found in country that is in the least hilly, nor in country that is swampy. Its habitat *par excellence* is a level ground, either near the banks of streams or on waste land near villages, deserted village sites being favourite spots. Another report describes the leaves as, generally speaking, bearing a very close resemblance to those of the tamarind tree, while the pods are smaller, and the tree itself is seldom higher than 10 feet. The pods when ripe are roasted, and the seeds then eaten, principally by the younger portion of the population. If a large quantity be eaten in this way, it has an intoxicating effect.

It would be interesting to know if this plant grows wild in any parts of Southern India, and we trust that our present remarks will direct sufficient attention to the subject to elicit some information on this point. There is little room for doubt that the local tanning industry must gradually die out unless some special agent such as the above can be produced locally.—*The Leather Trades' Review*.

BONE MEAL.

We are constantly being asked by our readers whether we consider bone meal (or bone dust) to be a good manure; whether it should be used in a fine or coarse state, and whether it is good for this or that crop. It appears to us that a few words of explanation are necessary. To begin with, bone meal as a fertiliser scarcely has an equal; mixed with saltpetre, cowdung, castor-cake, or linseed-cake it has been found to produce very heavy outturns when used for field crops. For coffee it has been found to give excellent results, either alone or when mixed with other manures. In the case of tea also it has been found to give very satisfactory results. To give our readers an idea of the value of bone meal compared with other manures in common use, we reproduce below analysis of ten samples of manures chemically analysed by Dr. J. W. Leather, Agricultural Chemist to the Government of India:—

Manures.	Moisture.	Organic matter.	Sand.	Nitrogen.	Phosphoric acid.
	Per cent.	Per cent.	Per cent.	Per cent.	Per cent.
Poudrett	34·01	8·18	48·27	0·44	1·15
Bone dust	7·90	27·51	5·06	4·69	23·49
Cowdung (Bazar) ..	43·26	18·86	31·77	0·53	0·29
Dung, litter and urine ..	62·15	17·92	15·82	0·59	0·38
Dung alone	80·06	10·94	7·51	0·36	0·29
Litter alone	46·68	26·28	20·57	0·84	0·37
Dung alone	78·45	10·06	9·91	0·30	0·19
Urine-earth from cattle getting concentrated food	16·73	10·11	65·29	0·44	0·23
Urine-earth from cattle getting no concentrated food	11·63	8·73	68·39	0·33	0·20
Sheepdung	50·01	16·26	26·02	0·87	0·53

From the above it will be seen that bone dust had the smallest percentage of moisture and sand, and the largest percentage of organic matter, nitrogen and phosphoric acid; the two last named are the two most important elements of plant-food. Potash and lime are also important constituents of plants. Of the former, bone meal has a trace, and of the latter 28 per cent., against 0·28 per cent. in cowdung. Taking all the foregoing circumstances into consideration, it will be readily understood that bone meal is a very valuable manure.

So far we have only discussed the question from the planters and agriculturists, point of view. In the garden it has been found to be of immense value, not only for flowering plants in pots and in the open bed or border, but in the kitchen and fruit garden as well. We have seen some remarkable results obtained from the use of bone meal for roses, aroids, ferns, and even annuals, such as heartsease, stock, etc. We have seen it used in combination with Ichthemic guano and cowdung for flowering plants, and with linseed-cake and saltpetre for cabbages, cauliflower, turnip, knol-khol, etc.; also for vines, peaches, plums, etc., in combination with linseed-cake. It has been given as a surface dressing to the orange tribe with great benefit. Pomeloes, especially, derive great benefit from its use. There is an idea prevalent that it takes a long time before bone meal can be absorbed by plants. Chemically this is no doubt quite correct; in practice the results obtained in the garden would seem to negative this theory. We have seen bone meal applied to Cannas, which were in a very poor condition. Two months after those very plants were over five feet high, and in robust growth, having sent up dozens of suckers. No other manure of any kind was applied. This would go to prove that the action of bone meal is more rapid than is generally believed. There is one point on which some misconception exists. It is considered by some that a coarse grist is useful for farm crops. Our own experience is that the finer the meal the more readily is it assimilated by the roots of plants. Therefore in order to derive immediate benefit from this fertiliser it should always be used in the shape of fine powder, whether for field crops, garden or pot culture. To those who intend exhibiting at the next flower show, whether flower, fruit or vegetables, we strongly recommend the use of bone meal.—*Indian Gardening and Planter.*

FRUIT CULTIVATION IN CEYLON

THE EXPERIMENTS WITH ORANGE GROWING IN UVA.

Under the first heading above, our London correspondent, in the portion of his letter published yesterday, makes reference to the scheme contemplated by Mr. A. J. Pearson, of Messrs. Brown and Co. some years ago, for starting orange-groves in Uva and says that he does not think the scheme ever got beyond a newspaper article. One of our representatives, who saw Mr. Pearson yesterday, learns that the chief difficulty the latter experienced in starting the scheme on a large scale was his inability to secure a suitable piece of land. Owing to this, and not having sufficient time at his disposal, Mr. Pearson has been unable to carry on the scheme as vigorously as he could have wished. At the same time he has by no means lost interest in the subject, and, as a matter of fact, gets regularly every year from Australia a fairly large number of trees for friends and others. Last year, for example, he imported about a thousand grafted orange and lemon trees. These have been planted in all parts of the island and are doing particularly well. On the Uva side they seem to thrive the best on account of the dry climate which prevails during the fruiting season, and at Hatton also they do well; but the weather, there is generally inclined to be wet at the time when the fruit is ripening. It would be impossible Mr. Pearson explained, to get accurate results of the experiments for a year or two, but many of the trees planted three years ago are now bearing fruit, and on a small scale, the scheme has been most successful. He thinks there are great possibilities for the cultivation of oranges and lemons in Ceylon if suitable land could be obtained,

Mr. Pearson is also of opinion that many of the deciduous sub-tropical fruits could be grown well in certain parts of the Island, such as the fig, peach, apricot, nectarine, persimmon, Japanese plum, &c. He states that he has seen splendid Peach trees at elevations of 4,000 ft. and over, but the fruit on them indicates them to be worthless mongrel seedlings, and there seems no reason why the very best varieties of grafted or budded trees should not do just as well. The deplorable habit of growing from seed is answerable for the bad quality of fruit that is general in the island, and if people would only realise, when planting fruit trees, that when they plant a seedling tree, or grow from a seed, the chances of obtaining fruit of decent quality are about 10 to one against, they would probably be at more pains to secure plants they could depend on. Then, in addition to the uncertainity as to the quality of the fruit, it has to be borne in mind that seedling trees take about eight years to come into bearing, whereas a healthy grafted plant with proper cultivation may begin to shew fruit in two years from planting, and should certainly do so in three years.

The orange industry in Jamaica has grown considerably of late years. That Island has no advantages over Ceylon as regards climate for citrus cultivation nor transport facilities, and it seems strange that an industry which is looked on as one of great importance in other parts of the world should be here so entirely neglected.

QUEENSLAND ARROWROOT.

With reference to the prices of arrowroot in Great Britain, which appear in British price lists as much hgher than can he obtained hy the growers and manufactures of Queensland who export the article, we wish to draw attention to the fact that Queens-

land arrowroot, under the provisions of the Food and Drugs Act, cannot be sold in Great Britain as arrowroot, and this is a matter of great importance to the growers here. The authorities in England, with whom the administration of the Act lies, have decided that the article made here and sent into the English market is not genuine arrowroot, because it is made from *Canna edulis* and not from *Maranta arundinacea*. Much correspondence has passed on the subject betweeen the Department of Agriculture here and the Acting Agent-general for the colony in England, Mr. Chas. S Dicken, who parcticularly interested himself in the matter, and placed himself in communication with Mr. Chamberlain, with the result that arrowroot made in this colony from the *Canna edulis*, can be sold in Great Britain only when labelled "Queensland Arrowroot." The Hon. A. J. Thynne, when Miuister for Agriculture, advised growers not only so to designate the manufactured article, but to add the words "Prepared from *Canna edulis*." So the matter stands; and when arrowroot is quoted in British price lists, it should be understood that in every case the standard arrowroots of St. Vincent, Natal, and Bermuda are referred to.

Those prices were given in a letter from the Agent-General to the Minister for Agrieulture, so far back as 1896, as follows:—

Bermuda	2s 2d	per lb.
Natal	6½d	,,
St. Vincent (1) ..	2¾d	,,
St. Vincent (2) ..	1½d	,,

The army and Navy Stores supplied samples of ve kinds with their prices, viz:—

Bermuda	2s 6½d	per lb.
Bermuda (kind) ..	1s 1d	,,
Natal (finest).. ..	9½d	,,
St. Vincent	3½d	,,
St. Vincent (fine) ..	6½d	,,

The reason for the wide difference in value was the limited supply of Bermuda. There is no sample or price given for Queensland arrowroot for the reasons stated

"Strictly speaking," says the Assistant Secretary of Inland Revenne, London, in a report on the subject to the Under Secretary of State, "the term 'arrowroot,' without prefix or qualification, should be restricted to the starch derived from plants of the genus *Maranta*, the most important member of which is *Maranta arundinacea*, a native of the West Indies, and which furnishes most of the genuine West Indian arrowroot. The Maranta starchd is perfectly distinct in its physical character and properties, and is readily identified under the microscope. A purchaser simply asking for arrowroot would presumably, hy use and wont, expect to be supplied with Maranta starch.

Tous-les-mois, or Queensland arrowroot, the product of the *Canna edulis*, is quite a different starch, and its physical properties and appearance are distinct from those of Maranta starch."

We are informed by Messrs. Lahey Bros. that the price of the Queensland article has varied much in price, sometimes falling to 1¾d per lh. or £16 per ton, with freight at ¼d per lb, sometimes reaching as much as 4d per lb, or over £33 per ton. The average price in Brisbane, the Messrs. Lahey stated to range from £12 to £20, or, say, an average of £15 per ton.—*Queensland Agricultural Journal.*

HONEY PRODUCTION IN PALESTINE.

The American Consul in Jernsalem, in a recent report gives an interesting account of the rear of bees and the production of honey in Palestine, which has always heen famons for its honey, although the methods in vogue were until lately very crude. The development of the industry hy the application of modern methods of late years is due to a family named Baldenspergen, which emigrated from Switzerland in 1849 and settled at Artas, seven miles north of Jerusalem, near the famons pools of Solomon. The father was always interested in bees and kept some in the native hives, which are long terra-cotta jars, and he aroused in his five sons an enthusiasm in the industry which has led to considerahle results. In 1880 they really commenced the work under an American teacher, and soon adopted the plan of carrying the hees about from place to place for the best food. Thus from Ramleh they had the hives taken on women's heads 12 miles to Yafa, where tho orange-blossoms were plentiful, so that in April there was an abundant harvest of this kind of honey, while at other times it was obtained from cactus and acacia blossoms. From another apiary and in other places harvests were obtained from lemon blossoms and from wild thyme. In 1884 the 50 hives at Yafaalone yielded 6,000 lb. of honey in less than a month. The Turkish officials soon cast thier eyes on the industry as a source of taxation, and at first charged about 5d. per hive, hut shortly after enormously increased the amount payable hy counting every door, window, and hole through which the bees could be seen at work as hives, so that 150 hives counted as 2,000. After much litigation the Baldenspergers were fonnd to owe the authorities £100 on account of a single apiary. This they refused to pay, wherenpon the houses were sold by auction in Jerusalem at 5s. each, hut when the officials came to deliver the hives to the purchaser, as they were bound to do, it was found that the hottom boards of the hives were unhooked, and the hees swarmed ont to attack their distnrbers. A compromise had to be made and the bees remained with their original owners. Then the local sheikhs demanded toll whenever an apiary was moved near their villages, otherwise the hives were stolen, fire or water being used to kill the bees. Indeed, now, abont a tenth of the honey has to be given away as blackmail. Occasionally even camel-loads of hives on their way from one feeding-ground to another are stolen hy the Beduins, so that the industry is heset by many obstacles and calls for patience, tact, and perseverance. A colony is about 35,000 to 50,000 bees, and in distrihuting these colonies great care is taken not to overstock any special locality. The Baldenspergers do a considerable husiness to exporting queen hees, and when their enterprise was threatened by exeessive taxation, they sold a large number of their hives to natives, whom they had trained, and to the Jewish colouy in the plain of Sharon, so that there are now 700 hives at work in the country in addition to their own colonies. Queen bees exported hy them have sold for as much as £3 each in America. All the honey prodnced finds a good market in Europe.—*English paper.*

LECTURE ON ORANGE CULTURE:

BY HON. J. T. PALACHE.
