I will proceed to point ont what is to my mind the best method of establishing a grove. Select a well drained piece of ground, let the size be according to your means, clear it of all noxious vegetation, then line it in 20 feet sqnare. It is best to begin with to get plants of good varieties from a nursery. Afterwards, as yon extend yonr cultivation, I will point out how you can supply yourself with yonr own hudded plants. Dig the holes fonr feet in circumference and two feet deep—then pnt your plants in, being careful to see that they have heen carefully taken up with all the fibrous roots, and in planting lay these carefully out on some loose soil so as to enable the roots to begin to take up the nutriment from the earth at the earliest possihle period. If the weather is dry cut back all the leaf branches, if wet you can leave them on, and if the plants have been carefully lifted and planted they wil grow without any stoppage. If the weather is very dry, water for ahout a week every day, after that every other day, until yon are satisfied that the plants have fairly started. Then proceed to cultivate the spaces between with catch

crops—beans, corn, cassava, potatoes, yams, etc., taking care always to keep round each plant clear so as to prevent crowding. The citrus plant cannot stand crowding or overshading as it immediately under such circumstauces develops disease and blight. Keep the soil for about four feet round the plant well forked, so as to let in light and air, and thus procure the best advantages of sunshine and showers.

Having started your grove—set to work to get a nursery. Prepare a seed bed by ploughing a nice level piece of land free from stones. Open trenches about one inch deep and one foot apart. Get Seville orange or hog shaddock seed and drop them in the trenches about one inch apart, and cover lightly. And when the seeds begin to grow be careful to keep the land round about well stirred and free from weeds. It is well to steep your seeds the night before you plant out in a solution of bitter-wood, to prevent them being eaten by any mice and other pests. When these plants are about eight months old they will be fit to put out in the nursery. Prepare the nursery land carefully. Plough deeply and then harrow it off. A portion of your grove in which you have not planted catch crops will do for this purpose and will effect a great economy, as whilst you are cultivating your nursery stock, you are also cultivating and improving your grove trees. Line off in rows two feet apart and drill out the plants six inches apart, and as they grow, stire the land round about well and keep the weeds down so as to give your plants all the advantages to be derived from the soil. Twelve months after the time of planting out from the nursery the plants will be ready to be budded. And if your grove trees have got on well you will get plenty of bud-wood from them, by cutting back some of the superflous shoots which they have put out. And I think I will best serve the purpose by giving you a practical lesson in budding—all the materials for which I have at hand. After the bud has been in 14 days—If you see it still green and beginning to close round the edges, you may be certain it has taken. Cut back the stock about six to nine inches from the bud. Those that have not taken, you leave to rebud another day. It is advisable not to cut the top quite off but half through and bend over the head, so as not to get an over-flow of sap to the bud and endanger its existence by repletion. When the bud has grown about a foot, and has hardened up, remove the top altogether and give the bud shoot the benefit of the entire flow of sap, it will then be able to utilize it all. When the bud is about three months old, with the aid of a sharp strong scissors, clip the head of the stock quite close to the apex of the bud, and this gradually heals over making for the plant one straight trunk, and you soon lose sight of the point where the bud was put in. It will surprise you how quickly these buds grow and how soon they outstrip seedlings. This grape fruit which you see here was only budded last November. And an important advantage not to be lost sight of in building is, that it is the only method of propagating the citrus family to ensure getting the original variety you wish, as owing to the ease with which the blossoms of this family are fertilized by bees and other insects, seedlings are always furtive and producing all sorts of hybrids, most of which are useless for any purpose. This shaddock is from a tree budded August gone, three years, from the far-famed Cinnamon Hill Shaddock, and it has come perfectly true to the original in shape and quality. Here also are Grape fruit budded from the Wilton Grape Fruit which in flavour, shape and quality, are the exact counterpart of the fruit from the parent tree. Here also are Navel Oranges, the bud of which came by book parcel post from the Riverside Groves in distant California, and not one of the trees from which these fruit were gathered are yet four years old—some of them barely three. I think these are examples which sufficiently prove that propagation by budding is the best to adopt and vastly superior to all others. The next question that should occupy the citrus growers attention is, what are the best varieties to grow. I am quite certain that of oranges there is no finer variety than the ordinary Jamaica Orange; and with cultivation, selection and propagation by budding, it will in time hold its own with any variety in the world; but in the meantime as our best market is in America, we have to consider the taste and prejudices of the consumers—hence it is well to calculate the varieties most highly thought of in America. Another very important desideratum is to have such varieties that come in at different periods of the season. To have a crop coming gradually to maturity and extending over the whole season, the following varieties will be found to meet these requisites to a great extent:—Boones Early—the earliest in cultivation in Florida, ripens in September, and I feel certain from what I see on my trees, this variety will be still earlier in Jamaica. The two next earliest are Centennial and Parson Brown—the Centennial is a very prolific bearer with a fine shaped fruit, follows close on Boones Early. The Parson Brown is a very fine Orange indeed, large and well shaped and a heavy bearer. For mid-crop, the Jaffa, Washington Navel, Pine Apple and the blood varieties, such as Ruby Blood, Jaffa, Blood and Maltese Blood are the best. The Washington Navel is the favourite Orange in California and the most generally grown there. This Orange I have discovered growing naturally here, and I have the word of a gentleman who has eaten this fruit in the Riverside Groves, that our Jamaica Navel is as good in all respects as its valued relative in California, Now here is the native Orange to to propagate and cultivate. We in Jamaica think too little of these things, and the following facts will illustrate what I mean. Thirty years ago the Washington Department of Agriculture sent to Bahia in South America, and got 10 trees of this variety, when they arrived in Washington only two were alive - when planted, only one grew; and it is from this one tree that the thousands of acre were planted in California now yielding million of dollare to their fortunate owners. Twenty-five years ago Captain Rivett brought from Bahia two trees of this very Orange and planted them at Petersfield, in St. Andrew—both grew, and up to two years ago they were the only two trees known in the Island. The Jaffa and Pine Apple are very vigorous growers in our Island climate and bid fair to make large compact trees capable of producing heavy crops of fruit, and I notice in the Parson Brown and Jaffa, an almost entire absence of attacks of insects and disease of all sorts which is quite remarkable, and for these reasons I would recommend these varieties for cultivation above all others. The late varieties—Hart's Tardiff, Kings's and Californian Joppa, complete a list which I think, will enable the grove owner to have Oranges from September to June of the following year, without the great loss from over-ripe fruit which would naturally be the case if only the early varieties were planted—or the long waiting, if only the late varieties were cultivated. The Joppa is a comparatively new variety. It is quite thornless and bears a seedless fruit, and it is said that the fruit will remain on the trees perfectly sound until June. Of the fancy varieties the Daisy Tangerine and the Satsuma are the best to grow, as they have a tough, leathery skin, which makes them keep well and good travellers. The Satsuma has only recently been introduced from Japan, and it is said that its keeping and travelling qualities are so good, whilst preserving the colour and qualities of Tangerine that it will soon take the place of all other fancy varieties. Another variety of the citrus family that is much valued in the Northern markets are Lemons, and the varieties best for cultivation here are Genoa and Villa Franca. The mode of culture and propagation is the same as oranges, but much greater care is required in the gathering, airing, and packing of the fruit. The above varieties grow her

with great vigor; and from tbe fact that I am now gathering fruit from trees not yet three years old, I feel confident in recommending the culture of Lemons to you as likely to add at no distant date, a valuable quota to our fruit exports. Yet another variety of valuable citrus family is the Pomelo or Grape Fruit. Americans have developed a great taste for this fruit, and when it gets better known in Europe it may have a great future, and be a source of wealth to this community; for no where else can better Grape Fruit be grown; and the rapidity with which this fruit grows and begins to bear is very encouraging. Some of our native varieties are excellent, whilst there are a great many bad and rubbishy hybrids that it will be useless to waste time and space to cultivate. Of the imported varieties Royal Pomelo, Triumph Walters and March Seedless are the best; whilst of natives, the Wilton and the Windsor are the best that can be procured, although there are no doubt, several other good varieties in the country. But whatever you do, select a variety of proved good quality. It will always pay to grow the best. The cultivation and propagation are the same as for oranges. The greatest troubles that the orange grower has to contend with are insect pests and disease. But the grove owner should bear in mind that his best weapon against these enemies is careful and constant good cultivation. Bear in mind always that insects and disease will always attack the sickly and weakly plants: whilst the well cultivated, vigorous growing plant will have within itself power to resist and throw off the attacks of its enemies, the weakly illcultivated plant will easily succumb. It pays therefore to keep out weeds and ply the cultivator regularly through your groves, if for no other reason than to keep your plants in vigorous growth, so that they may be able to resist the encroachments of their natural enemies. Time will not permit me to give you an elaborate lis of Latin and Greek names of the insects that are enemies to citrus cultivation, but the coloured plate which I have here will show you which are your friends and which are your enemies, for by that wonderful provision of a beneficial providence one set of insects prey on the other, so as to preserve the balance of nature. There is however one active little enemy to combat against; an enemy whose name is legion, and who if allowed to follow out its own plans will nip off the embryo leaves of the plants the moment they appear above the ground. I refer to those very industrious creatures whom the primers hold up to us as an example to emulate, but it could be wished that their proverbial industry was more tempered with judgment in consideration for struggling humanity. I mean ants, of course. They evidently regard your citrus leaves as special dainties, and must be taught to keep their distance. An application of air slaked lime or hard wood ashes on the seedling bed and a planting of strong solution of bitterwood on the larger trees, will damp their ardour. Another enemy is the rust mite which attacks and destroys the fruit and exhausts the oil cells and renders the orange unmarketable. Here is an orange attacked therewith. A solution of one pound whale oil soap to five gallons of water, and applied with a brush to the affected parts of a tree just before the blooming season, is an effective remedy. Sulpher is also a good thing to spray with for this insect. The scale insect is another dangerous enemy, and I have here a limb with some scale on it. The Laybird is its greatest enemy, but if no Ladybirds are in your grove a solution of lime, kerosene oil and water is a very effective remedy. And here is one of the most deadly enemies to citrus cultivation, the beetle, we know as Fidler. It feeds in the leaves of the trees, then deposits its eggs at the root of the trees, and in time produces the larvæ which feeds on the bark of the roots, and as the roots are barked the whole tree ere long feels the loss of its necessary nutrition, and twig after twig, branch after branch, dies back, often puzzling the owner to determine the trouble. So soon as you notice the dying back begin, search carefully round the root of the tree, and you will find numbers of larvæ, very like "Mackaka" worm but smaller with a hard black pointed beak. Deal out death to every one and apply about half lb. of sulphate of ammonia and this will drive them away. Prune the trees, carefully back, removing all dead or dying branches. Prune the roots also cutting away the barked roots to give those left alive a chance to recover vigour. Wage perpetual war against Mr. Fidler wherever you see him—let death be his certain lot and thus keep down a dangerous pest..—*Journal of the Jamaica Agricultural Society.*

TEA CIRCULAR ON TEA REFUSE TEA WASTE AND DAMAGED TEA FROM MESSRS. BARLOW AND CO. 37, STRAND, CALCUTTA.

Dear Sirs,—A considerable quantity of the above occurs on all factories from various causes, and is swept out of the tea house and thrown among the bushes or on the ash-heap. Hitherto there has been nothing else to do with it. We have, however, lately learned that, though useless for human consumption, it has a certain value for other purposes. We recommend you, therefore, to have all the following collected and put into *good* old rice bags and sent down to us in these bags, when we will dispose of it for you to the best advantage.

Tea Fluff.—This is fairly abundant in every part of the sifting room, and should be regularly cleared off the walls, roofs, beams, etc.

Tea Refuse.—This includes all pickings during sifting. Tea blown into odd corners from the dryers, teas accidentally left in the corners or under bins, etc., etc., till soft and unfit for mixing with sound and marketable teas.

Tea Sweepings.—This includes all tea house sweepings after the work is done, freed of dirt and dusty earth or sand as far as possible.

Damaged Tea.—Any tea rendered unfit for mixing with sound and marketable tea, from any cause whatever, such as water, fire, or smoke, should be collected and put separately into bags. Any sunk tea, or tea otherwise damaged by water, should be re-dried as soon as possible.

It is however, to be practically noted that any such damaged tea is to be kept entirely separate, and not mixed with the above, till you have received instructions as to what is to be done with it.

Such tea should not be thrown away, as it is of some value.

Tea Dust.—Not fit for human consumption on account of the earthy dust mixed with it, should be sent down in bags.

We believe it is the practice with some concerns to sell the above refuse locally. This is a most objectionable practice, as it frequently gets into the hands of natives in Calcutta, and possibly out of India, and is sold as tea much to the detriment of the reputation of Indian teas. The practice is, therefore, most harmful, apart from all sanitary considerations. We trust you will do your best to stop such traffic.

We give our absolute gurantee that none of the, supplies of the above sent to us will be used for human consumption in any way whatever.

N.B.—Tea stalks by themselves are useless and should not be sent down, as we are advised at present, but any normal mixture of stalks with the above refuse will not effect the sale.

Please advise us about what quantity of the above you will have available from now to the end of the present season. On hearing from you, instructions will be sent to you for forwarding it to Calcutta. We are, Dear Sirs, yours faithfully, *Per Pro* Barlow and Co., H. W. Sutcliffe.—*Indian Gardening.*

COFFEE IN DAYS OF OLD IN CEYLON.

(By a Coffee Planter of the "Forties".)

Dublin, Sept. 4.

I read the *Overland Observer* and find allusions therein to things that draw me back to the good old times when in full vigour I roamed over the hills looking after coolies, engaged in holing, lining, and planting. My first experience was on "Alpittykande," the property of Robert Craig and "Mahaleecumbura," the property of Postmaster-General Lee and Mr. Saunders, of the Customs. In those days when forest lands could be got at 5s the acre, many of the Civil Servants invested and some made money.

My object in writing this note was on seeing

"ALPITTYKANDE'

mentioned, in a late issue of the *Observer*. I well recollect when I traced a path from the Monument and had it widened out to run "pack bullocks," for I did not like my men to be beasts of burden. Subsequently the track was extended to Gampola, and as this track succeeded well, a deputation of the Superintendents waited on me from the other side of the main road, asking m to trace a path to their estates. These were the first private roads in the Kaduganawa district, and to show their value "Alpittykande," Mr. Craig's property, sold for £12,000, Messrs. Lee and Saunders were offered £35,000 by the same purchaser, but refused and subsequently lost in the disastrous years 1845-1846 and 1847, when I gave a bushel of parchment for a bushel inferior rice.

Well, to return to

COFFEE

which was ruined by hoe and scraper, I must bear record to the only practical Planter I ever met in Ceylon (George Crosbie). After he had planted "Bowhill," near Nawalapitiya, he never allowed hoe or scraper to be used by any of the weeding gangs: instant dismissal was the punishment of any infringement. The consequence of his wise rule was a growth of *moss* all over the planted portion, and in seasons when shorthanded he had the berry picked from under the trees and cleaned at his store, such coffee realising 5s per cwt. more than parchment cleaned at Colombo. After his death new-fangled ideas were introduced, hoe and scraper came into requisition and soon the soil which "G C" tried to secure for the nourishment of the coffee tree was running off as pea-soup to enrich lowlying paddy fields; the trees roots exposed and gradual decay. For ten years the average of Bowhill was 10 cwt. 1 qr. 15 lb. per acre; after the new change it dropped off to 9 cwt. 7 qr. 5 lb. and 3 cwt. per acre and eventually like all estates similarly treated, became worthless. Poverty brought disease which like any other plague extends and lays hold of good and bad. In this case, however, there was no remedy, for as coffee is a surface feeder and the soil which should be strictly conserved was wasted. The soil on Ceylon hills is light, and never can be replaced by any artificial manure, and to keep cattle is unproductive, as I know by experience. I never saw a coolie drop his basket of manure beside a tree that had to be holed to receive it, but I said there goes 3s.

How far

TEA

will pay I have no opinion to offer as I never was engaged in its culture. It is a shrub that will grow from Pidurutalagalla to the Fort of Galle, and from what little experience I gleaned from a relative modern machinery has not added to the flavour of tea. I recollect the small plot Mr. Grant had on the road from Nuwara Eliya to Kandy which was cured by *hand labour*, and certainly *none* of the machine-cured tea can at all come up to it in flavour. Mr. G. always sold his at three rupees a lb. and I would give that amount in preference to 1s of the present stuff sold under the name of Tea. The Beaulys of Dublin have still a small quantity of tea, part of a cargo that they had from China about 50 years ago. On State days they regale friends (they belong to the Society of Friends) and no greater treat could be offered. This particular tea was *hand-cured*.

R.

CEYLON PLANTERS' RUBBER SYNDICATE, LD.

This is the title of a proposed Company of which the memorandum and articles of Association appeared in a recent *Gazette*. The object is to acquire lands in the Malay Peninsula or elsewhere for the purpose of producing rubber, tea, coffee, cinchona, cacoa, cardamoms, rhea, ramie, plants, trees, etc., and the nominal capital is R90,000 divided into 180 shares of R500 each. The signatories are:—A R Wilson-Wood, Kotagala; W H Aitken, Dikoya; Wm. P Halliley, Nanuoya; P J Gaisford, Talawakele; Prior S Palmer, Dimbula; Ernest Hamilton, Dolosbage; and Harry Whitham, Dolosbage.

EXPERIMENTAL TEA CULTIVATION IN SOUTH CAROLINA.

In the last report of the British Consul at Charleston a section is devoted to describing the results of experiments in tea growing in the State. At Summerville the experiments began about ten years ago. At the beginning they were conducted on a small scale, but they have been gradually increased, until now over 50 acres have been planted with tea. When the plants arrive at full bearing the yield should be at least 10,000 lb. of high-grade tea annually, and this, it is supposed, will suffice to show conclusively whether tea may be profitably grown under existing local conditions of climate, soil, &c. The problem of providing cheap labour for gathering the leaf was solved by training a band of negro children. The South Fraser tea garden, containing a little over two acres, has done very well so far. The bushes were raised from seed planted in 1892, produced from a celebrated garden near Hang-chau. This tea is not exported from China, as it costs about 6s 6d per lb. at Hang-chau. The Summerville garden is in very good condition, the unsuccessful plants amounting to about 4 per cent only, and visitors acquainted with Oriental gardens have expressed surprise at its luxuriant and uniform growth, comparing favourably with similar gardens in the East. The bushes are thick, somewhat low in growth, and globular in form, the leaf, as a rule, being rather small and quite tender, and adapted for the manufacture of either green or black tea. The soil is a clay loam, with a stiff, dry subsoil; it has been heavily enriched every spring with a high-grade fertilizer at the rate of 600 lb. to the acre, and the yield of dry tea last year reached 500 lb. per acre, while few gardens in China yield over 200 lb. The 1898 crop amounted to 3,000 lb. in all, and was sold at a profit of about 25 per cent. The black tea produced there has a distinctly characteristic flavour, and, like some of the choicer Oriental teas, its liquor has more

strength than the colour indicates. The severe cold weather of last winter appears to have conclusively tested tea culture in South Carolina, so far as climate is concerned. The unusually cold weather did not materially diminish the crop, the percentage of plants apparently injured was small, and of those killed still smaller The production is necessarily dear, owing to the comparatively high price of lahour, and this difficulty must be met by greater productiveness, substitution of machinery for hand labour in the factory, and by the cultivation and manufacture of those qualities of tea which, from inherent chemical causes, cannot be transported from the East without losing their delicacy of flavour. One essential to greater productiveness is ahundance of the richest plant food, natural or artificial. High-class teas in the East are dried at low temperatures in order to preserve those volatile principles that give them delicacy and flavour. They do not retain their best qualities for any length of time, and cannot for this reason be advantageously shipped abroad. Herein may be found the most profitable field for tea experiment in America, as there can be no competition from abroad in the higher grades if it can be demonstrated that their successful cultivation is possible. It has been suggested that probably the best chance for success in this direction will lie in the development of selections of long Pekoe tips for the manufacture of Mandarin tea such as is made in China. —London *Times*, Sept. 3.

PUMPKINS AS A FODDER.

Writing to the *Auckland News*, a farmer says: "My experience with the pumpkin is, all the animals that I have, including the cats, relish it; cooked or uncooked, every part, seeds and all, disappear quickly. For a number of years I have used various foods for dairy purposes—potatoes, turnips of several kinds, mangolds, also green maize. The root crops are costly to produce; too great a percentage of water in them. The mangold gives well-flavoured milk and butter when used or fed with good grass hay. The best results I obtained was from the pumpkin with grass hay and prairie-grass. Whatever the experience of others may be, my opinion is that the three above-mentioned foods are superior to all others for dairying or fatteuing purposes. The pumpkiu is highly nutritious, the prairie grass is far superior to any of the other grasses as hay, or nsed in the green state. The pumpkin is easy of cultivation, clean to handle, no cost of digging as in root crops. Should anyone elect to use the three foods, aud after fair trial they find them more suitable aud profitable foods, their advice and knowledge would be very acceptable. The most convenient method to produce the pumpkin and prairie-grass would be to grow both in one suitable paddock—say three acres—one acre pumpkins, and two acres grass. When pumpkius are taken off, prepare for grass; break up one acre of grass, and use for pumpkins, or, in other words, use in rotation. A stack of good meadow hay as a standby is very desirahle. The result will be, with a good shelter shed, good milk and hutter, and rich manure."

REID'S BREAKER OR TEA LEAF EQUALISING MACHINE.

AN IMPORTANT IMPROVEMENT.

A machine that has been before the public for a number of years, and onc that has proved its merits and usefulness by the large number of sales, is the Self-Feeding Tea Breaking Machine, introduced by Mr. George Reid, of the Meleng Tea Estate.

An improvement has recently been made in this machine. The hopper arraugement and the fluted roller have been done away with, and a large rocking tray is substituted. It was found at times when the tea was carelessly fed into the hopper, that more dust was made than was desirable, and moreover, foreign substances, such as nails, pieces of bamboo, &c., which in the best regulated tea-houses do sometimes manage to find their way into the tea bulk, were not easily detected. The rocking tray, above alluded to, presents a large surface, on which a whole basketful of tea may be emptied, and spread out, the tea being gradually moved towards the "Breaker" by the vibration of the tray, and any foreign substances can be easily detected and removed. Moreover, no possible breakage, or rubbing, of the tea can take place, until it comes in contact with the knives, or cutting teeth, in the interior of the machine.

This tray is moved by a small eccentric on each side of the projecting driving spindle, and is balanced by weights; it works noiselessly, and a most satisfactory report upon it has been received from Assam, where the new attachment has been thoroughly tested.—*H. and C. Mail*, Sept. 14.

Bogus Tea.—During the past year 226 samples of tea, representing 3,322 packages when tested at the Government laboratories, were found to contain exhausted leaves, or to be mixed with sand or other illegal substances and were consequently refused admission for home consumption. Of these 3,322 packages 2,274 were exported, presumably as being good enough for foreigners, and 1,048 packages were destroyed. It would be interesting to learn more about this tea, and to discover where it comes from and where it goes to, that is the 2,274 exported packages. We trust they are not described by the name of Indian or Ceylon in some foreign country where the knowledge of tea is very limited.

When China Wakes Up.—Indian and Ceylon planters are often told that one of these days China will rouse herself and become a formidable competitor in the attempt to control the tea markets of the world. In this connection it may be noted that in the Geographical Section of the British Association an address was delivered on Tuesday by Mr. G. Chisholm, upon some consequences that may be anticipated from the development of the resources of the Chinese Empire by modern methods. He assumed that its development was about to progress. Referring to tea and silk he said that: "In the silk trade China had felt constrained, by the example of Japan, to discard primitive hand methods of manufacture, while in the tea trade the severe as well as continuously progressive competition of Ceylon and India had taught the Chinese a salutary lesson, and induced them to make experiments with leaf-rolling machinery, the product of which was found to yield high prices in London." Mr. Chisholm claims that the development of China was bound to have world-wide effects, on a scale of extraordinary magnitude. Among the consequences that might be anticipated from this opening up were: —(1) A rise in prices in China, especially in the industrial regions; (2) the creation of a demand for food stuffs not likely to be supplied by China itself, a demand which in itself would he one of the most powerful causes contributing to maintain the rise in prices; (3) the imparting of a great stimulus to the food-producing regions most favourably situated for meeting this demand, more particularly Manchuria, Siheria and Western America and probably the Pacific States of North America to a greater extent than Canada; (4) perhaps the most important of all would he the creation of a tendency to a gradual but prolonged rise in wheat and other grain prices all the world over, reversing the process that has been going on since about 1870.—*H. and C. Mail*, Sept. 14.

TEA MACHINERY AND TEA FACTORIES:

MR. J. A. WILLIS TAYOR ON THE SUBJECT.

A planter, upon whose knowledge of all that concerns tea and tea gardens we can thoroughly rely, writes us as follows:—"I see that some of the Indian papers refer to this book as one of 'exceptional interest,' but I fear that anyone practically acquainted with tea planting who reads this treatise with the idea of discovering new ideas or enlarging his knowledge of the subject with which it professes to treat, will be disappointed. I am under the impression that the author has never been upon a tea plantation or seen a tea bush, and this is obviously a drawback when writing about the cultivation and preparation of tea for the market. He tells us that the chemistry of tea is a subject upon which he has barely treated, but with the cultivation of the plant and the process of manufacture or preparation of the leaf he has been forced to deal to a certain extent, in order to be enabled to describe intelligibly the various machines and apparatus employed.

"In his refereuce to cultivation and manufacture he gives the ideas of recent writers, and there are liberal quotations from the views of Mr. Christison and Mr. Crole, which are duly acknowledged. I fail to see the relevancy of the description given of the various kinds of steam ploughs, steam draining, and ditching machines, and the different systems of steam cultivation, as there is no attempt to solve the problem how they could be profitably employed on tea gardens. While admitting that it is not altogether impossible that level grass land might be prepared for planting, and that steam ploughs in this connection might prove useful, I do not see, nor does Mr. Wallis Taylor explain, how such operations could be profitably carried on, even if the steam cultivator could be moved about and kept constantly employed upon grass land extensions. The idea, if it is suggested, that these cultivators could be used upon forest clearings, planted gardens, or on hill-side gardens, is a somewhat remarkable one. As a preliminary to his account of tea machinery he describes, the author devotes some space to bridges, portable railways, steam and electric traction tramways, oil engines, refrigerating machines, &c., and here, no doubt, as an engineer, he is quite at home, but I cannot see the point of that which is written so far as its application to tea, or tea making or manufacture is concerned. In describing the various machinery used in the manufacture of tea, Mr. Wallis Taylor treats of some thirty-seven tea-driers, including machines that, so far as I am aware, never came ino actual use, and others that are obsolete. Even in dealing with such a well-known maker as Mr. Jackson, whose dryers are named, no drawing is given of any but the Britannia, which has been superseded by an improved invention by the same maker. The chapters on Tea Machinery are apparently compiled from the Patentees' Catalogues, with the addition of some illustrations drawn from the Patent Office. A study of the complete catalogues of the few firms who now manufacture tea machinery would therefore be much more to the purpose from a practical point of view than this elaborate volume.

"In regard to tea chests, a list of woods from which they are made is given, but from the 36 different kinds named the 'Toon,' decidedly the best, is omitted, while the reference to patent chests is altogether inadequate and incomplete. The book is well illustrated, is got up nicely and contains useful memoranda on various engineering and mechanical points, but I cannot discover that the volume, the net price of which, I believe, is 25s, throws any new light on tea manufacture or tea machinery.—*Home and Colonial Mail*, Sept 14.

THE (CEYLON) PLUMBAGO COMPANY.

The first ordinary meeting of the Plumbago Company, Ltd., was held on Sept. 12 at the offices, 57½D, Old Broad-street, E.C., Mr. D C Rutherford presiding.

The Chairman having expressed his regret at the absense of Mr. Pyman (the Chairman of the company), said the shareholders were aware that was only the statutory meeting, and as there was no business to transact it would only be necessary for him to take up their time for a few minutes. The company was registered on 16th May last, and the working capital amounting to £10,000, was fully subscribed by the signatories to the memorandum and articles of association, and four shillings per share had been called up. On 22nd May Mr. Alpine Wodehouse-Pearce was appointed managing director of the company and he sailed for Ceylon on the 13th June, and since his arrival there, he had been and still was inspecting the properties in which the company was interested, and his reports were generally of a satisfactory character, especially so in regard to the Talgaswella Estate. He (the Chairman) regretted that there had been considerable delay in the shipment of the necessary mining machinery on account of the engineering firms being so fully occupied, but the orders were now completed and the last shipment would be made on 15th inst. Mr. William Shedlock was engaged as engineer to the company, and he sailed for Ceylon on 23rd August, and up on his arrival he will set to work to erect the machinery upon the property selected by Mr. Pearce as quickly as possible.

The proceedings then terminated with a vote of thanks to the Chairman.—*Financial Times*, Sept. 13.

[To prevent mistakes we may point out the gentleman who presided was not *H. K.* Rutherford who has nothing to do with the Company.—ED. *T.A.*]

PLANTING AND SPORT IN TRAVANCORE

ELEPHANTS GALORE—A BIG SNAKE.

An ex-Ceylon planter writes under date 21st Sept.:—

"I think you will be interested to know that I shot a cobra at the Kaduakarum bungalow last December, 1899, which measured 10 feet 1 inch: no snake yarn as I have the skin.

"I resigned charge of T— estate to take up work here as a manager of three estates. These estates have been abandoned for a long time, so that I have a lot of work before me. The labour is plentiful as all the coolies going to and from Peermaad have to pass through Placart through which the main east road runs. Rice, of course, is the same and I can buy it from R3·50 to R4 per bushel. Wild animals are abundant, as are also red deer, elk or sambur, bison and elephants. I saw no less than 33 elephants in a flock yesterday, about 800 yards away from my plackers, and I believe

there were up to 30 of them, some of which had not come round the hill when they were disturbed.

"I will give you acreages, &c., later on as I have some tea to recover from jungle. The total in land is 1,258·98 acres."

ANOTHER SCIENTIST FOR PERADENIYA, CEYLON.

Mr. A G Tansley, who studied botany at Cambridge, and there knew Messrs. Willis, Carruthers and Gardiner, and other of the younger scientists who have recently visited Ceylon, arrived on Sept. 30th, by the ss. "Occana,"—says our evening contemporary—to join Dr. Lang, who has been in this island two months, engaged in botanical investigations. They will continue at Peradeniya together, until November or December, and then will start for the Malay States. Mr. Tansley, who will stay with Mr. Carruthers while at Peradeniya, will, during his six months in this part of the world, more especially study the lower forms of plant life. In August last, shortly before starting, he met at Cambridge Mr. J Stanley Gardiner, who recently conducted an exhaustive researeh in the Indian Ocean atolls. [Mr. Tansley is, we believe, an old pupil of Dulwich College—a school which is constantly sending up scholars who attain distinction in the sister Universities.—ED. *T.A.*]

RUBBER INDUSTY IN MANICA.

The "Manica Mining Journal" is complaining of the destructive way in which the rubber industry is exploited by Indians in Manica. Until quite recently (it says) the wealth of the country in india-rubber was known only to Indians, who traded with the natives at considerable profit to themselves. The Indian stores buy yearly about 12 tons of india-rubber, of a value of nearly £4,000. On that sum they have something like 60 per cent. profit, or a net return of £2,400. The complaint is not that these Indian traders should make handsome profits on their transactions, but that in the making of them one of the most important natural products of the country is being ruined. The natives bleed the lianes very carelessly, in many cases killing them, in order to lessen the difficulty of their task. To mitigate, if not to remove, this evil, our Manica contempory suggests that the Mozambique Company should charge a yearly licence of £100 or more per stone to all india-rubber buyers, and, further, that the working of the lianes should only be permitted to the concessionaires who bind themselves when the season is over and the crop gathered to plant again a certain number of new trees, and strictly forbid any working to the natives. The Mozambique Company has already granted one concession under these conditions, and it is, no doubt, the intention to impose them in future contracts.—*India-Ruberr Journal*, Sept. 17.

THE GRAPHITE INDUSTRY OF BAVARIA.

In a report on the economical condition of Bavaria, Mr. Harford, of our Legation at Munich, says that graphite is one of the most valuable minerals found in Bavaria, and like the lithographie stone, represent almost a monopoly for the country, as the only formidable competitor in the supply of natural graphite is Ceylon. The production in Ceylon has, however, decreased in the last six years from 30,000 tons to 12,000 to 15,000 tons annually, causing a great rise in prices, as the deficit could not be made good from other sources. The price of Ceylon graphite ranges from £59 to £75 per ton. In Bavaria the graphite deposits are found near Passau, and are inferior to the Ceylon graphite, as, while the latter is nearly pure, the former has about 60 to 75 per cent of earthy substances mixed with it. The Passau graphite however, can be purified by a very simple and inexpensive process, and a substance produced that is quite equal to the Ceylon graphite. Unfortunately this process is little used, as the deposits are spread amongst a number of small proprietors, who work on a small scale in the cheapest manner possible; the result is that there is waste of raw material, of which it is said that nearly 90 per cent is absolutely thrown away owing to the unscientific system of working which must lead to the premature exhaustion of the deposits. In 1898 there were 49 graphite works in Bavaria, employing only 216 men, which produced 4,593 tons of graphite, worth £19,583.—London *Times*, Sept. 10.

THE PRECIOUS STONE CUTTING INDUSTRY OF BIRKENFIELD.

The cutting and polishing of precious and semi-precious stones forms the chief industry of the little principality of Birkenfeld, up among the hills of the Nahe River in Oldenburg, and gives employment to over 5,000 persons. Although an improved factory system is gradually superseding the laborious methods of former times, there are, nevertheless, plenty of the old polishing and cutting works, which bear evidence to the lives sacrificed to this industry. The United States Consul at Mainz says that in the early days of the trade, agate quarries existed in the adjacent hills, and this stone was cut and polished by a very laborious method, which is still practised, although the agate quarries have long been exhausted, and the raw material—as well as amethyst, jasper, opal, topaz, &c.—has been imported (since about 1834) chiefly from Brazil, whence it is shipped to Birkenfeld, to be cut, shaped, and polished for the jewellery trade. The usual method employed in cutting and polishing these stones is as follows:—In a rude hut by a stream, which furnishes the power, four large grindstones about 4 feet in diameter are so fixed that their axes are only about one foot above the floor, into which a slit is cut, so that part of the grindstone is below its level The lowest portion passes through the water, thus keeping the stones constantly wet. The operator has a bench or block of wood, about 18 inches high, hollowed out to receive his chest and body. On the bench he lies at full length, and with his fingers holds the small piece of opal, amethyst, or other stone which is to be cut, against the grindstone slightly above the level of the floor: in this position the men lie from morning to night, day after day. Consumption usually carries them off at an early age, but other men are found to follow this vocation, as the earnings are comparatively high. The operator usually owns his grindstone, or at least half of one. This represents an investment of about £20, and a skilled lapidary can earn from £3 to £5 per week. He does not usually cut and polish stones on his own account, but generally contracts with manufacturing jewellers, who supply him with the stones in the rough to cut and polish at a certain price per gramme (gramme = 15·4 grains). As the stones, even in the rough, represent quite an outlay of money, the honesty of the workman must be greatly relied upon, for nobody can say in advance how many grains of finished stones a certain piece of opal, amethyst, or the like may yield. Besides these semi-precious stones, precious stones such as diamonds, &c., are also cut and polished there, but this is an entirely different branch of the industry, and is chiefly carried on in

factories with modern machinery. Another branch of the industry in the district of Birkenfeld is the cutting of cameos. Pearls are also polished, drilled, and cut, and shipped in large quantities to all countries.—*Journal of the Society of Arts*, Sept. 14th.

FRUIT-CULTURE FOR NORTH CEYLON.

It is quite the thing to talk and write about new industries for Jaffna or for Ceylon, but much of what is written is impracticable, and hardly worthy of serious consideration. The Northern railway is now assured, and with communication with the metropolis, it behoves Jaffna to be wide awake to its own interests or others will be coming in and starting new enterprises and taking away the profits that really ought to belong to Jaffna. We should like to call attention to a matter of minor importance believing that the time has come when enterprising men should bestir themselves. We refer to the setting out of such fruit trees as will grow here readily, and the fruit of which will be in demand even more than at present when railway communication has been established.

THE ORANGE

for example, might be more extensively cultivated. Why should not men who have a little capital, invest it in planting out two or three acres in orange trees of approved varieties. Colombo now gets shipments of oranges from Italy and Australia, but let our sweet juicy oranges once be brought upon the market and in spite of some defects, they will supplant those imported from other countries. As it is, no one person has more than a few trees. We should like to see a number of small gardens—say two or three acres each—started in localities where these fruit will do well. If good healthy trees are set out this year they will begin to bear in three or four years; and as the orange tree seems to be short lived, new gardens should be planted every two years or so. Better also to graft on the good varieties, so as to be sure of your fruit. The oranges from Copay and vicinity are thought to be especially nice; they are sweet and juicy and have a thin outer skin or rind. And the experiment might be tried of grafting on scions of the Sicily, Florida and California navel, oranges. The soil should be thoroughly prepared and the trees watered regularly and also properly pruned in order to insure the best results. Along with the orange could be raised limes which are already in demand.

There is another fruit which might be more extensively raised, and that is

THE GRAPE.

There seem to be two varieties, one more solid and less juicy than the other. The very sour grapes that one gets hold of so often, no doubt belong to one of these varieties, but the vine has not received proper treatment or the fruit has been gathered too early thus accounting for the acidity. The grape is grown principally in another locality of the peninsula in the vicinity of Pandeterripoo, and we believe the cultivation could be largely increased if some men of enterprise and a little capital would take it up. There are other varieties that possibly might do well though it would be well to consult some authority before investing. The vine needs careful treatment, and its enemies are numerous. As to

THE PINEAPPLE

it does not seem at all likely that the Jaffna variety will ever be in much demand when we have such luscious varieties of this fruit grown in Badulla, Matale and other localities in the hilly country of he island. But what about

GRAFTED MANGOES?

Would they not always be in demand? At present there are few, comparatively speaking, of grafted trees in the country. The fruit brings a higher price in the market than the ordinary kinds, and there should be a good demand for it when the railway is opened. Every year there is a greater demand for young grafted trees we are told, and in time there should be no lack of good fruit.

Other fruits might be mentioned, but at least a beginning might be made with these. The attention of our people needs to be called to the changes that are bound to take place when Jaffna is no longer isolated.

Our Assistant Government Agent, Mr. Leake, has started a class in Agriculture, but whether Horticulture is included or not, we cannot say. It might be well for some of our prominent men to turn their attention to this branch of farming.—Jaffna "Morning Star," Sept 27.

THE PROPOSED ZOOLOGICAL GARDEN FOR COLOMBO.

SITE SELECTED.

The geographical position of Colombo makes it eminently fitted as a centre at which might be organised one of the very best Zoological Gardens in the East. An attempt to carry this out is about to be made by a syndicate of Colombo gentlemen, and from what we can gather, there is every promise of the undertaking proving a huge success.

In an interview recently, Mr. John Hagenbeck, whose very wide experience in the organisation of Zoological and Botanical gardens in various parts of the world will be available in connection with the starting and carrying on of the Colombo "Zoo," stated that the site for the Garden had been selected in the Cinnamon Gardens

CLOSE BY THE HAVELOCK RACE COURSE.

The last novelties, the newest buildings, and the best possible arrangements will be introduced, and with this object in view Mr. Hagenbeck has been travelling all over the Continent and has got together a collection of sketches which will be of great value to him in making the gardens up-to-date and smart. The first object of the gardens will be the education of the children, to show them what animals exist and where they come from. There will, at the same time, be something for the scientific to see and learn.

A band-stand is to be built, the Military and Volunteer bands will be engaged, and in the course of time moonlight fêtes and concerts will be organized. There will be "fashionable days" for the more opulent visitors, and there will be days when a lower charge for admission will be made. Another feature is to be a restaurant, run, probably, by one of the local hotel managers, and it is hoped that the "Thirty Committee" may be able to see their way to establish a Tea Kiosk.

COLLECTION OF CEYLON ANIMALS TO BE MADE FIRST.

In the first instance a collection of Ceylon animals will be got together, and then Mr. Hagenbeck will obtain specimens from the four corners of the earth. He hopes, and we think he may confidently expect, to get help from the residents of Ceylon, European and native. Mr. Hagenbeck, in consequence of his business connections in various parts of the world, contemplates no difficulty whatever in getting together a varied and valuable collection of animals, and firmly believes that the Zoological Garden is to be *the* future attraction of Colombo. Amongst other attractions will be a pleasure gardeu for the use of children, with swings, "merry-go-

rounds, performing animals and other forms of amusement. Elephant rides will, of course, be a prominent source of fun. It will be the endeavour of Mr. Hagenbeck, in designing the plan of the Zoo, to give as much space and freedom to the animals as possible. The cages for both birds and beasts will enclose as many trees as is necessary, and the surroundings will be as near nature as practicable. In all, the grounds will cover about 20 or more acres.

THE MODE OF ADVERTISING.

With regard to advertising the Colombo Zoo and making it as widely known as possible, large boards will be fixed in prominent positions at the jetty, notices will be placed in the hotels and at various points of vantage in our thoroughfares. Another mode of advertisement will be the distribution of small hand bills, or cards, to the passengers, the American style of advertising being followed as closely as possible.

The Zoo is to be opened each day of the week, including Sunday—on which day, of course, concerts will not be held—and the time of closing will be 6 p.m. or 6·30 p.m. A good portion of the revenue is expected to be derived from the charges for the elephant, dromedary and camel rides. Help has been promised from the Zoological Garden proprietors in India, who offer to send animals at cost price. All gifts of specimens to the Zoo will be acknowledged in the papers the same as they are in London.

"We hope to make an actual start with the laying out of the grounds next month, and as soon as the buildings are ready we can very quickly get the animals housed, remarked Mr. Hagenbeck. The site has to be surveyed in order that the places for the ponds may be fixed upon and that the necessary levelling may be done. "It may be," said Mr. Hagenbeck "that the gardens will be ready by the time the troops come back from China." The directorate will be composed of about half-a-dozen well-known European and native residents of Colombo.

Season and family tickets will be issued, but the charge for admission has not yet been settled.

The idea is to incorporate a botanical section with the Zoo, and in this connection, it is hoped that some help may be given from those in authority at Peradeniya Gardens.

We have every belief that under the experienced and able guidance of Mr. Hagenbeck the scheme will turn out a success in every sense.

TROPICAL AFRICAN RESOURCES.

(Before the British Association.)

Mr. Edward Heawood, in the course of a paper dealing with the commercial resources of tropical Africa, said that at least 70 per cent. of the total trade of Africa fell to the countries of the extreme north and south, leaving the whole of tropical Africa, with an area of some nine millions of square miles, a total trade of at most £30,000,000, of which nearly £7,000,000 belonged to the small islands of Mauritius and Reunion. Among historical reasons for the smallness of the existing trade were the attraction exercised during the age of great discoveries by America and the East and the consequent neglect of Africa, the political condition of the African peoples, and the effects of the slave trade; geographical causes were found in the massive form of the continent and consequent absence of natural means of communication and the unhealthiness of the coast lands. That many of these causes were not necessarily permanent was shown by a comparison with Brazil, which afforded a close parallel with tropical Africa in many respects. This showed that, given natural resources capable of supporting an increased export trade, the commercial future of tropical Africa need not be hopeless. The resources of a new country might be classed as exhaustible, principally minerals, and permanent, chiefly animal and vegetable products, the second group being more important. They might be again subdivided into jungle products, which, though not necessarily exhaustible, were likely to suffer diminution, and cultivated products. The former might, under cultivation, be transferred to the latter subgroup, which was the most important of all. In Brazil, for instance, the vast preponderance of the exports was made up by the four products coffee, sugar, tobacco and cotton. Rubber and timber, at present jungle products, and cacao, made up the seven principal resources of Brazil. In tropical Africa, jungle products, principally rubber and palm-oil and kernels (total annual value over £1,000,000), were at present those on which the export trade mainly depended. A period of development of plantation products had, however, set in, and coffee, cacao, cotton, tea, &c., had been grown with success in various parts. The chief difficulties to be encountered arose from the want of means of transport and the scarcity of labour; but these were now in a fair way to be overcome. The modern tendency for each country to depend for tropical produce largely on its own colonies must favour the commercial development of Africa, while the comparatively low population of Africa per square mile rendered it probable that it would in the future play an important part in providing a food supply for the more thickly peopled continents.—London *Times*, Sept. 12.

DEVELOPMENT OF CHINA.

(Before the British Association.

Mr. G. G. Chisholm had a very instructive paper on "Some Consequences that may be Anticipated from the Development of the Resources of China by Modern Methods." He said that the subject, which was one of enormous magnitude and deserved a careful study, would engage the attention of the world at large for a long time to come. He assumed that the development of China was about to begin. There were political and economical causes which must force on this development in spite of the opposition of some sections of the people. The chief political cause was that the Chinese had themselves been compelled to resort to the methods of Europe and America in self-defence. One railway, at least, was constructed by them for purposes of defence, and they were also compelled to have arsenals in different parts of the country. There were economic causes. So long as China desired to sell a pound of silk or of tea she must compete with other countries, and the competition of Japan had compelled the Chinese silk producers to adopt some of the modern methods. In the case of tea competition came not so much from Japan as from India and Ceylon. That competition, however, had also been continuous and progressive, and the Chinese had lately been compelled to make experiments with the leaf-rolling machinery used in India and Ceylon. Having learnt their lesson from this competition, they had established cotton mills with the most modern machinery in several places, and these were kept working night and day, including even the most sacred Chinese holiday. Attempts had also been made to establish the iron industry. All these causes tended to introduce modern methods of transport into China. In his belief the objection of the Chinese to these improvements had been much exaggerated. Although, no doubt, the governing classes were hostile to them, the great bulk of the people were inclined to welcome them. What, then, would be the consequences of this development when it came about? First, there would be

a rise of prices in China, especially in the industrial regions. The pecoliarity of the position of China was this—that it was the one region in the world with all the means for industrial development on a gigantic scale that remained to be opened up. So far China had been a country of phenomenally low prices owing to the fact that the means of communication were so bad that outlying parts were practically cut off from one another, and the cost of transport being so great, there was no outside market for the disposal of produce. The country was enormously rich in coal, iron ore, and cheap and efficient labour. Three provioces were especially richly endowed—namely, Hunan, Szu-chuan, and Shan-si. The last-named gave the most promise of immediate development because of its remarkable mineral richness and its proximity to navigable waters. A district in the mountainous regions of this province was so rich in minerals that it was estimated that a railway would pay although in some parts it would cost as much as £16,000 a mile. A second consequence that might be anticipated from the development of China was the creation of a demand for foodstuffs not likely to be supplied by China itself—a demand which in itself would be one of the powerful causes contributing to maintain the rise in prices. A third consequence would be the imparting of a great stimulus to all the food-producing regions most favourably situated for meeting the demands of China, more particularly Manchuria, Siberia, and Western North America, probably the Pacific States of North America to a greater extent than Canada. But perhaps the most important consequence of all was that the result of China coming into the world's market as a country demanding foodstuffs would be the creation of a tendency to a gradual but prolonged rise in the price of wheat and other grains all the world over, reversing the process that had been going on since about 1870 as the consequence of the successive opening up of new countries. If this last-mentioned consequence of the development of China came into operation it would have an effect of very great magnitude, very wide-reaching in space, very far-reaching in time, very diverse, and very complex.

BIG GAME IN AFRICA.

(To the Editor of the Daily Graphic.)

SIR,—Socalled "sportsmen" have been so ruthless in the destruction of big game in Africa that, at the present day, large tracts of country which formerly abounded in hartebeestes, antelopes, koodoo, eland, &c., are now desert wastes so far as livestock is concerned. In the *Daily Graphic* of August 10th I saw a paragraph dealing with this subject with quotations from a Consular report made by Mr. Commissioner Sharp. What led me to write this was a chance glance at an advertisement in a Cape newspaper, the "Wynberg Times," and advertisement which proves that big game is already becoming scarce in South Africa. It is as follows:—

ANIMALS WANTED.—I will give £150 each for Mountain Zebras; £100 each for ordinary Zebras, going in harness; £100 each Blue Hartebeestes; £500 a pair Young Hippopotami; £40 a pair Wart Hogs; £50 a pair Cape Hunting Dogs; £20 a pair Kaffir Cranes. Large Antelopes, Brown or Tortiseshell Hyænas, £40 per pair, Koodoo, Eland, or other large Antelopes high prices landed Southampton. Persons having friends upcountry please communicate, &c., &c.

If something is not done many varieties of interesting animals will shortly become extinct.—Yours faithfully,

"A TRUE SPORTSMAN."

CEYLON TEA PLANTING.

REPORT BY THE NEW INDIAN EXPERT.

Mr. Harold H Mann, who passed through Ceylon on his way to take up a post in India, has now issued a report on what he saw and gathered here. The following are references to it in the *I.P.G.*:—

The appendix to the report contains a short report from Mr. Harold H Mann on his visit to Ceylon when *en route* to India. Mr. Mann's remarks afford most interesting reading. The Committee of the Indian Tea Association desired that he would visit Ceylon on his way out to this country and the object of his visit was laid down in the following terms:—"You will take advantage of the opportunity to make yourself acquainted with the tea gardens in Ceylon, and to learn what you can as to the scientific methods and treatment of the plant which have been found of service *especially in increasing the yield per acre* and in maintaining the health and vigour of the bushes. (The italics are ours.) Surely the sentence in italics was inserted by a mistake. With over-production staring us in the face, and thousands of new acres coming into bearing, what shall we do if we increase our yield per acre? Ceylon has already over-reached herself in this direction, and done an injury not only to herself but to us also in flooding the London market with cheap teas. If Mr. Mann's mission to India is to teach us how to increase our yield per acre, planters may well exclaim —"Save us from our friends." To increase our yield per acre in the same way as Ceylon has done, would, under present circumstances, simply spell ruin to us. It is to be hoped that Mr Mann has disabused himself of the idea that Indian planters want him to teach them how to increase their yield per acre. Mr Mann clearly points out in his report the vast difference that exists in planting condition between the island and ourselves, he emphasizes the entire difference in the method of culture and treatment of the plant in Indian and Ceylon tea gardens. In India, while the plucking of the leaf and the manufacture of tea from it is confined to the nine months of the year, —April to December—(Mr Mann says six months), in Ceylon it is continuous. This, of course, has an enormous influence on the culture generally, on the manuring, and on the treatment of the pests and blights affecting the plant. Pruning is done, within limits, when most convenient, and not necessarily at any particular season. Except in the low districts, an annual pruning even is not necessary, and on some of the higher estates it is the custom to allow three or even four years to elapse between the pruning without harmful effect. Passing over Mr. Mann's remarks as to the nature of the soil in Ceylon we will briefly notice what he has had to say regarding manuring. In the island a great deal of careful and systematic attentions has been paid to this matter, with the result that it is now almost considered essential to manure all except the richest land. He states that in Ceylon it is universally recognized that

MANURING SHOULD BE DONE.

The differences of opinion on the subject are only concerned with the amount and kind of manure which it will pay to apply. According to Mr. Mann the best authorities are in accord that the foundation of the manuring should be the burial of the green prunings, preferably

with lime or basic slag. Some danger has been anticipated from the encouragement given to fungoid pests by this means, but up to the present the danger has been found to be illusory, especially since lime and basic slag have been buried with them. It seems essential, however, writes Mr. Mann, that the prunings should be (1) buried green, (2) *completely* buried, (3) buried with some "blight destroyer" such as lime or basic slag. Of these two "blight destroyers," basic slag is usually preferred as it also affords a means of applying phosphoric acid and the lower oxide of iron at the same time as the lime. Mr Mann has been assured that in almost every case where the trials continued for a sufficiently long time, this burial of the prunings had been a distinct success. On one estate he was shown prunings, buried six months before, filled with the feeding roots of the tea plant, while the prunings themselves had a pleasant "leaf mould" smell. As to the further manuring of the tea plant opinions are divided, says Mr. Mann, as to whether a more or less "forcing" mixture should be applied; as to whether the manuring should be for quantity or quality, and as to whether the manures should be forked in round the tree or buried in the holes where the prunings had previously been put. Opinion seems, however, to be tending in favour of not attaching *too* much importance to a large immediate increase of yield by means of a "forcing" manure, the final result of which *may* be to wear out the bush, but rather to try and obtain a moderate increase of yield at once, at the same time build up the bush for future seasons.

The manures Mr. Mann found chiefly in use were cattle manure, rape cake, castor cake, dried blood, sulphate of ammonia and nitrate of potash, superphosphate, basic slag, bones and potash manures. Castor cake was in much favour, but manures containing very much sulphate of ammonia or nitrate of potash were not recommended by the best authorities.

Mr. Mann states that although green manuring—say, with a leguminous weed such as *crocolaria striata*—had been strongly recommended, he was not able to find an estate, in the course of his tour, where it had been tried. Green manuring with the ordinary weed growth of the land is not used in Ceylon, for on practically all estates hand weeding is adopted and all weeds kept down. Mr. Mann was astonished at the general freedom of gardens from insect pests and fungous blights, after what he had previously heard.

THE HARD WOODS OF PARAGUAY.

Quebracho is one of the most profitable woods in Paraguay. It yields an extract used for tanning leather. The forests of Paraguay are said to be full of it, and among other trees in the unexplored territory west and north-west of Paraguay are the following:—Virapuita, virara, lapacho (very heavy, and a fine hard wood much in request in Buenos Ayres), jacaranda, palo santo (which derives a fragrant odour from its resin, and from which a fine extract is made), and curupay, which is excellent for building purposes, and whose bark contains tannic acid. The United States Consul at Ascencion says that quebracho and the other woods named are found in the west and north of Paraguay. In the south-eastern part, 360 miles along the Alto Parana, stretches a forest full of the most precious hard woods as follows:—Incienso, with an extract used as incense in the churches; curupay and lapacho, the last more abundant than in the north; urudai, timbo, iviraro, piteribi, quayavi, &c. Cedar grows widely, the trees are about 80 feet high and 12 feet or 15 feet in circumference. The bark is used for tanning. A league of land in Paraguay containing cedar costs about £200.—*Journal of the Society of Arts*, Sept. 14.

PLANTING NOTES.

FOREST CONSERVANCY.—The very pith of Mr. Broun's Report for 1899 is in the following:—

RE-ORGANIZATION OF THE DEPARTMENT.—During the year under report the Department has made a new start and a vigorous one. The proposals of the Forest Re-organization Committee having been approved of by Government, no time was lost in carrying them into effect. Fellings, instead of being made, as hitherto, here, there, and everywhere, were concentrated in specified localities according to market centres, trees were stamped for sale, and enumerations of growing stock were made to ascertain the potential capabilities of our forests. At the same time, demarcation lines were cut, round proclaimed reserves, 10 feet broad, round other forests 6 feet broad, and compartment lines were cleared, the total length of lines cleared and re-opened aggregating to about 1,084 miles. Notwithstanding the expenditure on these works, the surplus revenue of the Department increased very considerably, as can be seen by reference to Chapter V., and, generally speaking, the Department can congratulate itself on the progress made.

THE ESPARTO GRASS TRADE.—The *Journal* of the Board of Trade publishes reports from our consular officers in Tunis and Algeria on the causes of the diminished supplies of esparto grass. From Tunis it is reported that the low prices in England do not make it worth the while of the Arabs to pluck the grass and take it down from the mountains to the coast. Several years ago the price on the English market was £12 per ton, while recently it has been only about £3. When the barley crops are good it is much more profitable for the Arabs to attend to them than to collect esparto, and even when the latter is collected on the mountains the Arabs sometimes leave it there rather than run the risk of loss in carrying it to the coast. Political troubles or military movements have had nothing to do with the supply of esparto. The acting Consul-General at Algiers says that the esparto business is mostly confined to two areas, in one of which labour could not be got to pluck the grass because of the barley harvest and the great fall in prices in recent years, while in the second, or Oran, area, political troubles and the military situation in Southern Algeria, as well as the excellent barley harvest, have had their effect on esparto. Much labour was required for military transport, and numbers of camels died, so that the means of carriage were diminished to a large extent. In addition, the esparto fields in part of Algeria are being exhausted by continual plucking, and the arrangements for transport to and payment in Great Britain are unsatisfactory, as there is no regular communication and the practice is to pay in England according to weight and quality there. The Acting Consul-General strongly recommends English buyers to have an agent at the port of loading to look after their interests and make all necessary arrangements for them. Competition amongst buyers at Oran is said to be so keen that prices are being paid in the interior which are higher than the market value in Great Britain.—London *Times* September 14.

SOLDIER SETTLERS IN SOUTH AFRICA.

TO THE EDITOR OF THE (LONDON) "TIMES."

Sir,—My experience relates exclusively to the Transvaal, and is not obtained from any hearsay or *en passant* information, but is the result of a 13 years' residence as farmer and landowner.

The first consideration on the subject of soldier settlers is—What parts of the country offer the best prospects, and what is the present price? Mr. Dicey, in the *Fortnightly*, states that "there are millions of acres of land throughout the veldt which could be had almost for a song." I know of no part, going round the southern to the western districts from Standerton to Zeerust, where a farm of 10,000 or 12,000 acres could be bought for less than £4,000 even any of those where the natural supply of water is limited to the irrigation of ten or 12 acres of land. A relative of Oom Paul has a farm near Standerton, suitable for horse-breeding, for which he refused an offer of £10,000. A farm in the Waterberg or Zoutpansberg districts could no doubt be bought at a much lower figure. Fourteen years ago there was a public sale by auction in Pretoria of a number of farms in those districts, the reserve price being £60, but not one of them was sold. No Boer would think of buying a farm in those unhealthy districts to reside there; they are also too far from Johannesburg, which is the only market in the Transvaal. I cannot endorse Colonel Stopford's opinion in the *Nineteenth Century* magazine that £500 would be sufficient to stock a farm for cattle breeding, as a means of livelihood for soldiers settlers. Thirteen years ago I bought good cows for £4 or £5, oxen for £7 or £6, but since the rinderpest they are difficult to get at three times the amount, and it would take three years before any income could be derived from the capital invested. The Rustenburg district, which is justly called the Garden of the Transvaal, is the most suitable part for soldier settlers; it is near the market, and anything will grow there from a potato to a banana. My own case offers the best argument in the matter. I was utterly unacquainted with farming when I bought my property, consisting of about ten acres of irrigable land, having one day's water per week; the dwelling-house was separated from the land about 200 yards, and there was no water, no garden, not even a tree near it. I made a large dam and a water furrow, 600 yards long from the brook above (about eight or ten days' labour). I planted in the early autumn about 300 fruit trees—viz, orange, lemon, peach, apricot, apple, pear, plum, cherry, and fig. The peach and apricot trees were three years old and bore fruit the next season, to the great surprise of my neighbours the Boers, who told me it was the wrong time of the year to plant and they would all die. Not less surprised were they at my success in goat and pig breeding. Their goats were continually sick, and they lost hundreds in two years. I commenced with 17 and in three years' time I had 60, besides those I sold and killed. They would not believe me when I told them that during the rainy season they should provide sheltered kraals for them. However, when they found that my goats increased, they followed my example, and there is much less mortality amongst them now. It was the same with horses. I never lost one in ten years. I did not mention that the purchase of the ten acres of waterland, which is called an *erf*, includes the right of cutting wood for home consumption and grazing for cattle over the whole farm of 8,000 acres; in fact, the whole farm is the joint property of ten owners, and we can, if mutually agreed, sell any portion of it, which we did last year, measuring out ten *erfen*, some of which were sold for £150.

There is suitable land enough for five times the present agricultural population; it is simply a question of water, and as soon as the war is over one of the first considerations engaging the attention of the Government should be the construction of dams, without which the contemplated soldier settlements will be a complete failure. No Boer would object to pay for the water; it would increase the value of his property at least 50 per cent., and the money invested by the Government would bring in good returns. I think the Government will encounter fewer difficulties in obtaining land than in providing settlers with the necessery number of oxen for ploughing and transport purposes, unless the oxen and mules now used for war purpose were instead of being sold, apportioned to the settlers.

There is little doubt that if roads are made, new markets created, and money spent on its development the Transvaal will offer a widely different future—an almost boundless field for the employment of industrial and agricultural immigrants; and to any man with a large family and a capital utterly disproportionate to the position in life to which they were born and in which he hopes to place them I confidently say—Go to the Transvaal, to its wider fields, its freedom from pretence and expense, its sunshine and pure, exhilarating air. There is not a happier being in the whole world than a Boer with his ten acres of waterland, a span of oxen, and a wagon; his only trouble is when his neighbour's pigs get into his garden and he has to shoot them.

Steenbokfontein, Zwaartruggens. G. S.

TOMATOES AND COLD ASHES

Coal ashes are generally conceded to be deficient of manurial constituents—at least of ammonia. According to "Johnson's Gardeners' Dictionary," however, coal ashes contain carbon, silica, alumin sulphate of lime, iron and potash, carbonate of lime, and oxide of iron, and are said to be a good manure for grass, Peas and Potatoes. Thus the assimilation o some if not all of these constituents is likewise beneficial to the Tomato, and probably in a marked degree. The relation of a case in point may go far to prove this. It was experienced by my brother when resident at Rhode Island, New York. Having no further use for a brick built pit, used for plunging half-hardy plants in pots in during the winter, it occurred to him to add more furnace ashes to the pit, and plant Tomatoes therein. A shovelful of fresh cow manure was the only additional stimulant added, merely placing it beneath each plant, returning the ashes to each hole, and then placing a plant on the spot, and when the plants became fully established the hose was freely applied during the summer, resulting in a heavy crop of fruit of fine size and quality; some of the plants extended to eighteen feet in length, year after year in the self same ashes, much to the astonishment of the neighbouring gardeners. Moreover, the "spot" or "sleepy" disease never made its appearance. I must state that the long deep pit was filled up the depth of five feet within eighteen inches from the top, thus leaving space of wintering bedding stock and a single Tomato plant was allotted to each sash space. Whilst, of course, the sashes were not required for the Toma-

toes during the summer and autumn seasons, but long laths were laid over the pit to train the plants on. The cow manure, of course, afforded a stimulant for the young plants. I have seen the advantage of coal ashes for Tomatoes mentioned in the *Journal of Horticulture* by, I think, Mr. Iggulden, and the testimony I give may tend to increase their use.

Were another case in point needed to prove the efficacy of coal ashes, I may instance that by an amateur grower of Zonal Pelagroniums, and whose success was remarkable with plants grown in 4-inch pots. The plants were grown in pure turfy loam, with perhaps a little leaf mould added; but nothing in the shape of manure was given afterwards, simply pure water. The roots, however, in due course penetrated through the bottom of the pots, and then completely permeated the layer of coal ashes, spread over the staging up which the plants were arranged.—W G —*Journal of Horticulture and Cottage Gardener* Sept. 6.

INDIAN COMPANIES.

A very reliable London authority has favoured us with the following comparative statement showing the falling-off in profits per mature acre of tea in a number of the Indian Tea Companies during the past nine years, We have added the third column, and totals showing the actual decrease :—

Companies.	Profits per acre. 1890.			1899.			Decrease.

Or a total decrease of about 45 per cent!

THE MANTIS AT THE ZOO.—The multi-coloured locust, which was sent home from South Africa by one of the C.I.V.'s, has unfortunately succumbed in the Insect House of the Zoo, but its place has been taken by a specimen of that curious insect known as the Mantis, which has also been brought from the Transvaal. These insects, of which there are several varieties, have, in consequence of the grotesque attitudes which they adopt, given rise to no end of superstitious ideas, Mouffet stating, in regard to the Praying Mantis, so named from the prayerful position of the fore-legs, that "so divine a creature is this esteemed that, if a childe ask the way to such a place, she will stretch out one of her feet, and show him the right way, and seldom or never misses." Like the mole cricket, these insects are very voracious and cannibalistic, and if kept together will fight to the death. One variety, of a beautiful green colour, is held in much veneration by certain African tribes, and another resembles fragments of withered stalks.—*Daily Graphic*, Sept. 8.

ANTI-TANNIC TEA INFUSER.

An informal meeting of the shareholders of the Anti-Tannic Tea Infuser Syndicate, Ltd., was held yesterday at 98-99, High Holborn.—The Chairman (Mr. F S D Scott) explained that he had called the shareholders together on account of certain articles which had appeared in a London newspaper. He contended that the concern had been absolutely undermined by Mr. Marshall, who was the patentee and manager of the syndicate, and in support of his contention he read extracts from various letters written by that gentleman while he was in the employ of the syndicate.—Mr. Marshall admitted that he was the author of the letters, and stated amid much laughter that his suggestion that the correspondence should be burnt was made because he did not desire that the letters should be kept in existence. After a lengthy discussion it was resolved that an ordinary general meeting of the syndicate should be called at as early a date as possible for the presentation of the report and accounts, and for the appointment of directors.—Mr. Ashworth and Mr. Sampson were nominated as directors on the understanding that in the meantime they should investigate matters and report to the ordinary meeting.—*Financial Times.*

MR. JACKSON'S TEA MACHINERY.

A NEW PATENT CLIP-ACTION TEA BREAKER AND EQUALISER.

We noticed a short time since the catalogue of Mr. Jackson's tea-preparing machinery, manufactured by Messrs. Marshall and Co., Limited, of Gainsborough, who, by the way, at the Paris Exhibition have just been awarded the Grand Prix in Class 35 for portable, vertical, horizontal, and compound engines, steam road-rollers, and thrashing machines and the gold medal in Class 19 for coupled compound engine with Marshall's patent trip-gear. Since the publication of the catalogue of tea machinery, Mr. Jackson has introduced a patent clip-action tea breaking and equalising machines, for which he claims special excellence, the points of advantage being the following :—

Simplicity and low first cost for great amount of work performed. Small space occupied, and small power required. No discolouring of teas.

Evenness of samples produced and freedom from dust.

Safety device for stopping machine automatically when an obstruction gets in between cutting rollers. A very important feature.

It is also claimed that there are no sharp edges to get gulled, and no wire mesh to get torn or knocked out of pitch. Positive feeding action of rollers and no complicated feeding apparatus.

This machine is, we believe, the outcome of a series of careful experiments to ascertain the right class of cutting edges necessary for an all round apparatus *suitable* for treating *both unassorted tea* as it comes from the drier; also for reducing and equalising large Pekoe, Souchong and Congou.

We understand that recent reports from users confirm the suitability of the machine for a variety of work without in any way having to adjust or change the cutting rollers.

The machine is of high-class construction, Messrs. Marshall's name being a guarantee of this. The wearing parts are few, and the *wheel gearing* is *cut from the solid cast iron by special tools* so as to ensure smoothness of running, and *to avoid noise.*

The cutting rollers are made up of discs of special iron; the teeth can be sharpened as they wear, or turned round on the shafts, so as to present a fresh cutting edge to the material when necessary.

A safety trip device has been introduced of a very simple nature, which is arranged to stop the machine when any foreign substance gets between the cutting rollers, and in the interim *no unbroken tea can escape*; the *driving pulley* in the meantime *runs loose on its axis* until the obstruction is removed and the machine re-started. It is claimed for this machine, the cost of which is £31, that it is capable of breaking and equalising 1,200 lb. of tea per hour, if run at the standard speed given, making *a smaller percentage of dust than any machine in the market and without in the least giving the tea a grey or dull appearance.*

A machine doing one third less work than the above-mentioned can be mounted and worked in connection with Mr. Jackson's new balanced sifter to equalise the tea prior to sorting.

The power required is stated to be nominal.

The driving pulley is 9 in. diameter, with 2½ in. face, and the speed is 280 revolutions per minute; the driving belt required is 2 in. wide, which can be supplied at the option of the purchaser.

We understand that the superintendent of the Dooars Tea Company, Limited, testifies to the excellent work done by this machine at the Bhogotpore factory.—*H. & C. Mail*, Sept. 21.

THE INDIAN TEA INDUSTRY.

DEFECTS AND HOW TO REMEDY THEM.

"COUNSELS OF PERFECTION."

Mr. J. B. Leslie-Rogers is writing a series of papers in the *Pioneer*, a good idea of which can be obtained from the following extracts:—

To begin with directors and all such controlling agents—men in the above capacity should be chosen for purely business reasons and not because they happen to have a considerable number of shares in the concern, nor because they happen to be conveniently handy. Money and brains do not necessarily go together and shares in a concern by no means imply that the holder is *au fait* with the requirements of that particular industry. Two qualifications are absolutely necessary in all controlling agents, be they proprietors or members of a

BOARD OF DIRECTORS.

They must have a special business aptitude and training, and they must have a personal knowledge of tea generally; and if among the shareholders men can be found with a combination of the above qualities, they should be unhesitatingly elected to the Board, regardless of how many shares they possess. But as is very often the case, while purely businessmen are available, there is no one with the requisite knowledge of tea production. All experience goes to prove that in such cases it would be infinitely wiser not to elect the full complement of directors from among the shareholders, but to have at least one place on the Board filled by an outsider who is a tea expert: the latter to attend all meetings and have the full powers and usual fees of the ordinary shareholding directors. Some professional opinion is absolutely necessary on every Board, as it is the only way directors can logically presume to direct a professional planter. In cases where any great and exceptional changes are contemplated in the working of an estate,—first the manager's opinion should be invited and it should carry considerable weight with the Board. Too often the manager is altogether ignored, to the detriment of the investors' interests. If further opinions are desirable, they should be obtained from leading planters from the same district, and in extraordinary cases even from experts in other districts in India. All such information should be adequately remunerated on the same principle as opinions are paid for in the medical and legal professions. Every director should be required to visit his plantation at least once during the first year of his election, and make himself personally acquainted with the manager and assistants, and the conditions under which they have to work: the manager being granted sumptuary allowances for all such business visits. The failure of either of these essential duties should immediately disqualify a director from holding any further office on the Board.

Proprietors who have a penchant for directing and controlling their own estates, might, with considerable advantage to themselves, follow somewhat similar lines. It is the height of folly, if not presumption, for any one who is not himself a trained planter to dictate to one who is. In most cases it would be advisable for proprietors to leave the conduct of affairs to the discretion of their managers; and if further professional or technical information is required it should be obtained from duly qualified men, and paid for as above recommended. But in all cases it should be remembered that

THE MANAGER

is the real *deus ex machina*, and his opinions should carry the greatest weight in all matters appertaining to his estate. Directors and proprietors are often too prone to excessive interference: they forget that their duty is not to despatch dictatory and arbitrary orders on every little detail of work, but only to lay down broad guiding principles for each year, within which the manager should have every possible latitude to use his own discretion and professional knowledge. The less interference in actual executive work the better, as tea cultivation and manufacture cannot reasonably be carried on by fixed rules and regulations like an ink slinging Government department. The success of a plantation, or in fact any business, depends almost entirely on the personal ability, experience, and foresight of the man in actual charge: being on the spot he is the best individual to judge what should or should not be done in the ever-varying conditions on a plantation; and his work should be judged more by results than by methods. To reduce a manager to a mechanical non-entity who merely carries out orders, often emanating from incompetent sources, is to kill all initiative responsibility and desire for improvements. No tea estate can remain stationary: it must either progress or deteriorate according to the management it is subjected to. To enable it to go onwards and be up-to-date it must have at its head the best professional talent that money or other inducements can procure. Once such a man is secured, he should be given a stake in the shape of shares, commission, bonuses, etc., and his pay should be liberal, with a prospective pension at the end of a certain number of years. It cannot be doubted that it would be to the owners and shareholders' interest to make the manager feel by generous and sympathetic treatment, that he had in future a settled and comfortable home. No man can be expected to put forth his whole heart and energy into his work if he has the constant dread before him of being suddenly turned out of his post at the caprice or cussedness of his proprietors or directors. Therefore to put the matter in a few words, it is essential for efficient and profitable management,

that the manager should be a man of ability and progressive tendencies; that his appointment should be made congenial as well as permanent; and that in his executive work he should be made practically independent of all outside interference. To enable owners to assume this desirable attitude towards their manager, it is of course necessary to presume that only capable men are appointed to such responsible posts. But unfortunately such is not always the case; and consequently retired business men and pensioned Government officials, who have no experience of tea, and are past all active work, besides

NE'ER-DO-WEELS OF ALL SORTS

and failures from every walk in life, are pitchforked promiscuously into tea, regardless of the fact that heterogeneous individuals who have proved themselves incompetent before are not likely to shine brilliantly in their newly adopted profession. By the above denunciation, I do not mean to imply that there are no good men in tea. There are many planters who would hold their own in any profession in the world, and for practical all-round men would be hard to beat anywhere But unfortunately this class is not sufficiently numerous to leaven the mass, and give it a tendency towards progress, while the inertia caused by what may be designated the bad bargains is so great that it constitutes a very serious and tangible drag on the profession. It is no wonder then that after over half a century of tea cultivation the industry is still worked on wholly unscientific and hap-hazard principles. The craze for economy, based generally on false premises, has also done much towards deterring good men from joining the profession. A penny-wise and pound-foolish policy is nowadays much in vogue. Salaries are reduced, commissions and petty allowances cut down, and often totally abolished; and old hands dismissed and cheap substitutes appointed in positions of responsibility for which the absence of all personal and mental qualifications wholly unfit them. This false economy has been carried to such lengths that instances are known where native garden clerks have actually been shoved into their former superior's appointments! A certain proportion of salary may thus be saved, and the clerical office work may be done to perfection—but at what a cost to the estate in other respects! Who that has seen such an instance of purblind policy, can honestly say, that degeneration, disorganisation, discredit and ultimate pecuniary loss, are not the concomitants of such an irredeemably foolish system of management. There is a wise native proverb which aptly illustrates the position. The saying is that "a load carrying donkey cannot hope to vie with the fleet-footed Arab," and the inference is obvious in business matters as well as in the animal kingdom.

An ideal planter would be a very paragon of perfection, as he is expected to know almost anything under the sun: an agriculturist, an organiser of labour and commander of men, a doctor, a lawyer, a trader, a merchant, an engineer, and a combination of half a dozen other learned professions. But without wasting our time seeking for such a compendium of knowledge, let me describe what are the qualifications absolutely necessary in a manager if a plantation is to be a real success. He must be a man of education and ability who can command obedience and general respect. He must possess great powers of organisation and be fearless of responsibility. He should have a thorough all-round knowledge, both theoretical and practical of his duties. And, lastly, what is perhaps most important of all, he must have progressive tendencies and scientific proclivities, and be well informed and up-to-date in all matters appertaining to his profession. Such a man is worth almost any salary for what goes towards his enhanced emoluments is recouped a dozen times over by increased efficiency and more profitable results. To enable such a manager to put forth his whole ability and energy in his work, he must be allowed a great deal of latitude and must not have arbitrary restrictions imposed on his time or methods of management. You must, for instance, necessarily reduce his compulsory office work to a minimum, so as to give him the greatest freedom of action in his far more important duties. To harass and worry him with petty correspondence and useless accounts is to deprive him of the faculty of clear thought, without which no real improvements or consecutive progress can be made. It would be sufficient, for instance, if he were required to submit his accounts but once a month, accompanied by a short explanatory report for that period. Then at the end of the year he would forward an epitome of the twelve months' accounts, with a general report for the whole season. All forwarding of daily and weekly reports and accounts should be unhesitatingly abolished, as such finikin clerical work has the inevitable tendency to reduce the head of an estate to the position of a mere mechanical automaton with atrophied mental faculties, unfit for responsibility or advancement of any kind.

A special allowance of one or two hundred rupees a year should be embodied in the annual budget of expenditure for subscriptions towards

TECHNICAL AND SCIENTIFIC PAPERS,

journals, books, etc., published in England, America and India; and a small library dealing with all professional subjects, connected however remotely with tea, should be maintained in every factory. Such adjuncts to self-improvement are at present conspicuous by their absence almost everywhere. Like the British officer of pre-Transvaal days, the average planter, it is to be regretted, is still inclined to think it derogatory to be seen studying his profession from an intellectual point of view. Besides the above technical literature, at least two daily Indian papers should be allowed, to enable the manager to keep himself informed of all political, commercial, and social movements which may have any bearing on the tea industry. I have known many instances of thousands being made by quick-witted planters, who have gleaned a bit of information from a daily paper, which has enabled them to secure large contracts, or important new markets, or otherwise change their working plans, before the non-reading individual was even aware that any new move was necessary. All local Planters' Associations should make it a point to have frequent general meetings for the discussion of any information that members may acquire from the above technical sources; and the Indian Planters' Association at Calcutta might be induced to offer an annual prize or medal for the best essay by a planter on some professional subject chosen each year. The same idea might also be followed with advantage by our various tea journals in their own interests, as well as

that of the industry generally. My purposes in making the above suggestions is to induce planters to read more, study more, and think a little more ; and thus create a greater interchange of ideas, which would eventually bring about some cohesion and community of interest, and result in raising tea-planting into what it ought to be, viz , a thoroughly organised and up-to-date scientific profession.

There have been many suggestions of late about starting an

EXPERIMENTAL TEA GARDEN

somewhere near Calcutta. The idea is sound, and ought to be encouraged. It eminently claims the support of the Imperial Government, which should, in my opinion, start such a garden as an economic branch of the Calcutta Botanical Gardens. But besides the above, I would strongly urge some modified form of experimental garden in each planting district, maintained by the planters themselves. In large districts where funds are available, a whole garden, of, say, a couple of hundred acres or so, might be appropriated for this special purpose, with a selected man in charge, devoted entirely to experimental work alone. In smaller districts, where a whole garden could not be afforded, there should be no difficulty in setting aside a few acres in one or more gardens for such a purpose. I am sure enthusiastic managers would be found, who would freely give their services, provided they were guaranteed against actual loss, while working out the prescribed experiments for the community ; and there is no reason why Government should not be expected to support such local experimental gardens with annual grants of money from Imperial or provincial funds. To get the greatest benefit from the above scheme, it would be necessary that the official experts in the Calcutta Central garden should not only be in constant communication with the experimental district gardens, but that they should also be at liberty to make personal tours through all these districts from time to time, for purposes of comparison and mutual consultations. The advantages that would accrue to the tea industry by a series of experiments under such varied conditions of soil, climate, and management, would be simply incalculable ; and it is to be hoped therefore that planters throughout India will heartily support the scheme, which promises to be so fruitful of good results.

Another suggestion, which I trust will receive due consideration, is the growing of

AUXILIARY CROPS IN CONJUNCTION WITH TEA.

Every plantation has bits of waste land which though unsuited to tea, are quite capable of producing other profitable commodities. Here again the experimental gardens would prove extremely useful in ascertaining the best products to take up. For instance, fruits vegetables, medicinal plants, herbs, roots, fibres tobacco, nuts, seed crops, and even good timber might all be grown with advantage. There is also the well known fact that all leguminous plants such as peas, beans, etc., and all pod-bearing trees, are actually of direct benefit to the tea bush and should therefore be grown in among the bushes, for the green manure and nitrogen they supply the soil. Besides crops, why should not mule and pony breeding be carried out in suitable localities. There is a valuable and ready market for all such animals in the army and Government departments ; and the Indian Government, I am informed, would very materially support any planter who aided them in this direction. Unfortunately planters as a body have not as yet educated themselves up to thoroughly realising the great agricultural and commercial advantages of these extra aids to tea cultivation. Inexperienced and unbusiness-like proprietors and directors are also much to blame in this matter, as without their active and sympathetic co-operation it cannot be expected that managers will break new ground, and risk their own interests. This short-sighted policy has gone so far that in many instances managers have received explicit injunctions not to attempt the cultivation or production of anything else but tea on their estates. Under such arbitrary restrictions, of course, it is impossible to expect experimental work or up-to-date go-aheadness of any kind. In every tea district there are peculiarities of climate and soil that lend themselves specially to some particular production. As soon as this suitable plant or animal is recognised it should be taken up without hesitation by planters as an "auxiliary," to supplement the financial "shortcomings of the standard tea crop." When tea seasons are bad and prices low such "auxiliaries" will often of themselves tide a garden over its financial and other difficulties. Relief and aid from this direction would be far more satisfactory than burdening the garden with further calls on shareholders and local banks. As a matter of sensible precaution we should not place all our eggs in one basket: when one lot comes to grief, we should still have others to fall back on ; and he is a wise man who foresees this possibility before the crash comes.

A FARMER'S EVERY-DAY LIFE.

NO. III.

(By Cosmopolite.)

It does not often happen that old sayings, with regard to the weather, are verified, but, this year, we have had an instance thereof in connection with St. Swithin's day, about which the old saw has it that, if it rains on that day, it will do so for every day for the following six weeks. This year it did rain on St. Swithin's day, and it continued to do so every day until the six weeks had run their course, when it suddenly cleared up, fine, dry hard weather set in, allowing us to complete the hay harvest successfully, and maturing the crops so quickly that now, in every direction, oats and barley stooks are to be seen, whilst the whirr of the reapers and binders can be heard all over the land. This is the first time during the past twenty years that the prophecy with regard to St. Swithin's day has proved correct, so I consider it much more of a fluke than a moral certainty, and any one putting his trust in the old saying would be apt to find that he had backed the wrong horse. However, as things are going now, we farmers have forgotten already the weary troubles in connection with hay-making, and are cheered by the prospect of a dry season for harvesting the other crops. In this district the crop is

AN EXCEPTIONALLY GOOD ONE,

but, owing to the late wet weather and heavy down-pours of rain, a great quantity has been lodged and twisted, so that it will be quite impossible to reap much of it

with binders, and I hear of many instances in which the farmer has decided not to use his binder at all, but has engaged extra hands; and this he finds will be cheaper than purchasing twine for the binder, that commodity having gone up terribly in price owing to the war in Manilla. In Britain, binders have not yet proved themselves such an unqualified success as they have in our Colonies, and this is owing partly to the fact that our crops are heavier and longer in the straw than the colonial crops, and so the binder is unable to clear itself; another drawback to binders is the fact that great downpours of rain occur often during our harvesting which make the ground so soft that heavy machines sink deep and are a terrible drag on horses. When a farmer takes to a binder, he tries to work with fewer hands, and then when he commences leading his crop and a fine day comes, he regrets the absence of these few hands which would have enabled him to work more carts and get through the work more expeditiously. In the Colonies several weeks of perfect weather can be depended upon at harvest time, so the farmers there are not compelled to hurry themselves as we are, when a fine day comes to pass.

I have frequently mentioned my want of faith in

ARTIFICIAL MANURES,

especially when bulky manure can be obtained, and I had my views supported in a remarkable manner the other day. I was travelling by train, and in the carriage with me there were several farmers and their better halves. Two of these agriculturists started a heated argument on the qualities of several artificials that they had been using, and whilst pretending to read my newspaper, I listened with rapt attention to the discussion. At last, with a view to settling their difference of opinion, one of the farmers turning to a very old gentleman, who was sitting next to me, said :— "What is your opinion, Hilly, about these manures ; you have been a long time farming and must know something about them ?" The old man mumbled away for a little, and then delivered himself of this opinion : —"I am 91 years of age, and have lived on a farm all my life; and during that time I have known artificial manures do a great deal of good to the merchants who sold them, but I never knew a farmer, who bought any of them, who was benefited one scrap by them," and I softly said to myself, "encore," whilst the two disputants simply seemed to totter in their intellects when they heard the sage's opinion.

Referring to railway travelling reminds me that the animated

HOLIDAY SEASON

has been characterised by the usual breakdowns of the railway service in Aberdeenshire, and much inconvenience have the farmers been put to, when going to sales or markets, by the uncertainty of the hours of arrival of the trains. Platforms are given up to a crowd of excited excursionists, pushing, rushing and tumbling as if they were all in the physical training of all footballers. You pay for a first-class ticket and are becomingly grateful if you get accommodation in a third-class carriage of antique design, built in the days when these were made after the similitude of cattle trucks. You are bustled and hustled, and have your coat nearly torn off your back, and, when you appeal to any one of the railway people for protection, they reply that you should be thankful if they carry you without loss of life or limb. The poet sings about "every door being thronged with suitors," and I think he must have had the doors of the carriages on our local railway in his mind's eye, when he thus unburdened himself. So much annoyance and inconvenience has the bad management, on our lines, caused the farmers, that most of them have again taken to the family gig and *shull*, or learned to ride the fiery, untamed bicycle.

For some years back I have observed that females, born on any farm, are superior to males, whether these be the off-spring of the horse, the cow, the sheep or man himself. I have asked other farmers their views on the subject, but farmers are not very observant, and so, in no single case have I received any information. I have, however, taken the trouble to observe

THE STOCK ON OTHER FARMS,

and am quite convinced that there is something in it after all, one of my neighbours, for instance, having always been more successful in the breeding of males than females. If this is anything more than a coincidence, it must have some foundation in the soil of the farm, and the food grown thereon. In my own case it has been somewhat remarkable. Ewes, bred by me, have for long maintained their position at the top price of the sale ring; but rams, of identically the same breeding, have failed to make their mark. Mares, bred on the farm, have proved exceptionally good, whilst horses have run to leg and become weedy. Cows, bred by me, have been, without exception, dandies ; but bulls I have never bred to please myself. Even my own laborers' families tend in the same direction, and having been long in my service their children have mostly all been born on the ground, and the girls are strong, robust, healthy lassies, whilst the boys run too much to weeds, have a sort of white-black-fellow look about them with no calves to their legs. The neighbour I have referred to must have had a similar experience, although he had never taken the trouble to think about it, for, although his steers for years were in the first flight at Smithfield cattle show, and his young bulls fetched the top prices at the county bull sales, he never yet bred a cow that was any thing of a credit to him. My readers may be inclined to fancy that I have discovered a mare's nest—well, perhaps I have. I only give facts and leave others to try to refute them. As another instance of my farm being more suitable for females than males, let me mention that I purchased, about three months ago, a number of cattle of both sexes; these have since been fattened and sold off the grass, the heifers having added

about 1 to 1½ cwt. to their weight when purchased, but the steers not having added an ounce, in spite of their improved condition and appearance. "Facts are things that winna ding."

POULTRY BREEDING IN BELGIUM.

The "poulet de Bruxelles" has a very widespread reputation not only among gourmets, but among all who have had the good fortune to travel upon the Continent and partake of it. The difference in quality between the fowl above mentioned and one of the same age and size of the ordinary variety is shown by the fact that the first is sold in nearly all the markets in Belgium at double the price of the other. For example, a young poulet de Bruxelles which would be considered about the size sufficient for a meal for two persons is sold for about 4s., whereas one of the ordinary variety can be purchased for between 1s 8d and 2s 6d. The excellence of the fowl seems to depend, as far as can be ascertained, on the careful manner in which the sitting hen is treated, the cleanliness observed about her, as well as the careful feeding of the young chicken until sufficiently developed for eating purposes. The United States Consul-General at Antwerp says that whether or not the methods pursued in Belgium differ from those followed by careful breeders in other countries it is impossible to say. The choice of eggs for setting purposes is considered a matter of great importance, and the freshest obtainable are almost invariably used. The best breeders seldom take eggs older than eight days for raising the best quality. Care is taken that the eggs given to one hen should be of the same age. The eggs when collected are kept at a very even and medium temperature until given to the hen, and are turned daily. This is done to prevent the yolk, which is lighter than the white of the eggs, from adhering to the top of the shell. The eggs chosen for the purpose above mentioned are also of an average size, those above medium being rejected, as they often contain double yolks. Eggs received from a distance, and consequently exposed to more or less shaking, are allowed to stand a day or two before being put under the hen. Great care is also taken that the eggs should be perfectly clean. The nest is prepared of straw or cut hay, perfectly clean, dry, and odourless. As a rule,

THE SITTING HENS

are placed in corners where the greatest quiet is obtainable, and are not exposed to great light. When so situated they are not disturbed for any other purpose than the placing before them of their daily supply of food and water. As the hen leaves the nest at least once a day to search for food to take exercise, etc., care is taken to place her food and water within reach of the nest, in order that the time that she is off the eggs may be materially shortened. When the young bird is hatched it retains in its body part of the yolk of the egg from which it was produced, which suffices to nourish it for the first twenty-four hours, during which period only warmth is required, which is furnished either by the mother hen or must be afforded by a warm cloth, in case of the necessity of awaiting the hatching of the rest of the brood. The food first given can be varied, but must be made up of ingredients containing large quantities of nitrogen, as this is required for the formation of the tissues. It is necessary, in fact, that the food should be composed of matter resembling in character an egg, together with milk. It is customary to mix with the food eggs, milk, and the blood of earth-worms, field-worms, and that of a commoner variety of fish; also to introduce, for the formation of bone, certain quantities of phosphate of lime, found in grain and flour. In the early days flour is generally given on account of the facility of its digestion, grain being substituted as the birds begin to gain strength. Wheat-flour is generally used. The grain given is wheat, rice, millet, buckwheat, and Indian corn, raw or cooked. Cooked potatoes are also often given as a change of diet. It is customary to vary the grain diet as much as possible, and to administer it mixed. The food ordinarily employed is made up as follows. Hard-boiled eggs and wheat flour are mixed in milk, a little water being added. To this paste is added a small onion finely cut up, together with lettuce when green food is scarce. The mixture is usually quite stiff, as food which is too moist is considered harmful for the young brood. After the first few days a small quantity of whole grain is mixed into the paste, but if rapid development is desired, the simple paste should be continued alone. Great care is taken to keep the young brood in a dry, warm locality, which precaution, together with the proper food, prevents inflammation of the intestines, and similar troubles. As a rule the birds are cooped up on wet days, and allowed to run about as much as possible only in fine sunny weather. In winter a more generous diet is given to enable them to withstand the cold. The daily ration of grain for the fowls is from 2½ to 4 ounces.—*Journal of the Society of Arts*, Sept. 14.

PLANTING IN HAWAII.

ONE OF THE NEW PLANTATIONS.

A recent ride through the Olaa and Puna districts of Hawaii shows rapid changes, which a few years ago would have been deemed impossible. The clearing off of stones, shrubbery and forest trees, which formerly gave the impression that the land was a swampy jungle of little value for farming or cane growing, is a task that cannot be accomplished in a day. Sugar cane will grow in almost any part of Olaa, without irrigation, and apparently with less labor expended on it during growth than in most other districts of Hawaii. The company has already cleared off a large area, some of which has been planted with cane, so that at this date perhaps 2,500 acres are growing, not in one tract, but in irregular fields. Some of this will be used for seed, and for replanting, where fields require it. Cane grows here very rapidly and rank—both good qualities in a new plantation, where rapid progress meets many drawbacks. The company has a heavy task before it in putting the land in good shape and condition including roads, which are too often hard to keep in good repair. Still, with a powerful mill, abundance of labor, and the best varieties of cane adapted to the various elevations, which can only be learned by trial, Olaa will eventually prove a bonanza to those interested in it.—*Planters' Monthly* for August.

BRITISH CENTRAL AFRICA.

THE NEED FOR A RAILWAY.

The small community of Europeans who reside in the British Central Africa Protectorate, and to whose enterprise is due the remarkable prosperity of that outlying part of the Queen's dominions, have for several years been appealing to the Home Government (says a writer in the *Scotsman*) to help them with the construction of a railway. The railway has been surveyed some time ago. It is to connect the lower Shire River with Blantyre in the Shire Highlands, and then go on to Lake Nyasa. The traffic along this

great trade route has of recent years become very considerable, and as yet no better means has been found for its transport than the primitive one of human carriers—men and women. Last year the export of coffee alone amounted to one thousand tons, while the imports, at a very moderate estimate, exceeded 3,000 tons. All this material has been carried on the heads and shoulders of native men and women, with the exception of what is carried on ox or mule waggons—this being a very small proportion indeed. As the manager of the largest of the Transport Companies in the country (the African Lakes Corporation, Limited,) said at a meeting of the Central African Chamber of Agriculture and Commerce:—"In the present state of the country tenga-tenga (*i.e.*, carriers with loads on their heads) is the only method which is practicable. Bullock transport is twice as costly. Traction engines would cost double as much. . . . There were not the cattle in the country to perform the transport work, and from his corporation's past experience cattle brought from the south had always proved costly in the extreme by reason of deaths and other causes." It appears, then, that—though something might be done by improving the roads and using lighter traction engines than have yet been tried—for all practical purposes the alternative lies between human labour and the railway.

The arguments in favour of the railway have been frequently stated. The reasons advanced are briefly these:—(1) That the transport has become so enormous that the majority of the available labourers in the country are occupied carrying loads, while the coffee industry is suffering seriously for want of labour. Many plantations were nearly ruined last year for want of labourers to hoe them, and in consequence of this the output of coffee is expected this year to be only 700 tons, instead of advancing, as it should have done, on the 1,000 tons of last year. (2) That—large as the number of carriers employed is—there is during several months of each year an almost complete block in the transport. This year the block has continued beyond the usual time, and threatens to become a permanent condition of things. The inconvenience to the planters, missionaries, and others of having their goods lying at the river waiting, it may be, many months for carriers is evident. (3) That it is inhuman to load native carriers with such heavy transport. The road from the lower shire river. Blantyre rises 3,000 feet in less than thirty miles, and up this steep incline practically the whole of the 3,000 tons of imports, including such things as kitchen ranges, steamer's boilers and plates, and sections of iron barges, has to be carried by sheer human strength.

QUININE AUCTION IN BATAVIA.

The American Vice-Consul at Batavia reports as follows on the third Java quinine-auction of June 27th last, held at the Merchants' Exchange:—This sale has been considered fairly successful, and the limits were mostly all realised. Beginning with P. N. II., packed in cases of 22·68 kilos. (50 lb), limited in lots at 21fl. per kilo. some 4,173·12 kilos (9,200 lb) were sold at 21·05fl. per kilo, thus exceeding the limit. Offers were then made at 20·95fl., which were at first refused, upon which the limit was lowered, and seven lots were sold at 20·75fl. per kilo. This action brought forth a protest from the first purchasers, who had brought at the limit of 21fl. The limit of 21fl. was again asked, but lots 211 to 300 were not sold, as the bids did not reach the limit. P. N. II., packing at purchaser's option, 4 lots were sold at 21fl. per kilo, but there was very little demand for this unpacked article.

P. N. III., was all sold at fair prices. Two hundred and sixteen kilos (476 lb) were sold at 25·40fl and 25·45fl per kilo, and 24 kilos (52·9 lb) at 25fl per kilo; the limit for these lots being 25fl. The limit of 21fl for P. N. II. is equivalent to the unit price of 0·08¾fl (3·5c) for the bark in Amsterdam.—*Chemist and Druggist*, Sept. 22.

PLANTING NOTES.

LOCAL PRODUCTS IN THE HOME MARKET.—Coffee futures look tired for the present, and no decided feature. Sugar and quinine should be purchased. Cotton (American crop) may be 9¾ to 11¼ millions. Coals are expected to be lower later on.—London *Cor.*, Sept. 14.

NEW TEA MACHINERY.—Mr. Jackson is again to the front as an inventor and on page 322 will be found a description of a patent clip-action tea breaker and equaliser which he has just brought out, and details of its advantages.

PRESERVATION OF THE NEW ZEALAND SNIPE.—It is urged by Sir James Hector that every efforts should be made to preserve the New Zealand snipe which was becoming very rare indeed. This bird, he says, is one of the smartest game birds that could be got. It retained all the characteristics of the English snipe, flew away in a zigzag manner, was difficult to shoot and afforded capital sport.—*Auckland News*, Sept.7.

BANANA AND PLANTAIN.—Considerable confusion seems to exist regarding the identity of these two fruits, yet the case is quite clear. Musa sapientum gives us the banana, while the fruit of M. paradisaica (or as it is now generally regarded M. sapientum var. paradisaica) is known as the plantain. The majority of the large "bananas" which reach our markets from Cuba are, says *American Gardening*, the yield of this latter plant, and hence are really plantains. The true banana, which, by the bye, has a number of varietal forms differing in size, colour and quality, has been pushed out by the larger fruit of the plantation, though the quality of this is decidedly inferior to that of the best bananas. It is the old story of size *versus* quality. The plaintain is 7-14 inches in length, produced 40-80 to the bunch, in form cylindrical, acutish and of a yellow colour: the flesh is firm and not specially sweet, and writers of authority on tropical fruits say it is not very good unless cooked. The true type of banana is 3-4 inches in length, 1½-2 inches in diameter, about 50 fruits to a bunch. The fruit is rounded above, narrowed to a sessile base and bright yellow in colour. So far good, our distinctions are pretty well marked, but there arises a new complication in what is known as the Jamaica banana or Martinique variety, which is perhaps the one chiefly imported to this country. It is much like the plaintain, but smaller, 7-8 inches long and it has excellent shipping qualities. The plant is regarded as a sub-variety of paradisaica, hence we are confronted with this relationship: The plantain is a variety of banana, and a variety of the plantain again is a banana! [Banana and Plantain are, in our opinion, synonymous terms.—ED. *J.G.&P.*] [In the East, but not in the West, Indies.—ED, *T.A.*]

NOTES FROM THE SEYCHELLES.

ARRIVAL OF KING PREMPEH OF ASHANTI.

It was in the forenoon of 11th September that the B.I. ss. "Dwarka" arrived at Mahi with King Prempeh of Ashanti, and King Asibi of Cocofai. Prempeh was accompanied by three of his wives, his mother and one or two brothers and about 40 followers. All sent from the Gold Coast to be interned in Mahé, and I suppose kept from further mischief. The usual apathetic view of life which prevails among the Creole and native population of the island was somewhat exercised by this

ADVENT OF ROYALTY,

to dwell with them and they gathered to some extent on the pier to see them land, but it was decided to take them in boats to the house which the Government had assigned for their residence near the Coast about four miles from the township. The landing of their Majesties was therefore very unpretentious and it was nearly dusk before it was accomplished. The house rented by the Government for their accommodation is a plain, but rather nicely situated building having about ten acres of ground round it, with flower garden and fruit trees. The party was accompanied by a Wesleyan parson or teacher, also black, to act as interpreter. I had an opportunity of seeing Prempeh the day before I left, as he then, with the chiefs of his following, paid a visit to the Administrator at Government House. Owing to his arriving too soon, he was taken to the verandah of a little house where there was a a merry-go-round, the wooden horses of which appeared to excite his curiosity as something novel, He was sitting there, an attendant holding a large purple umbrella over him, whether he walks or whether he sits. I understand this umbrella is always held over him. Prempeh seems about 30 years' old and for an African is fairly good looking, although his features give one the impression of violent passions subdued by circumstances. His lips are not over thick, his teeth are fine, regular and very white, and he has good eyes and nose. His dress is similar to the toga of the old Roman right-arm entirely bare with a loose white robe-striped with colors, one end of which is thrown over the left shoulder. A green ribbon circlet of an inch wide with patches of gold on it is his only head-gear. His walk is slow and not without a certain dignity. Two stools were borne by attendants, but I understand he sat on chairs at Government House, which he did not like. His Honor in uniform receiving him outside in the grounds.

As regards matters generally in the Seychelles the visit of

THE "ECLIPSE" AND "POMONE"

in July helped to make social life lively for a week or so. We had also a visit from an Italian man-of-war, and the English yacht "Victoria," chartered by the Prince de Broglie was there for some time, owing to the illness of the Prince.

The last four months have been very dry the rainfall for that period being only 10 in. as against an average for eight years of 21. However, it seems to have suited the

VANILLA VINES,

as rarely has there been seen such a promise of flowers as was everywhere apparent when I left. They were then commencing to come out abundantly and the total product of beans next year is variously estimated at from 50,000 to 70,000 kilos. Several good plantations have been purchased by Englishmen, new arrivals within the last year or two. Liberian coffee is flourishing abundantly, but as the price is so low, (20 to 25 cents a lb,) that it does not pay for the cost of preparation, and several planters are not taking the trouble to gather the berries.

The B.I. Co. have, owing to the demand on their resources of steamers, thrown up their contract for the line between Bombay and Zanzibar calling at Seychelles. This does not suit the producers of coconut oil which will now have to find an outlet in and via Mauritius.

It is much to be regretted that while one can get from Colombo to Mahé in seven days, the only way of getting back thereto is by the long round via Mauritius.—*Cor.*

CEYLON TEA IN PARIS.

MR. R. V. WEBSTER TO THE FRONT.

Mr. Jas. Westland has returned with a very high opinion of the extremely good work done by Mr. R. Valentine Webster at the Paris Exhibition, in Paris generally, and indeed throughout the world, on behalf of Ceylon tea. Mr. Webster has not only two central depôts in Paris, but 20 Restaurants within and 52 outside the Exposition, besides 63 hotels and 256 Thè-Cafés in the French metropolis all taking Mr. Webster's Ceylon tea. In Switzerland he has also a large number of agencies and customers. Mr. Webster advertises freely in Paris by means of the motor cars, as well as in other novel and attractive forms. He has illustrated pamphlets and circulars in French and his sample packets now before us are got up with much taste and just in the way to attract French and other Continental customers. Mr Webster has sold as much as nearly 1,000 francs worth of tea in his Exposition stand in one day. Lipton's agent, although in a better position, did not seem to be doing so much.—Mr. and Miss Westland spent sixteen days in France on the way out.

INDIAN TEA ASSOCIATION.

FIRE INSURANCE—TEA PESTS—TEA IN TRAVANCORE.

Calcutta, 25th Sept. 1900.

The Nagaisuree Tea Company, Limited.—Considered file of replies to the Committee's Circular No. 45 of 13th August, in which the views of members of the Association were invited upon the rates fixed in the Fire Insurance Tariff on Tea Garden Buildings, which was introduced by the Calcutta Fire Insurance Agents' Association in 1896. The principal items in this Tariff respecting which complaints had formerly been made were: (1) The additional rate of 2 annas per cent charged if the engine and boiler are inside the building, or in any building communicating therewith, except by double fireproof doors. (2) The additional rate of 4 annas per cent charged if fans are used. (3) The excessive rates fixed for withering and fermenting houses. (4) The excessive rates fixed for carpenters' shops. From the replies received it appeared to the Committee that the general opinion of members was favourable to the reduction of these rates

being pressed for. But a number of other suggestions had also been made; and it was decided to submit the replies, for report, to a Sub-Committee consisting of Mr. A Tocher and Mr R Magor, who had been previously asked to take up the matter.

Considered file of papers regarding a proposed visit of Dr. Geo. Watt, C I E, the Reporter on Economic Products to the Government of India, to the Darjeeling Tea District. Dr Watt had informed the Committee that he was engaged on the preparation of a new edition of his book on "The Pests and Blights of the Tea Plant;" and as he had not hitherto visited the Darjeeling Tea District, he was desirous of seeing some of the chief estates there before republishing the book. He proposed to spend six weeks in the district, leaving Calcutta on the 8th October; and he asked that a tour extending over that period should be arranged for him. The Committee had been in communication with the President of the Darjeeling Planters' Association on the subject; and had been informed that arrangement were being made for Dr. Watt to visit a number of gardens, the names of which, and further particulars would be furnished as soon as possible. This information was to be conveyed to Dr Watt. It had been arranged that Mr. Mann should accompany Dr. Watt throughout at least a portion of the tour.

Considered letter, dated 17th September, from the Honorary Secretary, Central Travancore Planters' Association, regarding the figures of tea production for Travancore given in the return of the Director-General of Statistics entitled "Statistics of Tea production in India." It was suggested that Mr O'Conor be asked to give detailed figures from the various districts in Travancore, viz, Central Travancore, South Travancore, and Kanan Devan. By so doing it was thought it would be possible to ascertain from which of the three districts the returns had been received which made the statistics for the whole area appear in the statement as 13,657,103lb. of uncured leaf and 8,775,789lb. of manufactured tea. It was added in the letter that these figures were manifestly inaccurate; and the assistance of this Association was asked in the matter. The committee decided to draw the attention of the Director-General of Statistics to the figures which appeared to them to be clearly inaccurate.—*Indian Gardening and Planting*, Oct. 4.

INDIAN AND CEYLON TEA.

It is a fortunate circumstance that as the production of tea in our gardens in India Ceylon increases, so also does the demand grow—fortunate, that is, for the producer of the leaf. In Great Britain the "cup which cheers" is becoming ever more popular, while on the continent of Europe, in Australasia and elsewhere the demand is steadily increasing. China as a producer of tea is now very far behind, although it is noteworthy that during 1899-1900 the imports from China into this country were higher by more than 8½ million pounds than in 1898-9, when 34 million pounds were imported.

The continuous progress made by British tea is especially remarkable in countries which, a few years ago, did not know what the British grown tea was. A striking example of this is afforded by America, where in 1894 the consumption was 4,723,000 lb. In 1896 the quantity had more than doubled, and stood at 9,474,000 lb. while last year no less than 17,226,000 lb. of Indian and Ceylon tea were required.

British planters can fairly be proud of this fact. It is due to their activity and foresight that the American market has been established. An extensive system of advertising was adopted, and the praises of British tea sung loudly and incessantly in the years of our friends across the Herring Pond, and, as it was found that the tea fully bore out the good things which were said about it, a demand for it became felt, which is now growing in the manner indicated by the eloquent figures we have quoted. A circular issued early in the present year by a New York house drew an interesting parallel between the condition of the East Indian tea trade in Great Britain was thirty years ago and that in America at the present time. We reproduce the figures quoted:—

Gt. Britain.	Lb. used	America	Lb. used
1866 ...	4,584,000	1894 ...	4,723 000
1867 ...	6,360,000	1895 ...	7.792,000
1868 ...	7,746,000	1896 ...	9,474,000
1869 ...	10,715,000	1897 ...	11,362,000
1870 ...	13,500.000	1898 ...	13,609,000
1871	13,956 000	1899 ...	17,226,000

From these figures one obvious deduction may be drawn. It is that if the teas are pushed in America as they have been of recent years, the parallel between the two countries' tea history will continue to exist, and all the leaf which is likely to be produced in India and Ceylon will find a ready market with Anglo-Saxon buyers. The advertisement expenses are met by a system of levying a "tax" upon tea growers, which in India is 4 annas per acre of cultivation, and ½ anna per maund of tea manufactured, but the Tea Associations of India and Ceylon, which work together amicably in their siege of the world's tea markets. While we are dealing with America, it is well that we should note the demand existing there for green tea, to which British planters are paying earnest attention. Experiments have not been altogether successful hitherto, but efforts in this direction are not being relaxed.

On the continent of Europe, British tea is also making headway. The opportunity afforded by the Paris Exhibition is being made the most of in the Tea Court, which is under the supervision of a gentleman experienced in exhibition work. British tea in cup is offered to all and sundry, while tastefully prepared samples are distributed gratis to visitors to the Court. Ceylon tea especially is making rapid headway in France, although it will have a hard and long fight to out China. The Frenchman has not yet learned to love tea as a beverage; he looks upon it more as a medicine. The Tea Court at the Exhibition will doubtless go far to disabuse his mind of this idea. China provides a very large proportion of the tea consumed in Russia, Germany, Austria and Belgium, but in these countries also, in spite of many difficulties and prejudice Indian and Ceylon are going ahead. Mr. J E M Harrington has been commissioned by the Indian Tea Association (London) to tour through Europe with a view to learning what steps can be taken to facilitate the supply and increase the consumption of the tea in which the Association is interested. Mr. Harrington's report will be awaited with much interest.

At home the consumption continues to increase, although not by any means in the same ratio as the production in India and Ceylon. It is with a view to the absorption of this surplus production that such strennous efforts are being made to foster the demand in other countries, the only alternative being much lower prices in London, to the delight of housekeepers and the dismay of producers. We reproduce a comparative statement of deliveries of tea in the United Kingdom for home consumption only. The table is taken from the report of the Indian Tea Association (London).

	1895-96	1896-97	1897-98	1898-99	1899-1900
	lb.	lb.	lb.	lb.	lb.
Indian.	121,000,000	123,750,000	127,500,000	138,605,197	145,520,457
Ceylon.	76,000,000	83,500,000	87,000,000	80,108,167	92,105,165
	197,000,000	207,250,000	214,500,000	218,713,364	237,625,622
Total for China and other teas	26,000,000	24,000,000	20,500,000	21,569,953	22,857,606
Season.	223,000,000	231,250,000	235,000,000	240,283,317	260,483,228

The above totals do not, of course, represent im-

ports into the United Kingdom, which in 1899-1900 amounted in all to 309,895,353 lb. of which 39,325,590 lb. were re-exported.

A severe blow to the tea industry has been struck by the imposition of an extra tax of twopence per pound as a result of the operations against the Boers. The man in the street believes that he is paying the additional tax. He is certainly paying more for his tea, while the prices obtained by the producer are lower. The troubles in China have helped to keep the price up, it is true, but it is also true that tea is unduly taxed. Coffee, which is in strong competition with the fragrant leaf, and is of about equal value, if the impost be deducted in each case, bears a tax of only three-half pence per pound, and cocoa only one penny.

In spite of this, however, and in the face of high rates of freight and exchange, the one pound draft and heavy warehouse charges, the sale of tea goes on increasing, and the great bulk of the increase is supplied by our great dependency and its neighbour, Ceylon. The keen, active, pushing planter will not waste time in groaning over the hardness of his lot, but will go on seeking new continents to conquer, and by the excellence of his tea and the pushfulness of his agents, will find markets for his product which will take as much of the leaf as he is able to raise.—*Investors' Guardian*, Sept. 22.

THE COOL PROCESS OF TEA MANUFACTURE.

To the Editor, *Indian Planters' Gazette*.

Dear Sir,—My patent cool-oxidizer is the result of special study and practical experience, extending over some years, and although it might be considered by some a bold statement, I maintain that my cool-oxidiser will never be beaten by any other method. I have data of the proper speed the air should move over the Mal, so that it can take the necessary oxygen in just its proper quantities. I take it that the method of covering up the mal with cloths is still in vogue, and that this idea originated in the endeavour to keep out the light; *it is wrong* the Mal has no earthly chance of oxidising under cloths, and only undergoes *putrid fermentation*, as distinct a process from oxidation as chalk from cheese. I can prove that there are, as your planter correspondent says, *two distinct processes*—one oxidation, the right one, and the other what I have designated above as putrid fermentation.

Facilitate oxygenation, encourage it by giving the Mal oxygent through moving air; but move the air, at the proper speed; have under control the moisture of the air supplying the Mal. Temperature 75° to 80°0 Fahr.; neither above nor below. Your readers may try "prolongation of the process by total absence of draught," and "refrigeration" if they choose, there is no invention or patent about this; but as sure as the sun rises each morning and sets each evening the liquors resulting from teas so manufactured will be as "soft" as castor oil.

I claim to be the engineer who first knocked into shape a machine for oxidising tea leaf. I hold the patent rights and shall take such steps as the law provides against anyone making, selling, or infringing my apparatus; but if any planter is wishing to turn his present so-called fermenting room into a cool-oxidiser I shall be pleased to help him in doing so, without charging any royalty, provided the necessary equipment is obtained from me, and my designs faithfully adhered to. It is more than probable that before 1901 is very old I shall be once more amongst your Indian readers, and although, as they say in the dramatic world, I have been "resting" since 1897. I have not yet ceased to interest myself in tea machinery.—Yours faithfully,

Nathan Sharpe,

HOW TO DEVELOPE TRADE.

MR. DE COURCY HAMILTON (FORMERLY OF CEYLON) TO THE FRONT.

ENGLISH TRADE WITH JAMAICA.

COMMERCIAL EXPEDITION.

A correspondent informs us that yesterday the commercial expedition organised by the Bristol Chamber of Commerce to visit the West Indies, for the purpose of promoting the home export trade to those islands, left Southampton in the Royal Mail steamer "Orinoco." The expedition, which is under the charge of Mr. de Courcy Hamilton, who has had a very extensive connection with the West Indies, is taking over one hundred cases of samples of all descriptions of merchandise, most of the chief manufacturers within a hundred miles of Bristol being represented. It is proposed to open an exhibition in Jamaica, to hold conferences, organise lectures, and in every possible way to bring under the notice of the population of the West Indies the merits of the English goods shown. The opening of the new fast mail and fruit service between Bristol and Jamaica, in January next, has stimulated the merchants of the West of England in the direction of improving the export trade to Jamaica and the neighbouring Colonies, and it is confidently hoped that a very large increase in this business will result from the present venture. Mr. A L Jones (of Messrs. Elder Dempster and Co., the contractors for the new service), together with many other gentlemen interested in the movement, journeyed down to Southampton, and gave the departing experts a hearty send-off.

In the course of the day the following telegram was dispatched to Mr. Chamberlain: "Just off to Southampton to bid farewell to expedition going to Jamaica to open exhibition of all the manufactures within a hundred miles of Bristol. Bristol is entering very heartily into this great enterprise to resuscitate the trade of Jamaica. This will be pleasant news to you, who have the interests of the Colony so much at heart. Shall do utmost to make venture a success.—A L Jones." To this the following reply was received by Mr. Jones from Mr. Chamberlain: "Thanks. I cordially wish success to expedition, and I anticipate great results from their inquiries and your energy.—Chamberlain."—*Daily News*, Sept. 20.

COVERING WOUNDS IN TREES.

Mr. Peter Van Metchen says that the wounds made in the stems of trees by pruning or otherwise should have the wood preserved to keep it from decay till the new bark and wood extends over it, but he thinks gum shellac dissolved in alcohol far better than paint. He advices to put the shellac into a wide-mouthed bottle, cover it with alcohol, and let it stand twenty-four hours, when it may be applied with a swab or a brush. It serves, as nearly as may be, as the substance of bark; is not affected by heat, or cold, or wet, or dry weather; and retains the sap up the cut, healing the wound without a scar. Any limbs cut of square on top will leave a dead end from 6in. to a foot, which will eventually dry and rot off. Limbs should be cut off slanting; never square on top, as is sometimes done, but this would be quite a task in 300 or 400 acre orchard.—*Auckland News*, Sept 14.

Correspondence.

To the Editor.

SCIENTIFIC MANURING AND TEA.

London, Sept. 20.

SIR,—The importance of the subject and the deep interest that is taken in the effects of manure by Ceylon Tea Growers must be my excuse for again addressing you, after a delay, owing to my absence from home.

A point has been made by those who disagree with me of the fact; that I quoted the injurious effect on permanent pastures of the continuous application of sulphate of ammonia by itself, it being argued that those who understand the subject would not apply it by itself, but only when balanced by a proper proportion of mineral manure. I described the condition of the plot treated with sulphate of ammonia by itself for the same reason that I presume it was applied, namely, that it is only when one manure is used without others that its effect can be determined.

But as regards the effect of sulphate of ammonia when balanced by other manures, on plot 9 of the Rothamsted experiments, since 1879 the following mixture has been applied per acre:—

500 lb.	Sulph. of potash
100 „	Sulph. of soda
100 „	Sulph. of magnesia
3½ cwt.	Superphosphate
400 lb.	Ammonia salts

which, it will be admitted, is a complete or "balanced" manure: the average yield has been 58 cwts. of hay an acre, against 24 cwts. from the unmanured. The grass is however rank and of extremely poor quality, almost valueless for feeding purposes; the finer grasses here are dying in patches, so much so that I feel sure that no one who saw the plot as it is now, would care to risk the health of any perennial plant by the use of a manure so exhausting to the soil.

I went over the Rothamstead experiments with Mr. Joseph Fraser and Mr. Forsyth and was glad of the opportunity of discussing the matter with two such good cultivators of tea and with one who understands manuring so thoroughly as Mr. Fraser.

I pointed out to them what I venture to say those who study the reports only and do not see the plots, do not find out and that is that though the yield of hay is good from the plot referred to, small patches are failing and that the hay is almost valueless, owing to its being so rank.

We went over, too, the Barley experiments which confirm the conclusion come to at Rothamsted against the use of sulphate of ammonia; now barley obviously requires a quickly acting manure, for it has to grow and mature between May and September and here the plot manured with rape cake and mineral manure was in better condition and shows a higher average yield than that treated with sulphate of ammonia and mineral manure, though the quantity of nitrogen supplied in both cases is the same.

You will have seen that since I last wrote to you on this subject, Sir John Lawes has died; in his death Agriculture has sustained a great loss and for myself I feel with deep regret that I shall no more be able to consult one who has always ready to give the result of his experience to anyone who showed an interest in scientific agriculture.—Yours truly. G. A. TALBOT.

ARTIFICIAL MANURING OF TEA.

REPLY TO MR. TALBOT.

Lake Bungalow, Kandy, Oct. 9.

SIR,—It is gratifying to see by Mr. Talbot's letter of 20th September to you that artificial manuring of tea has its importance admitted, though tardily, in a quarter where all such manuring used to be deprecated.

As regards the use of sulphate of ammonia, Mr. Talbot throws no further light on the question. Doubtless it was applied alone at Rothamsted for the purpose Mr. Talbot mentions; but its tendency to exhaust the lime in the soil must have been chemically known before the practical experiment, to which he refers, was made. In all probability, therefore, it was not applied for a series of years only to prove that tendency, already deduced, but to watch its general effects on permanent pasture. This can hardly be said to apply to tea cultivation.

Nor, I think, can any rational conclusion be drawn, of any use to the tea planter, from the results Mr. Talbot quotes of the application of a mixed manure over a series of years to a field of hay. The mixture is such as no prudent planter would apply to tea and there is not much similarity between a hay crop and a tea field, and a vast difference in the climates in which the two have to be grown.

That an immense amount of information and interest for the tea planter is attached to the Rothamsted experiments goes without saying, but Mr. Talbot has not given us the benefit of anything useful yet, though I understand he lived in the neighbourhood and paid frequent visits.

I have used sulphate of ammonia for ten years, but *never*, of course, alone, and I use it still; and it is within my knowledge that Mr. Joseph Fraser has done so for a year or two longer and still does so. No bad results of any kind have yet shown themselves, and that is all any one can say. It may, however, interest your readers to know that Mr. Fraser wrote me after his visit to Rothamsted as follows:—"The visit to Rothamsted disclosed no new fact, in regard to sulphate of ammonia and its distinct tendency to exhaust lime, that I was not aware of. As regards the appearance of the grass plots, it might quite reasonably have been expected," &c., &c. I need not take up more space by quoting from his letter, for doubtless you will hear from him direct. —I am, &c., A. MELVILLE WHITE.

COFFEE IN DUTCH GUIANA.—Owing to the very low prices obtained for the coffee grown in Dutch Guiana, which is almost entirely of the Liberian variety, it is on some estates being gradually replaced by cocoa. The crops for 1899 was 360,481 kilos.—*Planting Opinion*, Sept. 28.

THE SCIENTIFIC MANURING OF TEA.

With reference to the discussion started by Mr. Talbot in the Colombo papers as to the advisability of using sulphate of ammonia as a manure for tea, we learn that Dr. Koller, of Messrs. Freudenberg & Co., had already referred the matter to Professor Dr. Wagner, who is looked upon as one of the greatest authorities on scientific manuring. The following is a copy of the reply received:—

Darmstadt, 19th Sept., 1900.

Agricultural Research Station for the Grand-duchy of Hesse, Director, Professor Dr. Paul Wagner, Privy Councillor to Dr. P. W. Koller, Colombo.

My Dear Doctor,—It is a moot point, whether preference should be given to Sulphate of Ammonia over Nitrate of Soda or preference to Nitrate of Soda over Sulphate of Ammonia. About a year ago at the instance of the "Deutsche Landwritschafts Gesellschaft"—a number of German Research Stations agreed upon thoroughly investigating this question by means of extensive experiments. At Darmstadt too this question has had our closest attention Our experience tends to prove that on the average—the efficacy of Saltpetre-Nitrogen is not quite equalled by a like amount of Ammonia-Nitrogen. There are however conditions in which preference is to be given to the Ammonia salts over Saltpetre; this is especially the case with a soil, light and permeable in which the Saltpetre-Nitrogen will be drained away very heavily during the rains. Also where no immediate return is looked for from the application of Ammonia salts should be given the preference.

Our experience is that if as you say there is a marked deficiency in lime (or if in spring the weather continues to be cold and consequently the Ammonia does not act quickly enough) the crop will be smaller than if Saltpetre-Nitrogen had been applied. However, if care is taken that the soil has a sufficient supply of lime there need be no fear of the Ammonia acting too slowly; for under the climate conditions prevailing in Ceylon a delay in the nitrification of the Ammonia is impossible to occur.

Experiments with tea plants we have been unable to make, but on the other hand we have no evidence to show that Sulphate of Ammonia should have a lesser effect on certain species of plants than on others. I cannot, therefore, concur with the view that there are positive reasons for deprecating the use of Sulphate of Ammonia as a manure for tea culture.—Yours faithfully,

Signed) WAGNER.

We learn further from Dr. Koller that to those manure mixtures, of which sulphate of ammonia forms a part, the necessary amount of lime is always added by basic slag, sulphate of lime or coral lime, to replace the quantity of lime in the soil used up by the sulphate of ammonia.—Since writing the above, Mr. Melville White's letter has come to hand confirming the use of lime in Ceylon along with sulphate of ammonia for tea, and also that twelve years' actual experience has shewn no bad results.

COCHIN COCONUT OIL TRADE.

The *Cochin Argus* of the 6th inst. says:—Both millers and speculators have been evincing a desire to sell forward, and a good business has thereupon resulted. We quote to-day R89/8 for prompt and R88/8 for one to four months' forward delivery per candy.

THE TEA INDUSTRY OF INDIA.

THE SERIOUS FALL IN PRICES

which has been brought about by excessive production has checked the opening up of more ground in this and other countries for the cultivation of the commodity, but, as it is, India has about half a million of acres under tea (or 82 per cent more than in 1885), which yield about 160 millions of lb. in an average year (or 161 per cent more than in 1885). The totals of the production of tea in other supplying countries are not accurately known, but, as showing the great changes that have come over the sources of supply within a short period, the following table of importations into the United Kingdom, which appears in the Moral and Material Progress of India report, is instructive:—

Year.	From China.	From India.	From Ceylon.
1865	93 per cent.	2 per cent.	0 per cent.
1875	86 do	13 do	0 do
1885	66 do	30 do	2 do
1895	16 do	46 do	32 do
1898	10 do	52 do	36 do
1899	12 do	50 do	35 do

From this it appears that in the thirty-three years, 1865 to 1898, the imports from China fell off as much as 83 per cent; that in the thirty-four years, 1865 to 1899, the imports from India increased 48 per cent; and that in the fourteen years, 1885 to 1899, the imports from Ceylon increased 33 per cent. Had it not been for the great success that rewarded the tea industry in Ceylon it is probable that Indian tea would now be almost as paramount in the British market as China tea was in 1865. But Ceylon, urged by the failure of coffee, took a leaf out of India's book, and now seems determined to keep, and even improve upon it. For the present, China has practically retired from the field of competition in Western Europe and America,* but she still grows much tea for her own and for Russian consumption; and, given the opportunity, she is still capable of adding enormously to the supply of tea for the use of her former customers in foreign parts. She has not yet, apparently, discovered the method for placing in distant markets teas of delicate flavour, and careful manufacture, at comparatively moderate prices, and until she does this the coarser teas of India and Ceylon will continue to be preferred by the ordinary consumer of the cheering beverage.

This, however, is pretty certain, that as no one who was counted wise in regard to tea in 1865 could have had a ghost of an idea of the extraordinary changes in the course of the trade that would be brought about before the century came to an end, so no one who is prudent would venture on the prediction that the proportions of the sources of supply will remain as they now are for many years to come. Most sincerely do we hope that India will not only retain, but will tighten her grip upon the tea trade of the world. But India's hold of the trade is not so secure that she can afford to take it easy, or dare to be indifferent to the tastes and prejudices of consumers. If, as she may well be, she is ambitious in respect of tea to live to please, she must bear in mind that she must please to live. Her consumption of tea is small as compared with her population; but the taste for tea

* No—not yet from America, to which 31¼ million lb, China tea have gone up to Sept. 28th, this season, against only 19½ million lb. to same date last season.—Ed. *T.A.*

grows with indulgence, and is stimulated by opportunity and low price. The inhabitants of India, unlike the inhabitants of China, cannot yet be included among the tea-drinking populations of the earth. But this may not always be the case, so that at no distant date a great demand for tea for consumption in all parts of this country may set in, and be difficult to meet. But for the present tea is cultivated primarily for export, and the growing of it gives profitable employment to 620,000 labourers in India, and adds some 5s millions sterling per annum to the value of India's exports. It also contributes considerably to the incomes of shareholders, mostly resident in the United Kingdom, in Indian Tea Companies.—*Mdras Mail*, Oct. 10.

THE CAMPHOR-MONOPOLY.

The British Consul for the district of North Formosa, in his annual report for 1899 (F. O. 2,525, 1d.) gives some interesting facts concerning the working of the camphor-monopoly, and as the bulk of his information has been received direct from the Formosan Government, it may be taken as official. There is now no camphor-trade to be done in Formosa outside that of the monopoly, and as we have already reported, the foreign merchants had entirely withdrawn from the business before the monopoly was instituted owing to the difficulties connected with the working of the camphor still in the interior. We now learn that the Formosan Government are assiduously planting young trees to make up deficiencies caused by consumption, and that a new Government refinery is to be opened this year, which it is expected will have a capacity for a daily output of 8.000 lb. What has so far been refined is said to be of good quality, though it appears to be somewhat rich in oil. It will be remembered that Messrs. M Samuel & Co., of London, wrote to this journal on April 7, pointing out that the Japanese Government did not intend to compete with British refiners, by refining camphor; so we presume the Consul's remarks apply solely to "half-refined" or "pressed" camphor.

The report next traces the steps which were taken by the Government to establish the monopoly which occasioned much suffering to the natives and others interested in the factories, but by degrees other employment has been found for them. A significant remark in the report is that the Government maintains a staff of guards and rangers who supply funds for keeping up friendly relations with the savages, so that it would appear that the industry is not conducted without a certain amount of danger, which may diminish as time passes. The total amount of camphor purchased from the licensed producers or manufactured between August 5, 1899 and March 31, 1900, was 20,437 cwt., and 15,535 cwt. of camphor oil. The report goes on to say that hitherto Formosan camphor was losing its good name in foreign markets owing to crude methods of production, but that the monopoly has done away with all these disabilities, inferior qualities having been got rid of, and more attention paid to the superior grades. As a proof of this the following table is given showing the amount of camphor produced under three grades, month by month, from August, 1899 (when the monopoly came into force) to March, 1900:—

1899.	1st Class. Catties	2nd Class. Catties.	3rd Class. Catties.
August	16,361	29,686	3,374
September ...	38,404	50,892	15,635
October	95,075	116,638	21,829
November ..	156,722	103,856	21,807
December ..	147,597	100,223	14,934
1900.			
January	171,165	88,218	16,250
February ...	126,802	52,656	6,207
March ..	241,098	74,819	7,925
Total ...	993,227	616,988	106,461

INDIAN GOVERNMENT CINCHONA.

Mr. W. M. Standen, director of the Government Cinchona-plantations, Nilgiris, has submitted to the Indian Government his annual report on the working of the cinchona estates and quinine-factory, for the year ending March 31, 1900. We gather from this that the season was altogether abnormal owing to the failure of two monsoon, but the drought has had no deleterious effect on the trees. The report shows that Mr. Standen has lost no time in utilising for the improvement of the factory and the plantations the valuable information he gathered in Java last year, as he is now conducting experiments in connection with the shading of the stems of the trees from the direct rays of the sun in order to produce a higher precentage of alkaloid in the bark. Mr. Standen wishes particularly to ascertain whether it would pay to protect the stems of old trees for this purpose, and he has accordingly selected a plot of six acres in an exposed position, and closely covered the stems of the trees with grass. The trees being large, the cost of the work was high, amounting to 58r. 2a. 10p. per acre; but the effect of the grassing on the appearance of the trees was most beneficial. The bark will be analysed when the trees have been under the protection of the covering for two years, and it will then be possible to show whether this mode of increasing the alkaloidal value of the bark is profitable or not. Another interesting experiment is being made to ascertain the yield of alkaloids from specially-manured plots. During the year 40,000 plants died, as against 47,600 in the previous year, nearly all the casualties taking place on the Hooker estate. Out of a total of 19,345 trees uprooted or coppiced on the estates for bark, 10.588 consisted of sickly and dying trees on this estate. It is observed that the land, originally poor grass-land and unfavourably situated, has been under cinchona for thirty years.

The total quantity of bark harvested on the Government estates during 1899-1900 amounted to 140,279 lb., or about 40.000 lb. more than in the previous year, the increase being largely due to the heavy coppicing that was necessitated. In addition to this, 223,811 lb. were purchased in the local market. One magnifolia tree, thirty-four years old, was coppiced, and yielded no less than 120 lb. of dry bark. The total quantity of bark worked up by the factory during the year was 344,312 lb., consisting of 318,881 lb. crown and hybrid barks, and 25,431 lb. red bark, and the alkaloids extracted amounted to 10,188 lb. (163,008 oz.) quinine sulphate, and 4,615 lb. (73,880 oz.) of febrifuge. The output was less by 38,640 oz. quinine sulphate than in 1898-99, but the idea was to make out 10,000 lb. of quinine sulphate, whereas during the previous year an effort was made to show how much quinine could be produced in the factory in one year with the present machinery. The output in future is likely to be restricted to about 10,000 lb., as this is reckoned to be sufficient for all requirements, unless the demaud should largely increase. The amouut of quinine distributed during the year was the highest on record, being 7,378 lb. (118,048 oz.) compared with the previous year's 2,748 lb. (43.968 oz.). This increase was due partly to a considerable increase in the requirements of the Madras medical stores and of Native States. The issue of febrifuge amounted to nearly 1,000 lb. more than in the previous year, being 2,676 lb. Upwards of 561,000 5-gr. quinine-sulphate powders, at 3 pies per powder, were retailed to the public from the post-offices in the Presidency. The Government found itself able at the close of the year to reduce the price from 3 pies to 2 pies—a reduction which it is hoped will encourage larger numbers of the poor to avail themselves of the benefit of the

medicine in this cheap and readily-obtainable form.

Coming to the financial part of the business, we find that the net profit on the operations of the estates amounted to R50,822, which is represented by stock valued at cost price; but, taking the stock of quinine at market value (1s. 7d. per oz.), the profit would have been R154,631. Mr. Standen estimates that the total cost of manufacturing the 10,188 lb. of quinine sulphate was R129,390 3a 9p., or R12 11a. 2p. per lb. and, taking the value of the rupee at nominally 1s. 3d., this works out at 15s. per lb., or about 11¼d. per oz. Since the commencement of the operations of the Madras Cinchona Department the charges have amounted to R33,19,101, and the receipts to R40,94,278, so that there has been an excess of revenue over expenditure of R7,75,177; while, after allowing for interest on receipts and charges, the net surplus to the end of last year was nearly 14 lakhs of rupees.—*Chemist and Druggist*, Sept. 22.

PLANTING NOTES.

Java Quinine.—The shipments from Java for June were five cases only. From July 1st to June 30th (twelve months) the shipment have been :—

	1899-1900	1898-99	1897-96
Cases ...	1,352	1,619	458

The following are the dates fixed for the remainder of the quinine-auctions to be held in Batavia this year.—Oct. 31 (4,000 kilos.), Nov. 28 (4,000 kilos.), and December 19th (3,200 kilos.).—*Planting Opinion*, Oct. 6.

The Cauvery Scheme: American Tender Accepted.—The Mysore Government have at length finally settled all the points that were at issue between themselves and the Government of Madras relative to the water of the Cauvery Falls, and they have accepted the tender (£140,941) of the General Electric Company of the United States, who have undertaken to complete within twenty months the installation of the plant required at Sivasamudram to generate 5,000 horse-power and to transmit it a distance of ninety miles to a central station on the Kolar Gold Fields. Arrangements are being made with the various gold-mining companies now at work on the Fields for the distribution of the electricity from the central station, and for the installation of motors to work the machines now driven by steam.—*Pioneer*, Oct. 1.

Vanilla in the Society Islands.—The quantity of vanilla exported from the Society Islands during the past year has been greater than at any previous period in the history of this Island, the figures being 130,113 lb. in 1899, as against 75,740 lb. in 1897, and 92,137 lb. in 1898. Its price, however, has sensibly decreased since 1897, for, whilst in that year, it realised on the local market as much as an average of 9s. 4d. per lb., it fetched only part, to foreign markets being overstocked, but principally, to the indifferent manner in which a great portion of the Tahiti vanilla is prepared for shipment by the Chinese merchants who, in order to remit to San Francisco and other places against goods received or ordered, buy up the green beans (often immature) which they casually and imperfectly dry, cure, and pack, whereby much of the aroma is lost. It may be said, however, that Tahiti vanilla properly treated before shipment, generally finds a fair market, although it cannot compete in quality with that from Bourbon, Seychelles, Fiji, and the West Indies.—*Planting Opinion.*

Rubber on the Burmo-Chinese Frontier.—The enormous rise which has taken place in the price of Indian-rubber is stimulating the trade in this article on the North-East frontier of Burma. The Kachins, however, have to go even further afield to get it. The township officer at Kaming reports that they continue to cut the roots of the trees, but that the competition among the Chinese rubber merchants is so keen that none of them will risk their status among the Kachin sellers by reporting specific cases. The practice accounts, no doubt, for the fact that the output from the forests within British jurisdiction in this area has fallen off to some extent of late.—*Indian Witness.*

The Date Palm in North-West Australia.—The Woods and Forests Department has sent to the resident magistrates along the North-West coast, and the wardens of the goldfields north of the Murchison, parcels of seeds of the date palm, for experimental sowing. Many of these officials are taking great interest in this effort to introduce the date palm, and have caused the seed supplied to be sown in various suitable spots throughout their districts. The warden of the Pilbarra goldfield, in particular, has paid close attention to this matter, and has promised to distribute a further supply of seed to travellers and others for sowing at pools, soaks, etc., all over his goldfield. The date palm commences to bear fruit in tropical and sub tropical Eastern Australia at the age of eight years, and survives through years of drought. It would, in time, prove a great boon to prospectors and others in the interior of the continent, and every effort should made not only to establish it in this colony, but to protect the plants as soon as they appear.—*Perth Morning Herald*, Sepe. 27.

Indian and Ceylon Tea Companies.—Says the latest *H. and C. Mail* :—

Mr. Seton's table, showing the results of the working of forty-five Indian tea companies during the season 1899 has been favourably commented upon by nearly all the financial papers. The average profit per pound was 1.74d, as compared with 1.43d in 1898; the average ratio of expenses to receipts, which have improved to 79 from 84 per cent, and the average profit on capital, viz., 6.59 against 5.56 per cent, are considered good evidence that the industry is now on a more steady financial basis, and not so liable as formerly to suffer from severe fluctuations.

This shows that 1899 was, on the whole, a better year than 1898 for Indian Tea Companies. From the tables given by our London contemporary we quote total results as follows :—

24 Ceylon Tea Companies.

Capital Total.	Acres Total.	Crop 1898 Total lb.	Crop 1899 Total lb.	Reserve Total £.
2,739,574	83,741	26,464,471	27,595,111	224,113

Working capital Total £.	Balance forward Total £.	Debns. amount Total £.
237.202	49,894	559,295

And again :—

45 INDIAN TEA COMPANIES.

Total Lands. Acres.	Total mature. Acres.	Total young Plants. Acres.
451,465	121,226	22,183

Average cost per acre R43; per lb. 6·60 pence; profit per lb. 1·74d. receipts per lb. 8·34 pence; ratio of expenses to receipts 79 per cent., profit on capital 6·59 per cent.; average dividend 5·64 p.c.; Total Reserve £569,153 or 7·14 p.c. on capital.

Fruit Culture for the Northi.—A useful article on this subject, which will grow more pressing as the Northern Line advances, will be found quoted on another page. We are glad to see the emphatic advocacy given to the practice of grafting, and prominence afforded to the orange and mango as two of the most suitable fruits for cultivation in the Northern Province.

Nuwara Eliya Tea Estates Company.—As will be seen from the letter with which the local agents, Messrs. Leechman & Co., have courteously favoured us an interim dividend has been declared of three per cent for the past half-year, being the same as on the previous occasion although the full dividend for 1899 was seven per cent—a rate which we trust will be realised if not exceeded this year.

Sugar Industry Commission in Behar.—Calcutta, Oct. 10.—The Government of Bengal has appointed a Commission consisting of Mr. J E O'Conor, Director of General Statistics, Mr. D M Hamilton, of Messrs. Mackinnon, Mackenzie and Co., and Mr. E A Hancock, Agricultural Chemist, to enquire into the prospects of a profitable revival of the sugar industry in Bihar, including the question of erecting central factories.—*Times of India.*

"Days of Old in Ceylon."—It is seldom now-a-days we hear from an ex-planter like "R." (writing from Dublin) on another page, who carries us back to the "forties," almost to the very beginning of coffee; and who passed through a time when £35,000 was offered for a Kadugannawa estate to another season when a bushel of rice cost a bushel of plantation coffee—the one being so high and the other so low in price!

Minor Products.—The following from the *Friend of India* is of local interest; and perhaps some of our readers who have seen Mr. Mollison's paper will favour us with particulars:—An interesting description of the methods of cultivation of the betel palm, of cardamoms, and of pepper, in vogue in the Kanara district of the Bombay Presidency, written by Mr. J W Mollison, M.R.A.C., has been issued by the Government Central Press, Bombay. It is pointed out that the system of manuring with leaf-mould causes immense destruction to the forest growth, and Mr. Mollison recommends an enquiry into the efficacy of castor-cake or safflower cake as a substitute.

The Camphor Corner.—That the cornering of camphor for its own purposes by the Japan Government is now ancient history is proved by the fact that it is fully reported on in two consular reports which we deal with this week. Such reports are not regarded as the source of prompt information but sometimes they are useful in bringing together details of a course of events which reach trade journals in instalments, and in throwing a little official light on these particulars. It is in this way that what the British and American Consuls say on the camphor monopoly is useful. Our consular representative in Formosa has been furnished with a report from the government of the island, and extracts from this appear on a later page.

Peermaad, September.—Tea prospects here point to a shortness of crop, as we have had very abnormal rain in June, July and August. At the west end of the district we measured, in June, 58·50 inches, in July 86·30 inches in August 86·10 inches, against 60,39·50 and 18 inches, in the same months last year. The wind has been worse than I have ever known it.—*Indian Gardening and Planting.*

The Pistachio Tree, *Pistaciho vera*, the species which yields the eatable pistachio nuts of commerce is deciduous, growing about 20ft. high, and a native of Western Asia. It is largely cultivated throughout Southern Europe. Its fruits are oval-shaped, nearly an inch long, and contain a seed with bright green cotyledons. The nuts are largely eaten by the Turks and Greeks, and also by the people of southern Europe, either simply dried like almonds, or made into articles of confectionery. Baron Von Mueller, in his list of plants for industrial culture, refers to an ingenious method of inserting the pistachio seeds into dry figs, to secure their power of germination during transmission to remote places. Some of our horticulturists should try and grow the pistachio.—*The Planter*, Sept. 22.

Peaches in Georgia.—In many sections of the State the Peaches decayed badly, owing to the excessive amount of rain during the latter part of May and almost the entire month of June. Many of the early shipments were rushed into market in bad condition, consequently brought no returns to the growers others whose fruits was in good condition received remunerative prices. Some late consignments fetched handsome returns. The fruit industry in Georgia is rapidly growing. Heretofore, when we have had a large fruit crop, the market being glutted, enormous quantities of Peaches have been allowed to rot in the orchards. This in a measure is now obviated, as a number of firms are running canneries, evaporators and distilleries. One cannery in this State has a capcity of ten thousand quart cans per day. Growers are also exercising better judgment in placing their consignments, thus avoiding glutting the markets.—*Journal of Horticulture and Cottage Gardener*, Sept. 6.

The Decadence of Coffee.—No one can accuse us of disloyalty to the old king. We stood by coffee in prosperity and adversity; but we must say we are compelled, albeit reluctantly, to abandon hope of its revival here. In India, too, its days would appear to be numbered, though it may hold on yet a while. An Indian contemporary thus summarises the situation:—The Halcyon days of the coffee-planter in India have apparently gone, not to return. At the end of 1899 there were 274,298 acres under coffee, all of it, with the exception of 450 acres, in Southern India. About 47 per cent of this area is in Mysore, where there were 128,010 acres under coffee last year, while 118,514 acres are devoted to the plant in the British districts of Coorg, the Nilgiris, and Malabar. The yield has been very poor since 1896, that of last year being the worst of the series and representing only about 17⅔ million pounds—or about half the production of fifteen years ago. The poverty of the crop is due to adverse seasons, the fall in prices, and leaf-disease. The production during the past ten years, on an average, has been 30,092,413 lb. almost the whole of which was exported. The foreign coffee imported during the last ten years has averaged 1,581,171 lb. of which 735,862 lb. were re-exported, so that 845,309 lb. of foreigh coffee were left every year for consumption in India, as against only 74,733 pounds of Indian coffee

LIME AND MALARIA.

EVERYTHING that tends to add to our knowledge of malaria—whether as regards the conditions which increase its spread or virulence, or the agencies which help to reduce its evil influence—is of interest to us as inhabitants of an Island which, despite its general healthiness, yields more victims to malarial fever than to any other ailment or epidemic. Indeed, fevers account for more deaths, probably, than all other diseases combined; and malarial fever is more widely prevalent among us than any other; and if it is not directly fatal to the same extent as other fevers, it enfeebles and ultimately conquers in most cases in which prompt treatment is not followed by adequate nourishment and care. It is, therefore, encouraging after all the literature that has confronted us on the mosquito,—which is a troublesome enough customer without being reckoned as an active agent in inoculating one with malarial poison—to find that there is something to set against the mischievous mosquito. Though one may not be able to overpower the diminutive enemy directly with a coat of lime, lime has been found indirectly to be a potent agent against malaria. In France, Dr. Roche has discovered that the presence of lime in the soil or in the water, helps to exterminate malaria; and it is a curious illustration of the inter-dependence of widely different industries that this medico-scientific discovery was first made in connection with experiments in Manuring! This fact is particularly interesting to us as advocates, in season and out of season, of adding to the fertility of the soil by the judicious use of manures. The disappearance of marsh malaria from Puisaye, after lime had been used in the district as a fertiliser, led to investigations which are still being carried on, and which reasonably point to the probability that in lime a very effective agent has been found to neutralise the spread of malaria. Another medical man, Dr. Grellet, has taken up the suggestion, the credit of which is primarily due to Dr. Roche; and he has written to the *Revue D' Hygiene*, that the liming of the soil for agricultural purposes, in various provinces in France which were more or less affected by malaria, has resulted in the reduction of malarial cases, almost in proportion to the quantity of lime used. It is for experts to say whether his statement that, in many countries whose conditions favour the existence of malaria, the freedom or prevalence of malaria is the accompaniment of a calcareous soil is true. Lower Egypt is cited as an instance; while, in France, the district of Beaune on one side of the Loire is free from malaria, whereas the district on the opposite bank, with its sandy and clayey soils, is subject to it. So also the Channel coast of France is free; while at the mouth of the Loire, malarial fevers are prevalent; if the same observation applies to Algiers. Now this is a point which deserves special investigation in Ceylon, and we may add that there are peculiar facilities for observation in the compactness of our Island and in the free distribution of medical men throughout all the provinces.

PLANTING IN DOMINICA.

TO THE EDITOR OF *THE TIMES*.

Sir.—I venture to beg you to give publication to a few lines dealing with one of our West Indian Islands and claiming for it the attention of those who are interested in colonial enterprise. I refer to Dominica, one of the Leeward Islands, and of which I am administering the Government.

Those beautiful isles, that are strung like a necklace across the throat of the Caribbean Sea, have never been "hoomed" by advertisements nor exploited by chartered Companies, and it is to be feared that in the case of Dominica, in particular, there are few of my readers who know much more about the island than that it is "somewhere in the West Indies," and consequently only vaguely connected in their minds with buccaneers, rum, and yellow fever. I am, therefore, addressing you in the hope that this may meet the eyes of young men possessed of energy and a moderate capital, who are inclined to become planters in a tropical island, and who may be induced to associate themselves with the progressive fortunes of one of our most beautiful and valuable colonies.

Dominica lies midway between the French islands of Martinique and Guadelope and, for administrative purposes, has been placed under the control of the Governor-in-Chief at Antigua. It is one of the most picturesque spots in the world, and its marvellous mountain scenery and tropical luxuriance evoked from Froude some of his finest pieces of word painting. Comprising nearly 300 square miles Dominica is one of the largest of our West Indian islands, and offers a great field for agricultural enterprise. The cultivation of sugar has been practically abandoned, and, after a long period of difficulty and depression, the island appears, at last, to be entering on a phase of prosperity that bids fair to be permanent. Thanks to Mr. Chamberlain's lively interest in our great "undeveloped estates," the Imperial Parliament was, last year, induced to vote a grant-in-aid to Dominica and, by its means, the magnificent highlands and valleys of the interior are now being made accessible. Over 100,000 acres of virgin soil are thus being rendered available for cultivation and the natural conditions for successful enterprise are present everywhere.

Unfortunately, the actual inhabitants of Dominica are possessed of but little capital, and their scanty resources have been heavily strained in their efforts to replace the unprofitable cultivation of the sugar cane by their present industries. Unassisted by extraneous capital and energy, the salvation of the island will be worked out but slowly, while, on the other hand, its great natural advantages ought, if made known, to attract to it an abundance of uninvested money and enterprise. The men who are wanted in Dominica are those of

THE CLASS THAT HAVE MADE CEYLON AND BURMA

what they are. They should be young, healthy, and energetic; supplied with not less than £1,000, willing to work hard, and to wait three or four years for a good return. In the course of the last two decades hundreds of Englishmen, attracted by judicious advertisements and "puffs," have been induced to sink their energy and capital in Florida and California, while our own colonies, far nearer home and presenting latent possibilities of much greater advantages, have remained unvisited and undeveloped. If those men had been induced to try Dominica, Grenada, Trinidad, or any of the other West Indian islands, where sugar is not the supreme fetish, they would probably have been rich today instead of bemoaning the struggles and losses caused by frosts, droughts, blights, and dear labour.

The climate of Dominica is excellent and particularly suited to those who are inclined to pulmonary complaints. Yellow fever has been unknown for 50 years, and there is very little malaria. White children thrive remarkably, and those who live in the hills are as rosy and fresh as any in England. The temperature

is never excessive. It varies from 53deg. to 90deg., according to altitude and season. The rainfall is abundant while a vast number of streams afford water power. There are no venomous serpents, and mosquitoes are not unduly obtrnsive. The soil is remarkably fertile, and is admirably suited to the cultivation of all tropical products notably that of fruit. There is a fair supply of labour, and wages vary from 8d to 1s 3d a day. Taxation is light, and the cost of living moderate.

The sugar industry, upon which the island once largely depended, has now become a minor industry, and its place has been taken by the cultivation of oocoa, limes, coffee, spices, oranges, and other fruits. All these products yield very handsome returns, and large areas have of late years been planted with them. The value of cultivated land in Dominica has increased very largely during the last two or three years, and it is a significant fact that very few owners of estates that have come into bearing are willing to sell their properties.

The exports of the island during last year were worth nearly donble those of five years ago. Very good incomes are being yielded by comparatively small estates, and the output of the island will, in a few years, attain a large volume. Over 1,500,000 lb. of cocoa are already exported annually, while Dominica has always been the chief producer of the lime jnice which is nowadays so extensively advertised. The soil and climatic conditions of the island are specially adapted to tho production of oranges, bananas, and pineapples, and a small experimental shipment of the last-named fruit proved recently to be the finest ever received from the West Indies.

A CEYLON PLANTER, OF GREAT EXPERIENCE, has lately embarked in the cnltivation of coffee in the higher altitudes, and the finest grades of the famous Jamaica "Blue Mountain" bean are found to thrive remarkably in lands over 2,000 feet above the sea. This industry is about to be very extensively developed. Vanilla of very high quality is also being produced and will soon become an important article of export. There is no reason why tobacco of the best grades should not be raised, and there are vast areas suitable for rubber.

The island possesses a valuable botanic station under the direction of Dr. Morris, C.M.G., Commissioner of Agriculture for the West Indies. Vast numbers of seedling plants of all the best varieties of economic products are kept on hand and may be purchased at much under cost price. An intending planter can thus save a considerable space of time in the cultivation of his product, and the returns are proportionately earlier. The officers of the Agricultural Department are ready to give valuable assistance and instruction to inexperienced planters, and many costly mistakes may thus be avoided.

CROWN LANDS MAY BE PURCHASED FOR 10s per acre, at present and facilities aregiven for payment. A planter who proposes to cultivate virgin lands should be able todispose of a capital of not less than £1,000. n Given this sum there is every reason to believe that a energeti oman would ina few years realise a handsome income from his plantation. Pineaples and bananas yield a orop in less than two years, coffee in less than three years, oranges and limes in four years. Cocoa requires five to six years to give large crops, and nutmegs give a valuable retnrn in eight years. The clearing and cultivation of virgin lands are very interesting operations, and, owing to the cool and clear atmosphere of the mountan lands, a white man can work as well there as if he were a couple of thousand miles further north of the equator. The forests abound in valuable woods, and a bachelor planter could build a comfortable cottage out of native materials for less than a hundred ponnds. The rivers are teeming with fish, and some shooting can be had.

Social life is very pleasant, and cricket, tennis and golf are played. There are good schools, an hotel, and several boarding houses. Dominica can be reached in 13 days from Southampton by Royal Mail steamers single fare, first class, £25. Numerous lines of steamships call at the island giving ample facilities for shipment of produce to the United Kingdom and to the States.

If the foregoing induce any of your readers to consider seriously the prospect of becoming planters in Dominica I would be very happy to afford any further particulars that may be desired. I shall be returning to Dominica on October 16 next; but in the meantime any communications addressed to me, care of Messrs. Grindlay and Co., Parliament-street, will receive my best attention.

With many thanks for the space you have been good enough to accord me,—I am, Sir, yonrs faithfully,

H. HESKETH BELL
(Administrator of Dominica).

GRAPHITE OR PLUMBAGO.

The least erudite laymen are aware at the present time that charcoal, graphite, and the diamond are primarily nothing else but carbon, and that each of the three bodies named represents an allotrophic modification of that element. Not long ago these substances were not properly distinguished from one another, and it was the common belief that graphite, lead sulphite, molybdenite, stibnite, and pyrolusite, on account of their similarity in appearance were identical, or at least belonged to the same family. To have cleared np this misunderstanding is the merit of Scheele, a Swedish chemist, originally an apothecary, who, imbned from youth with a spirit of investigation, developed into one of the most sucoessful chemists of his time. To his exertions chemistry owes the discovery of some of the elementary gases then absolntely unknown, and the first distinctive features relating to the class of bodies enumerated above. Towards the year 1779 he found that graphite when warmed with nitric acid generated carbon dioxide; while molybdenite which was regarded as a kind of graphite owing to the fact that it produced a black streak on paper, changed under these conditions to a white oxide or earth, as these bodies were called at that time. From these observations he drew the conclusion that graphite must be a body related to carbon, a result which has since found ample confirmation.

The mineral graphite is of special interest to the mining fraterinity, for the reason that deposits of this mineral are found in various parts of the world. A short description of its occurrence and properties seems, therefore, to be in place, the more so as the mineral is not always fonnd in such a state of purity as to warrant its immediate application, and foreign admixtures or gangue must be eliminated in certain cases.

Graphite received its name from the Greek term meaning "to write, an appellation which is quite appropriate and characteristic, so that other designations, like plumbago, blacklead, and even "carburet of iron," which have passed over into the present nomenclature from less enlightened times, must necessarily appear as qnite superfluous and improper.

Almost every part of the civilised world having contributed its quota to the production of graphite to some extent, the enumeration of the most prominent mines of this kind only seems of importance. Thus the Borrowdale Mine, in Cumberland, which yielded during the sixteenth and seventeenth centuries an annual revenue of £40,000, and remained during that period the only producer, placed only 45 tons on the market in a recent year. The product from this mine was formerly considered as the best material for manufacturing pencils, and it was worked only for a few weeks in the year, for fear of exhausting the deposit. This diffidence in the capacity of the mine was only too well justified, for the Borrowdale Mine does not connt any more with the producer of graphite at the present time.

The next graphite deposit of extraordinary size—having since its discovery become famous owing to the great quantity of material stored up in it—is the Ceylon mine, which, counting all the hands at work in mining and the manufacture of articles prepared from graphite, employs 24,000 men, women and children. A great deal of the Ceylon graphite finds, however, its way to Nuremberg, Germany, where the well-known Faber pencils are prepared, and 5,500 people find employment in their manufacture. Formerly the granular variety of graphite found at Borrowdale was thought to be exclusively applicable to the manufacture of good pencils, but recently it has been found that pure material, when ground finely, then mixed with a cement, and the mass thus resulting subjected to heavy pressure, produces a good grade of merchandise. By the addition of fine clay to the ground material, any degree of hardness can be imparted to the graphite stem enclosed in the wooden part of the pencil. The recently-opened graphite deposits of Southern India are becoming of increasing importance as producers, although not, as yet, threatening the premier position of their more southern neighbour, Ceylon.

Artificial graphite having been obtained in the laboratories of chemists as a casual by-product, it was expected that a closer study of the reactions involved might lead eventually to its manufacture. This expectation, however, has not been realised until lately, for the reasons that the methods known till 1894 were almost exclusively of an expensive and impracticable nature. Of these the method of heating charcoal with molten iron, and dissolving the latter by means of acids from the mass resulting, deserves mention, for the reason that it was followed persistently with the intention of producing an artificial graphite, and that it received an unusual impetus by the introduction of the electric furnace. Henri Moissan, a French chemist, has become prominent in this regard by his experiments performed in a reverberatory electric furnace of his own invention, the apparatus having movable electrodes and allowing of continuous operation. Moissan, having investigated the graphite formed in cast iron under various conditions of temperature and pressure, found that soft iron, when mixed with an excess of carbon from sugar, and heated in a carbon crucible in the electric furnace with a current of 2,000 amperes and 60 volts for ten minutes, dissolves large quantities of carbon, and becomes so pasty that the crucible can be inverted without the contents running out. The graphite obtained from this iron ignites in oxygen at about 650°; it contains only 0·28 per cent of hydrogen, and is, therefore, much purer than graphite from ordinary cast iron. Large works are now established at Niagara Falls for the manufacture of artificial graphite by the Acheson process, the author of which is also the inventor of the artificial abrasive carborundum.—*Mechanical World.*

BRITISH FORESTRY.

Upon the Chiltern Hills, where beech is extensively grown for the furniture-makers of Wycombe, well-managed beech woods are returning five times, and in many cases six times, the annual income that the adjoining agricultural land is yielding, Mr. John Nisbet tells us in a new book. In the case of the West Wycombe estate the account books show that for over a hundred years, the annual income from the woods has been thirty shillings an acre. These are, perhaps the best results that are now obtained in any part of England. In most cases the results are very different, partly owing to want of care, but more oftener to want of knowledge. Forestry is a science that must be studied, and an art that must be practised as much as medicine or surgery. Dr. Nisbet mentions a case of a landowner who, even under his present system of management, is getting more than £1,000 a year out of his woods and who pays his forester fifteen shillings a week. This means that a capital of over thirty thousand pounds in timber is being administered by a man of no education at a wage of £39 7s 6d a year; yet the scope for increasing the capital value and the annual yield must be enormous:—

"It can hardly be denied that British landowners as a class, are decidedly apathetic with regard to forestry. So far as game preservation is antagonistic to good management of the woodlands, that matter has been fully dealt with in the last chapter. Other three causes, perhaps in some cases equally powerful in this direction, are want of funds, want of encouragement offered by the State to induce landowners to plant waste land, and danger of fires along railway lines..... As most landowners have merely a life interest in their estates, and as the calls on their purse are many (beginning with the heavy demand on succession), they have not, as a rule, much money to spare for forming plantations which are only likely to yield substantial returns after their individual tenure of the estate is at an end."

"As matters are, our woods and forests now only aggregate about three million acres, and are so inadequate for the supply of existing requirements in timber and other woodland produce, that our imports under these heads amounted to the enormous sum of over twenty-five and a third million pounds sterling during 1899. Of this, over five million pounds were for rough-hewn and over sixteen million pounds for sawn or dressed timber, practically all of it coniferous timber from the Baltic, Scandinavia, and Canada, which might quite well be grown in the British Isles. Making a liberal deduction for the value of labour included in these coniferous imports aggregating over twenty-one million pounds, the undeniable fact is laid bare that Britain annually pays, and principally to foreign countries, no less than between eighteen and nineteen million pound sterling for pines and fir timber which could quite well be grown in Great Britain and Ireland. There are some sixteen million acres, now practically unproductive, available for this purpose; and if our existing woods and forests were managed on business principles, and State encouragement were given for making large plantations under economical management, Britain might in the future be self-supporting as to all the coniferous wood required for building purposes..... If our present three million acres of woodlands were trebled in extent, and were well managed on business principles, in place of being under uneconomic management as game coverts and pleasure grounds as is now mostly the case with British forests, this would merely be able to supply existing requirements, and no more. Nay, even if we had twelve million acres under forest, and all under the best of management, they would probably be just about able to supply the demand for timber likely to exist at the time plantations now formed may become mature. Past experience has shown that the demands for timber are constantly increasing, despite the more extensive use of substitutes like iron and stone for constructive purposes."

CINCHONA.—The N. V. Vriesseveem cinchona-bark department at Amsterdam report the shipments from Java from August 21 to September 24, 1900, at 1,249,000, Amst. lb., and the total from January 1 to September 24 at 6,450,408 Amsterdam lb. The exports from Ceylon for the week ending September 3 were 270 lb. only.—*Chemist and Druggist*, Sept. 29.

OUR PEARL FISHERIES.

We are specially gratified to find that His Excellency the Governor and Mr. Chamberlain have dealt so promptly with Sir Wm. Twynam's special Report on the Pearl Fisheries, and that the result is to secure so long and useful a Report from the Director of the Natural History Department of the British Museum. The whole Correspondence will be found elsewhere. Professor Ray Lankester, as is natural, rather magnifies the "mission" which he recommends should be taken up; and while we concede its importance, we cannot see why a Scientist who would be allowed to continue his four months' professorial work in England, each year, should, besides all expenses, have so handsome an allowance as £1,000 a year, considering the local staff that would inevitably be necessary. Still, if the desired work could be accomplished within three years, this amount should not be grudged to a first-class man, and we should suppose that Professor Herdman of Liverpool (whom we met in the Isle of Man four years ago when he was leading a section of the British Association) stands in the very first rank, having given special attention to oysters and oyster fisheries. We are a little disappointed that no reference is made to Professor Saville Kent, who has done so much valuable work around the Australian coasts on the fisheries, including those of oysters for pearl shells and pearls, and also has published (at three guineas a copy) a very elaborate, illustrated volume with the results of his labours. But, of course, Professor Herdman must be acquainted with all that has been attained in that direction. It is especially encouraging to learn from Professor Lankester that Mr. Holdsworth who came out for five years during the administration of Sir Hercules Robinson was *not* the right man in the right place, since he was not a trained Scientist, but only acquainted with sea-fishing as a sportsman! (Those were assuredly the days when "jobs" were freely perpetrated by the Colonial Office and Sir Hercules Robinson had his full share of them, e.g. when he wanted a trained expert to reform and supervise the Prisons of the Colony, a retired R. N. Captain, son of a peer, was sent out to him!) Dr. Lankester would have emphasised his opinion as to the utter failure of the "Holdsworth" Mission, had he recalled the fact that that gentleman never had the good fortune to witness a Pearl Fishery while in Ceylon! We therefore sincerely hope that the Council of the Royal Society may recommend, and the Government appoint, Professor Herdman, F.R.S., (or Professor Saville Kent) to come to Ceylon on a Three Years' Mission, and we only trust that the four months' Professorial duty at Liverpool may not clash with the best period of the year—February to May—for inspecting and working on our Pearl Oyster Banks. It is of special importance that the Scientist, whoever he may be, should have the practical help, and the benefit of all the vast experience, of Capt. Donnan, while Sir Wm. Twynman can also be referred to on moot points. Under these auspices we should certainly anticipate valuable practical results from such a Mission as Professor Ray Lankester recommends and we hope it may be arranged for in time for the approaching working season at the Pearl Banks:—February-May, 1901.

MALIGNED MOSQUITOS.

THEY WERE NOT MADE TO PREY ON HUMAN BEINGS.

Some interesting information about mosquitos has been recently issued by the United States Department of Agriculture. It is not much consolation to those who are subject to the irritating attacks of these insects to know that in the opinion of Dr. Howard, the entomologist, the mosquito was not made to prey on human beings or any other warm-blooded animal. The fact remains that he does it. Besides being a nuisance the mosquito delights in intoxicating beverages. A male mosquito has been observed sipping beer, and a number of them—again males, be it noted—placed under a bell jar with a single drop of port wine became hopelessly intoxicated staggering about in a ridiculous manner.

It is only fair to the mosquito to say that the latter was an experiment by Prof. A E Schwartz. There are bad mosquitos and those that are worse. But the worst of all seem to belong to a part of America (nnnamed) where some soldiers were forced to sleep with their heads thrnst into holes in the earth and their necks wrapped round with their hammocks. It is comforting to know that mosquitos cannot fly long distances though they may be carried 15 miles by a strong wind. This at least keeps them to circumscribed areas.

Numerous methods of combating and destroying these pests are mentioned such as pouring kerosene over marshy districts where they breed, the placing of carp in these marshes to destroy their eggs. In New Jersey a primitive but effective system is in vogue. A baking-powder box is nailed on the top of a long stick and some kerosene poured in. The merry householder then scans the ceiling and pushes the cup under the resting mosquito into which it soon falls—a victim of the Standard Oil Trust.—*Morning Leader*, Sept. 21.

ELEPHANTS IN MADRAS.

Twenty-five elephants were captured in the Madras Presidency during the year ending the 30th June last, which is the largest catch on record. Of these, six died, and of the 25 captures, 18 were in North Malabar. All the five elephants captured in South Coimbatore died, owing, it is said, to the extreme heat and want of suitable fodder consequent on the prolonged drought on the Anamalais. Besides elephants, 23 bison, 1 pig, 1 bear, 19 sambhur, 1 tiger and 1 wild sheep also fell into the pits. Of these, 8 died or were shot, while the rest either escaped or were released. One of the men engaged in shooting the bear accidentally fell into the pit, and was so badly mauled that he died soon afterwards.—*Madras Mail*, Oct. 12.

PRODUCE AND PLANTING.

Regulating Supplies.—We regret to learn that owing to a want of unanimity the committee of the Indian Tea Association has resolved that it is not practicable this season to continue the arrangements for regulating the quantity of tea to be brought forward weekly, and therefore the responsibility will rest upon the brokers to advise their respective merchants as to selling or holding back supplies.

THE RUSSIAN TEA MARKET.—According to the Customs returns, the remarkable features in the import trade of Odessa in 1899 are the increased demand for Ceylon and China teas, which attained the high figure of 7,500,000 lb.—a substantial advance of about 1,000,000 lb. over 1898—and for coal, of which the importation has been nearly quintupled; that is, from 32,480 tons in 1898 to 160,200 tons in 1899. Ceylon tea is consumed in increasing quantities, and is competing favourably with China teas. Japanese tea has been introduced, but does not suit Russian tastes, and cannot compete with Ceylon teas, either in quality or in price. The bulk of the tea imported into Odessa passes in transit to Moscow and other towns. The trouble in China will, it is feared, affect this trade, as the vessels of the Volunteer Fleet, which carry tea at preferential rates of freight, are at present engaged as Government transports, and in many instances have already declined cargo from merchants.

INDIAN TEA ASSOCIATION, (LONDON).

A meeting of the Committee was held on the 25th instant, when the following members were present:—Messrs. D Cruickshank (in the chair), G W Christison, J S Hulbert, F A Roberts, J N Stuart, and A G Stanton.

WORK IN AMERICA.—A proposal to divert a portion of the funds towards advertising green tea in Canada was not agreed to, no green tea being yet available.

WORK ON THE CONTINENT.—A letter from Mr. J M Harrington, dated 22nd instant, with reference to certain tea rooms in Rome, was read, and the Committee resolved, before granting a subsidy, to await further particulars regarding the same.

ERNEST TYE, Secretary.

—*Home and Colonial Mail*, Sept. 28.

COCONUT MILK.

The Colonial Museum at Haarlem, in its annual report recently published, has raised, at the request of an old planter, the question whether a market could be created for preserved coconut milk. As thousands of tons of dried coconut (coprah) are annually shipped, the milk of which is thrown away when collecting the kernels, hundreds of gallons of coconut milk are wasted for want of a proper method of preserving this refreshing beverage. It has been suggested that by adding a slight quantity of silicic acid the fresh milk in air-tight bottles would prove to retain its qualities, so much appreciated in Southern countries.—*Sells' Commercial Intelligence.*

THE WINTER RICE CROP IN BENGAL.

From the preliminary forecast of the winter rice crop of Bengal for the year 1900 which has been issued we extract as follows:—

The Provincial total of the normal area under winter rice now stands at 31,023,000 acres against 31,076,400 acres shown in the final forecast of the preceding year. The area sown with winter rice this year is estimated at 28,883,300 acres against 31,344,700 acres in 1899. On the whole, the season has not been altogether favourable for the winter rice crop.

According to the estimates made by the District Officers, the outturn of the winter rice crop this year for the Province, as a whole will amount to 87 per cent of a normal crop, as compared with 90 per cent as finally estimated last year.—*Pioneer*, Oct. 11.

THE CONSOLIDATED ESTATES COMPANY, LTD.

Ninth Annual Report of the General Managers submitted to the Shareholders at the General Meeting held at 34, Great St. Helens, E.C., on Wednesday, the 3rd October 1900, at 11-30 a.m.

The General Managers have the pleasure to submit their ninth annual report and balance sheet, together with statement of accounts for the crop year ending 30th June, 1900.

The profit and loss account shows a balance (including £671 6s. 6d. brought forward from last year) of £7,101 18s. 7d. after paying interest on the debentures, and an interim dividend of 4 per cent on the preferred shares.

Out of this sum the General Managers propose—

To pay a balance dividend of 4 per cent on the preferred shares making 8 per cent for the whole year, which will absorb ..	£1,480	0	0
*To set aside for redemption of 5 per cent of the debentures at 103	2,575	0	0
To pay a dividend of 5 per cent on the ordinary shares, requiring ..	1,950	0	0
To place to Reserve Fund ..	500	0	0
Carrying forward the balance, viz.:	596	18	7
	£7,101	18	7

The following shows the result of the year's working, viz.:—

NET PROCEEDS OF CROP.

	£ s. d.	£ s. d.
1,651,410 lb. tea at an average net price of about 5 15-16d per lb. realised ..	40,742 11 1	
Cocoa, Cardamoms, Cinchona Bark, and Cinnamon	1,266 16 1	
Surplus on produce brought forward from 1898-9 ..	110 9 6	
Interest account ..	188 6 8	
		42,308 3 4

EXPENDITURE ON ESTATES.

Messrs. George Steuart & Co.'s drafts—R449,584 at an average of 1/4 31-64 per rupee .. £30,885 6 8			
Less—Balance of coast advances 423 16 4			
	30,461 10 4		
Bonus to Superintendents —R8,250 @ 1/4 1-32 ..	551 1 6		
		31,012 11 10	
		£11,295 11	

The past season in Ceylon has been very favourable for the flushing of tea, and this fact combined with the good effects of liberal manuring, and a system of somewhat coarser pulcking on some of the Company's Estates, has resulted in a large increase in the intake of Tea: the total crops amounting to 1,651,410 lb. against an Estimate of 1,326,000 lb. Unfortunately however this increase of the crops has been more than counteracted by a further fall in the price of tea and the rise in Exchange, but owing to some economies in the cost of production, the net result of the season's working is about the same as that of last year.

Exchange has again been rather more unfavourable to the Company, the average cost of the Rupee having been 1s 4 31-64 (for drafts at three months' sight) against 1s 4-11-32 for similar drafts last year. The rate now currrent is, however, only 1s 4 5-16d.

* By the Articles of Association it is provided that five per cent. of the Debentures must be redeemed before any Dividend can be paid on the Ordinary Shares.

No new properties have been acquired since the date of the last Annual Report, and the total acreage of the Company's Estates remains the same. The following statement shows how this acreage is distributed. A slight error in the acreage of the Sorana Estate in the last Annual Report is now corrected.

Name of Estate.	Ceylon District.	Tea Full Bear'g.	Tea partial bea'g.	Tea Recently Planted.	Reserve Suitable for Tea.	Other Products, Grass Waste, Water, &c.	Total Acreage.
Wattegodde	Dimbula	800	Nil	25	Nil	70	895
Hoonoocotua	Kotmale	560	25	15	45	117	762
Tallagalla	Kalutara	515	Nil	102	60	23	700
Ellagalla	Matale	223	8	9	38	167	445
Rutland	Hewaheta	443	6	70	85	59	663
Warriagalla	Nilambe	493	61	26	57	624	1,261
Sorana	Kalutara	263	158	125	81	131	758
		3,297	258	372	366*	1,191	5,484

The capital expenditure for the purposes indicated in the last annual report which was estimated at £3,000, actually amounted to £3,012 5s. 0d. thus bringing the total amount at debit of the Factory and extension account to £4,333 13s. 6d., while for next season the expenditure on this account is estimated at about £1,800 (chiefly for the extension of the factory at Warriagalla to provide for the increased intake of leaf on that estate) which would increase the debit balance to a little over £6,000. To provide for this, and further requirements of the same nature, it is proposed at the end of this year to make a small issue of shares and debentures, full particulars of which will be given in two or three months' time. The issue will in the first instance be offered on favourable terms to the shareholders then on the Register.

A tabulated statement accompanies this report showing the progress of the Company since its commencement, which it is hoped will be found interesting to the shareholders. They will see that notwithstanding the fall in the price of tea and the rise in exchange, the Company has been able to hold its own fairly well, chiefly owing to the gradual increase of crops arising from the extension of cultivation, and the General Managers recommend a continuation of the policy of such extension, provided the necessary additional capital is forthcoming.

The Estimates for the New Season have been carefully framed, and are as follows:—

	Expenditure. R.	Tea Crop. lb.
Wattegodde ..	107,916 ..	400,000
Hoonoocotua ..	73,044 ..	260,000
Ellagalla ..	32,723 ..	110,000
Tallagalla ..	59,599 ..	230,000
Warriagalla ..	63,653 ..	230,000
Rutland ..	63,502 ..	220,000
Sorana ..	57,486 ..	230,000
Totals R457,923 @ 1/4⅜=£31,243 14s 0d		1,680,000

Also about 25,000 lb. of Cinchona from Rutland, 7,500 lb. Cardamoms, and 1,680 lb. Cocoa from Warriagalla, and 15,000 lb. Cinnamon from Sorana; the value of the whole of such products being estimated at about £1,500.

The Ceylon Agents report that the Company's Estates are in good order and appearance and that the Tea seems remarkably free from pests and blight, though the latter has given some trouble on Tallagalla. Samples of the soil from this Estate have been sent home and subjected to a careful chemical analysis with a view to ascertain the most suitable manures to strengthen the soil and thus enable the bushes to throw off the blight. The recommendations of an eminent Agricultural Chemist are being carefully carried out and there seems to be every hope of their proving successful.

The General Manager have pleasure in informing the Shareholders that as the result of continued agitation on the part of Importers, the Wharfingers have consented to reduce their charges on tea by an additional 10 per cent. all round to take effect on all shipments that arrived after 1st July. This concession will result in a saving to the Company of about £200 per annum.

ARBUTHNOT, LATHAM & Co.,
25th Sept. 1900. General Managers.

* Of which 299 acres are planted with Cardamoms, Cocoa and Cinnamon.

RATWATTA COCOA COMPANY (CEYLON).

The following is the report of the Directors submitted at the annual meeting held in the Queen's Hotel, Kandy, last month:—

THE DIRECTOR'S REPORT.

The Directors beg to submit their report and statement of accounts for the season ended 30th June, 1900.

The Directors regret to have to report that the original estimate of 300 cwts. cocoa has not been secured; this is attributable to the drought during the early months of the year.

The total cocoa crop secured amounted to 208 cwts. 2 qrs. 1 lb. which sold at an average of a little over R43 per cwt.

The tea crop including 1,520 lb. made from bought leaf amounted to 53,510 lb., against an estimate of 50,000 lb., which sold for an average of 30·57 cents per lb. against an average of a little over 33½ cents the previous year.

On the year's working the crop bearing portion of the estate shows a profit of R5,320·65, which has been carried to credit of profit and loss account.

The present appearance of the cocoa is very satisfactory; no sign of disease and the trees looking healthy and vigorous.

The prospects for the coming season for cocoa seem to be favourable, fine blossoms have for the most part set well.

Now that the young tea clearings are coming into hearing, the returns of leaf should show a marked increase annually for some time to come.

The estimate of cocoa for the coming year is 400 cwts., and that of tea 75000 lb. together with 6,000 lb. made from bought leaf against an expenditure of R33,807·50.

The following is a definition of the Company's property as at 30th June:—

		A.	R.	P.			
Cocoa planted	1893 ...	72	1	2			
Do do	1894 ..	85	0	29			
Do do	1895 ...	65	2	07			
					223	0	19
Tea planted	1890 (and Cocoa)	118	3	27			
Do do	1896 do	4	0	00			
Do do	1897 do	99	3	27			
Do do	1898 do	75	0	00			
					317	3	14
Grass	... ..				3	0	00
	Total cultivated				543	3	33
Jungle	... ..				181	0	00
	Total acreage				724	3	33

During Mr. Gordon Pyper's temporary absence from the island Mr. T C Huxley is undertaking the duties of Managing Director.

Under the articles of association Messrs. T C Huxley and A Collingwood Smail retire from the Directorate by rotation, but are eligible for re-election.

An Auditor has to be appointed for the current year. The appointment rests with the meeting.

PLANTING NOTES.

"FIRE INSURANCE TARIFF ON TEA GARDENS BUILDINGS."—It will be observed from extracts in our daily that the Committee of the Indian Tea Association in Calcutta have been considering "excessive rates" fixed for various buildings; and a Sub-Committee is appointed to report. Should not the Ceylon Planters' Association co-operate and work in unison with the Calcutta body in this matter?

"INDIAN AND CEYLON TEA"—is the heading of an article in the *Investors' Review*, which we take over in our daily and *T.A.* It contains some interesting facts and figures and offers encouragement to persevere with the American and Continental campaigns. We see the Indian planters look to Mr. Harrington to tour through Europe and report on the best steps for pushing their teas. Home consumption keeps up; but the war tax is strongly condemned.

THE BANANA A MORAL EVIL.—According to the report of Sir H. Johnston, we may congratulate ourselves upon the fact that the banana does not grow in England. The idleness and vacuity of the lives of the natives in Uganda are, according to him, entirely due to this plant. It practically grows itself, and once it is planted no trouble need be taken about it whatever. The tree grows up, bears a couple of bunches of fruit, and dies down again in rather less than a year. However, it throws up shoot after shoot from an underground rhizome, and these in their turn grow up into trees and bear fruit. A banana tree planted seems to go on for ever, and the only thing its grower has to do is to pick the fruit. —*Mail paper.*

"FLIMSY MICA."—This is the name that has fallen to the thin films into which refuse mica plates are split—says an Indian contemporary—and which find a market, even though classed as "waste." The thin films of mica are used in the preparation of micanite, an American new patent, which serves as a cheap substitute for mica slabs of large sizes and is used largely in connection with electrical machinery. The films are laid out by hand with a special gum cement between each layer and when sufficiently thickly built up they are subjected to enormous pressure under heat and when cold retain the cohesion of natural slabs of mica. Mica is a great resistant of heat, and it has also been suggested that mica "waste" might be used to advantage for overlaying the roofs of houses in hot countries. The trade in "flimsy" mica is in its infancy and the prices realised seem to vary considerably with reference to colour, size and thickness, so that it is by no means easy to fix an average value for the purpose of calculating the Government royalty, which is 5 per cent. *ad valorem*, and an inquiry on the subject has been dealt with by the Board of Revenue. As a tentative measure the Board resolves to fix the valuation of "flimsy" mica, at the rate of 6 annas per lb. for spotted, cloudy and lined mica; and of 10 annas per lb. for clear mica. The rates now prescribed will be subject to revision at the end of a year in the light of the experience which may be gained during the interval.

INDIAN COOLIES FOR FIJI.—The ship Rhine arrived, from Calcutta, on Thursday, with 492 coolie immigrants, after a prolonged voyage of ninety days. This is the fourth and last vessel due to arrive from India, this year. The number of passengers brought by the four vessels total some 2,000, while the departures amount to about 400—an addition to the coolie population of 1,600 people.—*Fiji Times*, Sept. 1.

CLOVES AND SLAVERY.—As all the world knows, it receives its supply of Cloves from the islands of Zanzibar and Pemba; the yield last year was 570,600 frasilas, or, at 35 pounds to the frasila, equal to 19,971,000 pounds! This is the largest crop over reported, and was 8,061,259 in excess of that of the preceding year. Notwithstanding this produce, however, the plantations are not being cultivated as they ought to be—a falling-off in this respect having become noted over since the edict abolishing slavery was promulgated in 1897. Nature has been very bountiful, but she must be assisted more by free labour than appears likely to be given by those "coloured persons" who find laziness more congenial to their feelings than moderately hard work. Attempts are made by means of fair wages to get work out of the emancipated slave; he is also templated by free grants of land in exchange for a certain supply of labour, but the bait does not appear to take freely. Some effort has been made to raise crops other than Cloves, but the results are unsatisfactory. Only time and every judicious management of the native workers rescued from salvery can be trusted to retain for the Sultanate that celebrity it so long enjoyed by the aid of slavery.—*Gardiners' Chronicle.*

RUBBER PLANTING IN TOBAGO.—We direct the notice of our planting readers to the letter of Mr. Short, a Tobago planter, on the growing of rubber in the West Indian island. The reports of Castilloa growth in Tobago are encouraging, and in reply to Mr. Short we may refer him—on the point of obtaining rubber from seedlings—to the process of a French rubber-planter in the Far East, which was recently recorded in our *Tropical Agriculturist.* In the case referred to the whole plant, bark and all, was taken and rubber extracted in paying bulk. We expect to hear more of the process, and how far it has been successful, before very long. The results will be duly published in our *Tropical Agriculturist.* If proved successful, we see no objection to the close planting, suggested by Mr. Short—except in so far as it is likely to hinder the rapid growth which would be the main object of such cultivation as our correspondent would then carryon.

SALE OF QUININE IN BURMA.—The Sanitary Commissioner of Burma says the scheme for the sale of quinine by post-offices in the interior of the province does not appear to have achieved much success. The Burman villager is said not to appreciate quinine, and though some are willing to use the drug if given to them, yet few wish to buy it and prefer their own remedies. In some instances deputy-commissioners report that the use of the drug is unpopular, and recommend that the scheme should be given up altogether. The sale of quinine-powders by post-office subordinates increased from 547 packets in 1896 to 1,527 issued in 1899, but the number issued to other offices decreased from 1,553 issued in 1897 to 998 issued in 1899. In Burma, where post-offices are so few, the dissemination of quinine among the outlying villages is dependent mainly on the district officers, who take little interest in the matter.—*Chemist and Druggist*

"HUNTING" AND PLANTING IN CEYLON BY THE LATE G. A. CRUWELL.

A LEAF FROM THE PAST.

Turning over old papers we have come across some manuscript in the handwriting of the late Mr. Cruwell, which is well worth giving to our readers even now. Mr. Cruwell was a great hunter in his day:—

Of course there are drawbacks to hunting as well as to billiards, card-playing, horse-racing, and other sports—and not only drawbacks, but dangers. Who does not recollect the fate of the unfortunate young German in Maskeliya, who was

KILLED BY A BUCK-ELK AT BAY

striking the hunter's knife into the heart of the inexperienced young hunter. Mr. F—— in Nuwara Eliya narrowly escaped a similar fate. Something of the same nature occurred in Haputale when a party of planters proceeded to Wellanwitte for a few days' hunting. They had to cross a swollen river over the log of a fallen tree. To enable their baggage coolies to do so, they had provided themselves with a rope to be stretched across for the coolies to hold on by. When clearing the brushwood on the opposite side one of the party fell into the river. The next moment the planter who was clearing the brushwood had him by the collar and tried to pull him out, but not being strong enough the poor fellow, who had fallen into the river, fell in a second time, and before any further assistance could be rendered he

FELL ON THE OTHER'S HUNTING KNIFE

which penetrated within a hundredth part of an inch of his liver. He had a very narrow squeak of it and a month's confinement to his couch. This happened not far from the K—— estate, and to show how fast news will travel in less than an hour, half the coolies of that estate came hurrying down to help their master, who was lying calmly under a huge tree, unable to move without experiencing agonies of pain. Dr. Moss was of the party and arrived on the scene just as W—— had sewn up the wound and successfully stanched the bleeding. He (the Doctor) took the more dead than alive hunter in hand. His coolies had in the meantime constructed a litter, covered with a mattress and pillow, and after being moved into this, he was carried back to his estate. In the night a fearful thunderstorm occurred, and the lightning shattered the big tree under which poor B—— had lain after the accident, all to atoms. The other members of the party wished to give up the hunt, but after consulting with the Doctor they continued their journey to Wellanwitte. The Doctor argued that the wounded man might be needlessly alarmed if the others did not proceed; and that he would be cheered to a certain extent if he saw his friends indifferent about him. The sequel proved the Doctor to have been right.

On a recent occasion another young fellow, also of the same estate, when out pig-hunting, had a finger of the left hand smashed and had to submit to an amputation. A few years ago there was

A YOUNG PLANTER KILLED BY HIS COMPANIO

who mistook him for a red-deer.

Hunting is especially an amusement to the man who cannot shoot and who cannot ride, and to whom his hunting-knife and spear are sufficient weapons. True there are some who combine all three accomplishments, but who that knew poor dear James MacDonald will not admit that he was about the *beau ideal* of a hunter and he never carried a gun? De Montenac was another hunter of this class.

This brings us to the "Circular" a great firm has issued to the Superintendents in its employ. Much, indeed, is to be said on both sides. The only individual planter who, rumour says, flung the "Circular" back at the sender's head, was an able, trusted Superintendent who, by his estate books and accounts, carried his employer's approval of his conduct, but who was given to a little *penchant* for hunting and could not resist the temptation, when

THE SNIPE WERE IN SEASON,

or when he heard a deer or an elk bark, to go hunting. No doubt he made up for it; but his conscience pricked him and he resigned at once. No one can blame him, nor can anybody blame the firm which, however, did not attach any particular weight to his

HUNTING AND SHOOTING PROCLIVITIES.

Submissiveness, humility, obedience are the attributes of slaves, and we all know that "Britons never never, will be slaves." And now since the *métier* of a coffee planter is to well understand and what coolies must and can do for a day's pay, when the cost of pruning, handling, and manuring is all laid down by estimates, and when the prices realised for the coffee are satisfactory, one cannot help thinking that the great and good firm issued the "Circular" more with the intention of putting their Superintendents generally on their guard, than for any other base or tyrannical motive. Certain it is the firm would never find fault with a Superintendent who would go at early dawn with his gun for a few dogs to hunt a hare or brace of hares or may-be a red-deer or go snipe-shooting after "muster" and running home to breakfast would require no leave-asking for that. If again the Superintendent were inclined to go for a week's hunting or shooting in the low-country, he ought to write to the firm that he intended doing so, and that the work in hand admitted of his doing so, and can it be doubted for a moment that the firm would grant him such a holiday? Quite another thing would be going to the Jymkhana in Nuwara Eliya, in crop time; or to the Races in Colombo, in September; or to the Badulla Sports in August. For such amusements leave should be asked, "circular" or no "circular."

In other respects, as has been previously stated, the nature of the country forbids travelling through the district as a source of pleasure, except on foot; and there are very few planters fond of climbing and descending. As a rule, therefore,

THE HAPUTALE PLANTER

may be regarded more in the light of a slow fellow than in that of a fast one, often victimised by loafers from other districts, but withal a kind-hearted and obliging creature. Almost the majority are married men and the minority would soon follow suit, if they had only the chance. Card-playing is, with the exception of a quiet whist party here and there, seldom indulged in. There is a billiard table at Haldummulla, which is chiefly monopolised by the few Europeans of that station and perhaps by a traveller passing through. There was often made an attempt at a Club; but it always sooner or later collapsed.

RICE-GROWING; A NEW COMPANY REGISTERED.

A new Company has been registered at the office of the Registar of Joint Stock Companies, under the name of the Walaway Estate Co., Ltd., for purchasing, leasing or acquiring Walaway Estate situated at Ambalantota, and for carrying on cultivation in paddy and tea, for manufacturing copra, coconut oil, &c., and to carry on business as bankers, storekeepers and shipping agents. The nominal capital of the Company

to be R125,000, consisting of 205 preference shares of R100 each carrying cumulative dividend of 8 per cent, 225 ordinary shares of R100 and 595 shares of R100 to be issued whenever found necessary. The profits, after paying cumulative dividend of 8 per cent for preferenee shares and 8 per cent dividend for ordinary shares, are to be divided as follows; two thirds to go to the shareholders, and one third to go to Mr. E Elliott, so long as he manages the business of the Company. The following have signed the articles of Association purchasing one share each :—Messrs. H Creasy, G H Alston, G W Carlyon, A Thomson, W H Figg, R E Shaw and Whittall and Co.

CHAULMOOGRA OIL AND ITS VIRTUES.

We have to acknowledge the receipt of an interesting and valuable monograph on Chaulmoogra Oil by Dr. G. Desprez of Paris.* The value of this oil, in the treatment of various skin diseases, but especially of Leprosy known to India and China for centuries, has been sufficiently recognised by its inclusion among the standard drugs of the Indian Pharmacopæia since 1868 and of the British Pharmacopæia since 1884. But what is not so well known is that the pure oil, from which alone the best therapeutic effects are obtainable, is hardly to be procured, unless it is specially extracted from the genuine seeds, which are themselves not easily distinguishable from allied species. It is in the original researches made in this direction, (for whlch he has been highly complimented by Dr. Prain, the Superintendent of Botanic Gardens, Calcutta) more perhaps even than in the valuable compilation of clinical cases from various sources illustrating the value of the oil in Leprosy, Syphilis, Tuberculosis, etc. that Dr. Desprez's pamphlet will be appreciated by medical men in the East. It is possible that a full translation of the monograph may be read before the local Medical Association shortly, and we may hope that some information will be given as to the cultivation of the plant yielding the genuine seeds.

RUBBER IN EQUATORIAL AMERICA.

M. Henri Jumelle, professor of the Faculty of Sciences at Marseilles, communicates to the *Rveue des Cultures Coloniales* a letter received from M. E. Ch. Van Issehot, an Engineer of Guyaquil, in which it is stated that the production of rubber in that country is diminishing daily. The forests situated near the coast do not contain any more rubber trees and it is found necessary to search up to the forests at the foot of the Cordilleras in order to find specimens of Castilloa, the destruction of which follows immediately on discovery. Rubber merchants have now commenced to search on the other side of the Cordilleras, but as it is necessary to descend again 1,000 metres (3,000 feet) into a country without roads or resources of any kind the exploitation is very different. All carriage is by porters.—*Indian Gardening and Planting*, October 11th.

* de Chaulmoogra—Etudes Botanique, Chimique, Pharmaceutique et Therapeutique par Georges Desprez, Docteur en-Pharmacie, Paris, J. B. Bailliere et Fils, 1900.

IMPROVEMENT OF COFFEE CULTURE IN S. INDIA.

"Fred. D M." writes:—At the meeting of the U.P.A.. S.I. held at Bangalore in August last, Mr. Gompertz, Chairman of the Shevaroy Planters' Association, suggested the introduction of the Brazilian system of coffee cultivation, which he stated is to give the tree more space for growth than it is allowed in Southern India. In the Brazils the space allowed is 12 feet between the trees, and in some instances he said even that space is exceeded, the result being better growth and development of the trees, and an average crop of 5 lb, of coffee per tree, and he estimates that the number of trees to the acre planted at 12 feet apart would be 300, whereas planting trees at 6 feet apart, as is now done in Southern India, the number per acre is 1,210. This large difference shows at once the great saving there would be in the cost of planting an acre of land by the Brazilian system—a saving probably of three-fourths or two-thirds of the present cost of cultivation—which would amount to something considerable in planting 100 acres of land. The produce of 300 trees, according to Mr. Gompertz's estimate of 5 lb. per tree, would average 12 cwts. 36 lb. per acre, which is about double the average crop produced at present from an acre of 1,200 coffee bushes. He made mention of an interesting experiment that is now being carried on on the Shevaroys by Mr. Leeming, a member of the Association, to practically test the value of the Brazilian system—for which purpose he had removed from one of his estates every other coffee bush from a lime originally planted 6 feet apart, and by that means increased the space between the bushes left in the line to 12 feet from bush to bush. The trees or bushes in the line so treated, Mr. Gompertz told the Meeting, have made luxuriant growth and are at present hearing a heavy crop—what it would average per tree it was not possible to say then, but he expected that in time it would break the Brazilian record of 5 lb. per tree.

I fully agree with the theory propounded by Mr. Gompertz, but I differ with him on one point, and that is my doubt of the dwarfed coffee bushes of the South Indian estates being capable, notwithstanding the advantages of the improved system of cultivation suggested, of producing the estimated average crop of 5 lb. per tree, in these days of leaf disease and repeated unfavourable seasons caused by drought; and it is upon the realisation of the estimated Brazilian crop of 5 lb. per tree that the advantage of the proposed change in cultivation hinges. From Mr. Gompertz's silence on the height of Brazilian coffee trees that bears 5 lb. per tree, I am led to believe that although in his remarks he mentioned *tree*, he means the ordinary 4½ feet bush grown on South Indian coffee estates. My impression is that the stunted coffee bush may, under favourable circumstances and improved cultivation, bear an average crop of about 2½ lb. per bush. It is unfortunate that Mr. Gompertz did not, when remarking upon the Brazilian system of cultivating coffee, make some allusion to the height the tree tree is allowed to grow there, as the quantity of crop a coffee tree is capable of bearing depends as much upon its height as upon the space allowed it for development.

There is a German method of lining for tree planting by which 500 trees to the acre could be planted at exactly 12 feet apart. By the ordinary method of lining Mr. Gompertz gets only 300 trees *to the acre*; consequently, many a square yard of land that goes to make up the acre is wasted, not only by the coffee but also by the tea-planter. But by the German method of lining every square yard of land of the 4,840 that go to make the acre is utilised, and, as stated above, after allowing 12 feet of space between the trees, 500 acres instead of 300 could be planted on an acre of land.—*Madras Mail*, Oct. 16.

TEA MANUFACTURE IN BAD WITHERING WEATHER.

In reply to a reference we made to Mr. A Cooke of the Chota Nagpore Tea Company *re* certain experiments made by him in tea manufacture that gentleman sends in the following, which will be of interest to our tea planting readers:—The experiment you read in my note had nothing to do with green tea. The experiment referred to (I think) was rolling heated leaf after it had got the proper colour—this improves the twist, without spoiling the liquor much. In bad weather, when withering is impossible or imperfect, I have always rolled the leaf and allowed it to get the proper copper colour for black tea; then, instead of firing the leaf fully, I warm it and get it flaccid, and then give a final roll; after which it is fully fired and dried.

This improves the appearance wonderfully without doing any harm to the liquor. *Good* black tea cannot be made in this way, but the intermediate firing saves the appearance. Unwithered leaf makes awful looking tea, all chips and ragged bits, and the liquor cannot be really good, but the above plan will give a fairly good appearance and no worse liquor.

During the wet days of the late cyclone I had leaf three days old and still *kutcha*, and had to roll it anyhow, or it would be in to smell bad. I rolled twice, twenty minutes each time, very lightly within a period of three hours and the leaf got a good bright colour. It was then heated and rolled again. Comparing the wet leaf in the sample cup with some ordinary tea made from well withered leaf, I found that the coppery colour was brighter, and deeper in the withered leaf and the liquor was much darker. The plan I wrote of does not obviate withering, but it minimises the loss from under-withering.—*Indian Gardening and Planting*, Oct. 11.

"PLANT SANITATION."

MR. J. B. CARRUTHERS' LECTURE.

Mr. Carruthers was called upon by the Chairman, Mr. E Webb, at the commencement of the meeting of the Northern Districts Planters' Associationon Saturday afternoon to deliver his lecture on "Plant Sanitation" with special reference to cacao canker.

The lecturer commenced by saying that sanitation was recognised in human medicine and with animals, but was not yet recognised with regard to plants. People recognised that dead bodies should not be left lying about and other such rules and he wished to impress on them the necessity of observing the same rules as applied to plants. Plant diseases, he said, could be grouped into three or four groups. First, diseases due to environment, *i.e.*, due to want of moisture, or excess of moisture and due to too high or too low a temperatue. These were neither contagious nor infectious. There were diseases caused by large animals as well as insects, such as the damage done by squirrels, *helopeltis*, red spider, etc. Those were subjects really looked after by his colleague, Mr. Green, and he thought he should not say anything about them. There was a more important disease in view of plant sanitation due to the tax of fungi and bacteria and it was in these they had to try and use sanitary measures as they were nearly all contagious or infectious to describe what fungus is. The lecturer took as the best instance the mushroom consisting of the spawn or *mycleium* below the ground and the portion above the ground known as the mushroom carrying the spores of the fungus which is the reproductive part. Spores may be considered as the seeds of the fungus. The mushroom was easy to see with the naked eye, but unfortunately the fungi which grow on cultivated plants were not so easy to recognise. The lecturer then went on to say that fungi were divided into two groups, viz, *Parasitic* and *Suprophytic*. *Suprophytic* fungi grow only on dead organic matter and were not so interesting to the practical man as they did no damage to cultivated plants. The *Parasitic* fungi were most important to cultivators as they caused much damage and were fatal to cultivated plants. He then went on to say that of the *Parasitic fungi* one that interested them most was the cacao canker which he explained to the meeting by means of pictures. With cacao canker as in other fungi when the planter first observed it and wrote to him (the lecturer) or any other such worker saying that the disease had just broken out, it had probably been in the tissues of the plant for months or perhaps years. The way the planter generally noticed it was by the production of the fruits of the fungus, but that only meant that the fungus had been in the bark a long time before producing its spores just as a flowering plant grew some time before producing its fruit. It was very important for planters to learn to recognise this in their earliest stages. The cacao canker could be recognised in its earliest stages by the discoloration of the bark and *cambrium*. The colonrs were different, from a yellowish tint to dark claret colour. This discoloration was due to the presence in the tissnes of the spawn or *mycelium* of the fungus *nectria*. His experience had shewn him that when this spawn had been in the tissnes for some varying time from ten days to a year, the spores were produced and they were to be noticed as whitish with yellow or pink tint masses coming through the bark. The lecturer then shewed pictures of the canker. Inside those masses were found, if magnified with a microscope, spores of two kinds, and those spores, if they lighted on any other cacao tree, and in the presence of moisture, would cause a second patch of canker. The only thing necessary for the germination of those spores were heat and moisture. There was always sufficient heat in Ceylon, and during a good many months of the year there was sufficient moisture. The first spore was more or less egg-shaped and the size could best be understood by saying that a layer of five millions covered a ten-cent piece. Almost simultaneously, or a little later, there were formed a larger spore crescent-shaped, having five divisions.

He then explained how the spores began to grow in presence of moisture. After these white masses had been formed, a careful observer would see some minute red bodies forced through the white masses but that did not occur until the portion of the cacao tree was dead. Those red bodies, each about the size of a pin's head, were seen in clusters containing another form of the fungus. On opening one of the red bodies he said there would be found a number of transparent bags or sacks, each containing eight spores, technically called *asco spores*; while the spores previously mentioned were called *gonodia* spores. The *asco spores* were fitted to carry the fungus

over a period of drought and it was probable that they could remain without growing, yet retaining their vitality for months, probably years. The *gonodia spores* were fitted to quickly spread the fungus while damp conditions prevailed. Unfortunately this fungus did not live only in the bark of the tree, it was found and only too commonly on the pods and its life history on the pods was the same as previously described except that the time taken to produce all its spores was very much less. On the pod the whole life history could be gone through within under 10 days, whereas the same number of months only sufficed when it grew on the bark. The canker on the pods was very important as it reduced the crop and it was still more important as it was the chief means of spreading the disease because of the rapidity the funges could grow in the softer tissues on the pod. With regard to rules for combating this and other diseases, in the first place it was perfectly clear that all spore masses as far as possible should be destroyed by burning and it was impossible to too strongly insist upon the fundamental importance of that measure. The lecturer then mentioned an instance of a small native holding not far from Kandy, which he visited recently on his way to an estate. He went to the holding and on examination found over 100 dead trees covered from top to bottom with spores, many others dying and the whole place practically a spore farm. Unfortunately there was no Ordinance in Ceylon to compel owners to reduce danger of infection and it would be a matter of importance to planters to consider whether they could not arrange some means of getting such spore farms treated on sanitary principles.

At the conclusion of the lecture, Mr. CARRUTHERS, in answer to some strongly expressed views of Mr. Chas. Gibbon, deprecated the views widely held by planters that there was any special predisposition of the cacao tree to take the canker. The lecturer pointed out that all views of that kind should be rigidly tested by carefully conducted experiments. In his experience healthy cacao trees were quite as liable as sickly ones to take infection nor did manuring enable a plant to "throw-off" the disease. This opinion was very common among horticulturists and farmers, but in the majority of cases of fungal disease it had no foundation.

Mr. GIBBON referred to the reported remark of Mr. Arden that cacao would cease to be cultivated owing to the canker.

Mr. CARRUTHERS in reply said that Mr. Arden, who was undoubtedly competent in horticultural matters, had stated his views on insufficient evidence having visited one estate and that badly cankered but from his (the lecturer's) knowledge of large areas of cacao, if care was used and money spent, the effects of the disease could be reduced so that cacao might be grown to a profit and might go on and increase.

The CHAIRMAN, Mr. WEBB, proposed a vote of thanks to Mr. Carruthers for his able lecture which was carried with acclamation.—*Kandy Cor.*

HOME-MADE GUANO OF UNEQUALLED EXCELLENCE.

Save all your fowl manure from sun and rain. To prepare it for use, spread a layer of dry swamp muck (the blacker it is the better) on your barn floor, and dump on it the whole of your fowl manure; beat it into a fine powder with the back of your spade; this done, add hard wood ashes and plaster (gypsum), so that the compound shall be composed of the following portions:—

Dried muck 3 bushels
Fowl manure, 2 bushels
Ashes, 1 bushel
Plaster, 1½ bushel

Mix thoroughly and spare no labour; for in this matter the elbow-grease expended will be well paid for. A little before planting moisten the heap with water or, better still, with urine, cover well over with old mats, and let it lie till wanted for use. Apply it to beans, corn, or potatoes at the rate of a handful to a hill, and mix with the soil before dropping the seed. This will be found the best substitute for guano ever invented, and may be depended on for bringing great crops of turnips, corn, potatoes, etc.—*Queensland Country Life*, Sept. 22.

PLANTING IN DOMINICA.

(To the Editor of the *Times*.)

SIR,—The very interesting account given in the *Times* of today by Mr. H. Hesketh Bell as to the capabilities of Dominica applies to most of the West India islands. As head of the Jamaica Botanical Department for long period of years I cordially endorse Mr. Bell's sympathetic declarations as to the latent resources of these islands—resources which are unsurpassed with regard to most of the cultures to which he has directed attention.

I shall not trespass on your space further than to say that Dominica, with which I am acquainted, presents peculiarly attractive conditions to young English adventurers to embark upon most of the cultures indicated by Mr. Bell. It may be further stated that it would be impossible to render a great service to hundreds of young well-to-do Englishmen than to recommend them to turn their energies to this most interesting feature of colonial life.—Yours obedient servant,

ROBERT THOMSON.

Grass Mount, Queen's-road, Forest-hill, Sept. 20.

SULPHATE OF AMMONIA OR SALTPETRE AS TEA MANURE.

With reference to what has already appeared *re* Sulphate of Ammonia as a Manure for Tea, Messrs. Freudenberg & Co. have now placed at our disposal the letter of another German authority, Professor Stutzer of the Government Research Station at Königsberg, who has taken a great interest in Scientific Manuring in general and Manuring of Tropical Plants in particular. The following is a copy of the letter referred to;—

"I have to acknowledge receipt of your letter of 21st August. Sulphate of Ammonia is an excellent nitrogenous fertiliser and there is no reason why it should be discredited in the cultivation of Tea. In Europe Sulphate of Ammonia has, of late, gained considerably in favor compared to Saltpetre and rightly so; the unit Nitrogen in the form of Sulphate of Ammonia now commands a much higher figure than that in the form of Saltpetre. Whether this is, in every case correct I should not like to maintain, I only mention it to show that our farmers fully appreciate the value of Sulphate of Ammonia.

There is no reason why Sulphate of Ammonia as a fertiliser should be discontinued in a Tropical Climate; it can be applied to Tea as well as to any other perennial. That it ought not to be applied by itself, but along with others Manures, supplying Phosphoric Acid and Potash, goes without saying."

VANILLA IN CEYLON.

A NEW PRODUCT—AS AN ADJUNCT TO TEA.

We commend the following practical remarks to the attention of planters up to 2,000, 3,000 and in some climates even 3,500 feet above sea-level. To have two or three acres of vanilla netting R1,000 per acre is an addition to an estate's income, not to be despised:—

(*By an experienced Planter.*)

Given a favorable season, vanilla cultivation—at the present price of the staple—is a most lucrative one, but the plant is keenly susceptible to climatic influences in its cropping.

An acre of vanilla, properly planted, can easily give 200lb of prepared pods, its present market value in Mauritius is R19 per lb.

In Madagascar, Bourbon, Mauritius and Seychelles it is subject to a disease which sometimes completely wipes out the vanilleries; but the inhabitants are not disheartened—they open up and plant other land to replant on diseased land is useless. The market value of vanilla depends on the latter being gathered at the proper stage—almost to a single day—and on its preparation. The latter appears easy, and many a crop has been spoiled through a novice imagining he 'knows all about it' after having seen a few hundred pods prepared. Only very careful observation and much practice will ensure satisfactory results in the preparation vanilla.

The plant is not jealous as to altitude. It grows and flowers freely from sea-level up to 2,000 ft. in the islands mentioned. It requires a moist heat and a fair amount of rain, but is intolerant of anything approaching swampy and ill-drained land.—E. H. E.

PRODUCE AND PLANTING.

The Apathy of Shareholders.—The letter on "Tea Companies and their Policy," which appeared in the *Financial Times* some two months ago, under the signature "Ex dividend," and was quoted in these columns, has drawn forth a note of sympathy from a correspondent serving with the Army in South Africa. This letter signed "Anglo-Indian," seems to be in harmony with the views of "Ex Dividend" about the apathy of shareholders in tea companies. "Anglo-Indian," who yearns after some kind of reform in the management of tea companies, says: "The general apathy of tea shareholders is a thing to be deplored, most general meetings of tea companies consisting of a gathering of directors and their friends. Being a shareholder in one of the largest tea companies registered in London, the working of the estates of which I was familiar with, I issued to the shareholders towards the end of the season 1897 a circular letter, in which I pointed out the reckless expenditure which was adopted by the company. Further, I particularised the meagre and conflicting accounts invariably presented to the shareholders, and suggested certain reforms therein. In answer to that circular letter the directors issued a rejoinder which was generally acknowledged to be as feeble a production as ever was ventilated by a presumably intelligent body of officials. I then issued a second circular letter hopping to stir the shareholders to combined action, which I pointed out was the only hope of reform. Numerous were the apparently grateful replies I received to both my circular letters, and many were the congratulations I obtained for having displayed several defts in the management of the company's affairs, not a little prolonged correspondence occuring with some, a few of whom were tea planters of many years' experience. Not unnaturally, I expected to find a representative gathering of shareholders at the next annual general meeting. At that meeting there were not over half-a-dozen shareholders present, including myself. Two of us had only had any knowledge of the tea industry, consequently the directors, assisted by one or two shareholders who I was convinced knew little of what they were doing, and understood less of what they were told, simply transacted business as they wished, and they have continued to do so to date. The outcome of such absolute apathy on the part of the shareholders is shown in the results of the last two seasons' working, and by the continued meagre 'accounts presented to the shareholders, accounts which consist almost entirely of a series of bulked items, and are, therefore, unintelligible from want of detail. Never since the company was first formed have the shareholders been told what the estimates were for either crop or expenditure for the ensuing season, particulars which the directors are always in possesssion of and yet do not voluntarily disclose to the shareholders. The auditiog of the accounts is, so far as I can judge, a farce, for no accounts such as those rendered to the shareholders are capable of being properly vouched for. On the other hand, if the accounts have been properly audited, the individuals responsible have received full and detailed information which has been withheld from the shareholders. I fully agree with 'Ex Dividend' when he says that the auditor should be the servant of the shareholders."

INDIAN PATENTS.

APPLICATIONS FOR THE UNDER-SPECIFIED INVENTIONS HAVE BEEN MADE.

No. 330.—Samuel Molyneux Bailie, mechanical engineer, Suntok, Assam. A tea-packing machine.

No. 332.—C S Bivar, tea planter, at present of Seconee, Silghat, Assam. Instantaneous withering of leaf for the manufacture of tea, whether green or black, or for any other purpose for which such a system of withering may be suitable.

No. 347.—Francis Dillon Bellew, licensed branch pilot, residing at 22, Royd Street, Calcutta, British India. A new or improved blender for tea and the like.

No. 354.—David Miln Salmond, planter, Mariawatte tea estate, Gampola, Ceylon. Improvements in tea-rolling tables.—*Indian and Eastern Engineer*, October.

RUBBER IN BURMA ANE CEYLON.

We had a very interesting visitor today in Major Wyllie (I.S.C. in Civil employment) of Burma, who is returning from leave by the ss. "Shropshire." He has for many years been interested in Rubber and Gutta cultivation, partly in connection with his official duties in the Rangoon district and has been a student for a long time of our *Tropical Agriculturist* and Planting Manuals, particularly that on Rubber (1st and 2nd editions). With this interest and his well-known botanical and practical tastes, it is no wonder that the Burma Government thought of Major Wyllie as the proper person to take charge of the new enterprise, sanctioned by the Viceroy, whereby 10,000 acres of land in Burma are to be devoted to rubber and perhaps gutta cultivation. Knowing this enterprise was coming off, Major Wyllie, while at home, tried

to get permisison to visit Brazil (for which mission his knowledge of the Portuguese language makes him peculiarly fit) to secure seed of different kinds of rubber—there is a species of castilloa which contributes largely to Brazil exports, of which little is known—and there are many other points which a good linguist and botanist (very different from an ordinary planter) could get cleared up. The India Office was at first favourable; but the China War breaking out with its call on the Indian Service, Major Wyllie was recalled and the trip to the West had for the time to be given up. We should think, however, with so large an investment as 10,000 acres in hand, that the Viceroy especially, will see the advantage of one so admirably suited as Major Wyllie being sent to Brazil and Central America, calling at Trinidad, as well as to Java, Sumatra and Ceylon to collate all useful information up to date and collect specimens. Here, in Colombo, Major Wyllie was only able to run to Heneratgoda Gardens where, however, he obtained some interesting specimens of different kinds of rubber and other plants to take away with him. He much regrets having no time to go to Peradeniya. He has been noting the "Hancornia" referred to in a recent circular from Haiti given in the *T.A.*, and he was interested in what we showed him of Mr. Godefroy-Lebeuf's experiments in Paris. He was able to guess at the correct name of the species of "Castilloa" mentioned in the last letter from this gentleman—"Castilloa Tunu" not "bunn" as printed the other day.—Altogether Major Wyllie reminds us much of Colonel Beddome of South Indian botanical fame—who used so often to visit Ceylon in days gone by, in his devotion to public advantage and single-minded attention to the special department he has made his own. We shall watch with interest the progress of the Burma enterprise and trust Lord Curzon will see the propriety of sending Major Wyllie to all important rubber-growing countries to enquire, collect and report. Such a Mission could not fail to redound to the credit—as well as material advantage—of the Indian Government which in times past did so much to introduce and promote cinchona cultivation, and to develope tea and other new industries.

EXPORT OF INDIARUBBER FROM INDO-CHINA.

The export of indiarubber from Indo-China has made considerable progress and is raised to 79,158 kilos for the first half of 1900, whilst in 1899 it was only 51,000 kilos for the whole year. Of this Saigon sent 9,676 kilos, while Tonquin was the larger exporter with 69,482 kilos. A great part of this came really from Laos and Annam and was transported to Tonquin.—*Tonkin paper*, Aug. 17.

THE SEYCHELLES.—We do not often hear from these out-of-the-way, vanilla-growing isles; but on our sixth page today will be found some chatty notes from a recent visitor, giving interesting first-hand information as to "Royalties" banished to the Seychelles; Men-of-war; and the Vanilla Crop.

CORAL REEFS OF THE INDIAN REGIONS.

Interim Report of the Committee, consisting of Mr. A Sedgwick (Chairman), Mr. J Graham Kerr, Professor J W Judd, Mr. J J Lister and Mr. S F Harmer, appointed to investigate the Structure, Formation, and Growth of the Coral Reefs of the Indian Region.

The Committee have received the following report from Mr. J Stanley Gardiner:—

The expedition under my charge has been carrying out work during the last eighteen months in the Laccadives, Maldives, and Ceylon.

During the month of May 1899 I toured through the raised coral-reef areas of Ceylon and round the coast In the north of the island these form a succession of higher and higher raised reefs down to Dambulla, broken only by isolated flat-topped peaks of older rocks, on the sides of which the successive elevations are sometimes clearly visible in horizontal lines of wave action. It is only in the topography of the older, often much dolomitised country that the previous existence of either barrier or isolated reefs is indicated. The greater part is formed of a mixed reef sand, and appears before elevation to have borne a considerable resemblance to the large mudflats round the islands of Viti Levu and Vanua Levu, in the Fiji group.

Round the coast of Ceylon, especially to the south, a recent elevation of five to twenty feet was found in broad flats by the sea. These are now invariably being washed away down to the low tide level, at which they persist, to a certain extent, as fringing reefs of varying breadth. The greater part of the west and south coasts is devoid, however, of any reef-growths, the shore being rocky or formed of fine siliceous sand. In May 1899 the rocky shore near Bentota was seen to be covered with small coral colonies, which were evidently a growth of the previous north-east monsoon. In September these had completely disappeared, having been washed away in the south-west monsoon. At Galle, Talpe and Weligama numerous recently living colonies of corals, particularly of the genera *Porites* and *Pocillopora*, of four to eight months' growth, were found completely silted up with sand and dirt of all sorts.

A noticeable point about the reefs immediately round Ceylon is the comparative absence of reef-building nullipores, which are a marked feature of all isolated oceanic reefs. In connection with this an attempt was made to examine the shoals two to six miles off the south and south-west coasts of the island, which indicate with the soundings the possible upgrowth of a barrier reef. The weather, however, at that season was so unfavourable that I was unable to dredge, land, or anchor on any.

Subsequent visits to south India and north Ceylon indicated clearly a former land connection between the two. The so-called Adam's Bridge and the islands of Manaar and Ramasserim, which the former joins, appeared indubitably to be the remains of a formerly elevated limestone flat, which has been more or less cut down by the sea to the low-tide level. The coast lines, too, of Ramasserim and to the north of the Jaffna peninsula were also probably at one time continuous.

The months of June, July, and August 1899 were spent in Minikoi, an isolated atoll, the most southern of the Laccadive group. Here I was accompanied by Mr. L A Borrodaile, who proposed to study various points connected with the Crustacea and Chætopoda. Unfortunately Mr. Borrodaile, who had been collecting these forms in Ceylon, almost at once succumbed to the climate, and after five weeks returned to Ceylon, whence he was at once ordered home. Every part of the island was visited: a survey was made and numerous cross-sections were run. From these it was clear that there had been an elevation of the original reefs to a height of at least twenty-five feet above low-tide level. Numerous observations were made on the currents at different

depths within the lagoon in reference to its shoals, &c. Work on this point could seldom be carried on outside the reefs, as originally intended, owing to the heavy north-westerly winds which prevailed. The lagoon was dredged to ascertain the distribntion of its corals, and a few water samples and temperature observations were taken.

Considerable attention was paid at Minikoi to the sand-feeding organisms, especially Holothuriæ, Enteropneusta, and Sipuncolida. These forms appear to be largely instrumental in finely triturating the sand, the small particles being subsequently carried out of the lagoon in a state of suspension. The boring organisms, too, are very important in causing the decay of dead coral and rock, especially in the lagoon. These, accordingly, do not form points of attachment for fresh reef-growths to arise, and owing to the larger surface exposed are the more readily dissolved by the water. Indeed all evidence collected showed that the lagoons of atolls may be, and are, very generally formed by the solution of the central rock of originally more or less flat reefs.

In October 1899 I left for the Maldive group, to which I was accompanied by Mr. Forster Cooper, who assisted me in all the work and very largely took charge of the dredging. The Soltan lent us a schooner of about eighteen tons, which we at once fitted out in Male, subsequently cruising through the northern atolls dnring the months of November, December, and part of January. About a hnndred islands in the atolls of Goifurfehendu (Horsburgh), S Mahlos, N Mahlos, N Miladommadolu, S Miladummadulu, Fadiffolu, and Male were visited, Numerous sonndings were made and dredgings everywhere taken. Horsburgh Atoll and the two atolls of Mahlos Madnlu in particular were thorooghly worked over.

Parts of January and Febrnary 1900 were spent at Hulnle, a small islaud at the south-east corner of Male Atoll, this being the month of Ramazan. A thorough survey of this island and its reefs was made, the whole forming an atoll of the second order, an atollon on the rim of an atoll, Large collections were obtained of the fauna of this atollon from all depths, together with observations on many special points. A set of corals of known period of growth was collected from an artificial passage through the reef to the landing-place of the island.

In February Mr Forster Cooper took the schooner off for a short dredging cruise in Male Atoll, while I remained in Male making special observations on the water temperature, currents, food, &c.

In March I was unfortnnately obliged owing to illness, to return to Ceylon, where I spent some time in hospital. Mr Forster Cooper meantime continued the work, taking the schooner and dredging the attolls of S Male, Felidu, Molaku, Kolumadulu, and Haddumati.

In April I returned with the s.s. "Ileafaee," a vessel of about 350 tons which I had chartered. Mr Froster Cooper was relieved in Haddumati Atoll and joined the steamer, the schooner being sent back to Male. We then proceeded to Huvadu (Suvadiva) Atoll, which we entered by a northern passage. The lagoon to the east was dredged and sounded, the positions of islands and reefs observed and four islands visited. A move was then made to Addu Atoll, the outer slopes of which and also the lagoon were dredged and sounded. The islands were charted in with the assistance of Captain Molony, and the majority were visited by some member of the party. On returning to Suvadiva the south and west sides of that atoll were dredged. On account of the heavy weather we were prevented from seeing Mulaku, which we had especially desired to visit.

Proceeding north to Male we skirted Haddumati Atoll and crossed Kolumadulu, then visited and dredged S and N Nilandu Atolls, subsequently anchoring in Felidu and Ari. The passages were sounded between the following atolls: Kolumadulu and S Nilandu, S and N Niladdu, Mulaku and Wattaru, Wattaru and Felidu, N Niladu and Ari, S and N Male. Three further lines of soundings were run across the central basin between the east and west lines of atolls.

More than three hundred dredgings were taken, and in addition large and, we believe, very complete collections were made of the reef-fauna at Minikoi and Hulnle four natives at least always accompanying and assisting us in this work. The collections of land-fauna we believe to be equally complete from these islands. Collections of the plants of five separate Maldivian islands are now in the hands of Mr J C Wills, Peradeniya Gardens, Ceylon.

A large number of anthropological measnrements and considerable enthnological colections were procured, of which we hope to give the Association an account at some subsequent meeting.

PLANTING NOTES.

CAMPHOR.—The market in Japan is very firm, crude being quoted at from 182s 6d to 185s per cwt., c.i.f. Inquiries on the spot show there is practically nothing to be had, although 192s 6d is quoted. In the drug-auctions 100 cases of pressed Formosa camphor in cases of 133 lb. net each were held at 205s. per cwt. Today, German refiners have reduced their price by 1d., per lb., and now quote 2s 1½d per ton, c.i.f., for prompt delivery. English refiners, however, are very firm, and the tendency is towards an advance, if anything.—*Chemist and Druggist*, Sept. 29.

THE TRIUMPHS OF ELECTRICITY.—Surely this is one of the most notable experiments with electricity in the East. An Indian contemporary writes, "the Mysore Government have at length finally settled all the points that were at issue between themselves and the Government of Madras relative to the water of the Cauvery Falls, and they have accepted the tender (£140,941) of the General Electric Company of the United States, who have undertaken to complete, within twenty months, the installation of the plant required at Sivasamudram to generate 5,000 horse-power and to transmit it a distance of ninety miles to a central station on the Kolar Gold Felds. Arrangements are being made with the various Gold-mining Companies now at work on the Fields for the distribution of the electricity from the central station and for the installation of motors to work the machine now driven by steam."

THE CONSOLIDATED ESTATES COMPANY, LD.—We give the very full Report of the Managers, Messrs. Arbuthnot Latham & Co., in our daily and *T.A.* In a separate table, the progress of the Company from the beginning is shewn and we notice the figures for 1899-1900 Besides the preference capital of £37,000 and ordinary £39,000, the Company has £46,700 of debentures (or £2,500 less than in the previous year). The total capital £122,700 represents 3,929 acres in cultivation so the rate per acre is not high, without counting 366 acres reserve fit for tea and over 800 acres besides. The last crop of tea was 1,651,410 lb. realising 5 15-16d average; the rupee averaged 1s 4 31-64d: total proceeds of crop £42,197 13s 10d and the profit £11,295 11s 6d. The dividends (8 per cent on preferences and 5 per cent ordinary) are the same as last year; but besides the reduction on debentures, the Reserve Fund now at £2,097 is £426 above last year. Altogether, therefore, the Company has done well during 1899-1900.

HUNTING AND HAPUTALE PLANTERS IN DAYS OF OLD.—On another page will be found some reminiscences by the late G. A. Cruwell which have never been in print before. They afford a peep of a Haputale planter's life in the hey-day of coffee, before there was any railway and only a few roads in Uva. G.A.C. gives some true incidents of injuries (some fatal) to hunters; but we never heard that he or MacLellan, Duff, Hood, Corbet or Rose suffered for all their gatherings in the "merrie greenwood" in the days when all was forest between Radella and Adam's Peak.

"OSTRICH-FARMING: WOULD IT DO IN UVA?"—It is suggested to us that one or more of our enforced visitors at the Diyatalawa Camp may have had experience in South Africa of Ostrich Farming, and may be able to say whether the uplands of Uva would at all offer a suitable region for the establishment of a farm? Of course the pursuit is usually associated with expanses of flat country; but we do not know that undulating patanas would be objectionable. Sand, and lime, or shells however, are said to be necessary for the birds for the development of bone. Water supply and fresh vegetable food could be managed in Uva. The food of ostriches in Egypt is said to cost 2d a day. Each adult bird, five years old, is estimated as worth £40. The annual crop of feathers, after three years old, equals about £4 10s in value on an average, and there are the young ostriches hatched each year, to count on against the general expenses. But perhaps there are enough of ostrich farms already in Africa?

HOW TO FREE A TOWN FROM MOSQUITOES.—In view of the now established connection between mosquitos and malaria, the following extract from the *British Medical Journal* is likely to be read with interest by many of our readers, especially in Calcutta. Expert opinion is pretty well unanimous that the mosquito pest can be controlled. All that is wanted is united action. It is a fair field for village improvement societies. At a meeting of the Societa Medico-Fisica Universitaria of Sassari, on 23rd March, Dr. C Fermi gave an account of certain experiments made in Sassari, in conjunction with Dr. Lumbau and Dr. Cossu-Rocca, with the object of freeing the town from mosquitos. He was able to discover all their breeding places in different parts of the city, in drains, cisterns, puddles, etc. The method adopted was the destruction of the larvæ by means of petroleum placed in the breeding grounds twice a month. The mosquitos were destroyed in shops by means of chlorine, and in houses by means of ulicides, such as a mixture of pyrethrum, chrysanthemum flowers, valerian, and Calamus aromaticus, or the "zanjoline" of Celli and Casagrandi. The results obtained were so satisfactory that Dr. Fermi concludes from them that it is always possible to free a town from mosquitos unless the conditions are exceptionally unfavourable—as, if it be situated in the midst of a swamp. He estimates the expense of freeing a town of fifty thousand inhabitants at 1,000 to 1,500 lire (about R1,000 to R2,000) a year. This includes the wages of the staff required to carry out the measures prescribed.—*Indian Gardening and Planting*, Oct. 11.

THE PHYLLOXERA IN SWITZERLAND.—This pest made considerable progress last year in Switzerland, and in Waadtlande (Vaud) the Vines were attacked with great virulence. Of the 6,568 hectares planted with Vines, thirty four hectares were devastated by Phylloxera. Although the percentage of ½ per cent., may appear small, the seriousness of the case lies in the fact that sixty-eight out of a total of 183 wine-growers, *i.e.*, roughly about one-third, had their vineyards affected. The owners hesitate to introduce the American Grape vines as stocks on which to graft, fearing a deterioration of the good quality of the wine, although nothing else can be done.—*Gardeners' Chronicle*, Oct. 6.

CALIFORNIAN VEGETABLES FOR LONDON MARKET.—In so excellent condition do all kinds of fruit arrive from California, that it was determined to try the experiment of introducing Asparagus to the English market. As we are told the experiment has been tried but the cool chamber of the steamer was a trifle too cool: the "grass" was frozen and so rendered unfit for marketing. Next season every effort will be made to furnish supplies of Asparagus in good condition to consumers here at a reasonable charge. It is a "long order" from the Pacific to Covent Garden. By-and-by it may be found possible to make it a paying concern to place orders for the same vegetable at the Cape.—*Gardeners' Chronicle*, Oct. 6.

THE SHAN STATES.—The resolution of the Government of Burma on the reports of the administration of the Shan States during the past official year has lately been issued in Rangoon. In the Southern Shan States the year was barren of incident; the people were prosperous, crime light, and the harvest good. Relations between the different chiefs were good, and those between Ken-tung and the adjacent French and Siamese territories were also good. Slavery was abolished in Ken-tung during the year by the chief himself after a visit that he made to Burma and Ceylon. Dacoity has disappeared, old roads have been improved, new ones opened, bridges constructed, and much other work of the same kind has been carried out. In the Northern Shan States also tranquility has been maintained, except in one frontier State, where the operations of the Boundary Commission between China and Burma were resisted by a petty local chief. Otherwise crime has decreased and many works of public utility are being carried out by the chiefs. Another memorandum describes the trade of the Shan States as nearly three-fifths of the total trans-frontier trade of Burma. It amounted to 178 lakhs of rupees last year, and when communications with Burma are in a better state a large growth in this trade must take place. The States send down to Burma cattle, ponies, provisions, such as potatoes, tea, and other articles not grown in Burma, as well as pigs, geese, and fowls. A considerable quantity of teak also finds its way down to the coast from the States. Of all the regions adjacent to Burma the Shan States appear to be the one in which land trade with that province is most prosperous and most likely to increase. The reports, in the words of the resolution, "afford striking proof of the benefits which have accrued to the Shan States from the settled government of the last 12 years."—London *Times*, Oct. 6.

Correspondence.

To the Editor.

IGNORANCE OF CACAO:—THIS PICTURE AND THAT.

Oct. 22.

DEAR SIR,—With reference to your remarks on cacao in Saturday's *Observer*, one might regard the word of a botanist, according to the vehement criticism by Mr. Chas. Gibbon in the local "Times," as something akin to the wand of a conjuror. The young botanist from Kew, Mr. Arden, could not be expected to give an opinion from personal experience on cacao cultivation in Ceylon, nor do I see how his general remarks as reported by the "Times" can have materially influenced any person of larger experience.* Is it not a fact, however, that at Kew there may be seen growing on a small scale practically all tropical products, the uses, value and cultivation of which the students at that institution are regularly taught? Is it not through Kew that our best varieties of cacao have been introduced to Ceylon? †

Mr. Carruthers, the Cryptogamist, in his report last year on the cacao disease, stated that "some estates are practically wiped out by the disease," whilst leading cacao planters declared that there were prospects of the cacao enterprise being doomed. It is not surprising therefore that a new-comer, taught in European principles of agriculture, should be led to the opinion that cacao "in the course of time" should have a bad time of it unless the present methods of cultivation were altered. "In the course of time" is an indefinite period. Mr. Chas. Gibbon, however, calls this "crass ignorance," and makes a direct libel when he says that Mr. Arden "goes on to describe a very exceptional instance of tapping trees to promote thick growth." Mr. Gibbon, for some reason of his own, interprets "topping" (which term in England meaning "coppicing," he apparently is not acquainted with) into "tapping" and he takes pains to show that this is not applied to cacao, which is ridiculous. It is amusing to see Mr. Chas. Gibbon use such big words to make a "contradiction" which he afterwards contradicts himself by stating that "the cacao has many enemies to combat." That cacao can, however, luxuriate in many parts of Ceylon, with careful cultivation, is amply testified.—I am, yours faithfully, ONE INTERESTED.

LIME AND MALARIAL MOSQUITOES.

Matale, Oct. 22.

SIR,—Last week you had an editorial, wishing to know the local experience of using lime as a preventive of mosquitoes. As you know there are several places in Ceylon that have lime in the soil. The Matale district (notoriously malarious) is full of lime; and yet mosquitoes and their larvæ are plentiful in every swamp. The only effective germicides are Jeyes' Fluid or Kerosine; and as neither of these is expensive they should be used for every swamp or pool in malarious localities.

By the way, can any of your readers explain why new clearings, digging up of soil, etc., should cause fever?

I am a believer in the mosquito malaria theory; but the theory does not cover the cases where a deadly outbreak of malaria follow the disturbance of the soil; as for instance, the outbreak of fever when the railway to Galle was being opened.

ENQUIRER.

[The mosquitoes to give an attack of malarial fever have first to feed on an afflicted patient: but turning up the soil in a malarious district releases germs which, imbibed, result in fever.—ED. *T.A.*]

VARIETIES OF CASTILLOA RUBBER IN CEYLON.

ss. "Shropshire," Oct. 23.

DEAR SIR,—I enclose a note of the references bearing on the dispute as to the identity of *tunu* or *ule* with castilloa elastica, and of C Markhamiana with C elastica, also of C elastica with the tree yielding the *caucho* rubber of the Amazon valley. The matter is, I am afraid rather, obscure still. But it would appear probable that you have *not* got the true Castilloa elastica in Ceylon. Perhaps your Paris correspondent might be asked to tell us what he knows about *tunu*.

Besides the references I have quoted, I rememberreading an article (I think in the New York "India Rubber World," two or three years ago) on the prospects of trade in Honduras in *tunu*, but to the best of my recollection the writer claimed it to be the source of *chicle* or chewing gum, which would make it out to be the *achras sapota*. This rather adds to the confusion than otherwise, but my memory may be at fault. I am sorry I cannot find this reference in my file My reference I. (b) seems to point to the possibility of *tunu* being a *balata*.—Truly yours, J. A. WYLLIE.

I.—*Ceylon Manual* "All about India rubber" 1899—p. cxvii.

(a) Plants sent out from Kew 1876 differ from *ule* of Mexico as described by Cervantes.

(b) *Castilloa* from Honduras three species. Two=*ule*, the third is *tunu*—said to yield a gutta percha.

(c) p. cxix—item IV., description of *tunu*.

II.—*Ceylon Manual*, p. cxx., Cross says there is only one species—difference is due to growth in sun or under shade.

III.—Ibid p. cxlviii. Clements Markham thinks there are two species—(1) C elastica (ii.) Markhamiana.

IV.—*Tropical Agriculturist* Sept. 1st, 1899, p. 206. Name *ule* or *tunu*=Castilloa in Central America.

V.—*Ibid, March 1st ,1899.* p. 602, C Markhamiana turns out to be a *perebea* species, so Sceligmann says.

VI.—*India-rubber World*, Oct. 1st, 1899, p. 4, Dr. Huber (Curator, Para Museum), says *caucho* of Amazon valley is a Castilloa—identifies it with C elastica or ule.

* How are people absent from Ceylon to know of Mr. Arden's experience? We scarcely think he could have meant his words to be printed as they stand: he was very cautious in his conversation with ourselves.—ED. *T.A.*

† But what does Kew know of cultivation on at large scale,—ED. *T.A.*

RUBBER EXPERIMENTS.

Paris, Sept. 26.

DEAR SIR,—Can any of your readers procure me sample of the plant you call Castilloa elastica in Ceylon? I believe the plant grown there is Castilloa bunn. Castilloa elastica is less injured by the temperature and there is an interest to know exactly what is the species grown.

About rubber barks, the results obtained vary. If the bark has been quickly dried by exposure to full sun, the rubber is more abundant than in barks slowly dried; fermentation in that case has destroyed parts of the gum. The bark quickly dried can after be exposed to moisture with less inconvenience than bark slowly dried. It is easily proved by bags of bark partly musty: if well dried first, the damage is not great; but fermented barks affected after by moisture, are quite unfit for any use. So, it is important if any of your readers sent me samples—to dry these quickly. Our Company for Extraction of Rubber is founded, and will buy on analysis any bark offered. The price will vary like for barks of cinchona.—Believe me, yours most truly, A. GODEFROY-LEBEUF.

P.S.—I have introduced this year several new rubber products,—such as, Forsteronia gracilis, Hancornia speciosa, Euphorbia speciosa—a new sort from Guinea, producing gum of inferior quality, but in very great quantity.

[We have just sent Mr. Godefroy-Lebeuf a parcel of Para rubber from a Ceylon planter who wants a report after analysis of the same. Can any one spare a sample of Castilloa bar —ED. *T.A.*]

IMPORTANCE OF LOWCOUNTRY GREEN TEAS; AND THE GLAZING OF TEAS.

Stagbrook, Peermaad, S. India.

SIR,—I was interested to see by your issue of the 12th October, that Arapolakanda had obtained such an encourging average for low-grown green teas, though of course, it would have been more satisfactory had the sales been made direct in America, Canada or Russia. However we may take it for granted that Colombo buyers, as a rule, are on the safe side. This being so, I would remind you that lowcountry green teas has been a hobby of mine for some years, and you will find, that while on June 20th, Mr. F. F. Street, in an interview, says:—"I certainly do not recommend the lowcountry planter to make green tea, etc., etc." that I not having seen his remarks, writing to the Press on 2nd July, 1900, said:—"I am of opinion *that low grown teas* will make the best green teas, and have *made experiments* which tended to prove my theory." If this opinion prove correct, or at any rate if "lowcountry" green teas can get as favourable prices as high-grown green teas, it will be of great benefit to all interested in the tea industry, for I take it that it is much more to the interest of the Planting Community to get low-grown black teas off the market.

I hope experiments are being made in "glazing" the teas as per my directions issued by Messrs. Brown & Co., Ld. as I am certain it protects the teas and enables them to be kept longer.—I am, dear sir, yours faithfully,

H. DRUMMOND DEANE.

THE MATURATA TEA COMPANY, LTD.

DIRECTOR'S REPORT

submitted to the Shareholders at the Third Annual Ordinary General Meeting, held at the Offices of the Company, 16, Philpot Lane, London, E. C., on Wednesday, 3rd day of October, 1900, at 12 noon:—

The Directors herewith beg to submit their third annual report and balance sheet for the year ending 3rd June, 1900. After bringing forward £678 10s 3d from last year's account, and after payment of Debenture Interest and London Charges (Directors' fees, &c.), the net amount of Profit and Loss Account is £2,464 14s 7d. A dividend of 3 per cent. has been paid on the Preference Shares for the half-year amounting to £120. A further 3 per cent. was paid on the Preference Shares on July 1st, making 6 per cent. for the year, amounting to £120. It is proposed to pay a dividend of 10 per cent., less income tax, on the Ordinary Share Capital which will absorb, £800. Thus leaving to be carried forward to next year a balance of £1,424 14s 7d. Total £2,464 14s 7d. The past year has again showed very satisfactory results, and the yearly earnings of the Company have been substantially increased. The Directors therefore feel justified in recommending a dividend of 10 per cent on the Ordinary Share Capital of the Company, as, after payment of this, there still remains a considerable sum to carry forward. £1,000 of the debenture debt has been paid off during the past year thus enhancing the value of the Preferred and Ordinary Capital. The thanks of the Company are due to the Superintendent for the excellent way in which he has worked the estate and more than maintained the quality of our tea notwithstanding that the factory during the greater part of the year, was in course reconstruction which made his work considerably more difficult. The last report from the Visiting Agent in Ceylon as to the condition of the estate is highly satisfactory. The crop for the past year amounted to 159,054 lb., which sold at a nett average of 8 88d. For the current year the crop is estimated at 140,000 lb. Mr. G. Alderson Smith retires in accordance with the Articles of Association, but offers himself for re-election as a Director.

FERNLANDS TEA COMPANY, LTD

ANNUAL REPORT.

Acreage

FERNLANDS.

Tea in full bearing ...	212	acres
Tea in partial bearing ..	7	,,
Grass and Jungle ..	52	,,
Total Estate ..	271	acres.

ETON.

Tea in full bearing ..	150	acres.
Tea in partial bearing ..	9	,,
Tea not in bearing ..	5	,,
Coffee in bearing ...	47	,,
Cardamoms ...	14	,
Grass, Jungle and Scrub ..	25	,,
Total Estate ...	250	acres.

Grand Total 521 acres.

The directors submit to the shar holders the accounts for the season ending 30th June last.

The tea crop of 150,067 lb. realised a net average of 48·35 cents per lb. after making a safe estimate for proceeds of tea for which closed accounts have not yet been received from London. Coffee crop was as foreshadowed in last year's report larger than that of 1898-99 though short of the estimate.

After writing off 10 per cent depreciation on buildings and Machinery, the balance at credit of profit and loss account is R19,256·16. In March last an interim dividend of 2 per cent was declared and paid,

which absorbed R5,500, and the directors now recommend the payment of a final dividend of 4 per cent, making 6 per cent for the year, and that the balance of R2,756·16 be carried forward to this ssason's working.

The estimated crops for the current season are 155,000 lb. tea, 25 bushels coffee and 1,200 lb. cardamoms, on an expend ture on the estate of R52,235·33.

On the resignation of Mr. G H Alston the remaining directors appointed the Hon. W H Figg to the vacant seat on the board.

The appointment of a director and an auditor will rest with the meeting.

THE NEW DUMBULA COMPANY LTD.

REPORT, SEASON 1899-1900.

The Directors have the pleasure of submitting the accounts for the financial year ending June 30th, 1900.

The season generally has been a favourable one for flushing, the yield has exceeded the estimated quantity, and is considerably in excess of that of the previous year. The fields affected by the frost last season have recovered.

The net average yield per acre was 539 lb., compared with 456 lb. last season, and the net average price 8·76d as against 8·28d in 1898-99.

The acreage of the Estate is—

Tea in bearing	...	2,200 acres.
Young Tea	...	150
Timber Trees	..	108
Grass Ravines	...	45
Buildings	..	22
Forest and Swamp		600
Total	...	3,125 acres.

The Estate is reported on as being in first class order, and the Tea very vigorous ; the Buildings and Machinery are kept in excellent condition ; an extension of the Factory has been sanctioned, so as to render the treatment of leaf as satisfactory as possible, a portion of the cost of this extension is provided for in the accompanying accounts.

The accounts now presented show a surplus of £23,222 6s. 4d., after writing off the amount of Tea extension, viz., £309 12s. 6d., and the amount of the Factory and Machinery account, viz., £206 4s. 8d., and providing £1,000 towards extension of Factory. The Directors propose a dividend of 20 per cent. per annum for the year ended June 30th last, 5 per cent. of which was paid in March, together with a bonus of 3 per cent., and the placing of £3,000 to the Reserve Fund.

The Board wish to express their satisfaction with the management of the Estate while under the charge of Mr. S. Payne Gallwey. Mr. Dick Lauder resumed charge on January 1st, and the Directors feel that the continued good working of the Company's property by the Resident Manager and Staff in Ceylon must commend itself to the Shareholders. By order of the Board. A. Crabbe, Secretary.

THE DUCKWARI (CEYLON) TEA PLANTATION COMPANY, LTD.

REPORT BY THE DIRECTORS TO THE TENTH ORDINARY GENERAL MEETING OF THE COY.

The Directors have pleasure in submitting the Accounts for the year ending June 30th, 1900. Profit and Loss account, after writing off 10 per cent. depreciation on value of machinery and buildings, shows a credit balance of £1,313 10s 2d for the year to which has to be added £1,514 8s 4d, the balance brought forward from last season, making a total of £2,827 18 6

which the Directors propose should be applied as follows :—

(1) In payment of seven per cent. Dividend of Preference Shares	..	£840	0	0
(2) In payment of seven per cent Dividend on Ordinary Shares ...		560	0	0
(3) In increasing Reserve Fund by	..	500	0	0
			—	— 1,900 0 0
Leaving	..	..	£927	18 6

to be carried forward to next year.

The returns of crop have been 321,026 lb. Tea and 8,779 lb. Cardamoms, against 277,408 lb. Tea and 10,012 lb. Cardamoms last season.

The estimates for the coming year are 300,000 lb Tea and 12,000 lb. Cardamoms.

The increased crops coming off the Company's estates have necessitated the purchase of more machinery. The outlay on this, amounting to £412 16s 5d, has been debited to capital account.

Mr. Troutbeck retires from the Direction by rotation, and being eligible, offers himself for re-election.

The Auditors, Messrs. Brown, Fleming and Murray, also retire, and offer themselves for re ppointment.

P. G. Spence, Chairman, and R. Cross Aitken, Secretary.

17, Philpot Lane, London, E. C., Oct. 1900.

THE HORNSEY TEA ESTATES COMPANY, LIMITED.

THE FOURTH ANNUAL REPORT, 1899-1900.

The Directors beg to submit to the shareholders the report and audited Accounts for the year closing the 30th of June last.

The crop has weighed out 191,844 lb., against last year 172,139 lb., giving an increase of 19,705 lb. of made tea.

The Directors regret that although the crop is larger, the profit earned is somewhat smaller than last year. This result, however, is entirely due to a fall in prices, which has affected the whole industry. The teas have been carefully made, and the quality has been quite as good as in former years. The markets, however, have been rather over-supplied with tea, owing to a season of very favourable weather in Ceylon, resulting in large crops and lower prices.

The cost of production, with manufacture, has been 29·30 cents, against last year 31·12 cents, or, in sterling, 4¾d per lb. Colombo, against 5d per lb.

The sales in London have totalled 28,435 lb. of tea, selling at an average of 9·87d per lb., and the balance of the crop has been sold in Colombo, and realised an average of 38·90 cents, equivalent to a London price of 7½d per lb., against last year 45·40 cents, or 8½d per lb. The average sale price for the whole crop has been equivalent to a London price of 7·94d per lb., or nearly 8d per lb., against last year 8 72d per lb.

During the 12 months the Coast Advance Account has been reduced by £97 13s 8d, leaving only £81 3s 3d outstanding.

The audited accounts show that, after paying all fixed charges and Preference Dividend for the 12 months, there is a balance at credit of Profit and Loss of £412 9s 7d. The Directors propose to write off £224 6s from preliminary expenses account, and to pay a dividend of 1½ per cent on the ordinary shares, absorbing £180, and leaving a small balance to carry forward. The Directors, in again writing off so large a proportion of profit to preliminary expenses account, are acting on the determination to close this account during five years, and next

year being the fifth year of the Company's existence the balance of £158 11s 8d outstanding should dis-, appear from the balance sheet.

It is well known to shareholders that this Company does not possess a factory, and that the Battalgalla Company is manufacturing Hornsey leaf. This arrangement has worked satisfactorily up to the present time, but next year the agreement to manufacture between the two companies expires, and owing to increasing crops, Mr. Saunders, the Managing Director in Ceylon, strongly urges that the time has now arrived when this company should build a factory and manufacture its own tea. Mr. Saunders also claims that he can manufaoture much more cheaply than at present. To meet the cost of a factory the Directors purpose issuing a further £3,000 in six per cent preference shares.

The Directors desire to express their best thanks to Mr. W S Saunders and to Messrs. E Benham & Co., the Colombo Agents, for the attention given to the Company's interest during the year.

In accordance with the articles of Association, Mr. W S Sichel retires from the Board, and being eligible, offers himself for re-election.

The Auditors, Messrs. Singleton, Fabian & Co., also offer themselves for re election.

CHARLES A. REISS W. S. SICHEL, Directors ; ALBIN B. TOMKINS, Secretary.

51, Lime Street, E.C., London, 1st Oct., 1900.

PLANTING NOTES.

THE OLD, OLD STORY.—The scheme for starting a trust to control tobacco planting in Deli, Sumatra), has fallen through from the impossibility of getting the planters to combine in the desired direction.—*The Planter*, Oct. 20.

SURVEYORS FOR NEW GUINEA.—Brisbane, Oct. 9.—The Surveyor-General was recently requested by the Lieutenant-Governor of New Guinea to select several surveyors for service in the island possession. All but one of these selections were made today. The appointments are :—Messrs. D Rutherford, Licensed Survey Department, Brisbane; H B Matthews, New South Wales ; and W J Callendar, Queensland. Mr. John Richmond, of New South Wales, has been appointed draftsman at a salary of £300 per annum. The surveyors will each receive £400 a year, and be allowed an assistant at £200 a year. They are to provide their own instruments, but the New Guinea Government will supply camp gear, boats, and native crews.—*S. A. Register*, Oct. 9.

PROPOSED INDIAN TEA CESS.

We publish below a letter from the Hon. Mr. G L Acworth, to the Secretary of the U. P. A. S. I., which has been circulated among the various District Planting Associations in Southern India. There is no reason to believe (says the *M. Mail*) that Calcutta and London brokers would refuse to collect a cess in the manner Mr. Acworth suggests. Where there might be trouble, however, is in respect to teas shipped direct to foreign ports and passed through the hands of brokers there, and teas bought without the intervention of a broker for shipment to foreign markets. Little difficulties of this kind will no doubt be taken into consideration by District Planting Associations. Mr. Acworth shows that a very important sum could be collected annually, and if this were prudently employed in advertising and pushing Indian teas, there would probably soon be an end to the cry of over-production.

The following is Mr. Acworth's letter:—"As it is possible that the Government of Bengal may still decline to impose a tax on tea for the benefit of the Foreign Market Fund, it is as well to be prepared with some alternative scheme, which will be acceptable to the great majority of Indian tea planters, and at the same time result in a Fund which will compare favourably with that raised by our brethren across the water. Such a scheme has been evolved by Mr. A F Bruce, of Calcutta, and, having received his permission to make it public, I laid it before the Central Travancore Planters' Association at our last General Meeting. With slight modification Mr. Bruce's idea has been accepted by the C T P A and I now write to ask you to place the matter before other Tea Associations in South India. Should they accept the proposal, it would be as well to pass it on to the Indian Tea Association in Calcutta and London at as early a date as possible. The scheme as accepted by the C T P A is as follows:—'That a charge of half a pie per lb. be levied on all tea sold in India, and of 1-24 of a penny per lb. on all teas sold in London. That tea brokers be requested to enter this charge in their account sales, and to forward the proceeds when collected to the Indian Tea Association in Calcutta and London respectively.' This charge would amount roughly to a sum of R4 lakhs per annum, against the present pittance of barely one lakh collected by India. Every concern, whether a public Company or a private garden, would contribute in equal ratio. The levy is so small that it would be felt by nobody. There would be no expenses of collection, for I feel sure that the brokers, if approached, would keep the money and forward it to the right quarter free of charge."

THE

AGRICULTURAL MAGAZINE,

COLOMBO.

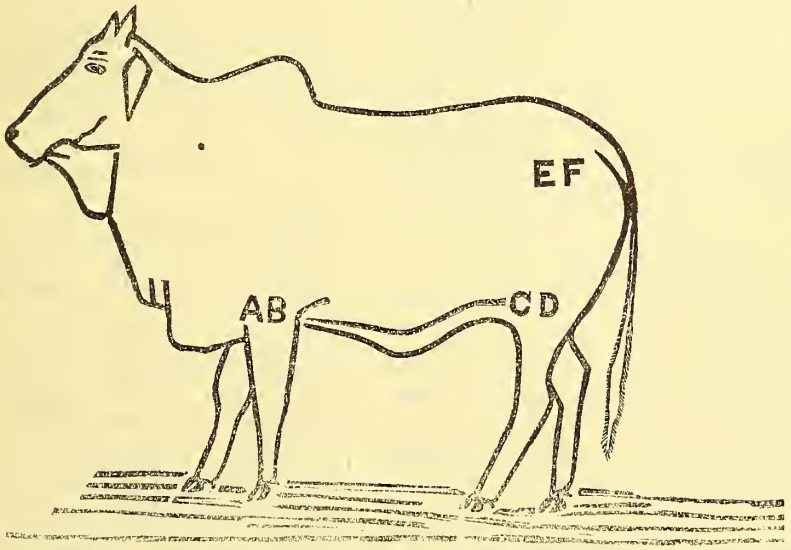
Added as a Supplement Monthly to the "TROPICAL AGRICULTURIST."

The following pages include the Contents of the *Agricultural Magazine* for November :—

Vol. XII.] NOVEMBER, 1900. [No. 5.

THE BRANDING OF CATTLE.

(Continued from last number.)



SPEAKING of the deterioration of hides, some years ago a letter was addressed by the London Chamber of Commerce drawing the attention of cattle owners to the reduction in the price of hides caused by carelessness in branding cattle, and suggested the possibility of a distinctive mark being made on the horns and hoofs of animals. This latter suggestion I consider unsatisfactory, for obvious reasons, in a country where the technicalities involved in the art of cattle stealing are so well understood. An Australian leather merchant went the length of inserting an illustration showing brands placed on inferior parts of the hide, with an announcement headed

important to stock owners, offering to give three shillings in advance of the market rates for hides not branded on the prime parts, the parts recommended being the thigh, upper arm, neck and cheek.* If cruelty is to be avoided and at the same time the commercial value of the hides is not to be depreciated, I consider the thigh and the upper arm the most suitable places, but I cannot give my support to branding on the cheek or neck. I have already given it as my opinion that the thigh and croop are the best places for branding and as a compromise with those who are anxious for the value of the hide I am so far prepared to modify my recommendation and join issues with them, as to consent to substitute the upper arm for the croop. Let these two places then—the thigh and the upper arm—be fixed upon as the most suitable on all grounds for branding for identification. The branding might commence at the upper arm, and if the space available is not sufficient it might be continued on to the thigh, and provided even these two places do not suffice, the croop might be included as a *dernier ressort*.

I have yet another suggestion to make, and that is that owners of stock should possess a branding instrument in which the initials of the owner, or any other selected letters or marks, should be designed in iron, so that the letters &c. might be of uniform size and conveniently impressed on the body by means of a handle to which the connected letters should be attached. That native blacksmiths are quite able to work out any design or initials in iron is evidenced by the fact that the Government Dairy branding iron representing the royal crown, and other irons representing initials, have been made by ordinary blacksmiths with no special qualification for the work. Such irons as I have referred to should not cost on an average more than R1. If owners of cattle are compelled to produce their branding irons, the design of which should be registered with an appointed village authority, who should perform the duties of an inspector of brands (an office which exists in some countries) it would be a great deterrent to cattle stealing.

III. Branding for Artistic Effect.

Branding with this object in view is cruelty pure and simple, without any shread of commonsense or humanity to recommend it. The man whose eye is pleased by artistic brandmarks must be put down as the product by a low state of civilization. The representations for artistic effect vary in design and magnificence. They are sometimes geometrical, sometimes floral, and sometimes representative of mythological deities, or symbolize supernatural influences. There should be no half measures in dealing with this inhuman form of the decorative art, and summary punishment should be meted out to those who practise it.

IV. Branding for Concealment of Theft.

It is by no means uncommon to hear of the brandmarks on stolen cattle being altered with the object of defying detection of the theft. These alterations are generally done under the plea of therapeutic or artistic branding, and in some instances are very skillfully carried out. Let us, for purposes of illustration, suppose that a particular bull bears three branded letters which are disposed of as follows : ෂු for Mullegama on the thigh, කා for Kalu on the abdomen, බ for Banda on the shoulder, and that the owner Mullegama Kalu Banda loses the animal. When the bull is found in the possession of the cattle lifter (by name Kiri Banda) the letter ෂු standing for Mullegama is entirely disguised by a highly ornamentative mythological design, and the necessary addition is made above the letter කා to alter it into කී, so that the initial of Kalu Banda becomes that of Kiri Banda. It requires expert knowledge to trace the difference between an old and recent brandmark, and very often it is quite impossible to make the distinction for there are ways and means of making new marks appear old. But if my recommendation that the possession of a branding iron with a specific design of letters or figures or marks be made compulsory, and the additional precaution enforced of having these brandmarks registered, two objects will be served, for both the pain of branding and the possibility of cattle thieving will be minimised. When the unlettered villager starts practising writing his initials with a hot iron, like a school boy at his first copybook, one can imagime the slow torture that many of our dumb friends are put to. Now this torture would be practically absent and at the same time there will be no latitude for increasing the dimensions in length, breadth, height and thickness, or the artistic effect of the lettering.

In view of the fact that both therapeutic (so-called) branding and branding for artistic effect are used as a blind for the concealment of theft, there is all the more necessity for prohibiting cruelty to animals practised on these excuses.

* [I am informed by a local authority that the loss on Ceylon hides due to depreciation on account of branding may be put down at two pence per pound.]

OCCASIONAL NOTES.

The following are the references to agricultural matters in the Governor's speech at the opening of the new Session of the Legislative Council on the 18th October :—The Commission which I appointed in January, 1899, under the presidency of Mr. Justice Lawrie, to inquire into and report on the advisability of establishing a Department of Agriculture, reported on 31st October, 1899. A majority of the Commission recommended the appointment of a Director of Agriculture to be assisted by an advisory board, and that there should be attached to the Department of the Director of the Royal Botanic Gardens, a Mycologist, Agricultural Chemist, Entomologist, and Veterinary Surgeon. A majority also recommended that the Irrigation Department should be combined with the new Department. After careful consideration in Executive Council of this report, and also of the views expressed by Messrs. Willis and Ferguson and others, I decided that the time had not yet come when the appointment of a Director of Agriculture would be justified, but that the formation of an unpaid Central Board on the same lines as the Central Irrigation Board, and of Provincial Boards under the Government Agents

would be desirable. The suggestion that a Mycologist, Entomologist, and Agricultural Chemist should be attached to the staff of the Royal Botanic Gardens was approved, and has been carried out. In December last a Committee composed of the Hon. Messrs. Taylor and Ellis, the Director of the Royal Botanic Gardens, and the Director of Public Instruction were appointed to consider the suggestion that the Agricultural School should be transferred to Kandy and placed under the direction of the Director of the Royal Botanic Gardens. The Committee recommended that the existing school be closed at the earliest possible date, and the buildings for the present be left in the charge of the Director of Public Instruction, and that the land be sold for building sites. They also recommended that if Government contemplated the addition to the Royal Botanic Gardens of an experimental farm or garden, the Agricultural School should be transferred to Peradeniya and be established there as a part of the experimental garden. This proposal has been accepted by Government, and Mr. Willis has submitted a scheme, now under consideration, for acquiring land suitable for the purpose at a cost which it is hoped will be largely covered by the sale of the land adjoining the existing school at Colombo.

There has been a good deal of correspondence, in the local press, as to the advisability of manuring tea with Sulphate of Ammonia. We are not much in favour of using the more soluble artificial manures in perennial cultivation especially in the wetter districts and steep hillsides, mainly owing to the fact that the practice is not to be recommended from an economical point of view; but we are far from saying that there is any positive harm to be feared—as some would make out—by the use of this fertilizer, if a due proportion of manures supplying the other important ingredients of plant food is also given to the plant. There is much harm done by the indiscrimmate use of special manures without seeing that at the same time that the other concomitants of plant food are also placed at the disposal of the plant. The reason of so doing is obvious enough and needs no further elucidation.

We are again growing lucerne from seed kindly supplied by Mr. J. W. Mollison, Deputy Director of Agriculture, Bombay Presidency. Two varieties were sent us, viz., English seed and Poona seed. Lucerne is grown as a profitable crop in India where it is used as hay for horses. Its ash contains six times as much lime as ordinary grass and the plant therefore requires a good deal of lime in the soil. It is thus particularly useful for feeding young growing stock. The following is the composition of lucerne hay: Moisture, 14·3; ash, 6·3; Albuminoids, 14·7; Fibre, 33·7; Starch, Sugar, &c., 28·5; Fat, 2·6. Of these the following proportions are put down as "digestible":—Albuminoids, 9·6; Fibre, Starch, Sugar, &c., 28·9; and Fat, 1·0. Lucerne hay contains twice as much flesh formers as wheat and oat hay do, bout the same amount of fat, but two-thirds the mount of digestible Starch, Sugar, and Fibre.

"Coffee Tea" would appear to be "queer mixture," but it is really a "tea" (*i.e.*, an infusion) of prepared coffee leaves. It is said to be used by the Sumatrans, who practically live on boiled rice and coffee tea, doing an immense amount of work and undergoing much exposure to the weather. It is reported to give "immediate relief to hunger and fatigue." The leaves and twigs are "roasted" over a smokeless fire, then rubbed by hand into a coarse powder in which form it is ready for use. The *Chemist* is quoted to prove that coffee tea contains all the characteristics of the bean while richer in theine. The Editor of the *Queensland Agricultural Journal* pronounces coffee tea as "a pleasant refreshing beverage." For ourselves we confess a partiality for "tea tea" (not that we have tasted any other) particularly when prepared from Ceylon leaf.

Recorded by Mr. C. Drieberg.

GRAFTING THE MANGO.

(*Concluded.*

When the young shoots which have sprung from the grafts have ripened, the old wood projecting beyond the graft should be sawn off close at the base of the new growth. As the new wood continues to grow, it will cover up the entire end where it was sawn off.

To remove a section of the bark for grafting, first make a cut through the bark with a small saw at the two ends, then take a broad chisel, the level side being set towards the piece to come out, and give it a smart blow. Now turn the chisel over to the opposite side, repeat the blow, and the piece will fly out if the sap is at all active. Should the piece fail to come off, put the chisel into the saw cuts and raise gently. If it still sticks cut further into the original saw cuts, split out the wood with the bark adhering, and whittle the wood out of the section

that has been removed, by means of a sharp chisel, without injuring the bark. Do not be afraid of injuring your good tree by removal of pieces of bark; the wound will heal in twelve months' time, and instead of hurting, the process may make the tree more fruitful.

Apropos of this subject of making the mango fruitful, the writer of the paper from which we are making these notes, (Mr. Horace Knight) is led to conclude from his experience that root pruning rather than branch pruning is to be preferred. The object is obtained by checking the flow of sap underground, instead of mutilating the trunk and limbs. Of course root pruning would not apply to trees which have become barren through neglected cultivation, impoverished soil, or through any foreign agencies affecting the tree above ground.

The object of grafting a number of good (different) varieties on one stock, is to get a good "blend" by cross-fertilization, as the flower spikes of the different varieties being in close proximity to each other, the chances of getting a new type of fruit, combining the good qualities of the different varieties, are much more favorable than if the individual varieties grew at some distance apart as separate trees. When the seedling from the tree bearing the grafts fruited, this new fruit tree will be available for future grafting or budding.

We now possess fibreless fruits, which, while extremely handsome are almost tasteless, while others are full flavoured but uninviting while some have size though not flavour in their favour. Here is where skill and judgment are required, viz., to unite all the described qualities in one fruit.

SIR JOHN LAWES—HIS LIFE AND WORK.*

By the death of Sir John Lawes on the last day of July, 1900, Agriculture loses one of the greatest benefactors it has ever had.

Born in December 28th, 1814, in the old Manor-house at Rothamsted, Herts, where nearly 86 years later he died, the deceased baronet was the son of the late Mr. John Bennet Lawes, whom he succeeded in the paternal estates in 1822, at the early age of eight. After leaving Eton he proceeded to Oxford, and passed some time at Brasenose College. His inclinations, however, were not much in the direction of classical study, and he shortly found himself in more congenial surroundings in the chemical laboratory of Dr. Anthony Todd Thompson, at University College, London. On entering into possession of his hereditary property at Rothamsted in 1834, he at once began experiments upon plants growing in pots, the investigations being subsequently extended to the field. One of the most striking results observed in these early days was the excellent effect produced upon the turnip crop by dressing it with mineral phosphates that had been treated with sulphuric acid. At once grasping the importance of this discovery, Mr. Lawes, as he was then, obtained in 1842 a patent for the manufacture of superphosphate, and thus laid the foundation of a great industry.

In the following year was taken the decisive step of establishing at Rothamsted a properly equipped agricultural experimental station.

Simultaneously, Mr. Lawes secured the co-operation of a young chemist, Dr. (now Sir) J. Henry Gilbert, and the association which was thus commenced fifty-seven years ago has been attended by the happiest results, as the numerous scientific memoirs that have issued year after year from Rothamsted amply testify.

Two main lines of inquiry have been followed, the one relating to plants, the other to animals. In the former case the method of procedure has been to grow some of the most important crops of rotation, each separately, year after year, for many years in succession on the same land, without manure, with farmyard manure, and with a great variety of chemical manures; the same description of manure being, as a rule, applied year after year on the same plot. Experiments on an actual course of rotation, without manure, and with different manures, have also been made. Wheat, barley, oats, beans, clover and other leguminous plants, turnips, sugar beet, mangels, potatoes, and grass crops have thus been experimented upon. Incidentally there have been extensive sampling and analysing of soils, investigations into rainfall and the composition of drainage waters, inquiries into the amount of water transpired by plants, and experiments on the assimilation of free nitrogen. Lest any misunderstanding should arise as to the attitude taken up concerning the last-named subject, it may be useful to quote the following from the Memoranda of the Rothamsted Experiments, 1900 (p 7):—Experiments were commenced in 1857, and conducted for several years in succession, to determine whether plants assimilate free or uncombined nitrogen, and also various collateral points. Plants of the gramineous, the leguminous, and of other families, were operated upon. The late Dr. Pugh took a prominent part in this inquiry. The conclusion arrived at was that our agricultural plants do not themselves directly assimilate the free nitrogen of the air by their leaves.

In recent years, however, the question has assumed quite a new aspect. It now is—whether the free nitrogen of the atmosphere is brought into combination under the influence of micro-organisms, or other low forms, either within the soil, or in symbiosis with a higher plant, thus serving indirectly as a source of nitrogen to plants of a higher order. Considering that the results of Hellriegel and Wilfarth on this point were, if confirmed, of great significance and importance, it was decided to make experiments at Rothamsted on somewhat similar lines. Accordingly, a preliminary series was undertaken in 1888; more extended series were conducted in 1889 and in 1890; and the investigation was continued up to the commencement of the year 1895. Further experiments relating to certain aspects of the subject were commenced in 1898, and are still in progress. The results have shown that, when a soil-growing leguminous plant is

*Abridged from a paper by Dr. Fream in the R.A.S.E. Journal.—Ed. *A.M.*

infected with appropriate organisms, there is a development of the so-called leguminous nodules on the roots of the plants, and, coincidently, increased growth and gain of nitrogen.

The experiments with farm animals began in 1847, and have been continued at intervals nearly to the present time. Amongst the points that have been investigated are the following:—

1. The amount of food, and of its several constituents, consumed (*a*) in relation to a given live-weight of animal within a given time, (*b*) to produce a given amount of increase in live-weight.

2. The proportion and relative development of the different organs, or parts of different animals.

(3.) The proximate and ultimate composition of the animals in different conditions as to age and fatness, and probable composition of their increase in live weight during the fattening process.

4. The composition of the solid and liquid excreta (the manure) in relation to that of the food consumed.

5. The loss or expenditure of constituents by respiration and the cutaneous exhalations—that is, in the mere sustenance of the living meat—and manure-making machine.

6. The yield of milk in relation to the food consumed to produce it; and the influence of different descriptions of food on the quantity, and on the composition of the milk. Incidentally, the results obtained from the inquiries just enumerated have furnished data essential to the consideration of such problems as (*a*) the sources in the food of the fat produced in the animal body; (*b*) the characteristic demands of the animal—for nitrogenous or non-nitrogenous constituents of food—in the exercise of muscular power; (*c*) the comparative characters of animal and vegetable food in human dietaries.

Amongst the field experiments there is, perhaps, nothing of more universal interest than the field—known as Broadbalk Field—in which wheat has been grown for fifty-seven years in succession, without manure, with farmyard manure, and with various artificial manures. The results show that, unlike leguminous crops such as beans or clover, wheat may be successfully grown for many years in succession on ordinary arable land, provided suitable manures be applied, and the land be kept clean. Even without manure, the average produce over forty-six years, 1852-1897, was nearly thirteen bushels per acre, or more than the average yield of the whole of the United States of America, including their rich prairie lands—in fact, about the average yield per acre of the wheat lands of the whole world. Mineral manures alone give very little increase, nitrogenous manures alone considerably more than mineral manures alone, but the mixture of the two considerably more than either separately. In one case, indeed, the average produce by mixed mineral and nitrogenous manure was more than that by the annual application of farmyard manure; and in seven out of the ten cases in which such mixtures were used the average yield per acre was from over to two to over eight bushels more than the average yield of the United Kingdom (which is rather less than twenty-eight bushels of 60 lbs. per bushel) under ordinary rotation. It is estimated that the reduction in yield of the unmanured plot over the forty years 1852—1891, after the growth of the crops without manure during the eight preceding years, was, provided it had been uniform throughout, equivalent to a decline of one-sixth of a bushel from year to year due to exhaustion—that is, irrespectively of fluctuations due to season. It is related that a visitor from beyond the Atlantic, talking to Sir John Lawes in Broadbalk Field, said, "Americans have learnt more from this field than from any other Agricultural experiment in the world."

Another field experiment of singular interest is that relating to the mixed herbage of permanent meadow, for which seven acres of old grass land were set apart in Rothamsted Park in 1856. Of the twenty plots into which this land is divided, two have been left without manure from the commencement, two have received ordinary farmyard manure continuously, whilst the remainder have each received a different description of artificial or chemical manure, the same being, except in special cases, applied year after year on the same plot. No one can inspect this field during the growing season without being impressed by the striking evidence it affords of the influence of different manurial dressings. So much, indeed, does the character of the herbage vary from plot to plot that the effect may fairly be described as kaleidoscopic. Repeated analyses have shown how greatly both the botanical constitution and the chemical composition of the mixed herbage vary according to the description of manure applied. They have further shown how dominant is the influence of season. To such an extent, it may be added, is this the case that a given quantity of gross produce of the mixed herbage may be one thing in one season, and quite another in another season, both as to the proportion of the different species composing it, and as to their condition of development and maturity.

(*To be concluded.*)

SOME BIBLE PLANTS OF CEYLON.

Another tree familiar enough in Ceylon gardens is the Pomegranate (*Punica granatum*). Its fruit is mentioned in Scripture under the name of *Rimmon*. The tree itself corresponds with the *Rhoa* of Dioscordus and the *Side* of Homer. The pomegranate is a native of Asia and was common in Palestine. Moses, speaking of the Promised Land, calls it "a land of wheat and barley and vines, and fig-trees and pomegranates" (Deut. viii. 8), while the spies who searched the land are said to have "brought of the pomegranates and figs" (Num, iii. 23). Several towns and villages bore the name of Rimmon or pomegranate (see. Josh. xv. 32; 1. Chron. iv. 32; vi. 77; Zech. xiv. 10). Saul tarried under a pomegranate tree (1 Sam. xiv. 2) and the prophets Joel and Haggai refer to the pomegranate (Joel. i, 12 Haggai ii. 19). The tree must have grown in Egypt during the time of the Israelites' sojourn there, for when in the wildness of Zin, they lamented the loss of the pomegranate (Num. xx. 5).

The pomegranate (the *Pomum granatum* or grained apple of the Romans) belongs to the natural order Myrtaceae or the myrtle family.

The fruit is made frequent mention of in the Songs of Solomon, iv. 3, 13; vi. 7, 11; vii. 12 and viii. 2).

The fact that it was a favourite fruit in past times is evidenced by the fact that models of the fruits were used to adorn the capitals of pillars (see 1 Kings vii. 18, 20, 42; 2 Kings xxv. 17; 2 Chron. iii. 16, and iv. 13; Jer. lii. 22), while the common pattern of embroidery work for the border of the high priests' blue robe and ephod consisted of pomegranates with golden bells between them. (See. Exod. xxviii. 33, 34; xxxix. 24-26.)

Besides the use of the fruit for its refreshing pulpy seeds, various parts of the tree are used medicinally, especially the root bark and rind of the fruit for tape worm. The latter is also used for tanning the finer kinds of leather.

MULCHING.

Mulching is done with more than one object. It is done to protect the roots of plants from injury caused by freezing and thawing and to keep the soil at as even a temperature as possible, and, secondly, it is carried on in hot weather to prevent evaporation of moisture from the surface of the soil.

All fruit trees, says the *Fruit Grower*, in an interesting article on Mulches and Mulching, are the better if properly mulched, as also newly-transplanted trees. Old straw and forest leaves will do for the purpose, or any coarse litter may be used, even to fresh straw and coarse manure, and if nothing else is available, fine soil or ashes can be applied. In the case of small crops grown over any extent, the whole surface of the soil should be protected, while in the case of trees a circle of at least 3 feet in diameter around the stem should on an average be covered—the size of the tree of course determining the extent of the mulching. In some soils mulching is of greater benefit than others, but as a rule it will be found profitable to mulch all small trees and newly-transplanted fruit trees.

But if mulching is not properly performed it might also do harm, and we would, therefore, quote the following passage from the *Fruit Grower* for the benefit of our readers, in order that errors might be avoided in carrying out this very useful operation of practical agriculture:—

It is as well to point out one or two things with regard to the operation of mulching in dry weather, as there is no doubt that its influence and efficiency are greatly misunderstood. The one great reason why mulches are applied in the summer months of the year is to prevent evaporation of moisture, as it is taken for granted pretty generally that in hot spells the damp nature of the surface soil is changed to dryness by the action of the sun. It is argued, as a rule, that the sun dries out the top layer of earth, and as the result the growing crops suffer. Therefore, these reasoners continue, we must keep the soil damp by the use of a damp or moisture-laden material, such as stable manure, and it is piled on thickly around the stems and over the roots of fruit trees and bushes. Now, the argument does not meet our views, and we shall show that it is not the damp material that is needed, for a layer of any dry material will secure the desired end in a far more efficient manner. Have you not noticed that when the old stable manure mulch has been applied close up to the stems of the ordinary pea plants in rows, that mildew generally results from the application? We have again and again, and there can be no doubt that the hot, moist condition brought about by its use at the time referred to is generally attended with these results. This being so, the application must be taken to be a wrong one. We remember testing this method once on twice with sweet peas, treated as ordinary garden peas. We read that "the flowering period of sweet peas will be considerably prolonged by the application of a thick mulch of stable manure during the hot weather," and we followed out this suggestion just to prove that it was unsound. Within a few days of the mulch being given we found the mildew running up the stems, and it was worse where the manure rested against them. Peas of any kind are not likely to be improved by mildew, however slight the attack may be. Now what we want to point out is that if the grower wants to prevent evaporation, he can do so by using a supply of dry ashes of any kind, and that dampness in this respect is not a consideration. By the use of a dry material we not only prevent evaporation, but do so in a manner which prevents any injury whatever to the plants or trees treated. The layer of dry material coming, as it will when distributed, between the air and the earth prevents evaporation and is a clean and natural process compared to the use of manure as some advise. It is an error to suppose that wet damp grass, manure, cut vegetable growth, or wet leaves, are better than a dry material for retarding moisture evaporation from the soil. If it is put to the test it will be seen that the dry material is the best and most effective of all, and though at first sight it appears strange to argue thus, yet it is true. A dry mulch will do wonders in this respect, and the more it is used in hot spells the better, particularly when it replaces the old stable manure mulch.

TOMATOES.

The following notes are culled from an article on "The Tomato and its Culture" in *Garden and Field*:—

Raising Plants.—Procure a small shallow box, such as a blacking box, or the top four inches of a kerosene tin, or half a kerosene tin cut on the flat, or a six inch flower pot, according to the number of plants you want to raise. If the box be four inches deep put quite one inch of drainage. Broken brick, gravel or sifted cinders do well. Over these put a thin layer of coconut fibre, fine dry grass, or such material, and fill the box with a mixture consisting half and half of rotten leaves and sand, or half sand, quarter old rotted cowdung and quarter fine free soil. Moisten this thoroughly without

soaking it, with warm water, and sow the seeds one inch apart. See that the soil does not get dry. When the plants are two inches high, or have four leaves besides the seed leaves, they should be pricked out and transplanted into three inch pots (for a limited number) or put three inches apart in boxes or in a bed.

From here they are finally planted out as soon as they are found to have developed into sturdy plants, even up to the time they are 12 or 15 in. high with shortly stalks as thick as one's finger, and with crown blossoms and side branches.

The tomato does not require a very great supply of water, but it must have enough to sustain its health and vigour of vegetation. For preference, rich, warm, mellow, loamy soil is best, but with care the plant could be grown in almost any soil. For early crops a warm, well-drained soil and a sunny aspect, sheltered from the south, south-west and south-east are necessary. The land should be worked deeply and manured well, preferably with both cattle manure and artificial fertilizers. The Americans find that too rich a soil, or one which is highly fertilized is not desirable, such soils tending to produce a too rapid and too large growth of the vine, thus partially defeating the object in view, viz., a quick growth of the plant and a rapid developement of fruit. The active fertilizing matter should be concentrated within the reach of the roots. A soil not naturally very poor, in which the added fertility may be provided both as to place and time, as will best serve the purpose, is most desirable. A light sandy loam high and well drained is perhaps the ideal for tomatoes, provided the proper nourishment is given from artificial sources.

The plants are best set four feet each way. A well-proved American practice is to apply 400 lbs. of Superphosphate and 200 lbs. of Potassium chloride per acre and thoroughly harrow it in when the plants are being set out, from 100 to 150 lbs. of nitrate of soda per acre are applied to the places where the plants are to stand. Three or four weeks later another dose of 100 to 150 lbs. nitrate of soda is given, the nitrate being mixed with very fine soil to ensure proper distribution. In this way the plants are in a position to readily make use of the nitrogenous manure and respond splendidly to the treatment. The soil should be well worked till the plants begin to cover the ground.

Local growers seem to fight shy of artificial manures, and appear to think that they will harm tomatoes, but it is time they took the hint as to the use of artificials from American cultivators who are such successful cultivators of the plant. In New Jersey, the average yield for 2,500 acres under tomatoes is given as six tons per acre, though 12 and 15 tons per acre have been gathered from large tracts in some parts. With such experience surely credit should be given to the Americans for a knowledge of how to manure the tomato. At the rate given per acre, the proportion of artificial manures required for the small plots generally found in vegetable gardens should not cost more than a trifle.

In getting out long stemmed plants it is best to bend down the length of the stem and bury it also, leaving the crown of the plant to come out perpendicularly from the ground.

CULTIVATION OF THE ARECANUT IN BOMBAY PRESIDENCY.

[A note by Mr. J. W. Mollison, Deputy Director of Agriculture, Poona.]

(*Concluded.*)

The bunches on a tree ripen unequally. vhe lowest bunch first, the uppermost last. Moreover, in the same bunch some nuts may be ripe and yellow and others unripe and more or less green. The ripe nuts are much the same size and shape as small apples. The outer skin is yellow, smooth, and shining. The inner husk is very fibrous and not easily removed. The first process in preparing for market is to remove the husk. This is done very deftly by means of the *hattigatti*. It is an implement like a sickle. It is fixed at the heel end of its blade securely into a hole near one end of a plank somewhat in the same way as if it were fixed in a handle. The back of the blade at the bent part rests in order to steady it in a notch in the plank. The blade of the sickle is presented in an upward position opposite to the workman. He sits on the other end of the plank. The plank is about 3 feet long, 1 foot wide and 1½ inches thick. The husk from each nut is cut out in sections. A nut is grasped in the palm of the hand and pressed against the point and blades. The husk is thus cut through to the nut, then by leverage a section of husk is jerked off. The nut with remnant of husk is turned in the hand so quickly that to an onlooker the action appears involuntary, and another section of the husk is removed like the first. With four or five movements of this sort the whole husk is removed. A clever workman can husk 5,000 nuts per day, but 3,000 is nearer the average. The contract rate for the work is one anna per 1,000 with two or three meals per day. The husked nuts are scraped free of fibre also by the *matti-gatti*. The process is essentially a scraping process and costs at contract rates 1½ to 2 annas per 1,000. The scraped nuts are next boiled for about two hours in fairly large copper pots. A handful of lime or of the ash of the bark of matti (*Terminalia tomentosa*) is added to the water. The presence of lime causes the water to become red or red-brown in colour as the boiling proceeds. The water also becomes thick with a resinous extract from the nuts. The boiling is continued until the eye-bud or germ of growth from each nut comes out or becomes absorbed in the extract. The nuts are removed by a long-handled ladle (zrāa). The ladle has perforations in its bowl which allow the extract to drain from the nuts back into the pot. The extract is again and again used for boiling fresh supplies of nuts, pure water as required being added from time to time to prevent the decoction becoming too thick

and concentrated. The extract after being used for boiliug repeatedly becomes deep red-brown and thick. It is then emptied into another broad-mouthed vessel which is placed under full exposure to the sun. The mass by evaporation thickens and areca catechu or *kossa* is the product. The nuts after boiling are dried in the sun and sorted into three kinds, *chikni*, *betta*, and *gotu*. *Chikni*.—These are unripe fruits got mostly from the upper unripe bunches of the tree. They become flat when boiled, and when cut are light coloured and agreeably flavoured. They sell by retail at a high price, but by the growers are uuually mixed with other sorts to ensure a satisfactory sale of the produce. These nuts after exposure to the sun are again soaked in the red extract, a basketful being immersed at a time. They are again exposed daily to the sun for four or five days, but are gathered up at night, otherwise they get dark coloured. The nuts are exposed to the sun in cane matting spread on a *mandap*. Sometimes bamboos or other means of support are placed over the inner court of the household, and the matting spread over this framework. The nuts when dry are ready for market and should be shining and bright-red brown in colour.

Betta.—These are ripe nuts. They are dried after the first boiling and then hand-rubbed with fairly thick extracts to which 3 or 4 per cent of lime has been added. This tends to deeper the colour. The process may have to be repeated two or three times. The colour becomes fixed by drying in the sun after hand-rubbing. When ready for market they are somewhat lighter coloured than *Chikni* and not so glossy or shining. They are rounder and larger.

Gotu.—Tnese are fully ripe or overripe nuts. They are usually fairly well coloured by the first boiling aud after exposure to the sun for several days are ready for market. The colour may be deepened and improved by the same means as described for betta. The three varieties are usually packed together by the cultivators in sacks. Sirisi and Kumta are the chief markets.

Ordinary prices for three varieties are :—

Chikni	R6 to R7	per maund of 48 seers of 20 tolas	
Betta	3 to 4	ditto	ditto
Gotu	2 to 2½	ditto	ditto

Betel palms are not much affected with disease. A borer does considerable damage. The borers cut a tunnel from the root upwards and in time reach to the growing top. The damage there done is so considerable that the top withers and wheu wind blows breaks off aud falls to the ground.

ARTIFICIAL CHANGES OF PHYSICAL PROPERTIES OF SOIL.

(*Concluded.*)

We thus see that not only the structure of the soil but also its temperature may be affected by mechanical means. Change from separate grain structure to crumbly structure generally improves, though to a small degree, the heat conditions of a soil, principally by reduciug evaporation. Rolling the soil is more effective because it increases the conductivity of the soil for heat, and therefore, under normal conditions of weather, raises the temperature of the soil. Loosening the surface of the soil by harrowing, hoeing, &c., results, on the contrary, in a decrease in the temperature of the soil. By covering the ground with dead matter (mulchiug) the temperature of the soil is increased or decreased according to the behaviour of the covering toward heat. If, for example, a thiu layor of black material (coal dust, black clay slate, &c.,) is spread over the soil, the temperature of the soil rises to a considerable degree, and crops on soils so treated are accordingly benefitted. Although this process, for evident reasons, is not applicable to cultivation on a large scale, still with delicate plants, especially in horticulture, it may be used to advantage. Spreading a layer of sand or gravel over humus soils causes a rise in the temperature of the latter, and wholly or partially prevents the frequent night frosts which occur during spring in such soils. Mulching with dead organic matter (stable manure, straw, &c.,) may be used to lower the temperature of the soil during the warm portion of the year. By the same means, the influence of the temperature of the air is diminished, and the soil protected from all excessive changes in temperature. This is due to the fact that all the materials mentioned are poor conductors of heat. Allowing stable manure to remain spread out during the warm months on the surface of the soil for some time before it is worked into the soil may unfavourably affect the moisture of the soil. In the colder portion of the year, however, it may be beneficial on account of its influence in raising the temperature of the soil. Under such conditions, however, the covering of manure may exercise a harmful influence on fine-grained clay soils rich in humus by preventing the loosening effect of frosts, which is so important for such soils. Beneficial results may be obtained by thinly spreading a mulch in the late fall over fields occupied by perennial forage plants, thus protecting the plants against low, and especially changeable winter temperatures. As, however, such a covering retards warming of the soil, the undecomposed remains of the mulch should be removed as soon as the temperature begins to rise in the spring. Keeping in mind the fact that covering the soil in this manner retards warming in spriug, this practice may also be utilised to retard the blossoming of fruit trees, thus diminishing or preventing damage from late frost. If the ground surrounding the trunk is covered in spring with a heady layer of straw the temperature is kept low, and in consequence the amount of water received through the roots is small, so that the development of the leaves and especially the blossom is retarded for several weeks, or until the organs of reproduction are then in little danger of freezing. Finally, the practice of keeping fields fallow (*i.e.*, without crops) is a means of increasing the temperature of the soil during the warm season. When the rise in the temperature is accompained by an increase in the water content of the soil decomposition of organic materials is promoted,

and a greater or less quantity of plant food may be leached beyond the reach of the plants by heady rains.

CHILLIES.

In discussing the possibilities of Chili cultivation in North-East Australia, the *Queensland Agricultural Journal* furnishes a good deal of useful information on the subject:—

Why should not Queensland enter upon the production of chilies on a commercial scale? The capsicums grow luxuriantly in all parts of the coast country, and bear fruit almost all the year round. Their cultivation affords far less labour than the cultivation of cereals, sugar-cane, or, indeed, of any other farm crop except Sisal hemp. The plants should be set at a distance of 4 feet in the rows, and from 5 to 6 feet between the rows. They will grow on almost any kind of soil, but prefer a dry, rocky soil with sandy loam, containing some lime. It is difficult to arrive at a correct estimate of the yield of the dried capsicums from a well-grown shrub during the year. Some estimate the annual return at 2 lbs., others say that 3 lbs. and even 4 lbs. may be reckoned on. The selling price of dried chillies in the London market varies from £18 to £34 per ton according to quality—for instance, in April, 1899, fair red Zanzibar sold at 29s. 9d.; good red Japan at 33s, 6d. to 34s. per cwt. The present wholesale price in Brisbane for dried chillies is 1s. per lb., equal to £112 per ton. A sample of capsicums grown in the West Indies, dull and uneven in colour, was valued at 20s. per cwt. What is evidently required is an article bright in colour, even in quality, and possessing great pungency.

The Government Botanist has received a sample of large red, sweet capsicum dried in such a manner that the skin is perfectly transparent and the seeds inside are quite dry, and can be shaken like the dried peas in a "rattle-pod." We have no information as to how the specimen was dried, whether naturally or artificially, but the pod was certainly not opened previous to drying.

A consignment of capsicums prepared in this manner would, no doubt, bring a good price in the English market. Another enticing method of preparing chillies for export is to bottle the long red variety in a solution of salt and water. This preserves the shape and colour of the fruit, and gives it a very attractive appearance.

The Bulletin of the Botanical Department, Jamacia, says on the subject of chillies:—"Pod peppers or capsicums, the fruits of *Capsicum annuum* and allied species, are a well-known spice and condiment. They are an indispensable ingredient in curries, and are largely consumed in the fresh and dried state and in pickles. Some forms of capsicum known as Bell peppers are entirely free from the acrid and burning pungency so characteristic of these fruits, and may be eaten cooked as a veges table or in salads.

Chillies, Bird or Guinea Peppers, the fruit of the shrubby *Capsicum minimum* (usually much smaller than the preceding) grow generally in tropical countries. These are in chief demand in commerce. When thoroughly dried and pounded, and afterwards passed through a hand-mill and sifted, they are the principal source of the well-known Cayenne pepper.

It is estimated that about 100 tons of dried chillies are annually received into England from the West Indies and the East and West Coasts of Africa.

In the *Kew Bulletin* (1892, p. 88) the following information respecting chillies was given in an article on the Agricultural resources of Zanzibar, contributed by Sir John Kirk:—

"The small red peppers, or chillies, are largely grown in the more dry and rocky part of the Island, where the upheaved coal presents a honeycombed surface that favours the accumulation of rich soil in the crevices. The pods are picked when ripe, sun-dried, and packed in neat bags made of the split fronds of the *Hyphæne* palm for shipment. This is an industry that has sprung up within the last thirty years."

Zanzibar chillies, as they appear in the market in a dry state, are small, red, thin, carrot-shaped fruits about 1 inch in length.

The following further particulars are contained in a report on the spice and other cultivation of Zanzibar and Pemba (F. O. Report, 1892, Misc. Series, No. 226):—

"The pepper plant growing in the island is *Capsicum minimum*, usually termed the 'shrubby capsicum,' and producing the bird's-eye chillies forming the basis of cayenne pepper. This is to be found in a small degree in every shamba, but the principal source from which the annual exports are derived is the eastern side of Zanzibar, and the cultivation here is chiefly in the hands of the Wahadinu people.

"Judging from observations made during my brief visit to this portion of the Island, east of Dunga, the chillie cultivation struck me as being of a very scattered nature, generally small isolated patches from half to 1 or 2 acres in extent, and combined with tobacco, tomato, pumpkins, &c. I regret my inability to quote the annual total exports, but I believe they are large, and an undoubted source of revenue. As the chillie is, as yet, the only product of any value grown in this less favoured portion of the island, I consider that this cultivation could be extended and that a little fostering care must be productive of much advantage, It is a cultivation easily carried on, and calling for no special trouble or skill, and the returns are certain and profitable. At present the people are so blind to their own interests as to purposely depreciate the value of this product. I understand, through fear of possible shortage by theft on the way down, owners actually damp the chillies before despatching, and it is often necessary, on their reaching the Government Customs godowns, to dry them as quickly as is possible as the only chance of saving them.

"Another variety of pepper (? *Capsicum annuum*) bearing a larger red and yellow pod is

also cultivated, but the produce from this is all consumed locally."

The latest account of Zanzibar chillies is contained in the report of Mr. Consul Cave, on the trade and commerce of Zanzibar, for the year 1897 (Foreign Office, 1898, No. 2129 Annual Series):—"The production of chillies has risen from 16,336 frasilas in 1896 to 17,698 frasilas in 1897, an increase of 77,670 lb. The average price was 2 dollars 37 cents per frasila, as against 2 dollars 57 cents per frasila during the previous year.* A better price than this could doubtless be obtained for Zanzibar produce if a little more care and attention were devoted to its cultivation and harvesting, but up to the present time it has been allowed to grow almost wild on the coral outcrop which covers the eastern portion of the island, and the slight personal discomfort which attends the handling of pods prevents the native from exercising any care in its picking and subsequent preparation for market. Attempts have lately been made to obtain a better sample on ground which has been specially cleared and prepared for the purpose, but the results are not yet to hand."

JAPANESE CHILLIES.

In a note on Recent Additions to the Museum of the Pharmaceutical Society (*Pharm. Journal*, 11th December, 1897), Mr. E. M. Holmes, F.L S., furnished the following interesting particulars, at an evening meeting of the Society, respecting Japanese and other chillies:—

"During the last three or four years there has been in commerce a very bright red variety of *Capsicum minimum*, Roxb. (*C. fastigiatum*, Bl.), said to be imported from Japan. In consequence of its clean, bright and attractive appearance. it has commanded a higher price than other varieties. Mr. J. C. Umney has recently directed my attention to the fact that this variety is less pungent than the Sierra Leone and Zanzibar varieties, although far superior to them in colour. On further inquiry I find that this fact is well known to drug and spice brokers. Mr. Umney points out that when an alcoholic tincture of either the Japanese or Zanzibar varieties is diluted with about 14 parts of water, the former gives a much clearer solution than the latter, indicating less oily matter. All the bright red Cayenne pepper until recently in commerce is said to have been imported from Natal in that state. The entire pod pepper imported from Natal is a variety of *Capsicum annuum*, much larger than the chillies, and of a dark red colour and very pungent, whereas the powdered Japanese and Natal Cayenne peppers, placed side by side, are indistinguishable in point of colour. The other principal varieties of chillies, at present in English commerce are, I am informed, those of Sierra Leone and Zanzibar, the former being of a yellowish-red tint, and the letter of a dull, dark red, and often of inferior quality, containing badly dried fruits, stalks, and foreign matter, but both are more pungent than the Japanese kind. The latter is, however, quite pungent enough for most people, although perhaps unsuitable, by reason of its lesser pungency, for medicinal purposes, as an outward application, &c. I am indebted to Mr. Young, of the firm of Messrs. Dalton and Young, for information concerning the different commercial varieties and for specimens illustrating them. My object in directing attention to these commercial varieties is to point out to students and to retail chemists that there are often differences in the qualities and appearance of the same drug, which are worthy of careful observation, not only from a scientific, but from a commercial point of view. Nepal Cayenne pepper is made from a small variety of *Capsicum annuum*, and is remarkable for its violet odour. Neither this kind nor the Zanzibar gives a red, but a brownish, powder.

The following comments on Mr. Holmes' paper were made at the meeting by Mr. MacEwan:—

"The subject of cayenne pepper was interesting to many chemists quite apart from medicinal purposes, probably more capsicum being sold for feeding birds than for any other purpose. The pepper used in that way was tasteless, and seemed to contain a large amount of fatty matter. It was dark in colour, and the object was to highten the colour of the feathers. It was supposed to come from *Capsicum aunuum*, and he should much like to know where it came from. It was only supplied by two or three houses, and attempts by others to obtain it had not been very successful. There was no doubt that the pepper as used was an untreated product. The late Dr. Brady, on his return from Japan, passing through Vienna, came across a comparatively tasteless pepper, which caused considerable discussion at the time, as there was a large amount of it on the market, but the substance had been pretty much lost sight of since. He thought it would well repay inquiry, as very little had been done on the subject of peppers since Dr. Thresh dealt with it about eighteen years ago."

According to a writer in Spons' "Encyclopædia," Div. V., p. 1803:—

"Several varieties of *C. annuum* have little or no pungency; one of these is abundantly grown in Hungary, forming the paprika of the Magyars. Another variety, cutivated in Spain, is imported into this country in powder for giving to canaries, to improve the colour of their feathers. The Nepal capsicums, which have an odour and flavour resembling orris-root, are the most esteemed as a condiment."

* A frasila=35 lb. avoirdupois.

The TROPICAL AGRICULTURIST
MONTHLY.

XX. COLOMBO, DECEMBER 1ST, 1900. No. 6.

SOME CATERPILLAR PESTS OF THE TEA PLANT.

TOWARDS the end of last year (1899) there were numerous complaints, more particularly from the Dikoya district, of serious and repeated injury by the small leaf-twisting caterpillar known as the Tea Tortrix. It was suggested, by the then Chairman of the Planters' Association, that a circular on the subject would be of assistance to the planters. Having insufficient data for the purpose, I asked for further particulars and dates of recent visitations of the pest, together with memoranda of the total monthly rainfall in the districts concerned. In response to my request a circular letter was sent to the various branches of the Planters' Association asking for the required information. In due course a large packet of correspondence, the result of this circular letter, was submitted to me by the Secretary of the Planters' Association. It appears, however, that in the letter in question the pest was referred to as "The Caterpillar Pest;" and it was at once evident, from the nature of the replies, that each observer had applied the term to the particular pest that had been the most notorious in his district; and that the correspondence referred to some five or six distinct species of caterpillar. Under these circumstances I have thought it advisable to draw up a circular on Tea Caterpillars in general, giving detailed particulars of those species that rank as really serious pests. This plan will be quite convenient, as the general treatment suggested will be practically the same for all the different species.

As a rule, caterpillar pests are of less real importance, and much more readily controlled, than are many less conspicuous plagues, but there are some notable exceptions.

It will be well to briefly outline the life-history of insects of the Order *Lepidoptera* (Butterflies and Moths), of which the caterpillar is but one of the earlier stages. The series consists of (1) Ovum, or Egg; (2) Larva, or Caterpillar; (3) Pupa, or Chrysalis (often enclosed in a cocoon); and (4) Imago, the Butterfly or Moth. This constitutes the single generation. A thorough knowledge of all these different stages is of great importance in the study of any injurious caterpillar. Such knowledge enables us to determine which may be the most vulnerable stage in the life of our enemy.

The destructive time is in all cases the caterpillar period, and to this stage, therefore, the chief attention must be paid.

With most of our caterpillar plagues in Ceylon a definite rise and fall is noticeable, commencing with a small brood, limited very possibly to three or four tea bushes only. Unfortunately this initial brood is almost invariably over-looked. Prompt measures at this time would prevent all further trouble. But these pioneer caterpillars are allowed to go through their transformations and eventually emerge as moths capable of reproducing their kind perhaps a hundred-fold. They distribute themselves throughout the surrounding tea, and pregnant individuals may be carried to distant quarters of the estate by the wind. They deposit their burden of eggs and die. In due course—varying according to the individual species from three or four weeks to as many months—a second and larger brood appears, very probably starting from several distinct centres. Even this more extensive brood may possibly not attract very much attention. The coolies observe a number of caterpillars about, but do not consider it their business to bring it to the notice of the superintendent. The consequence of this inattention is that a few weeks later the caterpillars appear in such countless numbers and effect such serious damage that it is impossible to overlook their presence. The superintendent becomes alarmed, collects and destroys as many of the caterpillars as he can, and probably prunes down the affected field

and burns the prunings, which is certainly the best thing to be done under the circumstances. But a large proportion of the insects is sure to escape, and a fourth or even fifth extensive plague of the caterpillars may appear at regular intervals. But a period is sure to arrive—varying usually from the third to the fifth brood—when the pest appears to reach its climax and to disappear as suddenly as it came, giving no further trouble perhaps for several years. This relief may be brought about by several circumstances. The natural enemies of the caterpillar (Ichneumon wasps and Tachinid flies) discover the plentiful supply of food and increase proportionately until they obtain the upper hand once more. A peculiar epidemic, allied to or identical with the disease that is sometimes so destructive to silkworms, often kills them wholesale, and is usually the principal agent in reducing the pest. This disease appears to be very infectious. Caterpillars killed by it become rotten and have a very offensive smell. The spores of the disease are distributed over the leaves of the plant and are eaten by the other caterpillars, which die in their turn. Fortunately the disease does not—as far as we know—affect the higher animals, but the process of tea manufacture would in any case purify the leaf. Weather is also probably an important factor in the rise and fall of these caterpillar pests. Though it may not directly affect the caterpillar itself it may have a very appreciable effect upon the enemies of the caterpillar. Thus, the damp warm atmosphere following copious showers of rain is particularly favourable to the growth and spread of the fungal epidemic mentioned above.

Remedial Measures.

In the case of leaf-feeding caterpillars considerable success has been obtained in other countries by spraying with mineral (usually arsenical) poisons. The Americans have paid great attention to these preparations, such as arsenate of lead and "green arsenoid," and are manufacturing them at rates that permit of their being freely employed. I have hitherto never recommended the use of mineral poisons for spraying tea plants, fearing the (possibly very remote) danger of the mineral accumulating in portions of the manufactured tea in poisonous quantities. But I now consider that all risk might be obviated by a simple precaution, namely, to stop plucking for a sufficient time after the application—10 days would be enough—to make sure that the plucked leaf shall have developed since the date of the application. Spraying could therefore be done immediately after a field had been plucked. The actual leaves that will be taken at the next round will be still in bud at the time of this application, and will unfold in the usual interval. These leaves will be quite free from any trace of the poison.

The most convenient form of sprayer is the knapsack type, which can be easily worked by one man with a second man to feed it. If arsenate of lead is to be employed as a spraying mixture, it may be used at the rate of 1 lb. to 100 gallons of water. The poison should be first made into a thin paste, and the rest of the water added subsequently. The addition of powdered lime (in equal weight to amount of the arsenate) is said to prevent any injury to delicate foliage.

Moth traps of the following description will often destroy a large number of the winged insects. A small coconut oil lamp is placed in the middle of a large tin tray or basin containing water with a film of kerosine floating on the top. The moths are attracted by the light and fall into the water, where they are killed by the film of oil. This trap will be of use only when the moths are on the wing. It will be found more effective on dark still nights, and should be placed well away from any counter attraction in the shape of bungalow lights. It will be useless during moonlight, it being a well-established fact that few moths are on the wing at such times.

But the good old rule that "Prevention is better than cure" is particularly applicable in the treatment of insect pests. As has been shown above, plagues of caterpillars are subject to more or less regular fluctuation, increasing until a certain climax has been reached, and then practically disappearing for a term. This disappearance is not complete. There must always be a few individuals carrying on the breed; their increase checked for a time by causes that are only partly understood, such as climatic conditions, natural enemies, and parasitic diseases, &c. It should be our aim to assist these natural checks by keeping a look-out for and destroying any caterpillars that may be seen during what we may call the "off season." The pluckers should be instructed to always remove and crush any twisted or folded leaves observed on the trees, and if any of the larger species of caterpillars are seen the tree should be marked and the fact reported to the superintendent, who should most carefully search that and the immediately surrounding trees and destroy every individual caterpillar found there. With plucking continued throughout the year, every single tea bush must pass under the hands of a cooly at intervals of about ten days, and if this system of observation is properly carried out it would seem almost impossible for any caterpillar pest of the tea plant to get out of hand. I cannot lay too much stress upon the importance of great attention throughout this off season or resting period, when the tea seems to be most free from attack. It is at such times that the planter is apt to be off his guard.

When caterpillars have to be collected by hand, they may be conveniently destroyed by placing them in a mixture of phenyle and water (1 to 20).

The following species have at different times come under observation as serious caterpillar pests:—

*1. The "Pale Tea Tortrix," *Capua menciana* Wlk.
*2. The "Variegated Tea Tortrix," *Capua* (undetermined species).
3. The "Leaf Roller," *Gracilaria theivora*, Wlsm.
4. The "Blue-striped Nettle grub," *Parasa lepida*, Cram.
5. The "Morowak korale Nettle-grub," *Thosea recta*, Hampson.
6. The "Green Nettle-grub," *Thosea cana* Wlk.
7. The "Fringed Nettle-grub," *Natada nararia*, Moore.
8. The "Red Slug," *Heterusia cingala*, Moore.
9. The "Small Bagworm," *Manatha albipes*, Moore.
10. The "Large Bagworm," *Clania variegata*, Snell.
11. The "Twig Caterpillar," *Boarmia bhurmitra*, Wlk.

No. 1.—The "Pale Tea Tortrix," *Capua menciana*, Wlk.

Eggs: not known. They are probably concealed at the base of the buds of the plant.

Caterpillar: dull green or greenish white, with a shining black head and a black horny patch on the back of the second segment. There are about 12 minute tubercles on each division of the body, from each of which springs a fine bristle. When full-grown the caterpillar is about ¾ inch long.

The larval stage occupies about a fortnight, after which the caterpillar fastens two leaves firmly together and turns to a dark mahogany-coloured chrysalis.

---

* Since the above was written and set up in print, specimens of Tea Tortrix have been kindly examined by Mr. J. Hartley Durrant, F.E.S., who reports that the supposed new species is not really distinct from No. 1: and that both these species should be referred to an earlier name,—*Capua coffearia* Nietner.

The moth usually appears in from seven to ten days' time, though one of my correspondents tells me that he has known twenty days to elapse before its emergence. It is an inconspicuous insect. The fore-wings of a pale reddish-ochraous colour, with some indefinite diagonal lines The hindwings straw-coloured, without markings. The expanded wings of the female measure nearly one inch. The male is somewhat smaller and of a darker tint. When at rest the wings are folded so that their outline is like that of the section of a bell.

The caterpillar of the Tea Tortrix makes itself obnoxious by its habit of spinning two or three tea leaves together and feeding upon the enclosed parts. When the pest is at its worst, the leaf may be destroyed over whole fields of tea, resulting in a very serious loss of flush. This species attracted notice ten years ago, and was reported, at intervals, from different parts of Dikoya and Dimbula.

More recently a distinct species has come into prominence in the same districts.* It may be called—

No. 2—THE "VARIEGATED TEA TORTRIX," *Capua* sp.

The carterpillar is scarcely distinguishable from that of No. 1. It is of the same pale-green colour, but the dark horny patch on the second segment is larger extending over the sides as well as the back of that segment.

The difference is more apparent in the moth, which is considerably smaller than that of *Capua menicana* being little more than half the size of the latter. It is of a brownish colour, with a blackish spot at the middle of the front (costal) edge of the wing, a curved reddish-brown patch across the middle of the wing, and a similarly coloured patch across the extreme tip. There is a very prominent tuft of scales which projects on each side from the base of the wings when they are folded.

From correspondence received, the pest seems to be most in evidence during the period from October to the following April. It is noticeable that the worst attacks are reported in alternate months, viz., October December, February, and April. I do not find that the amount of rainfall has any very marked effect upon the prevalence of the pest. Returns from an estate in Dikoya show that there was a very bad attack in October, a wet month, during which 23.73 inches of rain fell on 24 days. The previous month had also been wet, 13·78 inches falling on 19 days. The next bad attack was in the first half of December, with only 5 wet days, after a comparatively dry November.

A report from Pundalu-oya notices a severe attack in February-March, both dry months, following a dry January. On this occasion the pest was said to disappear with the April showers.

It would appear that the caterpillars are not directly affected by the weather, though they may be indirectly so. For when—as often occurs at the climax of the plague—an epidemic attacks them, the most atmosphere during rainy weather will be most favourable to the rapid growth of the disease. And this I have repeatedly found to be the case.

The districts chiefly affected by this particular pest are Dikoya, Dimbula, Pundalu-oya, and Ambagamuwa. The following quotations from correspondence will give a good idea of the destructive habits of the insect:—

"Dikoya, 17th December, 1899.—The fields attacked are generally three to six months after pruning, just when the very best flushes are coming on..... I collected in cooty sacks the eaten leaves and burnt and buried them, often burning 400 to 500 lb. a round .....On Friday last I had 80 pluckers, and we did 20 to 25 acres, and collected and buried 500 lb of this leaf. It is a great loss and delays all the work, besides the extra expense in collecting and burying. We have had these visitations before, but I have never seen it so bad as it has been this year, and it materially reduces the yield. I pluck regularly so as to try to keep ahead of the caterpillar, but so far have not succeeded in keeping it under."

"Hatton, 3rd February, 1900.—Period from brood to brood of the carterpillar pest: three months. Duration of chrysalis stage: 20 to 21 days. [This is an unusual length of time; in my breeding cages moths appeared after 8 days,—E.E.G.J..... The pest does not seem to be much affected by weather, as the caterpillar glues leaves together with silk, and so is not much washed by rain. It prefers a sunny slope, and is not so marked where tea is exposed,"

"Pundalu-oya, 7th May.—I always notice that after the first spell of wet weather the caterpillars seem to die off. This season the attack began in December, earlier than usnal, owing to failure of north-east monsoon rains, I had the caterpillars on surface of bushes thoroughly removed every 8 days when field was plucked, but it was impossible to get all those in centre destroyed: coolies could not see them, nor could I. The effects, however, were manifested later on by the riddled appearance of bushes.....Here the Tortrix only attacks tea 9 to 12 months after pruning, just when it should be flushing its hardest, I calculate I have lost from 30 to 50 lb. made tea per acre on the 50-acre field attacked this season,"

It is evident, from the above correspondence, that when once the pest has reached the destructive stage, it is practically impossible to keep it under by hand-picking alone. It will run its course and die off from natural causes after reaching its climax. But I must again repeat that by proper attention during the off-season the pest may be prevented from getting ahead. When it has become widely established the most likely means of checking its course would be to spray the trees—as suggested above—with arseuate of lead, Paris green, or some similar poison, immediately after a round of plucking, the bushes being then allowed to run for from 10 to 12 days before next plucking. The leaf then plucked will have developed since the application and will be quite free from the poison. In the meantime—if the work has been thorough—most of the caterpillars should have died from eating the poisoned foliage.

No. 3.—THE "LEAF ROLLER, "*Gracilaria theivora* Wlsm.

Egg: deposited singly on the under surface of the leaf.

Caterpillar: pale yellow or greenish, with an indistinct darker line along the middle of the back. A few short colourless bristles scattered over the body. Leugth about three-eighths of an inch.

Moth: fore-wings dark purple-brown, shining with iridescent tints and crossed by a triangular yellow patch; hind-wings dull black; front of head bright yellow; thorax purple brown; abdomen black above yellow beneath.

The life-history of the insect is interesting. The following description is extracted from my early work on "Insect Pests of the Tea plant" (p. 62):—

"The egg is deposited by the parent moth on the under side of the leaf. As soon as it is hatched the young caterpillar burrows into the tissue of the leaf and passes its early life as a leaf-miner. Its track is visible on the under side only, and always terminates on a small pocket formed by folding over a portion of the edge of the leaf. In this recess the caterpillar sheds its skin, after which it deserts the burrow and takes to the leaf-rolling business. If the leaf in which it has been mining is still tender enough for its purpose, it sets to work on the spot; but should this leaf be too old and hard the caterpillar will travel along the shoot to the nearest soft one and roll it up from the tip to about the middle, fastening the sides together with silk. Within this shelter the insect passes the remainder of its larval period, feeding upon the inner folds of the leaf. Sometimes two or more of the larvæ live together, but usually each roll is occupied by a single tenant. When abont to change into a chrysalis, the caterpillar spins a flat silken cocoon in a shallow depression on the leaf. After about two

* See foot-note on page 372.

weeks the moth appears. In this stage it may be observed running about upon the tea leaves, or resting with the head and anterior parts erected and the body supported by the first two pairs of legs only, the other legs and the antennæ being closely folded along the body. Several species of Ichneumon wasps prey upon the caterpillar. In wet weather many of the caterpillars are drowned by the water that accumulates in the cavities of the rolled-up leaves."

This insect does not often assume the importance of a pest, though it is always present in moderate quantities. But I have on more than one occasion received notice of rather serious attacks from the Badulla, Bandarawela, and Udapussellawa Districts. I quote from a recent letter giving particulars of one of these attacks:—

"Bandarawela, 6th January, 1900.—The leaf-roller was prevalent here last season to a marked degree. It seems to appear on the arrival of the north-east monsoon. The injury became very noticeable about January. Every affected leaf was plucked off—as advised—and I found by about the end of February that the pest had disappeared, partly owing to my having pulled off the rolled leaf and partly owing to the grub being drowned by the rain. On the setting in of the last north-east monsoon I noticed the caterpillar again starting work. I immediately gave to each of the pluckers a cooty sack to contain all the rolled leaves, which they were instructed to take off. I am pleased to say the estate is now practically free. I notice that the grub makes specially for young leaf on young tea. Into the older tea it has made very little incursion."

For this pest hand-plucking is the only practical remedy. The caterpillar is too well protected to be reached by any insecticide. The fact that in rainy weather it becomes drowned in its retreat suggests that a plentiful spraying with plain water might bring about the same happy result, but such spraying would have to be repeated many times to produce anything approaching the conditions of a rainy season.

"Nettle-grub" is a popular term applied to a certain family of caterpillars provided with tufts of stinging hairs. When the caterpillars are accidentally or carelessly handled the sharp points of these hairs enter the skin, break off, and at the same time some of the highly irritant fluid that occupies the swollen base of the hair is expressed into the wound. This action has its advantages as well as its disadvantages from our point of view. The coolies, when plucking the tea bushes, will become quickly apprised of the presence of the caterpillars: the spot can be marked, a careful search made at once, and the brood exterminated before it spreads. Four separate species of these "Nettle-grubs," have attracted attention as pests within recent years.

No. 4.—The "Blue-striped Nettle-grub," *Parasa lepida*, Cram.

Eggs: laid in clusters of from 15 to 20, closely overlapping each other like the scales of a fish, which they resemble also in their flattened oval shape. They are almost transparent; the embryo can be seen through the shell.

Caterpillar, broad and comparatively short; rounded in front and behind: bright yellow-green, with a rich lilac stripe along the middle of the back and a bright blue stripe on each side, each stripe bordered by a darker line of the same tint. The poisonous spines are arranged in tufts along the body; they are pale green, four tufts near the head and another pair near the tail tipped with scarlet; there are four large black spots at the hinder end of the body. Specimens that have been feeding upon tea are much more brightly coloured than those that have been reared upon coffee leaves. The latter are ornamented with green stripes and spines upon a pale greenish ground. They might easily be mistaken for a distinct species. The legs of these caterpillars are rudimentary.

Cocoon, hemispherical, dark brown, closely resembling the tea stems upon which it is usually placed; thin, but very compact. The chrysalis is contained in this cocoon.

In from four to five weeks the moth makes its appearence, escaping from the cocoon by a lid-like opening at one end. It is a pretty insect; the fore-wings chocolate brown with a broad emerald green band stretching obliquely across them; the hind-wings buff, tinged with chocolate at the margins; front and sides of the thorax emerald green: and a small spot of the same colour at the base of the two front legs.

The caterpillars are gregarious, and are sometimes present in such large numbers as to completely defoliate the trees upon which they are feeding. A neighbour who sent me specimens told me that more than fifty of them had been removed from two adjacent tea bushes. In another instance, a group of four or five trees were left quite bare, and the superintendent, searching for the cause of the mischief, received practical demonstration of the stinging properties of the caterpillars.

I have had no recent complaints of damage from this species. It usually confines its attacks to a few trees only. The grubs when found should be removed and destroyed, but under the circumstances some other method than hanopicking will be found advisable.—*Royal Botanic Gardens.*

(To be concluded.)

GREEN TEA—HOW TO MAKE IT.

I have read with interest the various letters that have appeared in your columns lately on the above subject, and, being an old green-tea maker myself, a few words of advice from me might be of use to those intending to try their hands at it. In my opinion, there is no necessity to make the slightest alteration in existing machinery, or in any way add to it; nothing could be better than a sirocco at a rather high temperature for withering the leaf. Treated in this way the leaf is in a far better condition for rolling than steamed leaf, and will keep for hours in the wet state without showing the least sign of fermenting.

There is no reason why every planter, when he finds himself blocked with leaf in very wet weather, as often happens (and, *is one of the chief causes of poor quality owing to an imperfect wither leaf being kept too long*), should not turn some of the leaf into green tea, and thus get rid of the excess and make better black teas of the balance. But, though this would be very convenient and useful to many during the worst months of the monsoon, it would never do to depend on it entirely for all the green tea we want to make.

We wish to capture a market already occupied by China and Japan, and to do this we must make tea that will equal theirs in appearence, as well as beat it in purity and strengh, and, to do this, we must alter our system of plucking and pruning. Anyone wishing to make green tea should set apart a portion of his estate to be treated exclusively for green tea and in doing this it is well to remember that the large leaf indigenons is not so well suited for green tea as the China or (so called) low-class hybrid jat. Most of the older estates in Ceylon have fields of this class, and these are the fields that should be chiefly devoted to green tea.

In plucking for green tea, the Chinese never pluck the shoot with the stalk, as we do for black tea. They take the tip and then the leaves, the stems being left on the bushes. *They do this even for their finest quality black teas, and, if we did the same, we should doubtless yet better prices and there would be no need to make green tea at all, as this system of plucking would in itself reduce the yield fully 20 per cent.*

But, though this would be a very simple way out of the difficulty of over-production, planters are not likely to adopt it on a large scale, yet for green

tea it is *necessary*, as it is practically impossible to get a twist on such wet leaf. If the leaves are attached to the stem, many of these shoots will be found to have rolled into a big ball without separating at all; but the system of plucking as described above renders more frequent pruning necessary, though of course, not so heavy as is usually done in Ceylon. This reminds me to say that I firmly believe this heavy pruning is at the bottom of all our troubles. We hack our bushes down in a most unmerciful manner, in order to make them run 18 or 20 months (*hacking is the only word for it—we can't call it pruning*); and the result is we have to wait 6 or 7 weeks before we can begin plucking; and then, for the next two months or more, we get leaf that is *utterly useless* for making tea, and if shipped by itself, would barely realise enough to cover costs. This is the leaf that should be destroyed if any, but what I say is DON'T GROW IT.

By pruning lightly every year, we should avoid all this useless rubbish, and I don't think we should lose anything in quantity, as a lightly pruned bush is ready for plucking in about a month, and begins at once to give big and regular flushes, whereas a heavily pruned bush not only takes longer, but after all the pruning shoots have been gathered, it takes a rest for another month or so before it begins to yield big and regular flushes; so that, in the one case there is a loss of two-and-half to three months as compared with a loss of only one month. Heavy pruning is necessary only once in five or six years.

I am glad to see that the Indian planters have at last made up their minds to do something to relieve the London market; but, even now they don't seem to have hit upon the right way—which is to capture the local market. I had some experience of that years ago, when I was myself an Indian planter, and I am positive, from what I saw and heard then, that, if the planters would set about in the right way to introduce their tea to the native community, 50,000,000 lbs. would not suffice to supply the demand that would soon spring up. Can't we manage to persuade them to do this?—OLD CHA. in *The Times of Ceylon*.

TROPICAL PRODUCTS.

A Demerara paper of recent date contains the following relative to cultivation of tropical products as pertinent here in these islands as there.

Persons unacquainted with the past history of the colony are continually asking "Why don't you grow coffee?" or why not cultivate fifty other things? They hand you a long list, including cotton, cacao, rice, spices, and even ground nuts, without thinking of the local conditions of the countries in which these articles are already grown, and of the possibility of overstocking the market. Calculations are often made showing that a certain product will pay at the present price, but no thought is given to the probable effect of increased production.

Sugar is a food, and as such its possibilities of consumption are greater than perhaps any other food products, except the different kinds of grain or corn. Rice may be put down as the best grain for this colony, but no one who has thought over the difficulty of turning a sugar estate into a rice plantation, and then of putting the product into competition with that from the East Indies, can come to any but an adverse conclusion. With other foods there will always be the possibility of overproduction, and that very quickly. Indian corn and cassava can be grown here to advantage, but in the case of the first we should have to compete with the United States and the second with Brazil. There is no probability of any very great increase in the consumption of cassava starch, farina or tapioca, and maize is so cheap that it is out of the question. Plantain flour might be useful, but unfortunately there is no market for it in quantity at present.

The story of sugar cultivation in the colony is an interesting one. It was commenced by the West India Company about two centuries ago in the neighbourhood of Kyk-over-al, from where it gradually extended down the Essequebo and into the Demerara But, although commenced in the upper districts, it was never anything of a success until the coast lands were taken up. The experience of the early settlers agreed with the late deductions of the Government analyst, that the river banks beyond the alluvium were barren, and hardly worth cultivating after two or three crops had been taken off. Only the high price of sugar once made it possible to carry on the cultivation by clearing new land as the old gave out. When it was discovered that on the lower banks and coasts this was unnecessary, the die was virtually cast which made British Guiana a sugar colony. Nevertheless the final decision was not come to all at once. Even then a sugar plantation required a large supply of labor, and many a poor man with but a few slaves found it suited his pocket to grow cotton and coffee, which then fetched what we should now consider magnificent prices.

Coffee was introduced into Essequebo in 1725 but at first it was a failure. The comparatively barren soil in the neighborhood of Kyk-over-al did not suit it, and then again the trouble of picking and preparing the berries was against it. So great was the failure that, although 24 bags were shipped in 1728, a few years after the Commandeur had to get a supply for his own table from Suriuam or Berbice. In the last colony coffee cultivation was more successful. It was introduced from Surinam in 1720, and soon became of so much importance that Berbice coffee was well known in the markets of Europe down to the emancipation. After Demerara had become settled coffee came to the front and took its place besides sugar. In the year 1745, when the first land grants in the Demerara river were made, only one bag of coffee was shipped from Essequebo, but from that time the export increased until it reached in the early years of this century about ten million pounds annually from Demerara, besides nearly seven millions from Berbice. Java, in No. 1 Canal, seems to have been the principal coffee estate in Demerara, and Anna Clementia the most important in Berbice, the latter producing 530,525 pounds in 1811.

Besides the high prices of coffee and cotton, there were other factors which helped to prevent losses on their cultivation. Slave labor was reliable—there could be no strikes, nor was Saint Monday observed anywhere. Then again the estate owners worked together. "You scratch my back, and I'll scratch your back" was in effect their motto. One lent his gang for picking, and in return similar help was given when required. Coffee picking was no doubt tiresome, although by no means laborious, still it had to be done, and done at the right time. It is generally considered that coffee came to grief on account of the emancipation, but this was not altogether the case. A time came when sugar and coffee were equal in price, or when advantages of the the former were so great that, with a small labor supply, it would be foolish to keep up a plantation of of the lower priced product.

Although cotton was one of the articles brought from Guiana by the first traders, who brought it from the Indians, it was not cultivated to any extent until the middle of the last century. In 1762 the produce of Demerara and Essequebo amounted to only ten bales, and it was not until the surrender to Great Britain in 1796 that anything like a "boom" took place. Then the three rivers were really opened, free grants of land were made, with the result that the whole coast from the Essequebo to the Corentyne, and even across to Nickerine, was a succession of cotton fields. Virgin soil, impregnated with salt, produced good crops, which sold at what would now be considered fabulous prices. The exports soon reached to over seven million pounds, and there seem to have been

prospects before the cotton planters. But very soon after the abolition of the slave trade, the Southern States increased their cultivation, and not being hampered by so many obstructions to their labor supply, the staple came down to a price which did not pay. Ruin was almost universal in Berbice, and Demerara was little better.

Only sugar was left when coffee and cotton fell; it was the survival of the fittest. Can we say today that there is the least chance of success with any other product? But, if there is hope, will it not be for a new body of men in new districts? Such being the indications, what a sad thing it would be for the colony if the coast plantations were ruined. When cotton fell, coffee and sugar were left. When coffee fell, sugar was left. If sugar falls, what then?

SOIL AND NATURAL FERTILITY.

A Rock is never a very simple agglomeration of chemical combinations, but the overlying soil—the dark, humus-stained, bacteria-riddled, worm-gathered, semi-organic mass—is a much more highly complex problem alike for the scientist and practical farmer. The former has to say how rocks can best be rendered into fertile soils, and the latter has to carry the work into practice. The soils of rocks may be roughly classed.

1.—The granitic soils are generally poor in phosphoric acid and destitute of lime.

2.—Clay soils are compact and tenacious, poor in phosphoric acid, but rich in potash.

3.—The liassic soils are remarkably rich in phosphoric acid and potash.

4.—The calcareous soils are very fertile, but less tenacious than the preceding.

5.—Ferruginous clays and sands are very poor soils, extremely deficient in lime and phosphoric acid.

When fertility is merely considered, and the most practical way of gaining it in a given time, the soil problems go far beyond any geological or chemical formulæ we can express our thoughts in as yet. They cannot take into account the vital action of millions of bacteria, or of the ground borers from the mole to the smallest grub. Every borer great or small, opens the ground and lets in the air, and the oxygen and nitrogen in their freely mixed state in the atmosphere have each a work to do in soil fertility. It is little use telling the practical agriculturist that nitrogen is not taken into combination directly in a bare fallow. What is going on below the ground while the soil is kept free from vegetation above? he demands, and is ready with a score of pointed questions at once. Why does soil grow richer and richer in proportion as it lies unused? Why does nitrogen gradually accumulate under permanent grass? Why does earth taken from a rich pea-growing soil, and lightly dusted over field sown with peas, produce a much heavier crop on the dressed portion? If the peas themselves are steeped for some time in a solution made by a rich pea soil and water, why do the plants grow more vigorously than those that have been sown undressed?

The nitrogen-fixing bacteria are everywhere, but in grass land more than in tilth, and where yard manure or cattle droppings are plentiful they are soon doing their beneficent work, aided by a free flow of moisture and air. Strange though it may seem to the ordinary agriculturist, the soil which seems to him such a solid thing is little more than an open sieve for admitting air and water. Grass, and good grass, too, can grow in "living water," it is the stagnant pool of cold water choked with carbonic acid gas and marsh gas, which prevents vegetation by excluding oxygen. Fresh water flows away into the earth drawing air after it, no small portion being entangled in it mechanically as well as absorbed. There cannot be a flow of water without a corresponding flow and inrush of air, and the soil requires both equally to reach the highest fertility. The nitrates, which gradually accumulating in the ground would destroy the activity of bacterial life, are washed away, while carbonic acid gas is forced downwards to escape by the under-drains, which are especially valuable in carrying it off, and therefore should only be sunk at a reasonable depth in retentive clay land. Few men, indeed, even when geologists and chemists, appreciate fully the action of rain and air together as makers of fertility. Bacteria cannot work without moisture, and the all-important nitrifying bacteria cannot work without a changing inflow of moisture and air. The soil, from its open state and sieve-like capacity, provides both conditions in ordinary seasons. The finding of good flows of water when wells are sunk, speaks with the clearest voice to those who can understand about the double aeration of the soil, caused by every shower, from the air it drives before it and draws after in its train. No wonder, then, that a heavy thunderstorm will make the burnt-up pastures a lovely emerald green in the driest seasons. The bacteria had been working in the warm soil till the want of moisture and accumulation of nitrates prevented further vital action. Then came the time of short brown grass, which "burned" more and more each day of brilliant sunshine. Broken weather and heavy rains dissolve the poisoning nitrates, feed plants with their rich store of food, and set the bacteria free to work by soaking everything with fecundating moisture and pure, cool air, which it brought entangled with it or in its train. The plants feed on the waste products of bacterial life, and the bacteria are busy purifying the soil by consuming all dead animal and plant substances, bringing them slowly into suspension and solution, ready for nitrification; fitting them for beginning the round of the life cycle once again. It is not much the presence of air in the soil as the presence of pure water and air together that makes a soil naturally fertile; and when the water is from the clouds it comes in the best shape, whether it be fluid or snow. Let those who find artificial manures cheap and paying use them as long as they will, or the soil will allow of it; but a good supply of organic matter in the soil seems to be nature's way of obtaining a growing fertility. The best manure yet made is that which the farm supplies through the bodies of its stock when fed on rich food. It is a good substitute for the work of the forest in making constant additions of organic matter to the soil. If a uniform and steady growth in quality is the thing aimed at, there seems no other way in obtaining it, when the soil is a sufficiently rich loam to retain a store of plant food. There are sands so sieve-like and clays so stiff, that in one case the water washes everything away, and in the other it cannot enter to do its work at all. A stiff clay may grow good grass in time with care, but a barren sand is past praying for; if you add clay and lime in the right proportions to make it fairly good, you are buying your land a second time over for self or landlord, and can never hope for a return in on the outlay. "It never pays to make land where it can be bought ready in the neighbourhood. Give me a clay, or loam lying on the clay, the richer the better, and I will try to make the thing go; but a barren sand will hold nothing." It would be impossible for most of us in Jamaica to get enough animal manure of this kind. In the north where there are large cities where fat stock is in great and constant demand for the butcher, it pays farmers to stable or yard their stock and feed them by hand on highly concentrated nitrogenous food, such as cotton seed meal, mixed with more bulky foods like hay, and save the manure, which is very rich in fertilizing elements, to apply to their fields; thus a double object is gained and there is no waste; the added weight of the cattle by the consumption of rich food pays the feeder, and the refuse saves the purchase of fertilizers. What we must do, is to add potassic and phosphatic artificial fertilizers to our

soils (for neither is it possible to get a sufficiency of wood ashes to serve the same purpose) and grow leguminous crops, even if it should only be cowitch; when such crops of peas and beans are so fertilized with potash and phosphates the bulk vegetation and the crop of seeds are both very large; enough seeds may be saved for future crops, and if chosen, some may be marketed if it is found to pay well enough to pick, shell, and cure; and the decaying leaves, stems and roots should then be broken up and mixed with the soil with fork or plough. This is copying nature's methods of conserving the fertility of the soil. The grass sod is constantly withering away and new grass springs up and the old; when this goes on for many years there is a continuous addition of decaying vegetation forming a deeper and deeper layer of loam. In the forest the leaves and twigs drop season after season; then trees get old, rot and crumble away, so that there is a constant addition of decaying vegetation covering the soil below where the roots are, and while the rain washes the fertilizing gases down, the rootlets strike upward eager to seize and absorb them. But nature works slowly, if surely, while man is impatient. So by planting peas and beans, which grow quickly and feed partly on the air, absorbing the atmospheric nitrogen through their leaves, pumping it down into the soil through their roots and developing profuse vegetation, the roots at the same time searching out and drawing up from the subsoil stores of potash which otherwise would have been locked up and unavailable to the principal crops, bananas or sugar cane, or whatever the crop may be, we can in three or four months, or at any rate twice a year, turn as much decaying vegetable matter rich in nitrogen and potash into the soil as nature might not do in many years in a forest. —*The Journal of the Jamaica Agricultural Society.*

IRRIGATED COFFEE.

Mr. C. Meenacshayya writes:—Will you kindly permit me to supplement by a few words the letter which you published about irrigated coffee. Most planters might have heard of the enormously large operations carried on by Messrs. Finlay, Muir and Co. in Travancore, in planting tea and coffee. One of their Chief Superintendents, Mr. William Milne, under telegraphic instructions from Calcutta, paid a visit to my plantation here on the 31st December, 1897, when my oldest plants were only two years old, plants which are now giving me about 7 cwts. crop. He was highly pleased, and told me that he was going to report very favourably. Under the impression that that Company might go in for irrigation coffee on a large scale in this Province. I mentioned the matter to the Dewan, Sir Seshadri Iyer, and he was so delighted with the prospect of that wealthy Company starting operations in this State, that he asked me to write to Mr. Milne giving assurance of every encouragement from the Durbar. I wrote to him accordingly, but I ascertained that the object of the visit was to see how far, if considered desirable, they might adapt their coffee-growing to a system of irrigation in Travancore. Mr. Brown, of the Cubbon, Bangalore, has a small plantation near Kengeri and he pumps up water from a perennial rivulet that runs below. I am not in a position to say what margin of profit can be attained if a small plantation is so expensively irrigated. There is a very large estate near Lavarakeri, about 15 miles from Bangalore, where arrangements are made for pumping water, also from a perennial stream, to fill up tanks; but I understand that the object is to grow mostly paddy and sugar-cane, though there is some coffee. A never-failing tank such as Berankenave or Marikanave will be the cheapest source of water-supply. I would recommend the formation of a Joint Stock Company amongst the planters, to raise a plantation on a large scale, say 500 or 1,000 acres under one of these tanks; the Durbar might be appealed to for granting land under special concessions. That acquired, the rest is plain sailing for which a small outlay will be adequate. Famine-years, as a rule, need not affect irrigated coffee. Famines occur, generally, not by a total failure of or a great deficiency in the rainfall of the year, but by unseasonable rains, when the dry crops, which are the staple food of the ryots, die out for want of seasonable rains; no amount of deluging afterwards could resuscitate them. A big deep tank, with a large catchment area, when once filled (it matters not in what particular month from June to January) will serve your plantation during the dry months.—*M. Mail.*

PLANTING NOTES.

Canadian Fruit Export.—We learn from the *Canadian Horticulturist* for October that a cold storage car for use on the Grand Trunk Railway, and special cold storage compartments of the same kind on board the steamers, have been prepared in place of the unsatisfactory appliances hitherto in use. Manchester will be the port to which the first shipments will be made, and should the results prove equal to expectations, other lines will be fitted up.—*Gardeners Chronicle*

Servian Plums.—From Belgrade we learn that during the present year, dried Plums to the value of 6,000,000 francs have been exported from Servia, and Plum jam to the value of 2,400,000 francs. In the year 1890, dried Plums were exported to the value of 7,300,000 francs, and jam to the extent of 1,300,000 francs. In addition to all this, considerable quantities of fresh Plums for use as table fruit, or for the manufacture of spirits, are exported each year. A considerable trade at one time existed with this country in dried Plums, but that has been swept away by exports from France and California of fruits which have undergone a double drying process.—*Gardeners' Chronicle.*

Conifers as Rain Gauges.—According to a recent number of the *Revue Horticole*, M. Felix Sahut has lately communicated to the Congres des Societes Savantes observations respecting certain plants that act as registering rain gauges. "Mention has already been made of the influence of certain more or less severe droughts in the French Mediterranean upon Pinus Laricio of Corsica, and Cephalonian Fir. The lengthening of the branches of these two species is always proportionate to the quantity of rain falling during those months of the year when it is most profitable to them. Co-efficients have been established indicating what the degree is for each month of the year. These co-efficients enable the relationship that exists between the amount of rain fallen, and the greater or less intensity of the vegetation which it has encouraged to be determined. It is shown that, under these conditions, it is possible to judge approximately the quantity of rain which has fallen by measuring exactly the length of the leader, or of the branch produced yearly on these species of Pine, and if the estimate is not absolutely proportionate to the quantity of rain registered by the rain-gauge, it closely approaches to it; and a still closer estimation may be made by taking into account the relative value of the results produced by rain in the several months of the year. It is, therefore, possible, to a certain extent, to use plants specially selected for this purpose as actual registering rain-gauges."—*Revue Horticole.*

NEW COFFEE SEED FOR B. C. AFRICA.

Mr. Balfour Blair moved a resolution regarding the necessity of getting new Coffee seed for the country. Seconded and carried. The resolution was on the following lines:—

This General Meeting of the B. C. A. Chamber of Agriculture and Commerce is unanimously of opinion that the Coffee seed should be imported into the Protectorate by H. M. Administration for the following reasons:

(1 The present seed has manifestly deteriorated owing to continuous in breeding. Since the first Coffee plant was brought to the Protectorate from the Royal Botanic Gardens, Edinburgh, there have been very few importations of fresh seed and most of the importations which were made were not greatly successful so that nearly all the plants in the Protectorate are from one plant and, as must infallibly happen in such cases, the stamina is steadily deteriorating and cannot be improved without the introduction of a new vigorous strain.

(2) In consequence of this large amount of in-breeding and the failure of stamina there is very grave risk of new fungoid and scale diseases breaking out the poorer fields, or, should any disease be accidentally imported the recent plants would have no strong existing power and would succumb readily to any pest which, in the present circumstances, would mean the ruin of the Coffee industry.

(3) The deterioration of the present seed is noticeable in the number of weak seedlings which are produced from the seed; in the failure to throw sound berry even in maiden crops; and in the failure of whole districts and estates to produce good and sound crops. These failures are attributed by many experienced planters to the deterioration of the seed.

(4) Owing to the very strict Regulations against the introduction of seed from countries invested with *Hemileia vastatrix*, it has been impossible for Planters to import seed from nine-tenths of the Coffee producing countries of the world and those countries which from their proximity to this Protectorate would be most suitable for seed purposes, such as India, Natal, etc., are absolutely debarred. This Chamber has always loyally supported H. M. Administration in the Leaf Disease Regulations, but they cannot fail to point out that these Regulations, act as a practical bar to the importation of new seed by private planters and hence our request that H. M. Administration should undertake this work. The few private importations which have taken place have mostly been from Jamaica and owing to the long distance and the delays incidental to private importation (owing to the Leaf Disease Regulations) these efforts have in many cases ended in failure as Coffee seed loses its vitality in less than six months. This Chamber is therefore of opinion that the importation could be undertaken most successfully by Government and they pledge themselves to bear any expense which might be incurred in introducing new seed.

(5) This Chamber would recommend that seed be imported by the Government direct from Jamaica (Blue Mountain Coffee), Trinidad, Brazil, Queensland, and any other places where H. M. Government find that there is no risk from Leaf Disease, such as the South Sea Islands some of which grow Coffee. They would suggest that such seed should be sent direct to Zomba by the quickest possible route and distributed to Planters in conformity with their indents for which the necessary deposit money has been paid.

(6) The Chamber recommend the above to the earnest consideration of H. M. Acting Commissioner as they are convinced that the matter is one of great importance and vital to the progress of the Coffee Planting industry of the Protectorate which is in danger of extinction unless new and vigorous seed is introduced at an early date as is done in other Coffee growing countries of the world.

PLANTING NOTES.

Jam for South Africa.—The Imperial Government has arranged to obtain from New South Wales, for the use of troops in South Africa, 300,000 lb. of Jam—peach and plum.—*Agricultural Gazette N. S. Wales.*

Liquid Manure for Tomatoes.—The following method of preparing liquid manure for tomatoes is recommended by a correspondent:—One peck of horse-droppings and half-peck of soot should be placed together in a bag, which should be sunk in any ordinary barrel with the head out. The barrel is then to be filled up with clean water, and the mixture may be used in the proportion of one to four of clear water until the soil about the plants is moist. This manure is suitable, not only for tomatoes, but for most other plants. In the case of tomatoes it would be an advantage to sprinkle a little of one of the cheaper forms of potash about the roots previously. Tomatoes do not require feeding with liquid or any other manure until the fruit is set and swelling freely. As the liquid is used, the barrel may be filled up with clear water, and after this has been done once or twice the bag may be stirred round with a stick or spade. In a small garden the manure will last for three or four months, but when it is evident that the liquid is getting weaker, the manure and soot must be renewed.—*Ibid.*

Dressing for Tender-Skinned Horses.—Horses with delicate skins are specially subject to saddle galls and sore shoulders, when worked to any extent in harness. Much may be done to render such animals less liable to injuries of this kind by the regular use of astringent applications calculated to harden the skin over their backs and shoulders. As dressings for this purpose, quite a number are employed by horse-owners in different parts of the country. One of the most popular, and also one of the most effective when properly prepared, is a home made decoction of oak bark. A brine made of common salt is also very extensively used, and usually with good results. Another excellent dressing, and one which is much easier to prepare than the oak-bark decoction, is a lotion consisting of 2 drachms each of alum and sulphuric acid in a quart of water. The parts which are liable to chafe should be freely sponged over with one of these dressings two or three times a day. After a time, skins so treated will harden, or toughen to such an extent as to give no further trouble.—Wattle bark broken up fine and stewed for several hours will make a good substitute for the oak-bark concoction. —*Exchange.*

CACAO INDUSTRY IN GRENADA.

Cacao growing is the staple industry in the interesting island of Grenada. Its prosperity for many years when other portions of the West Indies were in a depressed condition was entirely due to the successful cultivation of cacao trees. With the view of drawing attention to the desirability of making every effort to maintain the productiveness of cacao estates in Grenada, the following interesting notes, written by Mr. George Whitfield Smith in 1892, are reproduced :—

"It is pleasant to notice one of the few instances in Grenada of a Cacao estate where, as the result of a careful system of manuring and draining, the proprietor gets from only twelve acres of Cacao a return equal to what many others receive from three times that area. I refer to Good Hope Estate in this island, owned by the Rev. G. W. Branch. On the advice of His Excellency Sir Walter Hely-Hutchinson, I called one morning on the proprietor, and was most courteously shewn over the whole plantation. Both Mr. Branch and his son, Mr. George Branch, most willingly afforded me all the information in their power. Wishing to be as clear as possible, I shall endeavour to adhere as closely as I can to Mr. Mr. Branch's replies to my questions concerning the working of his estate.

' 'I have been the owner of the property for over twenty years. Good Hope contains 22 acres—eight acres of this are in canes and pasture. I estimate that the buildings, yard, and entrance occupy another two acres, so that my extent of Cacao cultivation cannot be much over 12 acres. I purchased the place for about £100; at that time it had a few neglected Cacao trees here and there. Many people ridiculed my attempt to grow Cacao there, as the land was considered by most persons as almost valnless for that purpose. However, be that as it may, I could easily borrow £2,000 to-day on its security if I wished to do so. My soil is rather poor for Cacao when compared with many other places; as you will see, in many places there is a bed of "tuff" not far from the surface, and you know, when the tap root of a Cacao tree touches this, there is an end of the whole matter.

'How, then, do you account for the flourishing state of your trees, when, to judge from their size the tap roots must long since have come into contact with this layer of "tuff"?'

'My Cacao trees have no need so drive their tap roots very deep, as I will shew you when we are going through the orchard The Cacao tree is naturally a deep rooter, but if it can meet with its nourishment near the surface it will undoubtedly develop its feeding spongioles wherever that nourishment is, and that is what happens in the case of my trees.

'Please explain how yon do this?'

'Willingly. My cacao orchards are, as you observe, on the slope of a hill, skirting the sides; therefore, among the trees, I have roads cut by simply digging down the slope to a level. These roads are sufficiently wide to admit the passage of a light donkey cart, and as they wind along the hillside in a corkscrew fashion you will understand how they serve a two-fold capacity. First, they act as roads proper, and, secondly they act as drains, since a small canal always skirts the upper edge for the whole of their length. Thus I have my Cacao field drained at regular intervals, and, in addition, my donkey cart can carry manure to any part of my estate.'

'How do you apply your manure?'

'Very simply: I just have the cart filled, and the driver upsets it at regular distances over the lower edge of these roads. I then go round as I can find time and bury this in. I likewise collect all leaves and bush from time to time, and bury these also. You will now see the effects of my system. Look down on the ground what you are walking on is not pure earth. Take up a handful of it. You will notice that it is a dense mass of fine rootlets or spongioles! These have been called into being from the amount of nourishing material which they find here ready for them, and have no need to go deep in search of food,

My system has converted the trees into surface feeders, and provided I keep them supplied with food I can fairly be said to have them well under control. Now, without manure the case is different; the tree has to push its tap-root deeper and deeper every year, in search of food, often it strikes "tuff" or "clay" then death ensues. Even when this does not happen, it stands to reason that a tree with a single tap-root supplied with a few scanty and half-starved rootlets, is in a poor way when compared with my healthy and vigorous trees which have an abundance of young roots, all eagerly sucking up the plant food around them. The good effect of this is easily seen when comparing the returns I get with those of neighbouring planters.'

'What do you average as a return from your 12 acres of Cacao cultivation?'

'About 87 bags per annum. This would represent a trifle over seven bags to the acre.'

'The old trees which you found on the place 22 years ago must be very old by this time: do they still bear vigorously?'

'Yes' quite as well as the young ones, and they seem good for many years yet, thanks to my manure system.'

'What do you consider to be a good yield per tree in pods per annum?'

It would be difficult for me to answer this and indeed I have never kept a record. My trees practically never stop bearing, but my son counted 205 ripe pods on one of the trees besides green fruit and flowers. As you can see most of them have each several dozen ripe fruit, green fruit, and flowers on them at the same time, so that my crop may be said to be continuous.'

'Do you purpose extending your cultivation?'

'No; the remaining portion of my land is too much swept by prevailing winds to be of any value for Cacao; besides, I find that it pays me better to keep a portion in cane cultivation or some other fodder, not from the profit to be derived from sugar, but because it enables me to feed my stock; without this I could get no manure, and without manure I could get no Cacao.

look upon my stock, therefore, as part of my working capital. People here seem entirely to forget this. I very often hear them speaking of the hard work they are having to get their plantation "covered in" as they call it, but if they knew what I know, they would find it more to their interest to keep one-fifth of their plantation in pasture lands and fields of fodder plants, and to keep several heads of stock to fertilize the other four-fifths.'

'What system do you adopt in storing your manure?'

'The old Barbados system, which I have found to work so well. I have all my animals kept in a pen, a portion of which is covered to afford protection in heavy weather. In this pen they stay nearly all the time that they are not in use. Their excrement is consequently collected in one place. I regularly cover this over with cut bush and litter, and at intervals I spread a layer of mould over it, and recover with litter. The result is, that at the end of a few months I have a mass five feet thick of the richest fertilizing material that I know of, and one that for our generous soil needs little assistance from chemical manures. In addition to this I use a large quantity of sheep manure, which I collect in a similar manner from my sheep farm at Point Saline.?

'Do you ever transplant your trees?'

'Often; and here, again, the beneficial effects of my system become apparent. I take up large trees with pods on them. There is no danger. not being deep feeders, they give little trouble. When a gap occurs through the death of a tree I fill it up as soon as possible.'

'What do you do in the way of pruning?

'I go through regularly and often, and break off all young shoots, and cut out any dead wood. You will see that my trees are perfectly clean of vines and lichens. A tree can't be healthy that has the pores of its bark stopped with roots of parasiticial plants.'

'What is your opinion about shade?'

'I find in my locality that shade is beneficial in the growing stage, but is inimical when the tree commences bearing, at least heavy shade is. This holds good with even the "Criollo" Cacao, of which, as you see, I have a large number. With me this is one of the hardiest varieties, and bears profusely. My trees have crossed with each other and now I have a great number of varieties shading off one into the other.'

'Do you use any care in selecting seed?'

'At first I was anxious to get my land planted up, so raised whatever seed I could get. Now, I select and replace a bad variety with a good one whenever opportunity offers.'

Do you grow other products with your young Cacao?

Always; such crops as yams, tannias, cassava, and canes come well with young Cacao, and, in my opinion rather do it good than otherwise, besides yielding catch crops of considerable value.'

What processs do you adopt in picking and curing? Do you separate the different varieties before sweating?

'With a small cultivation like mine it would be difficult to get a sufficient quantity of Criollo or any other variety at any one time to set up separate sweating boxes. I see the advantages of it, and regret that I cannot do so. My last account sales, however, are very satisfactory, and shew a receipt of 72 shilling per cwt., which, taking all things into consideration, is very fair indeed. The process of curing is that generally pursued in Grenada, and needs no special explanation."

More recently the following suggestions have been prepared by this Department with the view of assisting local efforts to maintain and improve the cultivation of cacao trees in grenada.

Commissioner of Agriculture—to Governor of Windward Islands.

Barbados, 26th May, 1899

Sir,—I have the honour to forward for Your Excellency's information a Memorandnm in duplicate prepared by this Department containing suggestion for renovating old and neglected oacao trees on the upper lands of Grenada.

2. During my recent visit to the island it was very forcibly impressed on my mind that, although the cultivation of cacao is steadily extending in the low-lands, the original areas planted in the mountains are gradually becoming nnproductive. Hence it is that the exports of Grenada cacao have not increased in proportion to the area actually planted.

3. In the general welfare of the island it is desirable that the old cacao areas should receive speoial attention. Now prioes are good is a favonrable opportunity for doing so, and I would suggest that the subject be brought before the Grenada Agricultural Society with the view of eliciting the opinion of the members in regard to so important a matter.

4. It is possible that the Agricnltural Society migbt assist small cultivators by affording information in regard to the best means for obtaining suitable manures at the lowest possible cost. It is desirable that all artificial manures snpplied in the island should be sold under a guarantee that they contain the percentage of ingredients and the composition stated in the invoice. I would add that certified samples of imported manures forwarded to this office by the Government with a copy of the invoice would be analysed free of charge.

I have, etc.,

(Sgd.) D. Morris.

Commissioner of Agriculture for the West Indies.

Memorandum on methods to restore old and neglected cacao trees on the upper lands of Grenada.

1. *Pruning.* All neglected and badly formed trees should in the first place be carefully pruned. This operation might he undertaken after the crop, possibly the months of February, March or April would snit for this work. Cut out all dead wood and nnhealthy branches. The utmost care should be taken to make all cnts perfectly clean, and as close to the main limb as possible. Too much importance cannot be attached to this point, especially as it is a practice in the West Indies to leave a small stump, of an inch or two in length. Whenever this happens it will be noticed the stump dies and decay spreads into the heart of the tree. Always trim the edges of a cut with a sharp knife The ensures a more rapid healing of the wound.

In the case of specially old cacao trees, it would be a good plan to make use of a sucker, preferably one springing from a point near the root, and allow it to grow up in the place of a parent tree. The old stem should then be gradually removed. By adopting this method and by paying proper attentiou to tillage and draining it is quite possible to transform, in a short time, an apparently hopeless field of old cacao stems into a healthy bearing one.

In very extreme cases it may be necessary to remove the parent stem altogether. This should he done about 2 feet from the ground, and one of the suckers allowed to grow up as described above. Where the main stem is entirely taken away the cut should not be made horizontally across the grain of the wood, but in a sloping direction, say at an angle of 450. The former method is strongly to be condemned as it allows the accumulation of rain water in the wood, tending to rot the stem and destroy the suckers.

Lastly, it is advisable to dress all cuts with a mixture of coal tar and whale oil, in equal proportions. This not only encourages the formation of new tissues, but safeguards the wounds from the effects of rain and the attacks of the borer and other enemies of the cacao tree.

2. *Cleaning the trees.* By this is meant the removal of moss, "Capitaine du bois" (*Loranthus*), "Love vine" (*Cuscuta*), and any other of the numerous parasitical plants which infest neglected cacao trees on the upper lands. The best season for this operation is during March and April. Showery weather should be selected if possible, as at that time moss is easily removed, without the least injnry to the bark of the tree. Blunt knives made of bamboo or preferably stiff fibre brushes shonld be used for the purpose. For removing "Capitaine du bois" all that is required is an ordiuary cacao picking knife attached to a long stick of hamboo. Care must however be taken to completely remove the plant, as any portion of it left on the branch of a tree rapidly grows again. The removal of the "Love Vine" (*Cuscuta*) is a more tedious operation. The only way in which it can be dealt with is to employ boys to climb the trees and to remove every particle of the plant by hand. The smallest portion left on a tree rapidly grows again. When this pest once becomes thoroughly established in a cacao field, it is then a most expensive matter to eradicate it. Apparently the plant is spreading in Grenada and every effort should therefore he made to keep it in check.

3. *Forking.* With regard to the amount of forking required for a cacao tree, the opinious of planters vary considerably. While some planters claim to have obtained the best results from a system of deep forking and liberal root-pruning, others maintain that they prefer a light turning over or loosening of the soil with as little disturbance to the roots as possible. It is quite probable in the case of a perfectly healthy cacao tree with a well balanced head and a full supply of leafy branches, that any great disturbance of the root surface would not be beneficial. These conditions however do not apply to neglected cacao trees on the monntain slopes. Such trees, as a rule, have few branches; this indicates that they also have a correspondingly limited amount of roots. Deep forking and draining will be of immense value wherever this occurs. Care must be taken not to mutilate or break the large roots, as these serve to secure the upright

position of the tree in the soil. Any of the smaller roots which are unavoidably broken, during the operation of forking, should be cleanly cut back. New roots will spring from this point and continue to nourish the the tree.

Forking, by turning up soil, exposes it to the action of the sun and air. By this means the soil is loosened, the capacity for retaining air and moisture much increased, while at the same time the removal of excess of moisture is greatly facilitated. As a rule it will be noticed that the soil around the roots of old and neglected cacao trees is water-logged and unwholesome. No air can penetrate into it, and, as the roots can only develop when air is present, it follows therefore that the growth of healthy rootlets in such a soil is completely checked. It is also well known that chemical change can only take place in the presence of air. Such a change therefore is not only arrested, but injurious combinations arise which discourage or destroy the roots of plants. It is therefore evident that judicious forking increases the porosity of the soil. Its effect is further strengthened if all leaves and vegetable refuse are dug in at the same time. Vegetable refuse or humus performs a most necessary function in damp clay. It serves to keep the small particles of the soil farther apart, and it thereby permits the free admission of air, on which so many important changes and combinations depend. It is doubtful whether it would be found advisable to bury vegetable refuse in a green condition in damp mountain lands. A better plan would be to allow it to become withered for a few days before digging it in.

4. *Draining.* This naturally follows the operation of forking. When heavy rains fall on clay lands a certain quantity of the water is absorbed by the soil and the remainder either lies on the surface or is carried away by drains and streams. Some soils are extremely porous and rapidly part with their moisture after heavy rains. Clay soils, on the other hand, retain water for too long a time, and thus become old and sour. The only remedy for this is drainage.

It being established therefore that land is drained with the two-fold object of removing superfluous moisture and of promoting a free circulation of air, it is important to remember that, unless the water in a soil is kept in circulation, no air can enter between the particles of it. On damp mountain lands drainage has also another important office. It prevents landslips and washes. The rainfall is usually abundant in such localities and the soil cannot absorb the water as fast as it falls. Hence landslips occur. This never happens in forest land, because the soil is bound together with a network of roots. When however the forest is destroyed, and the land tilled and planted with cacao, the loose soil is then easily swept away by heavy rains. After a shower each stream and watercourse demonstrates most clearly that a large quantity of surface soil has been carried away, until finally, unless care is taken to prevent this by a proper system of drainage, there is nothing left but the bare sub-soil from which cacao trees cease to obtain any nourishment.

Surface drainage is the only method practicable in cacao fields. All such drains should be carefully laid out with a view to prevent washes. No drain should be made straight up and down the face of a hillside. Advantage should be taken of ravines and natural water courses wherever they occur and "contour" drains, 18 inches wide and 2 feet deep, should be regularly led into them at a distance of 40 to 50 feet apart. These drains should be made at an incline of 1 foot in 15, according to to the steepness of the land. By having a system of drains made at any easy gradient, such as that above described, it is possible to recover a large quantity of the soil washed out of the land. It might be found beneficial to have all contour drains cleaned out at regular intervals during the rainy season and the ould spread between the trees.

5. *Manuring* is the next step necessary to restore old cacao trees. Manures supply the soil with the food required by the plants. This food may be either deficient in the land itself or taken out of it by cultivation. To the small grower pen manure would probably prove of the greatest value. Pen or farmyard manure is what is known as a general manure, and can be applied with safety to all soils and to all plants. It is of the greatest value, not only on account of its manurial action, but also on account of the mechanical action, which the burying of large quantities of trash and other refuse exercises on the particles of the soil. Pen manure should always be applied about 4 feet from the stem of the tree, in a shallow trench, and should be lightly covered with soil. In cases where the soil has been long neglected and contains a large amount of sour organic matter, it may be found necessary to apply a top dressing of lime, a few months before using farmyard manure. Lime acts beneficially in many ways. It decomposes all kinds of vegetable matter in the soil and corrects any acidity due to the presence of organic acids. It also has a good effect on the mechanical condition of soils. On stiff and retentive clays it pulverizes and lightens the particles, thereby improving the drainage and reducing any undue excess of organic matter. On soils deficient in available lime a top dressing of about 4 tons per acre would probably be required. When applying calcareous manures they should be kept near the surface and not deeply buried in, as lime quickly sinks into the soil and has a tendency therefore to run away from the roots of the plants.

Artificial Manures. Professor Harrison after an exhaustive examination of the soils of Grenada recommends generally Basic Slag or Thomas Phosphate powder. This should be applied broad cast in quantities of about 2 lbs. per tree on the forked surface. It should afterwards be lightly worked in and a top dressing of about ½ lb. of nitrate of soda or sulphate of ammonia per tree may subsequently be given.

Governor of Windward Islands—to Commissioner of Agriculture.

Windward Islands.
Miscellaneous.

No. 72. Grenada, 31st May, 1899

Sir,—I beg to acknowledge and thank you for your interesting and useful letter G. 1439 of the 26th instant embodying suggestions for dealing with old and neglected cacao trees.

2. I have directed the publication of your letter in the Official Gazette. It will also be laid before the Grenada Agricultural Society as you desire.

3. Too much importance cannot be attached to the question of the suitability and composition of artificial manures locally imported for use in the island. I had intended to have earlier written to ask you what quantity of each kind you required, and would suffice for purposes of analysis. Would it not help the question to have also specimens of soil from exhausted cacao areas? Kindly let me know.—I have, &c., (Sigd,) ALFRED MOLONEY, *Governor*

SOME FUNGI OF THE CACAO TREE.

(With Plate.)

BY J. H. HART F.L.S.,

Superintendent, Royal Botanic Gardens, Trinidad.

One of the earliest records of disease among cacao trees is that given by Long in his history of Jamaica. In 1671 Long states that there were as many as sixty-five "walks" in bearing, while in 1882, only small patches, of no great extent remained. Long also records that the Plantation were destroyed by a "blast."

What this blast was there is little evidence to prove, but taking one interpretation of the word, "to strike with some sudden plague," it may possibly have been occasioned by the rapid spread of some indigenous parasitic fungus. The time of

the occurrence has been fixed by a 19th. century writer as "sometime during the last century."

The late Sir L. A. A. De Verteuil, K.C.M.G., M.D., in his book on Trinidad, page 431, states:—"The prosperity of the Colony had now reached its culminating point, Cacao selling at a high price. But in the year 1727 according to Guimilla, not a disease exactly, but a blight attacking the pods under certain atmospheric influences, destroyed the crop." Later, he records that the *Forastero* variety was introduced and succeeded beyond expectation, and writes. "It is this quality which is cultivated in our days."

In 1898 attention was specially called to a disease which attacked the pods of cacao destroying a large percentage of the crops in many districts in Trinidad.

The matter was taken in hand by the Botanic Department and close investigation showed that the pods were destroyed by a parasitic fungus which could be speedily propagated by inoculation with spores taken from diseased fruit. Several cultures of the fungus were made, and these, with other living materials, were sent to Kew for examination and report.

The results of this examination were published in the "*Kew Bulletin*" for January and February 1899, as follows:—

"Microscopic examination revealed the presence of two distinct fungus parasites; one being the well-known *Phytophthora omnivora*, De Bary, a species closely allied to *Phytophthora infestans*, De Bary, the cause of the potato disease; the other a *Nectria*, which proves to be new to science, and will be known as *Nectria Bainii*. The *Phytophthora* was present on all the pods sent and may be considered as the cause of the present epidemic in Trinidad.

The same, or a closely allied species, appears to be the cause of the cacao-pod disease in Ceylon.

PHYTOPHTHORA OMNIVORA. *De Bary.*

"This fungus, as indicated by its specific name, is not fastidious in its choice of a victim, and has been recorded as attacking various species of plants belonging to the following genera:—

Acer, Alonsoa, Abies, Cleome, Clarkia, Cereus, Epilobium, Fagus, Gilia, Larix, Lepidium, Melocactus, Œnothera, Picea, Pinus, Solanum, Sempervivum, Salpiglossis.

If the fungus is confined to the fruit of the cacao tree it is obvious that infection each season must necessarily be derived from some outside source, the spores for this purpose being in all probability often produced on diseased fruit or "shells" lying on the ground under the trees; nevertheless, being able to leave on such a variety of host-plants, infection of a plantation for the first time might every possibly be attributed to wind-borne spores produced on some other kind of host-plant. This may appear to be poor consolation. However, it is well to be in possession of all known facts and possibilities in connection with the subject under consideration. The life-history of the fungus is well known, having been carefully studied by De Bary, Hartig, and others.

The conidial form of frnit appears as a very delicate white mould on the surface of the part attacked. The conidia or reproductive bodies are ovate or egg-shaped, being attached at the broad end to a very slender stalk, which shrivels and liberates the conidium when mature. This condition of the fungus flourishes for a few weeks during the period of active growth of the host-plant; and as the conidia are produced in immense numbers and in quick succession, and are dispersed by wind, insects, or rain, being washed from diseased parts of a tree to healthy parts, it can readily be understood why the pest spreads so quickly when once established. Conidia that happen to alight on young pods germinate at once, penetrate the tissues, and quickly produce a new centre of disease which furnishes more conidia in due time.

During the period occupied in the production of the external form of fruit described above, the mycelium of the fungus spreads rapidly in the substance of the pod and gives origin to a second form of fruit imbedded in the tissue of the pod. These reproductive bodies, known as resting-spores, remain for some months in a passive condition, and are eventually liberated by the decay of the pod: when they germinate, the bodies produced on germination being conveyed by wind to the young pods, germination in their turn, enter the tissue, and in a few days' time produce the conidial form of the fungus on the surface of the pod.

Preventive Measures.—If it is ascertained that the fungus is not harboured by the other plants growing in the neighbourhood of the plantation, but is confined to the cacao trees, then prevention becomes an easy matter. It depends on having every diseased fruit collected and burned; for the only possible cause of infection in the first instance must arise from the germination of resting spores developed in diseased pods, and so long as these are allowed to remain on the ground under the trees the disease will continue to spread. But the fungus may also attack other wild plants, and thus become firmly established and defy extermination.

The following measures should be taken to combat the disease:—

(1) Spray with Bordeaux mixture, commencing when the pods are quite young, and continuing at intervals of ten days.

A dilute solution should first be used until its effect on the fruit and foliage is ascertained. A small quantity of dried blood should be dissolved and added to the mixture; its adhesive property is much increased and fewer sprayings are required.

(2) Remove all diseased fruit from the tree, if practicable, otherwise a continuous supply of conidia will be furnished until the fruit decays. Do not allow diseased fruit or "shells" to remain on the ground. All such should be collected and burned.

(3) Endeavour to ascertain, by careful examination, whether the fungus may not be also parasitic on other hosts; it very frequently attacks seedlings, and would be recognised by the wilting of the attacked parts, and by the delicate white mould-like conidial form of reproduction."

The disease had some years previously been observed in Trinidad, but no special study was made of it. It was detected by Professor Harrison in Surinam, and in Grenada by Mr. G. Whitfield Smith, but little notice however was taken of it until the end of the year 1898, when its rapid spread caused some alarm.

The disease was observed to be most prevalent in places where the atmosphere was humid and where the pods had been allowed to rot beneath the trees.

NECTRIA BAINII, *Massee.*

"This parasite causes semi-circular dark blotches to appear on the pods, the diseased portion becoming soft and watery. At a later stage the blotches become covered with a lovely interwoven layer of yellowish-rust coloured or orange mycelium which is studded over with the minute red perithecia or fruiting organs of the fungus.

This parasite may possibly be quite rare, but great care should be taken to arrest any attempt on the part of the fungus to attack the trunk of the cacao tree, for as already stated the destructive canker disease of Ceylon is caused by a *Nectria*."

"*Nectria Bainii*, Massee—*Perithecia* gregaria. mycelio maculiformi flavo—ferrugineo vel aurantiaco iusidentia, sphaeroidea. rubra, lanosa, dennm supra calvescentia, 300-350 *Microns* diam. *Asci* cylindraceo-clavati, breviter pedicellati, octospori, 80—90×7—9 *Microns Sporæ* distichæ, oblongo-ellipticæ, utrinque snbacutæ, 1 septatæ, 10—12 + 5 *Microns* hyalinæ.'—Geo. Massee.

"The *Nectria* appeared on two pods, and this again possesses many points in common with the *Nectria*, which has caused such destruction to cacao trees in Ceylon by attacking the bark of the trunk and branches, as described by Mr. J. B. Carruthers,

At present, no mention is made of other other than the pod disease in Trinidad, but the fact of a parasitic *Nectria* being present, necessitates the prompt execution of measures calculated to prevent the parasite from extending its ravages."

It will be seen therefore that the Kew authorities were of opinion that the *Phytophthora* was the cause of the destruction of the pods, and later evidence appears to confirm this view.

There is however considerable danger to be apprehended from the spread of *Nectria*, or second species discovered.

Subsequently another, and yet un-named, species of *Nectria* has been found destroying the bark of cacao trees in Trinidad. Thus there are three distinct fungi, which are known to attack cacao trees in Trinidad.

It has been found that *Phytophthora* attacks pods at all stages of their development and frequently when partly ripe, and experiment proves that, owing to the attack of the fungus, there is a loss of weight of 25 per cent. in the beans produced, and, at the same time, a very considerable fall in their quality.

In the old authorities quoted, there is some evidence that a disease existed which was very destructive to cacao, but the exact nature of which was undetermined. It is further reported that it was impossible to grow the indigenous varieties and an imported strain was introduced which proved to be more hardy.

From the results of the attacks recently experienced coinciding in some points with the old records it is probably to be inferred that the diseases of the 18th. century were similar visitations to those of recent years.

There is distinct evidence, however, that the older kinds of cacao were not wholly obliterated, and that the introduced variety has since intercrossed with the original. It does not appear, however, so far as present imformation goes, that those strains bearing greater relation to the indigenous types, are more susceptible to disease than *Forastero*, for the latter appears to suffer equally with others from the attack of *Phytophthora*.

The evidence in support of the view that the older "blasts" and "blight," attacking the pods a century ago, are the same as those of to-day, is incomplete and wanting. The probability, however, that they are identical is an impression which is widespread.

It would be no little satisfaction to the planter if they could be proved identical, as it would show the intermittent character of the pest, and relieve growers of the fear of constant attack. A fact, which favours their being identical, is their partial disappearance during the dry season of 1899 and 1900. This may however be due partly to the adoption of the measures of prevention which were recommended. So far as can be gathered from the evidence at present to hand, it would appear that although these fungi have only recently been discovered, and their life history and destructive character made known, it is probable that they have always been present, and, if sufficient care is exercised, may be kept within due bounds, and will not succeed in seriously damaging the crops. The character of the organisms and their mode of reproduction teaches that the careless and untidy planter will be the greatest sufferer, when a succession of seasons are experienced favonr able to their growth, while he who keeps his cultivation clean, and in good order may expect to escape with minor injuries.

ANIMAL MANURES.

A MALODOROUS subject is the dung-hill, withal it is one of great and growing importance to the agricnlturist and planter, I am afraid the best of us have more or less lamentably failed in grasping its full import in the economy of Agriculture. As usual in matters of agricultnre the Americans and Canadians are greatly to the fore in entering deeply into the subject.

I should suppose there is nothing more distressing to read than a lot of laboured satistics yet some statistics are really eloquent and interesting of such a kind I conceive those in connection with manures of animal origin. For example the U. S A. Department of Agriculture calculates there are in the States 16,000,000 horses, 53,000,000 cattle, 45,000,000 hogs and 45,000,000 sheep and if these animals were kept in stalls the year round the fertilising properties of the manure produced would amount to 2,071,400,000 dollars. This enormons total is derived from a consideration of the value of nitrogen, phosphoric acid, and potash as commercial fertilisers.

I suggest very seriously to the Indian Agriculturist that while we keep the mere phrase manure, we at the same time come to a serious consideration of the three great ingredients of soil fertility, namely, nitrogen, phosphoric acid, and potash; and look into the matter in the same emiuently practical business-like way the Americans do. A man sells 2,000 pounds of wheat, in that 2,000 lbs. of wheat, he has also sold approximately R21·8 worth of nitrogen, phosphoric acid, and potash; that much of the fertility of his soil is gone in other words that much of his capital account is for the time being absolutely depreciated. And consequently unless such an one means to deduct so much from cash acconut clearly he steadily works to nought, in other words he comes to a time when the sum total of the fertiiity of his soil is gone, save the indestructable residue, which will merely give the amount of crop derived from the fertilising properties of rain: and some consideration from rotation of crops, particularily legumes. This state of things may satisfy the Indian ryot, who apparently labours to merely live or rather exist, and who would not labour at all if by any means he could exist without it: but the European planter, the intelligent zemindar, and the agriculturist who see some thing in life more than mere existence should bestir himself to a much fuller appreciation of the commanding importance of animal mannres in agriculture. Elaborate and conclusive investigation into the character of animal manures reveal a whole set of facts of great importance to the agriculturist; and many of which are sadly neglected, resulting in great loss to the soil and considerable revenue to the producer. First, it is important to note that very quickly after being voided animal manures commence to ferment: horse and sheep manure very rapidly, and pig and cow manure more slowly. This ferment is due to minute organisms belonging to two great classes those which demand an abundant supply of air and die without it, and those which grow without oxygen and die when exposed to it: known to science as aerobic and anaerobic ferments. In this matter of fermentation lay a great deal, indeed all the possibilities of a rich fertilising manure, or a blackened mass of comparatively worthless material largely depleted of its nitrogen, and phosphoric acid and potash.

Dr. Voelcker's experiments show that manure preserved in heaps under cover after a year had lost 14 per cent of its nitrogen, the same exposed 30 per cent, and in thin layers exposed 60 per cent at the end of one year. Elaborate experiments by the Canadian Department of Agriculture show that after three months about, no advantage accrues from keeping mannre, on the contrary a steady depreciation sets in. It would appear that by this time the micro-organisms of the manure and which, by the way are largely excreted with the manure have done their work of breaking up and simplifying the organic portions of the manure quite sufficiently and that after this period further decomposition ont of the soil is more likely to represent a loss than gain of soluble fertilising matter, particularly nitrogen. This apart the case is made out most abundantly for a system of preparing manure, so that it shall retain all or nearly all its fertilising properties, *i.e.* its nitrogen, potash, and phosphoric acid, and this can only be done to the

best advantage under cover where it is not exposed directly to the sun, but most of all to heavy rains. Manures allowed to ferment their own way, and exposed to all weathers are very far from being what they look to be; indeed they may be likened to the glitter without the gold, the form without the substance and since a worthless manure costs just as much to put on the field as a good one, the very serious loss is inexcusable. A simple and effective, and cheap arrangement is that of the French agriculturist who make up two flats with cemented inclined bottoms and between the two is a pit or small well, and into this is inserted a cheap manure pump for the purpose of systematically pumping out the drainings on to the manure heaps; if the draining is insufficient then water is added in droughtly weather. The cardinal principle is to prevent a violent ferment which sufficient moisture does, but the manure should also be compactly and firmly built up, so as to exclude excess of air which would give the aerobic ferment too much scope for action to the detriment of the manure. This is especially applicable to horse manure which ferments rapidly and violently, unless thoroughly wetted and well compacted. All sorts of odd places may do for the purpose of preparing mannre where it exists in only reasonable quantities, but it should be nnder cover of some kind. The manure must be uniformly mixed, and if need be wetted and kept from start to finish thoroughly moist and all drainings regularly returned to the manure: then when the manure is ready it should be promptly put on the field and ploughed in, or if this is not convenient I suggest the covering of it up with a layer of soil until required. Experiments and analyses go to show that manure merely tossed into a pit or heap and exposed to the elements lose half its fertilising matter in six months, while on the contrary carefully preserved and made manure under cover makes a difference of ten bushels of wheat and four tons of potatoes per acre.

People in this country seems to hold a high opinion of cow manure, but the U. S. A. Department of Agriculture gives the relative fertilising value of manures as follows:—Poultry, sheep, pigs, horse, cows thus it will be seen cow manure comes last, but the sum total of manures from a cow is more than double that from a horse in the course of a year and, moreover, the fertilising value of a manure does not exhaust its value by any means least of all in a tropical country like India: a good dressing of cow manure will last much longer and show its effects long after a similiar dressing of horse manure has disappeared.

Numerous analyses show that the value of all animal manures bears a direct relation to the kind of food they receive. For example, linseed and cotton seed meal abstract from the soil per ton 105 and 135 lbs- of nitrogen respectively. Turning to a table sbowing the amount of nitrogen in manure from many kinds of feeling stuff, linseed meal figures at 16 dollars worth of nitrogen per ton of manure. Cotton seed meal at 20 dollars ditto whereas tnrnips fignre at 0·48 and Indian corn meal at merely 453 per ton and so on.

Analyses show that all mannres contain from 50 to 95 per cent of the fertilising matter contained in the food stuffs consumed, so it necesarily follows that the value of manure can be gauged roughly from the nature of the food given.

Animals which have reached maturity and do not grow, more or less, excrete practically all the fertilising matter of the food stuffs consumed. On the other hand milch cows and young growing animals excrete from fifty per cent of the fertilising matter consumed.

The urine of animals varies considerably, but it is highly important to note the urine is even more available than tha manure of some animals, containing as it does a large percentage of perfectly soluble fertilising matter, especially so in the case of horses, and sheep, but analyses show that urine; is nearly wholly deficient in phosphoric acid and that by far the best plan to obtain an uniformaly high fertilising manure is to use the urine with the solid manure

The following table shows the immense importance of securing the nrine of all animals, and represents the amount of nitrogen in solid and liquid after complete removal of water from both :—

	Nitrogen, Solid Per cent.		Liquid. Per cent.
Horses ...	2·08	...	10·9
Cows ...	1·87	..	10·0
Swine ...	3·00	...	12·0
Sheep ...	1·78	..	10·4

Generally one-half and sometimes much more of the nitrogen excreted will be found in the urine and a large portion of the potash, but little or no lime or phosphoric acid. Nearly, all the potash and phosphoric acid in food stuffs is excreted by animals; and the urine is much richer in nitrogen than the solid matter, hence combination of both is the best of all.

But since nrines are especially rapid and effective in setting up ferments, care at all times is required never to allow the heaps to over ferment or become dry, otherwise the loss of nitrogen in the shape mainly of ammonia becomes very great.

CONCLUSION.

(1) It is a matter of first class paying importance for the agriculturist to give the strictest attention to his manure heap; (*a*) for the high rate of fertilising matter properly managed it may contain: (*b*) for the additional value in aerating and keeping the soil in good physical condition.

(2) Animal manures should be systematically kept moist and in this country well compacted into firm heaps under cover ont of the way of the fierce sun-heat and rains.

(3) No good pnrpose is served in keeping manure after three months ont of the soil, but if unavoidable a good plan would be to cover over the heap with a good layer of soil.

(4) Cow and pig manures being of a slow, steady fermenting character should be mixed with rapid highly fermenting manures such as horse and sheep.

(5) It is highly important to secure all urine and incorporate it with the manure.

(6) The fertilising value of all animal manures bears a direct relation to the quality of the food stuff the animals receive, highly fed animals giving rich manures and poorly fed ones light manure.

(7) The following substances are good for fixing the nitrogen of manures and generally preserving them —superphosphate, gypsum, and kainit (a mannfactured form of potash) for cow and horse manure at the rate of about a lb. per 1,000 lbs. of manure and for sheep and pig manure about 4 ounces per 1,000 lbs.

CAMELLIA.

Banana Caltivation in Fiji.—The exportation of fruits, and especially of Bananas, continues to rise, and according to the report of the German Consul, the value of the exports rose from £25,477 in 1898, to £30,606 in 1899. Nevertheless this crop is considerably less than could be obtained. The plants are subject to a disease, the canse of which is not as yet ascertained. During the first year no injurions appearances are remarked, and the plants bear handsome bunches of fruit, bnt suddenly they become unhealthy and must be grnbbed np. With the aim of overcoming the disease, new plantations are laid down, but nnder the disadvantage of getting always further from the seaports. Some of the planters are importing varieties of Bananas from other countries, in the hope of obtaining one or more which may resist the disease.—*Gardeners' Chronicle.*

COFFEE IN DISTANT LANDS:

GUATEMALA.

In a short notice issued by one of the principal London commission houses, in March of this year (1900), we find the following words :—

"The quality of coffee from Guatemala up to date leaves much to be desired this year, and the great defect is frequently noticed that it has not been sufficiently dried, a fault which causes the fruit to suffer much both in colour and quality. Once more we advise our friends the planters to see that their coffee is perfectly dried, otherwise they expose themselves to inevitable losses."

Such remarks call for no comment, only reasonable carefulness is needed to avoid such criticism as this.

The political disturbances of the autumn of 1897 were the cause of the planters losing a great part of their crops that year, owing to the Indians, who contract to come down for the picking season, remaining away through fear of being forcibly enlisted for the army. The most productive coffee district was also for some time in the hands of the revolutionists. These circumstances combined with the serious fall in prices that took place in the marks of the world had as a result, that the small quantity shipped, which was mostly of an inferior quality hardly paid the shipping expenses, to say nothing of the working expenses of the plantations. As a rule, also, the planters were left without any funds to keep their lands in good order free from weeds, which grows very rapidly here, greatly prejudice the bearing powers of the trees so that the foreign houses very reluctantly had again to provide funds to their customers in order that the following crop should not be lost. That crop (1898) again turned out very small, the planters had been properly cared for, for the owners only being able to do the most necessary work on them, and being deeply in debt they began to get disheartened. The prices of the coffee continued to fall heavily, and coffee-planting seemed, in this country at least, to leave a serious loss on the year's working.

As a consequence very little re-planting was done, and as this was also omitted to a great extent during the preceding two years, and old trees are continually going out of production, the next crop will also be likely to suffer somewhat as regards quantity, and perhaps quality, as the young trees give the best beans.

As regards the crop of 1899, now being shipped, it is again found to be below the average, but all is not yet shipped and statistics are not to hand.

The quality is also said not to be as good as in former years. The weather last year was not favourable to the growing berries, and the product has suffered both in colour and in size.

On the other hand the prices realised in Europe have been so far highly satisfactory, owing to an improvement in the position of the coffee market in general and probably owing also to the falling-off in the shipments from Brazil.

If this rise in prices continues, it is quite possible that many planters who appeared some months ago to be hopelessly involved may, by hard work and devotion to their duties, come well out of their financial difficultics. In order that they may so extricate themselves, however, it will be necessary not only that prices of coffee remain high, but also that internal tranquillity should reign in the country, so that labour can be obtained, and also that the tax on the export of coffee should not be raised again immediately, now that it appears that coffee-planting is once more a profitable form the industry.

The high rate of exchange has of course, immensely benefited planters as the expenses of production, shipping, etc., are paid by them in the depreciated currency of the country.

The cost of production varies considerably in every district, but, putting it roughly, including shipping and forwarding expenses at 20 dol. per quintal, and the net result after sale of the coffee at 40s. per quintal, it will be seen that if the exchange were at 100 per cent. as it was a few years ago, before the commencement of the present economic crisis, there would be no profit at all. Consequently the present momentary prosperity of the coffee-planters depends almost entirely on the high rate of exchange, for it is certain that wages, etc., would not be correspondingly reduced should the natural currency again fall to par or to within 100 per cent.

The planters who owe no money abroad, but who in times of prosperity borrowed money of the banks here and thus only have to pay in the depreciated currency are, of course, very favourably placed. For instance, local buyers of coffee, at one time a month or two ago, paid freely the price of 65 dol. a quintal of parchment coffee, and as it probably did not cost more than 15 dol. a quintal (actual cost of labour, without interest on debts or capital) the planter is in a position to credit his bankers a fair proportion of his debt including over-due interest, and retain a sufficient sum for working expenses during the year. Those (the great majority) who borrowed gold in Europe are unfortunately not in such a happy position, for although they are also slightly better off for the rise in prices their profits when converted into gold do not leave them much with which to pay their debts and carry on the work of their plantations.

The Director-General of Agriculture, a Department of Government only founded in the middle of the year, has issued an interesting report to the Minister of Public Works, in which he explains the efforts the new department are making to encourage and improve agriculture throughout the country. To this effect a circular was addressed to each departmental political chief calling on him to forward a yearly report of the agricultural and other works and statistics of his department. This being quite an innovation, the reports returned at the end of the past year leave something to be desired in the way of detail, especially with regard to agriculture, but, on the whole, a decided impetus seems to have been given to the great national industry, and fuller and more trustworthy statistics are forthcoming than have ever before been obtainable.

The Director-General says :—

"The programme traced out for this department by the laws under which it is established is very wide, and if the circumstances of the Treasury were other than they are something would already have been done to encourage the various branches of industry under its care, by means of spreading widely a knowledge of the modern system of cultivation by the distribution of pamphlets and paper on agriculture, seeds, plants, etc., all of which, however, would have necessitated outlay, which, for the present, Government is unable to make.

"The department has every confidence in the good results which agricultural experiments will yield in countries which, like Guatemala, may be said to be beginning to learn the art of cultivation, because the conviction of the truths spread in print is not grasped by the minds of the majority of agriculturists except when impressed by practical results."

The Director points out that a coffee planter may learn many useful lessons by watching the results of the methods employed by his neighbours, engaged in the same pursuit, and that as he studies the methods of others who grow various diffierent products, his general knowledge of agriculture will be greatly increased. In view of these opinions, the Director proposed to the Minister of Public Works the establishment of a model farm on the National lands as soon as the financial difficulties in the way should have beco overcome.

Various examples of the efforts of the department to encourage agriculture and impiant confidence as to its impartiality were given, as for example labourers who had been sent by the local authorities in different departments to work on the plantations near the coast at the very moment when they were commencing to sow wheat and maize were upheld in their complaints, while, at other times, labourers ordered to work on the roards at the time of the coffee harvest, thus depriving the planters of labour at the most important period, were sent back to the harvest.

On the future of coffee production, the Director writes :—

"This department under my care considers that the almost prohibitive duties which exist on coffee in foreign countries will always be an obstacle to any scheme having for its aim the generalisation of coffee in the world is enormous, and as this increases, the consumption does not seem to increase at the same rate. The instability of the market for this fruit commenced about two years ago, and we can judge of the results by the compromised condition in which these countries find themselves which have devoted themselves entirely to its cultivation.

"If for reason extraordinary we are still permitted to keep our place in the markets of the world, we must seize the opportunity to think for the future.

"Long is the list of vegetable products which we can export, with greater advantage than coffee perhaps, and certainly without running the risks to which is exposed a fruit produce by all the continents of the world with the exception of Europe. We have a multitude of plants whose utility we scarcely suspect, but which are well-known and valued abroad, plants which grow wild in our fields and which are continually destroyed as their value is unknown.

"Such for example is the plant which the Indians use for thatching their houses, and whose long, flexible and strong roots are used abroad in the manufacture of brushes, brooms, &c.

"This product is well-known in Europe, and Mexico exports this plant alone to the annual value of 3,000,000 dol., the preparation being of the most simple nature and consisting only in pulling out the roots with care not to break it, washing it and drying it in the sun.

"The value of this product in New York varies from 7 to 17c. gold per lb., and the cost of production and transport does not amount to 5c. We must also remember that this plant is obtained in districts so arid as not to permit the cultivation of other planters and that the severity of the climate does not affect it, which has fruites, recommendation."—*Planting Opinion.*

PLANTING NOTES.

"West Indian Bulletin."—The fourth number of the first volume of the *West Indian Bulletin* includes paper on: Moth Borer in Sugar Cane, by H. Maxwell Lefroy; Sugar Cane Experiments at Barbados, by Prof. J. P. d'Albuquerque, and J. R. Bovell; Experiences with Seedling Canes in British Guiana, by F. J. Sgard; Sugar Cane Experiments in Louisiana, Fixation of Atmospheric Nitrogen by Leguminous Plants; Tree Planting in Antigua, and Care of Pasture in Antigua, by the Hon. Francis Watts; Cacao Industry in Grenada Fungi on the Cacao Tree, by J. H. Hart; Agricultural Education in English and in French Rural Schools; and Fumigation of Seeds and Plants. The article mentioned above on the Caca disease is accompanied with an illustrative plate.—*Gardeners' Chronicle.*

Timber 1,000 Years Old.—Experts seem to be divided as to which of the two hard woods—Jarrah and Karri—of Western Australia is the most durable. Jarrah wood piles 2 feet 2 inches square, driven thirty-three years ago at the Largs Bay pier, were found on examination to he as sound as the day they were put in. Some specimens of Karri wood taken from a fence were examined in London, and though the wood had been underground for twenty-five years it was perfectly sound. A specimen of Jarrah wood under similar circumstances showed serious decay. Timber of the Tamarisk or Shittem wood has been found perfectly sound in the ancient temples of Egypt in connection with the stonework which is known to be at least 4000 years old.—*Journal of Hoticulture.*

Lavender Farming.—Why not earn a living by scent farming? That is the latest hint to the unemployed woman with a certain amount of capital. At Mitcham, Willington, Sutton, Banstead, and through the neighbouring districts vast quantities of scent-producing crops are grown. A contemporary describes a recent visit to one of these scent farms, occupying an area of over 600 acres, covered with broad breadths of Lavender, Peppermint, Rosemary, Camomile, and Pennyroyal. In the centre of one field of Lavender, comprising some 70 acres, the owner has erected a two-storied chalet, from which commanding views are obtained of all the neighbouring fields. It was delightful in such a breezy atmosphere to breathe the delicious odours given off under the influence of a July sun, the power of which puts strength and merit into the oily organs of the purple blue spikes which wave in every direction. As there must always be a world-wide demand for these sweet commodities, it would seem to be an undertaking eminently adapted for ladies. Firstly, the right kind of land must be acquired, a deep sandy loam, preferably overlying chalk. A plantation of Lavender stands four years, and it costs about £40 per acre to prepare and put out the young plants, so that there is but trifling return the first year; after this they commence to be productive, and in favourable times the crop will give from 20 to 30 lbs. weight of oil per acre, which in good quality is worth about 40s. per lb. The fine odour and strength of the British product makes it worth from four to six times that of continental growth. August is the month for cutting and distilling. As the season approaches all is hustle and activity. Lavender is cut with a sickle, laid with regularity in mats, carried to the great vats, and after a boiling process of about two hours' duration the rich oil comes out through its proper channel, and is soon prepared for the wholesale druggist to handle.—*Journal of Horticulture.*

PEARL OYSTERS AND PEARL FISHERIES:

MEETING OF THE CEYLON BRANCH ROYAL ASIATIC SOCIETY ON OCTOBER 27.

The meeting on Oct. 27th at the Colombo Museum, was one of the most successful and interesting to the general public of those which have been held for a long time past by the Royal Asiatic Society. The presidency of His Excellency the Governor added distinction to the occasion and assisted towards attracting a larger audience than even the great interest of the subject might have secured. The number present would doubtless have been increased but for the heavy rain which was falling sometime before the meeting began. His Excellency, in the speech of the evening, was in one of his inimitably happy moods, drawing together the threads of the discussion in dexterous fashion, illuminating all with abundance of humour and adding just so much official encouragement as regards the development of our pearl fisheries as was generally to be desired. The discussion elicited by Mr. Collett's excellent paper and Captain Donnan's practical remarks was valuable as well as full of interest.

H.E. the Governor, Sir West Ridgeway, presided, and was supported by the Bishop of Colombo, Mr Oliver Collett (the reader of the paper), Mr John Harward, Mr R Ponsonby, P.S. to the Governor, and Mr Gerard A Joseph; while among those present were:—The Hon. H H Cameron and Mrs Cameron, Mrs Collett, Mr S M Burrows, Capt. J Donnan, Mrs and the Misses Donnan, Mr and Mrs Ferguson, the Misses Ferguson, Mr R H Ferguson, Mrs Collett, Mr S J C More and Mrs More, Mr A Haly and Miss Haly, Mr F Crosbie Roles, Mr C Harward, the Rev. W R and Mrs Peacock, Mr and Mrs Frederick Lewis, Miss Halliley, Mr H J C Prior, Mr E E Green, Mr C M Fernando, Dr. W G VanDort, Miss VanDort, Mr H VanDort, Mr A F Mahn, Dr. W H de Silva, Mr W E de Silva, Mr P E Morgappah, and a number of others.

After the minutes had been confirmed, the following new members were elected:—Messrs. J W Robertson, W.A.D., J Perera, and A F Mahu.

His Excellency then introduced Mr. Collett, who proceeded to read his paper:—

MR. COLLETT'S PAPER.

The Pearl Oyster Question, which has always had a special interest for the Members of this Society, has of recent years become one of growing general importance; for, in proportion as diamonds are becoming more plentiful, the demand for pearls, as ornaments, is likely to increase.

It might be said that there is little that is new to be discussed before this Society regarding pearl fisheries, seeing that the subject has already found able mention in two valuable contributions to our Journals.* But, hitherto, no attempt has been made to treat the matter from a zoological standpoint, or to go over the field of research systematically, with a view to show in what special particulars the methods employed in conducting the various pearling industries of the world chiefly differ.

I now propose, therefore, to lay these aspects of the matter before you, and at the same time to endeavour to bring to a focus all information that is up to the present on the subject of pearl fisheries.

And first let me remark, in regard to the term "fisheries," that its employment here is, in a strictly scientific sense, incorrect, since the animals by which pearls are produced properly belong to the class *Mollusca*, and not to that of *Pisces*. However, in this connection we chance to have the opinion of an eminent zoological authority.

Lecturing, in 1895, at the Royal Colonial Institute* upon "Whales and Whale Fisheries," the late Sir William Flower, then Director of the British Museum (Natural History), remarked:—

"It happened to me a few years ago to receive a semi-official inquiry from the Colonial Office as to whether a lobster was a fish, because an important point in the dispute between the French and English about the Newfoundland Fisheries depended upon the interpretation of an old treaty in which the word 'fish' occurs. After giving the modern naturalist's definition of a fish, by which a lobster is clearly excluded from the class, of course, I found it necessary to remind my correspondents that in such a case the real answer to the question lay in the sense in which the word was used at the time of the treaty, and by those who were parties in drawing it up, and if that could be ascertained it would be more to the point than the strictest of scientific definitions. Now on turning to what was in the beginning of the present century, our greatest authority on the meaning of words, I find in *Johnson's Dictionary* (I now quote from Todd's edition, 1818) 'fish' defined as 'an animal that inhabits the water.' Without doubt this was the general and popular view, as the universally used expressions *shell-fish* lobster and oyster *fisheries*, *whale fisheries*, and even seal *fisheries* abundantly testify. I therefore cannot say that in a certain vague and antiquated sense of the word, 'fish' may not be applied to the animals of which I propose to speak to you."

The seeker after detailed information concerning pearl oysters does not find an abundance of material at his command. On the contrary, the literature dealing with these animals is extremely poor and deficient. It is a remarkable fact that although countless references to pearls occur throughout history, and although the many published accounts of the pearling trade form quite a literature in themselves, there exists at the present time but one work in the English language devoted to pearls, their history, peculiarities, and various uses,† and no single work (so far as I am aware), in any language, which gives an account of the natural history, habits, and instincts of the animals by which pearls are produced.

At the present time information upon these points is only to be obtained by laboriously searching over the many scattered statistical reports issued from different pearling stations. As a rule, these reports are drawn up for purely commercial purposes, or with the object of laying down rules and regulations for the conduct of the fisheries. Yet, here and there, valuable zoological observations occur, by means of which it is possible to form some idea of

† "Pearls and Pearling Life."—E. W. Streeter, London, 1886.

Note.—"Gold, Gems, and Pearls in Ceylon and Southern India"—published by the *Observer* Press in 1888—contains much valuable information on the Ceylon fisheries.

the biological conditions which exist at different pearling centres. And from such sources as these a great part of the material here dealt with has been derived.*

VARIETIES OF PEARL OYSTERS.

Pearls are produced by quite a number of different molluscs, and some of these are very widely distributed. Among the bivalves, the great *Tridacna*, the common oyster (*Ostra edulis*), and many species of *Pinna* produce pearls.

They are also found in certain species of *Unis* and *Anodonta*—fresh-water shells—which furnish the river pearls of Europe and North America. Certain univalve shells also produce pearls, for example:—*Strombus gigas*, the giant "conch-shell," and several species of *Turbinella*. These produce the pink pearls of the Bahamas and of the West Indies generally.

The ordinary pearls of commerce may be divided, roughly, into two classes, viz., false or "seed" pearls, and true or "Oriental" pearls. The two kinds differ greatly both in beauty and value, and are produced by two very distinct genera of shells. These are (1) *Placuna*, with a single pearl-bearing species, which belongs to the family of *Anomiidæ*; and (2) *Meleagrina*, which includes several pearl-bearing species, and which belongs to the family of *Aviculidæ*.

Placuna placenta, commonly known as the "window-shell" of the Chinese (because its semi-transparent valves are frequently used in China for illuminating dwelling-houses), is the "pearl oyster" of the Red Sea, the Persian Gulf, Karachi, the Bay of Tamblegam near Trincomalee, and the Eastern Archipelago generally as far as Hongkong. Although it produces only "seed" pearls, an immense number of people are annually employed in its collection. The pearls themselves are seldom of much value, though there is generally a demand for them in the markets of the East. They are, however, of little importance in the present inquiry; and so we need not further consider them here.

TRUE PEARL OYSTERS.

All of the species of true pearl oysters belong, as I have just said, to the family of *Aviculidæ*—or "wing-shells—and with this family it will now be necessary for us to form some acquaintance. In the first place, it is one of most respectable antiquity. No less than three hundred species have been recorded in the fossil state, some even from the lower Silurian strata. As a large number of these fossil forms have been discovered in northern latitudes, it is probable that at one time in the earth's history the family was very widely distributed, though it is now almost entirely restricted to tropical and temperate seas. At present only twenty-five recent species are known. Of this number, five, which belongs to the genus *Meleagrina*, are now fished for pearls. These constitute the pearl oysters of Madagascar, Ceylon, Japan, the South Sea Islands, Panama, California, and the northern and western Coasts of Australia. Zoologically speaking, they do not belong to the true oysters (*Ostreidæ*), but are much more nearly allied to the mussels, being furnished with a *byssus*, or "cable," by which they are in the habit of mooring themselves to rocks and other substances at the bottom of the sea.

The classification of the different species (and varieties) of *Meleagrina* has not yet been systematically worked out; consequently, their correct identification is a matter of considerable difficulty. We find, for instance, quite a number of shells—bearing both pearls and mother-of-pearl—designated by the common name of *M. margaritifera*; whereas, in all probability, they belong to very distinct species. True, *M. margaritifera* (the mother-of-pearl oyster) does frequently produce pearls, but it differs in many important particulars from the other pearl-bearing species of *Meleagrina*—the shells of which are not, as a rule, of any value as mother-of-pearl.

The geographical distribution of the pearl-bearing species of *Aviculidæ* appears to be as follows:—

1. *Avicula* (*Meleagrina*) *margaritifera*, Lin.—The large tropical pearl oyster of Northern Australia, the Pacific, and the South Seas generally. It is the mother-of-pearl shell of commerce, and although it often contains pearls it is chiefly fished for the sake of its shell alone.

2. *A.* (*M.*) *imbricata*, Rve.—The pearl shell of the northern coast of Western Australia. It is said to be closely allied to the Panama species. It produces pearls, but its shell is of little value.

3. *A.* (*M.*) *fimbriata*, Dkr.—The pearl oyster of the Gulf of California and the Bay of Panama.

4. *A.* (*M.*) *Martensii*. Dkr.—The pearl oyster of the Japanese Seas.

5. *A.* (*M.*) *fucata*, Gould.—The pearl oyster of the Gulf of Mannar. It also occurs in the Torres Straits and (probably) in the Arabian Seas.*

The pearls produced by the above five species are of every shade of colour, from the pale golden pearl of Northern Australia to the lustrous black gem of the Bay of Panama. Those most generally admired however, and which command the highest prices, are of almost transparent whiteness, with a slightly azure reflection. They are known as the "pearls of the Orient," and are produced by the pearl oyster (*M. fucata*) of the Gulf of Mannar.

NATURE AND FORMATION OF PEARLS.

It will be necessary for us to pause here for a moment to consider what is up to the present time known of the nature and formation of pearls, in order that this discussion may have a sound basis.

* I take this opportunity of expressing my thanks to Mr. R Etheridge, the Director of the Australian Museum, Sydney, N.S.W., and to Mr. Charles Hedley, the Conchologist of that Institution, for valuable reports and statistics. Also to Professor H A Pillsbury, of the Academy of Sciences, Philadelphia, U.S.A., and Mr. T Nishigawa, of the Imperial Fisheries Bureau, Tokyo, Japan, for information kindly supplied. Further, I am under a special obligation to Mr. John Ferguson, of Colombo, who has most kindly placed at my disposal a valuable collection of Papers relating to various pearl fisheries.

* Mr. Holdsworth, the Naturalist engaged by the Ceylon Government in 1867 to investigate the pearl oyster question (but who unfortunately never had an opportunity of seeing a fishery, and, according to Sir William Twynam, never saw a pearl bank with oysters on it), was the first to point out the distinction between the Gulf of Mannar oyster and that of the Persian and Arabian Seas (*Placuna placenta*). Some shells from the Persian Gulf shown to Captain Donnan appeared to him to exhibit no differences from the Mannar species ["Gold, Gems, and Pearls," p. 374]—from which I conclude, having regard to his (Captain Donnan's) great experience, that the Mannar oyster also occurs, though perhaps sparingly, in the Arabian Seas; and this may account for the occasional discovery of fine "Oriental" pearls in that region.

Pearls are an excretion of super-imposed concentric *laminæ* of a peculiarly fine and dense nacreous substance consisting of membrane and carbonate of lime. The question of their origin has a special attraction for the zoologist, since it still forms one of the unsolved problems of science. Pliny held the belief that they were drops of dew or rain which fell into the shells when opened by the animals and were then altered by some power of the mollusc into pearls. This view obtained all over the East, and—strange to say—Columbus found the same belief popular among the natives of Mexico. Moore thus alludes to it in his poem "Peri and the Pearl":—

"And precious the tear as that rain from the sky
Which turns into pearls as it falls in the sea."

At the present day it is popularly supposed that all pearls have for a nucleus a grain of sand which has become coated with nacre by the animal; but this is simply a conjecture which has gradually become regarded as a fact. As a general rule, it is some organic substance, which behaves in the same way as epidermis when treated with certain chemical re agents. In some districts one kind of nucleus seems to be more common than another, and this is how the different results obtained by observers in different localities may be explained The most generally prevalent nuclei appear to be the bodies or eggs of minute internal parasites—such as *Filaria Distoma, Buccephalus*, &c. This was pointed out by the late Dr. Kelaart, in his Report to the Ceylon Government on the Pearl Oyster of Aripo;* and his observations were supported by Humbert, the Swiss Naturalist, who accompanied him to the pearl banks in 1895. More recently, similar observations have been made by Mr. Edgar Thurston, of the Madras Museum;† and the latest conclusions of Science appear to be entirely favourable to the "parasite" theory.

The fact that pearls may be artificially produced by inserting small shot or grains of sand between the mantle and the shell of the animal has long been known. The Chinese have been specially successful in producing pearls in this way; but the best of them are of inferior colour and brightness, and their value is comparatively insignificant. Linnæus, who was aware of the possibility of producing pearls artificially, suggested the collection of a number of mussels, piercing holes in their shells with a fine auger to produce a wound, and afterwards "parking" them for five or six years to give the pearls time to grow. The Swedish Government consented to try the experiment, and long did so. Pearls were produced, but were of little value, and the enterprise was finally abandoned as unsuccessful.

The distinction between fine pearls and these intrusive bodies coated with nacre was recently demonstrated in an important Paper read before the Académie des Sciences, Paris, by M Léon Diguet. He alleges that the latter have only the iridescence of mother-of-pearl, and are in origin analogous to the deposits which increase the shell. The true pearl, he contends, has no connection with the shell itself, but is a pathological calcification or "stone," and seems to arise from parasites. It begins with a small sac of humour, which becomes gelatinous and calcifies in a series of concentric layers, while at its centre may be found a cavity holding organic matter, the remains of the parasites which gave it birth.*

"Pearl," says Saville-Kent, "is, unfortunately, one of the substances impermeable to the recently discovered Röntgen rays; otherwise the solution of this mystery . . . might be easily achieved. May be, however, in the near future a new xx., xxx., or other occult luminant will be evolved which shall possess the property of laying bare and naked the nuclei of pearls.†

THE PEARL FISHERIES OF AUSTRALIA.

The pearl fisheries of Australia have of late years developed considerable proportions; they are conducted in the Torres Straits, on the coast of Queensland, and on the northern coast of Western Australia. Here the large pearl oyster *M. margaritifera* is fished, primarily for the sake of its shell, which furnishes the mother-of-pearl of commerce. Pearl themselves, when discovered, are regarded as more or less of a chance product, and are frequently appropriated by the hired diver and boats' crew—and this may be said to be commonly the custom in all the pearl fisheries of the South Seas. The total value of the pearl-shell fishery of Queensland alone amounted in 1898 to £109,401 sterling

On the northern shores of Australia, in addition to the mother-of-pearl shell (from which almost all Southern pearls are derived), there occur two other species, viz., *M. imbricata*, Rve., and *M. fucata*, Gould, which produce pearls. The latter is identical with the pearl oyster of the Gulf of Mannar; but is, curiously enough, regarded with disfavour in the Australian region, where it is known as the "bastard" shell,—probably because its shell is of little value as mother-of pearl, and also, perhaps, because it does not produce fine "Oriental" pearls in the Southern Seas.

The pearling grounds of Australia are leased out to various companies and individuals by the Government. These leases are granted only to approved persons, and are subject to certain important conditions and stipulations. No shell below a certain standard of growth is allowed to be removed from the banks; and all shell shipped for exportation must be submitted to the inspection of a Government official specially appointed to guard the industry. Pearls may only be purchased by licensed dealers, and the Government reserves to themselves the right to prohibit at any time the collecting of pearls and pearl-shell on any particular part of the coast. A constant guard is maintained over the banks, and certain areas are prescribed by the Inspectors when they have reason to apprehend any danger to the oysters from the results of overfishing.

In the Australian fisheries modern diving apparatus is largely employed, the same being periodically inspected by Government in order to prevent the use of defective gear. Diving for pearls by native divers without diving dress seems likely to be discontinued in this region—especially as it is now found that, as a rule, the best pearl oysters flourish at depths beyond the reach of unprotected divers.

On the whole, these fisheries appear to be conducted upon a more up-to-date and advanced method than elsewhere. Some interesting experiments in

* "Report on the Natural History of the Pearl Oyster, Trincomalee," 1859.
† "Pearl and Chank Fisheries of the Gulf of Mannar." 1894 p, 18.

cultivating pearl oysters were made by Mr. W Saville Kent, F.L.S., late Commissioner of Fisheries to the Government of Queensland and Western Australia; but the very short period over which his investigations extended, and the limited facilities which he enjoyed for the conduct of his research, rendered it impossible for him to achieve results of any value. He however showed that artificial fertilisation and incubation are quite possible, though the questions of conservation and protection from enemies still remain to be dealt with.*

THE PEARL FISHERY OF JAPAN.

In the Bay of Agu, in the Province of Shima, Japan, an extensive pearl fishery exists. The pearl oyster of this region (*M. Martensii*) appears to be the most northerly situated of the pearl-bearing species of *Meleagrina*, and it lives under conditions which more nearly resemble those which obtain on the oyster banks of Europe—where the true oyster (*Ostrea edulis*) is cultivated—than those which surround its own congeners in tropical seas. The Japanese pearl oyster lives in quite shallow water, and is left exposed upon the banks at low tide. This condition of things would seem to present special facilities for artificial cultivation; but unfortunately, on this very account large numbers of the shells perish of the cold in winter. Professor Mitsukuri, of the Imperial University, Tokyo, has inaugurated an elaborate system of cultivation, which gives promise of good results. One of the principal features of the scheme is the collection of the "spat" in shallow water, and its transference to comparatively deep water—6 to 7 fathoms—where the temperature is more equable. Here the young oysters are constantly watched and protected against the attacks of predacious foes. I hope to be able to obtain further particulars of this interesting experiment as the work proceeds. At present fuller information is not available.

Artificial cultivation after the Chinese method has also been attempted in Japan; but, so far, only hemispherical pearls, whose bulbs are attached to the shell, have been produced. Japanese pearls are not commonly seen in the markets of London and Paris, probably because there is always a demand for these at home.

THE PEARL FISHERIES OF CALIFORNIA AND PANAMA.

In the time of the Jesuit Missionaries the Central American pearl fisheries were actively carried on, and produced great wealth to those engaged in the industry. But they afterwards fell into decay, and for many years the banks were thought to have been exhausted. More recently, however, the industry has been revived—chiefly owing to the introduction of modern diving apparatus, which has proved of great utility.

Mr. Townsend, of the U.S.A. Fish Commission, says: "It is not unlikely that the adoption of the submarine engineer's suit by the pearl fishers of La Paz must have been the step which led to the continuance of the pearl fishing industry, for the search for shells can now be pursued into deeper waters than in the days of the naked divers, the best of whom could not descend a dozen fathoms. Half that is rather more than a practical working depth." And again in the same report, Mr. Townsend says "Whatever of romance has hitherto enshrouded the naked diver for pearls in the sea, he is now practically a submarine labourer who uses all the modern diving paraphernalia available. No longer plunging for sixty seconds into the sunlit green water that covers a coral bank, he puts on a rubber suit with glass-fronted helmet, and, suitably weighted with lead, descends for hours to gather pearl oysters, which are hoisted in a wire basket by his companions in the boat above, who also supply him through a rubber tube with the air he breathes." *

M fimbriata is the pearl oyster of this region, but *M margaritifera* is also fished here as elsewhere in the Pacific. Here again, mother-of-pearl shell is the principal object of the search, its value being sufficient to pay the expense of the fishing, leaving any pearls which may be obtained a clear gain. In America also, as in Australia, the banks are rented out for fixed periods to different pearling traders.

In the Pacific the oysters are usually opened with a knife. This, if properly performed, is said to be the best plan, for pearls are considered liable to become discoloured if the animal is allowed to decompose before the shell is opened.

THE PEARL FISHERIES OF THE GULF OF MANNAR.

The principal fishery in this region is that conducted on the eastern side of the Gulf, in the neighbourhood of Aripo, Ceylon—the pearl banks on the Indian coast having now almost ceased to be remunerative.

At the Conference Meeting of the Colonial and Indian Exhibition in 1886, Sir James Longden (formerly Governor of the Island) remarked that the pearl fishery of Ceylon was "one of the most ancient—perhaps the most ancient industry of the world; that it was carried on today as it had been for two thousand to three thousand years; and that it owed little or nothing to modern civilization in the manner of getting from the depths of the sea that wonderful beautiful product of Nature,—the pearl. †

The Ceylon fishery, besides being entirely carried on by unprotected native divers, is further distinguished from those which we have just been considering in being the only fishery in the Tropics where pearls alone are sought for, irrespective of the shells, the nacreous lining of the valves of the Gulf of Mannar oyster (*M fucata*) being of little or no commercial value.‡

It will not be necessary for me to enter into details here regarding the methods employed in the conduct of the Ceylon fishery. They have already been fully described by Capt. Steuart, Sir Emerson Tennent, Mr. Vane, Mr. Edgar Thurston, and, quite recently, by Sir William Twynam in his very complete and elaborate report just published. § Let it suffice to say that the industry is now a Government monopoly, carried on

* See Appendix to the Report of the Government Resident of Thursday Island for 1898, by S. Pace, F.Z.S.

† Proc. Roy. Col., Institute, 1886.

‡ The mother-of-pearl oyster (*M margaritifera*) also occurs, though very rarely, in the Gulf of Mannar. See Thurston, "Pearl and Chank Fisheries of the Gulf of Mannar," 1894.

§ (1) Tennent, "Nat. Hist. of Ceylon," p. 373; (2) Capt. Steuart, "Account of the Pearl Fisheries," 1813; (3) Vane, "Pearl Fisheries of Ceylon," R A S Journal, vol. X., 1887; (4) Thurston, "Pearl and Chank Fisheries of the Gulf of Mannar" 1894; (5) Twynam, "Report on Ceylon Pearl Fisheries," 1900. See also the many valuable "Inspection Reports" by Capt. Donnan, Inspector of the Pearl Banks, for the last thirty-seven years.

under the inspection and control of specially appointed officers, the system which was formerly in vogue of renting the pearl banks having been entirely discontinued since the year 1837.

There appears to have always been a considerable amount of uncertainty in respect of the amount of revenue derivable from this industry. Writing in 1697 for the instruction of the Political Council of Jaffnapatam, the then Commandant of that town justly remarked that "the pearl fishery is an extraordinary source of revenue on which no reliance can be placed as it depends on various contingencies which may ruin the banks or spoil the oysters." This statement holds good after a lapse of more than two centuries—indeed, the periodical disappearance of oysters from certain of the banks sometimes for many years at a time, may be said to form one of the peculiar characteristics of the Ceylon fishery.

Nevertheless, since the British occupation of the Island a sum equal to more than one million sterling has been derived from the fishery ; and the matter is therefore one of immense importance to to the Government of the Colony.

CONSERVATION OF PEARL OYSTERS.

The question as to whether any means can be adopted to conserve the oysters upon the beds and thus to place the industry upon a more stable and permanent footing, must in the first instance depend upon a knowledge of the physical and biological conditions ruling upon the different banks. There are reasons for supposing that these conditions undergo frequent change ; but the cause, or causes, thereof have yet to be definitely ascertained. It is well-known that the northern and western coasts of Ceylon are being gradually uplifted from the sea. On this account* it is possible that an increasing amount of sand—which is very injurious to all bivalve molluscs—is finding its way from the northern rivers into the waters of the gulf.† It may also be that changes in the temperature, and in the degree of salinity of the water, have the effect of rendering certain of the banks untenable to the oysters for more or less prolonged periods. Further, it is stated upon good authority that the strong ocean currents from the Bay of Bengal, which sweep round the coasts of Ceylon and Southern India, contribute largely to the causes which denude the oyster banks. Altogether, it will be seen that this question is one of some difficulty, and that it must involve the solution of quite a number of local marine problems.

On the western coast of South America, which is likewise at present being upraised from the sea, ‡ pearl fisheries formerly existed which gave rise to wealthy and populous cities—"whose very ruins have now perished." Yet, doubtless some day Science will provide means for the revival of these industries possibly—as in the case of the fisheries of California—by the introduction of special diving apparatus ; for after all it may be found that the oysters have merely migrated seawards into deeper and more sheltered waters.

In regard to the question of artificial cultivation and conservation it is important to observe that the pearl oyster—like the Strassburg goose—only becomes of special commercial value when it has developed certain conditions of organic disease. We have already seen that pearls must be regarded as a pathological product, and we find this conclusion well supported in the records of the fisheries. These contain frequent references to the number of pearls found in diseased and dying Oysters ; and experienced divers are apparently agreed that the probability of finding pearls is always greater when the oysters are crowded together, and become humped and distorted in shape ;* and at the same time afford cover for all kinds of marine worms and parasitic creatures. Thus unhealthy conditions of living must presumably be encouraged in order to promote the diseases which lead to the formation of pearls. In the course of an address to the Malacological Society of London, in 1896, Professor Howes, referring to the peculiar characteristics of certain marine mollusca (chitons) remarked : "In its bearings on the conditions of local distribution in shallow water, on bathymetric extension, and specific variation as related to these influences, the experimental method appears to me to give promise of most important results in Malacology. Just as the physiological graduates off into the pathological, the full significance of many a healthy or a diseased state becoming intelligible only on a knowledge of its opposite, so, in the hands of the experimentalist, the normal phenomena of animal life will most assuredly in course of time become illumined by prolonged and careful study of the organism under changed conditions. And from all that is now going forward it is plain that the pathologist holds the key to many a life problem."

THE CHAIRMAN then called upon Capt. Donnan to offer remarks on the subject. Capt. Donnan spoke as follows:—

CAPT. DONNAN'S REMARKS.

In regard to the remarks upon the similarity of the Gulf of Manaar Pearl Oysters to those of the Persian Gulf, and the suggestion that the former is comparatively rare in the Arabian Seas, I will relate how I came to ascertain that the Gulf of Mannar oyster is found in great abundance in the Persian Gulf. When I went to England in 1875 I took with me a small sample of Ceylon Pearl Oyster shells to ascertain if they were of any commercial value, and during my visit to London, I went into the office in Mincing Lane of Messrs. Brooks & Faith, Produce Brokers, saw the head of the firm, and asked him if my sample of oyster shells was of any commercial value. He looked at them and said "these are what we call Lingas from the Persian Gulf." I replied, "that they came from Ceylon." He said, "don't tell me that, I know better," and pointing to a shelf on which there were a large number of oyster shells, said, "there are your shells, they have come from the Persian Gulf, and large quantities of them are sent to us regularly from Bombay." He then examined my sample and said, "You have been polishing them up, and if you had not done so, they would have been worth thirty shillings per cwt." I replied that the only polishing they had was that of being exposed to the sun and rain on the beach at Sillavaturai for twelve months.

---

* Mr. Boake, in his *Monograph of Mannar* (1888), tells us that a pearl bank at one time existed on the north of that island ; and according to ancient Sinhalese records, there were formerly pearl banks in the vicinity of Mount Lavinia. It is significant that of the 85 pearl banks in the Gulf of Mannar, viz., 19 on the Ceylon coast and 66 on the Indian, only two the Cheval and Modragam banks, are now profitable.

† "Man-ar" is Tamil for "sandy river."

‡ Darwin, "Naturalist's Voyage in the 'Beagle.'"

* These small thick oysters are called by the people "Koddai-pakku," viz. "arecanut oysters" (Twynam's Report, p. 59).

The Lingas on the shelf were similar in every respect to the Gulf of Mannar oysters.

I have recently seen in print that the annual value of the Persian Gulf Pearl Fishery is £300,000.

On my return to Ceylon I obtained the sanction of Government to send home a trial shipment of pearl oyster shells, and in December, 1876, the shells of 12,000 oysters that had been lifted for a sample of pearls for the fishery of the following years were sent to the Crown Agents to dispose of, in communication with Messrs. Brooks & Faith, but subsequently they reported that the shells were of no value.

However, the Gulf of Mannar Pearl Oyster shell must now be of some value, as during the recent fisheries men were sent by mercantile firms in Colombo to collect shells for shipment to Europ

MIGRATION OF OYSTERS AND EMPLOYMENT OF DIVERS WITH DIVING DRESS.

It has frequently been surmised when oysters were reported to have disappeared from a bed and no traces left of them, that they had probably migrated to some other more suitable locality, into depths beyond the capacity of native divers to reach; and that the employment of European divers with diving dress might be the means of tracing them, or of finding new beds of oysters.

My experience of pearl oysters is that they only move about in their young stage, say up to one year old, and after that age they remain on the bed they settle down upon, if a rocky bed, until they come to ripe old age, unless they are forcibly removed; but if they happen to come on a sandy bed, they would have no means of holding on, and would most probably be drifted away and destroyed.

I am led to this conclusion, by observing that it is only during their young stage that I find, when at anchor on a bed of oysters, that they attach themselves to the vessel's cable. The fact of the oysters mooring themselves by such a strong cable as they do, would also bear out this conclusion, for if they were in the habit of moving about always, it would be unnatural for them to moor with many threads of their byssus, when one or two threads would be sufficient for a temporary resting-place. But supposing they were in the habit of migrating and got into depths beyond the capacity of the native diver, say 10 fathoms as his greatest working depth, the configuration of the bed of the ocean, in the neighbourhood of the Pearl Banks is such, that a short distance would take them into depths beyond the capacity of even the diver with diving dress, as the edge of the bank of soundings is very precipitous.

It has often been suggested also, that better results would be obtained on the pearl banks by the employment of divers with diving dress, both at inspections of banks, and at fisheries; but as a matter of fact, I have had experience of the diver with diving dress in both these cases.

Some years ago a European diver was employed regularly at inspections of the banks, and in April, 1884, I had four European divers along with native divers, employed in the fishing of a bank of oysters off Chilaw; when I found the native divers brought up in a day's work as many oysters per diver as the European divers.

At inspections of the banks, it is necessary to get over the ground quickly, as there are very large areas to be examined, and the native diver, who can be taken about in a handy rowing boat, making a dive when wanted, during which he goes over a space of about 20 square yards, and brings up a sample of what is on the bottom, over that area, all in about one minute, is just the man required. I have never known any of the native divers employed at inspections to give a false report of the state of the bottom, and I have found that I could form a far better idea of the state of a bank from their reports, than I could from that of the European diver, who could not move about as quickly as the native.

In this connection I will relate an amusing incident that occurred during the fishery off Chilaw in April, 1884. One morning the European divers reported to me that there were no oysters where the vessel was anchored, and ked for it to be moved to another part of the bank. I knew from the native diver's report that the vessel was anchored on the best part of the bank, so I called up four native boats, and told the tindals to work close round the ships, which they did, and their native divers sent up oysters, 50 to a dive. On seeing this the European divers began work again, and found oysters. Some time after they had been working, I was looking over the vessel's side, and observing the life line of one of the European divers being violently jerked, I called out to his attendants to haul him up quickly, believing that some accident had happened, and that the poor man might be hauled in unconscious or even dead, but when landed on the stage, he was very much alive, for when the front piece of his helmet was removed, he bawled out in a stentorian voice "Where's the man who stole my oysters." He then explained that he had kept a basket at the foot of his ladder to hold the oysters as he gathered them up, and that when he returned to the basket with the last handful of oysters required to fill it, he found the basket empty and oysters gone, and that his rage at this mishap caused him to tug so violently at the life line. The oysters had been commandeered by one of the native divers (belonging to one of the boats working close by), while the European diver was away from his basket.

This I found out some time afterwards, but as there was no evidence available at the time, the thief escaped punishment, much to the annoyance of the European diver.

PHYSICAL CHANGES IN THE BED OF THE SEA ON THE PEARL BANKS.

As far back as my experience goes, there have been no material changes of this nature. It is true the divers have at times reported small portions of the rocky part of a pearl oyster bed to be covered with a layer of sand a few inches deep, and on one occasion during a small fishery off Chilaw, the divers reported, the oysters were being covered up with sand; and that they had a difficulty in getting at the oysters as they were swayed to and fro by the sea, although they were at a depth of 9 fathoms. This was evidently caused by a heavy ground swell rolling in at the time, and if it swayed the divers about, was also probably causing the silting up of sand on the oysters. These occurrences are, however, rare, or have been rarely noticed. The bed of the Cheval and Modrigam Paars seem to remain undisturbed by physical changes, as the area and configuration of their rocky portions have been fairly maintained during my time. No silting up or upheaval in their neighbourhood can be detected by the soundings, which have not decreased during the last seventy years. Changes, however, are taking place on the shore in that

neighbourhood. The cliff opposite the "Doric" is gradually washing away, and much of the island of Karraittivu has disappeared since I first knew it. On the other hand the spit forming the western side of Dutch Bay has been extended into the sea in a N.E. direction about one mile during the last 40 years.

ENEMIES OF THE PEARL OYSTER AND CURRENTS.

The enemies of the Pearl Oyster are no doubt many, as it seems to be the nature of all animal life in the sea, to prey upon each other; but the chief ones to be feared and destroyed, if possible, are the various species of fish that feed on the bottom, and for that reason are commonly called rock fish. These, with the exception of skate are, however, only destructive to the pearl oysters when they are young and their shells tender ;say up to the age of 18 months or 2 years, after which age the smaller kinds of rock fish, which appear to be most numerous do not do much harm.

Generally speaking, when I have been at anchor on a bed of young oysters, the crew of the vessel have caught many rock fish, the stomachs of which were found to contain many fragments of the young oyster shells, thus proving the source of their food.

A bed of young oysters no doubt attracts these rock fish, which appear to come on it in great swarms, and although the young oysters are very numerous, and are generally very thickly spread over large areas, I have counted as many as 40 attached to the fragment of an old oyster shell, yet their enemies are numerous also, and are capable of causing much destruction, often completely annihilating the whole bed, leaving not a vestige behind when I visit the bank a year later; so that if some means could be devised of destroying or keeping these rock fish away from a bank of young oysters for a couple of years, there would undoubtedly be more Pearl Fisheries. If, for instance, fishermen could be induced to take say 200 canoes to one of these beds of young oysters, and fish on it daily for 2 or 3 months, it would have a very good effect, and might possibly cause the dispersion of the fish which readily take bait, and the numbers likely to be caught would well reward the fishermen.

Currents must also be classified amongst the enemies of the pearl oyster, for although they bring the spat on to the oyster beds, they also occasionally sweep mature oysters away from the beds.

The most noteworthy current on record is that which in December, 1887 swept away a very valuable bed of oysters, estimated at 155 millions, from the Cheval Paar. Ten millions of them were found during the fishery in the following March, from two to three miles in a S.-easterly direction from their original position. Attributing this to a current I enquired of the man in charge of the steam tug "Active" doing guard duty on the Cheval Paar at the time, and he reported that in the middle of December there was a strong current lasting a week, running in a southerly direction, and was so strong, about 4 knots, that he had to drop a second anchor to prevent the vessel being dragged away by it. The fishermen on Karraittivu island subsequently confirmed the existence of a strong southerly current running in December.

The loss of that bed of oysters was a loss to Government of at least 20 lakhs of rupees.

On this occasion I was able to make an interesting experiment as to the ability of pearl oysters to resist a current. The divers had brought up a large Pinna shell with several oysters attached to it by their byssus. The "Active" was got underway and the Pinna shell towed in the sea alongside. The oysters held on for an hour, while the "Active" was going at a speed of 4 knots, but when the speed was increased to 5 knots they shortly began to drop off one by one. Although the oysters resisted a 4-knot current for one hour, they evidently had to give way when the strain of a current of that velocity was prolonged for a week. I doubt very much their ability to resist even a 3-knot current for that length of time.

Young oysters have a much stronger hold than oysters advancing to maturity. The divers often remark when on young oysters, that they could not bring up many, as they were holding on fast; but when they come away easily the divers say they are fit for fishing.

There is no record of a current similar to that of December, 1887, having occurred previously and I look upon that one as very exceptional, particularly as to its course which was in a S.-easterly direction.

I am of opinion that it was caused by an unusually large volume of the N.E. Monsoon ocean current flowing into the Gulf of Mannar, and seeking an outlet by sweeping round the head of the Gulf, and down its eastern shore, until it joined the main stream, on its course from the coast of Ceylon towards Cape Comorin. It is well-known that the current from the Bay of Bengal in November and December, runs south along the east coast of Ceylon at the rate of 2 to 3 knots an hour. It curves round the south coast, and after rounding Galle, takes a N.-westerly course past Cape Comorin. Some times it follows the west coast of Ceylon to the north of Negombo, and then branches off towards Cape Comorin. A larger volume than usual coming this way would probably advance further up the coast than Negombo, say to Chilaw and then branch off towards Cape Comorin, and in that case some portion of the stream might before reaching Cape Comorin be deflected along the Tuticorin shore and then follow the course I have described. I cannot account for a S.E. current on the Cheval Paar in December in any other way.

There are also unknown enemies of the pearl oyster. For instance when oysters too young for fishing are found dying off in large numbers, it has not yet been discovered what causes them occasionally to be in that condition.

The question of discovering means of successfully securing pearl oysters against their enemies is a most difficult one to solve. Currents are uncontrollable, and as regards living and unknown enemies, success against their predations appears to me to be very doubtful. Yet in these wonderful progressive times there is no knowing what the employment of scientific skill to deal with these questions might be able to accomplish.

ARTIFICAL CULTIVATION OF PEARL OYSTERS.

I have tried a small experiment in cultivating Pearl Oysters, by depositing a quantity of young oysters in an excavation which I had made for them in the Sillavaturai coral reef, three miles from the shore; but it was not successful.

In March, 1885, I had 12,000 oysters 18 months old lifted from the Cheval Paar, and placed in the tank on the reef, three hours after they were lifted; having been kept in the meantime in a boat half filled with seawater. But, when I returned to Sillavaturai the following year they had disappeared. I then constructed a new tank on a more sheltered part of the reef, 12 feet square and 4 feet deep at low water, much mud was found between the branches of the coral, but it was all well cleared out, and a quantity of coral stone was placed in the bottom of the tank and around the side on top of reef to protect the tank from wash of sea at high water.

When this new tank was completed it seemed an ideal place for such an experiment, beautiful clear water in it, and not a sign of mud. 5,000 oysters 2½ years old taken from the Cheval Paar were placed in it; and 1,000 in a large wooden cage, made for the purpose, which was weighted with stone and sunk in 9 feet of water half a mile rom the beach.

I left Sillavaturai on that occasion in hope of my experiment being successful; but alas! on my return a year afterwards I found the oysters in the beautiful tank on the reef—all dead—having been smothered in 18 inches of mud, at the bottom of it, which had been washed into it from adjoining parts of the reef by the S.W. Monsoon sea, and the cage was found broken up, and the few oysters left in it were dead: and thus ended my experiments in artificial cultivation. I subsequently thought of making a preserve on some part of the eastern shore of the island of Karraittivu, but had to give up that idea, as I found on searching for a suitable spot, that it was all muddy bottom, which would have been fatal to young oysters. There appears to be no sheltered spot on the west coast of Ceylon suitable for pearl oyster cultivation. Some of the bays in Trincomalee harbour might prove suitable, and if so, they would be, I believe, the only places likely to be found for this experiment in Ceylon. The late Dr. Kelaart succeeded in taking pearl oysters from Sillavaturai in chatties round to Trincomalee, and in keeping them alive for some time after.

In connection with this subject the question arises whether or not, in the event of pearl oysters being successfully reared in shallow water, it would be necessary to lay them out in their natural beds to produce pearl. During a visit I made in 1867 to the edible oyster preserves on Hayling Island near Portsmouth, I was informed that it was necessary, when the young oysters had attained an age of one year or more in the preserves, to lay them out on their natural beds to fatten, and this might be found necessary also in the case of pearl oysters for the purpose of producing pearls. The native headmen who were employed at fisheries and inspections of the pearl banks years ago, declared that oysters found in shallow water never contained pearls, and that only those found in deep water were of any value. I have not had an opportunity of testing this theory; but if it is correct, then any scheme of pearl oyster culture attempted hereafter would have to contend with the risk of young oysters, after transference to their natural beds, being at the mercy of their enemies, almost as much as they are now; and in that case, Trincomalee would be too far away from the beds in the Gulf of Manaar, as the cost of transference of the large number of young oysters required to produce a fishery would be prohibitive, even if found feasible. There are no known pearl oyster beds on the east coast of Ceylon. The headmen's theory is, however, supported by the fact of a bed of pearl oysters on the Kondatche Paar being abandoned in 1855, owing to the oysters being unremunerative in pearls. This bank lies in 3 to 3½ fathoms water, three miles from the shore.

The following quotation from Mr. Edgar Thurston's Bulletin No. 1 on Pearl and Chank Fisheries of the Gulf of Manaar, 1894, is significant:—

"The artificial cultivation of the pearl oyster was attempted some years ago in a nursery made in the shallow muddy water of the Tuticorin harbour without success; and in his final report to the Ceylon Government, Mr. Holdsworth expresses his opinion, with which I thoroughly concur, that there is no ground for thinking that artificial cultivation of the pearl oyster can be profitably carried out on the Ceylon coast, as the conditions necessary for the healthy growth of the oysters are not to be found in the very few places where they could be at all protected or watched."

Discussion.

Mr. HALY on being called upon to speak, remarked, that he knew nothing more about the Pearl Oyster—nor did he take any special interest in it more—than any other invertebrate of the great Indo-Pacific Fauna. As to its migrations it shares that habit with numerous species of widely different classes. Last year, he accompanied Professor Gooderich to Trincomalee in hopes of obtaining certain species abundant there in 1887 and 1890; but although the whole coast and harbour were carefully searched not an individual was procured. In the same way a very large and handsome *Aplysia* or sea-hare and a species of *Melibe* (a most strange and remarkable mollusc) appeared in August and September in Weligama bay; this year the *Aplysia* cannot be found and the *Melibe* is scarce. When he expressed his surprise to Mr. Gooderich at the disappearance of the species formerly so abundant at Trincomalee, Professor Gooderich stated that the same phenomenon occurs on every coast. A scientific inquiry on a large scale therefore, into the Pearl Oyster fishery could not fail to beof great benefit to the Museum as tending to throw more or less light on the habits of numerous species of widely remote classes.

H.E. THE GOVERNOR next called on Mr. FERGUSON, who said:—I suppose it is because I am the oldest member on the roll of the Society in Colombo that I have been asked to propose a cordial vote of thanks to Mr. Collett for the interesting and extremely useful paper he has read to us this evening. In any case it gives me very great pleasure to comply with the request. It is interesting to note that from time immemorial, there have been fisheries of Pearls and Pearl Shell all round the Indian Ocean, on the African, Asiatic and Austral coasts—from Mozambique to the Red Sea and Persian Gulf, to Karachi, the Gulf of Mannar—the Tinnevelly and Ceylon coasts—the Burma coast at Bahrein—the Saigon, Philippines and Bornean as well as Chinese coasts and up some of the Chinese rivers, and also round one-half of Australia. Our Ceylon fisheries are among the oldest and most famous, seeing that a European visitor found 8,000 boats at work about the middle of the 14th century. But then in the Book of Job, some 3,500 years ago, there was mention made of both "coral and pearls." In Europe,

pearls of value have been got from the mussels fished in our Scottish rivers—the pearls in the Scottish Crown now forming the regalia of Great Britain were all got in the Tay and the pearls gathered there in three years (1761-1764) were valued at £10,000. A fine pearl similarly found in the Conway is said to be in the Royal Crown of England. Now remembering that the Scottish mussel is allied to the so-called Ceylon pearl oyster, it will be seen that pearls can be cultivated in quiet river estuaries as well as in the deep water on Ceylon banks, and in the case of Australia inside the barrier reefs. —I have taken a special interest in this question of Pearl Oysters and their Culture ever since I visited Western Australia in 1875. Sir Wm. Robinson, a brother of Sir Hercules, was Governor there and he kindly put all available information about the local Pearl Shell and Oyster fishing, then in their infancy, at my disposal. I met the gentleman who first discovered that the blisters on the inside of the large pearl shells contained fine pearls, of a golden yellow or white colour, some of which were valued up to £1,500 each; while one cluster known as the "Southern Cross" was valued up to £10,000. Captain Donnan may be surprised to learn that in those early days so plentiful were the oysters within the barrier reef on the west and north-west coast of Australia that the pearlers simply waded in and pulled up from the reefs in shallow water an ample supply of large oysters, some of them with very fine pearls. This fact is also mentioned by Saville-Kent; but the case is very different now, all the fishing being in deep water—only it seems to show that such oysters flourish and develop pearls even in comparatively shallow water. The readiness with which pearl oysters adhere by their byssus is shown by some 40 being found on a single Pinna or Razor shell and by Mr. Saville-Kent's experience of their growing above a mangrove swamp off N.-W. Australia. There is great encouragement, too, for culture when we know that the happy little family for which each oyster prepares a dainty home numbers, on an average, as many as 12 million eggs and this when the parent is but one year old. An English dramatist has told us that "an oyster may be crossed in love," but there is ample margin to go upon; and our little *meleagrina* is most enterprising and able both to climb a wall and take a walk, justifying that other poet of "the Walrus and the Carpenter" when he said:—"Oh, oyster come and walk with us." (Laughter.) I trust therefore that the step taken with so much promptitude and public spirit by Your Excellency and approved by the Secretary of State, in referring Sir William Twynam's Report for the highest scientific opinion in England, may result in a Scientific Mission of Enquiry and Experiment. Professor Ray Lankester would seem to be a little unjust to Mr. Holdsworth who signed himself F.L.S., F.Z.S., and who first showed us the difference between certain pearl or pearl-shell yielding oysters. But it was a fact that Mr. Holdsworth had never seen a fishery or even a bank covered with our oysters; and therefore there was much reason to hope that Professor Herdman, F.R.S.,—if he came out, now that he and the scientific world knew so much more than in the "sixties," and especially if he had the help and experience of our expert, Capt. Donnan, and was also lent the aid of Dr. Thurston by the Indian authorities (who ought to be asked to join in the Mission with Ceylon)—would be able to give us results worthy of his high reputation and keen powers of observation. There was a great deal of literature, including accounts of Pearl Fisheries and Experiments, to be collated—there might even be later Reports in reference to Californian and Central American Fisheries, than Mr. Collett or himself had obtained;—but not the least interesting contributions to place before Professor Herdman would be both the valuable papers read that evening, and Mr. Collett by introducing the subject and giving the Society so good a paper, had laid the members and the whole intelligent community of Ceylon under a debt of gratitude for which he deserved the cordial vote of thanks he thus proposed with great pleasure. (Applause).

DR. VANDORT:—I have much pleasure in seconding the vote of thanks to Mr. Collett, for the very interesting paper he has just read to us. Although it professes to be only a *resumé* of imformation derived mostly from sober scientific journals and statistical reports of a not especially enlivening nature, it has nothing of the *dry-as-dust* character traditionally associated with scientific papers, but reads more like an article intended for a popular monthly than a contribution to a staid scientific journal like ours. To some extent, no doubt, he has been inspired by his theme which appeals to so many interests,—historic, poetic, economic, and even political over and above its scientific aspects, and has even allowed himself to subordinate the instincts of the born naturalist to the demands of literary art—as for instance in sandwiching the only technical portion of his paper—not the least important from a scientific point of view—between a quaint disquisition on the right of an oyster to be called a fish (reminding one of Baron Cuvier's famous criticism of the French Encyclopedist's definition of a crab)—and an interesting speculation on the folk-lore relating to the origin of pearls. I, for one, was hoping that while in this mood he would, even while accepting the ugly theory (if scientifically established which I doubt) of the parasitic origin of pearls, have protested against the scientific barbarity, which has no excuse, of robbing the pearl oyster,—our Ceylon oyster,—of its legitimate time-honoured beautiful Greek name, associated with a thousand poetic legends and at least one great Biblical illustration, and substituting for it a vile, inappropriate Latin term, which means, not only *painted* and *coloured*, but false and counterfeit. But like a true Englishman, it is the commercial, practical aspect of the subject which has engaged his attention, rather than its æsthetic side, so I am not surprised to find him strike the key note of his paper in the introductory announcement, that since Diamonds like South African shares are going up, the Ceylon Government and the Ceylon Public had better look after their interests in local fisheries, as Pearls are sure to follow suit. After such a warning, it is hardly necessary to say, that in the selection of his scientific facts, he has *collated* them (if I may be excused the term) so as to keep in view all those that are likely to be of general interest and eschew what would be technical and comparatively uninteresting. I should have wished, however, he had given the natural history of the bivalve he had selected for his subject, a little more of his attention on the paper he has read to us, as no one could have dealt with it better with his extensive reading and special researches in this section of Natural Science. I have no intention of detaining the meeting at this late hour and shall therefore confine myself only to one or two points of practical importance, on which I shall be glad to be enlightened by Mr. Collett. The first refers to the question mooted originally by Dr. Kelaart in his Report of 1857, are oysters monœcious or dioecious—in

other words, are the two sexes found in separate individuals, or are they all female or hermaphrodite capable of breeding by self-fertilisation. Now, according to Dr. Kelaart, who is universally acknowledged to be the highest authority on the subject, there is no proper distinction between the two sexes, except in the contents of the *ovarium* or egg-bag, which in 97 or 98 per cent contain *ova* at all stages of growth even from birth, and only in one or two per cent contains the fluid essential for cross-fertilization and no ova at all. These oysters then represent the male individuals, though there is nothing in the external coat, or internal structure to distinguish them from the others. The practical importance of this fact comes in with the light it throws on a possible frequent cause of the disappearance of oysters from old oyster beds. For, if cross fertilization be essential to the production of a healthy progeny as Darwin has established and large colonies of such progeny growing together are necessary to form a productive "band,' as Kelaart has shown, the destruction of the few males by any accidental cause, may suffice for the extinction of an entire bank of oysters. Mr Collett himself to whom I referred this point before the lecture was good enough to explain to me that he believed that the female oyster has it in her power to change her sex, as often as she chooses, a wonderful fact, if it be the case; only it is to be hoped that Nature has limited this marvellous power of self-transformation to the oyster, which exceeds, I think all that the new woman with all her claims for woman's rights could imagine in her wildest dreams. But I believe even Mr. Collett is not quite sure on this point, so that one of the most important problems connected with the life history of this bivalve still remain to be solved by science. Another point on which I should wish to be enlightened by Mr. Collett is with regard to the formation of pearls. He has given in his adhesion to the parasitic theory and even quotes Dr. Kelaart in support of it—but a careful reading of Dr. Kelaart's reports, both of '57 and '58, seems to me to show that while he only countenanced the parasitic theory as accounting for exceptionally, as it were, the formation of pearls in some cases, he never abandoned his original theory made from actual observation that the true nuclei of true pearls are the ova of the pearl oyster itself as a rule, and only exceptionally the ova of parasites that enter its body with its food, while only inferior and irregular false pearls result from the artificial intrusion of particles of sand, etc., to serve as nuclei. So far as my reading goes Dr. Evarard Home in the last century was the first to advance the theory of abortive ova being the nuclei of pearls, and Dr. Kelaart at first accepted it with a modification by saying that it was not the ova which are left behind in the *ovarium* but those which escape through the over-distended coat of the egg-chamber, when it ruptured as it may easily do near the hinge, when they would bury themselves in the interstices of the mantle and so become the nuclei of pearls. But in his later report of 1859 he says he was so fortunate as to find an entire ovarium charged with no less than 32 pearls, and still another which he did not open, but which appeared to contain as many more—thus completely confirming Dr. Home's theory. Both these specimens he sent to Dr. Owen, and are now to be seen in the Museum of the College of Surgeons in London. How, or whence the *nacre*, or pearl-lining substance was formed for these pearls in the ovary, Dr Kelaart would not or could not determine, but he supposes with great probability—what science at the present day can easily confirm—that the ovarium membrane can secrete it. For it is a curious circumstance that human pathology affords analogous illustrations, both of abortive ova and even embryos becoming the centres of new and varied forms of all growth--and sometimes of concretions of an intensely hard character known as lithopadia—but still more curiously that the lining membrane of the ovary from which proceed these metamorphosed but unimpregnated iva sometimes secretes the most extraordinary structures such as bones, teeth, hair &c., without any trace of embryonic formation, which may even grow from the ovary of the embryo itself, and become serious pathological tumours in after-life, It is unnecessary for me to point out the bearing that this theory of Dr. Kelaart's has on the proper method of oyster culture. Entirely opposed as it is to that now proposed, based on the theory that conditions which favour the entrance of parasites which foster disease are the best for pearl formation. In conclusion, I am sure that Mr. Collett will do Dr. Kelaart the justiceto acknowledge that although there may be no ponderous monograph in any language on the natural history of the oysters—and a great book, according to the great proverb, is not seldom a great evil,—his reports on the subject, though written nearly 50 years ago, are as complete as far as they go on the subject as could be desired. There has been little that is new that has been discovered by naturalists since, to supply the desiderata Mr. Collett refers to in his paper. I say this, because I do not think Ceylon has sufficiently acknowledged the debt of gratitude she owes Dr. Kelaart for his researches, in connection with the Ceylon Pearl Oyster. One of the earliest sons of the soil—belonging to the Burgher community, who having secured a British degree, entered the Army Medical Service, where his reputation as a scientist generally—as Geologist, as Botanist, as Zoologist, especially as a Conchologist in connection with the subject of Pearl Oysters—has received the recognition of the whole scientific world. (Applause.)

After the vote had been carried by acclamation,

Mr. Collett, in rising to reply, said he would like to answer one or two points raised by Dr. VanDort. Firstly, he would refer to Sir W Twynam as regards the pathological and zoological study of the oyster; that authority said that our knowledge in this respect was still almost nil. His own paper had been entirely theoretical, summarising the latest writings on the subject, and he (the speaker) had taken it up more as a zoological recreation for a busy planter than with any scientific experience of the subject. Dr. VanDort had expected him to put into the paper more than he (Mr. Collett) had intended. He was very gratified at the reception his paper had received; he could feel that if it had done nothing else, it had elicited a most interesting discussion and he thanked them all for their cordial vote of thanks. (Applause).

The Bishop of Colombo proposed a very hearty vote of thanks to His Excellency for occupying the chair that evening. In any assembly of the inhabitants of Ceylon they were very much pleased to have the Governor with them and the members of that Society felt that in a particular degree. They were very grateful to His Excellency for having made the effort to come out on that wet night. Cynical outsiders might say that a meeting of the Royal Asiatic Society would be the very place to come to on a wet night, because they would be sure to find something dry. (Laughter.) Such a person would have been hopelessly wrong, on an occasion like that evening. He was not aware to what extent His Excellency gave a personal study amidst his many vocations to those matters which particularly occupied them as a learned Society, but it was quite certain that in one branch of their proceedings H.E. encouraged them by his presence that evening as in that part of their proceedings in which they tried to lay or develop that scientific basis upon which alone could be soundly erected any structure of utility in any work, especially of production of any kind. And their Governor had shown them by the interest that he had taken and the efforts he

had made for promoting the scientific side of agriculture and providing a scientific staff for placing upon the most sound basis the great industries and productions of the Island, that he recognised what a Society like that tried to teach, what they were trying that evening and on all similar occasions to teach to the people of Ceylon, *i.e.*, that only upon a thorough scientific study of the facts and the natural laws that commerce and production and works of usefulness can be well conducted. (Applause.) They were very glad that H.E. should be amongst them on such an occasion and that they should have such support. There were many times when their papers dealt with matters, the utilitarian tendency of which could not easily be discovered. (Laughter.) The Society existed in a great measure in order to keep before the minds of men that knowledge was valuable for its own sake. There were also times when the bearing of knowledge, scientific knowledge in particular, upon the practical needs of men and Governments came within their purview and on such occasions they were extremely thankful to have the presence of their Governor. (Applause).

Mr. S M BURROWS said that, while he felt a strong sense of his unworthiness for the task, he congratulated himself on the honour done to him that night in his being asked to second the vote of thanks to H.E. the Governor for being present that evening. He said that His Lordship and he had often met on various boards that arranged no doubt adequately for the instruction of others. It was strange that they should thus meet on an occasion when arrangements had been made no doubt equally adequately for the instruction of themselves. (Laughter.) He came to the meeting that evening knowing about as much of the pearl oyster as he did of Chinese, and he went away feeling he could pass a very fair examination on the many scientific aspects of its study—from the highly technical terms so glibly mentioned by Mr. Collett to the case of the "oyster crossed in love" so unexpectedly brought in by a later speaker, Mr. John Ferguson. He begged to second a very hearty vote of thanks to His Excellency for presiding, a distinction which had heightened the interest of the gathering that night.

H.E. THE GOVERNOR.

HIS EXCELLENCY, in returning thanks, said: I am extremely obliged to you—to you, my Lord, for the gracious terms in which you have proposed; to you Mr. Burrows for the kindly terms in which you have seconded; and to you, ladies and gentlemen, for the cordial manner in which you have passed this vote of thanks which is in no way merited by me. It is a great pleasure to me to be present at the meetings of this branch of the Royal Asiatic Society, and I only wish my duties would permit me to attend more frequently. Perhaps on occasions when you are having a learned and scientific discussions I might feel like a fish out of water or to use a more appropriate simile, an oyster off its bed. (Laughter). But when this Society is assembled to discuss an unusually utilitarian question, how to conserve, how to protect and how to advance one of our great industries I feel more at home. Nevertheless I must confess that it was with conflicting emotions that I learnt that the paper today was regarding Oysters and how to conserve them. (Laughter). A poet of old,—Virgil, I believe—Mr. Burrows will correct me if I am wrong—said there is no one more bitter than a beautiful woman whose charms have been spurned. (Laughter). There is here no lady who has been in that unpleasant position; but my charms have been consistently spurned by the Oyster since I assumed the administration of this Colony. (Laughter). And yet no man was more kindly disposed to the Oyster than I was when I landed here. (Renewed laughter). I looked forward keenly to making his acquaintance and anticipated the great advantage that would follow upon such intimacy. (Laughter.) Indeed I may say that I built castles in the air, at any rate on his shells I built many a railway and many an irrigation scheme (Laughter). Unfortunately I have been persistently boycotted by the Oyster. (Renewed laughter). And now my feelings towards the Oyster have greatly changed and I begin to remember that he has always been hostile to me personally—that I have never taken an Oyster that has not disagreed with me. (Loud laughter). Altogether I begin to look upon the Oyster as a capricious, deceitful fish or mollusc or, as Mr. Haly expresses it, an invertebrate creature. (Laughter). These being the feelings I entertain towards the Oyster when I was called upon to consider measures not for its destruction, but for its conservancy, I was greatly perplexed. (Laughter). It is difficult for a just man to satisfy his own private vindictive feelings and do his duty as Governor of the Colony, but happily the difficulty no longer exists. Thanks to Mr. Collett these conflicting feelings have been reconciled because he tells us that the pearl is a pathological product; that is to say, only disease in the dying oyster can produce the pearl and therefore what we call the Conservancy of the oyster is only to produce those unhealthy conditions of life which will make it diseased or dying (Laughter). Under those circumstances I am one with you all in your desire to conserve the Oyster. (Laughter and applause). Joking apart, I think this talk on our fisheries will not be without its advantages if it has induced us to consider and reflect whether more scientific treatment, more scientific procedure could not be adopted than that of two or three thousand years ago. Dr. Haly is not, but no doubt ought to be a member of the Legislative Council:—if he had been he would have known that that wise and sagacious and far-sighted entity—the Hon. Treasurer, who is present will bear me out in describing it as such,—the Government of Ceylon (laughter) has already taken up the matter and has approached the Secretary of State, and through the Secretary of State the learned Societies and the learned Professors of these Societies, on this subject and that from two learned Professors—Professor Ray Rankester and Professor Herdman—we have had two very valuable reports. Professor Ray Lankester, as is the way with some scientific men, has, to use a vulgar term, opened his mouth too wide. (Laughter). He has seen the opportunity of enriching the scientific world at the cost of Ceylon and he has proposed a costly mission which will no doubt collect much valuable information which would not only be to our advantage, but to the advantage of all Oyster-bearing countries. Therefore I think Mr. Ferguson's suggestion is a good one that the cost of such a mission might be divided

between those countries interested—India, ourselves, and others; but if such co-operation is not possible then I think we might adopt a middle course such as Mr. Ferguson also suggested and get Prof. Herdman if he can spare his valuable time to come over here and in collaboration with Captain Donnan, our great practical expert—they will be, I am sure, able to give us some very valuable information especially regarding that interesting question—the life history of the oyster. Ladies and gentlemen, I think we must all feel very grateful to Mr. Collett for the very interesting paper he has read. He said it was his zoological recreation. To us it has not only been a zoological recreation but zoological instruction, and I think we are much indebted to him for this practical and useful discussion which has followed the reading of his paper. I thank you again for the very kind way in which you have received it. (Applause.)

At the close His Excellency shook hands with Mr. Collett and Captain Donnan, and inspected all the illustrative objects displayed around the table. He evinced considerable interest in the diving apparatus exhibited by Captain Donnan and the specimens of pearl shell which had been laid out The audience was some little time in dispersing even after His Excellency had left.

To Capt. Donnan, Mr. Collett and Mr. Gerard Joseph belongs the credit of adding much to the interest of the meeting by the display of these "curios" as well as utilitarian displays connected with Pearl Fisheries. A section of a pearl was under a powerful microscope; a display of different kinds of oysters including the largest "meleagrina" from Australia; copies of Mr. Saville Kent's large and profusely-illustrated books and other literature were made available and suspended at one side was an ample object-lesson of the mode in which the native diver did his work for Capt. Donnan, with stone held by coir ropes, place for his foot, the coir basket in which to gather the oysters, &c. The diving apparatus was mainly of coir and consisted of a rope with a heavy lead weight attached, beside a receiving basket of coir (in shape like an inverted tam-o'-shanter) into which the oysters were placed by the diver; as many as 100 pearl oysters could be placed in the one basket at a time.

The function terminated shortly after 11 p.m.

SNAKE BITES AND ANTIDOTES.

The following from the paper on Snakes by Dr. Gunther, of the British Museum, in the *British Encyclopedia*, is worth reproducing :—

No antidote is known capable of counteracting or neutralising the action of snake-poison. Some years ago injections of ammonia or liquor potassæ were recommended, but there is the obvious objection that hardly in one out of a thousand cases of snake-bite would either the appliances or the operator be at hand. Fayrer's experiments, however, have distinctly disproved the efficacy of this remedial measure. Equally useless is permanganate of potassium; it is indeed true that a solution of this compound destroys the properties of snake-poison when mixed with it; and therefore such of the poison as remains in the wound will be neutralised by the external application or injection of the permanganate, but the remedy is entirely without effect after the poison has passed into the circulation. Treatment is therefore limited to endeavours to prevent by mechanical means the poison from entering the circulation, or by chemical agencies to destroy or remove as much of it as possible that remains in the wound, and to save the patient from the subsequent mental and physical depression by the free use of stimulants. Whatever is or can be done must be done immediately, as a few seconds suffice to carry the poison into the whole vascular system, and the slightest delay diminishes the chances of the patient's recovery. Courageous persons badly bitten in a finger or toe are known to have saved their lives by the immediate amputation of the wounded member. To the mode of treatment summarized by Gunter* but little can be added. (1) If the wound is on some part of the extremities, one or more ligatures should be made as tightly as possible at a short distance above the wound, to stop circulation; this is most effectually done by inserting a stick under the ligature and twisting it to the uttermost. The ligatures are left until means are taken to destroy the virus in the wound and other remedial measures are resorted to, or until the swelling necessitates their removal. 2 The punctured wounds should be enlarged by deep incisions, to cause a free efflux of the poisoned blood, or should be cut out entirely. (3) The wound should be sucked either by the patient or some other person whose mouth is free from any solution of continuity. Cupping-glasses, where they can be applied, answer the same purpose, but not with the same effect. (4) By cauterisation with a red-hot iron, a live coal, nitrate of silver or carbolic or mineral acid, or by injections of permanganate of potassium, the poison which remains in the wound can be destroyed or neutralised. Ammonia applied to the wound as a wash and rubbed into the neighbouring parts is likewise undeniably of great benefit, especially in less serious cases, since it alleviates the pain and reduces the swelling. (5) Internally, stimulants are to be taken freely; they do not act as specifics against the virus, but are given to excite the action of the heart, the contractions of which become feeble and irregular, to counteract the physical and mental depression, and to prevent a complete collapse. Brandy, whisky, and ammonia in any of its officinal forms should be taken in large doses and at short intervals. The so-called. "snake-stones" can have no other effect than, at the best, to act as local absorbents, and can be of use only in the very slightest cases.

Elsewhere he says :—

"Certain stones reputed, on insufficient grounds, to possess efficacy as antidotes to snake-bites are known as snake-stones."

ANTI-VENOMOUS SERUM.

(Prepared by Dr. A. Calmette.)

INSTRUCTIONS.†

The antivenomous serum is serum taken from an ass or a horse immunised against venom of snakes. It will retain its effects if kept in as cool a place as possible, away from day light and without taking the phial out of its box. At or above the temperature of 50° Cent.—122° Fahr.—the serum becomes inactive. Its preservation has been guaranteed by adding a very small quantity of camphor.

Preventive Power.—The preventive power of the serum is, at the least, of 10,000 *i.e.*, it is sufficient to inject rabbits preventively with a quantity of serum equal to 1/10,000th of their weight

**Reptiles of British India*, London, 1864, 4to.

† Referred to a week ago, but held over daily owing to continuous pressure on our space.

to enable them to bear, one hour afterwards, without their being intoxicated, a dose of 1 milligramme of dry venom of *cobra capella* of medium activity, said dose sufficient to kill proof rabbits in less than four hours.

THERAPEUTICAL ACTION.—If injected in sufficient quantity to persons bitten by snakes, the anti-venomous serum will prevent the effects of the venom providing intoxication is not too far advanced. It must be injected as soon as possible after the bite. Generally its intervention is still very efficacious an hour and a half after the bite with adults who rarely die but three hours after the bite of the most dangerous species of snakes.

The serum is active against the venom of all species of snakes existing in the ancient and new world. It has been experimented with the venoms of the *cobra capella* and *trimeresurus* of Asia, the *naja haje* and *cerastes* of Africa, the *crotalus* of America, the *bothrops* of the West-Indies, the varieties of *pseudechis* and *hoplocephalus* of Australia and the *vipers* of Europe.

The dose to employ varies according to the species of the biting snake, the age of the person bitten and the time of the intervention.

Generally 10 cubic centimeters are sufficient for children under 10 years and 20 cubic centimeters for adults. However, when the bite comes from a very dangerous species, such as the cobra capella, the naja haje, the crotalus, the bothrops of the West-Indies, it will be prudent to make one single injection at first of a double dose.

TREATMENT OF VENOMOUS BITES.—The first precaution to take is to surround tightly the bitten limb as near as possible to the bite and between the latter and the trunk, with a strip or handkerchief.

The wound will have to be washed with a solution of hypochlorite of lime diluted to 1 gramme for 60 of water previously boiled, titling between 0 lit. 800 to 0 lit. 900 of chlorine per 1,000 cubic centimeters.

The dose of serum must be injected in the subcutaneous cellulary tissue in the right or left side of the belly, and with the usual antiseptical precautions.

Then, with the same syringe, 8 or 10 cubic centimeters of the solution 1/60 of hypochlorite of lime will be injected altogether, but in the different parts surrounding the bite and in the passage of said bite. These injections are intended to destroy, there, the venom which has not yet been absorbed.

From that time, the strip can be taken away from the limb; the patient must be frictioned and coffee or tea be administered, and he be covered warmly so as to provoke an abundant perspiration.

The administration of ammonia or alcohol must be avoided; it would only be injurious both to the patient and to the treatment by the serum.

It is also unnecessary to cauterise the bitten limb either by red iron or chemical substances.

IMPORTANT.—Drs. making use of the above serum are earnestly requested to communicate the results obtained by its application to Doctor A. CALMETTE, Directeur de l'Institut Pasteur de Lille (Nord).—*Pasteur's Institute of Lille.*

MINOR INDUSTRIES: VANILLA; ALOE FIBRE; AND SOAP.

(*Communicated.*)

IN the good old days when Coffee was king, the Ceylon planter scouted the idea of making money by minor industries. To have done so would have been to place himself without the pale of civilised society. But the collapse of coffee taught a salutary lesson. Planters are wiser in the present generation; and, so long as the calling be an honorable one, are not fastidious as to the source from which they can derive an income. It has already been shown how valuable an adjunct vanilla would be to the main industry—tea. Another product suggests itself, viz.: Aloe Fibre. There are thousands of acres in Ceylon suited to its cultivation. Once planted it requires little or no attention. Its market value certainly fluctuates considerably, but there is always a margin for profit. At the outbreak of the Spanish-American War it rose to over £30 per ton; its present value is from £22 to £23. The cost of cutting, carriage, gratting, baling, &c., is about R140 per ton—freight and London charges £6 per ton. It will be seen from these figures that, at its present price, there is a profit of about R100 per ton.

Again, with coconut oil at our doors, why are there no Soap factories? With coconut oil as the basis, a good household soap could be manufactured in Colombo for about R250 per ton. For anyone "in the know" there is a fortune in soap-making in Ceylon.

E. H. E.

[And yet our big Oil Mills, that used to manufacture soap regularly, could only find a market by exporting to Calcutta and Mauritius, though we imported about two hundred thousand rupees' worth a year, the figures being R269,340 of soap last year! And now the local manufacture is abandoned.—Aloe-growing has been tried, but the labour of preparing the fibre ran away with the profit, in the case of planters in the Kurunegala and Uva districts.—ED. *T.A.*]

PLANTING NOTES.

FATAL SNAKEBITE.—The lamentable death of one of Mr. Oliver's Chief Assistant Engineers on the Northern Railway from snakebite, breaks through the record that for 60 years no death of a European from this cause has occurred in Ceylon. The greatest sympathy is due to the young widow, and other relatives at home. Mr. Ievers should see to it that Jaffna—Hindu temples and all—are cleared of cobras if it be true they are encouraged for some reason. Let a license fee be imposed, and there will be no protection, or a reward be offered for every snake's head brought to the Kachcheri.

SCIENTIFIC CULTIVATION.—Ceylon tea and other planters will be interested in the following extract from a letter received by us from Mr. Joseph Fraser:—

"I visited both the Rothamsted and Dalmeny manuring field experiments and found much that was interesting and suggestive. Those directing the Dalmeny experiments are strong on the need of getting the land into condition favourable for the growth and development of the nitrifying organisms and where leguminous crops are being raised, to the conditions, favourable, to the microbes involved, in the fixation of free nitrogen through the root nodules. The whole results are being drawn up for publication in pamphlet form, and form what I gathered when there, the details when worked out will be of great practical value."

Correspondence.

To the Editor.

SNAKE-BITE AND CURE FOR HUMAN BEINGS AND CATTLE.

Sir,—The terribly sad case of snake-bite resulting in the death of Mr. White of the Northern Railway Extension, reminds us that we should make known as widely as possible such treatment as has been attended with success in cases of bites, from venomous reptiles. In Ceylon we do not hear much of death from snake-bite among the natives (and it would be interesting to discover why this is,) but the return of such deaths in India, for 1899, gave 22,480 for human beings and 3,793 for cattle. Dr. Watt gives the following under the head of *treatment*:—

"Immediately on infliction of the bite, a ligature should be applied very tightly about the limb at a short distance above the wound and several other ligatures at suitable distances further up. The flesh around the marks should be excised freely, the surface of the wound should be scarified, washed and squeezed, and bleeding should be encouraged. The amount to be excised around the fang-marks must depend upon the looseness of denseness of the surrounding tissues, and their consequent tendency to allow the poison to diffuse freely or not. The actual cautery may be applied to the deeper portions of the wound, where the poison may not have been removed by the excision. Stimulants, such as alcohol or liquor ammonia in 15-drop doses in an ounce of water, may be given, but over-stimulation should be avoided, and during the administration of stimulants, liquid nourishment should also be exhibited (prohibited?). If depression be marked, mustard plasters may be applied over the heart, on the pit of the stomach, or on the nape of the neck. The patient should be allowed to rest in a well-ventilated room, protected from the sun; in cases where the prostration is extreme, methods of artificial respiration and galvanism may have to be employed. Amputation should at once be had recourse to in cases when the snake is known to have been one of a markedly poisonous character, and the bite is in one of the fingers or toes. In wounds of the larger members or of the trunk where free excision is possible, amputation may not be necessary. The intravenous injection of ammonia or of liquor potassæ do not apparently do much good, but they may be injected freely into the poisoned part. The local application of permanganate of potash is strongly recommended by some authorities. Various methods of treatment, all more or less founded on superstition, are employed by the natives of India, and every now and then alleged specifics for the poison of snake-bite have been vaunted, but as yet no antidote is known which is capable of neutralising the action of the poison. The so-called "snake stones" can have no other effect than at best to act as local absorbents. They are for the most part merely pieces of charred bones which by absorbing from the wound the poison charged blood may be of use in slight cases of snake-bite."

There are, of course, numerous drugs used among the natives of Ceylon and reported to cure snake-bite, but we are not concerned with these at present, as what we would like to suggest is the use of some common and handy substance, such as chloride of lime or iodine, or other treatment that can be adopted without loss of time, for it is most important that whatever has to be done must be done quickly.

Some time ago we read interesting accounts of Dr. Calmette's work in Paris in connection with the preparation of a therapeutic serum against snake-bite, and this preparation is, no doubt, now procurable for inoculation purposes. But Dr. Calmette himself recommends that in the absence of the serum, chloride of lime is the next best remedy. The Doctor's recommendation is based on a study of the blood of bitten animals. It was found that in such blood the corpuscles lost their shape and agglomerated; the blood was thus unable to do its work; in other words the fatal results were due to paralysis of the lungs caused by stoppage of circulation by the coagulated condition of the blood. This discovery led to some very interesting experiments with the result that the chemical treatment referred to was found to be efficacious. The chloride of lime should be free from absorbed water, and for use should be taken from an hermetically sealed bottle. One part by weight should be dissolved in two parts of boiling water, but the solution should never be made until it is about to be used. This should be injected subcutaneously with a syringe all around the wound and also under the skin of the abdomen, that it may enter into the circulation as quickly as possible. Dr. Calmette estimates that from 20 to 30 centimetres of the solution will suffice to save the life of a man bitten, it being administered in doses of five-cubic centime each time. Of course time is an important element in the matter.

In conclusion we would quote a passage with reference to Dr. F. E. Brown's cure for the bite of rattle-snakes, which he says he used successfully in his practice in the United States: "I have treated thirteen cases of snake-bite in my practice with simply marvellous results—even restoring life and health when the patient was supposed to be dying. My first cure occurred many years ago. A little child, say three or four years old, was brought home with two ugly gashes on the instep by a fair-sized rattler. I suppose I saw the child about an hour after the bite, with limbs badly swollen and in great pain. I applied iodine to the wound and gave the child drop doses every ten minutes for an hour, then every half hour until decided improvement. The child took 10 to 15 drops in all. Next morning the father reported that the child had perfectly recovered and was playing about as usual. My last cure was about one year ago. A lad about 15 years old, while reaching under some boards for hen's eggs was bitten on his right hand by a large rattler. He was brought to me with hand and arm enormously swollen, and scarcely able to stand on his feet. I pursued precisely the same treatment as in my first case, except that I doubled the dose. He took in all perhaps 25 drops. He recovered rapidly, with no outward results. It is equally efficacious in the treatment of dumb beasts." Dr. Brown here goes on to refer to the cure of a cow which was in a bad way after the snake-bite, which, on his advice, was dosed with 10 drops every 10 minutes for an hour, then every hour for a time. The result was entirely satisfactory even in this case. It would be interesting to know if any of the above remedies have been tried locally, and if so with what success.

INTERESTED,

CACAO IN CEYLON: AND MR. CARRUTHERS.

Dear Sir,—As Mr. Carruthers' remarks on cacao canker at the N D P A meeting on the the 20th ult. have caused considerable discussion in the press, I send you a copy of a

letter I have written to the "Ceylon Standard" on the subject and should be glad if you could find room for it in an early issue as I think what Mr. Carruthers actually did say, ought to be well understood.—Yours faithfully,

E. WEBB.

MR. CARRUTHERS ON "CACAO."

Hindugalla, Peradeniya, Nov. 3.

The Editor "Ceylon Standard."

Dear Sir,—My attention has been called to a leading article in your issue of the 29th ult. headed "Mr. Carruthers on Cacao," which is, I think, calculated to give a very erroneous impression of the matter. In the first place Mr. Carruthers never offered to give a lecture, but, in accordance with the wishes of several members of the N D P A, I, as Chairman, invited him to be present at our meeting on the 20th and to give a short address on plant sanitation in connection especially with the cacao canker which was to be followed by a discussion so that those interested in cacao might have an opportunity of knowing what was being done to eradicate the disease.

During the discussion, Mr. Carruthers, who, by the bye, spent a whole year in investigating the disease and in visiting various Ceylon cacao estates, stated, in answer to a question from Mr. C Gibbon, that *as far as his experiments went* no predisposition in the trees was necessary for the attack of the fungus, but he never said cacao was doomed; in fact he reiterated his opinion that cacao would continue to be a most profitable product in Ceylon, if proper measures were taken, though as in duty bound, he warned planters against the disease.

I think, such addresses and discussions, *especially if properly reported*, should be most useful in keeping us informed up to date as to what is being done both by scientists and practical planters to fight the diseases, cacao and our other products are liable to, and I regret that anything should be said in the press or elsewhere to discourage them.

I should be obliged if, in justice to Mr. Carruthers, you would give publicity to this in your paper, and I must say, I think it much to be regretted that you did not obtain more accurate information before writing the article.—I am, dear sir, yours faithfully.

(Sgd.)EDWARD WEBB, Chairman, N. D. P. A.

MALARIA AND AGRICULTURE.

Nannoya, Oct. 26.

Dear Sir,—The following extract from remarks by Professor Celli (Director of the School of Hygiene, University of Rome) on the Epidemiology and Prophylactics of Malaria, will, I am sure, interest not only "Enquirer" but your other readers too. Under the head "Agriculture and Malaria," the Professor says "It can now no longer be admitted that the simple stirring up of the soil in malarious places determines the liberation of the germs of this infection. On the other hand, any movement which in any way alters the hydraulic conditions of a given area may really become a local cause, predisposing to the development of malaria: marshy vegetation, composed of canes, rushes, water-lilies, cresses and *conferoæ*, is very favourable to the life of the larvæ, and is, therefore, also favourable to and a concomitant of malaria by favouring the existence of the larvæ of *anopheles*. Thus irrigated meadow lands in malarious places, whenever the water becomes quite or almost stagnant in the afferent or efferent channels, and still more rice fields, with their clear and almost still water and typical palustral vegetation, constitute the best habitat of these larvæ. Hence, as is known, the formation of rice fields causes the re-appearance of malaria where it had become extinct and where it already exists, they are a very active focus of production."

The article from which I am quoting is a very lengthy one. But the above should suffice to throw light on "Enquirer's" query. Later researches have both modified, but still more, substantiated the professor's thories, and those interested would do well to read through his article fully in the British Medical Journal of Feb. 10th.—Yours faithfully,

GEO. E. P.

PRESERVING COCONUT MILK.

Colombo, Nov. 10.

Dear Sir,—Referring to the article in the *Tropical Agriculturist*, vol. xx. page 342, I beg to say that "Silicic Acid, *i.e.* Quartzose Sand", cannot preserve coconut milk at all, as is said in "Sell's Commercial Intelligencer." I believe the writer of the article refers to "Salicylic Acid", which chemical is often used for preserving wines, beer, etc., notwithstanding it is strictly prohibited in all European countries. I suggest the method of Prof. Sohxlet, viz., sterilising the milk at 212° F. a procedure that is much used for preserving cowmilk for infants. I should think this is also the best way of preserving coconut milk. —I am, dear sir, yours faithfully,

DR. P. W KOLLER.

PLANTING NOTES.

European Plants and Commerce.—In Europe 4,200 species of plants are gathered and used for commercial purposes. Of these 420 have a perfume that is pleasing, and enter largely into the manufacture of scents and soaps. There are more species of white flowers gathered than of any other colour—1,124 in all. Of these 187 have an agreeable scent, an extraordinarily large proportion. Next in order come yellow blossoms with 951, seventy-seven of them being perfumed. Red flowers number 823, of which eighty-four are scented. The blue flowers are of 594 varieties, thirty-four of which are perfumed, and the violet blossoms number 308, thirteen of which are pleasantly odoriferous,—From "*Journal of Horticulture.*"

Planting in Nyassaland.—We have had many good letters from British Central Africa from our well-known correspondent "H. B."—but none perhaps so crisp and chatty and full of the right sort of information as the one we publish elsewhere. "H B" specially points out how some of the surplus of Ceylon "creepers" could not do better than try B.C.A.—easy as A B C, we gather, would be the career before them—for great progress has been made there. The drawbacks however, are hinted at, so that the advice is neither visionary nor unpractical. Further long accounts of "Leopard" and "Lion" experiences by "H B" must be withheld for the present and will probably appear most suitably in our Christmas number.—"H B", gives a list of several Ceylon men now in Nyassaland.

THE CEYLON PEARL FISHERIES: PROBABILITY OF A SCIENTIFIC MISSION.

Mr. Collett's zoological recreations have borne fruit to some good purpose, and the Council of the local Branch of the Royal Asiatic Society, with Dr. Copleston as President, may congratulate themselves on giving occasion for an interesting and profitable evening, but above all for drawing forth the very encouraging utterances from the Chair made by His Excellency the Governor. There is good reason to believe that a local Enquiry and Mission directed by Professor Herdman, F.R.S., of Liverpool University, will be fruitful in useful practical results. He has long devoted himself to Marine Biology and he was selected to conduct the scientific enquiry as regards the edible oyster round the British Coasts with reference to alleged diseases to which it gave rise. No doubt Dr. Herdman has also been a close observer of all that Mr. Saville Kent (who has apparently fallen out of view of the scientific world of late years) learned and did off the Queensland Coast, in Torres Straits and off North-Western Australia in reference to Pearl Oysters, and the Culture of the same both for Pearls and Pearl-shells. He must also have read of Dr. Thurston's enquiries and reports off Tinnevelly and in the Gulf of Mannar and he will have seen how he, as well as Holdsworth, and we suppose Twynam and Donnan, are well-nigh hopeless of the successful Culture or even Conservation of our particular oyster or mussel at any point round the Ceylon or Indian Coasts. On the other hand, he cannot but read with interest of the experiments of Dr. Kelaart—a worthy predecessor of the many "sons of the soil" who have reflected credit on Ceylon by their scientific and intellectual attainments—and then among the rest of his successfully transferring the *meleagrina* oysters from Arippu to Trincomalee; why not, with all modern appliances, establish a successful culture in some part of that sheltered bay? Capt. Donnan thinks deep water essential to the formation of pearls; but Saville Kent did not find that to be the case in Torres Straits or off Western Australia. It may be said he was dealing with a different kind of *meleagrina*; but he successfully experimented up to a certain point, with the small as well as the large kind. And is it too much to anticipate that there may be an interchange between even Australia and Ceylon and India of their several oysters. Why, in fact, should Professor Herdman's Mission not embrace Queensland and Westralia (and indeed South, for North, Australia) as well as India and Ceylon. But if these Governments fail us,—although we are very confident that Lord Curzon at least, will readily respond to any reasonable proposal from Sir West Ridgeway or Mr. Chamberlain,—yet, we think our Governor is right in saying that Ceylon alone even, should not hesitate to engage Professor Herdman, if only the expense is made a little more moderate than was indicated by Dr. Ray Lankester. Ceylon has certainly the largest pecuniary stake. Not a million, but very nearly a *million-and a half* pounds sterling have been received by the British Government from Pearl Fisheries in the 104 years it has administered Ceylon; and it cannot be said that any full and satisfactory Scientific Mission has, so far, ever dealt with the question of Conservation and Culture. Considering the many and varied ways in which pearls are formed—from the fresh water mussel's treasures in Scottish and Welsh rivers, to the unequalled gems found in the meleagrina's of the Gulf of Mannar, and yet again to the large golden yellow or white pearls "faked" or evolved by skilful experts out of the blisters on the large mother-o'-pearl-shell-yielding oysters of Australian waters; and considering also the several extremely interesting and even successful attempts at forming pearls artificially or through the aid of molluscs in Europe—especially in France,—we think there is every reason to anticipate material as well as scientific advantages from such a Mission as that proposed for Professor Herdman, F.R.S., in connection with our Ceylon Pearl-oyster Banks and Fisheries. If it be the case that the erratic molluscs refuse to listen to the charming of our present Governor, charm he never so wisely, and that Sir West Ridgeway may have to leave our shores without ever seeing a Fishery or even seeing a Bank covered with millions of young oysters; yet His Excellency may rest assured that his name will always be associated with one of the most interesting and important Scientific Missions ever arranged in connection with a Ceylon industry,—if we so may term the rich and romantic Pearl Fishery which has made our island and the Gulf of Mannar famous from time immemorial. Surely after reading Saturday evening's proceedings in full, there is no intelligent person in Ceylon who will deny that a Pearl Fishery is one of the most valuable sources of public wealth, and that, as an industry, it demands every attention and encouragement in the direction of judicious conservation and scientific development.

Mr. Elliott's Paper on "Native Agriculture" and its Improvement—referred to in the Legislative Council last month was published in full in the *Tropical Agriculturist* for November. Mr. Elliott draws a distinction between Planting and Native Agriculture: the former, he considers, can be served from Peradeniya; the latter by a reformed Agricultural School to be continued under the Department of Public Instruction. Our objection to this course is that it would not secure the personal interest, attention and responsibility of the Provincial and District revenue officers and their headmen, without which we are hopeless of any real permanent progress being made in the improvement of native agriculture.

STATISTICS OF THE PRODUCTION OF COFFEE IN INDIA.

[The two tables appended state the facts regarding the production of coffee, the first in abstract for the fifteen years 1885 to 1899, the second in detail for the two years 1898 and 1899. It should be noted, however, that the figures, for which the Government are dependent upon the planting community, are imperfect and defective,—planters, for unknown reasons, sometimes withholding information.]

AREA.

At the end of 1899 there were 274,298 acres of land under coffee in India, all, with the exception of 450 acres, in Southern India. The production of coffee is in fact restricted for the most part to a limited area in the elevated region above the south-western coast, the coffee lands of Mysore, Coorg, and the Madras districts of Malabar and the Nilgiris comprising 90 per cent. of the whole area under the plant in India. About 47 per cent of this area is in Mysore, where there were 128,010 acres in 1899, and the plant is grown on 118,514 acres, being 43 per cent of the whole, in the British districts of Coorg (72,296 acres), the Nilgiris, and Malabar (46,218).

In Madras cultivation on an extended scale is practically restricted to the two districts already mentioned and to Salem and Madura. Coffee is also grown in Burma, Assam, Bengal, and Bombay, but in all these provinces on a very restricted scale.

PRODUCTION.

The yield has been very poor since 1896, that of last year being the worst of the series, and representing only about 17⅔ million pounds, this quantity being hardly more than half the production fifteen years ago. Though the recent poverty of the crop has been due in the main to adverse seasons in Madras, Mysore, Coorg, and Travancore, the fall in prices since 1897 has removed the stimulus which had been given for a few years to the further expansion of the coffee-growing area, while disease has combined with adverse climatic conditions to reduce the yield.

Taking 100 to represent the area and production in 1885, the ratio of yearly increase or decrease is as follows:—

	Area	Production.			Area	Production.
1885	100	100	...	1893	109	109
1886	97	90	...	1894	117	101
1887	103	109	...	1895	119	115
1888	104	76	...	1896	121	75
1889	110	85	...	1897	116	69
1890	114	63	...	1898	118	68
1891	111	113	...	1899	115	50
1892	110	97	...			

PERSONS EMPLOYED.

According to the statements there were 27,634 persons permanently, and 82,656 temporarily, employed on the coffee estates in 1899, making a total of 110,290 persons, which is equal to one person to about 2½ acres.

EXPORTS AND CONSUMPTION.

The following figures are the average of the ten years ending 1899-1900:

		lb.
Indian coffee	Production	30,092,413
	Exports	30,017,680
	Left in India	*74733*
Foreign coffee	Imports	1,581,171
	Re-exports	735,862
	Left in India	*845,309*

The principal countries to which were shipped the Indian coffee exported in the last three years were (in lb):

	1897-98.	1898-99.	1899-1900.
United Kingdom	12,773,376	17,392,480	17,640,000
France ...	8,607,872	9,356,816	10,847,536
Ceylon ...	293,888	505,680	1,224,272
Austria-Hungary	591,360	1,023,568	298,704
Germany ...	297,584	618,688	292,544
Australia ...	199,024	265,440	272,496
Asiatic Turkey and Persia ...	863,856	131,264	137,984
Arabia ...	630,896	229,488	85,232

PRICES.

Coffee is not sold, as tea is sold, before shipment for export, and therefore there is no Indian quotation of price. The average prices in London for East India plantation coffee since 1874, are here subjoined with their variations, taking the price of 1874 as the datum = 100. Prices dropped last year, as a consequence of the great expansion in the production of Brazilian coffee, to the lowest level known:

	Per cwt. s.	d.	Variation.		Per cwt. s.	d.	Variation.
1874 ...	92	1	100	1887 ...	94	9½	103
1875 ...	107	4½	117	1888 ...	85	6½	93
1876 ...	108	2	117	1889 ...	99	10	108
1877 ...	110	0½	120	1890 ...	106	2½	115
1878 ...	107	6	117	1891 ...	105	2½	114
1879 ...	100	10	110	1892 ...	104	2½	113
1880 ...	99	9	108	1893 ...	105	4½	114
1881 ...	91	4	99	1894 ...	101	—	110
1882 ...	85	4	93	1895 ...	101	2	110
1883 ...	85	7	93	1896 ...	99	11	109
1884 ...	76	4½	83	1897 ...	94	8	103
1885 ...	75	3½	82	1898 ...	78	1	85
1886 ...	79	7½	86	1899 ...	65	2½	71

J. E. O'CONOR, Director-General of Statistics.
September 6, 1900.

PRODUCE AND PLANTING.

TEA: A WARNING.

Some recent comments made on the authority of the Calcutta "Englishman" by the "Globe" of last Saturday are calculated to work a considerable amount of mischief to the tea industry of India and Ceylon. The statement in the "Globe" is as follows:—"If the Calcutta 'Englishman' is accurately informed there is a growing disposition among Indian tea-planters to follow the same suicidal course that brought China tea into such grave disrepute. Until recently, the almost invariable practice in Indian gardens was either to destroy or use as manure the sweepings of the factories. To some extent this rubbish is composed of tea dust, but sand, and even worse refuse, also enter largely into its composition. In some samples subjected to analysis, fully 50 per cent was not tea at all, and the buyer was consequently cheated out of half his money's worth. The same discreditable fraud is said to prevail to an even greater extent in Ceylon, with the result of a downward tendency in prices, both in the colony itself and in the European market. As the sweepings only fetch five rupees a maund—80lb—it cannot make much monetary difference whether they are destroyed or sold. On the other hand, the depreciation of market values, consequent upon the lowering of quality, must involve a serious loss to the whole trade, while sooner or later Indian and Ceylon teas will be ousted from European favour by competitors with better characters. The matter is of such pressing importance that no time should be lost in dealing with it by measures of a sufficiently drastic sort. If nothing less will serve, the Indian and Ceylon Governments will have to prohibit the sale of sweepings under heavy penalties. It is not merely the commercial future of the industry that

is at stake, but the well-being of thousands of natives." It is to be hoped, in the interests of tea growers, that the "growing disposition" here referred to is not general, and that it will be promptly abandoned where it is practised. If the idea becomes prevalent amongst consumers that India and Ceylon teas are losing their reputation for purity it will be a sorry look out for the industry. From inquiries made in London, we are sorry to find that there is some ground for the warning of the "Englishman," although we cannot think that the practice referred to is carried out on a large scale. It would, indeed, be a suicidal policy if rubbish finds its way to market, and surely planters do not need to be told that it would be likely to inflict incalculable injury on British-grown tea, which has hitherto been held in high repute on account of its purity.

Not so Good as it Looks.—Tea growers have been under the impression that tea dealing was a lucrative pursuit, and that in the matter of profits it left the poor grower a long way in the rear. It is quite certain that large sums of money have been made by certain firms who advertise largely, but that prosperity in the tea trade abounds seems to be a delusion, if we may accept the following on the subject from the "Produce Markets Review." This journal, referring to the wholesale tea trade, says: "The great changes in the methods of the distribution of tea during the past few years have had a very marked effect upon the wholesale branches of the trade. Everyone regrets the disappearance of many highly respected firms as a proof of this, and it is well known that those who remain in the business find it a very difficult thing, in some cases, to make ends meet, and in others, to maintain a sufficient return on their capital. When the difficulties commenced a wrong remedy was unfortunately adopted. The wholesale tea trade had been for so many years a very prosperous one, that it was thought that the way to make its prosperity return was, not to cut down expenses, but to add to them, by making concessions to buyers, especially in the length of credit given. The result is notorious in the grocery trade, for while the retailer pays promptly for his sugar and other goods, as in fact he is obliged to do if he is to buy properly, he keeps his wholesale tea house waiting. Another inducement to trade has been to offer special discounts to buyers, which the sellers certainly cannot afford. Such concessions simply add to the crushing expenses current in tea, which are far away and above a reasonable amount, and very much in excess of those in any similar branch of the grocery trade, It appears likely that a crisis is at hand, and that something will have to be done to check the tide of futile endeavours to attract trade at the cost of the seller, who gives away more than his profit in unrecognised additions to his expenses. The only way to increase business is to sell cheaply, but to do this is impossible if expenses are to be still further added to and then lost sight of. Let people openly cut in prices as much as they please, so long as they know what they are doing, but in tea a vicious system of private concessions is ending in the ruin of the wholesale trade without real benefits to the retailer. Indeed, he also undoubtedly loses, if he is a man of means, by the encouragement of people with none, through the lax system of credits."—*Home and Colonial Mail*, October 12th.

PARAGUAYAN FRUIT.

Guava is one of the most abundant of Paraguayan fruits. There are immense numbers of trees throughout the country and women bring the fruit in bushel baskets to Asuncion. It is a round yellow-skinned fruit about as large as a five shilling piece and contains many small seeds. The tree looks like a plum tree and yields about one bushel and a half. The guava season is from Jan. to April and commences again in August. This fruit, says the United States Consul at Asuncion, makes a delicious jelly, clear and light red in colour. The fruit is also used to make paste. Naranjitas, or small bitter oranges, produce excellent preserves. They are about the size of a lemon. The bitter taste is removed by immersion in running water, and the orange entire—skin and pulp—is preserved. This orange is said to hold the flavour much better than the sweet variety. Three years after planting the tree is ready to bear and it sometimes bears twice a year. The lemon, or limon as it is called in Paraguay, is not found in as great abundance as the naranjita, but is also of extensive growth. It is not quite as large as our lemon and is preserved entire like the naranjita. The lemon tree produces from two to three bushels. Aguai is a most delicious fruit, the size of a plum, with two or three shiny seeds. The tree is the size of a large apple tree and yields about four bushels. Many are found in the vicinity of Asuncion, especially in the town of Lambare, also in Campo Grande. Abacaxis is a kind of Brazilian pine-apple that has been introduced into Paraguay and grows abundantly. It is very juicy and exceedingly sweet. It is stated by experienced persons in Paraguay that the abacaxis when preserved will retain its flavour and remain fresh for years.—*Journal of the Society of Arts*, Oct. 12.

SNAKE-BITE AND EUROPEANS IN CEYLON.

Our evening contemporary is wrong in saying that no European previous to the sad death of Mr. L F White, Railway Engineer, had been killed by snakebite in Ceylon, that is if Colombo harbour be considered part of the Colony. In the olden days when all the Colombo trade with Europe was done by sailing ships, barques and even brigs *via* the Cape, one of the last-mentioned lying low in the water was climbed by one of our deadly sea-snakes which got up the cable and lay close to a young sailor who was sleeping on deck. The latter towards morning turned round, was bitten and screamed out. His companions saw the snake, and at once a boat was launched and the poor lad taken to hospital; but he died either on the way or soon after arrival there. That, we have always reckoned, was the only authentic case of a European victim previous to this most lamentable occurrence in Jaffna. "Most lamentable," because, clearly, if Mr. White had known what to do, there is a possibility that his life might have been saved. (Each Engineer and indeed new arrival for the Ceylon jungle should have a copy of "Medical Hints" or some such useful pamphlet for guidance.) First there ought to have been a simple, but very tight ligature tied round his arm above the bite; but even before this, or simultaneously, the part bitten ought to have been cut freely with a penknife or razor and the part made to bleed freely. But let us give specific advice on the authority of the late Drs. Elliott and Dickman:—

Snake-Bites.—Pinch up the skin between the finger and thumb and cut out a piece about the

size of a shilling. Be sure you cut out the scratch made by *both* fangs of the snake. If you cannot pinch up the skin, stick a pin or anything else to lift it up; but in any way cut or dig out the piece. Any knife—whether pen or table knife—will answer. Have no fear of the consequence of your cut: there is no artery near the surface that you need be apprehensive of opening. A bandage will therefore stop any bleeding that may follow. Cut, however late, and cut boldly, for life often depends upon your doing so. *Liquor Ammonice* in 20 or 30 drop doses should also be given every hour or every two or three hours, according to the urgency of the symptoms. Pain is first complained of in the part bitten, which rapidly extends upwards; pain is also complained of in the belly, aftewards breathing becomes laborious, an impediment in swallowing is felt; and the pulse and respiration become barely perceptible, before dissolution takes place. Spasms are sometimes recognized. Bites from the *Tic Polonga* are sometimes followed by discharges of blood from the stomach.

There have been many narrow escapes of Europeans from snakes in Ceylon: one of the most thrilling was that of the V. A. in Belihuloya resthouse who found on lifting his pillow in the morning, a good-sized cobra curled round his gold-watch and which had probably been under his head most of the night!—It is truly surprising that poor Mr. White did not at once take some step to deal with the bite on his arm. We trust the warning his case affords will be widely noted.

GOOD NEWS FOR CACAO PLANTERS.

Good news for Ceylon planters of cacao will be found embodied in the "special report" from Mr. H. Hamel Smith given below. Discussing the prospects for 1901, the writer considers an increased supply of the product is necessary, and he is almost certain that prices are to go higher. Considering the careful study which our correspondent bestows on the market and countries of production for cocoa, much reliance may be put on his judgment and estimates. It is true that he points out how higher prices may check the retail trade, and pleads for the maintenance of average moderate rates; but really does it not seem as if the retail prices of cocoa, as well as of tea, coffee, &c., have run too low; and that considering the good wages of the working classes, a little stiffening all round should do no harm? In any case, to judge by the crop and other statistics given, there is encouragement for Ceylon planters to extend their cultivation, if only suitable land and the vigorous, suitable kind of plant are available. North America is fast on the way to become a great cocoa-consuming country; but as Americans cannot get the supply fast enough, we trust that many will turn their attention in that country to good Ceylon tea.

COCOA PROSPECTS FOR 1901.

AN INCREASED SUPPLY NECESSARY.

(By Harold Hamel Smith.)

As far as can be judged, cocoa prospects for 1901 point to the world's supply being larger than this year's, but not equal to the receipts of 1899; yet in spite of this prices are likely to go higher.

In proportion to the supplies received in 1899 it will, I think, be found to work out as 94 against 102, or about ten per cent less. Compared to this year (1900), counting teh year as from January to December, the Guayaquil and African crop will be larger; "Other West Indian," Bahia and Carupano about ten per cent larger all round, whilst in Trinidad, Colombia and Para, I expect to see a decrease.

The crop of the whole of the Island of Hayti or San Domingo, which comprises Samana, Sanchez and Jeremie, is an unknown quantity, and though it has beome an important one, it seems no trouble is taken keep a record of the number of bags that are shipped each year; hence it is often used, like the boy who stands in the centre of a seesaw, to "bull" or "bear" the market, according to the wish of the speculator. By some it is estimated at 50,000 bags, whilst others say that it must be nearly 200,000 bags! Those in whom I have most confidence put it at 75,000 to 80,000 bags. Lately attempts have been made to use the Cuban crop in the same way; but from all accounts this crop will be unimportant for some years to come.

On the other hand although next years receipts are likely to exceed this year's, as I have already said, I believe the average price of cocoa

WILL BE HIGHER.

That is not to say that at times, owing to pressure to sell for financial or other reasons, spells of low prices may not occur; but that at the end of next year manufacturers will find that the average price of the cocoa they have purchased during the year (1901) will cost them, say 4s to 5s, higher all round, than what they paid in 1900,—same as this year it has cost them, I am told, about 7s dearer (71s against 64s), than it did in 1899. A most satisfactory outlook, the planter will say; but if he goes into the matter properly, he will find that it is better for his interest to keep prices more on a parity, say at 72s to 75s for good red Trinidads, than to have it at 85s one year, and at 65s and even 45s the next, and this can only be done by keeping the market sufficiently supplied with the raw material to prevent its being pinched; otherwise the high price will drive a large number of the smaller makers out of the trade, and instead of having as now, more buyers than sellers, there will be plenty of sellers, but only a few buyers.

The reason why cocoa is likely to go dearer next year is not so much that the present rate of increase in the consumption will be augmented to any unexpected degree; but to the fact that last year manufacturers made very large purchases which enabled them to store up, in their private warehouses of which no returns are published, large invisible stocks, which not only rendered them independent of the market and enabled them to buy only when it suited them to do so but these stocks being an unknown quantity, prevented accurate estimates being made of what raw material there was on hand, and had a depressing effect on the market. By next year

THESE STOCKS

will have run out, or have assumed very small proportions, and to carry on their trade properly, the makers must make them up again, and it is on account of the replenishment of these invisible stocks that I anticipate a higher range of prices next year, for the circumstances under which the sales will be made will be different to what they were in 1899, when the visible supply was 55,000 bags, more than it is now (on 31st August the combined stock of London and Havre was 202,734 bags, against 257,734 bags in 1899) and the sellers uncertain what stocks the makers held.

This year has undoubtedly been a very trying one for makers in more ways than one; for whilst selling prices have not been advanced with drinking cocoas, not only has raw cocoa been high, but the sugar, and with cheap cocoas, the arrowroot as well; even the packages, for this has been a famine year in the paper trade, and the tinfoil have been much dearer. Confectioners and retailers of eating chocolates are already complaining of the rise in the wholesale price of the sweetmeat, and being unable to put up the price retail, their profits are reduced to such an extent that, important as the chocolate trade has become, it hardly pays them to handle.

Now this is just what must be avoided if the

CONSUMPTION OF COCOA AND CHOCOLATE

is to go on increasing, for it is to the eating chocolate trade, more than to drinking cocoa, that we must look for any substantial and regular increase in the demand, and there is no doubt that the demand will go on increasing if it is not prevented by the high price of the raw article, which must below enough to leave a reasonable profit to the retailer, and yet let them sell the goods at popular prices. Otherwise the goods will notbe pushed; and as in this world nothing stands still, if you do not push your goods you cannot get on, and therefore, you go back. As to the prospects of the present rate of consumption being maintained, if not increased, the following paragraph taken from a book on Cocoa published by the largest manufacturer in America speaks for itself:—"If the increased consumption of the last 37 years is continued until 1934, and that is altogether probable, in view of the fact that cocoa is one of the very few articles which contain all the essentials of a perfect food, the amount of crude cocoa required by this country (America) alone will be nearly

600 MILLION POUNDS."

Hence it is to the interest of every cocoa planter not only to extend his cultivation, but to increase the crop of what he has already got planted, by improved methods of cultivation, manuring, pruning, &c. To make cocoa planting profitable you must be up-to-date in the methods employed, otherwise you lose the increase in the crop, that is part of your profits. and if this increase does not come, and pretty quickly too, there will be a scarcity of the raw material, and though at the time planters may feel elated at the high prices they would obtain, in the end they would suffer, for owing to their want of foresight they would be starving, instead of feeding up, the goose that is now laying them golden eggs.

IMPROVEMENT ON COFFEE CULTURE IN SOUTH INDIA.

(To the Editor "Madras Mail.")

Sir,—I beg to differ with the idea prevalent among some of my brother planters that an acre of coffee in Brazil contains three hundred trees only though planted twelve feet by twelve feet. It is distinctly stated in Laërness "Coffee Culture in Brazil and Java" that in the former country the land is pitted twelve feet by twelve feet, and in each of these pits four coffee stumps are planted, one at each coruer of the pit, so that this will give three huudred clumps to the acre; as each contains four trees, this works out 1,200 clumps to the acre. These four stumps being planted so close together naturally make very little growth inwards, that is towards each other, but grow luxuriantly outwards; hence this wide space of twelve feet between the clumps is essential to their healthy growth. If one side of a tree is cut away and kept free of shoots, the other side will make most abnormal growth, and this is what takes place in a lesser degree with the clumps If single trees were planted at twelve feet apart the spread of brauch would not be nearly so extensive as that of the clumps; hence a smaller space would be just as suitable, say eight or nine feet. Both in the Brazilian and Leeming's system the trees are left to Nature and attain a height of twelve feet aud upwards. Conclusions as to what is the right distance to plant apart cannot be drawn from seeing Mr. Leeming's trees, as these were originally topped at the usual height four feet, and only will it be possible when his new clearings left entirely to Nature. attain maturity. Planters with coffee planted 6 ft. by 6 ft. and who wish to adopt the Leeming system would do well to cut out every alternate row diagonally, which would leave the field 8½ ft. by 8½ ft. In these days, when the borer is committiug such havoc in most Indian coffee districts, the fact must not be lost sight of that shade, both from the shade trees and the coffee itself, is inimical to its spread, and that open spaces with its attendant sunlight encourages the pest, also that there are four chances to one against the whole clump being destroyed by borer. I quote from Laërnes the following:—"In the Santos zone, the first step there is to dig a pit from 2 to 2½ palmo square and of equal depth. It is immediately filled up half a palmo with the earth that has been thrown out which the slave presses down a little. Then a mudas stump is taken and placed at one of the corners of the pit, in such a way as to allow the fibres to be spread out. After these have been covered with a little earth, a second is planted and so on till there is one at each of the 4 corners. The spaces left between the plants are not uniform everywhere. According to difference of soil to the physical aspect of the estate and its height above the sea, planters in the Rio zone generally leave spaces of 12 ft. by 12 ft. 12 ft. by 14 ft., 14 ft. by 14 ft. and even 15 ft. by 15 ft. palmos, while in the Santos zone the spaces are 14 ft. by 14 ft. 15 ft. by 15 ft., and by way of experiment during the last 3 or 4 years sometimes 16 ft. by 16 ft. 18 ft. by 18 ft. and over 20 ft. by 20 ft. palmos. It is needless to observe that this method of planting does not produce Brazil single-trunked coffee trees, such as are almost universal in Java, but very wide-spreading coffee shrubs, that is to say a brood of 8, 10 or 20 slender stems branching out from the mudas stump. As regards the height of the shrub, though it is difficult to state an exact average, seeing that the breadth aud growth of the plant frequently depend on the altitude of the plantation, yet we may safely assume that in the Rio zone the full-grown

coffee tree is from 8 to 12 palmos high, while in the Santos the standard varies from 10 to 16 palmos." I may here state that a palmo is equal to 8⅝ inches.

Shevaroys. C. K. Short.

—*Madras Mail*, Oct. 24.

Sir,—Adverting to "H. W." 's letter in your issue of the 25th instant, I fail to see how, apart from its impracticability in general planting, a greater number of plants than 302 can be got into an acre by conducting the operation in regular hexagons with 12 feet sides, and having a plant in the centre so that all the plants may be 12 feet apart. In a hexagon of this size every two adjacent triangles form a rhombus whose sides are 12 feet by 12 feet, and there are three such rhombic figures in the hexagon, whose superficial area, therefore, is 48 square yards, and this is space just enough for three plants. It will be observed that the centre plant of each hexagon becomes the corner plant of a rhombus 12 feet by 12 feet so that this practically amounts to planting 12 feet apart, only instead of in squares we have the figure slightly altered, but with the same area. I avail myself of this opportunity of correcting an error which crept into my letter of the 18th instant—in it "more light rain" should read "more light and air."

Gudalur. H. H. G.

A SOUTH MYSORE VIEW.

South Mysore, Oct. 26.—The interesting articles in your issue of the 16th, and subsequently, on "The Improvement of Coffee Culture in S. India," have been read with interest by many planters here. The prospect of picking such big crops with so little trouble is certainly a most dazzling one, but I venture to think there is not one planter in this district who is sufficiently sanguine of success, to cut out any of his existing coffee on the mere chance of such a prospect attaining fulfilment. Borer removes quite enough of our coffee trees yearly, and the difficulty of growing supplies, especially on old estates, has become a difficult and expensive matter. It is permissible to think that borer and leaf disease would attack coffee planted 12 feet by 12 feet just as severely as coffee planted 6 feet by 6 feet is now attacked. Shade trees are proved to be an absolute necessity in this district for the protection of the coffee during the drought from December to April and to reduce the devastation by borer to a minimum. This fact alone serves to demonstrate clearly under what entirely different conditions coffee is grown here to the conditions which obtain in Brazil and in some of the other coffee districts of S. India.—*Madras Mail*, Oct. 30.

TEA CLEARING HOUSE.

This Association was formed some years back for the mutual advantage of the wholesale tea trade and of the wharfingers. The institution has proved beneficial in some respects, especially in promoting despatch in the delivery of teas. Instead of the various whole sale houses having to send the documents round to the very numerous wharves scattered along the Thames bank, they are handed in to a central office in Mincing Lane, which saves considerable time, especially as the same system applies also to the returns of the unused portions of warrants to the owners. There is no doubt, however, that the Tea Clearing House, as at present constituted, has become injurious to the interests of a considerable portion of the trade, and particularly to those of the tea planters and importers, and of the home trade. This is because the members, on its formation, agreed only to buy teas lying at certain specified warehouses, while on the other hand non-members were excluded from the benefits of the Clearing House. People were also tempted to join it by being given discounts of 5 per cent off some of the charges, on condition that these were not allowed to other people, such as the retailers who buy tea. We have always objected to the latter portion of the arrangement, as coming perilously near those secret commissions which form such a canker in trade. These discounts have in some cases been recently increased.

The result of the creation of the Clearing House monopoly has been that, while the imports of tea have enormously increased, the warehouses at which it is placed have remained stationary in number. As a consequence, the dock and warehousing charges on tea have been maintained, and they are, as is generally admitted, exorbitant as compared with those on any other commodity. For instance, they are double those on coffee, an article which is dearer on the average than tea in bond. Tea warehousing has also become an extremely profitable business, so much so that it has been embarked upon by syndicates of merchants and others, who have become part proprietors of Tea warehouses, and who import tea in order to obtain the housing. The whole system militates very greatly against the interests of the tea planters, who have, as everyone admits, very great difficulties to contend with without the additional one of a warehousing monopoly in London coupled with excessive charges. No relief can be obtained from the Customs, who at present absolutely refuse to license more bonded warehouses for the storage of tea in London, and who will not receive payment of duty except at the specified warehouses on their list. This acts as a great hindrance to the proper development of the tea trade in London, but while the Clearing House exists in its present form no change can be expected. It is interesting to know that a leading firm of wharfingers has now seceded from the Clearing House, and it remains to be seen whether the trade will or will not re-assert its liberty of buying where it pleases. Tea-growers, importers, and dealers should also be represented in the working of the Clearing House.

The following circular has recently been issued on the subject, and it would certainly appear that the advantages of the Clearing House would be better acknowledged by an annual money payment, than by maintaining a tea warehousing monopoly.

"Tea Clearing House Committee, 21, Mincing Lane, September 27, 1900.

Sir or Gentlemen,—The Committee of the Tea Clearing House beg to notify to you as a subscriber that Chamberlain's Wharf Limited, are no longer members of the Tea Clearing House, and are, therefore, not entitled to its privileges. Having regard to the terms of Rule 14 the Committee have decided, in order to avoid inconvenience to the trade, to suspend that Rule so far as regards teas already purchased by buyers, and now lying at Chamberlain's Wharf, and teas already catalogued for sale at that wharf. I am, your obedient servant, (Signed) G J Poock, Secretary."

EXTRACT FROM RULES.

"Rule 14.—No subscriber shall be entitled to warehouse or deposit tea with, or employ in connection with tea, any dock company or tea warehouse-keeper who is not a member of the Clearing House, or to purchase or sample any tea from the warehouse of any non-member."—*Produce Markets' Review*, Oct. 6.

MANURING TEA IN THE AGRAS, CEYLON.

This is going to be a bumper year for Mr. Strachan's fine group of estates on the Agras—St. George, Hauteville, &c. Under the very able management of Mr. W. B. Jackson, this group has now reached an average of 800 lb. made tea per acre all over which, considering the elevation, is as good as anything in the island. Mr. Jackson was one of the first to commence burying his prunings, adding some lime, and latterly basic slag. He is a believer also in bones, castor-cake and some sulphate of ammonia. In fact, he has proved the advantage of the mixtures recommended by Mr. Joseph Fraser, for judicious cultivation, and his tea is throughout in very vigorous condition.

ABUNDANCE OF TEAK FROM SIAM.

The teak rafting season this year, at Bangkok, is expected to be one of the biggest on record. The rains have been very heavy in north Siam, and, with the great volume of water in all the rivers, teak that it has been impossible to get out for several years back is now being rafted down. It is confidently expected that long before the end of the rafting season the present high prices for teak at Bangkok will begin to fall.—*Straits Times*, October 23rd.

STUDIES OF NATURE OF THE RUBBER.

It must have occurred to every practical man concerned with the compounding and vulcanization of India-rubber, and thus confronted often with vexatious problems, that the source of much of his trouble might perhaps lie in the history of the material in his hands prior to the date of its arrival at the factory. The removal from a piece of rubber of moisture and foreign substances is comparatively easy; the real difficulty is in the proper appreciation of the mass when nothing but rubber remains. Not even the work of the most expert chemist is a sure guide to whether a certain lot of rubber to-day will yield exactly the same results in manipulation as a lot previously handled, of the same commercial grade and apparently identical in quality.

Undoubtedly the methods or processes of coagulating rubber will yet occupy a more important place in connection with the valuation of this material than has been true hitherto. It appears entirely reasonable that, all things else being equal, a difference in the treatment of two lots of rubber during the process of coagulation might lead to a difference in quality of the product when subjected to treatment in the factory, and particularly in the fabrication of the finer grades of goods. Who can say in how many cases the early deterioration of an article of rubber manufacture has been due, not to a lack of skill or care in compounding or vulcanization, but to the methods or agents employed in coagulation?

It is practically admitted by scientific experimenters with the *latex* of the rubber tree, that the nature of the process which we term coagulation is far from being clearly understood. At least there is a want of agreement as to how this phenomenon occurs, and this amounts to the same thing. If, therefore, it remains to be pointed out how coagulation takes place, the best coagulating agent for the *latex* of each particular rubber yielding species can hardly be named with certainty.

On another page appears a contribution from a careful student of the problem here referred to—Superintendent Hart, of the Trinidad botanical department—whose conclusions appear to us to merit attention. Naturally, this is a branch of study which cannot be followed in a practical way by the great majority of our readers, but it may serve to interest the factory superintendent, the manufacturer, and even the dealer in rubber goods and the consumer, to know that scientific investigation is attempting to prepare the way for a more intelligent supervision of the preparation of rubber from the initial stage.

A single sentence from Superintendent Hart's paper will indicate that the nature of his studies has a more practical aspect than might at first be apparent to the casual reader. He says:

A sample of *latex* treated with nitric acid in excess, shows that the acid absolutely destroys the rubber contained in it for general use, and deprives it of elasticity and its power of coagulation.

It may be inferred that specimens of crude rubber affected injuriously by the coagulating agent, but not enough to produce the full effect here mentioned, may find their way into the market, and finally to the factory, resulting in the production of decidedly unsatisfactory goods.

Another assertion in the same paper will be received with interest by those planters in America and elsewhere, who have been looking forward to the production of rubber from young cultivated seedlings. It is this:

The difference between *Castilloa* rubber taken from young branches and that from matured stems has been well observed at the Trinidad experiment station.

The latter quotation recalls an article published in *The India Rubber World* of April 15, 1894, by Mr. Francis Harvey, an associate member of the Institution of Civil Engineers, of England, recording his observations in the rubber districts drained by the Orinoco river. He suggested that the quality of rubber produced in some sections had deteriorated as compared with a period several years back, owing to the admixture of the sap of mature trees with that of immature saplings, and also the mixing of the gums from trees of different species, all of which he believed would be found an obstacle to the manufacture of high class rubber goods.—*India Rubber World*, Oct. 1.

SOME TEA PROBLEMS.

An intelligent anticipation of future developments as indicated by the direction of present demands must be a profitable recreation and therefore requires no apology for bringing into print. The planter has today thrust upon him some urgent demands which he must meet if he would survive. There is the demand for economy in expenditure on the production of tea, there is the demand for better quality and a greater proportion of it; and besides these the industry requires some measures to be taken for its future security from wasting blights and diseases. On the proper solution of these problems depends the prosperity of Indian tea-planting, and certain modifications in procedure, are indicated as at once called for.

The first of these in spite of what has been said lately to discount the value of expert advice is to raise a greater outturn from the same area or to keep the outturn stationary on a smaller area. This the experience of Ceylon shows to be possible by the employment of manures, but, indeed, that object lesson was hardly needed to prove the already known value of scientific plant feeding. It is arguable that with manures twice the number of plants could be profitably planted in an acre of land than the 2,000 odd which seems to be the present allowance. What is wanted now is not a large quantity of big leaf, but a numerous progeny of tips. What serves the large Souchong leaf that the market says must hereafter be left on the bushes? The saving of labour in hoeing and weeding and the increased outturn of better quality per acre would very materially affect the general position.

It is also worth while to ask whether the system of pruning now followed will not have soon to be abandoned as radically wrong in principle. I would have tea planted in solid hedges as in the old days and allowed to grow as such. The flat tabular form is, I think, the most unsuited that can be devised, having regard to the physiology of plants. Nature points out the pyramidal form as the proper one. Pruning then should become a process for elimination of decadent or inferior growth only, very different from what it is now, and plucking might have to be done on stepladders. Planters who talk of "plucking surface" forget that that surface is never full, and, moreover, the bush would necessarily become just as broad in a pyramidal as in a tabular form, and plucking surface so far as that determines anything would not suffer.

On improvement of quality I hardly think many planters set much store. Quality is a relative term, and all tea said to possess quality only holds that distinction in reference to some other not so good. It follows therefore that in a general improvement the position would not be bettered; nevertheless quality is a fad with many people whom we cannot afford to ignore.

It is very doubtful whether better quality all round would hasten the annual increase in the consumption of tea, and better quality all round would certainly not of itself bring better prices without increased demand at the same time. I am not of those who believe that all the improvements and care of the last 20 years have resulted in deterioration of quality. Most certainly quality has gradually bettered, yet prices have gone down, and the man who says they have gone down relatively as quality has gone backward is not worth arguing with. Much of the China crop is made in the same way it was ever made and under the same conditions exactly, yet there also prices have gone down.

But for progress' sake quality ought to—and I believe does—steadily go forward and upward by slow degrees. The policy of "direct from tea-garden to tea-pot" has much to answer for in keeping down quality. Tea requires time and a great deal of it to mature, and instead of "direct" being a recommendation, it is the reverse. Who that has tasted well-kept tea three years old would give it for tea three months old, or doubt the wisdom of hurrying it "direct from tea-garden to tea-pot." Yet the phrase is a catchy one and for its sake the planter has suffered much in pocket and reputation. Doubtless the planter can improve quality, but only at the expense of a decent volume of crop. With closer planting and forced growth much may, however, be accomplished, and it is in this direction rather than in manipulation in the factory that his efforts will be best rewarded.

All this so far as the tea plant is concerned is striving in an artificial direction, which Dr. Watt tells us involves blight and disease. To combat these by medicaments and decoctions of sorts is futile; when tea can only survive by virtue of sulphur and black soap, we shall be in a bad way indeed. In China 1,500 years of artificial treatment has not hurt the tea plant and can it be said that India has not the means of perpetuating her industry on similar lines? A disease-resisting hybrid is quite possible, and until that is forthcoming we have the old China *jât* itself. The present wants of the tea planting world seem to point to a revival of the China *jât* or its near relatives. Immune from most blights it grows like privet, well nigh impossible to kill above ground; it may be slaughtered, but adventitious buds on the roots rejuvenate the whole plant in a few months. It is an early yielding plant. Hail might be laughed at by the owner of China *jât*; you never come amiss to China, it always has a crop of silver downy tips during the growing season. With China, the planter may at will relax his field supervision, for in no operation can the bush be permanently damaged. The want of size in the bush is made up for by number. Until therefore a hybrid is produced combining the best proved qualities of the indigenous with those of the China, here lies the salvation of tea. In the day which is surely coming when only the extreme tip of shoots will be plucked, the China will be the heaviest cropper, and its leaf weight for weight with indigenous under the conditions, will, when manufactured, bring in more money than the other.—X.

—*Indian Gardening and Planting*, Oct. 18th.

A MONSTROUS BLACK COBRA.

(*From a Correspondent.*)

TRAVANCORE, Nov. 2nd.—It was a revelation to me to hear in the course of last week from a Mahomedan officer of the Government Telegraphs that he saw, one noon, on the public road from Quilon to Shencottah, 31st milestone, a black cobra (*Krishna Sarpom* or *Kari Nagam* as he called it) 30 feet long, 15 inches in breadth, and having a hood which he roughly estimated at 18 inches broad. He and his coolies, who numbered about 60, were working in the jungle when the monster appeared and the men were scared, as they took it to be a mountain-snake which they were afraid would devour them; but when they pelted at it, it could scarcely move, it was so dull and sluggish, due to the fact, as my informant believes, that it had had a heavy meal. But every time that the coolies pelted, it raised its hood and showed that it was a cobra. It was for some time moving forwards and backwards on the road while pelted, not being able to find out a way to escape, but at last discovering a crevice in the parapet wall on the road side descended into the ravine below and dashed off at an enormous speed, which my informant tells me was incredibly fast. He measured the trail of the snake with a tape and satisfied himself that it was 15 inches in breadth. The length he ascertained also with the tape trying to remember, as well as he could, the points on the ground where the snake's head and tail were. This can only be approximately correct, as also the estimate of the 18 inches breadth at the hood. Will your readers enlighten me through your columns, whether they can believe this story? There are specialists on the subject of snakes in Travancore, one of whom is

Mr. H S Ferguson. For my part, I can assure him or other specialists that the Telegraph subordinate, whose name I have taken down for future identification, has no motive for inventing a story of this kind or for wantonly exaggerating what he saw.—*Madras Mail.*

[The easiest thing in the world to exaggerate under the above circumstances and probably the length and breadth were doubled.—Ed. *T.A.*]

PLANTING NOTES.

New Varieties of Cacao.—Those interested in cacao planting will read with much interest the proceedings of the Cacao Committee of the Planters' Association which we publish on another page. Some very practical questions were circulated by Mr. Carruthers, the Government Mycologist and we trust that the result of the experiments that may be carried out will be such as to afford a guide to the prevention of disease and the healthy cultivation of new varieties.

Tea Company Meetings.—We direct attention to the reports of several Tea Companies which we publish elsewhere. Speaking at the annual meeting of the Associated Tea Estates of Ceylon Sir Alexander Wilson, who occupied the chair, gave a very full and clear statement of the position of the Company and pointed out that the directors had come to the conclusion that it was necessary to treat the principal estates more liberally with manure, the expense to be re-couped, it was hoped by the increased yield; and Mr. Bethune also supported the policy of manuring. The Duckwari Plantation has done so well as to enable the directors to recommend a dividend of 7 per cent on ordinary shares. Last month the annual meeting of the Ottery Tea Company was held, when a final dividend of 3 per cent, making 6 per cent for the year was declared; under the circumstances these must be considered satisfactory results.

Planting, especially of Rubber, in Mexico.—Mr. J. C. Harvey sends us an interesting letter on this subject, and especially on the value of land in Mexico. What he tells us about the fertility of the soil and the growth of his Castilloa rubber trees is enough to make Ceylon rubber planters discontented. But there are drawbacks even in the Central American Republic and we cannot have everything. Still at Heneratgoda, in two years, Castilloa trees were 16ft. high and 16 inches round the base of the trunk; and at ten years the largest was 38 inches in girth a yard above the soil and about 50ft. high; while Major Gordon Reeves reported trees at 8 to 10 years old 25 feet high and 30 to 36 inches in girth. The Castilloa likes a stormy climate and deep rich soil: in its native habit at it grows to 180 feet with a girth of 15 feet or 180 inches. All this by the way: Mr. Harvey shows the very different growth on poor gravelly soil. We hope he will write again and tell us about his Cacao and Vanilla as well as the progress of his rubber. One grand advantage possessed by Mexican planters is the splendid market for their produce offered so near to them in the United States—no need to send any produce to Europe.

Rhea Fibre.—An enquiry from an Uva planter the other day led us to enquire from Mr. Manley Power how his Kurunegala experiment with Rhea was getting on. He is good enough to send us, in reply, the following interesting information:—"In reply to yours of 20th, I beg to state that we cut the produce of our seven acres of Rhea fibre and decorticated it. I have just sent home a sample to see what they will give us for it, as we have some two tons of ribbons ready to send away if we get a good offer." We trust the price offered may prove amply remunerative, and so encourage an extension of the enterprise.

Rubber.—The German Consul in Payt-Piara (Peru) reports the discovery of large rubberaorest on the Niera River, a branch of the Amazon. An expedition has been organised to start for the interior to secure the right to collect the rubber. The increasing demand for rubber has drawn attention to the advantages of cultivating gutta—a leading product of Java, and several of the neighbouring islands. A recent number of the "Straits Budget" points out that guttapercha trees growing wild cannot meet the growing demand which must soon outrun the supply unless gutta plantations extensive enough to meet future needs are laid out. Gutta leaves have been freely resorted to in order to eke out the supply. A company has recently been formed at Batavia to develop this branch of industry.—*India Rubber Journal*, Oct. 15.

Coral Reefs of Ceylon and Maldives, &c.—Mr. Stanley Gardiner's Report which we published in our last issue is a very interesting one and we shall put it on record for reference (in a more correct form) in our monthly periodical. Mr. Gardiner considers the whole of the North of the island as far inland as Dambulla as comprising coral reef areas, and he shows that, undoubtedly, Ceylon and India were formerly connected by an elevated limestone flat as also Jaffna and Rameswaram. What he also tells us of his observations from Bentota southwards, the alternate appearance of coral colonies in the N.E., and their washing away in the South-West, monsoon is of much interest. We sincerely trust that Mr. Stanley Gardiner may be able to resume his observations in Ceylon and the islands to our West.

Manuring and the Value of Cattle Manure.—We direct attention to some useful analyses of different kinds of cattle manure, supplied by Messrs. Freudenberg & Co., (of the Hulftsdorp Mills' Manure Works) and given on another page. Planters cannot fail to be interested in the results given and especially in the summing-up which shows that ordinary cattle manure is really not worth for its chemical constituents. more than R7 per ton, or if there has been no waste of nitrogen—the manure being covered in and otherwise protected—the value may rise to about 12 rupees per ton! This is very little; but do the chemists make a proper allowance for the value of "bulk" in a fertiliser,—for returning to the soil so bulky an article as cattle manure?

THE OTTERY TEA COMPANY OF CEYLON LIMITED.

ANNUAL REPORT.

The Directors beg to submit to the shareholders their report and acconnts for season ended 30th September, 1900.

The crop secnred amounted to 172,956 lb. tea' against an estimate of 160,000 lb., showing an increase of 31,401 lb, over last season.

The tea cost laid down in Colombo cts. 23½ per lb. as compared with cts. 27·31 for year 1898-1899, whilst the nett average price realised was cts. 39·55 against cts. 46·91 last year, and cts. 42·40 in 1897-98.

A sum of R3,019·65 was spent on machinery, of which R579·65 has been charged to expenditure, and R1,183·99 for manure has also been similarly charged, making a total amount of R1,763·64.

Last season R2,827·60 was spent on manure, of which R1,827·60 was included in the ordinary expenditure, the balance R1,000 being paid for out of the Reserve Fund.

After making provision for the interest on mortgage, &c., the balance of profit available amonnts to R24,503·60. Of this amount R8,940 was absorbed by the payment of an interim dividend of 3 per cent to 31st March last, and the Directors now recommend that the amount of R2,440, which has been transferred to machinery account (being the balance of R3,019·65 mentioned previously), be written off for depreciatiou, that a final dividend of four per cent be paid absorbing R11,920, and the balance of R1,203·60 be carried forward to the next acconnt.

In terms of the articles of Association, Mr. R H S Scott resigns his seat on the Board, but, being eligible, offers himsef for re-election.

An Auditor will also have to be appointed for season 1900-1901.

THE SCOTTISH TRUST AND LOAN COMPANY OF CEYLON, LTD.

ANNUAL REPORT.

Report by the Directors of the Scottish Trnst and Loan Company of Ceylon Limited, to the Twenty-third Ordinary General Meeting of Shareholders, to be held within the Company's Registered Office, No. 123 George Street, Edinburgh, on Wednesday, the 24th day of October 1900, at 2 o'clock afternoon. The Directors present their Twenty-third Report, being for the year to 31st August 1900.

ESTATES IN THE COMPANY'S POSSESSION.—The yield of tea for the year exceeded the estimate, though the estates, situated as they are in different districts and at different elevations, show varying results. The average yield per acre was 393 lb. While the general average cost of production was rednced, the net average price realised was lower than in the previous season. The return from coffee shows a gradually diminishing quantity.

FACTORIES, BUILDINGS, AND MACHINERY.—During the year additional motive power for Annfield and Sarnia, and the formation of the Government road to Annfield, necessitated considerable outlay. Minor additions to buildings, upkeep of young tea and of fuel reserves, had also to be provided for.

In the current season machinery will be required for Brookside and Sarnia, and an extension of the factory at Alnwick cannot longer be delayed.

DEBENTURE DEBT.—The balauce of the Debenture issue was paid off at the term ef Martinmas 1899.

MORTGAGES HELD BY THE COMPANY IN CEYLON.—During the year the Tonacombe Estates Company Limited of Colombo repaid a snm of £1,000 to account of their debentures held by this Company.

ACCOUNTS.—The balance at the credit of profit and loss account is £5,827 19 2

And the directors propose to pay a dividend of 5 per cent per annum, free of income tax	£2,250 0 0	
Note.—Two and a half per cent of this was paid as an Interim Dividend at Whitsnnday 1900.		
To pay bonus of 5 per cent free of income tax.....	2,250 0 0	4,500 0 0
Leaving ... to be carried forward to next accouat.		£1,327 19 2

ACREAGE AND CULTIVATION OF ESTATES.—The olowing figures may be of interest to the shareholders as showing the extent of the Company's properties and the area under cultivation:—

	Tea.	Young Tea.	Forest and Fuel.	Patana and Grass.	Coffee, Buildings, etc.	Total acres.
Alnwick	348	132	234	227	...	941
Annfield,	251	..	28	...	10	289
Brookside,	181	60	35	1½	5	282½
Kaipoogala,	277	2	66	75	..	420
Rahanwatte,	258	21	20	9	..	308
Sarnia,	417	93	130	245	90	975
Total,	1732	308	513	557½	105	3215½

In recording an expression of their appreciation of the services rendered by the Estate Superintendents, the Directors desire to make special reference to the long and valued services of Mr Edward Hope, for many years Manager of Kaipoogala, who died in June last, on his way home, after retiring from the Company's service.

Mr. A Gordon Dickson, one of the London Agents, returned to this country in February last, after a year's residence in Ceylon, during which he visited the whole of the Company's Estates.

The Directors have taken advantage of the presence in England of Mr R S Templer of Messrs. Cumberbatch & Co. of Colombo, and of three of the Superintendents, now on furlough, to discnss with them various subjects relating to the practical working of the estates. A conference with these gentlemen has been arranged, and will be held in Edinburgh previous to the meeting of Shareholders.

The Director retiring by rotation is Mr John Wilson, who is eligible for re-election.

The Directors have, with regret, to record the death of the Hon F J Moncreiff, C.A., for many years Auditor of the Company. The audit of the accounts for the financial year under review was entrusted to the late Mr. Moncreiff's firm, Messrs. Moncreiff and Horsburgh, C.A. The Directors ask the approval of this interim appointment, and recommend the election of the firm as Auditors for the current year.—By Order of the Board, FRANCIS A BRINGLOE, Secretary.

KINTYRE TEA ESTATES CO., LD.

FOURTH REPORT OF THE DIRECTORS

to be submitted at the general meeting to be held on Thursday, the 25th day of October, 1900, at 12-30 o'clock, at the offices of the Ceylon Association in London, 61 and 62, Gracechurch Street, E.C.

The Directors have the pleasure to present the accounts for the twelve months ending 30th June, 1900. The estimated tea crop for the season was 480,000 lb and this was again largely exceeded, the total secured amounting to 540,279 lb or up-

wards of 40,000 lb more than was harvested during 1898-99. The average cost of production was estimated at 26 cents per lb, but a considerable saving on this figure was effected, the actual average cost being 24⅛ cents, the lowest yet attained by the company. The board think these figures reflect great credit on the management of the company's estates; the profit, however, is less than last year, owing to the lower prices realised for the company's teas, the fall in price being ¾d, the produce of Ceylon estates of a medium and low elevation having generally fallen fully 1 a lb. The net profit amounts to £4,586 6s 5d, and after paying directors' and auditors' fees, &c., income tax, and commission to superintendents, there remains a balance at profit and loss account of £3,961 8s, to which has to be added £121 11s 11d brought forward from last year. The board have paid half-yearly, as usual, the dividends on the preference shares, amounting to £1,000, and an interim dividend of 2½ per cent on the ordinary shares, which absorbed a further £1,125; they have set aside £250 for wear and tear of buildings and machinery (making a total of £1,000 on that account), and they now recommend the payment of a final dividend of 3½ per cent on the ordinary shares (making 6 per cent for the year), for which £1,575 will be required, leaving £132 19s 11d to be carried forward to next year. A sum of £228 16s 5d was expended on the Ayr Estate factory and machinery, and on the upkeep of the 33 acres of young tea which is not yet in bearing, and this sum has been charged to capital account. The sum of £90 17s 8d has been added to coast advances during the year, and the whole of the advances outstanding have been certified by the superintendents to be good and recoverable. The average yield of tea in full bearing was 650lb. per acre, and the gross average price realised in London was 7·03d. per lb., while the average rate of exchange was 1s. 4½d. per rupee. The estimates for the current season point to a tea crop of 521,000 lb., to cost 24.62 cents per lb.—*H. and C. Mail*, Oct. 19.

KORALE TEA ESTATES.

ANNUAL REPORT.

Report of the Directors, to be submitted at the Fourth Annual Ordinary General Meeting of Shareholders, to be held at the Office of the Company, on Thursday, 25th October, 1900, at 3 p.m.

The Directors now submit the Report and Accounts for the year ending 30th June, 1900 which have been duly audited.

	£	s	d	£	s	d
The net amount at Credit of profit and Loss Account after providing the General Expenses is	1,564	2	2			
To which should be added the balance brought forward from 30th June, 1899	169	6	11	1,733	9	1
To dispose of which, it is proposed to pay a dividend of 3 per cent. on the perference Shares which will absorb ...	1,436	11	0			
Directors' fees ...	150	0	0			
Expenses of Formation written off	100	0	0			
And to carry forward a balance of	46	18	1			
				£1,733	9	1

In presenting their Fourth Annual Report the Directors regret that though the estimates of crop from all the Estates have been fully realised, and the quantity of tea secured has been considerably in excess of last year's yield the lower range of prices has reduced the earning power of the Company, and they are thus prevented from declaring as good a dividend as last year.

In accordance with the Articles of Association Mr H W Brett retires from the Board, and being eligible offers himself for re-election.

During the year Mr W S Bennett, the Chairman of the Company, visited Ceylon and reported favourably upon the effective and economical management of the Estates and their good order and condition, and despite the poor results of the past year, the Directors desire to record their appreciation of the services of the Agents and Managers in Ceylon, whose efforts they trust will during the current year be attended with a result more satisfactory to the Shareholders.

THE GOOMERA (CEYLON) TEA ESTATES COMPANY, LTD.

DIRECTORS' REPORT.

The Directors beg to submit herewith their Sixth Annual Report and Balance Sheet, for the year ending 30th June, 1900. The accounts, after paying debenture interest and London expenses, show a loss of £173 6s 6d., which amount, when deducted from £203 2s 8d., the balance standing to the credit of Profit and Loss from last year, leaves a credit balance of £29 16s 2d. to be carried forward. The Directors very much regret the poor result of the year's working due entirely to the low prices ruling for the class of tea which the Company's Estates produce. The total crop amounted to 269,104 lb., realising a net average of 5·23d., against 234,817 lb. realising a net average of 6·29d., last year. The Estates of the Company are reported to be in thoroughly good order. A few further improvements to machinery and factory have been made, and charged to current expenditure during the past year. The Directors have been impressed by the necessity of largely increasing the output of the Estates by higher cultivation, and have consulted the leading authority on manuring in Ceylon, Mr. Joseph Fraser, who has embodied his views in a voluminous

report which can be seen at the office of the Company. The Directors propose acting upon the advice given them, and trust that the result will be to the advantage of the shareholders. The Directors did not draw their fees for the latter half of the year and propose waiving them. Mr. B F White retires in accordance with the Articles of Association, and, being eligible, offers h mself for re-election. The auditor Mr. J D Stewart Bogle, C. A., retires and offers himself for re-election.

THE SOUTH TRAVANCORE TEA COMPANY, LIMITED.

DIRECTORS' REPORT,

to be submitted at the fourth annual ordinary general meeting. to be held on Tuesday, October 30th.

The directors beg to submit herewith their fourth annual report and balance sheet for the year ending 30th June, 1900. The outturn of tea was 311,709 lb. being 38 291 lb., below the original estimate, against 337,961 lb., last year. This shortage was entirely due to an extremely severe and abnormal drought during a portion of the year, which adversely affected the flushes. The average price realised was 5·38d. per lb., as against 6·03d. last year and 5·55d. the year before. The gross profit was £2.158 13s 11d., against £3,339 15s 10d., last year and £1,304 15s 3d., the year before. After providing £250 for the Debenture Sinking Fund and placing £300 to coast advance reserve, the nett profit amounts to £853 19s. which, with a balance of £467 16s 2d. carried forward from last year, leaves a sum of £1,321 15s 2d. which the Directors propose to dispose of as follows :—Preference dividend for the year £825. (This has already been paid). Leaving a balance to be carried fsrward of £496 15s 2d. In view of the present depressed state of the tea market, and of the falling off in the yield and prices during the past season, the Directors do not propose to distribute any dividend on the ordinary shares, but recommend that the balance of £496 15s 2d. be carried forward to the new year. The area under tea now amounts to 730 acres. The reports on the condition of the Company's properties from the Manager and the Visiting Agent are of a satisfactory nature. Mr. Stewart and Mr. MacDonald continue to give the Directors satisfaction in the exercise of their duties, and the falling off in the profits is in no way their fault. The Manager's estimate for the present season is 340,000 lb. In accordance with the Articles of Association, Mr. T C Owen retires by rotation, and, being qualified, offers himself for re-election. The Auditors, Messrs. Jackson, Taylor, Abernethy & Co., retire, and. being eligible, offer themselves for re-election.

THE CAROLINA TEA COMPANY OF CEYLON, LTD.

REPORT

of the Directors to be submitted at the eighth annual general meeting of shareholders, to be held at the offices of the agents, Messrs. Frith, Sands & Co., Winchester House, Old Broad Street, E.C., on the 31st October, 1900.

Your Directors beg to submit the balance sheet and profit and loss account for the year ending 30th June, 1900. The nett profit is £6,926 8s 4d ; amount brought forward from last year at credit of the ordinary shares £1,199 9s 9d = £8,125 18s 1d. From which has to be deducted debenture interest £2,450, leaving an available balance of £5,675 18s 1d which it is proposed to appropriate as follows :—To reserve fund £1,200; to new clearings, buildings and machinery £1,000; to a dividend on the ordinary shares of 6 per cent. (of which 2½ per cent. was paid on 26th April, 1900) £3,000 = £5,200; and to carry forward to the credit of the ordinary shares £475 18s 1d.

The crops secured during the season compare as follows with those for season 1898 1899 :—Tea from estates 1899-1900, 1,131,333 lb. ; 1898-1899, 961,757 lb. Cocoa from estates 1899-1900, 414 cwt. 1898-1899 555 cwt. The tea crop cost 4·78d. free on board Colombo, as against 4·61 per lb., in 1898 1899, the increase being due to the higher average rate of exchange of 1s 4 15-32d., as against 1s 4 9-32d. The average gross sale price was 7.06d., as against 7·65d. for the previous season. This fall being about on a par with the decline established in Ceylon teas generally, and alone more than accounts for the diminished profit shown by the returns. The yield of cocoa would have been larger had the Udapolla estate not suffered from severe drought during the blossoming season. The excess in the total expenditure on crop account over that for the previous season, was caused by the increased crop of tea, and by the inclusion of a sum of R4,653·80, equivalent to £319 6s 9d. for new clearings and upkeep, the cost of which in previous seasons had been placed to capital account. Including the sum of £1,200 to be added this year, the Reserve Fund now amounts to £9,600, besides which £1,000 is being placed to the credit of expenditure on new buildings, machinery, &c., to cover recent outlays on the Carolina factory, as referred to in the last report. Your Directors are pleased to state that in a special report on the company's estates, which was made by Mr. Megginson, the late estates Manager, during his visit to Ceylon this year, he confirms the advices previously before them that the properties are in a thoroughly satisfactory condition; that the extensions to the tea area, on which much capital has been expended since the Company's formation, have proved most successful and are giving a full return on the outlay ; and that the estates are being worked on the most economic lines, consistent with efficiency and a due regard to their future. The staff in the Company's employ continues to give entire satisfaction. Your Directors have appointed Mr. Wharram Megginson to a seat on the Board, rendered vacant by the retirement of the late General Hopkinson, C.S.I., so that they might avail themselves of his intimate knowledge of the estates and their working. The Directors retiring by rotation are Mr. H St. J Oscar Thompson and Mr. C A W Cameron, who, being eligible, offer themselves for re-election.

PROGRESS AND PLANTING IN NYSSALAND, B. C. AFRICA.

(*By an ex-Ceylon Planter.*)

MLANJI, B. C. AFRICA, Oct. 1st, 1900.

I had a run into Blantyre to see the annual AGRI-HORTICULTURAL SHOW which took place on the 5th and 6th ultimo. My daughter and I left here at 7 a. m. and reached Blantyre, 40 miles, at 6 p. m , journeying in a machella, hammock slung on a bamboo pole with eight carriers each. What physique these niggers have to carry my weight, 13 stone, two men at a time, one at each end of the pole, changing from one shoulder to the other and relieving each other by turns as they get tired, trotting along like a pair of Pegu ponies—coolies could not do it. Four men to a chair with a lady in it pumps the Tamil in no time. The Show was not up to much. The people in this country do not seem to realise the amount of good such an exhibition does, and people say : "Oh ! what have I got to exhibit, so and so has better than me ; it's no use my trying, I'll get no prize, &c." Of course if everybody was to say and think the same, there would be no exhibitors at all.

We took in 20 exhibits and got 14 1st prizes, the principal ones being for coffee, ginger, turmeric, tea, fibre, butter, jams, cheese, The

number of European visitors to the Show would be about 250 including ladies, whose bright and cheerful countenances and handsome dresses added charm to the scene.

SIX CEYLON MEN

sat down to lunch, the day of the sports, at one table—Anderson, Moggridge, Robins, Power, Gay and myself. There was only one absentee, Lloyd, who by the way turned up to the Concert on Saturday evening. I counted over 200 Europeans on the sports' ground and every one looking the picture of health, including two Doctors. One of the latter I asked if there was anybody in Hospital? "No," was the reply, in rather a sharp tone!!—as if his professional services were not much required. He remarked, however, that the country appeared to be becoming more healthy. Notwithstanding the critics who assert that we are dying off like flies, and gambling with life, living in such a climate, we can live and do live well enough and enjoy life and work too. It was said, not long ago, that children could not live here. Why? I saw

FAT BABIES

in Blantyre (by the way Mrs. Hardy's, a Mlanji one, was the fattest, but I must not say the prettiest or I may get hauled over the coals by the parents of others) which would take a prize at any English Baby Show. What do you think? There are also to be seen fat rosy-cheeked youngsters with big pith-hats on, the very pictures of health, playing about in the open in the sun all day; surely with ladies and children galore, the climate cannot be so deadly as people would make out.

Ceylon seems to be overstocked with

CREEPERS OR GRUBBERS

at present. Why not send some of them over here; there is room enough in all conscience. Land and living is cheap, but I suppose they funk the climate, although they do not mind the glory of fighting the Boers. By the way I have a son who has been all through the war, and has not got wounded even, lucky boy: it is really marvellous how some escape.

COFFEE

is not looking over bright about Blantyre, There has been no rain for months, and the outlook is not promising by any means for the coming crop. We in Mlanji had 3½ inches of rain last month, which brought out a good blossom and set it well. This is a better tea than coffee country, the climate is so uncertain; but one likes to stick to coffee as it is not such a tedious cultivation as tea.

We have one great advantage here having a Sanatarium at our very door. In five hours or so I can get up to 6,000 or 7,000ft. elevation—perfection of a climate, but too cold and frosty when the sun goes north—May to August; but it is cold and bracing enough down here then.

I tried to kraal some

ZEBRAS

last month, but the men I sent to build the stockade built the gate on the wrong side, and the noise made in the changing of it drove the herd away. I am going to try again soon.

I bought a horse out of a batch of about 20 and it died from fly-bite within a week after I got it here, and the other horses all died, too, having been bitten on the journey here. H. B.

VARIETY OF PRODUCTS IN MEDIUM PLANTING DISTRICTS.

In mentioning the sale of Alpittikande in July last, we referred to the variety of products cultivated on this old favourite property, namely tea, cacao, coconuts (growing remarkably well) and arecanuts; but in addition there are over 40 acres of cinnamon fit for peeling and 10 acres under paddy, in splendid condition; while among minor products, there are pepper, erythroxylon, coca, camphor trees (prospering well), rubber and vanilla. Ten different products on the one property must be an unusual sight. Can this list be beaten anywhere else on a hill or low country estate?

SUGAR-PLANTING IN THE STRAITS SETTLEMENTS.

DRAWBACKS AND DIFFICULTIES AS WELL AS PROGRESS.

From an interesting letter from the Chief Manager of the large Sugar undertakings in the Malayan Peninsula to which frequent attention has been drawn in these columns, we learn that the present undertakings there have not been such plain-sailing as was anticipated:—"On one estate, Geelong, I am glad to say that after fighting sickness amongst the coolies and staff, we have at last got over the troubles incidental to opening up new land. A fine new factory has been erected and starts working this week on an excellent crop of canes extending over more than 1,000 acres, which area should be quadrupled in two years. At another estate, Rubana, on the Perak River, misfortune has overtaken us in the shape of crowded hospitals from ordinary ailments, but latterly cholera which we have only just managed to stamp out. Then to crown all, the rats came swooping down on us and ate down the whole of the canes—some 500 acres—which throws the estate back nearly a year. It has been most disheartening; in fact a long night-mare to me, but I now begin to see daylight through it all."

RUBBER FROM LEAVES.

Dr. Axel Preyer treats in the German *Tropenpflanzer* of the practicability of extracting rubber from the leaves of rubber-bearing trees. He describes certain quantitative experiments made with the leaves of the *Hevea brasiliensis*. In the first experiment the tree was aged 22 years; 500 leaves were treated; the latex was expressed from the leaves by manual pressure and coagulated with citric acid. Result 0·325 gramme (about 5 grains) of utilisable caoutchouc. In the second the plant was aged 18 months, same number of leaves and same process. Result 0·27 gramme (about 4 grains) utilisable caoutchouc. Dr. Preyer makes the following calculation with regard to cultivation on a commercial scale. *Hevea* plants of 18 months require but 10 centimetres (4 inches) of space between them; each plant carries 40 to 60 leaves, on an average 50, which answers to ·027 gramme caoutchouc: there would then be in a hectare (2½ acres) 1,000,000 plants giving 27 kilogrammes (59½ lb. avoirdupois) of caotchouc, even admitting that the yield could be doubled by mechanical extraction, which is doubtful. Dr. Preyer considers that it would remain too insignificant for remunerative culture.—*Indian Gardening and Planting*, Nov. 1.

THE NILGIRI GAME ASSOCIATION.

ANOTHER CONSIGNMENT OF TROUT OVA.

(From a Correspondent.)

Ootacamund, Nov. 4.—A meeting, after a lapse of fully six months, was held in the District Collector's office on Friday. Besides the President, Mr. C J Weir, as Collector of the District, and Mr. G Hadfield, Deputy Conservator of Forests, who has undertaken the duties of Honorary Secretary of the Association, there were present Sir Frederick Price, Captain Beadnell, Messrs. Pascoe and Herbert Brown.

A letter was submitted from Messrs. Andrews and Andrews, of the Surrey Trout Farm, expressing their regret at the failure of the two last consignments of trout ova, and offering to present the Association with 10,000 ova frec of cost, provided the Association would pay the necessary packing and shipping charges, and suggesting that the consignment of ova be placed in charge of any of the members of the Association, who happened to be travelling back to India. The Honorary Secretary circulated a note with the above letter to the following effect :—" After the sad experience of the last two consignments, it is inadvisable to send for any more ova. Mr. Douglas may be asked if he could arrange with anybody in England to see to the careful packing of ova to ensure the safe arrival at Madras." It was resolved to thank Messrs. Andrews and Andrews for their liberal offer, and say that the Association would communicate with them later on. The Honorary Secretary was asked to place himself in communication with Mr. Douglas in this connection.—*Madras Mail*, Nov. 7.

TWO RUBBER-YIELDING TREES COMPARED.

Dr. Axel Preyer in the German *Tropenpflanzer* makes a comparison between *Ficus elastica Castilloa elastica* grown for rubber side by side near Subang in Java. The plantation visited by Dr. Preyer consists of 40 hectares (100 acres) of *Ficus* dating from 1864, but exploited since 1881. On an average of seven years this plantation aged 35 years gives a mean yield of 600 grammes of solid rubber per tree per year. The yield from year to year however varies enormously. In 1899 the total production of the plantation was 3,060 kilogs.; in 1895 about 3,520 kilogs.; in 1896 about 1,670 kilogs.; 1897 about 3,270 kilogs. A kilogramme equals 2 1-5lb. avoirdupois. At the same time there are astonishing variations between the trees themselves ; from 100 grammes to 12 kilogs. The latter phenomenal yield was obtained one year, without apparent reason from a tree tapped exactly in the same manner as the others. For some years past *Castilloa* has been put down, especially on the path borders, in the cultivation of Liberian coffee. Judging from the short experience of the plantation, says Dr. Preyer, the mean production of *Castilloa* aged 8 years would be 200 grammes of solid rubber per tree per year ; at the same time there has appeared the exceptional yield of 2 kilogs. As there are 400 *Castilloa* trees to the hectare and only 125 *Ficus*, the yield for the former at 200 grammes equals 80 kilogs. to the hectare and for the second at 600 grammes only 75 kilogs. ; therefore even at present despite the difference of age there is an advantage of 5kilogs. in favour of *Castilloa*. The rubber from the latter also fetches a higher price. In 1899 it was sold at Amsterdam at 5 20 florins per kilog. against 5 florins for *Ficus* rubber. Dr. Preyer however is of opinion that a plantation devoted to rubber on a large scale with European supervision would not prove remunerative even at present prices. Rubber seems to him to be an enterprise specially suited to be pursued as an accessory in other cultivations where the general expenses are already provided for otherwise.—*Indian Gardening and Planting*, Nov. 1.

THE EXPLOITATION OF RUBBER RESOURCES.

A PANAMA RUBBER PLANTATION.—The rubber plantations of the Las Cascadas Plantation Co., Limited, which are situated at Las Cascadas, in the district of Emperador, department of Panama, republic of Panama. This plantation has been in existence since January, 1890, when the then proprietors planted 40,000 India-rubber cuttings, none of which has yet been tapped, and they have been adding to these year by year. They also have a large quantity of coffee and cacao trees, the majority of which are now bearing.

DEVELOPMENT IN BOLIVIA.—The wealth of the rubber resources of Bolivia has been demonstrated fully, but they remain closed to the world in large part because (1) of the sparse population and (2) lack of capital in that republic, but still more so because (3) of the lack of convenient means of transportation. The only means of transportation supplied by nature is the outlet through the river Madeira into the Amazon, and this is rendered almost impassable by numerous cataracts. From a Bolivian source comes news of a French undertaking to build a railway connecting the headwaters of the river Acre with those of the Madre de Dios, the advantage of which will be that the whole navigable river system of Bolivia can then be connected to the Acre, which discharges into the Purns, and that into the Amazon —thus giving Bolivia access to the Atlantic seaboard without reference to the Madeira. The Acre district now exports about 2,000 tons of rubber yearly. It is estimated that the opening of the region which the proposed railway would make possible would soon increase this amount to 20,000 tons yearly.

CONCESSIONS FOR GATHERING RUBBER.—The government of Venezuela has granted to Senor Juan Dall 'Orso, of Maracaibo, a concession for exploiting India-rubber and other products on 15 square leagues of government lands in the district of Colón, state of Maracaibo, for a period of fifty years. He agrees to pay 40 bolivars (=$7·72) for each 100 kilograms (=220 pounds) of Rubber exported ; also, to distribute seeds of the Pará rubber trees among the planters of that district. A concession covering 18,662 acres has been granted to Senor Alejandro Ortega Martinez, in the same state, on the same terms. Maximillian Doremberg has obtained a concession for the exploitation of India-rubber, Chicle, and timber in the department of Palenque, state of Chiapas, Mexico, obligating himself to pay to the government $24 (silver) per ton of Rubber and $18 per ton of Chicle exported.

EXPORT DUTIES ON RUBBER IN PERU.—A decree of the Peruvian government dated May 23rd provides that for rubber lands for which concessions are granted by the minister of public works, a rental shall be paid of 2 *sols* per *quintal*, or practically $1 per 100 pounds, for all rubber extracted. In addition, an export duty is imposed of 5 cents per kilogram on Caucho and 1 cent (?) fine or Jebe rubber, there being 100 cents in the *sol*, worth 43·6 cents, gold.

MEXICAN NOTES.—The Tabasco Commercial Co., with headquarters at Springfield, Massachusetts, are developing a tract of 15,000 acres in the state of Vera Cruz, Mexico, between Coatzacoalcos and Frontera, cutting mahogany and preparing to plant rubber and other crops.—*India Rubber World*, Oct. 1.

CEARA RUBBER.

has not always been considered of the highest value by the Ceylon planter. But from a report I have been reading, styled "The Diplomatic and Consular Report of Bahia" for July 1899, there is a good deal more to be said for it, apparently, than what used to be, at all events, thought in Ceylon. The present day planter, of course, may, for aught I know, be more fully alive to the virtues of "Ceara" than his predecessor. The writer of the aforesaid report begins the subject by a description of Para rubber, which, though aware of its high place commercially, he rather deprecates planters cultivating, on account of the unhealthy districts in which it flourishes. He suggests as alternatives the "Mangabera," and "Manicoba" varieties, but as the former requires from eight to ten years growth before yielding, I pass it over. Coming to

THE 'MANICOBA" TREE.

he says:—"Considering everything the 'Manicoba' plant shows many advantages over other varieties. It is easily planted from seeds or saplings, grows in six or eight months in any kind of soil to a height of six feet, and will begin yielding in about three years a considerable quantity of milk, far more in proportion than any other rubber tree in existence." He then cites the case of a planter known to him who has recently planted over 100,000 "Manicoba trees" and intends increasing the number to a million, being fully convinced that a very few years will show extraordinary results.

But what has all this to do with "Ceara," some person may ask? Simply this, that in another pamphlet by Mr. Thistleton Dyer, he says that he has identified the fruitful "Manicoba" tree with the "Ceara" plant. A retired Ceylon planter, with whom I was discussing the subject, tells me he had many Ceara trees on his estate, and never once troubled to tap them; he thought so little of them. If there are any planters still who are of the same way of thinking, the extracts quoted above may perhaps lead him to reconsider the question.—*London Cor.*

A FARMER'S EVERY-DAY LIFE.

No. 14.

(By Cosmopolite.)

HARVESTING AND SHEEP SALES.

The month of September has been,—as usual with agriculturists,—a very busy month, harvesting having been in full swing, in addition to all the big sheep sales of store lambs, so that those who deal as much in sheep as I do, have been kept pretty well on the trot. The moon, which has just run its course, came in on a Saturday, and full moon fell on a Sunday, reminding one of the old prophecy:—

"A new moon on Saturday,
On Sunday at its prime;
If it comes again in seven years,
'T will come in plenty time."

It was during the course of a moon, with these characteristics, that

THE TAY BRIDGE

was b'own down and believers took every opportunity of drawing the public attention to the result, as being in keeping with prophecy. This month that has just passed over to the majority, however, has not kept up its character, for it has been windless and rainless, but with heavy fogs at night and sunshines during the day, so that another of the cherished beliefs of our youth has gone by the board. Cutting has almost been completed, and in some cases, farmers with the earlier and higher crops have begun leading the grain to the stack yards, with the usual result that much of it is heating and spoiling, so that extra work has been caused by turning the stacks, to let them cool.

PREMATURE "LEADING."

The so called practical farmer is very fond of leading his crop before it has had time to be killed in the stock, and no number of lessons seem enough to teach him wisdom. Yet he continues, year after year, to abuse the grain merchant for giving him a shilling or two less, per quarter, for his grain which has been discoloured, than what his more patient neighbour gets, who has allowed his crop to remain in the stook until it was ready for leading I fear that too much grain has been led before it was ready, this year, for I already hear the whirr of thrashing machines all around me, and excited farmers, whose stacks are heating, may be seen chasing the proprietors of travelling thrashing mills, and begging of them to come and thrash out their grain before it is quite useless. The outcome of this ridiculous haste is that grain will be knocked down in price, as the merchants will only consent to take grain that is soft and discoloured at a very low rate, and unfortunately, this brings the price of a good sample down also. I was speaking on the subject to the doyen of the grain trade in this locality, and he darkly hinted at prices going steadily downwards, and all because the so-called, practical farmer will persist in leading his grain before it is ready to be stacked. The grain merchant I refer to was, in the early fifties, a digger on Bendigo, at the same time as Lord Salisbury, and referring to that circumstance, it appears that Lord Robert Cecil was considered one of the strongest men and best miners on the gold field. I have no doubt his early experience as a digger has been of service to him in his after-life as a politician and premier of Britain.

THE WEATHER

of the past month has been more delightful than any we have had this year, although, personally, I have had no complaint to find with the drippy weather of the past summer as it exactly suited my land. and I find that I have a finer crop than ny I have had during my term here,

and my men, who have been with me all the time, have formed the same opinion. I heard a story about a farmer, in this neighbourhood, who pins his faith on

ARTIFICIAL MANURES AND THE "FIVE COURSE SHIFT,"

and who has had the usual result, namely, a poor crop. He was speaking to a neighbour of mine, and proudly boasted that he had finished his harvesting in three weeks' time, and had his crop all safe under "thack and rope." My neighbour drily replied: "I dinna care for they shortsome haresties, I like ain that taks a hantle o' wark and a lang time aboot it"; and these are my sentiments. When a man finishes his harvesting in a very short time, it is not a sign that he is a specially smart worker, but is generally proof of his being a mighty bad farmer and the grower of poor crops. I intended sending, this time, some peculiarly bright thoughts which occurred to me, in connection with the harvesting of the crop, but found, after putting these into elegant language, that some Shakespeare or Longfellow or Carlyle had anticipated me, and not unfrequently used my very words. If those fellows had never been, it had been millions in my pocket.

INSURANCE.

Insurance of buildings is not the only outlay in that direction that farmers have to meet, for most of them insure everything about the place, not forgetting their stock and even their labourers, the latter being a very necessary item, in these days of a master's liability. I have had my men insured for many years, but only twice have I put forward any claim against the company, both occasions being on account of sickness, for which I received 12s 6d per week during the time the sick man was off work. In the event of accident by which a labourer is permanently injured or killed, the Company stands between the insured and the claimant. Life insurance in Ceylon was a subject receiving considerable attention lately and clear proof was produced that risks were less in your island than in this country; but I lately read an article which proved that Ceylon was not the safest place in the world to live in, but the fields of our up to-date battles. Cæsar, it was pointed out, thought very little of a fight in which 50 per cent of the participants were not killed out-right. In Napoleon's time the killed in battle averaged 25 per cent, in the American Civil War 20 per cent, and in our own little South African debate, it has been only 7 per cent. "At this rate," the article continues "in a few years more, the only really safe place for a timid man, will be in a big battle, and the insurance rates on the lives of military gentlemen in active service will be lower than the rates on tract distributors or hotel porters."

SUGARLESS TEA AND UNSALTED MUTTON.

Referring to the war in South Africa reminds me that I read in the *Observer* a letter from one who had been in the hands of De Wet as a prisoner. One sentence ran thus:—"For the first four days of our captivity we lived on nothing but meat, and I can tell you we got as weak as rats."* Now this fact I can corroborate, for, when I was a youngster, living, along with a companion, in the *terra incognita* of New Zealand, we ran short of everything in the shape of food, except tea and mutton; we had no flour, sugar, salt, &c., and, for four weeks, we existed on unsalted mutton and sugarless tea, and so weak did we become that we could scarcely walk a hundred yards, and we both became permanent believers in the old saying that "bread is the staff of life." When the boat, which was wont to bring provisions to us, ultimately did arrive, my comrade seemed unable to justify his appetite, and, after watching the truly magnificent way that he gorged himself, I asked if he was enjoying himself. "Yes, thank you," he replied, but what I don't like is the long time that is wasted between the meals!"

THE SWALLOWS

left us, this year, on the 28th of September, the same date as they have chosen for their departure, 17 times out of the past 19 years. How they know when the day comes round is one of those things that no fellow can understand.

PLANTS AND THEIR TREATMENT IN AMERICA.

We have to acknowledge with thanks receipt of the following from the Agricultural Department at Washington:—

Progress in the treatment of Plant Diseases in the United States, by B T Galloway, Chief of Division of Vegetable Physiology and Pathology.

Progress of Commercial Growing of Plants Under Glass, by B T Galloway, Chief of Division of Vegetable Physiology and Pathology.

Progress of Plant Breeding in the United States, by Herbert J Webber and Ernst A Bessey, Division of Vegetable Physiology and Pathology.

Two Diseases of Red Cedar, caused by Polyporus Juniperinus N Sp and Polyporus Carneus Nees. A Preliminary Report by Hermann von Schrenk, Instructor in Botany, Henry Shaw School of Botany, Special Agent, Division of Vegetable Physiology and Pathology.

COFFEE IMPORT DUTIES IN FRANCE

Havre, Oct. 15.—According to information obtained here, it is not correct, as reported from Bombay, that Indian coffee exported to France will in future have to pay double the duty levied upon Brazilian coffee. Coffee grown in British possessions will, on the contrary, continue to enjoy the benefit of the French minimum tariff indefinitely. Venezuelan coffee is the only coffee affected, as France has no commercial treaty with Venezuela, and the duty on coffee from that country will therefore be double what it is on other kinds. The duty fixed on Venezuelan coffee was at first to be applied to all coffee coming from Venezuela after September 21; but since this decision was taken, and in consideration of the protests made by the different Chambers of Commerce, this date has been extended until December 31. Meanwhile, a treaty is likely to be concluded with Venezuela, and then the import duty on coffee will be the same for all.—*Home and Colonial Mail*, Oct. 19.

* Because there was precious little *of that meat* if we remember aright, in this case.—ED. *T.A.*

THE TUTICORIN PEARL FISHERY.

The preliminary arrangements for holding the pearl fishery off the coast of Tuticorin were made by Captain Baker, the Superintendent of Pearl Fisheries, Tuticorin; but as he was suddenly taken ill, Captain James the Port Officer, Negapatam, was deputed to carry out the work. The fishery commenced on the 12th March last and lasted until the 28th idem, when it had to be closed as the divers were unwilling to continue the fishery owing chiefly to the immature condition of the oysters and the low prices realised by their sale. Though the revenue derived by Government during the fishery was more than sufficient to cover the expenses of working, the net profit (R11,033) says the Madras Board of Revenue, fell much below the estimated income (R93,000) and the fishery cannot be said to have been on the whole a success. It proved disastrous to the poorer folk—the boatmen and the divers who are reported to have realised hardly enough money to provide daily food for themselves and their families. It began badly by a combination among the merchants to keep down prices and when it became an undeniable fact that the oysters were immature and had a very few pearls, a panic set in so that for days together there were no sales of the Government share of the oysters, and the boatmen and divers had to sell their shares for what they could get. Captain James attributes these results to the commencement of the fishery, a year too early. He estimates that the oysters were only four years old, and that they were too young to be fished. A sample of 5,000 oysters was opened by him during the fishery and the pearls extracted from them were valued by a dealer at R17-4-6 only, that is at the rate of R3-7-3 per thousand. The valuation reported by Mr. Baker in respect of the sample of 8,500 oysters lifted in October last was R10-2 per thousand, but, whatever the reason, the event has proved that that estimate was considerably over the mark. Having regard to the fact that valuation by experts is the chief practical guide for deciding whether or not a fishery should be held in a particular year, the Board considers that the method of estimation and appraising the pearls should be placed on a sounder footing.

The question of the possibility of a further fishery next year is not dealt with either by Captain James or the Collector. As a large stock of oysters appears to have been left on the bank, the Board considers that a sample should be lifted early in October or November next and a Report submitted on their condition in view to decide whether there are any prospects of a more successful fishery in 1901. It appears that some of the boatmen and divers of Tuticorin were at feud with the Jadi Talaivan and that their obstructive attitude contributed partly to the poor results of the last fishery. Mr. Bedford, the Collector, suggests that a system of rewards and punishments would be of use in dealing with a temporary panic such as that which took place on the present occasion, by enabling Government to exercise more control over the divers and boatmen. He proposes to consider the question at the time of holding the next fishery and his views will be awaited. The Board regrets to have to record the death of Captain James, who took much interest in and did much hard work in connection with the recent fishery. Mr. Bedford considers that the strain and worry incidental to the task must have told greatly on his constitution. The Government has approved the Board's proposals and shares its regret at the death of Captain James.—*Madras Mail*, Nov. 2.

PLANTING NOTES.

Castilloa Rubber.—We direct attention to the letter with which Major Wyllie has favored us. Perhaps Mr. Willis may be able to settle the question raised as to the varieties of "Castilloa" rubber now in Ceylon.

Tea for Caffeine.—In his report for 1899, the principal chemist of the Government Laboratory at Bombay states that 226 samples of tea, representing 3,322 packages, were found to be mixed with sand and others substances, and were refused admission for home consumption. Tea which cannot be passed for use as a beverage is mixed in bond, with assafœtida and lime, and used for manufacturing caffeine.—*Chemist and Druggist*, Oct. 27.

Dutch East Indies.—Tea Trade.—The *Moniteur Officiel du Commerce* points out that the fall in the prices of coffee in the consuming markets has caused increased activity in tea cultivation in Java. Within the space of nine years the exportation of Java tea to Amsterdam only has more than trebled: in 1891 it was 20,639 cases (a case generally containing 40 kilos.), and in 1899 it was 69,320 cases. At Amsterdam the prices of tea in 1899 showed the following fluctuations :—

	Highest price. Florins.	Lowest price. Florins.
Flowery Pekoe ...	1.52	0.38
Orange Pekoe ...	0.60	0.30
Broken Orange Pekoe	0.51	0.38
Pekoe Souchong ...	0.41	0.25
Souchong ...	0.38	0.29

A Fruit Paradise is Southern Arabia or Felix Yemen, as described by Mr. Zwemer in a book just published. We quote from a review in the *Spectator*:—

"The day after leaving Mabek brought us to the beginning of the happy valleys of Yemen, very different from the torrid coast. A country where the orange, lemon, quince, grape, mango, plum, apricot, peach, apple, pomegranate, fig, date, plaintain and mulberry, each yield their fruit in season; where wheat, barley, maize, millet and coffee are staple products, and where there is a glorious profusion of wild flowers—called 'grass' by the unpoetic camel-drivers. A land whose mountains lift up their heads over 9,000 feet, terraced from chilly top to warm valley with agricultural amphitheatres, irrigated by a thousand rills and rivulets, some of them perennial, flowing along artificial channels, or leaping down the rocks in miniature falls. A land where the oriole bangs her nests on the dark acacia, the wild doves hide in clefts of the rock and the chameleon sports his colours by the wayside under the tall flowering cactus. Such is Yemen."

"The road from Ibb to Yerim has perhaps the finest scenery of any part of Yemen; never have I seen more picturesque mountains and valleys, green with verdure, and bright with blossoms,—scabiosa, bluebells, forget-me-not, golden rod, four-o'clocks and a large oleander trees. The cacti plants were in full bloom and measured twenty feet against the mountain passes. Two thousand feet below one could hear the sound of the water rushing along the wady bed.'

JAMAICA TO SUPPLY FRUIT TO ENGLAND.

Our columns have this week borne testimony ot the fact that a new era is dawning in the relations of the United Kingdom with one of our oldest colonies. From the beginning of next year a new line of steamers, built specially for the rapid conveyance of tropical fruit, will be established by the firm of Elder, Dempster, and Co. to run fortnightly between this country and Jamaica. The steamers are to be of large size and adequate speed, and will run direct from Bristol to Jamaica in about 12 days. They will carry mails and passengers, and the service will receive a subsidy of £40,000 a year, to be paid partly by the Imperial Government and partly by the Government of the colony. It is a condition of the contract that the owners of the line should purchase 20,000 bunches of bananas for conveyance by each ship, paying for them at the market price of the day. It will be seen at once that this is no ordinary development of maritime and commercial enterprise, though even from that point of view it is not without interest as reviving the old historic connexion between Bristol and the West Indies. It is really a great Imperial undertaking, warmly advocated by the late Royal Commission on the West Indies, and now warmly espoused by Mr. Chamberlain as a salient feature of Imperial policy. The cultivation of the banana promotes and develops many other valuable cultivations, as was shown at length by our Special Correspondent whose letters on the West Indies we printed at the close of last year. It is thus no extravagent estimate that the value of the fruit exports from Jamaica may in a few years exceed the present value of all the exports from the island and may amount in the end to at least £2,000,000 a year. In 1896 the export of fruit from Jamaica amounted to over 4,000,000 bunches of bananas, to nearly 10,000,000 cocoanuts, and to nearly 100,000,000 oranges, not to mention other fruits, and it has since largely increased. In the height of the banana season it is no uncommon thing for eighteen steamers to leave Jamaica in a week for the ports of the United States, principally Baltimore, Philadelphia, New York, and Boston. As the supply is inexhaustible the same thing may some day come to pass in the ports of this country. In the meanwhile the establishment of the new direct service, even on its present footing, should offer to those who love the sea a very inviting temptation to visit one of the most beautiful islands in the world. The climate of Jamaica affords every variety of tropical temperatnre except those which are oppressive and relaxing; its scenery lacks no element of tropical majesty and tropical enchantment. Now that it is possible to reach the island in less than a fortnight, and to spend a month there without being absent more than eight weeks from home, surely many a sea-loving Englishman, with imagination enough to appreciate the historic associations of the British Antilles and taste enough to enjoy the glories of tropical scenery at its best, will say with Kingsley "At Last" and seek the shores of an island which more than any other perhaps in the whole world typifies and illustrates the Imperial instincts and triumphs of his race. Let us hope, too, that those who go will return convinced that Froude was mistaken in thinking that the sons of the Empire are no longer worthy to bend the bow of Ulysses.—London *Times*, Oct. 13.

THE FOREST DEPARTMENT.

Western Province.—The plantation at the Model Farm at Kalutara has been weeded each month, the expenditure on upkeep being R393·63, or R14·58 per acre. The jak are reported to be doing well and beginning to seed, while the ingasaman and lunumidella are dying out. The Para rubber plantation at Midellena in the Pasdun korale had to be abandoned. The top soil was washed away by heavy rain, and elephant deer completed the destruction of the plants. The expenditure on this plantation up to the time when it was abandoned amounted to R128·47. There has been no expenditure on the other plantations, although I have requested the Assistant Conservator to remove the suppressed trees at Botale and Polonnaruwa.

Hill Reserves.—In the Nanuoya strip plantations the *Eucalyptus robusta* are doing fairly well and require some light thinnings, but the strips originally planted with *Eucalyptus Globulus* and *Acacia decurrens* are not a success. Luckily a large number of standards were left in these strips. At Conical Hill the strip plantations amounting to 38½ acres in compartment I., have made a considerable stride since last year. The very fine plantation at Haputale now requires thinning or coppicing in strips. The coppice made in 1896 is now almost as tall as the uncut strips of 1888-89. The coppice shoots are on an average over 12 inches in girth, whereas the uncoppiced poles planted in 1889 are only about 19 inches in girth. An additional area of 2 acres was coppiced and yielded 263 cubic yards of firewood, which were sold for R526. As the cost of coppicing 2,223 trees was R111·15 and of bringing the wood to depot was R118·60, the net surplus on the transaction was R296·25, or R148 per acre, which for a plantation ten years old is good. Windfalls in this plantation gave 142 cubic yards of wood and 290 small poles, which sold for R348·40, the cost of the work being R175·40.

In the nursery clearings at Nuwara Eliya the undergrowth of brambles, &c., was cut down. This plantation is doing well as is also the plantation of *Eucalyptus Globulus* behind the Kachcheri, which should be coppiced.

BREATHING TIME.

HOW TO CURE PULMONARY DISEASES.

If during the coming winter the observant pedestrian should notice innumerable excited people striding through the streets with a stick across their backs and between their elbows, he must not jump to the conclusion that London has suddenly lost its senses. For this form of exercise is part of a treatment which is now rapidly becoming popular—the cure for asthma, bronchitist and all the other pulmonary diseases which trouble and distress the dwellers in our foggy, smoke-laden cities. Hitherto the asthmatic person has kept indoors as often as possible, carefully shutting windows and doors, and keeping a roaring fire blazing in the grate. Now he is bidden to fling his windows open, to sleep even with his windows open, and, moreover, to keep in the open air as much as possible. But this is not all. He is taught that it is not so important what he breathes as how he breathes. Breathing-exercises, then, are part of the cure, and here not only the sufferer from bronchial catarrh is concerned, but even the woman of fashion anxious to maintain her good looks. For fifteen minutes twice a day women of fashion, asthmatic patients, and, indeed, all the world, are bidden to stand out of doors, preferably in the sunshine, and holding the chest up, to inhale slowly through the nose, and then as quickly exhale the breath through the month. Of course, everyone knows that it is through the nostrils he should inhale, and it is quite probable that many of humanity's ill nesses are due to improper breathing; but, at the same time, it will be an almost superhuman feat to make mankind breathe through the nostrils.—*Globe*, Oct. 19.

SUN-FLOWER CULTIVATION IN RUSSIA.

Our Consul-General at Odessa says in his last report that there is a growing demand in Russia for oil-yielding seeds, particularly for those of the sun flower. Until recently there were but few mills for expressing this oil, and the grocers finding no market sent their seed abroad. Now, however there are mills in Russia which require large quantities of it, and they offer the growers higher prices than those obtainable abroad. With the increasing home demand a decline in the exports of oil-seeds may be looked for in the near future. Samples of sun-flower seeds were asked for by the Government of Bengal, where it is intended to try them. The Consul-General from personal experience states that the plant will grow very luxuriantly in East Africa, and he suggests that it may be found a suitable crop for other British colonies. In Russia it is found that the best results in sunflower cultivation are obtained from a well-tilled soil, with not too much clay in its composition; it should be well-ploughed in the autumn and harrowed in the spring. The seed should be sown in April or May in every second or third furrow, One or sometimes two or three seeds should be put into the ground at a distance of two to four inches apart. Broadcast sowing may also be resorted to, care being taken that only one seed falls in every two square feet. The quantity of seed required per acre is twenty pounds; the yield, if good, should be about 1,600 pounds. The yield in oil of seed in husks is seventeen per cent; without husks, twenty per cent. The seed is much liked as a light refreshment by the poorer Russians, and is sold in the streets by hawkers, to be eaten as nuts are eaten in England.—London *Times*, Oct. 8.

DEVELOPMENT OF THE SOUDAN.

FORESTRY.

The Anglo-Soudanese Government has taken up the question of the development of the vast Soudanese forests, which may be a very possible source of future wealth, and an expert in forestry from Burmah has been appointed to study and report on the best methods of intr oducing improvements and utilising this potential source of wealth. Mr. C E Muriel, Deputy Conservator of Forests in Burmah, has, wit h the consent of the India Office, joined the Anglo-Soudanese Government for one year, the unexpired portion of his furlough. Mr. Muriel arrived in Cairo on Wednesday from England, and will shortly proceed to the Soudan.

Sir William Garstin, in his report on the Soudan, says;

"It is very much to be hoped that a scientific examination of the Soudan forests may ere long be carried out under the superintendence of an expert. An Indian forest officer (from Burmah for choice) might be deputed for this purpose. It is certain that much valuable information would be obtained from his report. Such an appointment needs no recommendation—its necessity is obvious. A trained forest officer could, moreover, render good service by advising the Government as to the best method of preserving the valuable fuel supply which at present exists on the banks of both rivers."

Although it is only a little over a twelvemonth since the report was published, the advice has been acted upon, and it is to be hoped that some serious attempt will be made to restrain the enormous waste of most valuable trees that now goes on. The supply, although apparently, inexhaustible, must speedily diminish, unless the cutting and felling of the areas is carried out upon some regular system which will permit of the young trees growing up and replacing those cut down. It is, of course, inevitable at present that the felling should be carried out in a wasteful manner. Fatigue parties are landed from the boats and are required to cut the largest amount of wood in the shortest possible time. The men have no idea of the value of the trees, and naturally select those which are nearest to the water and easiest cut. Should this practice be continued, it is certain that a few years must see a great diminution in the belt adjacent to the river. On the Blue Nile even the valuable gum-producing acacias are being felled for fuel.

The vast forests of the Soudan line the banks of the Upper Blue Nile and extend, in an easterly direction, to the Abyssinian frontier. In the Bahr-el-Ghazal Province also, particularly in the Bongo country, large forest tracts exist. The ebony tree (*Dalbergia Melanoxylon*) is met with south of Karkauj, on the Blue Nile, and again in the vicinity of the Sobat River. This tree does not, in these latitudes, attain to a very large girth, nine inches being apparently its maximum diameter. It must, however, be very common in these forests, as most of the principal houses in Omdurman are roofed with it. The value of the *Acacia Arabica*, from which the white and red gum is obtained, is well known; while the other kinds of acacia, such as *Acacia Nilotica* (in Arabic, "Sant"), is the chief source of the fuel supply. The bamboo is met with in the ranges of hills to the south of Famaka, and, according to some, the mahogany tree is found in the forests round Fazogl and in the Beni Shangul country. The means of transporting such woods can only be by the river. Unfortunately, neither the ebony nor the acacia will float in water, and, therefore, such transport is debarred in these cases. If a good and serviceable timber tree can be discovered in the Blue Nile forests which can be floated down the river to Egypt, a large source of revenue will undoubtedly have been found. Extensive saw-mills might be erected at Assouan, utilising the power available at the dam, now under construction, and an important timber trade might one day arise.

On the White Nile, in the Bongo and Rohl districts, the india-rubber creeper (*Landolphia Floribunda*) is found in great profusion. If the rubber yielded by this creeper be not of quite so good quality as that obtained from the india-rubber tree (*Ficus Elastica*), it is still of sufficient value to be counted as an important asset in the future trade of the Soudan. This plant, which has large laurel-shaped leaves, and a white flower resembling a jasmine, requires several years to mature before yielding rubber in any quantity. The natives obtain what they require by tapping the stem, usually in such a reckless manner that the creeper dies under the operation. The india-rubber tree should certainly flourish well in most parts of the Soudan, more particularly south of Khartoum. Although this tree takes from twenty to thirty years to arrive at a girth sufficient to permit of regular tapping, its yield is so valuable (about 3*l.* per tree per annum) that its introduction into the country is well worth attempting.

The above brief resumé fully shows the necessity of beginning a careful study of Soudanese forestry. It will be long before the Soudan will have a Woods and Forest Department organised on the Indian model, but the Anglo-Soudanese Government is to be congratulated on having secured the services of an expert, and we shall look forward to Mr. Muriel's report with great interest.

TOBACCO CULTIVATION IN THE SOUDAN.

A proclamation, signed by Lewa Jackson Pasha, as Acting Governor General of the Soudan, appears in the *Sudan Gazette* giving notice that the cultivation of tobacco is entirely prohibited North of Khartoum. South of Khartoum it is permitted

only with the consent of the Moudir. Such consent may be granted only in districts where tobacco was regularly grown in the time of the Dervishes.—*Egyptian Gazette*, Oct. 16.

A COLONY OF VEGETARIANS.

A colony of vegetarians are living on Tagula Island, a tiny bit of land, in the Dutch archipelago, about 700 miles south-east from New Guinea, and 1,000 miles north-east from Australia. Under the leadership of a Methodist clergyman, the Rev. James Newlin, of Ohio, some seventy people sailed from San Francisco in 1890 for Hawaii. They believed that a higher plane of Christianity was to be reached by a vegetarian diet and freedom from contamination with degenerate mankind. So they gave up their friends and homes in the Eastern States. Tagula Island was finally chosen for their colony. There were about fifty good-natured natives there who welcomed the new comers. There have since been accessions to the colony of people from England, Australia and America.—*New York Sun.*

IDENTIFICATION OF FIBRE.

While a great deal has been published on the identification of the different fibres in commercial use, much of this has not had a truly commercial aspect. It is frequently difficult to identify a fibre from the description given in commercial text-books, especially where fibres closely resembling each other are examined under a microscope after the ordinary treatment or mount.

A writer, in speaking of the microscopical identification of some useful fibres, says that the separation of the ultimate fibres by teasing is tedious, and often leads to a very unsatisfactory mount. The best way is to remove by chemical treatment the resins cementing the ultimate fibres into the filament. This is more difficult with some fibres than with others, those having a high content of silica being usually the most refractory. In this particular, sisal and manila are the most noteworthy.

In a commercial laboratory, where results should be obtained as quickly as possible, a quick temporary mount has to be made which will show the characteristics of the fibre necessary for identification; and in order to prepare the fibre for such a mount, a suitable chemical treatment not occupying too much time is a great desideratum. The best method consists in boiling the fibre in a 2 per cent solution of caustic alkali, washing and suspending the fibre in water, and passing a stream of chlorine gas through it until it is thoroughly bleached and the gums thoroughly destroyed. This may also be done by placing the specimen in a solution of chlorate of potash acidified by hydrochloric acid. At this stage the filament is entirely destroyed, but the ultimate fibre retains the form of the filament. The material is then rinsed in alcohol, and mounted in Canada balsam in the usual way. After this treatment there should be no difficulty in teasing out the ultimate fibre.

The fibre may then be examined under a microscope or micro-photographed. The best method for the examination of fibres is with artificial light, using a polariser. The joints or markings on the fibre seem to have a different rotatory power, or at least they are brought into a more distinctive effect in relation to the rest of the fibre. This is also true in photographing, and the best photographs have been obtained by using an arc light and polarising the rays. The markings are more distinctly brought out when the analyser and polariser are in such relative positions that the background or field is almost totally dark.

To distinguish between sisal and manila is one of the hardest problems of fibre identification, but little trouble has been found after treating the fibres in the manner described above. The characteristic appearance of manila is very much enhanced by the chlorine treatment, and the same is true of sisal. The sisal is very much coarser than manila, and tapers considerably more; when properly prepared the dark centre is seldom apparent. It has, however, after the treatment mentioned above, peculiar markings, having transversal cross-makings which appear to form X's upon the fibre. The peculiar formation of the cotton fibre is so distinctive as to need no comment. Wool, with its peculiar scaly appearance, is also very distinctive, and where wool and cotton are found together they are readily distinguished by an ordinary mount. The above treatment has never been tried on animal fibre, for the reason that nothing would be gained.

Silk is also distinctive; it is quite even, but occasionally little nodules are noticed in the side of the fibre, and for this reason it is not as regular in width as manila. It has apparently no markings, and its ultimate fibres are also its filament.

Among the textile fibres the most difficult to distinguish one from the other are flax and ramie. They are used in the same class of work, when ramie is used at all, and have the same general microscopical appearance. Ramie, at first sight, looks very like flax, although, upon a minute examination, a difference will be observed. The ultimate fibre of ramie is usually coarser, the bamboo-like joints are larger and more marked, and have quite a different appearance from that of flax as seen with a moderately high-power glass.—*Textile World*, Boston, Mass.

BANANAS.

Sir Walter Besant in his column in *The Queen* has the following :—

Bananas should become cheap; they stood for a long time at the figure of 2d apiece which is now preposterous. They became popular about twenty-five years ago, being then sold, as I said at 2d. They are now with many children almost as much an article of diet as potatoes, and I should say, more nutritious. There are several ways of eating them. The best is the simplest and the most obvious; the next best is the banana fritter, made just like an apple fritter; the third way is to "triturate" the fruit with a fork, to pour over it a tablespoonful of claret and to add a little sugar. It can then proclaim a rivalry with strawberries and cream, the more readily because the banana is generally taken when strawberries are not in season.

Molluscs and Pearls.—There is no end to the number of ways in which pearls can be secured naturally or artificially. Here is one of the latest reports of the kind :—"A novel method of producing real pearls from ear-shells (*Haliotis*) has been tried with some success by Monsieur L Boutan, who has described his experiments to the Paris Academy of Sciences for 1898. The method practised is to drill a small hole in the shell of the living mollusc, at a considerable distance from the margin, and to introduce through this aperture one or more minute globules of mother-of-pearl; the mollusc being then returned to its native element. From their position, the introduced globules are prevented from escaping, and in due course are coated with nacreous deposit thus producing really fine-pearls."

CACAO CULTIVATION.

Mr. Carruther's Circular.

At a recent meeting of the Cacao Committee of the Ceylon Planters' Association, Mr. Carruthers spoke on the importation of new varieties of Cacao from foreign countries and stated that the Director, Royal Botanic Gardens, asked him to represent him at the present meeting He thought he might safely promise on behalf of the Director his co-operation and to undertake to get any small importation, *i.e.*, if any member could specify any particular seed.

Mr. Carruthers read questions (annexed) which he had circulated lately to cacao-growing countries in the West Indies with a view to Ceylon planters also answering them. Mr. Carruthers also indicated that if the Committee will decide what experiments should be undertaken, action would follow.

The Committee should accordingly draft a list of certain experiments desired by cacao planters.

Mr. Carruthers had drawn up a few notes which he read, both as to disease and as to means to combat or cure the disease; if practical men were satisfied that experiments had been successful; or if a cure had been effected in specific instances, what was the general effect. As regards native holdings badly diseased, influence should be used in such cases to get rid of dead trees on these native gardens in the neighbourhood of estates.

Resolved:—"That Mr. Carruthers and Mr. Huxley be asked to draft suggestions for experiments to be undertaken, and that they be circulated to the Cacao Committee as soon as possible, (II) that the Government Agents of the Central and North-Western and Uva Provinces be invited to use their influence with the Headmen in the cacao districts in the direction of getting proprietors of cacao estates and gardens to cut down and burn cankered trees with a view to preventing the spread of the disease which, if neglected, is likely to jeopardise the prosperity of the industry, both in European and native hands."

The Cacao Committee of the Planters' Association then adjourned.

QUESTIONS REFERRED TO WHICH MR. CARRUTHERS LATELY CIRCULATED TO CACAO-GROWING COUNTRIES IN THE WEST INDIES.

Is the mature Cacao shaded, and if so for what reasons, *i.e.*, from the sun or wind?

What shade trees are used and at what distance apart in each case?

Do you find the shading is beneficial to healthy Cacao? How does it affect the crop?

Does shading affect the attacks of insects such as Helopeltis, Thrips or any local insects?

What effect has the shade on diseases caused by fungi on stem, branches and fruit?

What distance apart do you plant the trees—are they planted at first thicker and afterwards thinned out?

Is any system of pruning carried out and if so what? Are suckers allowed to remain?

What proportion of fruit that is set, eventually reaches maturity? To what cases do you attribute the withering or drying up of pods in their initial stages?

What is the average number of ripe pods produced by a tree in full vigour?

To what age does the Cacao grow under favourable conditions?

What is the average annual percentage of deaths of trees and to what causes are they due?

How long do the individual leaves remain on the tree?

Do any varieties suffer less from parasitic or other diseases, if so which? Have you any reason for attributing their immunity to any special characteristic?—A. Philip, Secretary, Planters' Association of Ceylon.

PLANTING NOTES.

Irrigation in India.—We learn from Simla, 27th October, through the *Pioneer*, that the Government of India in reviewing the irrigation reports for 1898-99 state that 21 productive works paid collectively 9·62 per cent on the capital outlay, the least remunerative being that of the Periyar project, which paid only 1·7 per cent. The total area irrigated by all classes of works was 18¼ million acres, the value of the crops raised being 39 1-7 crores of rupees.

South India and the Ceylon Tea Exports.—The Wynaad correspondent of the *Madras Mail*, writing upon the most recently revised estimate of the current year's tea exports from Ceylon, says:—"These figures are calculated to make the owners of tea property in this part of Southern India anxious as to the prospects of their growing tea industry, but it is to be hoped that when all the well opened gardens on the plateau arrive at maturity we shall be able to record average yields of 600 lb. per acre, while the cost of placing and selling the teas will not exceed 5¼d., and that as Indian teas have for many years past averaged higher prices than those from Ceylon, our new staple will hold its own successfully." Excellent confidence, but there is also the factor of "pushing foreign markets," in which campaigns we venture to think Ceylon is still some way ahead of India.

Assam Rubber for Westralia.—The Woods and Forests Department has received from the inspector-general of Forests, India, a supply of Assam rubber (Ficus elastica), a portion of which is being distributed to resident magistrates, wardens, etc., throughout the tropical portions of Western Australia, for experimental sowing, and with directions as to cultivation. The rubber grows equally well on high or low land, in forest or grass country, but preferably on a light sandy loam, and, provided it is shaded from the direct rays of the sun in the early stages of its growth, is easily raised from seed To give some idea of the value of this tree, it may be stated that the import of rubber into the United Kingdom amounted in 1884 to 198,000 cwt., representing a value of £2,266,000, and the demand has vastly increased during recent years. In Assam a tree of Ficus elastica is tapped when it attains about the age of 25 years. When 50 years old the yield is about 40 lb. of rubber every third year, and continues till the tree is over 100 years old. The white sap flowing from cuts in the trunk is poured into boiling water, stirred until it gets firm, and is then taken out, pressed, and finally washed with lime water.—*Perth Morning Herald*, October 11th.

Mysore and the Coffee Stealing Act.—The report on the working of the coffee stealing prevention act in the Mysore Province shows only seven cases during the year against 19 in the previous year. The diminution is due to the deterrent effect of exemplary punishments awarded.—*Times of India.*

The Peanut Oil Industry.—The American Consul at Marseilles reporting lately on the peanut oil industry observes that more oil is extracted in Marseilles from oleaginous seeds than in any other place in Europe and the industry is beginning to flourish again after the depression produced by the introduction of American cotton seed oil and the failure of the seed crops elsewhere. As no special machinery or process is employed in the manufacture of peanut oil as distinct from other oil seeds the manufacturers crush arachides, or peanuts when the market is favourable but not to the exclusion of other seeds. Last year over 71,000 tons of peanuts reached Marseilles: at Bordeaux a large quantity of West African nuts of good quality is crushed and there are some mills in the north of France, but Marseilles stands pre-eminent in the industry. The nuts are scarcely ever ground whole as this produces inferior oil and cake of little value. In fact a large quantity of the nuts arrives shelled after which the inner or red skin is removed as much as possible by processes resembling those for cleaning wheat in flour mills. These are described in detail in the report. After the kernels have been separated and cleaned they are ground and enveloped in strong fibrous mats, are subjected to hydraulic pressure, and the clarifying of the oil done by means of filters and fuller's earth. The husks are sometimes ground with the cake and form an inferior food for cattle and when coal is dear they are used as fuel in the oil mills. The crude oil runs out thick and troubled, and must be filtered to make it a bright yellow, while if it is to be water white in colour it must be treated further with animal black and fuller's earth. It is stated that no alkaline lye is used, but the art is somewhat secret. The source of supply are Bombay, Mozambique, and Senegal. In some years the African supply is wholly swamped by the supplies from India, and at one time it seemed that Africa would be unable to compete permanently with India. But though the latter still sends large quantities of nuts to Marseilles it appears to be using more and more of its crop at home, so that while the imports between 1890 and 1895 were mostly from India, in 1896 to 1899 they were mainly from Africa. In the earlier year of the decade American cotton oil menaced the crushing trade of Marseilles with extinction because of its low price, but apparently new demands for oils have arisen for the production in Marseilles has returned to its former average and prices also after serious derangements have resumed their old level. There has been a world-wide decrease in the amount of animal grease, while America is consuming her own cotton seed oils in vastly increased quantities and the consequence is an increased demand for vegetable oils. Although the production of the nuts in Africa is enormous no improvement in the mode of cultivation or the price is anticipated for years to come. The soil is readily exhausted by the crop and nothing is done to restore its virtue; labour, though cheap is thriftless and hard to obtain when wanted and transporation is defective. The uses of the oil are numerous; it is described as "the most polymorphous of all oils, adapting itself to all purposes, including nutrition, lighting, lubrication and blending." It is the most difficult of all oils to detect when adulterating olive oil for its chemical reaction is white. The best qualities are in fact used for the table, either pure or mixed with olive or sesame oil; as an illuminant it gives a soft white light; when neutralised it is much esteemed for lubricating and is always preferred to cotton seed oil. It is also largely used in the manufacture of soap, and is the characteristic component of the famous Marseilles white soap.—London *Times*, Oct. 13.

Dendrobium Densiflorum.—Mr Fraser Smith, The Gardens, Cullen House, Cullen, N B, encloses a photograph of Dendrobium densiflorum, grown by him, which this season has been much finer than usual, having twenty-one trusses of its beautiful yellow flowers. This is a special variety which he had sent him from Java, twelve years ago. It has much longer pseudo-bulbs, and larger trusses of flowers, which are richer in colour than in any other variety. The plant has flowered regularly for the past ten years.—*Gardeners Chronicle*, Oct. 13.

Uganda Coffee: Best in the World.—The development of the coffee-growing industry in tropical Africa is interesting as showing the rich resources of that region for plant production. The first coffee seed was introduced from Kew by missionaries less than five years ago, and from it have sprung the extensive crops now under cultivation. Last season the quantity exported from Uganda alone was over one hundred tons, which will be greatly exceeded by this season's production. Experts say that the quality of the Blantyre coffee is the finest the world can produce, the flavour being superior even to the famous Mocha. The great drawback is the lack of transport, which, however, will be met by the completion in the near future of the Uganda Railway.—*Daily Mail*, Oct. 8.

Egyptian Phosphate Deposits.—*The Egyptian Gazette* of Oct. 10th, contains the following interesting information:—

The Survey Department has just issued a Report on the phosphate deposits of Egypt. The Report contains the result of the investigations of the members of the Survey in the Keneh Moudirieh, in the districts between Keneh and Kosseir, and in the Dakhleh Oasis. In the concluding chapter containing the chemical Report on the phosphates the writer, Mr. A. Lucas, says, "The native phosphates will be useful to all classes of Egyptian agriculturists. They will be useful to the Fellahin and small farmers who know nothing of superphosphates, nor would be able to pay for them if they did, for to these classes the choice is not between an imported soluble phosphate and a native insoluble phosphate, but between this latter and none at all They will be useful also to those who do know and can appreciate the difference between a soluble and an insoluble phosphate, but whose conditions of work are such as to make the cost of imported manures prohibitive, and for whom it is no longer a question as to which of the two gives better results, but whether it is not wiser to use what lies at their feet rather than to allow their land to become impoverished. And to the large landowners the native product will be of value in supplementing the imported and high priced article. I am strongly of opinion therefore that these recently discovered phosphates ought to prove of great value to Egyptian agriculture, for the following reasons:—

1. They occur in immense quantities.

2. With the exception of those found in Sinai and Dakhla they are easy of access and fairly close to the river and railway.

3. By means of a very inexpensive operation, namely, simple grinding, they can be prepared ready for use.

4. They constitute a really valuable and cheap manure of a kind that is much needed.

5. No other phosphatic manure of similar value exists in the country and the price of imported phosphate manures is such as to render them in many cases prohibitive.

THE GARTON LECTURES ON COLONIAL AND INDIAN AGRICULTURE IN EDINBURGH UNIVERSITY—is the heading of a paper by Robert Wallace, Professor of Agriculture and Rural Economy in the *Asiatic Quarterly Review* from which we learn :—

The expiring century seems an auspicious occasion for the new departure which has been made by the establishment and liberal endowment by Mr. Robert and Mr. John Garton, of Newton-le-Willows, Lancashire, of a course of at out fifty lectures on "Colonial and Indian Agriculture" which are to be initiated in the current month in connection with the chair of Agriculture and Rural Economy in Edinburgh University. The first half of the course, which will be delivered by the Professor of Agriculture before the end of December, will be inaugurated on October 18 by an address on "Famine in India," a subject likely to prove of peculiar interest at what, let us hope, may be the closing epoch of the most prolonged, if not the most disastrous, of the recurring trials of physical endurance from starvation to which our Indian peoples have been periodically subjected. The ordinary work of the class will begin with a general view of the agriculture of India, including the main features of the Presidencies and other great political divisions, with special reference to geology, soil, climate, peoples, and chief products.

Further on we are told :—

The smaller Crown Colonies will not be neglected, and the second section of the course will close with a discussion of such miscellaneous subjects as exports of agricultural produce from the Colonies and India, and the relations of the agriculture of the Colonies and India to that of the Mother Country.

THE TRUTH ABOUT RAMIE.—We were always more or less suspicious about the glowing accounts given of the fortunes in "ramie" or "rhea" fibre, and we regret, in the interests of producers, and especially of plucky pioneers, both in Ceylon and elsewhere, that the following discouraging bit of news comes to us from a Bradford correspondent of Sell's *Commercial Intelligencer*, who writes in the latest issue as follows :—

For the sake of planters in our colonies and investors at home a few words in review of the history and possibilities of ramie may not be out of place. From the manufacturer's point of view the business career of ramie can only be regarded as catastrophic. No single English firm has yet succeeded in dealing profitably with the material, and it is quite within the truth to say that a quarter of a million sterling has been irretrievably lost in the attempt. To put the comparison with cotton in a nut-shell: raw cotton can be made into yarn for some 2½d per pound; ramie costs in process at least 1s per pound. To compare the possibilities of ramie with wool and with silk betrays a complete ignorance of the nature of these two materials. Ramie is harsh and wiry, with none of the warmth and softness of wool or the beauty and pliability of silk. Ramie is much dearer than flax, and has the unfortunate faculty of shrinking when wet; its lustre is metallic in appearance, and ramie cannot be dyed to a good black. Seven English firms to the writer's own intimate knowledge have ruined themselves in ramie. Indeed the seven may be extended to ten, if change of hands be calculated. Two concerns in Germany are moderately successful with the material, the process employed being the familiar one of carding in lieu of combing the "filasse." The Teutonic quasi success is attributable to cheap power, cheap labour, and to the fashion in yarn and fabrics differing from English canons. Ramie booming is a perennial event, and it is as well to let the seamy side see light once in a while. Chapter and verse can be given in substantiation of the statements above—samples, prices, and all particulars.

CHINESE HEMP, OR RAMIE GRASS.—Ramie grass, ro hemp, as it is called in the Customs returns, has increased steadily, says a consular report from Kiukiang (China), during the past few years. It is cultivated largely in the adjoining province of Hupei, and shipped from Kiukiang to the Shanghai market, whence it finds its way to Japan, Canton, Chinkiang, and other Chinese ports, where it is turned into the grass cloth so much worn by natives during the hot weather. Three crops are gathered during the year; the first, which is planted in the previous autumn, comes to perfection about the middle of June, the second in July, and the third about October. The second crop is inferior to both the others, as it only remains in the ground about a month and the excessive heat stunts its growth. The first is generally the best, and in good seasons attains a height of 70 inches. It is made up in bales according to length of the stalks, and fetches from 12 to 10 taels per picul of 133 lb., the price depending upon the market in Japan, whither about 60 per cent of the total out-turn is exported. The second and third crops average about 11 to 8 taels per picul. The Consul adds, "I have only heard of one consignment having been made to the London market. German merchants are said to be purchasing it in Shanghai, and one trial shipment has been made to Hamburg direct from this by a native hong, which practically monopolises the trade here. Account sales have not yet been received, so it is not yet known how the venture has turned out." The quantity shipped in 1895 was 37,009 piculs; in 1896, 46,668 piculs; in 1897, 48,925 piculs; in 1898, 57,400 piculs; and in 1899, 70,156 piculs.—*Chamber of Commerce Journal* for October.

MANGOES FOR ENGLAND.—The London correspondent of the *Bombay Gazette*, writing on October 12th, says a conference between Mr. Tata and the Peninsular and Oriental Company on the question of establishing the export of mangoes from Bombay on a commercial basis which, in the course of the summer, was mentioned as likely to be held this autumn, duly came off this week. There were present Sir Thomas Sutherland, Sir Owen Burne, and other Directors of the P. and O. Company, as well as Mr. Tata and Sir George Birdwood. Nothing can be formally decided in the matter until it has been brought before a meeting of the Board, which will probably be held today, but I understand that the basis of the arrangement come to is that Mr. Tata and those associated with him will guarantee a shipment of 500 tons of mangoes and other merchantable Bombay fruits, the P. and O. Company during the next mango season, say April 25th to June 5th, providing for one or two of their refrigerator steamers engaged in the Australian meat, butter, and fruit trade calling on their homeward voyage at Bombay. Mr. Tata is now engaged in coming to an agreement with some of the London fruit-importers, but it is hoped he may be able to do better than that by establishing reciprocally advantageous relations with one of the great co-operative stores in the Metropolis. It would probably be easy to dispose of 500 tons of good mangoes in the West End alone in a single day at one shilling each. A few mangoes sent to a Bond Street shop last summer were almost instantaneously sold off at five shillings each, and stringy turpentiny Madeira mangoes now on sale in various London shops are selling at one to two shillings a piece.—*Pioneer*.

PLUMBAGO MINING IN CEYLON.

VIEWS OF AN EXPERT.

Mr. Alfred J Hodgkinson-Carrington, C.E., M.E, A.M I.C.E., M.A.I.M.E., of 26 Bloomsbury Square, London, W.C., who arrived in the island on the 12th October by the P & O steamer "Rome" from Australia, again made a brief stay at the Bristol Hotel, having returned from a visit of inspection to the Moragalla Mines; and, after revisiting the mines, he left for England on the 22nd ult. Asked for an expression of opinion concerning the plumbago industry in Ceylon, Mr. Carrington stated to our contemporary that owners of mines are working by

EXCEEDINGLY PRIMITIVE METHODS.

They apply absolutely no scientific methods in the working of the mines, and, unfortunately, whatever machinery is used, has been put up by men who did not thoroughly understand mining engineering. This had, naturally, caused a general prejudice among natives—miners and mine-owners—against any innovations in the methods of working, or the introduction of mining plants to assist them in their operations.

"There are very many mines in the Colony," said Mr. Carrington, "which have been worked by the primitive methods to a certain depth, and then abandoned, just at the stage when the working should have proved remunerative if under skilled direction and with proper machinery. This has a very prejudicial effect on plumbago mining in the island generally, and must be a source of great loss to the community at large, and those engaged in mining in plumbago particularly. Such English Companies as own mines in Ceylon are taking steps for the working of their mines on a more highly-skilled basis, and it would be largely to the interest of the natives, who are the owners of the most valuable mining properties in the Island, if they would follow the example of their European *confrères*."

EFFICIENCY OF NATIVE MINERS.

Continuing, Mr. Carrington said he knew of several instances where good mines have been lost through the want of improved methods of working. He has been rather struck with the efficiency of most of the native miners in different parts of the island. Thus it was not for the lack of good labour that the industry is at present in a crude state, for the native miners under proper scientific supervision would be able to do good work.

A SUGGESTION.

The method of working in shifts of twenty-four hours is prejudicial to the health and efficiency of the miners. This custom might be discontinued with mutual advantage to miners and mine-owners.

Mica-Mining in S. India.—The Mica-mining community in the Hazaribagh and Gaya District numbers 42 Europeans and 7,500 natives. It is in contemplation to form a Mica-mining Association for the purpose of representing the views of this body to Government in all matters relating to the industry.—*Madras Mail*, Nov. 14.

PLANTING NOTES.

Benefit of Criticism to the Tea Industry.—All matters connected with the tea industry, says the *Indian Planters' Gazette*, are having the sharp shears of criticism applied to them, and they will come out of the ordeal all the better for the "pruning": like the tea bush itself, the industry will be all the better for the cutting, and, like the tea bush, will prove itself ever green, taking a fresh lease of life and all the better for the change. This is why we have such hope in the industry, the more it is assailed the better it will thrive. The old rotten time-worn branches, useless twigs, and leathery leaves being cut away and thrown aside, the tree itself will spring afresh into a new and vigorous life and yield abundantly. Pessimists would have us believe that tea is played out, but such is as far from the case as an old tea bush may be said to be played out. It only needs the knife to renew its youth.

Stone-cutting and Polishing.—An excellent little manual of instructions upon this subject, by Mr. Geo. Day, F.R.M.S., has reached us from the publishers, Messrs Dawbarn & Ward, 6, Farringdon Avenue, E.C.—price 6d. It forms No. 26 of the Useful-Arts-and-Handicraft Series. Nos. 1-13 and 14-25 are bound in two volumes (post free, 8s) and form a possession, than which no more excellent gift could be made to the carpenter, smith, or other serious or fancy worker in wood, steel and even stone. Single numbers are sold at 6d each. Stone-cutting is a little more difficult than the mere polishing of a pebble, and it may be developed into very elaborate and artistic work. It is undertaken for various purposes, principally:—

1. To provide a large flat surface (or two surfaces) for polishing, without having to grind away a large proportion of the pebble.

2. To slit stones into thin layers, increasing their translucency and beauty.

3. To give stones several angles or facets, giving variety in coloring and reflection.

4. To fit the stone for setting, as a personal ornament or for some useful purpose.

The quotation of the following "table of hardness" may indicate to some extent the great usefulness of the knowledge which the booklet set forth, as well as the simplicity of treatment:—

1 Talc (jet, cannel coal, steatite, etc.)—Easily broken or scratched with finger-nail.

2 Rock Salt—Scratched with difficulty by the finger-nail, but readily cut with a knife.

3 Calcite—Not to be scratched with finger-nail, but easily with a knife.

4 Fluor Spar—Can be but slightly scratched with knife, but easily attacked with a file.

5 Apatite—Does not scratch glass, or only faintly; does not give out sparks against steel; easily scratched with flint.

6 Felspar—Easily scratches glass, is scratched by a file, and gives some sparks against steel.

7 Quartz (agate, jaspar, chalcedony, etc.)—only slightly scratched by file; gives sparks readily against steel.

8 Topaz—Very hard; is not scratched by file.

9 Sapphire—Hardest of all except the diamond; scratches all other stones.

10 Diamond—Scratches all minerals, but is not scratched by any.

Correspondence.

To the Editor.

PROTECTION OF BIRD-LIFE.

La Martiniere College, Lucknow,

November 1st, 1900

DEAR SIR,—The Government of India is desirous of making a further enquiry into the question of the destruction of the bird-life of this country. It is probable that, if a proper case be made out, further restrictions will be placed on the indiscriminate slaughter of birds for their plumage—a policy which has had such disastrous effects in other countries.

The Government has requested that a report on this matter be compiled as soon as possible, and, in order that such may bear due weight, it has been determined to obtain the opinion of as many of the leading ornithologists in this country as possible.

Feeling assured of the great interest that you take in the welfare of the birds, I venture to ask you to be so kind as to peruse the following questions and to return to me your opinions as early as possible.

(I) Are you aware of any trade in birdskins, or feathers, being carried on in any district, and, if so, where?

(II). Is the trade, if any, increasing or decreasing?

(III). If you know of any regular destruction of birds, please name the principal species affected, and furthermore state whether any of them are threatened with extinction,

(IV). What effects have you noticed on the bird-life of closed or reserved forests, as a result of the latest Government regulations?

(V). Has the destruction of any particular species in any way affected the agriculture of a district, either for good or ill?

(VI). Are there any tribes, or castes, in your district (if so name them) whose time honoured and immemorial custom it has been to destroy birds for the sake of their plumage?

(VII). Do you think it likely that an act restricting the destruction of bird-life would be received favourably by the natives in your district, or do you think that any such legislation would be regarded as oppressive and an interference with tribal customs?

(VIII). Do you think that, even if there is no trade in feathers in your district at the present moment, that the conditions are such that the trade if established would prove profitable to the merchant, and inimical to bird-life?

(IX). Do you think that it would be advisable to introduce measures restricting the destruction of birds, they would such action in your opinion be unnecessary?

Trusting that you will give this letter your fullest and most careful consideration.—I have the honor to be, Your most obediently, WILLIAM JESSE.

GOURAMI FISH FOR CEYLON:—A QUESTION FOR THE CEYLON FISHING CLUB.

Oxley Island, Nov. 3.

DEAR SIRS,—I fell in today with a volume, six months of 1898, of your *Tropical Agriculturist*, and was much interested in looking through it. On page 432 I was reminded of a forgotten promise to report the result of the frog experiment: pray pardon my faulty memory. I regret to say only a few of the frogs lived, and they, after a few weeks, disappeared.

I read with interest "C.D."'s letter about the Gourami. I presume you have by this time acclimatized it in Ceylon. If not, I may be able to assist you in the matter. I am thinking of going to England about March next, and would be willing to take a sufficient number, say fifty to eighty, to establish them in Colombo. I would undertake to do this for twenty-five pounds, delivered on board the ship into tanks supplied to me: a couple of *tin*, not zinc, lined boxes about 3ft. by 2ft. by 2ft. would do. I purpose taking ceratodus to England and the gourami might share their tanks to Ceylon. If you know of anyone (or any club) that will agree to this proposal, please inform me at your earliest convenience so that the necessary arrangements may be made. The Superintendent at the Zoological Gardens, London, informs me that their two ceratodus, also those in Paris, which he had recently seen, are alive and well.—Yours faithfully,

D. O'CONNOR.

"THE THEORY OF MANURING" (AND FARMYARD MANURE).

Colombo, Nov. 9th.

DEAR SIR,—Referring to the extract from the "Journal of Horticulture" dealing with the composition and manurial value of Farmyard Manure, we beg to give below for comparison seven analyses of cattle manure, A made by Mr. John Hughes, B made by Dr. Ruempler C D, and E by Mr. Cochran, F, the analysis quoted in the *Observer*, and G, an analysis recently, made by Dr. Koller, in charge of our Hultsdorf Mill's Laboratory :—

ANALYSIS OF CATTLE MANURE: PROPORTION OF NITROGEN, PHOSPHORIC ACID AND POTASH.

Manure.	Water.	Phosphoric Acid.	Nitrogen.	Potash.	Analyst.
	per c.	p. c.	p. c.	p. c.	
(A) Sun-dried Indian Cattle Manure	7·22	0·54	1·47	0·63	Mr. Hughes
(B) European Cattle Manure with litter	?	0·32	0·68	0·80	Dr. Ruempler
(C) Ceylon Cattle Manure No. 1	80·4	0·25	0·45	0·95	Mr. Cochran
(D) Ceylon Cattle Manure No. 2	74·67	0·09	0·64	1·07	Do
(E) Ceylon Cattle Manure No. 3	67·00	0·08	0·47	0·36	Do
(F) Farmyard Manure	?	0·22 to 0·36	0·40 to 0·53	0·4 to 0·53	From the "Journal of Horticulture"
(G) Ceylon Cattle Manure from Upcountry	50·34	0·35	0·33	0·41	Dr. Koller

To facilitate comparison of the respective value of the different cattle manures, we have reduced the percentage of samples A, C, D, E, and G. to the amount of lb. nitrogen, phosphoric acid and potash present in a ton of cattle manure dried at 212° F.

ANALYSIS OF CATTLLE MANURE, DRIED AT 212° F.: PROPORTION OF LB. NITROGEN, PHOSPHORIC ACID AND POTASH PER TON MANURE.

Manure.	Phosphoric Acid.	Nitrogen.	Potash.	Analyst.
	lb.	lb.	lb.	
(A) Sun-dried Indian Cattle Manure	13·04	35·42	15·21	Mr. Hughes
(C) Ceylon Cattle Manure No. 1	28·70	51·66	108·56	Mr. Cochran
(D) Ceylon Cattle Manure No. 2	7·96	56·59	94·62	Do
(E) Ceylon Cattle Manure No. 3	5·43	31·90	24·44	Do
(G) Ceylon Cattle Manure from Upcountry	15·79	15·15	18·09	Dr. Koller

Now the comparison of these analyses shows a remarkable difference between the various manures. It is most marked in the percentage of potash and nitrogen, due no doubt to a large amount of urine in samples C. and D.

As regards the percentage of nitrogen in cattle manure, this partly depends on the age and food of the cattle, but to a great extent on the loss of nitrogen which has escaped into the air in the shape of ammonia. This loss in nitrogeon which we estimate at 9½ lb. nitrogen per ton manure equal to 40½ lb. sulphate of ammonia, can be easily prevented by the use of an ammonia-fixer.

But even then one ton cattle manure per acre would be insufficient to maintain so much as a small crop. Unless several tons are applied per acre, the soil will be more and more impoverished by each successive yield. To strengthen the plants and thus produce a larger yield, artificial manures should be used. The amount of plant food in cattle manure varies so much that planters can never know what they are buying in cattle manure, while artificial manure has the advantage that it can be purchased on guaranteed analysis. However, if cattle manure can be procured at a low rate, it can be applied along with artificial manure. We take the value of one ton cattle manure to be as follows:—

7½ lb. Nitrogen, equal to 36 ½ lb. Sulphate of Ammonia	R4·00
7½ lb. Phosphoric Acid, equal to 17½ lb. Conc. Superphosphate	R1·42
9 2 lb. Potash equal to 18½ lb. Muriate of Potash 50 to 52 per cent potash ...	R1·24
	R6·66

If an Ammonia Fixer has been used about 8 to 9½ lb. nitrogean equal to 39 to 46 lb. sulphate of ammonia should be added which have a value of R4·26 to R5. The total value would be R11·66 outside and we doubt whether at this figure cattle manure can be procured in Ceylon.

FREUDENBERG & Co.,
Hultsdorf Mills, Manure Works.

THE TONGAN BEAN: A USEFUL VEGETABLE.

Gampola, Nov. 5.

SIR —I desire with your permission to bring to the notice of the public the merits of "The Wonderful Tongan Bean" introduced into Ceylon by our enterprising florist and seedsman, Mr. E Spearman Hughes of Kandy. The Tongan Bean is a native of Tonga, and it admirably suits our climate and soil, and its cultivation on a large scale will profitably pay. It is a hardy evergreen perennial climber producing immense quantities of large flat beans of an excellent and nutritious quality, simply used like our French Beans. In a moderately warm climate and good soil, I estimate that a few plants of this bean will supply a whole family with its delicious, wholesome, and nutritious vegetable for about eight to nine months in the year It is also a lovely ornamental plant; I have many trained on bowers and trellis fences surrounding my bungalow. The beans are very delicious when picked very young, and boiled whole. The seeds are slow to germinate, so I have carried out Mr. Hughes' instructions in soaking them in hot water before planting, and have met with remarkable success in raising heavy crops. I can confidentiy recommend them to any one requiring beans of a special quality for their gardens.

I have also some plants of the velvet or magnet beans just now, and will be able to give the public some details of its merits in my next.—I am, sir, yours faithfully, H G.L

HEAVIEST YIELD OF TEA.

18th Oct.

DEAR SIR,—Can you, or any of your readers, give the highest yield ever given by tea, (Ceylon or India.)

1. By an estate of 300 acres or upwards?
2. By a field of 28 acres or upwards?

Yours truly,
"BY DAND."

[Surely, Mariawatte, Gampola, answers the description? See figures in our "Handbook and Directory" where it will be found that the 100=acre field has yielded an average of 1,137 lb made tea for 14 years; while over the whole estate or 450 acres about 930 lb. have been made per acre.—ED. *T A*]

CINCHONA PLANTERS AND QUININE MANUFACTURERS: PROSPECTS OF BARK AND A WORD OF WARNING.

SIR,—It is now some years since I predicted that the Quinine Manufacturers would kill the goose that laid their golden eggs.

The advice was not taken to hear. the continuance of large profits was insisted upon, necessitating a further depression of the unit and the consequence was that the goose died. When its actual decease took place, it is difficult to state; but there is ample evidence that the manufacturers have at last realised that the dear thing is dead, dead as a door-nail. Turning from metaphor to fact, nobody will deny in the face of the unit at present ruling, that consumption of quinine has over-taken production. Nor is there any doubt that it will do so to a far larger extent during the next five or six years, for that at the least is the period necessary to bring matters to a state of fair balance again. The reason for this is evident; it takes five to six years under the most favourable circumstances to grow cinchona fit to bark. Some of the quininc manufacturers may see fit to doubt this statement of supply and demand and no doubt think that as in the good old days, they need only raise the unit for a time to induce large harvesting and shipment, and thereupon will be able to knock it down again and secure the large profits, incidental to this often-

repeated manœuvre. But they leave out of consideration, that, although they have grown fat and sleek upon it in the past, many cinchona planters have been ruined by it and their estates abandoned or planted up with other products and though some, who have been able to last out, are now reaping mighty profits from their ability to do so, they are in the minority. Once more the move may be effective, but only once and it will accentuate the difficulty they will have to deal with afterwards.

What has been the reply of Java to a steadily rising unit? A decrease in shipments, as against the increase which manufacturers doubtless expected. The bark shipments from Java for the last nine months are a million and a half pounds short of what they were during the same period last year and a million lb. short of what they were the year before. These figures in themselves are instructive, for they show that last year Java tried its best to respond to a higher unit and did put in half a million lb. more, (thus enabling the manufacturers to again reduce the unit) only to fall short, all the more during the present year. I believe this fact has caused some astonishment everywhere, probably most of all in Java itself. It is largely due to a theory that a comparatively small number of large trees per acre would give the same amount of bark as, or more bark than a number of smaller ones. In very many places the thinning out of the smaller ones has therefore been quietly proceeded with and now that it is the turn of the large ones left, they are proving a disappointment. Nor is this strange; for it is not the bark on a large tree that is so much thicker and heavier than it is on a small one, it is the wood inside the bark. This is no doubt one of the reasons why oak is grown in coppice, when its object is to provide bark for tauning, though there are other reasons as well.

But by this, I do not wish it to be inferred that there is not a lot of bark left in Java: such a statement could be so easily disproved that there would be no object in making it. What I mean to indicate is that there is not the large amount of *superfluous* bark, either on the estates or held in stock that was expected. If there had been, it would have been rushed in and Java planters would have been unable to keep control of the market as they are now doing. It must not be forgotten that they serve two ends in doing so; they keep up the price of bark and they keep up the price of the quinine they themselves manufacture. That, no doubt is one of the most important factors in the situation, that they are no louger quite at the mercy of the quinine manufacturers in Europe, and they have probably all learnt the lesson that a lb. of bark at a 2d unit is equal to 3 lb. at a 1d unit as regards net results on every 4 per cent bark.

As to India and Ceylou, they are just now putting in rather more bark than usual; but that is a flash in the pan, which will not last. Stocks of bark are exhausted and the area under cinchona bark has dwindled to an insignificant acreage. Take for instance, the district that I write from. This was in past time, specially a district for cinchona, which with a rich soil and suitable climate was at its best. There were about 2,550 acres supplying a good deal of bark well known under the "Elephant Brand". Of these, there are only 1,100 acres left and even a great deal of this has deteriorated, and has been coppiced. Speaking well within the mark, I should say there was not more than 1-3rd of the bark in the district that there used to be. Any very large amount put into the market must therefore, of course, mean coppicing or uprooting. And, if this is the case in a district that made cinchona its speciality and, because of its rich bark and well grown trees, was able to hold out longest, no further illustration is needed, if what has happened in other districts even where cinchona has not died out of its own accord.

As I am one of those whose Cinchoua prospects at all events have been ruined by the policy of the Quinine Manufacturers, I cauuot be expected to look upon them with any particular favour. Yet, I cannot blame them for doing the best they could for themselves, even while I think they were unwise in their way of doing so. It will at all events be interesting to know what they intend doing in the future. Their wisest policy would undoubtedly be to be as generous as they can, to reduce their margin of profit to a minimum and thus by a good aud stable unit to encourage the planting of as much cinchona as possible in the uear future and the cultivation of every cinchona tree iu existence. It is, of course, impossible to tell what stocks of quinine they hold and what of bark; but although these will form a larger factor in their calculation, they must put them against a period of, as I have stated, five to six years of decreased production and a steadily increasing demand. It will naturally be difficult for them to exercise the large-hearted policy I advocate; yet in their owu interests if not in the interests of humanity, it is necessary. Any manœuvre, tending towards a rapid overthrow of the unit from its present position, would decrease the amount of cinchona which will otherwise be planted out in the near future. Whereas an expression of opinion on their part and a desire shown to equalise profits as betweeu themselves and the growers and to keep the unit up for some years to come, would foster schemes of planting. It would also prevent the owners of cinchona from rushing at their trees and cutting them down, so as to have their bark in, while the good times last. By this it would tend to keep the supply of bark up during the time the new openings will require to grow into bearing. There is, however, another factor to be considered by the quinine manufacturers and that is the deterioration of cinchona generally and especially the deterioration of available seed.

They may rest assured that a large amouut of the cinchona planted out recently and a larger amount of that about to be planted out in the near future, will not grow into anything worth barking. And even where good seed can be obtained and good plants raised there will not be much suitable land available. All this the planter knows; but the manufacturer does not know. It would probably be to the interest of the manufacturers if they were to send a capable man round the Cinchona Districts of the World and get a reliable report made for them. This, they should, in fact, have done a couple of years ago, or more, when they could and would probably as a result have bought up a very large acreage at very low prices. That chance they have allowed to pass, nobody is likely to part with cinchona now, excepting at a very high figure. But apart from the basis of calculation which such a report would furnish them with, a basis, which I feel sure would agree with my views as above given, they could probably do a good deal to promote planting up of suitable land or acquire such land and get it planted up for themselves. It may be asked "Que diable prit il donc dans cette galère?" Why should this cinchona planter go and advise the quinine manufacturers what to do in their own interests, instead of leaving them alone to reduce the production of bark still further by promoting a rush of harvesting "à tout prix." He surely, knowing all that he says, he does, would hold his bark and come in at the fabulous prices that would ensue.

In answer to this I would state my belief that it is better for the general success of trade in any article of commerce, that there should be a certain amount of stability as against sudden rushes up and down. Such stability, would I believe, be promoted by the policy I suggest.

Again, I think it is doubtful whether a unit ruling much higher than the present one could be a lasting benefit to the cinchona planter. I do not believe that the present price of quinine will have any affect on its consumption, but if it went much higher this might occur.

Again, a considerable rise in the price of quinine and bark might lead to a renewed importation of large quantities of forest bark from South America and thus again slump the market, or it might lead to chemical production of quinine from that all-producing coal tar at remunerative prices.

I believe that it will be best for the Cinchona Planter to be content with the 2½d unit and the Quinine Manufacturer with the 1s 6d an ounce and it is with this object in view that I have written. Even these figures seem lacking in humanity, when so many thousands of fever-stricken are crying out for cheap quinine, but I have personally suffered too much by cheap quinine, not to feel that even a medicine should be distributed through the world at some profit to the producer.—Yours very truly,

J. VON ROSENBERG.

Manalé, near Devikolam, 7th November 1900.

PLANTING NOTES.

THE BOMBAY TEA COMPANY, LIMITED.—This Company, which is not an Indian company, as its name implies, but a retail trading company having branches in most of the Northern towns, has declared an interim dividend of 6 per cent per annum, on both preference and ordinary shares, being the same as previously. Dividend warrants were sent out on Friday, Oct. 26th, 1900. —*Grocers' Journal*, Oct. 27.

THE TEA PLANTER.—The *Revue des Cultures Coloniales* for August 5th has an artiele on tea, giving, an outline of an elaborate paper by Mr. Jules Koch that appeared in Engler's *Botaniscle Jahrbuch* (Botanieal Annual). "On the Genus Tea and China Tea." The article, it seems, is very earefully drawn up, in its original (Wilhelm Engelmann, Editor' Leipzig).

GOURAMI FISH FOR CEYLON.—We direct the attention of pisciculturists, and espeeially the members of the loeal Fishing Clvb, to Mr. D. O'Connor's letter elsewhere. We saw no better way of finding out whether Mr. O'Connor's services were loeally reqnired than by the publication of his offer. The gourami is a very valuable tank fish and Mr. O'Connor has established a reputation as a zooloogist and colleetor and for his suecess in carrying speeimens of different kinds from Queensland to England and *vice versa*. It may be a question whether the Ceylon Government should not be approaehed with reference to the introduction of gourami into some of the village tanks? "C.D." will be interested in Mr. O'Connor's letter.—Part failure should not prevent a fresh trial.

THE LANKA PLANTATIONS CO, LTD.

ANNUAL REPORT.

Report presented at the Twentieth Ordinary General Meeting of the Lanka Plantations Company, Limited, held at the Office of the Company, on Wednesday, the 14th November, 1900, at twelve o'clock noon precisely.

1. The Directors now submit their Report for the twelve months ending 30th June last, together with the Balance Sheet and Accounts of the Company made up to that date and duly audited.

2. The coffee crop shipped to London amounted to 174 cwt. 3 qrs. 13 lb., and realised £573 8s 5d, Last year, the crop shipped was 722 cwt., and realised £2,843 10s 2d The acreage under coffee alone was nominally 120 acres, and of this, 70 acres are to be planted with tea this season, and the remainder next.

3. The total crop of cocoa gathered on Yattawatta amounted to 1,099 cwt., and realised £4,121 8s 5d. against 1,655 cwt. last year, which realised £5,5 9 18s 10 l. The cost of fourteen acres new land, and the net expenditure on clearings not yet in bearing, are charged to capital account. On the same estate 565lb. Cardamoms were gathered, realising £32 8s 4d.

4. The tea received from the Company's estates amounted to 947,194 lb., and has been sold at an average of 6·98 per lb. net, realising £27,566 4s 7d. Last year the Company received 769 578 lb. which was sold at an average of 7·44 per lb. net, and realised £23,862 4s 4d. The season was favourable, and the older fields are responding to the manure that has been applied to them.

5. The average rate at which drafts were negotiated on account of the season's crops was 1/4 4/32, per rupee against 1/4 9·32nds last year.

6. The following statement shows the approximate acreage and state of cultivation of the Company's estates on the 30th June last, as per recent surveys

Estate.	Coffee.	Tea.	Cocoa.	Grass.	Chena and Patena & Waste.	Forest and Timber Trees.	Total.
Ampittiakande Arnhall	20	444	...	4	256	70	794
Fruit Hill	..	227	..	...	10	..	237
Fordyce, Garbawn, Gonagalla, and Paramatta	...	798	..	5	..	135	938
Rappahannock	...	322	..	31	30	90	473
Rillamulle	...	195	..	..	343	22	560
Thotulagalla	100	281	..	..	64	111	556
Yattawatte	...	...	751	95	309	82	1,237
	120	2,267	751	135	1,012	510	4,795

7. The net profits for the past year amounted to £7,511 0s 2d, to which must be added the sum of £952 1s 6d the balance brought forward from the year 1898-99, making together £8,463 1s 8d.

8. Having already paid a half-year's interim dividend on the Six per Cent. Preference Shares to the 31st December, 1899, amounting to £426 6s 0d, the Directors recommend payment of the Dividend on these shares to 30th June last, reqniring (less property tax) £422 12s 6d, and having deducted in anticipation £999 4s 5d, being one-tenth of the sums charged to Suspense Account during the ten years ending 30th June, 1900, they further recommend a divident of 8s per share, being 4 per cent (free of income tax) on the Ordinary Shares, amounting to £6,000, carrying forward a balance of £6'4 18s 9d to the next account.

9. Mr. Edward Pettit, the Director retiring on this occasion, being eligible, offers himself for re-election.

Mr. John Smith the Auditor also retires and

being a shareholder offers himself for re-election.
—By order of the Board,

C. M. ROBERTSON, Secretary.

12, Fenchurch Street, London, E.C, 2nd Nov., 1900.

THE CENTRAL PROVINCE CEYLON TEA COMPANY, LTD.

REPORT OF THE DIRECTORS

to be submitted to the Shareholders at their fourth annual ordinary general meeting, to be held at Botolph House, Eastcheap, E.C., on Monday, the 5th November.

The Directors beg to submit to the Shareholders the audited accounts for the year ending 30th June, 1900. The total crop of tea from the estates for the past season was 843,388 lb., against 780,395 lb. of the preceding year, being an increase of 62,993 lb The total sales, including bought tea, were 1,206,555 lb , averaging 5·633 d per lb., being ·71d less than last year, equal to a loss of profit on the estate crop of over £2,000 by the fall in price alone. As regards cocoa, the crop amounted to 315 cwt., against 533 cwt. last year, the average price being 66s 9d per cwt. as against 58s 4d. There were during the season 243 acres of tea not yet in full bearing. The profits have again been slightly affected by a higher rate of exchange, which averaged 1s 4·34d per rupee as against 1s 4·23d last season. The net profits for the year amount to £3 850 2s which with £1,873 4s 9d brought forward from last year, shows a sum of £5,723 6s 9d to be dealt with. Of this amount £1,500 has been applied to the payment of an interim dividend at the rate of 6 per cent per annum on the Preference shares to 31st December, 1899. The Directors now recommend a dividend of 6 per cent per annum on the Preference shares to 30th June, 1900, and a dividend at the rate of 2 per cent per annum on the Ordinary shares, together absorbing £2,500 and leaving £1,723 6s 9d to be carried forward to next account, as against £1,873 4s 9d last year. The Colombo Agent and Director, Mr. F M Mackwood, is now in England and he states that the Company's places are in good order as to roads, drains, buildings, &c.

COLOMBIAN RUBBER CO, LD. (67,537).—Registered Oct. 23, with capital £100,000, in £1 shares, to adopt an agreement with the Compagnie Generale des Caoutchoucs de Colombie to develop and work, by extraction, cutting or otherwise, rubber forests in Colombia or elsewhere, and to carry on the business of rubber planters, growers, cultivators and merchants, timber merchants, saw-mill proprietors, etc.—*Investors' Guardian*, Nov. 3.

THE

AGRICULTURAL MAGAZINE,

COLOMBO.

Added as a Supplement Monthly to the "TROPICAL AGRICULTURIST."

The following pages include the Contents of the *Agricultural Magazine* for December :—

Vol. XII.] DECEMBER, 1900. [No. 6.

REPORT OF MR. C. DRIEBERG, B.A., F.R.A.S., SUPERINTENDENT OF THE COLOMBO SCHOOL OF AGRICULTURE.

THE condition of the School of Agriculture remains the same as before, no provision having been made for giving effect to the improvements suggested by me in previous reports.

The Commission appointed by His Excellency the Governor "to inquire into and report on the advisability of establishing a Department of Agriculture" has made no recommendation with reference to the re-organization of the school, so that the long-deferred question of setting it on a better footing has still to be dealt with. At the request of the new Director of Public Instruction I have just drawn up a lengthy special report on the school.

The largest number of students on the roll in 1899 was 22, the average for the year 16. This is rather below the usual number (about 20), and is to be attributed to the uncertainty of the future of the school.

On the results of the final examination held in November, three students became entitled to the first-class certificate granted by the Department: E. Jayatilleke, G. Jayasinghe, and P. C. F. Fernando.

The third batch of Forestry students trained here passed out in February, and consisted of the following:—Messrs. J. S. Perera, M. B. Seneviratna, G. Rajapakse, W. E. Rowlands, W. Ferdinands, and D. E. Tiathonis. With their departure a new class was formed, composed of Messrs. O. M. Mack, F. Jayatilleke, E. C. Fernando, L. B. Tennekoon, D. C. de Silva, and J. F. Cooray.

The staff of the Colonial Veterinary Surgeon has been increased by the appointment of Messrs. D. Dias and A. M. Fernando (old boys of the School of Agriculture) as stock inspectors.

The Government Veterinary Scholarship for the study of veterinary science in Bombay was awarded to J. E. Fernando of the School of Agriculture, who left for India in November. The previous scholar, Veterinary Surgeon Chinniah, elected with commendable enterprise to start work on his own account, and now commands an extensive practice in Colombo.

I have nothing special to report as regards the Training School and Practising School.

The Government Dairy is now in its seventh year. The dairy herd was free from any form of contagious disease in 1899, and there were but six deaths for the twelve months, three among the cows and three among the calves. This is an excellent record considering the size of the herd. Thirty cows and three bulls were purchased at a cost of R1,564·86, while twenty-nine cows and two bulls and fifty-six young animals bred on the farm were sold for R4,337·26.

Milk to the value of R21,895·64 was supplied, of which R4,823·07 worth had to be purchased to meet the demand from the hospitals, which at different periods required more milk than the Dairy was able to supply. The necessity for the purchase of milk remains a serious defect in the

management, and the only way of avoiding it seems by the Dairy arranging with the Medical Department to supply only as much milk as it (the Dairy) produces. It should be possible to make a monthly forecast of the milk that the Dairy can supply under normal conditions, so as to permit the hospitals to arrange beforehand for the supply of milk in excess of the estimated quantity.

Mr. H. O. Morel, one of the agricultural students, who, with a view to acquiring a knowledge of dairying and cattle management, voluntarily acted as assistant to the Dairy Manager (with much acceptance), has become Manager of Mr. De Soysa's Bagatelle Dairy.

The following statements and returns are annexed :—

A.—Receipts and Expenditure of the Government Dairy, 1899.

B.—Receipts and Expenditure of the Model Farm, 1899.

C.—Financial Statement of Government Dairy and Model Farm, 1899.

D.—Capital Account of the Dairy.

E.—Balance Sheet showing the position of the Government Dairy Farm at the end of 1899.

F.—Live Stock Return.

The success which attended the Fruit and Flower Show held in 1898 suggested the resuscitation of the old Colombo Agri-Horticultural Society on 6th August of the same year. The first Show under the auspices of the revived Society was held at the School of Agriculture on 21st and 22nd July, 1899. The Exhibition, which was on a much larger scale than that held in the previous year, was a most successful event in every respect. After meeting all expenses connected with the Show a balance of R586·40 remained to the credit of the Society. It would, I think, be a good plan to hold future Shows in other centres in the Western Province besides Colombo; the benefit of the Show would then be more far-reaching than if they are always held in the capital.

The following is a record of the rainfall at the School of Agriculture for the year 1899 :—

	Inches.		Inches.
January ..	4·43	July ..	·66
February ...	2·66	August ..	1·01
March ..	1·73	September..	1·06
April ...	9·99	October ..	16·40
May ...	21·24	November..	6·89
June ..	12·73	December..	6·30

The total rainfall for the year was thus 85·10 in. The wettest month was April, but the greatest amount of rain which fell in any one day was 7·65 in., recorded on Friday, the 19th May—that is, between 9·30 A.M. on Thursday the 18th and the same time on Friday the 19th May. The total rainfall for 1899 fell short of that for 1898 by 1·48 in.

The Magazine published in connection with the school is now in its eleventh year, and the publication is, I am convinced, appreciated by those whom it is intended to benefit.

I trust that with the dawn of a new year and a new century some decisive step will be taken by Government towards placing the School of Agriculture on a better footing, whereby it may fulfil its object more worthily.

C. DRIEBERG,
Superintendent.

Recorded by Mr. C. DRIEBERG.

THE GOVERNMENT DAIRY AND DAIRYING IN COLOMBO.

The Administration Report of the Director of Public Instruction for last year contains the following appreciative remark with reference to the Government Dairy:—"The Dairy has done well, as usual. It has supplied excellent milk to various hospitals, and—what is still more important—it has introduced a useful breed of cattle into the Island."

The financial statement attached to the report of the Superintendent of the School of Agriculture not only shows the working of the Dairy for the past year, but reviews the result of its work since its establishment up to the date of the report, and this retrospect only goes to prove the fact that as a commercial undertaking this instruction has been a success.

Now there are many who would be inclined to ask how this success has been attained. We take it that it is to be ascribed to more than one cause. Of these, the selection of a useful breed of cattle, referred to by the Director, is perhaps the most important. To attempt to carry on a Dairy with the breed of cattle native to Ceylon would be a foolhardy undertaking, as good milking qualities—if they ever existed in them—long ceased to characterise these animals. The ordinary South Indian or "Coast" breed of cattle found in our cattle marts, and usually kept as milking stock by the Tamil cattle-keeper and milk vendor, only suits the conditions of this class of people, and is by no means adapted to the requirements of an establishment such as the Government Dairy, the reason being that the average output of milk is too small for successful working. It must be remembered that the produce of dairy cows should realize enough not merely to pay for their feed but also for their attendants, and for both not only during the period they are in milk, but also when dry and until they come into full milk again. In addition to all this there must be the margin of profit. Of course in the case of the native milkman the cost of attendance will be saved, as the owner himself tends his animals. There may be other good milking breeds of Indian cattle, but they have yet to be discovered and introduced into Ceylon *as profitable dairy stock* that will do well when kept in large numbers. The so-called Nellore cow and the English cow may thrive under special conditions and with individual attention, but they are unsuitable for a dairy of any size. The introduction of the Sind breed into Ceylon must, therefore, be put down as one of the chief factors in the success of the Government dairy, and for this the Superintendent must take credit, as nothing was known of these cattle in Ceylon till he "discovered" them and arranged for the first consignment of stock for the dairy.

The adequate provision made in the way of building and grazing accommodation, and the precautions for preventing the Dairy Stock coming in contact with outside cattle, are other causes of the Government Dairy's success. The cows of the native milk vendor are usually poorly housed in crowded, ill-ventillated and damp localities, and either permitted no exercise or allowed to wander about roadsides at nights, exposed to the night air, so that they might find grazing as best they can and at the same time take the risks of contracting contagious and infectious diseases, which, for want of a sufficient surrounding area, even threaten them in their sheds.

Another matter to be remembered as regards the Government Dairy is that it is under good supervision and good management, both of which are wanting in the so-called dairies scattered about the town, where no rules or regulations are enforced for carrying out the various operations involved in good dairying. Is it any wonder then, with so precarious a livelihood, that the native dairyman resorts to illicit means in order to supplement his legitimate income?

CLINICAL NOTES.

By D. A. Chinniah Veterinary Surgeon.

A case of cancer in a slut came under my treatment about two months ago. The animal was brought to me on the 12th of September in a very emaciated condition, and as she shewed great weakness I could not perform the complete operation I decided on. For the same reason I dispensed with the use of chloroform, and then proceeded to make a vertical incision in a line with the anal and vaginal openings.

Under proper antiseptic precautions I inserted my fingers into the cavity and after a vaginal and rectal examination with the help of my left hand, I was able to trace and draw out the horns of the womb, but instead of removing the ovaries I only cut off about 2½ inches of the horns together with the neck and appendages. The wound having been sutured and treated for some time, I performed a further operation on the 8th of October, and removed the cancerous mass. I had the satisfaction of ultimately seeing this dog regain its health. I may mention that the animal was the property of Mr. Chapman Dias of Mutwal, Colombo.

Subsequent to my first operation for worm in the eye (*Filaria Occuli*) performed on the 22nd of April last year, I had two other cases brought to me. One came a day after it had been unsuccessfully punctured by a farrier and the other was sent from Matara in a state of complete blindness,—this animal, too, I was led to believe, having been previously punctured without good results. This subject was a property of Dr. Asserappa, and it was sent for the operation on the 8th of October. As on the previous occasion, I threw my animal, but dispensed with the use of Cocaine. I tried to use the speculum for the first time in this operation, but abandoned it finding my fingers more effectual in preventing the eyeball from moving. With the help of a candle light—which brings the parasite to the surface—I found no difficulty in removing the worm. In both the cases the eyes were restored to their former useful condition.

PRACTICAL HINTS TO HORSE-OWNERS.

By D. A. CHINNIAH, O.S.V.C.

CHAP. II. (*continued*).—FOOD AND FEEDING.

The question of *quantity* of food can only be decided on after considering the digestive capacity of the animal, his speed, amount and nature of work, and the climate in which he is being used. The time of feeding must also to a great extent be regulated by the owner.

It is not advisable to use an animal much before two hours after feeding, as otherwise there will be a tendency to indigestion, and colic and other stomach troubles may result. In England horses are fed as frequently as four or five times a day, but in Ceylon they are fed twice or at the most three times. As digestion in hot climates is slow, frequent feeding is not advisable. A fact that is as a rule ignored is that the concentrated food (grain, pulses, &c.) requires more time to be digested than the natural herbaceous diet. It is quite common to see a *muttu* giving his horse an allowance of grass just after he has had his regular feed. This is not to be recommended. Let us for a minute consider the physiological functions of the horse's stomach in relation to digestion of food. The stomach of the horse is for its size the smallest among our domestic animals. The digestion of concentrated foods (grain &c.) takes place mainly in the stomach itself, and the time occupied in the process varies approximately from 2½ to 3 hours. On the other hand the digestion of the bulky grass or hay takes place in the larger intestines, while the absorption of water is carried on in the colon. On these physiological facts are based the following rule as regards feeding:—First give water, second give the grass, and third give the grain. It may not always be convenient to adopt this sequence, but it is as well to instruct *muttus* not to give water or grass for about three hours after the concentrated food has been consumed.

The main advantage of feeding horses on concentrated food is that the capacity of the digestive canal is reduced, and that this allows of greater scope for the expansion of the lungs required by fast work. Ignorant of this fact, the hired-gharry muttu makes a point of stuffing his horse with grass during intervals of work, and in this way ruins its digestion. Overloading the intestines just before work impedes the action of the lungs and causes *broken wind*, commnoly referred to as "panting."

Visitors to Ceylon who spend the greater part of their time in plying about in hired gharries, know the inconvenience of being drawn by horses attached to these vehicles, and Prof. Wallace on a recent visit made special note of the "ruined digestions" of the common hired horses, caused undoubtedly by the indiscriminate use of grass and water during intervals between work. As a result, some of these unfortunate animals are found, to move with difficulty and discomfort to the accompaniment of natural barrel organs within their stomachs!

SIR JOHN LAWES—HIS LIFE AND WORK.

(*Concluded.*)

About 130 papers and reports on the Rothamsted experiments have been published, most of them in the joint name of Sir John Lawes and Sir Henry Gilbert. It would serve no purpose to enumerate the different subjects treated of, suffice it to say that much information of a useful character and founded upon the valuable data supplied at Rothamsted was given to the world in these papers. Sir John also contributed voluminous papers to the philosophical transactions of the Royal Society, the Journal of Chemistry and other Scientific Journals, and drew up two valuable reports which were presented to Parliament. He also appeared on several occasions as a lecturer on agricultural and allied subjects. A few years ago the Rothamsted papers were collected in seven octavo volumes for presentation to various national institutions throughout the world.

The unique feature of Rothamsted—which is the oldest Agricultural Experimental Station in the world—is the long unbroken continuity of its investigations. It would have been nothing less than a national calamity had these ceased at the death of their founder. Sir John Lawes must have felt this, for he foresaw it, and with laudable munificence and admirable public spirit set asid a sum of £100,000 for their permanent continuance. The fund is administered by the Lawes Agricultural Trust Committee, the work of which began ten years ago, and will now go on uninterruptedly despite the lamentable death of the donor.

Prior to his death Sir John was approached with the view of his occupying the office of President of the Royal Agricultural Society, but his advancing years and the infirmities of age prompted him to decline the high honour. Among the many honours that were bestowed on the late baronet, was the awarding of the Royal Medal jointly to himself and Dr. Gilbert by the Royal Society, of which he was a member. In 1893, the year of the jubilee of the Rothamsted Experiment, a national monument was raised to Sir John Lawes, and the highest in the land joined to do honour to "one of the most disinterested as well as the most scientific of our public benefactors," who had laboured for fifty years for the cause of agriculture.

In concluding his excellent account of the life and work of Sir John Lawes, Dr. Fream pays the late baronet this handsome tribute:—

In his successful efforts to wrest from the soil its secrets, Sir John Lawes established facts which were unknown—undreamt of, even—in the pre-Victorian days, when he first began his experimental inquiries. Many of the truths that he discovered have now become incorporated with the stock of common knowledge, and have benefited the agricultural practice of all progressive countries. He worked, indeed, for mankind, and happily for the results, he was actuated throughout by an unswerving purpose. The fame of the Rothamsted Station is worldwide, and visitors from beyond the seas were always im-

pressed by the charming old Manor-house, so beautifully set among its sylvan surroundings, a fit type of the "homes of England." They invariably carried away, moreover,—as did all who visited the station,—agreeable recollections of the goodness of heart and the courtesy of the great yet unassuming man whose remains were laid to rest, amid every sign of sorrow and respect, at the Parish Church, Harpenden, on Tuesday, September 4. Of him it might well have been written:—"Thou shall come to thy grave in a full age, like as a stock of corn cometh in his season."

MISS ORMEROD, ENTOMOLOGIST.

We received by the last mail, from the author, presentation copies of the Manual of Injurious Insects and Methods of Prevention, and a paper on Flies Injurious to Stock, by Miss Eleanor A. Ormerod, F.R., Met. Soc., &c., the Consulting Entomologist of the Royal Agricultural Society of England and Honorary and Corresponding member of various other societies connected with Agriculture and Entomology. The work is accompanied by an excellent portrait of Miss Ormerod from a photograph by Messrs. Elliot and Fry.

We learn from the agricultural press that Miss Ormerod has quite lately received the honorary degree of L.L.D. from the Edinburgh University, and she is the first lady so honoured. The subject of our notice, who has a world-wide fame as an Economic Entomologist, has for the past twenty-three years devoted her attention to the study of insect life injurious to agriculture.

Daughter of Mr. George Ormerod of Sidbury Park, Gloucestershire, she began the study of Entomology in 1853 from pure love of the science, and fifteen years later was awarded a silver medal by the Royal Horticultural Society for a remarkable collection of drawings and models illustrative of insect pests and their depredations.

Miss Ormerod's help has always been available to anyone communicating with her either in England and from abroad, and that too free of all charge. It is estimated that on an average she received and replied to 1,500 letters every year.

In addition to her scientific qualifications, Miss Ormerod reads freely Latin, French, German, Italian and Spanish, and with a dictionary at hand, also Russian, Dutch and Norwegian. Amongst her most appreciated scientific friends were Prof. Huxley, Prof. Westwood of Oxford and Dr. Riley of Washington. Miss Ormerod's residence is Torrington House, a beautiful place standing in a garden of about two acres, at St. Albans.

In the Preface to the new edition of her work Miss Ormerod makes special mention of the good work done by her sister Miss G. E. Ormerod, as her "colleague and unfailing and skillful helper." And in concluding the Introduction to the book, she writes: "I fully trust it may often be found of service in lessening the losses which at present (and often solely for want of having a little plain information at hand) add greatly to the burdens which weigh down agricultural prosperity," and goes on to promise "so long as it may be desired, and health and power are granted me, I trust to labour to the best of my ability in the cause of Injurious Insect Prevention." We would desire to record in the pages of this little magazine our own high appreciation of the admirable work done by this gifted lady, whose name is familiar enough even in far-off Ceylon, and to add the wish that she may possess an abundance of "health and power" to add to the good work she has carried on with so much ability. We hope to summarise in a future issue Miss Ormerod's excellent "introduction to Entomology."—containing many useful hints—for the benefit of our readers.

HINTS ON MANURING.

The following useful information is summarized from an article on Rational Manuring in the *Queensland Agricultural Journal*:—

Agricultural Chemistry has demonstrated that plant-life calls imperatively for three prime forms of food. These three are nitrogen, potash and phosphoric acid. The produce of the land (whether grain, grass, fruits, milk, &c.) remove from the soil large quantities of nitrogen, potash and phosphoric acid. A portion of these food elements would be returned to the soil if the manure of cattle kept in the land is used, but yet a good deal would still be lost, and the productive capacity of the land can only be maintained by the use of commercial fertilizers.

The most popular materials for supplying nitrogen, and which are largely used in the preparation of commercial fertilizers are nitrate of soda and sulphate of ammonia, in which the nitrogen is in a soluble and available form. Nitrate of soda is particularly adapted for top-dressing during the growing season, and is the quickest acting nitrogenous fertilizer. Leguminous crops are known to draw on the atmosphere for their nitrogen, and hence nitrogenous fertilizers are unnecessary for such crops. On the other hand by taking advantage of this property of leguminous crops, we may obtain from them a portion (and sometimes even all) of the nitrogen required by other crops. If ploughed under, the legumes will not only furnish nitrogen to the soil, but also humus, which improves its physical condition. This is known as "green manuring." On sandy land and in a hot climate, it is not advisable to plough under a heavy growth of these plants while in a green condition. If the soil is very deficient in vegetable matter, the crop should be allowed to die upon the land and then be ploughed under in cool weather. If it is necessary, however, to plough under a green crop, a good dressing of lime, not less than 30 bushels per acre, should be applied to prevent injurious souring of the land.

Barnyard or stable manure is regarded by many farmers as "a complete fertiliser." This is correct only so far as it contains all three of the fertilising ingredients, but these ingredients do not exist there in the proportions required by most crops. Stable manure contains propor-

tionately too much nitrogen and not enough phosphoric acid and potash to be considered a "complete fertiliser."

By a proper rotation of crops and by "green manuring," stable manure can, in fact, be dispensed with, and in some cases such a course is even preferable. The old saying that stable manure is indispensable to successful farming is not now regarded as an axiom. A manure containing an excess of nitrogen will unduly increase the growth of leaf and straw at the expense of fruit or grain. To avoid such a result, stable manure should always be supplemented with artificial fertilisers containing phosphoric acid and potash.

Wood ashes are a valuable source of potash, but the amount contained in them is small and variable. Muriate of potash (potassium chloride) is the cheapest form of potash and the best form, except in special cases where chlorine affects the quality of the crop, as with tobacco and oranges. For these latter sulphate of potash should be used. Kainit is another form of potash salt, containing the chloride, and is specially valuable on sandy soils. It is valued not only for its fertilising properties but for its beneficial effects as a destroyer of insect pests and a remedy in certain forms of plant disease.

The amount of kainit which should be added to fresh stable manure to prevent loss of ammonia through heating is 1 lb. per day for each cow or horse or for eight head of sheep. The kainit will save more than its cost in the value of the nitrogen which it retains, and will possess its original value as potash food.

Swampy and peaty soils, which consist largely of humus, and which, as a rule, are rich in nitrogen, derive only slight benefit from stable manure. Such soils need lime, potash, and often phosphoric acid. The application of these forms of fertiliser is followed by largely increased crops. Phosphoric acid and potash will prove of slight value when applied as "top dressing" during the growing season. When so applied, these fertilisers will stay on the surface and out of the reach of the roots of the plants. Phosphoric acid and potash are "fixed" or retained by the soil. They are not volatile, nor do they leach through the soil. It is quite different with nitrogen. When organic matter, exposed to the air, decomposes, a portion of the nitrogen present volatilises and is lost in the atmosphere. The remainder, unless absorbed by vegetation, is finally washed away. Nitrogen in the form of nitrates readily leaches through the soil. Nitrate of soda may, therefore, well be applied as a top dressing during the growing season.

The commercial fertilisers now in the market are the most desirable supplements and substitutes for stable manure that can be obtained by the farmer. In complete fertilsers the nitrogen, phosphoric acid, and potash are skillfully compounded in various proportions. They are in a finely ground and thoroughly commingled condition, can be applied by drilling, and can be easily mixed with the soil. Their value has been accurately determined by the various agricultural associations, and the interests of the farmer carefully protected.

THE CULTIVATION AND CURING OF TOBACCO.

1. Soil and Climate.

A light soil or sandy loam, well drained and containing an average amount of organic matter and rich in mineral matters is considered to be best suited for tobacco cultivation. Tobacco grown on clay soils is too coarse and inferior in quality, but clay soils usually give heavy yields. Soils rich in organic matter or humus produce a better sort of tobacco of the kind fit for making cigars than clay soils. The principal tobacco-growing districts of Bengal are Rangpur, Cooch Behar, Jalpaiguri, Purnea, Darbhanga, Mymensingh, Nadia, Muzaffarpur, Jessore and Manbhum Murshidabd, Dinajpur, Chittagong, Dacca, Tippera, Bhagalpur, Pabna, Monghyr, Cuttack, etc., named in order of importance. The Chittagong tobacco* commands the highest price in the market, viz., as much as R22 per maund, the Rangpur tobacco selling from R6 to R12 per maund. The tobacco of other districts enumerated above is sold at R3 to R7 per maund. Ignorance of the method of cultivation and of curing causes in many places inferiority in the quality of leaves, but the difference in flavour is, no doubt, also due to influences of the soils and climate.†

2. Chemical Composition.

Tobacco requires particularly good soil and heavy manuring, as it is richer in nitrogen and in mineral constituents than almost any other crop. The composition of the leaves vary very much in both nitrogenous and ash constituents according to the richness of the soil or the amount of soluble plant food contained in it. The amount of nitrates in leaves may be as much as 10 per cent of the dry matter. The ash of Indian tobaccos varies between 16 and 28 per cent, the greater part of which consists of carbonate of lime. The soluble portion of the ash chiefly consists of potash salts, the proportion varying from 5 to 35 per cent.

The following table taken from Johnson's "How Crops Grow," page 378, gives the average constituents of tobacco ash :—

Percentage of ash	24·08
Composition of the Ash.	
Potash	27·4
Soda	3·7
Magnesia	10·5
Lime	37·0
Phosphoric acid	3·6
Sulphuric acid	3·8
Silica	9·5
Chlorine...	4·5
	100·00

* The Chittagong Hill Tracts produce the best tobacco in Bengal. This is generally used for making cigars by the Burmese. There are three varieties : (1) Khao Doung; (2) Mri Kheoung, and (3) Rigri Kheoung. The excellence of these varieties of tobacco, it is said, is due to the speciality of the soil rather than to any peculiar mode of cultivation or of curing. The leaves are cured in the way in vogue in Rangpur and Jalpaiguri.

† Cow-sheds are commonly used by the rayats for drying tobacco; this gives a bad flavour to the tobacco.

Potash should occur chiefly as carbonate (or ordinary wood-ash,) in the soil, and the richness of a soil for tobacco is chiefly due to the abundant presence of nitrogen, potash and lime, as nitrates, carbonates, sulphates and phosphates. From this it will appear that the most appropriate manures for the tobacco crop are ashes (or crude potassium carbonate), saltpetre, gypsum and lime. But as manuring is expensive, soils naturally rich in nitrogenous and ash constituents, that is, very fertile soil should be chosen for growing this crop.

3. Rotation.

Tobacco is sometimes grown after jute or Indian corn has been harvested, but very often it forms the only crop of the year. It can be grown for three or four years successively on the same ground.

4. Seed-Bed.

The soil of the seed-bed is dug up with spade and manured with rotten cowdung and ashes and then raised artificially about 6 inches. When the ground has been well pulverised, it is levelled. Seed is sown thin, so that each seedling may have about one inch of space round it. After sowing, the seed is lightly covered up with earth. The seed-bed is kept covered with mats until germination takes place. It is necesary also to keep the seedlings protected from rain and heat of the sun. They may require to be watered at intervals of two or three days. Seed is generally sown in the middle of Bhadro (first week of September). In dry laterite soil it is best to do the sowing early, *i.e.*, about the second or third week of August. Half an ounce ($1\frac{1}{6}$ tola) of seed is to be sown to produce plant required for one acre; but loss invariably occurs owing to patches of seedlings growing too thick. It is therefore advisable to grow seedlings from one ounce of seed for one acre of land. Sometimes ants do considerable damage to seed and seedlings when ashes sprinkled round and over the seed-bed prove efficacious.

5. Preparation of Land.

The soil for the tobacco cultivation should be prepared during the months of August and September. Eight to ten ploughings are necessary. Deep cultivation and thorough pulverisation of the soil are most important. The soil should be liberally manured with well-rotted cowdung and ashes. The soil is then to be levelled with a light harrow. It is needless to say that even poor soil can be made to produce a good crop by proper tillage and heavy manuring. Soils destitute of potash, unmanured soils or soils manured with flesh, humus, calcium chloride, magnesium chloride and potassium chloride produce a bad burning tobacco which is unsuitable for making cigars. The use of cowdung also should be avoided in raising tobacco for the manufacture of cigars. Potassium carbonate, saltpetre, potassium sulphate, and calcium sulphate (gypsum) are the best manures for tobacco intended for cigars. They give to the leaves a sweet flavour and burning quality. Gypsum is excellent as a top dresser, and its use is particularly recommended to Indian cultivators. Crops manured with it suffer less from the effects of drought and require less irrigation. Gypsum is a byeproduct in the manufacture of the ærated waters and can be obtained very cheap,—at 4 to 8 annas per maund. The mineral manures are used generally from $2\frac{1}{2}$ to $4\frac{1}{2}$ maunds per acre. Ordinary household ashes also are an excellent manure for tobacco. They contain a large amount of potash and lime, and are particularly recommended for clay and humus soils.

6. Transplanting.

When the seedlings are about 3 inches high in the nursery, that is, after they have shown three or four leaves, which takes place within six weeks from sowing time, they are fit for transplantation. The transplantation begins in the beginning of Aswin (the 3rd week of September), and extends as late as the end of Kartick (middle of November). Early planting is preferable, especially for dry climates. The seedlings should be planted in the evening 3 feet apart from one another. Smaller varieties, as Hingly, Motihari, etc., may be conveniently planted 2 feet apart. The transplanted young seedlings are to be carefully watered for the first few days until they strike root. Irrigation may be afterwards necessary at intervals of about ten to twenty days, according to the nature of the soil. In Rangpur and Jalpaiguri a hand plough is repeatedly dragged by a man alternately along and across the tobacco fields, which serves the purpose of hoeing and stirring the soil. This is done until the flower buds are seen. In places where artificial Irrigation is required, regular hoeing is wanted—twice after each irrigation, or four times in a month.

7. After-treatment.

A few days before the plants run to flower, their buds and lower leaves should be nipped off, and they should be so pruned that only eight leaves, and on no account more than ten, may be left to each plant from the top. In Jalpaiguri finely-powdered earth is used to stop bleeding or overflowing of sap from the broken parts immediately after pruning. This mode should be followed in other quarters. Plants reserved for seeding should be topped in this way, but left to flower and seed. The plants always bring forth shoots by the side of the stalks of leaves pruned, and care should be taken to prune off the shoots every now and again until the leaves are mature. The longer these buds and shoots are kept, the more injury is done to the leaves required to be gathered.—*Indian Agriculturist.*

(*To be concluded*).

GENERAL ITEMS.

Senor V. Marcano, one of the leading medical authorities of Cuba, has discovered that the juice of the Pineapple materially aids in the digesting of the proteids of both animal and vegetable foodstuffs, while R. H. Chittenden, of the Connecticut Academy of Sciences, asserts that the fresh Pineapple juice is a constant and powerful digestant of albuminous matters, acting in both alkaline and acid media, but more energetically in neutral than in either of the others. In fact, chemists have separated the active digestant

principle and put it in the materia medica. This substance, closely analogous to pepsin, is known as bromelin. Pineapple juice has been found to be most efficacious in throat troubles and diphtheria, as the juice dissolves the fleshy tissue, such as is found in these ailments. A cure of diphtheria in a most marked and, in fact, abandoned case is reported in the *Druggists' Circular* as follows:—"For three or four years I have been hearing of the use of the Pineapple juice for the cure of diphtheria, but though little of it. Recently, however, it has taken better shape in the report of a case where the child was given up by the doctor, and a friend coming in remarked that he had known children relieved by the Pineapple. The physician in attendance said, 'Get it and try it; it can do no harm.' A ripe Pineapple was got and the juice expressed and given in teaspoonful doses slowly. It seemed to clear the throat, swallowing was much easier, and in a few hours the child was sleeping. Recovery followed. The Pineapple was used in a number of cases subsequently, with success, in the same neighbourhood, and the people think it better than medicine." In bronchitis, Pineapple juice has been found to be excellent medicine by Dr. Flascher in softening the mucus. His formula is as follows: "Slice the fruit, sprinkle with sugar, heat to boiling and strain. The dose of syrup so obtained is about two tablespoonfuls." In Cuba the Pineapple is highly esteemed from the fact that it is in general use as a mild laxative. From the Pineapple itself pharmaceutical chemists have separated a crystalline substance which they call mannitol, which is in active use in compounding prescribed medicines for throat and lung troubles.

In reference to the polishing of rice we read in the *Queensland Agricultural Journal* that according to the *Grocer*, fashion demands a bright lustre in rice placed on the European market, and this is secured by rubbing off a dull outer coating of the grain, which has been shown to have a food value nearly twice as great as the rice grain after polishing. The polishing process, however, greatly improves the appearance of the grain, and it is now almost universally practised in cases where the rice is intended for the markets of the West. The material secured off is sold under the name of rice flour. The polishing is effected by friction against pieces of moose hide or sheep-skin, tanned and worked to a wonderful degree of softness, losely tacked round a double revolving cylinder of wood and wire gauze. After the polishing the rice goes to the separating and shifting screens, made of different sizes of gauze, by which it is graded before packing.

The Banana seems much to the front at the present day, and comes in for a good deal of laudation: the banana plant, says M. de Lovedo, in *El de Progress Mexico*, will feed 150 men from the product of one hectare of land so planted; while the same area in wheat would only supply food for six individuals; for the same space and under similar conditions of cultivation, its produce is 40 times that of potatoes and 100 times that of wheat. The fruit of the banana contains 72 per cent of water, 2·14 per cent of nitrogenous matter, and 22 per cent of saccharine substances, the latter giving it its great nutritive quality.

We have all heard of mummy wheat which is said to have been raised from grain found in the hands of Egyptian mummies some 3,000 years old, and now comes the story which we read of in the *Queensland Agricultural Journal* of Mr. R. A. Stewart, a saddler of Kowes, Isle of Bute, growing peas from seed found in the tomb of an Egyptian king! A characteristic of this pea is that the white flowers have a beautiful red centre, surrounded by a white corona. The plants grew up strong and vigorous to a height of 6 feet, the pods averaged 2 to 3 inches by half an inch, and the peas are said to be of excellent flavour.

The chief Camphor-producing country is Formosa, where it is a Government monopoly. The reason for making it such appears to have been, among other reasons, the reckless destruction of trees and the great fluctuations in price, as well as the want of uniformity in quality in the article previously. The Government has passed strict forest regulations, and by wise forest administration Formosa is capable of supplying the world with 6,000,000 or more pounds (English) of camphor annually. The quality is established, and the price fixed not only locally but abroad. Tenders are invited for the lowest price of sale in foreign markets, and in March, last year, the monopoly of sale in foreign markets was secured by Mr. T. Arai of Messrs. Samuel, Samuel & Co. The above interesting facts are recorded in the *Brisbane Courier*.

The *Louisiana Cultivator* referring to Indian corn says:—This wonderful plant that can so nearly supply all the food required for man and beast, bids fair to do still better in the early future. While it is now the dominant crop in American agriculture, it seems to promise even higher food values in the future. It stands supreme as a fattening food, and the bassis of fat cattle and pigs in America. It is also fed largely to working animals, and analyses show that it contains sufficient protein to make it reasonably good food for them, though not so good as oats, the typical worker's food, because of its high proportion of protein. This nitrogenous matter it found chiefly in the germ of Indian corn, hence the size of the germ in a measure indicates the proportion.

If tomato plants show signs of disease by the unhealthy appearance of the leaves, or scabby fruit, they should be at once sprayed with Bordeaux mixture of a strength of 4 lbs. bluestone (sulphate of copper), 4 to 6 lbs. quick lime and 40 gallons water.

What does an inch of rain mean? Few persons have a definite idea. An acre, if calculated out,

will prove to be 6,272,640 square inches. An inch deep of water on this acre will be as many cubic inches of water, which, at 231 to the gallon is equal to 27,154 gallons. This immense quantity of water will weigh 228,190 lbs. or 114 tons. One hundredth of an inch (·01) alone is equal to over one ton of water to the acre.

It was reported in the *Government News* some time ago that for some unaccountable reason a large proportion of the rice grown in South-west Louisiana turned out red. The coloured rice was found by chemists to be as nutritious as the white, but still there is a prejudice against the former and this affected the selling price.

The following recipe is given by the *Queensland Agricultural Journal* to prevent rust: Melt one lb. lard and one ounce camphor. Skin the mixture carefully and stir in a sufficient quantity of black lead to give the metallic colour. After clearing machinery thoroughly, smear with the mixture and let it remain for a day and then rub clean with a soft cloth.

Says the *Sydney Mail*:—Small particles of cinder and metal are constantly getting into the eyes of engine-drivers and stokers. They have one invariable way of getting them out. No sooner has the driver of an engine got a nasty bit of grit in his eye, then his companion, the stoker, opens the eyelids quite wide and licks out the unseen fragment—which might produce tragic results sometimes—with his tongue. The public knows little of this heroic remedy, but on every line in the world it is being applied every hour of the day, All surgeons recognise that this is often, with all their beautiful instruments, the only way. And amongst the thousands of women connected with the English fishing trade who have to clean herrings it is also practised as the only method of getting ont of the human eye the very minute herring scales that lodge there and scon produce serious mischief if not removed.

Four hundred ponnds weight of hen manure is equal in value to 2,400 lb. of farmyard manure. In a ton of fowl manure analysis showed 48·60 lb. phosphoric acid, 48 lb. potash, and 67 lb. nitrogen; whilst farmyard manure contained only 6 lb. phosphoric acid, 10 lb. potash, and 11 lb. nitrogen in one ton. Much of the value of any manure depends upon its freshness, and whether it has been kept under cover and dry.

The TROPICAL AGRICULTURIST
MONTHLY.

XX. COLOMBO, JANUARY 1st, 1901. No. 7.

SOME CATERPILLAR PESTS OF THE TEA PLANT.*

(*Concluded from page 374.*)

O. 5.—The "Morowak korale Nettle-grub." *Thosea recta*, Hampson.

The eggs of this species have not yet been observed, but they are probably laid upon the surface of the leaves.

Caterpillar: lozenge-shaped, slug-like, of an applegreen or yellowish-green colour, often with a series of irregular red patches on the back. Stinging spines arranged on small tubercles in a marginal and two dorsal series. Head concealed on the under surface. The insect has no legs, but progresses in a slug like fashion. The fully grown caterpillar measures from ½ to ¾ inch in length.

Cocoon: dark brown, egg-shaped, compact, and smooth, attached either to the under surface of a tea leaf or in the angles of the twigs and stems. When the pest is at its height, the cocoons may be found in clusters on the twigs, the leaves of the trees having been completely devoured. Specimens kept in captivity remained as cocoons for from 17 to 21 days.

Moth; grayish brown, with a rather furry body. The female has a blackish spot in the centre of the fore wing and two faint lines, one near the base and the other near the tip. The basal line stops short of the front or costal edge of the wing. The male has a darker patch at the base of the wing bounded by a short white streak which (as in the female) does not reach the costal edge. The male moth has an expanse of ¾ inch. The female is rather larger measuring slightly more than an inch across the expanded wings. The male may also be distinguished by the stouter (feathered) antennæ, the corresponding parts of the female being thread-like. (Excellent figures of the caterpillar, cocoon, and moth appeared in "The Indian Museum Notes," Vol. IV., No. 2.)

I have been acquainted with the present species as a tea pest, for about eight years. A correspondent, writing in the *Ceylon Observer* of July 27, says that he can remember a severe attack as far back as 1885. I first received specimens from the Ambagamuwa district, where large acreages of tea were defoliated. I next heard of it from Balangoda. The pest has probably asserted itself repeatedly in different districts, but the outbreak in Morowak korale seems to have caused a quite unprecedented scare. The superintendent of the estate on which it made its first appearance in that district has kindly supplied me with the following particulars:—

"I first noticed it on July 15; it was seen on about half an acre of tea. After two days it had spread over about 3 acres, and then at the rate of about five acres a day over 25 acres of tea. [This rapid extension of the affected area could not have been caused by any actual migration of the army of caterpillars, which are sluggish and travel very slowly. It is doubtful even if they wander far from the bush upon which they were born. It probably arose from successive batches of eggs hatching out on consecutive days, deposited by months which had dispersed from the centre of infection, where a smaller previous brood had undergone its transformations unnoticed.—E.E.G.] The damage done was not of a permanent nature; but the caterpillars eat out almost every vestige of green leaf, and the whole 25 acres were stripped almost bare. When I found I could not prune quick enough to overtake its spread, I pruned broad belts round the area attacked, burning the prunings and sweeping the ground. I found the insects seemed unable to cross these belts, and as I pruned out all the tea inside it died fast, exposure to the sun and want of sustenance apparently combining to kill it.

"In about five weeks from its first appearance it had disappeared nearly entirely, although I found a few insects here and there in other parts of the estate. When, however, the young flush grew (about

Royal Botanic Gardens' Circular, No. 19.

five weeks after pruning) I found it covered with a minute form of the same insect. Under the lens it showed the same shape, colour, &c., as the original insect, and here and there it grew to nearly full size after some days. I stripped all the young flush off for about four rounds, and after that it again disappeared and I have not been troubled with it since. [This renewed attack after pruning can only be accounted for by supposing that a number of the cocoons had escaped observation at the time of pruning, being possibly concealed in the angles of the stems and branches. These may have emerged as moths in three weeks' time and, failing leaves for the purpose, laid their eggs on the bark of the pruned trees. The eggs would have hatched out in about 10 days, when the young larvæ would commence feeding on the new flush. It is doubtful if they would have thriven under these conditions, as these caterpillars usually prefer the more mature leaves and avoid the young flush.—E. E. G.] I cannot find out anything about its propagation, which has puzzled me completely. I could find no trace of the moth; but on all the trees attacked small round cocoons, black, about the size of a pea, with a smooth bark-like shell and a neat little trap-door at the top. were deposited thickly where the branches forked, I was astonished to find that whereas at first insects about half or three-quarters size emerged from these shells, later on a considerable proportion of them hatched out a grub-like winged insect, something like a white ant, but with small wings. I found, moreover, that as the full-sized insects died they shrivelled up, and in many cases I found small white lice-like insects clinging to the carcasses. I am inclined to think it was from these that the very small grubs which attacked my young flush came."

There must have been some error of observation here. The insect develops in quite the normal way, from egg to caterpillar, caterpillar to chrysalis (enclosed in its cocoon), and finally chrysalis to winged moth. It is possible that some confusion may have arisen from cocoons having been broken open, when the caterpillar, reduced in size, would be observed awaiting its transformation into the chrysalis stage. I cannot explain the "grub-like winged insects," unless they could have been the newly-hatched moths, before their wings had properly expanded. The "white lice-like insects" were undoubtedly mites, which quickly swarm upon such dead matter, and could, of course, have had no connection with the subsequent brood of small caterpillars.

Before this outbreak could have assumed the proportions described in the above correspondence, there must have been at least two earlier and smaller broods. I can only repeat my warning—to keep a good look-out for these preliminary broods, and destroy them before they have had time to gain ground. When the pest is at its height, if the attacked field is nearing the proper time, pruning will be the best remedy, care being taken to effectually destroy all the prunings, and to search for and remove all cocoons attached to the stems of the trees. If the field is only just coming into bearing, the foliage may be thoroughly sprayed with arsenate of lead or some similar insecticide, which will poison the leaves and the caterpillars feeding upon them. No leaf should be plucked from such trees for at least 14 days. The actual leaves that will then be taken will have been disclosed since the application of the poison.

No. 6.—THE GREEN NETTLE-GRUB," *Thosea cana* Wlk.

The caterpillar of this moth is practically indistinguishable either in form or colour from that of *Thosea recta* described above. It is perhaps more usually without the red patches on the back, but this character is very variable in both species. The two insects have similar habits and appear to be equally destructive.

The moth of *T. cana* may be distinguished by its more uniform grayish-brown colour and by the absence of the short white-streak which marks the fore-wing of *T. recta*. *T. cana* has two indistinct brownish lines accross the wing, with a small brown speck in the space between them.

I have recently received specimens from the Kelani Valley district, where the pest appears to have been prevalent for more than a year, and to have steadily increased its area of attack in spite of persistent attempts to check it by handpicking. My correspondent wrote as follows in March of the present year:—

"The insect is just now present in great numbers I am catching as many as 2,000 per cooly. It attacks the same field every time, a somewhat poor jat of tea, appearing—as far as I can make out—about every two or three months. Sick and small bushes are quite denuded of leaves. On healthy trees the leaves are almost eaten through, a thin skin only being left on upper side of leaf. [This is the work of the quite young caterpillars. The older insects will eat right through the leaf.—E.E.G.] This insect appears to me to change colour as it grows, being at first green with yellow with a somewhat transparent appearance. [This is just before pupation.—E.E. G.] I can find no cocoons, nor any eggs; the insect seems to come all at once. [The eggs would be extremely difficult to detect. The cocoons are probably attached to the stems.—E.E.G.] Healthy indigenous tea adjoining the fields attacked has so far escaped, with the exception of a very few individual trees. For the past three weeks we have had a most severe drought, and this attack is, I think, the worst I have experienced. A portion has just been cut across and allowed to run up again. Out of an area of 635 acres, all in one block, two fields only, one of 100 acres (2½ years) and another of 100 acres (1½ year), are attacked. A field in which the insect first appeared is now quite free."

An examination of particulars of rainfall supplied by the same correspondent for the year 1899 seems to show that the pest was at its height during the S.W. monsoon. April, with 20·35 inches; May, 27·55; June, 21·52; July, 10·72; and August, 5·47, are bracketted together with the remark that the caterpillars were very numerous over 80 acres, and that the collecting coolies were bringing in from 1,000 to 1,200 insects apiece. In September, October, and November, though a larger area was involved, the caterpillars are reported as being "not nearly so numerous."

In the above case large numbers of coolies have been employed in collecting and destroying the caterpillars, but apparently with little success in checking the attack. The fact is, that when once the pest has attained such vast proportions, it is almost impossible to eradicate it by artificial means. One-hundredth part of the same energy applied at the time of the earliest broods would have been much more effective. In young tea, such as the above, which is not in plucking, spraying with some arsenical compound could be freely employed without any possible danger.

No. 7.—THE "FRINGED NETTLE-GRUB," *Natada nararia*, Moore.

Egg; very inconspicuous, oval, flattened scarcely raised above surface of leaf, very pale green, transparent, showing the colour of the leaf through it. They are laid singly on the upper surface of a tea leaf, and can only be distinguished by holding the leaf at an angle, when the surface of the eggs shine with a metallic iridescence.

Caterpillar; varying in colour, pale green, yellowish green, or whitish green, often with a broad reddish brown or purplish stripe on the back, which is constricted or interrupted at a point near the middle and again near the hinder extremity. This dorsal stripe has usually a darker outline of the same tint. All round the margin is a fringe of long pointed tubercles bearing tufts of stinging spines, and a row of smaller spiniferous tubercles on each side of the

dorsal stripe. The spines on three or four of the tufts on each side near the head are blackish; all the others are green. The head, as usual in this family, can be withdrawn into a little pocket, and the caterpillar has no legs. When fullgrown it is little more than half an inch in length. It rests on the under surface of the leaves.

Cocoon; broadly oval, almost globular, dull reddish-brown, smooth. The moth escapes by a lid-like opening at one end. The cocoons are attached either to the leaves or twigs of the plant, or to the fallen leaves and rubbish below the tea.

Moth; male, pale ochreous, the middle of the fore-wing covered by a reddish brown patch, in the centre of which is a black spot. Antennæ strongly feathered. Expanse ¾ inch. Female, dull brownish-ochreous, fore-wing darker. Antennæ thread-like, Expanse 1 inch.

Moths in captivity emerged from the cocoons after 17 days.

The Uva tea districts seem to enjoy almost a monopoly of this species as a tea pest. Though it is a widely distributed insect throughout the Island, and certainly occurs in all the tea districts, yet I have received no reports of damage to tea or of its occurrence in unusual numbers in the Central Province.* My first acquaintance with it—in its character of a pest—was in November, 1897, when I received specimens from Badulla. And quite recently several estates in Passara have suffered severely from the same insect. A correspondent writing on the 10th January, says:—

"The pest was first noticed on this estate early in July last year, when the caterpillars were half-grown, along the roadsides, under the Grevilla trees. They gradually spread over almost the whole estate, stripping about 100 acres of all leaves. For some time 500 coolies were collecting a bushel a day of the cocoons from under the fallen leaves. They seem to turn to chrysalis, moth, and caterpillar simultaneously in all parts of the estate, and run through the changes of their existence in about two months. Early last November, in many of the fields, clouds of the moths appeared at dusk. The moths were in existence also early in September. They completely disappeared for about three weeks while the eggs were hatching. I have never identified the eggs. At the time I write there are still a few caterpillars to be found, but I hope, if January continues wet, the damp may kill the survivors, as it has done before. I found them also on many jungle trees near the tea fields."

This correspondent adds memoranda of the monthly rainfall, from which it appears that the broods of July, August, and September occurred during the spell of comparatively dry weather, but the brood that was so noticeable early in November followed a distinctly wet month, October showing a fall of 15·94 inches.

In April of the present year I personally visited the Passara district and the estates that had been subject to this pest. The bushes had completely recovered from the attack, and no permanent damage was noticeable. The superintendent, however, was of opinion that there was not such good wood to cut into at the next pruning as should have been found in a healthy field. I was informed that the cocoons were nearly always found under fallen leaves below the bushes—often attached in clusters of five or six to dead Grevillea leaves, seldom on the leaves or twigs of the growing plant.

During my visit moths of *Natada nararia* were flocking into the verandahs of the bungalow at dusk, attracted by the lights. I experimented with a simple moth-trap, a coconut lamp in the middle of a basin of water. But very few moths were captured in this way, possibly owing to the presence of a brilliant moon at the time. This plan should be tried again on moonless nights.

* Specimens have since been received from the Rangalla district.

No. 8.—THE "RED SLUG," *Heterusia cingala*, Moore.

Egg: narrow, elongate, very pale yellow. I have never found the eggs *in situ* in the field, But some moths that were kept in a breeding cage for the purpose of study deposited their eggs loosely on the floor of the cage. It is possible that in nature they are deposited in crevices of the ground at the foot of the plants upon which the caterpillar is to feed. The young larvæ hatch out in four weeks' time.

Caterpillar: broad and comparatively short. Brownish red to bright brick red. With six longitudinal series of small tubercles, on the summits of which are two or three short hairs and one or two pores which secrete a globule of clear viscid fluid, giving a dewy appearance to the living caterpillar. There are the normal number of legs, six on the front and ten on the hinder part of the body. Length of full-grown caterpillar slightly over one inch.

The cocoon is formed in the fold of a leaf. It is tough and closely woven, of a pinkish straw colour. It contains a creamy white chrysalis. Caterpillars that formed their cocoons in my breeding cage on January 2 emerged as moths on the 22nd of the same month.

Moth: fore-wing black with metallic green reflections, with a creamy white patch at the base, a broad creamy white bar just before the middle, and some creamy white spots towards the extremity. Hind-wing peacock blue suffused with black, with a very broad pale primrose-yellow band across the middle, and some yellowish spots towards the extremity. Anterior half of the body peacock blue and black, posterior half bright yellow. In the male the antennæ are broadly, in the female narrowly, feathered. The expanded wings measure 1⅝ inch in the male and 1¾ inch in the female.

The moth flies in the daytime, and might easily be mistaken for a butterfly on account of its bright colours. When handled it emits some frothy matter which has a strong pungent smell very like that of the English ladybird beetle, which is thought to afford the insect protection by making it distasteful to birds, &c. I have received reports of injury by this pest from the Pussellawa, Pundalu-oya, and Rangalla districts, and more recently from Passara and Lunugala. On some estates in the latter district the attack appears to have been very severe. Acres of tea bushes were completely defoliated, and the affected fields were said to have looked as if they had been burnt. The caterpillars were observed in large numbers in November, in the following January, and again in April. I have been unable to determine the exact length of the caterpillar stage, but the complete life-history of the insect appears to occupy about ten weeks.

These caterpillars have no stinging hairs, and may be handled without any unpleasant results. They should be collected and destroyed whenever seen, together with the cocoons, and all dead leaves should be swept up from below the bushes and burned.

The caterpillars are fortunately subject to the attacks of a parasitic fly (*Exorista heterusiæ*, Coquillet.) This fly fastens its eggs upon the back of the caterpillar, the young maggots penetrate the body of their host and feed upon its contents, taking care not to touch any vital spot until they are ready to undergo their own transformations. The diseased caterpillar has usually sufficient strength to spin its cocoon, but collapses without turning into a chrysalis. The sudden disappearence of this pest, after reaching its climax is usually due to the work of this useful parasite, though sometimes a bacterial disease is still more effectual in the work of extermination.

BAGWORMS AND FAGGOTWORMS.

These are the larvæ of various species of moths belonging to the family *Psychidæ*. They have all very similar habits, though differing considerably in appearance. The caterpillars construct for themselves cases in which they pass the greater part of

their existence. In fact, the female insect never leaves its case, but lays its eggs and dies inside it. These cases have always a strong foundation of finely woven silk in the form of a tube which closely envelopes the caterpillar, but different species embellish the outsides of their cases in different fashions. Some (*e.g*, *Clania crameri*) arrange small twigs longitudinally all round, till the whole has the appearence of a small faggot of sticks. *Clania variegata* sometimes adopts the faggot form, and at other times uses large pieces of leaf as an outside covering. Another species fastens short lengths of twig side by side in a spiral. Another places the minute sticks transversely, forming a four-sided case. *Psyche minor* adopts a chevaux-de frise-pattern of erect fibres and pieces of grass, and occassionally adds some minute snail shells by way of ornament. And a large number of the smaller species have smooth cases partly constructed of minute pieces of bark and licheus. As the caterpillar increases in size, the case is let out from time to time and fresh material worked in. When feeding only the head and front part of the body is extended, the case meanwhile being moored to the leaf by a thin silken cable. At the slightest alarm the head is retracted and a flexible curtain is drawn tightly across the entrance. When the time for its resting stage arrives, the caterpillar firmly anchors the case to a leaf or twig and closes the mouth of the tube with silk. It then turns round inside the case with its head towards the hinder opening of the tube, and changes to a chrysalis in this position. If the insect happens to be a male, it will eventually (in from two to six weeks' time) emerge as a moth, usually of a dull brownish or blackish colour, sometimes with colourless transparent wings. But the female insect does not leave her dwelling. She shuffles off the chrysalis skin inside the case and awaits there the attentions of the male. As the head of the female is next the only available entrance to the tube, and her body being some five or six times as large as that of the male, it follows that her partner must be possessed of a very flexible and extensile organ; and we find that the abdominal segments of the male moth are accordingly capable of very great longitudinal extension to meet the special circumstances. After impregnation the female deposits her eggs—still within the case—and dies. It is said that the young larvæ make their first meal from the dried carcase of their parent. They then emerge into daylight and soon build small tubes for their individual protection.

From the fact that the females are wingless, it is evident that these pests can spread only in the caterpillar stage. It is probable that the very young larvæ are distributed by attaching themselves to the coolies' clothing, or they may be carried for some distance by the wind. Otherwise it would require a very considerable time before a large field could be affected from a given centre.

No. 9.—THE "SMALL BAGWORM," *Psyche* (*Manatha*) *albipes*, Moore.

It is this species that gives the most trouble on tea estates. The caterpillar lives in a conical grayish case, with a few fragments of bark or leaves attached to the outside.

The male moth is dark brown, with white feet (whence the specific name). It has a wing expanse of ¾ inch. The female moth is a whitish, fleshy, grub-like insect, merely a bag of eggs. It remains concealed within its larval case.

This insect has frequently been reported as destructive to tea plants in new clearings in the Kelani Valley districts. After defoliating the plants it does still further mischief by gnawing off the bark. Hand-picking is the only practical remedy. Plants in which the bark has been eaten away must be cut back below the injured part.

No. 10.—THE "LARGE BAGWORM," *Clania variegata* Snell.

This species is sometimes troublesome on local patches, but seldom affects any large acreage.

The caterpillar is enclosed in a bag of grayish silk, to which large pieces of leaves and an occasional twig are often attached. The male insect usually covers its case with pieces of twig, turning itself into a miniature faggot. But the larger-bodied female seems to find the sack-like case the more comfortable form. It remains there till it dies.

The male moth has rather narrow pointed wings, streaked with different shades of brown. Expanse 1½ inch. It is seldom seen, the females being much the more common.

The species occurs commonly throughout the tea districts, and has been reported as defoliating small groups of bushes; but being a large insect it is easily seen, and should be collected and destroyed whenever observed.

No. 11.—THE "TWIG CATERPILLAR," *Boarmia Ithurmitra*, Wlk.

The caterpillar has exactly the appearance of a dry twig when at rest. It belongs to the family of *Geometridæ* or "Loopers,' which have only two pairs of legs at the hinder extremity of the body and progress in a leech-like fashion. When at rest they clasp a branch with these terminal feet and extend the body rigidly, in which position they are almost indistinguishable from a dead twig. The colour of the insect assists the deception, being mottled and streaked in different shades of brown. A full-grown caterpillar measures 1½ inch.

The chrysalis is formed just below the surface of the ground. It is of a reddish colour, smooth and glossy. It remains in this stage for about 14 days.

The moth is very pale brown, minutely specked and spotted with darker markings which form wavy lines across the wings. Expanse from 1½ to 1¾ inch. The moths rest, during the daytime, flattened against a tree trunk or rock, with wings expanded, in which position their colour harmonizes remarkably with their surroundings.

I have been unable to locate the position in which the eggs are deposited,

Although this insect has been observed commonly in Ceylon for a great number of years, it is only within the last month that it has been brought to my notice as an insect pest. Its work on an estate in the Kandy district has now well earned for it this reputation. I was able to pay a personal visit to the place, and found the caterpillars simply swarming on the tea, which they were rapidly defoliating. I was shown a large Grevillea clearing, across half of which the plague of caterpillars had swept. They had stripped these trees bare, together with the young Cardamom plants growing below them, and had treated several Iron-bark Gums in the same manner. On turning up the ground underneath the Grevilleas, the chrysalides were found in large numbers just below the surface. The manager of the property has given me the following history of the pest, as observed by himself. It has been noticed on this particular Grevillea clearing for the previous three years, but to a smaller extent, increasing its area of attack each consecutive year. It usually appears in February and disappears during the rainy season. The pest always starts at the top of the ridge and works downhill, directly against the prevailing wind. In the present year the plague of caterpillars continued well in August, at which time the moths were appearing in thousands, coolies being employed to catch them as they were resting on the bark of the trees. Over 50,000 were said to have been destroyed in this manner in the space of one week, a single cooly bringing in sometimes nearly a thousand moths. The showery weather greatly assisted in the success of this work, as the moths are sluggish at such times and do not readily take wing. The manager was advised to prune the zone of tea upon which the caterpillars were then feeding and to fork lime into the soil with a view to the destruction of the chrysalides. All prunings were to be burned or

buried. At the time of my visit it was noticed that large numbers of the caterpillars were dying, attacked by some fungal disease that had an extraordinarily rapid action. Apparently healthy specimens collected that morning were dead and covered with fungus ten hours later.

The fact that this pest makes its first appearance, each year, on full-grown Grevillea trees will make it difficult to stamp it out at its commencement without sacrificing such trees. The spread of the pest is not due to an actual migration of the caterpillars, but to the fact that the moths move onwards and lay their eggs where there is food for the future larvæ. Between the months of February and July, the period when the pest is usually prevalent, there have probably been three or four distinct generations. It has not yet been determined what becomes of the insects during the rest of the year. This is a point that requires investigation. It is possible that a few individuals carry on the breed. Or it is again possible that eggs laid in July and August may remain dormant until the following February.

There are several other caterpillars that attack and do a certain amount of injury to the tea plant, *e.g.*:—

The Tea Borer, *Zeuzera coffeæ*, Nietner
The Cutworm, *Agrotis suffusa*, Hubner.
The Yellow Tussock, *Dasychira, horsfieldi*, Saund.
The Small Tussock, *Orgyia postica*. Walker.
The Atlas Moth, *Attacus, atlas*, Linn.
The Lobster Caterpillar, *Stauropus alternus* Wal.

But the present circular deals more particularly with those that have been found to occur in such numbers as to seriously affect the crop.

In conclusion, I would again emphasize the importance of being beforehand with the caterpillars. Stamp out the earlier broods before they have time to breed and to extend their area of operation; pluck off all folded and twisted leaves as regularly as "banji" is now removed; and encourage coolies and kanganies to observe and report the earliest appearance of any caterpillars on the tea. Specimens of every caterpillar pest should be sent in to the Entomological Department for identification.

E. ERNEST GREEN,
Government Entomologist.

Royal Botanic Gardens,
Peradeniya, August 15, 1900.

TRANSPLANTING LARGE MANGO-TREES.

Most men have their own particular way of removing and replanting trees of large dimensions, but to those who have not essayed the task this appears a big job to tackle. It is for such persons these remarks are intended. The writer makes no pretensions to a special knowledge of the subject, but having successfully removed and replanted a number of large-sized mango-trees, the method adopted is here given for what it is worth.

Of course, there is a great deal to be taken into consideration to insure success, especially if it be intended that the tree shall retain its foliage. If this is not a consideration, the top may be cut back, and the labour of removing considerably lessened; and thus the risk of losing the tree reduced to a minimum. If the tree is taken from a warm friable soil, and from a secluded position, and replanted in a position having all these favourable conditions reversed, success cannot be expected. If the soil is the only thing that is likely to militate against success, the unsuitable soil may be taken out and good soil be substituted for the reception of the tree. If the tree is removed from where it enjoyed all the moisture it required, and is placed in a dry position, and then neglected, total or partial failure will result. If the last condition is reversed, success is certain. Granted that these, and many other little matters which generally appeal to common reason, are carefully thought out beforehand, the work, instead of being a trouble, will proceed with a fascinating pleasure, and, having succeeded, the man is justly proud of his accomplishment.

A strong box, measuring 30 inches square by 20 inches deep inside measurement, will do for trees having a height of from 8 to 12 feet and a corresponding diameter measure through the top; 10-inch by 1-inch pine boards will do for the sides and ends. The ends of the box will be exactly 30 inches long; the sides will measure just 38 inches long. You will want eight pieces of 3 x 2 hardwood, 20 inches long; two for each corner. The ends of the box must be nailed on to the edge of the hardwood pieces; the sides to the hardwood on their flat, and all flush with the pine. You will observe the ends of the box are nailed to the hardwood on their edges; this brings the thickness to 4 inches at each end, so that, when the ends are put in, this takes up the 8 inches allowed on the sides, making inside measure 30 inches square, and outside 38 inches by 32 inches, with the four corners bolted together on the outside. Having made the sides and ends, stand the two sides up—the hardwood outside— and put in the ends, hardwood outside. This brings all the hardwood pieces flat together, with 1 inch thickness of pine between them. Now cramp the corners together on an even floor, and bore ⅝-holes 5 inches from the top and 5 inches from the bottom, and bolt together; 5½ inches by ⅝-inch bolts will do nicely. When you are nailing the pine to the hardwood, avoid driving nails where the bolt-holes will be, and be sure not to split the hardwood with the nails. Now you have a box without top or bottom as yet. These will be mentioned later on. You need not bolt one end in, as this will have to be done after it is placed around the tree to be taken up.

How the Tree is Taken up.—Place the three sides of the box round the tree, and bolt in the end. See that it is all tightly screwed up, and square it so that the trunk of the tree is in the middle. Now proceed to cut away the soil all round the outside of the box, and, as every 3 or 4 inches are removed, drive down the box with a wooden maul, striking on the hardwood corners. A little judgment will be necessary, as the sole object is to get a solid cube of unbroken soil compressed inside the box. Should you encounter stones that will be in the way of the box going down, they must be carefully taken out. As soon as you uncover a root, cut it clean through with a chisel and mallet, so that the bottom edge of the box does not grind on it as it goes down. If you sever the roots as soon as they are visible, and without removing any more soil, there is a firm bottom to cut on, and less injury will be done to the roots and cube inside the box. Continue cutting away the soil, and driving down the box till it is down level with the surface. (If the soil has been banked up around the tree, it should be removed and made level before the box is placed in position. Even then it may be found necessary to sink the box below the surface to get in all the side roots, but not to the detriment of the surface roots.) You may now nail on the cover, from which it will be necessary to cut out two half-circles to fit the trunk in. Pack some grass or bagging tight between the edge of the boards and the trunk to act as a fender to prevent injury to the bark. Having put on the cover, you may excavate 1 foot deeper all round the box, giving yourself plenty of room and keeping the loose soil well out of your way. Now undermine the box on whichever side you intend to let the tree down (for the tree and box must come down on its side so that the bottom may be nailed on). While you are undermining the box, and before you attempt to let down the tree, see that all the tap-roots are carefully cut through; for if any are left uncut when the tree comes down, they will pull the cube partly through the bottom of the box. This precaution will prevent unnecessary forms of speech and much waste of time.

It will be just as well to prop up the front of the cube to prevent the tree coming down unex-

pectedly. Of course, you see the necessity of clearing away plenty of soil to allow the top of the tree to fall into a hollow space. If this is not done the tree, when down, will lie at an angle which will make it very awkward to trim off the soil and roots. We will suppose the tree, with the cube inside the box, is now lying on its broad side. Then proceed to cut away all the soil that is protruding beyond the bottom edges of the box. Cut the soil off nicely square across, and then whatever roots there are can be sawn off level with the soil The bottom may now be nailed on and the tree up-ended.

If the sun is hot it soon suffers while lying down, for the under surfaces of the leaves are tender and quickly scald. Hence the necessity of getting the tree upright again as expeditiously as possible. Before beginning operations, it will be as well to have a look round to see how near you can get to the tree and which position will be best for getting it into the dray. You will want strong hardwood skids—4 inches by 4 inches by 18 feet long will do. The ends of these may be placed under the box before the tree is up-ended, with the other ends of the skids resting about 18 inches on the dray; a roller is placed on the bottom of the dray at the ends of the skids, it will land the box well forward with little effort.

The dray must be well propped up fore and aft, and the wheels can be left down into the soil to reduce the incline. If the ruts are dug out the shape of the wheels, it will keep all steady. The soil can be cut away from the front of the wheels when you are ready to start away with the tree. Greasing the skids will help considerably. All lever movements must be made with great steadiness and precaution, especially when the tree is about midway on the skids, for if too much play is allowed, and a gust of wind comes along at the same time, an accident may result. Pieces of 3 by 1 hardwood battens nailed on the bottom flush with the outside edges will keep the box nicely square on the skids while you are levering the tree into the dray, which to the uninitiated looks a dangerous job. These pieces of battens are just as useful to subsequently guide the tree down the skids off the dray.

To Plant the Tree.—Having placed the dray within about 15 feet of the spot where the tree is to be planted, put one end of each skid under the box, the other ends to reach the hole, but to one side of it then slide the box gently down the skids till it reaches the ground. Now turn it over on its broad side with the bottom of the box presented to the hole it is to be planted in, with 2 or 3 inches hanging over. Prise the bottom off with the crowbar, and up-end the tree. This requires small effort, as the top will about balance the box. The tree being now upright in its new home, you can take the nuts off the bolts, and prise the box asunder with the bar. Lift the pieces out, and fill in the hole round the tree. If, when you are prising the box apart, you see the cube of earth is likely to fall to pieces, remove one side only, fill in that side, then take out another, and fill that in till it is all done. If a number of trees are to be shifted, the top and bottom of the box should be bolted together instead of nailing. For this purpose use ½-inch iron rods screwed down 2 inches at each end with nuts and washers to fit. The rods will need to be 24 inches long. The bottom, in this case, should be hardwood, and the battens before mentioned can be permanently fixed on the outside boards. Whether the top and bottom are nailed or bolted on, it will be necessary to cut the boards longer than the width of the box to allow for any bulging that may possibly occur. If bolts are to be used, the holes should be slotted quite 1 inch long. Now, as the top and bottom cannot be put on at the same time, it will be best to screw on the top, temporarily putting the screws between the slots. The total cost of taking up and replanting a tree such as shown on the dray (box included), amounted to £2. One man succeeded in doing all the work of the tree on the dray without any help whatever.

[A precisely similar interesting process is adopted in Paris, where very large trees are often transplanted. The French foresters think nothing of transplanting trees 20 to 30 feet high with a corresponding diameter.—Ed. *Q.A.J.*]

ORANGE GROWING IN CALIFORNIA.

To those who are interested in fruit-growing, one of the most interesting sights in one of the two great horticultural tents in the late Paris Exhibition, was the display of fruit staged by the Arlington Heights Fruit Company. If one can believe literally every thing which has been said and written about Riverside "the greatest Orange growing district on earth," this place comes nearest to the earthly paradise of which the mediæval poets and prose writers dreamed and spoke, Its advantages are bewilderingly numerous, and, *inter alia*, "it has no millionaires and no paupers." The delights of Riverside, and the enterprise of the Arlington Heights Fruit Company are duly set forth in a dainty little pamphlet, and when our dear cousins across the water take up the cudgel—in this case it is a pen, we know that they are not going to be unpleasantly modest about their own achievements. The present writer would gladly respond to the "Greeting and invitation from Riverside," but the little pamphlet is silent on the "incidentals" of passage-money and hotel bills! But the facts quoted in the pamphlet are of very great interest, and California is undoubtedly a wonderful country, whilst "Riverside is the exponent and example of the highest development in California—material, moral, social, intellectual." He must be a cantankerous person who wants more than this. Mr. Chauncy M. Depew tells us that a man who owns 30 acres in California is a country gentleman. "He does just about work enough to keep himself in good physical condition and class from 3,000 dollars to 4,000 dollars a year. I know one man who makes 3,000 dollars a year on 10 acres of ground. They press the button, and Nature does the rest."

The orchard area of Riverside is 30 square miles, or 19,200 acres, in which are growing 1,536,000 Orange-trees, so that until some other district can adduce figures in excess of these, the claim of Riverside to be the greatest Orange-growing locality in the world must remain undisputed. These trees planted 20 feet apart, and the produce for this season is estimated at about 318,024,000 Oranges, and the product of this district is stated to be one-third of the output of the State. The money value of this enormous quantity is calculated at 6,000,000 dollars, or an average of over 671 dollars for every man, woman, and child, in the district. Although Oranges are chipped from Riverside every month in the year, the bulk of the crop is exported between Dec. 1 and May 1. Riverside is especially favourable for the cultivation of the Orange for it has all the essential elements of success; an ample water supply, the proper soil, the right altitude, and the absence of fogs. The selling value of Orange (bearing) groves vary from 500 to 2000 dollars per acre. The most favoured variety in the Riverside district—where indeed it may be said to have been raised—is the Riverside Washington Navel, the king of Oranges; it has stood the test of twenty-five years cultivation, and maintains its superiority.

Riverside, in its Magnolia and Victoria Avenues, possesses "two of the most famous avenues in the world;" their combined length is 20 miles, mostly through continuous Orange-groves, and within the limits of the city; whilst in the city park may be seen the largest and finest collection of Cacti in America, "if not in the world." *W. Roberts.—The Gardeners' Chronicle.*

RUBBER TRADE IN BRITISH GUIANA.

With reference to the report on the rubber-trees of the colony, Mr. Quelch said he found on enquiry that a report corresponding in detail to what the Society wanted, was being prepared by Mr. Jenman for the Government, and as it would be possible to secure copies of this report, all he had judged it desirable to do was to prepare a short report merely, which might be distributed in the meantime to those enquiring about rubber-trees. He then read the following report, for which a vote of thanks was passed:—

The rubber trees of the colony may be classed under two heads, namely, those that yield india-rubber proper or caoutchouc, and those that yield balata or guttapercha. In all cases, the product consists of the dried milky juice yielded by the trees when the bark is cut. Technically and economically, the differenees between the two products are very marked, and even in the rough state they are readily distinguished by the character that at ordinary temperatures india-rubber is always highly elastic, while balata is comparatively inelastic. For the collection of both balata and india-rubber in the colony, licences are required to be taken out, and a royalty is charged on the amount collected.

Balata is obtained from the well-known bullet tree (*Mimusops balata*), which occurs widely distributed in the lowlying lands of the colony, more especially in the Berbice, Canje, Mahaicony and Pomeroon districts. The trees reach a height of about 100 feet, and a diameter of from three to four feet, yielding a hard, heavy and durable wood. In general appearance, size for size, they are not unlike the sapodilia trees, to which they are closely related.

To obtain the milk, a series of oblique right and left cuts along the trunk, leading to a central perpendicular channel, is made, to the bottom of which a small clay cup or tin is fastened to catch the milk as it runs. The cuts should be carefully made so as not to damage the tree, and if properly done, they heal up within the space of about four years when the tree may again be tapped As the milk runs but for a short time, the quantity obtained at such bleedings is comparatively small, and it has recently been proposed that the edges of the gashes should be sliced off daily for a few days, by which larger supplies are obtained, care being taken not unduly to drain the tree so as to cause its death. Experiments in Penang on Para rubber trees have shown that by this means larger and larger quantities of milk are obtained for several days, and it is likely that this method is applicable in all cases of rubber production.

The séparation of the rubber from the watery milk is practised in many different ways: as for instance by drying in the sun, by artificial heat, by chemical precipitation, and latterly, it has been proposed, by centrifugal machines. It is claimed that the purest result is obtained by the last method; but hitherto artificial heat has been chiefly in vogue, and has generally been productive of the most satisfactory results. The balata industry in the colony has been greatly extended recently, more than 330,000 lbs. having been exported last year, though the amount fluctuates considerably from year to year.

Of the native trees yielding india-rubber proper, but little is really known. It is certain that several trees are to be found over the colony generally, of many different species, that yield rubber—presumably of commercial importance—but up to the present, little has been done to exploit this probable source of wealth. From the reports published by Mr. G. S. Jenman, Superintendent, Botanic Gardens, we know three of these rubber-plants from which small quantities of rubber have been obtained and examined, but larger quantities are needed before, from a commercial standpoint, they can be compared with the different kinds in the market. These three plants pass under the common names of "Hatie," "Touchpong," and "Macwarrieballi."

The "Hatie" (*Hevea spruceana*) is closely allied to the Para rubber-tree (*Hevea brasiliensis*), and grows in the colony in corresponding situations to its southern representative; that is, in alluvial lands more or less swamped and inundated at high water. The tree grows to a height of from 40 to 60 ft., with a diameter of about twenty inches, straight of trunk among other trees of the forest, but spreading and branching by the waterside where it is exposed. "The leaves are trifoliate, on long stalks crowded together towards the ends of the branches from between which the flower opens. The leaflets are entire, oblanceolate in shape, acute, polished green above and bluish green beneath. The fruit is a three-cornered capsule with seed of the size of a small nutmeg." The Hatie is common in the upper estuaries of the great rivers and in the various creeks leading therein, but the trees are always more or less scattered, though an abundance of young plants can be obtained in their neighbourhood.

The Touchpong (*Sapium biglandulosum*) appears to be a common tree both on the high lands of the interior and on the lowlands of the coast. Examples are met with in many parts of Georgetown where they are known by the common name of gum-tree. It is closely related to the Jamaica milk-wood or gum tree, and grows to a larger size even than the bullet-tree. It will readily be recognised by its broadly lanceolate, entire leaves, of from 5 to 9 inches in length, with two glandular spots, on one each side of the short stalk at the base.

The Macwarrieballi (*Forsteronia graeilis*) is one of the bush-ropes of the interior, where it appears to thrive in the more rocky and gravelly places. Mr. Jenman found it on the high ground near the Great Falls, Demerara River. It is closely allied to the milk-withe of Jamaica, and like that plant appears to produce excellent rubber. Being of comparatively small size, about 4 inches in diameter, the stem yields only a small amount of milk, but the milk is extremely abundant in relation to the size of plant.

Besides these three species, others such as the kumakaballi and the cow-tree are also known to be rubber-yielding, and in fact experiments are in course of completion at the Botanic Gardens for the identification of other species and their establishment in cultivation.

That foreign species of rubber trees can easily be established in the colony, is evident from experiments in plantations in Ceylon, Penang, and other parts of the world; but seeing that one of our native forms is so closely allied to the Brazilian plant that is noted for the production of the best rubber, it would seem to be worthy of enquiry whether our own species is not equally valuable. The subject certainly deserves serious consideration.—*Timehri*,

DRAINAGE OF LAND.

Too much attention cannot be paid to this subject. Artificial draining is the primary part of successful agriculture, and even in the early days of Rome, the draining of land was extensively carried on.

HOW TO KNOW WHEN DRAINING IS NECESSARY.

1.—Whenever after rain water remains in the furrows or stump holes.

2.—When the soil sticks to your shoes or horses' feet and farm tools.

3.—Whenever you see water in the footprints of a horse or other animals.

4.—When animals sink deeply into the soil.

5.—When the rays of the sun form a hard crust on the soil.

6.—Whenever after heavy rain the little holes in the ground show more water in them than in other parts.

7.—If after rain a stick is put into the ground and taken out, water will rise in the hole.

8.—If crops will grow better when land is gathered up into small ridges

In the first place we get rid of the stagnant water, both on the surface and below it. Stagnant water has an injurious effect on vegetation, it is deprived of its oxygen, and while it remains in the soil it prevents fresh water from taking its place. Water held in suspension is detrimental to plant life and must be kept moving, it also opens the soil and lets the air in after it. The theory of draining is well illustrated by a flower-pot with a hole in the bottom, the water will either give life or death to the plant; it gives life when it can pass through the pot, but plug the bottom up and let the water stop, and death is the result.

SOME BENEFITS TO BE DERIVED FROM DRAINING LANDS.

1.—Draining removes stagnant water from the surface and subsoil.

2.—It lengthens the season, well-drained land can be worked much sooner after rain.

3—It deepens the soil.

4—It warms the soil by stopping evaporation.

5—It equalises the temperature of the soil.

6—It carries down soluble substances to the roots of the plants.

7—It prevents injury from drought and wet.

8—It improves the quality and quantity of the crops.

9.—It increases the effect of the manures.

10.—It prevents the heaving of the soil.

11—It helps to prevent disease in plants.

12—It increases the general health of the locality.

A good soil, with a gravel subsoil, need not be drained, but with a stiff clay subsoil it is necessary. The deeper the drains are the further apart they may be placed. Before commencing to lay down a system of drains; an outlet for the main drain must be found, and the drains marked out so as to give the necessary fall, a fall of 3ins. in a 100ft. will be sufficient, the bottom of the drain must be kept smooth and must be carefully graded. Care must be taken to avoid, if possible, bringing the subsidiary drains in at right angles to the main drain, as this impedes the flow of water at every junction. The main drain should be made amply large enough to carry off the water from all feeders. Great difference of opinion exists as to the depths of drains, they vary from 1½ft, to 6ft., much depends on the nature of the soil, retentive soils require deep drainage, the deeper the drains the wider they may be apart—*Journal of the Jamaica Agricultural Society.*

PLANTING NOTES.

MR. J. H. BURKILL, an assistant in the Herbarium at Kew, and formerly in that at Cambridge, has been appointed assistant to Dr. Watt, the Reporter of Economic Products, Department of Agriculture, in Calcutta, and will leave this country in January next.—*Gardeners' Chronicle.*

LARGE SHIPMENT OF APPLES.—We learn from Boston, U.S.A., that some two or three weeks since the largest shipment of Apples on record was made from that port for Liverpool. This shipment consisted of 28,285 barrels of all the best varieties suited for the Christmas market. —*Ibid.*

LINNEAN SOCIETY.—On the occasion of the evening meeting held on Thursday, December 20, 1900, at 8 p.m., the following papers will be read: 1. "On the Structure and Habits of the Ammocharides," by Mr. Arnold T. Watson, F.L.S., &c. 2. "The Flora of Vavan, one of the Tonga Islands," by Mr. T. H. Burkill, M.A., F.L.S. 3. "Warning Colours in Insects," by Prof. E. B. Poulton, M.A., F.R.S., F.L.S.—*Ibid.*

A WONDERFUL IRIS.—Mr. Peter Barr writes to us from Victoria, regarding a new German Iris staged by Miss Love at a local show:—"Those who visited the Tatura Show on Wednesday, October 17, must have seen Iris Painted Beauty. It was conspicuous in the fine, but crowded, box of cut flowers staged by Miss Love, of Tatura, and was, during the day, the cynosure of the exhibits. Its beauty was of a very exceptional, marked, and distinct character. An expert gave it as his opinion that no Iris of so much refined beauty had ever before been seen in this or any other country. It belongs to the group commonly known as German Iris. The flower is pure white.—*Ibid.*

"FROSTING" SHRUBS.—Your correspondent, "W. C.," will find the following method satisfactory if carefully followed out. Procure a tub or pail according to the size of the shrubs or branches to be treated, put in enough whiting and water to make it of the consistency of paint, then add enough liquid-size to make it adhesive —about a pint to a pailful of mixture; well stir it together, and keep it stirred while using. Having the shrubs ready at hand, dip them in the mixture, then let the superfluous stuff run off; having ready a flower-dredger containing "Jack Frost Powder" (which can be purchased at any good fancy shop), and sprinkle the shrubs there with while moist; let the dressing dry gradually, and keep them in a dry place till wanted. Small pieces of the common Gorse dressed in this way, and placed in pots or dishes with a groundwork of small Ferns and moss, make a striking contrast to small Codiæums and Cocos Palms for the decoration of the dinner-table for the Christmas season.—A. S. COLE, Moncreiffe Gardens, Bridge of Earn, N.B.—*Ibid.*

THE CHARDUAR RUBBER PLANTATION, ASSAM.

RESULTS OF TAPPING.

Mr. J A McKee, Conservator or Forests, Assam, has recently published a report giving the results of tapping operations carried out in compartments 3. 4, 5, 6, 7 and 8, etc., of the Charduar Rubber Plantation in the past season of 1899-1900.

AREA AND OUTTURN.

2. An area of 474 acres, containing 6 810 trees, was worked over, yielding 4,502 lb. of clean and dry rubber, as per detail below, and it should be noted that the trees in compartments 3 and 4 were tapped for the second year in succession, having been also operated on in 1898-99:—

		Acres.	Trees.	Clean rubber yielded. lb.
Compartment 3	...	1·66	25	24
Do. 4	...	94·31	1,499	863
Do. 5	...	126·84	1,849	1,176
Do. 6	...	77·25	1,116	889
Do. 7	...	80·39	1,060	833
Do. 8	...	73·73	980	657
Roadside trees	...	20·00	281	60
Total	...	474·18	6,810	4,502

COMPARISON WITH THE PREVIOUS SEASON'S OUTTURN.

3. The above figures give an average outturn of 9·5 lb. of clean rubber per acre and ·66 of a pound of clean rubber per tree. In the previous year, the figures of outturn were very similar, being 9·4 lb. per acre and ·52 of a pound per tree, the outturn per tree being reduced by the Bomani Hill Plantation containing 8 acres, in which the trees are planted much more densely, and are, therefore, smaller than at Charduar, the actual density being 92 trees per acre in the former compared with only 14 per acre in the latter. It is, however, noteworthy that the Bomani Hill area yielded 9·5 lb. of clean rubber per acre, or about the same quantity as the average outturn for the whole area of 322 acres worked over in the season of 1898-99—a fact which tends to prove (the trees being of equal age) that a densely-planted area does not yield more rubber than one sparsely planted—while, on the other hand, it must have cost more to plant out originally and to establish as a going concern —see also remarks in paragraph 15.

OUTTURN OF TREES TAPPED TWO SEASONS IN SUCCESSION.

4. Compartments 3 and 4, which were tapped for the second season in succession, yielded practically the same outturn as in the previous year, the figures for compartment 4, containing 1,499 trees, being ·60 and ·58 of a pound of clean rubber per tree for the first and second year respectively, while the few trees (25) tapped in compartment 3 this last season yielded ·96 of a pound per tree, as compared with ·70 of a pound per tree obtained from the entire compartment in the past year, the greater outturn this season being doubtless altogether due to the fact that the trees operated on were specially selected ones.

METHOD OF TAPPING: DIFFERENT TOOLS USED.

5. Mr. Copeland, the Deputy Conservator of Forests, under whose careful personal superintendence and management all the operations were carried out, reports that tapping was commenced in the first week in December, or six weeks earlier than in 1898, the object being to escape the rain, which, however, does not seem to have been effective, rain having fallen off and on during the whole tapping period. It is also reported that three different tools were employed on the work, compartments 6, 7 and 8 being tapped by Nepalese and Assamese, in the old and usual manner, with *kukris* and *dhaos*, whereas compartments 3, 4 and 5 were tapped by Garos with half-inch carpenters' gouges introduced for the first time as an experiment. The gouge was worked with a small mallet and is reported to be the best of the three methods, as it does not damage the tree so much as the *dhao* or *kukri*, shallow wounds, only bark-deep, being made, instead of the deeply incised and jagged wounds caused by the last-mentioned tools. In this connection, it is important to remember that the rubber cells are located in the inner bark layers, and that to obtain the *latex* flow, it is unnecessary to wound any portion of the cambium. It is, therefore, expedient that the tapping tool employed should be capable of being controlled and guided to a greater extent than is practicable with a *dhao* or *kukri*, which can be used only with a forcible, and, oftener than not, a damaging cut.

6. The plantation was inspected by the Conservator as recently as the 13th of the present month, when it was observed that bark was already forming over the gouge cuts, that is to say, within eight months of the tapping operations, and it seems safe to predict that these kinds of wounds will be thoroughly healed twelve months after their first infliction. The *dhao* cuts, on the other hand, take longer to heal, and compartments 1 and 2 that were tapped in January 1899, are only now recovering from the operation. Roughly speaking, it may be stated that these kinds of cuts take six months longer to heal than those made with the gouge.

COMPARISON OF RAW OUTTURN OBTAINED BY DIFFERENT TOOLS.

7. The outturn of raw, uncleaned rubber obtained by the different methods was slightly in favour of the *dhao* and *kukri*, compartments, 6, 7 and 8 yielding ·79 of a pound per tree, as compared with ·65 of a pound per tree yielded by compartments 3, 4 and 5. But the slight difference of outturn in favour of the *dhao* is more than counterbalanced by the greater damage caused to the trees, while it is reported by Mr. Copeland that the loss in weight caused by the extraction of foreign matters is in favour of the gouge—the actual ratio based on the results of carefully weighing the first two days' tappings being as three to 5. Unfortunately, the clean rubber obtained from the different compartments was subsequently not kept separate, when it became impossible to correctly differentiate between the clean outturn resulting from the use of the different tools, and the figures exhibited under this head in Statement A attached are considered to show results too favourable to compartments 6, 7 and 8, at the expense of compartments 3, 4 and 5.

NEW TOOL RECENTLY DESIGNED.

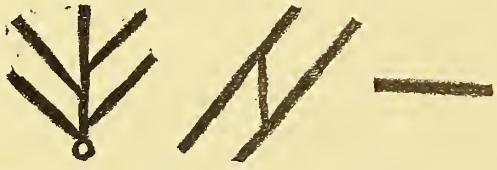
8. In this connection it may be noted that, with the help of Messrs. Ahmuty & Co., Calcutta, a new kind of gouge has lately been made, which promises to turn out better for the work than either of those above mentioned.

LOSS OF WEIGHT BY INTERMIXTURE OF FOREIGN MATTERS, &c.

9. Considering the figures relating to loss of weight, owing to cleaning and drying, as a whole, it would appear that, on the raw material as first collected, this loss came to about 5½ per cent—a proportion which compares favourably with the results of the previous year, when this form of wastage amounted to as much as 9 per cent, and which proves that some factor was present in the season's operations which tended to raise the quality of the raw outturn obtained.

DIRECTION IN WHICH CUTS SHOULD BE MADE.

10. The cuts were made horizontal or only slightly oblique, it being noticed that the wounds bled in proportion to their horizontal direction, and that any considerable deviation from this direction resulted in a slower and reduced flow of rubber. Experiments on untapped trees were made personally by the Conservator with the view of testing this point, arrow-shaped (the Brazilian method), oblique, as well as horizontal cuts being made, when it



was very apparent that the *latex* flowed far more freely from the last kind than from either of the others. No examination of the bark or bast has yet been made to test the cause of this observed fact, which is not in agreement, it is believed, with experiments made elsewhere on rubber-yielding trees and plants of other species.* But an enquiry will be instituted with the help of Dr. Watts, the Government Economic Reporter and the Director of the Forest School, with the view of obtaining information on the point. In the meantime, it seems safe to hazard the opinion that the rubber cells must be placed in more or less vertical rows, and that, in fact, in arrangement they resemble somewhat an arterial system, when it will be readily understood why a horizontal cut must be much more effective in tapping their contents than a vertical or oblique cut of equal length.

RUBBER RESIDUUM AND WASTAGE DISCUSSED.

11.—Another point was tested at the same time by the Conservator, which perhaps helped to create the opinion that the tapping operations, as performed in 1898-99, were of an unnecessarily careless or wasteful nature. Allusion is here made to the fact that, when the rubber is stripped from the cuts, a milky, and sometimes copious, residuum runs out of the wounds down the tree, and as no arrangement is made to collect this overflow, the impression may have been carried away that it represented wastage. But the Conservator was able to prove to his satisfaction that this residuum, which closely resembles rubber-milk in appearance, contains no caoutchouc, and is capable of being practically absorbed by blotting paper or of being evaporated in the sun. In fact, it consists practically of little else than water and contributes no appreciable proportion of the true wastage, which seems to be wholly represented by that portion of the *latex* which spurts out of the wound during the actual process of tapping and overflows on to the trunk or branches of the tree, or is sprinkled or drips on to leaves or undergrowth at its base. But all this apparent wastage is carefully collected and cleaned, and although it sells at a greatly reduced rate in the London market, the proportion it represents to the quantity of clean, good material collected is not of any great importance. This last season, this particular kind of rubber amounted to 128 lb. weight out of a total 4,502 lb. of clean material obtained, or rather less than 4 per cent; and it was sold separately in London at 1s 10d instead of 3s 7d per lb, which is equivalent to a gross loss (excluding charges) of R165 on a possible R10,844, or about 1½ per cent.

FINANCIAL RESULTS ON RUBBER SOLD IN LONDON. 12.—The financial results of the operation were decidedly satisfactory as will be seen from the following figures :—

	£	s.	d.
4,323 lb. of clean rubber (reduced in London to 4,280 lb.) were sold at 3s 7d per lb.	766	16	8
128 lb. of ground rubber (reduced in London to 122 lb.) were sold in London at 1s 10d per lb.	11	3	8
Add—Interest, 7 days on £201-5-0	0	3	10
Total receipts	778	4	2
Deduct—London charges, including freight from Calcutta	59	17	11
	718	6	1

	Rs.	a.	p.
Equivalent at exchange of day	10,732	12	3
Deduct—Calcutta charges	52	15	9
	10,679	12	6
Deduct—For plantation charges, tapping, cleaning, packing, freight to Calcutta, etc.	3,839	2	0
Net profit	6,840	10	6

A net profit, therefore, after deducting all charges, of R6,840 10-6 was realised on the 4,451 lb. of good and inferior rubber despatched to England from the Plantation, which is equivalent to R122-15-3 per maund of 80 lb. or Re 1-8-7 per pound as compared with Re 1-2-3 per pound realised last year.

OTHER RUBBER. 13.—Besides the above rubber sent to England for sale, a balance of 51 lb. was disposed of in the following manner, which will make up the total 4,502 lb. obtained from the season's tapping operations—see paragraph 2—

Sent to Reporter on Economic Products, Calcutta		10
Do	Agricultural Chemist, Dehra Dun	2
Do	Curator, Government Garden, Nilgiris	½
Do	Ranger Venkatramana, Forest Department, Madras ..	1
Sold locally for R51-8-0 ..		35½
Kept as sample in stock ..		2
		51

TAPPING CHARGES AND BROKER'S REPORT ON QUALITY OF RUBBER. 14.—Full details of all figures discussed above will be found in Statement A attached to this report, and in this connection it only seems necessary to draw attention to two more points, *viz.*, the reduced expenditure effected on tapping operations and the favourable report of the London Broker on the quality of the

* Vide *Indian Forester*, XXVI., page 317.

rubber forwarded for sale. In regard to the first point, it should be noted that, in the previous season, an item of R1,198 was incurred on the purchase of coal tar for smearing over the wounds caused by the *kukris* and *dhaos*, partly as a heal ing application, but chiefly as a preventive or check on illicit tapping that might subsequently be made on the trees that had been worked over departmentally. This last season no expenditure has been incurred under this head, as it seems doubtful that the application of tar is of any utility and the danger of illicit tapping is not considered sufficiently great to justify the considerable expenditure above mentioned. By eliminating this part of the original procedure, and by reducing the actual expense of tapping, the cost on the material landed in Calcutta was reduced from R94 to R70 per maund of 80 lb., the actual figures being as follows :—

Cost of	3,363 lb. of rubber obtained in 1898 99	R3,967
Do	4,502 lb. do do in 1899-1900	3,839

With regard to the second point mentioned above, Messrs. McLeod & Co. of Calcutta, through whose firm the rubber was despatched to London and sold, write as follows :—

"People who have examined our parcel inform us that it is the finest stuff ever seen here from Assam. Last year's shipment could scarcely be improved upon in matter of cleanness and condition, but this parcel is more presentable, the packing being better done."

Doubtless, the better packing in *acme* tea boxes lined with cloth, instead of despatching the product in bags, as was done in the previous season, had much to do with the better price paid, 3s 7d per pound having been realised as against 3s 4½d in 1899.

SUPPLEMENTARY EXPERIMENTS.

15. In a Statement B, which is not here reproduced, Mr. McKee gives a detail of the girth and crown or spread measurements of 10 per cent of the trees that were tapped last season. The results are interesting so far as they go, and tend to prove, as might be expected, that the outturn of rubber is in proportion to the spread of the trees. Abstracted, the figures give the following results :—

Number of compartments.	Total number of trees measured.	Total girth measurements.	Total crown measurements. Maximum diameter.	Total yield of rubber of measured trees, in tolas.	Remarks.	
		Ft.	Ft.			
1	2	3	4	5	6	
					Spread per tree.	Outturn per tree.
						tolas
4	100	1,064	6,416	3,362	64' ...	33¼ = ·83 of a lb.
5	162	1,446	9,844	5,414	61' ...	33½ = ·83 ,,
6	95	703	6,035	3,896	63' ...	41 = 1·00 ,,
7	96	649	5,815	3,769	61' ...	39 = ·97 ,,
8	97	475	4,487	2,281	58' ...	29½ = ·73 ,,

The girth measurements of the trees are so difficult of being made in a uniform manner, owing to air roots which form supplementary stems having a tendency to anastomose, that the figures under this head may be ignored ; but if the figures relating to the average spread, of trees in the different compartments are compared and it is borne in mind that the trees in compartment 4 were tapped for the second year in succession, it seems that, as above stated, the largest outturn is obtained from the trees having the best and widest crowns.

RESULT OF TAPPING TREES THREE YEARS IN SUCCESSION.

16. Another interesting statement is that attached to this report as Appendix C, which shows the result of tapping 21 good selected trees in compartments 2 and 3 for three years in succession, 1896-97, 1897-98, and 1898-99. This experiment should have been commented on in last year's report, but seems to have escaped observation. Abstracted, the results were as follows :—

Number of trees.	Yield in lbs.		
	1896-97.	1897-98.	1898-99.
21 ..	46	48	9

and they seem to prove that, although the first two years' operations will yield nearly equal outturns—agreeing in this with the figures quoted in paragraph 3 for compartments as a whole—there then, in the third year, comes a terrible falling off of 75 per cent. And as the trees in question, for the most part, are specially good specimens, and, in fact, are the dominant trees in compartments 2 and 3, the experiment should warn us to be very careful in working over the plantation too frequently, in successive years, without giving the trees sufficient time for recuperating from their former tappings. The figures also prove that the small quantity of rubber yielded per tree by our tappings must be considered the maximum that can safely be extracted from them at present. Mr. Home's estimate of 2 lb. per tree made when forecasting the outturn of 1898-99 was evidently of too sanguine a nature for the compartments as a whole.

FUTURE OPERATIONS.

17. With the meagre information as yet at our disposal, it is not safe to arrange for work more than one year in advance. Next season, therefore, it is proposed to tap compartment 4 for the third year in succession, with the object of verifying, in a more decisive manner, the results obtained from the limited experiment mentioned in paragraph 16 and recorded in the attached Statement C. But should the results of tapping the first 100 trees of this compartment show conclusively that the outturn is much smaller than on previous occasions, the work in this area will at once be stopped. In addition, compartments 9, 10 and 11 of the Charduar Plantation, containing 251 acres and 3,490 trees, and the eastern block of the Khulsi Plantation, containing 88 acres and 2,400 trees, will be tapped for the first time. The Charduar trees will be 19 and 20 years old and those at Khulsi 23 years old, and it expected that they will yield, at the rate of 9 lb. per acre, a total of 3,051 lb. of clean rubber fit for despatch to London. Subsequent operations should be guided greatly by the result of tapping compartment 4 for the third year in succession. If the outturn is poor, it will, I think, prove that, in the present condition and age of the plantation, it is only less wrong to tap the trees two years than three years in succession, and the practice should be discontinued, As a tentative measure, under these circumstances, three years' rest should be

allowed to each area after having being tapped over. On the other hand, if no bad results follow, the re-tapping of No. 4, compartments 1, 2 and 3 that were last tapped in 1898-99 may be again operated on in 1901-1909, as well as compartment 4 for the fourth year in succession.

CONCLUSION.

18. In conclusion, the following deductions have been made from the points brought out by the figures and observations discussed in the above report. In some cases these observations still require more proof before they can be formulated as rules for the guidance of future operations; but it seems convenient and likely to be useful to attempt such deductions as a means of attaining steadily, if gradually, to a correct method of plantation management:—

(1) That in the present condition of the plantation, only about 9½ lb. of clean rubber per acre can be safely extracted from the trees at one tapping (see paragraph 16).

(2) That a densely-planted area does not necessarily yield more rubber per acre than an area of the same age in which the trees are relatively much fewer (see paragraph 3).

(3) That the out-turn of a tree in rubber seems to be in proportion to its crown or lateral spread (see paragraph 15).

(4) That a carpenter's gouge or a modification of this tool is best adapted for tapping, as it does less damage to the trees than the *dhao* or *kukri*, and enables the rubber to be collected with a smaller intermixture of foreign matters and dirt (see paragraph 5, 6 and 7).

(5) That only horizontal cuts should be made during the tapping process, as neither oblique nor vertical cuts yield the same quantity of rubber (see paragraph 10).

(6) That the expensive application of tar to the wounded trees is not justified by any commensurate result, and may be discontinued (see paragraph 14).

(7) That so far as experiments have been made, there are grounds for believing that the trees cannot be tapped three years in succession without showing signs of exhaustion, and that if this is proved to be correct, it is also probably only less wrong to tap the trees two years in succession (see paragraph 16 and Statement C).

(8) That neat and careful packing has an important effect on the selling price obtained for the rubber in the London market (see paragraph 14).

—*Indian Forester.*

THE VALUTATION OF RAW RUBBER.

BY H. L. TERRY, F.I.C.

Probably there is no other body of similar importance or intrinsic value which is bought and sold on less scientific lines than is india rubber in its various qualities, and it can be asserted with confidence that in the case of no other regular article of merchandise has less progress been made in the way of putting the sale and purchase on a scientific rather than "rule of thumb" basis. Not that there is anything to be wondered at in this when we consider all the facts, the problem to be solved being undeniably one of considerable perplexity, but all the same, seeing the progress that has been made with regard to putting the sale of other organic products on a scientific basis, it might have been supposed that something would have been attempted in the case of rubber. As my present title may lead the reader to imagine that I am here about to propose some scheme to effect the desired result, I may as well put in a disclaimer at once, my present effort being limited to a few casual remarks on the subject generally, though it is hoped that such remarks may not be entirely without interest, even if their perusal fails to throw a gleam of light into the gloom that still surrounds the matter in the minds of those who are more competent to hold forth on it than I am myself. In using the term rules of-thumb, I do not wish to be understood as doing so in a derogatory spirit, because, even if the case is not similar in all trades, there is no doubt that the practical man who uses his senses of sight, smell and touch is in the rubber trade often superior to the scientist. For an opinion of value on many rubber products it is much

safer to consult a foreman of long experience with the particular class of goods concerned, than it is to refer to the scientific man unless the latter, which is not always the case, has studied the manufacture closely in the works. And this seems to hold just as strongly with the raw rubber; at the present time this is bought by the practical man who employes his senses alone and extreme caution should be evinced by those who say that this position of affairs is all wrong, and that rubber should be bought and sold on chemical analysis.

Now, as regards chemical analysis, everything depends upon the sampling. Unscrupulous mining agents can get any result they wish from a gold reef by omitting to work upon a really average sample for their assays. This sampling is a matter really of great complexity and occupies a considerable amount of time, but its importance cannot be exaggerated. At the Rio Tinto copper and sulphur mines in Spain, the sampling, in order to get a representative assay, is carried out in a very comprehensive manner, the company priding themselves on the effectiveness of the system which they have worked out. With rubber, the case is very similar unless a really average sample were taken from bulk, the results of the chemical analysis, say the determination of dirt, water and resin, might easily be very misleading. No doubt, with proper methods, an average sample could be obtained, but at what cost of time and labour? Rubber is much more difficult to work than is the case with the general run of minerals, and where time enters largely into the question, the difficulties, in my opinion at least, in the way of getting an accurate valuation of a few tons of African ball rubber would be found practically insurmountable. In some cases where the quality is pretty uniform, the chemical method might prove of utility, but we have to remember that uniformity is the exception rather than the rule, so we must base our calculations accordingly. It certainly seems desirable that some agreement could be come to between dealers and buyers as to the amount of water in raw rubber; at present, where the amount of water varies to such an extent, it is rather like buying a pig in a poke. The subject has before now come up for discussion in the correspondence columns of this journal, but I do not remember that anything definite was come to. Not so long ago I remember reading of a case in London, in which a rubber firm made a claim for loss of weight, the difference between the weight invoiced and that actually delivered being accounted for by the water which had percolated the cask. I forget how the claim resulted, but the point is an important one. If some arrangement could be come to with the exporters to send the rubber on board ship with a maximum of, say 10 per cent. of water, there would be an advantage in freight charges, and it would certainly prove an easier matter for the purchaser in England to arrive at the value of the shipment. As the case stands at present, the commoner qualities of rubber are bought in a rather speculative way, and it becomes of importance for the management of the works to estimate their value for the several purposes to which it is intended to put them. Now, here considerable progress has been made compared with former years, though it must be confessed that the very elaborate methods of testing which have been worked out at some of the German works have not commended themselves to the trade as a whole, the suspicion having gained ground that unless you have a scientific staff employed at a low rate of remuneration the time and trouble involved in carrying out the tests are not justified on the score of expediency. It may not be without interest to give a few details of the testing system, as carried out, or said to be carried out regularly at one of the largest German rubber works. The apparatus employed is very similar to that used in testing textiles or metals; that is, a weighing machine. to which is attached an iron rod with a grip, and at the other end an iron rod with a grip, worked by a cog-wheel, as in the ordinary lifting jacks. This explanation may not be particularly clear, but it is difficult to describe machinery in a few words or without the advantatious aid of diagrams. Fine Para is taken as the standard, and its stretching power and resistance to rupture ascertained, and a series of comparative tests are made with other rubbers, in which way it can be ascertained whether a particular rubber tested is not too dear, compared with Para reduced to the same standard. For instance, when the rubber tested is found to be 35 per cent. under the quality of Fine Para, while its price is only 25 per cent. under, an indication of moment is obtained. For mill purposes, a table is made showing the stretching and resistance to rupture of the various compounds and is referred to on occasions when it is proposed to alter the composition of the mixings. In this way it is found possible to avoid any variation in the quality of the goods, moreover, these tests, it is said, have proved useful in the case of claims brought against the firm for supposed defective work. This brief account of what is done in some quarters in Germany will suffice for the present occasion; it is a good illustration of the scientific bent of the German mind, and in this case, there is every reason to suppose that advantage accrues from its adoption. The German passion for detail, however, is not always justified by results, and the Englishman is apt to treat its excesses with but scant respect. I am open to correction in the matter, but I do not think that the German method of testing rubber finds its counterpart in England, though I am not at all inclined to say that it could not be introduced into our works with advantage. Some years ago I adopted a comparative method of testing the value of washed raw rubbers, depending on the melting points. Naturally the rubber which contains the most resinous constituents melts the soonest, and the relation between tensile strength and melting point is a very close one. The table which I made naturally commenced with Para and ended with African Flake, the other brands of rubber taking up their positions at intermediate stages. In this way, by strict attention to details of time, best results of value can be obtained, showing not only the difference which exists between the various brands of rubber, but also to what all extent variations occur in the tensile strength of rubber which is always sold under one name, and which is commonly supposed to be of uniform quality. There is no doubt that failure to recognise the differences existing in the quality of rubber is a fruitful source of trouble, because it leads to incorrect vulcanisation. Especially is this likely to be the case where the goods are submitted to mechanical tests of great stringency, as, for instance, in the case of buffers for certain of our railway companies, and it is a fair presumption that trouble which has occured in the past might have been obviated if the rubber, previous to mixing, had been put through some sort of test, such as indicated above, to enable an opinion to be arrived at with regard to its exact quality. In the absence of such testing, there must always be an element of chance about the results of vulcanised mechanical rubbers as regards the important particular of tensile strength, and when trouble arises it is rather too much the tendency to put the blame on some workman or other, whereas it is more probable that the real cause lies in the failure of the workman's superior to recognise that the time of vulcanisation, or the percentage of sulphur might have been altered with advantage. However it may be said that here I am somewhat transcending the limits of my subject, though it is always permissible when advocating a change of policy or procedure to state clearly in what direction benefits may be expected to accrue from the innovation. The subject as referred to above, is clearly seen to come under two heads, which have little in common, viz: the testing of raw rubber before purchase, and the test-

ing by mechanical means, of the purchased rubber to ascertain its fitness for particular purposes. At the present time, there does not seem much prospect of any improvement being effected in the first case; in the second case, however, it seems of moment that rubber manufacturers should seriously ask themselves the question as to whether the time and trouble which are devoted to the matter in Continental works are justified or not by results. It is a question which cannot be answered offhand, but only in the light of results, and I am not in a position to give what may purport to be a decided opinion one way or the other. I may, however, by way of commentary, remark that the trouble involved, to say nothing of the capital outlay on testing machines, should be in proportion to to the output of the factory in the class of goods which the tests are ment to benefit; in other words as the same emount of time and trouble in testing would be necessiated for the filling of a small order by a small factory, as in the case of a Government or railway contract by one of our largest manufacturers what would be justifiable in the latter case might not be so in the former, as the expense incurred would not bear proportionately on the cost of production. There are other points, of course, that call for consideration, but the limits of space preclude my saying more on the present occasion, so I lay aside my pen with the hope that these remarks may severe as an incentive for some more competent writer to give the journal the benefit of his views on the subject.

THE GARTON LECTURES ON COLONIAL AND INDIAN AGRICULTURE.

PROFESSOR WALLACE.

The Inaugural Address on Famine in India.

INDIA AND CEYLON.

Introduction.—General view of Agriculture of India, including the main features of the Presidencies and other great political divisions—Bombay, Madras Central and North-West Provinces, Punjab, Bengal, Assam, Burmah, and Ceylon—with special reference to Geology, Soil, Irrigation, Climate, Peoples, Famines and Chief products.

Tillage Implements.—Indian Ploughs, Native Harrows, Hoes, Seed-drills, and Hand Implements. European Implements and their suitability or unsnitability to Indian conditions.

Cultivation and Crops.—Rotations and Mixtures. Tillage before and after sowing. Seed and sowing. Harvesting and preparation for market. Commercial uses. Diseases and Injuries. Classification of Crops into Cereals, Pulses, Oil Seeds, Fibre, Fodder and Miscellaneous Crops, with special reference to the production of Wheat, Barley, Rice (Paddy), Maize, Millets (*Juar Bajra* and *Ragi*), and Sorghum—Gram Horse-Gram, Lentil, Pea, Ground Nut, Rape, Linseed Caster-cil Plant, Sesamum—Cotton, Jute, Ramei, and Hemp—Lucerne and Guinea Grass, Sugar-cane, Tobacco, Cinchona, Tea, Coffee, Indigo, Poppy—the commoner valuable Grasses of India, and their cultivation as practised at the Allahabad Grass Farm and other milstary stations in Northern India—Grass Cutting—Haymaking—Silage.

Irrigation,—Land and other conditions snitable and unsuitable for irrigation. Location and relative advantages of Canal, Well, and Tank (Lake, &c.,) Irrigation. Quantity of Water necessary for various crops and time of application. Water lifting appliances—The common leather bucket, the Persian Wheel, the Picotta (lever lift), and the hand scoop lift.

Manures.—Village refuse, Nightsoil, Cattle Manure (partly used for fuel), Ashes, Bones, Fish Manures, Saltpetre, Green Mannre, Castor seed refuse.

Live Stock.—Characteristics of Indian Cattle—Mysore, Kistna River, Gujarat, Kankreji, Nagar, Sind, Hurrianab, Malwi, Deccan, Southern Maratha, Konkan, Kanevarya, Goranea, Bagondha, Madras Red, Trichinopoli, Gir, Nellore, Kangam, and Cinhalese—value as working and milch cattle. Buffaloes—Jaffarahad Gujarat, Nagpur, and common breeds—their general characteristics and special milking qualities. Horses and Mules. Goats and Sheep. Common Diseases of the Domesticated Animals.

EGYPT.

Introduction. Physical features—Soil, Climate, Population. The Fellahin or cultivating class.

Irrigation.—The Rise and Overflow of the Nile—The Ancient Basin system of Upper Egypt—The Indian Canal System introduced into Lower Egypt—Drainage—The system of washing Salt Land.

Manure.—Pigeons' Dung—Ashes Sabakh (Crude Saltpetre).

The Chief Crops.—Divided into Winter, Summer, and Autumn Crops, with special reference to Cotton, Sugar-cane, Barsim (Clover), Wheat and Barley, Maize—Rotations and Methods of Cultivation.

THE SMALLER CROWN COLONIES.

Main Points of Interest in—West India Islands, British Guiana, the Straits Settlements, Uganda and other African Continental Possessions and Islands—Islands in the South Atlantic and Pacific Ocean.

Miscellaneous.—Relations of the Agriculture of the Colonies and India to that of the Mother Country—Exports of Agricultural Produce, &c., from the Colonies and India, with special reference to Earth Phosphates, Bones, and other manures, rozen Meat, Cotton, Grain (including Wheat), Tea and Coffee, Sugar, Fresh Fruits, Spices, &c.

MANILA HEMP AGAIN.

Manila Hemp is not hemp at all, but it is the fibre of the *bark* of a species of plantain tree; its botanical name being *Musa textilis, Nees* and belongs to the *familia Musacea.* This fibre is produced only in these Islands, although no effort has been spared to produce it in Borneo, Java, Sumatra, India, New Guinea, Australia and Africa, but without success. Formerly when it was shipped direct to the States it was invoiced as *Plantain Bark Fibre,* but during the past 40 years it has been called Manila Hemp. Its value was early recognised by the American whalers who used to frequent this archipelago over 100 years ago. Before the days of steam, when the crack American clipper ships ran between Liverpool and New York the smart appearance of those ships with their sails of snowy cotton duck and riggings of Manila Hemp contrasted very strongly with the British ships with their canvas sails and Russian Hemp rigging. Nothing in the world equals Manila Hemp for running rigging as it does not rot nor harden when wet like Russian hemp and its lightness and strength as compared to Russian hemp made it a valuable article for standing rigging before the days of wire rigging. Formerly an American Steam Cordage plant was located at Santa Mesa and the huge 12 and 16 inch hawsers for towing up the Hoogli to Calcutta were made here, as well as the famous whale line used by the Pacific whalers, which was shipped to San Francisco and Honolulu. The United States navy has a rope walk at the Boston Yard and the cordage for the navy is made there ont of Manila hemp. The manufacturing of cordage is a very simple matter, but it requires the services of men who know their busines and they receive high salaries. The Manila hemp tree requires a pecular soil and a certain amount of moisture and sunshine, without these three conditions the fibre is valuless, besides the tree has to be cut down at a certain period of its life otherwise it is nseless for hemp purposes. The natives go into the Lates or hemp plantations is gangs generally of two men, a woman and a boy. One man fells the trees or "ponos," the woman trims the trunks and the leaves, and splits them into the requisite length, the boy carries hese slabs to the other man, who with his crude contraption

separates the film from the pulp. The hemp is then dried in the sun, and sold to the owner of the Late. On average days work for a gang of three persons is about 25 lbs. of cleaned hemp. The cleaning of the fibre from the pulp is very severe labor, and a man can only work at it for 3 days in the week, the earnings are very small and the life of a hemp cleaner is a short one, as a rule. These uneducated natives go into the nearest hemp Late, clean up the hemp and deliver half to the owner as his share, then sell to him the other half as their share. The owner of a hemp Estate has no sinecure, if he starts a new plantation and sets out his "ponos" he will have the monkeys and wild hogs to contend with: the former pulling them up to see if they are all growing and the latter rooting them up for food, what is left over requires from two to three years to mature, and during this period the "Late" must be kept clean from the rank growth of a tropical jungle in order that the young trees may receive their proper nourishment, then comes the tussle with the men, and if there is anything a native detests it is clearing a hemp estate from weeds. Up to the present time no appliance has been invented to cleanse the fibre from the pulp, and it remains to be seen if some cute Yankee" can get up such a labor saving machine. Fully 60 @ 75 % of the hemp finds its way eventually to the States where it is in great demand for "binder twine" for the wheat fields as well as for the boring of artesian and oil wells, to say nothing of the demand for cordage. The principal competition it encounters as a "binder twine" factor is the "sisal" grown in Yucatan, but a wheat farmer will readily pay double the price for Manila twine in preference to sisal, although the implement company may assure him that the latter is "just as good," but a smart wheat raiser knows better." When the railroad through Siberia is completed, and the rich "steppes" along the line are converted into wheat fields, a new market may result for Manila hemp.—*Manila Times.*

DATE PALM PLANTATIONS.

In his annual report the Couservator of Forests, writes as follows in reference to the date palm plantaions in the interior:—I am glad to report that the date palms in the far north continue to develop in a most satisfactory manner. Progress has been especially marked in the seedling plantation at Lake Hamy, as well as among the Algerian palms planted there. The seedlings are now from 3 ft. to 5 ft. high, and their general growth has been so uniform that a person working among them can only partly be seen. Many plants of either sex have also flowered. The Algerian palms have made great progress; some are quite 10 ft. high. They have developed numerous suckers, and is anticipated that some of these will soon be strong enough to transplant, and thus increase the existing number. Sufficient fruit was borne by one or two this year to show that a fine sample of superior quality may be ultimately expected when they get into full bearing. Unfortunately the only one remaining of the two received from Algeria, which were marked as being male palms, has now turned out to be a female, and it produced a few dates this season. This is to be regretted, has had there been a male of exactly the same kind of date, the use of its blossoms as a means of fertilising the others would have rendered it highly probable that the fruit subsequenely yielded by seedlings raised from the dates these palms produced would have shown little if any departure from the original excellent type of date. Fortunately, however, a parcel of fruit was obtained from Tunis last year through the courtesy of Professor Perkins, the dates from which are very similar in character to the "Deglet Nour" date from Algeria, and as seedlings are being raised from this seed the loss sustained will be somewhht modified.

The palms at Hergott continue to thrive and dates have again been ripened there, this being the eighth season that this fruit has been produced in the north. The occurrence of light rains, however, during the ripening period rather affected the quality of the dates this year, as the unbroken continuance of a dry arid heat is indispensable to the thorough perfection of the dates: but as this is a very exceptional experience at that time of the year it may be a long time ere it occurs again. A further effort has been made during the year to increase the number of seedlings in the experimental plot at Oodnadatta. On November 27, 1899, 236 seeds, which were obtained from Tunis, as already indicated, were sown there by the foreman [Mr. N. W. Wilson,] and most of them germinated, but only 24 were found to be living when he again visited the block on April 30, 1900. This number, however, with those that were alive the preceding year total 36, and with a little more attention it is expected that the area will be stocked quite full enough.

As the train goes up from Hergott and back only once a fortnight it will readily be understood that the intermittent nature of the rail service renders operations here very difficult, and necessitates leaving the plants to take their chance, as under present circumstances a resident officer cannot be maintained without incurring too heavy an expenditure. But while this retards the ultimate completion of the plantation it affords valuable evidence as to what may be expected when the seed are simply sown and left to themselves, which it was the object of the experiment to sow.

The number of palms at Hergott and Lake Harry on June 30, 1899, was 3,013. The total increase from seed at Hergott for the year ending June 30, 1900 was 9; and at Oodnadatta 36. The total alive at Hergott on June 30 last was 277; at Lake Harry, 2,475; and at Oodnadatta, 36.—*Adelaide Advertiser.*

BANDA NUTMEGS.

An Indian specialist, describing Nutmeg gardens in Banda, says: "The agreeable scent which is wafted from the wood invites us irresistibly. The high canary, warringin, and teak trees act as a protection against heavy showers and gales for the conical Nutmeg trees whose foliage is formed by pointed leaves hanging down from the branches shooting out regularly Between the shiny foliage sparkles the ripe open fruit of which the dark brown nut is the kernel, while the bright red mace envelops the nut as an elegant network. Occasionally we meet in the wood with bamboo bushes and other vegetation. Sweetly blows the cool air, invigorating and bracing is the scent of the Nutmeg, while the wood echoes with the merry voices of men and women gathering Nutmegs, and children picking canary nuts, mingled with the various sounds of the cooing nut-pigeons (manoek faloer,) parrots, the Indian nightingale (baikolie), the canary-yellow karajamoe."

A peculiarity of the nut-pigeons inhabiting the Archipelago is that they swallow the fruit bodily and discharge the nut whole and undigested. This curiosity, which no doubt leads to the distribution of the plant, was formerly connected even with its sex as shown in Vogel's remarkable passage; "If the bird that drops the nut is a male, the tree growing from it will be male too; if the bird is a female, the tree will be a female as well, whilst if the bird happens to be still a virgin, the tree that grows from the swallowed nut will be one of the best in the woods."

Whilst nature produces 100 male against 100 to 200 female trees, it is a fact that only the female yield fruit. On the whole the latter bear fruit when ten years old, but their produce at that age is still small. In the year immediately following, the produce increases rapidly, gradually again more slowly, until the highest point of production is reached between the twentieth and twenty-fifth year continuing undiminished during twenty-five years. Only then, about its

sixtieth year, a decrease may be noticed. Many trees, however, reach a much greater age; some of them are said to complete a century.

The Nutmeg trees bear blossom and fruit without intermission, in every stage of ripeness, and so nuts may be gathered all the year round. The greatest abundance, however, falls during the months of July and August.

The Nutmeg itself is the kernel of the fruit, which is pear-shaped, of the colour of a peach, and consists of four parts; the outer fleshy part, then the membranous substances covering the shell of the Nutmeg and known to commerce as mace, then the shell, and finally the kernel or actual Nutmeg.

The greatest care is required in gathering and handling the fruit. Twenty-four hours after the opening of the fruit—a sure sign of its ripeness—the nut will drop to the ground, thus injuring the mace-network and deteriorating its proper quality, as its lying on the soil makes it apt to become wormy. On the other hand, the closed fruit may be still unripe, and knocking these down would be highly injudicious.

Work commences at 5 o'clock in the morning at the ringing of a bell, when men, women, and boys and girls over sixteen years go out into the woods armed with the gaaigaai—a long stick with a prong at the end—to break off the ripe fruit and a basket to carry the collected nuts.

The wood is the all-in-all to the labourer. It is his place for work and recreation. It is his club, and even the spot where the young man seeks his future wife when the overseer is out of the way, notice of whose approach is kindly given by the friends of the young couples imitating the call of the nut-pigeon as a danger signal.—*New York Merchants' Review.*

RICE THRESHING AND HULLING IN INDIA.

The Indian cultivator cannot be expected to understand the scientific cultivation of rice, nor can the Indian *bunniah* be expected to realise the value of mechanical threshing and husking, or hulling, of rice. From time immemorial the paddy has been threshed and husked by the most primitive methods, which the people of the country have found good enough to meet their requirements. The importance of labour-saving machinery is not yet appreciated, and we can quite understand that a mechanical contrivance costing a thousand rupees, and intended for the purpose of the husking rice, is looked upon as an expensive luxury. But when it is realised that such a machine pays for itself in one year, and after that is a source of clear profit to the owner, land-holders will begin to see that it is to their advantage to invest in such a labour-saving and money-making machine. In such matters, however, it seems to be generally accepted that if the *Sirkar* were to take the initiative in introducing labour-saving machinery in Wards' Estates and show the advantage to be gained by such, the neighbouring zemindars would have an opportunity of seeing such machines at work, and thus be induced to invest in them to the advantage of their own as well as their ryots' pockets. We are led to these observations by a perusal of a most interesting article in the *Journal* of the Jamaica Agricultural Society for July 1900, on the cultivation and treatment of rice in Jamaica, by Rupert H. Lindo, a perusal of which will repay anyone interested on the subject.

After describing the cost of land, etc., selection of land, cleaning and preparing land, nursery for rice plants, planting out and reaping (all of which opperations are fairly well understood in this country), the writer goes into the questions of threshing, drying, hulling and preparing for market. Threshing is performed in this country by the ancient method of trampling by cattle, but were a threshing machine used out here, one small machine, worked by a small engine of two horse-power, could thresh 170 bushels per day of eight hours, each bushel, say, of 40lb., or equal to 6,800lb., equal to 170 maunds per day. Compare this with the outturn of the *ryot* by the old method, and we get some idea of the value of a steam thresher.

The writer of the article under reference then proceeds to describe hulling and preparing for market, and we cannot do better than quote his own words. He says: "This is the most important part of the process for treating rice, and it is the point that we have been aiming at from the very start; for, besides growing rice successfully, the next thing in importance is to place the paddy in the best condition possible for the huller to handle. Of course, one can always resort to the old mortar and pestles [these are used in India.—ED., *I. G. & P.*], but what can they do with 20 acres of rice yielding 1,200 bushels of paddy? The huller I use is of the 1895 patent, and is made by the Engleberg Huller Company of New York, and cost, landed in Jamaica, £60. They are pefect machines, all things being equal." The writer then gives detailed instructions as to how this machine is to be used, and suggests the central factory system for threshing and hulling rice. Such a system would seem to be well suited to this country, as the small tenants and cultivators cannot be expected to invest in a costly machine. The threshing and hulling could be done on the same principle as the cane-pressing is done all over Behar by the proprietors and patentees of the Beheca Sugar Mills. For an innovation of this kind to be successful it is essential that it should be initiated by the Government, as the people have faith in any undertaking that the Government patronises.

Those who desire to introduce mechanical threshing and hulling may be interested to know that the 'Engleberg" Rice Huller, so strongly recommended by Mr. Lindo in the article under notice, can be had at Calcutta from Messrs. Macbeth Brothers and Company, 2, Pollock Street, whose advertisement has been appearing in our pages for some weeks past. The price of a single Huller complete is R1,100.—*Indian Gardening and Planting.*

ACKNOWLEDGMENT.—A paragraph appears on page 336 of the *Tropical Agriculturist* for November 1st, which is taken from the *British and Colonial Druggist* without acknowledgment, we regret to find. The paragraph is headed "The Camphor Corner."

LIMES AS A GERMICIDE.—It may not be generally known that fruit acids are germicidal, but the information is of special value to planters generally. The juice of lime and lemon is as deadly to cholera germs as corrosive sublimate, or sulphur fumes, or any other disinfectant. It is so powerful a germicide that if the juice of one lime or lemon be squeezed into a glass of water, that if then left standing ten or fifteen minutes, the water will be disinfected. It makes little difference where the water has been obtained, or whether it has been boiled or filtered. This is a fact worth knowing, for anyone may at any time find himself under circumstances in which it is impossible to get either boiled or filtered water. In such a case the juice of a lime or lemon will purfiy the water perfectly.—*Indian Planters' Gazette.*

COFFEE UNDER A CLOUD.

[You might like to make extracts from the enclosed cutting taken from a recent number of the London *Globe*.—J. HUGHES.]

In a particular sense, the fragrant beverage has for many years past been most appreciated in this position. The affinity of coffee with "the weed" is an ancient discovery. There is a Persian proverb which declares that coffee without tobacco is meat without salt; while the Arabs say that a dish of coffee and a pipe of tobacco are a complete entertainment. And probably the majority of "men who dine" would agree that no dinner can be regarded as complete without the presence of those comfortable peace-makers at the end of it. For some time past, however, coffee has been under a cloud of far greater density than that raised by the worshippers of my Lady Nicotine. It is admittedly an exquisite beverage; but there are fashions in the best of good things, and even perfect institutions at times come under their sway. For the moment, coffee has almost entirely lost its domestic claims to consideration. Its presence on the breakfast-table is exceptional; and as for coffee at the great event of the afternoon—where is it? Or, to go a step farther with the cynic, what is it when it is there? We need not pause for a reply. As a social factor, the annual consumption of less than three-quarters of a pound of coffee per head of the population of Great Britain is quite insignificant. It leaves us, so to speak, at the very bottom of the coffee-tree the top of which is reached in Holland; the Dutch, with an allowance of twenty-three pounds per head, being by far the greatest coffee-drinkers in Europe. In England, therefore, coffee is now passing through a phase of almost total obscuration. Doubtless it will presently emerge, perhaps, to become again the radiant centre of social life. Of course, the connoisseur—the man who "feels" a cup of perfect Moka as a youthful poet does his first sonnet—still gets his coffee as of old. The majority, however, are obviously indifferent; they are content to wait till the cloud rolls by.

The praise of coffee has been so universal that its merits may well be taken for granted. More curious is it to trace the leading cause of its decline. And that which probably underlies all the multifarious reasons assigned is the fact that its preparation involves a little more care and trouble than tea. Ours is a trouble-saving age, and we are apt to adopt what is nearest and readiest. What is not easily done is easily left undone. Given good tea to begin with it is difficult to be at cross-purposes with the teapot. An optimist has even declared that "nothing is easier than to make good coffee." But he is manifestly in error; it is easier to make bad. To say that "the dullest girl can be taught to make good coffee in three lessons" is against the common experience of domestic life. But as a rule the coffee-maker is not solely in fault; the common failure of the beverage to attain a reasonable standard of excellence is due to more than one cause. Determined, however, to agitate in this useful branch of reform, and starting with the planter's maxim, "old coffees, young teas," there is no reason why ordinary householders should not mature the bean in their own store-closets. It should be kept raw, and preferably in small bulk; the grateful aroma being due to a volatile oil which is developed in the process of roasting. If kept too long afterwards the flavour deteriorates, but even this may be to some extent received by carefully heating the ground coffee before use. The connoisseur declares that coffee should not be boiled, nor even allowed to "stand" for any length of time. And this, indeed, is the very crux of the question. Of course the delicate aroma and fine flavour may be entirely lost by excess of boiling; and it is to avoid such a contingency that the expert assures us that "right" coffee should be a simple infusion, instead of the too customary decoction. Unfortunately, however, the experts themselves are largely at variance on this point. Some of the most experienced makers allow their coffee to "boil up" for a single minute, and with a most satisfactory result. Others—among whom was Brillat Savarin—simply infuse their coffee like tea. In short, scarcely two persons make it in precisely the same way at all points, nor is there any royal road to this great achievement.

A FARMERS' EVERY-DAY LIFE.

NO. 15.

(By Cosmopolite.)

THE HARVEST.

How delightful it is to sit at one's "ain fireside," listening to the howling of the wind in the chimney and the ceaseless patter of the rain on the window; and to know that everything on the farm is secure, the stacks in the yard, trim and cool and already for a harvest thanks-giving, as soon as the clergy may think proper to announce such a day of fasting. I know that all my neighbours cannot be in this equable frame of mind, but I speak for myself on this occasion, and am thankful that I have got through this rainy harvest so successfully, although it has been an anxious time whilst it lasted. The peripatetic steam mills are engaged night and day thrashing out the heated stacks of the careless farmers, and the price of grain is going down by leaps and bounds. In a month or so all this par-boiled grain will have been worked off the market, and then I hope the price will go up again, and those who have good grain to sell, may get a fair price after all. There are great complaints about the grain turning out short in quantity, to the extent of a sixth of the expectations and I am, therefore, somewhat anxious to have a day's thrashing, so as to get a fair idea of my probable outturn. It is a very amusing thing to hear some old farmers talk (especially after their third or fourth nip) about the wonderful crops they have grown in their time, and the grand prices they got for them whereas now—alas! alas!! Comparisons are sometimes painful. But what imagination some of those old fellows must surely have particularly on the subject of

OAT CROPS

about which they expatiate with overwhelming eloquence. I suppose it is true that as one grows older one's pleasure is chiefly found in reminiscence and so those farming raconteurs must find it a relaxing pastime to babble about their past history and achievements, giving play to their fancy as they embroider the details of some specially enjoyable narrative. Why has no eminent author sprung from the ranks of the agriculturists—one who could give to the world, at a popular price, an edition of stories gathered on market days or in the peaceful retirement of the publican's booth? Such a book entitled "Fairy Fancies from Frivolous Farmers" would, no doubt, sell well and become a standard work on the shelves of all village libraries.

During the past few weeks the great

SHORT-HORN SALES

of the North have been much in evidence, and exceptional prices have been agoing, the purchasers having been chiefly Foreigners, Englishmen and Colonials. The top average was secured by Mr. Duthie, of Colynie, with £150 8s; but even unknown breeders made averages of £50 and £60. Although the best short-horns in Britain are bred in Aberdeenshire, this is not the class of cattle mostly kept by our farmers, the black-polled being the fancy breed of the district, and the one that has carried the name of Aberdeenshire to the front at every show of beef-producing cattle that has been held in Britain. Since McCombie of Tillyfour carried everything before him, at Paris, with his Black-Polls from Aberdeenshire, the breed has never gone back, and these still remain the champions of the World.

In every agricultural paper, as a matter of fact, the greatest number of articles and the greatest amount of space is taken up with the subject of

DAIRYING.

Now, there is no doubt about it that money is made by dairy-farming, but neither easily nor pleasantly. One hears a great deal about the joys of a dairy farmer's life; the buckets full of frothy milk, and the mild-eyed cows, chewing the cud as they cheerfully give up the lacteal fluid to their kind friend, the dairyman. But there is another side to the question, and one about which I have lately been cross-examining a dairy farmer,—a man who has gone through the whole curriculum, from under-milkman to boss of the milk buckets, and his views are, I think, likely to interest my readers. The ordinary routine of this dairyman's work is as follows:—He rises at 3-30, milks about a dozen cows; washes himself in icy-cold water; takes a hasty meal by the dim religious light of a candle; drives off to town, a distance of five miles, and distributes the milk to his customers before seven o'clock, this being done in the dark during the winter time, unless when a moon happens to be on the *tapis*. He gets home again, just when most people are about to break their fast, and then he proceeds to cut chaff for a few hours, a horrible grind, which, however, gives him plenty of exercise. Then he has to milk the cows again, and, in the evening, feed them and get his own supper. After that he has six hours in which to clean himself, get ready for next day's work and try to get some sleep, and no sooner has he fallen into a sound sleep than he hears the usual morning call and knows that it is half past three. Now this jolly sort of a life goes rolling on, not for five or six days, but for seven in every week, and so, I think, no one should grudge the dairy-man his profits, when the miserable existence which he leads is made known. I suppose I am the only farmer in Britain who buys his milk, in preference to keeping cows, as I find it more profitable to do so; and also because the work of the farm goes on more smoothly without the irritation connecetd with a lot of dairy cows.

COFFEE, CINCHONA AND CARDAMOM PLANTING IN SOUTH INDIA: THE KANAN DEVAN DISTRICT.

SIR,—In your issue of October the 20th, you reprint from the *Investors' Review* without comment an article on the "Kanan Devan Produce Company, Limited." I hold no brief for Sir John Muir or his Companies, have nothing to do with them in any way as a shareholder, or otherwise, and am as much disposed as anybody to criticise much of their action and policy. I have no doubt Sir John Muir and his co-Directors can take care of themselves as regards this attack and as clever-headed businessmen know what they are about. But the article in question is likely to harm the prospects of the Kanan Devan District generally, both as regards its credit and its position towards the Madras and Travancore Governments. For, although the Kanan Devan Produce Company own the greater part of the Kanan Devan District, there are some private owners as well holding a considerable acreage of land, and, although not dependent on the Company, the outsiders' future is, to a certain extent, bound up with its prosperity, or otherwise. This is emphasised by the fact of there being a Planters' Association in existence consisting of the Company's representatives and the outsiders, of which I have the honour to be President.

My opportunities for judging of the Company's prospects and properties are therefore considerable and are augmented by the fact of my having been for nearly twenty years a resident planter in the district. I am not prepared to take the pessimistic views of the writer of the article in question, and, in justice to the credit and welfare of the district, I trust you will allow me to state my reasons in your columns.

The figures quoted in the article, and which are no doubt correct, are, as they stand, misleading. No statement of the age of the area opened is appended, and one would be led to suppose that almost the whole of the acreage is unproductive. This is not the case, as operations by the Company were commenced in 1894. While the estates purchased, several of them at very low prices, date back many years previously, there are at present on these Hills and belonging to the Company 3,000 acres in mature bearing and 2,000 acres in partial bearing; 7,800 acres are immature. The reserve forest and grass in this district is some 100,000 acres. The latter is ignored in the article! In Assam, I believe, the Company hold between 2,000 and 3,000 acres of tea and some 7,500 acres of first class freehold forest.

It should be recollected that a practically new and difficult district has been opened up and that enormous difficulties of transport have had to be and have been successfully overcome. Thus, for instance, the capital outlay includes 34 miles of cartroads with tramways, a wire ropeway from a ghaut of over 6,000 feet to the low-country and ⅔ cost of 10 miles of a cartroad in the low-country, the latter designed and built to take a light railway.

But the benefits of this liberal initial outlay will hereafter be apparent in many ways quite apart from the fact that any more land opened in the future will be capable of being brought to bearing point at an expenditure of not more than £20 per acre. The estates have been carefully blocked into large areas and well conneeted and traversed by good roads and will, therefore, be easy of management and superintendence. The number of factories required will be reduced to a minimum. The cost of transport of tea and other produce down and estate requirements up will be rendered as low as possible, and thus only will produce be able to compete with other districts, more favoured as regards

situation. It has been carefully calculated that the cost of a lb. of tea, f.o.b., will not be more than 25 cents. Thus, while produce will be put on the market at a low rate, it should be remembered that all the tea will be high grown from 4,700 feet to 6,500 feet, that it is all grown in magnificent forest land and that therefore both yield and prices should be high. It is true that, at present, prices realised are not very sumptuous, but this is partly due to Travancore teas not as yet obtaining the attention they deserve in the market, a position that will remedy itself as a larger supply creates a larger demand; partly it is due to inadequate factory accommodation, a matter which is being remedied as fast as possible; partly it is due to all the tea here being young and giving a cup of insufficient flavour and strength. The fact that the Company possesses considerable Cinchona estates in full bearing is slurred over in the article; these should, during the present year alone, give a nett profit of some £23,000. Speaking generally the estates and the district should be seen and compared with others of a like age before an attempt is made to criticise the Company's present position and future prospects. Armchair criticism of figures is an easy matter, but no doubt, these figures were carefully considered before they were sanctioned and undertaken.

But it is further impossible to look upon this large concern merely from the point of outlay representing so and so many acres opened. There are the huge reserves of land not yet dealt with and they represent a large share in the capital outlay, dormant at present, but which will in time undoubtedly be utilised. Thus, apart from the reserves of forest suitable for coffee, tea, and cinchona, there are large areas of land suitable for rice and other food products where some day the Company will be able to grow all that is required to feed its estate labour.

Then there is a large area of higher grass land in the Kundalé valley close to the wire rope outlet, eminently suited for a Hill station sanitarium situated at 6,000 feet above sea-level with a rainfall not exceeding 50 inches with magnificent scenery and well watered by the clearest and coldest of streams, this should become a favourite retreat for the man from the plains. For this to come about and the land to become valuable for settlement purposes, the long-deferred railway from Ammayanaykanur will first have to appear. But as that also will again mean a reduction in the cost of tea, f. o. b., there is no doubt Messrs. Finlay, Muir & Co., will see to its coming. Then there is the magnificent water-power, at present running to waste, but some day, though perhaps not in the immediate future, to be utilised in conjunction with the almost pure iron lying beside it. In conclusion, it is my belief that, in spite of the large capital drawn attention to in the article, the estates being well opened will pay well and that many years will not pass before this is one of the most flourishing among Planting Districts.

J. VON ROSENBERG.

—*Planting Opinion*, Nov. 17.

CINCHONA PROSPECTS.

We direct the attention of all interested in cinchona (and we are glad to think the number is increasing in Ceylon) to the long letter given in our last issue—with which Baron von Rosenberg, of North Travancore, has favoured us. Our correspondent is well-known as one of the most enterprising planters of cinchona trees in Southern India, and as a proprietor who, through good and evil report, has adhered to his first love and who has therefore, merited a better return for his capital and labour than has, we fear, as yet been secured by him. But the Baron well knows that he is only one among many thousands of planters who failed to realise their expectations in cinchona. No more romantic story has ever been written in connection with planting enterprise in the tropics than could be penned in the history of cinchona planting in India and Ceylon from the day Clements Markham—still hale and hearty in England—brought the first precious plants from far Peru to the Nilgiris and Hakgala, forty years ago. At first utterly despised as only a "medicine" plant by the ordinary tropical planter, or put out as a quick-growing, handsome shrub for avenue or wind-belt purposes,—with the failure of coffee and the harvesting of the first bark from the said belts, (realising as much as 10s per tree nett of crop), there came a wild rush into "cinchona" with the disappointing result only too well remembered even now in Ceylon. Not only were planters bitterly disappointed, if not ruined, when the enormous export in one year from Ceylon of fifteen million lb. took place; but cinchona dealers and brokers in London—who at one time monopolised and made a good thing out of the trade—found themselves utterly at sea in their estimates and with large unsaleable stocks in hand, and had to wind up and disappear. Even quinine manufacturers suffered severely and several factories also disappeared. If ever, therefore, any men had full warning as to the need of caution, they are the planters of cinchona, the dealers in bark and the manufacturers of quinine; and yet our correspondent today thinks a further and special word of warning not to be out of place. He holds that we are in now for a period of decreased production extending over the next five or six years—and this we can quite believe—and simultaneously, that the demand for quinine during this same period is likely to increase steadily. The "unit" should, in our correspondent's opinion, be well maintained if not increased during this period, and that would enable planters to do justice to their trees, and would also encourage further and careful planting, especially in India and Ceylon. There is much good sense in all this. We have to guard, on the one hand, against a temporary "boom" in prices leading to a rush into harvesting and even into "prospecting" in South America; and on the other, against such a fall as would discourage planting altogether. Baron von Rosenberg thinks that the happy medium is found in 2½d. as the price per unit in bark and 1s. 6d. as the selling price per ounce of quinine. If that be the case, long may such rates be maintained. Our correspondent winds up by giving a much-needed warning as to the seed used by cinchona planters. That seed generally has deteriorated, is only too true. We think that seed from old trees in Java, Ceylon and India should only be used when interchanged and that none should be utilised in the country of its growth, except under entirely new conditions,

Still better would it be to get a fresh supply of seed from Peru or Bolivia, if the collection and carriage were feasible at a moderate outlay. As regards "planting" we know that a good deal has been done in Ceylon in a quiet way this year. One proprietor in a favorite district is planting twenty acres with cinchona and doing all possible justice to the experiment; while others are following our advice about planting up boundaries, the sides of paths, ridges, &c., with the graceful cinchona chiefly of hybrid or officinalis varieties. May a full measure of success be attained in these experiments.

TOBACCO AS AN INSECTICIDE.

An authority in the Antipodes gives, in the *Agricultural Gazette of New South Wales*, the following advice as to best way of using the ordinary dried tobacco leaf as an insecticide: "For aphis, the roots of the affected trees are bared, and the tobacco, ground to powder, is dusted well over the roots and ground about them. A ring of tobacco dust is put round the trunk of the tree just below the surface. The earth is then thrown back, and when rain comes the nicotine is washed out of the tobacco, and gets spread over the roots, killing all black or woolly aphides with which it comes in contact. Secondly, as a wash: one pound of waste tobacco will make about four gallons of wash, and half pound of soap is added to make it more adhesive. The leaf can be steeped in cold water over night, and the soap boiled up and added; but most orchardists boil up the leaf and soap together straining the resulting liquor and applying it hot. Tobacco is a contact poison, and is the best known remedy for soft-bodied things like aphides, but it does not affect scale insects very much, when they are full grown and protected by their shelly outer covering. If tobacco wash could be sprayed on to the larvæ of scale insect it would destroy them wholesale."

FRUIT &c. IN WEST AUSTRALIA.

It has been said that "Westralia is all Sin, Sand, Sorrow, Sore-eyes and Sir John Forrest." This is certainly most untrue. I have been on a visit to the Great Southend Agricultural District (on the Railway Liue from Perth to Albany) and have seen enough to convince me that the precious ore is not the only attraction in this vast land. I stayed for about a week at Rataning, a great farming centre. The crops on many of the farms are magnificent and the orchards, it would be difficult to equal anywhere. I saw fruit orchards on which not a drop of water has ever been poured and over the whole area of which one could travel and not find a withered leaf. The abounding vigour of all

THE TREES AND VINES

is the outstanding fact that attracts the attention of most visitors. Oranges do not do well but apricots, apples, cherries, almonds, &c., are in their element—the two former doing splendidly. I saw cherry trees that you could not touch with your hand without touching fruit. These cherries fetch one shilling per pound on the ground. In an orchard that despatched 33 tons of grapes last year I could not discover a single "supply" among the vines, though I went round twice. A Homestead Farm of 160 acres can be had in this district for £1. Of course, the canny Scot is here, and there are 19 Macdonalds alone in this one district.

LIME AS A FERTILISER.

Lime is a good fertiliser, but not for all plants. It is beneficial to some, injurious to a few, and indifferent in result to others. "Farmers' Bulletin" No. 77, issued by the United States Government Agricultural Department, gives good information on this subject. From it we gather that the following are some of the plants which have shown marked benefit from the use of lime. Spinach, lettuce, beets (all kinds), gumbo (okra), salsify (vegetable oyster), celery, onion, parsnip, cauliflower, cucumber, egg plant, cantaloupe, asparagus, kohl-rabi, cabbage, dandelion, Swedish turnip, pepper, pea, peanut, martynia, tobacco, sorghum, alfalfa, clover, barley, wheat, oats, timothy, and Kentucky blue grass. Not only was the crop greater, but in many instances it was ready for market much earlier where the soil was limed. There was at least two weeks' difference in kohl rabi in this respect. Tobacco not only made a much better growth when limed, but the ash was much lighter in colour. Those that are injured by liming are suradella, water melon, blue lupine, and common sorrel. Standing between the two groups of plants given above are a number which when they are supplied with all of the nitrogen they required in a readily assimilable form such as nitrate of soda, show little or no benefit from liming. Among those are Indian corn, common millet, Hungarian golden millet rye, potatoes, carrot, Rhode Island bent (grass), and redtop (grass). On a very acid or sour soil even those plants would be benefited by lime by virtue ot its helping to change the nitrogen into readily assimilable nitrates, provided sulphate of ammonia, blood, tankaje, fish, cotton seed meal, plant-roots, etc., were present as sources of nitrogen. Intelligent farmers in malarious districts may make their own choice from the above facts and be properly guided in the use of lime for agricultural purposes.—*Indian Agriculturist*, Nov. 1

HYBRID FRUITS.

An article on "Conifers," in a recent number of the *Speaker* mentioned the immense improvements which careful selection and cultivation have made in flowers and fruits: but the vast promise which the hybridisation of fruits seems to hold out was not mentioned—that is crosses between fruits of the same class. One may, perhaps, wonder whether something of the same sort might not be attempted between vegetables. A few years ago an enterprising amateur gardener and fruit-grower at Blandford had some hybrid fruits—crosses between mulberries and raspberries, blackberries and raspberries, strawberries and raspberries, &c. Perhaps it was prejudice, but I thought the unerossed fruit superior. The other day, Mr. Forrester, Lord Portman's steward and a famous and successful cattle-breeder, showed me some very fine hybrids, called Logan berries, between the raspberry and the blackberry. They were darker in colour than raspberries, and much larger and longer, and really very nice eating, though use has much to do with one's appreciation of flavours. The Loganberry is reported to be an American hybrid between the red raspberry and the blackberry. The berries are of enormous size, fully as large as the largest blackberries, which in form and structure they resemble. They are deep reddish-maroon in colour, melting and without a core, and very firm. Gathered, or on the bush after being ripe, they keep a long time without spoiling. The flavour is rich and sharp, with a dash of the raspberry and of the blackberry, mellowed, and refined, but distinct from either, and so luscious, novel, and agreeable that the Logan berry cannot fail to become a great favourite as a dessert fruit, while as a preserve it is said to be unequalled. The canes are strong and vigorous, semitrailing in habit, and very prolific. They fetch 2s. 6d. each, or 24s. a dozen, but no doubt should

they get into general favour prices would fall materially before long.

A paragraph in the *Times* not long ago is suggestive and interesting: its substance is somewhat as follows:—At a meeting this summer of the Royal Horticultural Society, a fruit was exhibited for the first time which bids fair to become very useful. Botanically, also, it is of considerable interest, the plant bearing it being a hybrid between the raspberry and the common blackberry. As the "Mahdi," as it is called, was raised by Messrs. Veitch, its origin is well authenticated, the seed parent being a variety of the raspberry known as "Belle de Fontenoy." The same cannot be said for the Logan berry from the other side of the Atlantic, though for this a somewhat similar parentage has been claimed. A high authority is of opiuion that the raspberry plays no part in its composition, and that both its parents were and American species of Rubus. This may be so, but cooked Logan berries are certainly much more like raspberries than blackberries, and have none of the tartness of the latter, but closely resemble the former. The "Mahdi" has very much the habit of the blackbeery, and in cultivation is trained in the same way. Its frus, says the *Times*' writer, recalls the dewberry of our hedges. There is the same bloom, but the number of fruitlets is greater. Careful investigation reveals many intermediate characters—for instance, the flavour of the "Mahdi" combines a preponderant influence of the dewberry with a suspiciou of the raspberry. The present writer would therefore hold that its parentage would differ largely from the Logan berry, though the latter when cooked resembles a luscious raspberry, the blackberry flavour being hardly perceptible. Most important is the time of fruiting as regards the economical future of the plant, for it comes into bearing as raspberries are failing and before blackberries are ripe; but the finest berries are produced early in the season—about the middle of July, that is. The "Mahdi" is very prolific and has considerable claims as a decorative plant: it would not, however, be placed upon the market for probably at least another twelve months.

The Japauese wineberry (*Rubus Phoenicolasius*) is another recent introductiou to our gardens and should be mentioned here. It bids fair to be a great acquisition to our gardens. Properly cultivated the plants bear a quantity of delicious fruit, which ripens well in a warm corner. The plant itself is hardy. It resembles in growth the blackberry, but the foliage is larger, with silvery reverses to the leaves, and the thorny stems have a deep crimson-brown tint, and are decidedly handsome. Until about half-ripe the fruit is concealed by a crimson, hairy, calyx-like covering, protecting it until it is as large as a fine blackberry; it has a clear wine-colour, transparent throughout. As each spray bears thirty or forty fruits and they are finely flavoured like the best sort of blackberry, it will be admitted that this latest addition to our fruit garden is not to be despised. Besides being valuable uncooked, the wineberry makes excellent preserve, its fine acid flavour making it specially suitable for cooking. The fruit is found on the wood of the former season, and the strong suckers thrown up in summer should be fastened back with wire, to expose them thoroughly to ripening sunshine. A mulch of rich soil in June over the roots helps the fruit to swell better and the plant enjoys abundance of liquid manure and water. It is highly ornamental in August with its scarlet berries and should be largely grown.

The Logan berry makes, as I can personally testify, most excellent jam and in a pie it is far better than the raspberry, while the blackberry is tart and commonplace in the comparison and not in the running at all. The seeds of the black berry are hard and disagreeable. Those of the Loganberry give no trouble.

As some hybrids have been so successful, one can surely hope that a great future lies before fruit hybridisers. Shall we not live to see many practically new fruits, and seeing what careful cultivation has done for raspberries and strawberries, it is possible that the gardens of the wealthy in a dozen years and, perhaps, too, in time, even those of the poor, may abound in splendid hybrid fruits, larger, more luscious, and more palatable than anything we now find in them.

Mr. and Mrs. Forrester, seeing my interest in a subject with which I can claim no special acquaintance, have drawn my attention to the Chinese artichoke (*Stachys Tuberifera*), a new vegetable of distinct flavour, to which the Royal Horticultural Society has awarded a first-class certificate. They say it is very palatable and profitable. It is described as a most agreeable, perfectly hardy vegetable, novel in appearance, and easily cultivated in any garden. The roots may be left in the ground through the winter and dug up as required; the surface of the earth should be covered to prevent frost hardening the soil.

The plant grows to a height of 9 to 15 inches, is free-branching, and forms neat bushes. From the axis springs a large number of fibrous roots, on which the tubers grow in immeuse numbers. The tubers are 1 to 2 inches long, and are half-an-inch in diameter at the thicker end, tapering to a point at their attachment to the root. They have a spiral appearance, are pearly white, and eaten raw, are intermediate in flavour between a succulent radish and a Jerusalem artichoke. Boiled, steamed or roasted and served with melted butter, in much the same way as the globe artichoke, they are delicious and make an excellent dish. When planting soil should be throughly pulverised so that the roots can run freely and the tubers can swell without hindrance. From 18 inches to 2 feet is the proper distance to put the rows apart and the distance between the plants should be 8 to 12 inches. Planted at this distance apart a bed 5 feet by 30 would give a good returu, sufficient for most families. As the tubers when exposed for any length of time get rather discoloured, they should be covered with soil till wanted for use.

ALFRED J. H. CRESPI.

CACAO PLANTING IN CEYLON: SPLENDID CACAO PODS.

A Colombo merchant writes:—"When so much is being written about the cultivation of cacao, the accompanying specimens, grown on Katugastota estate, may interest you and show you that there is still a future for cacao."

We have scarcely ever seen finer pods. Here are the weights and measurements of the two pods before us, which we must send round Fort offices for inspection:—

13 in. long by 13 in. in girth, weight 3½ lb.
14 do. by 14 do. do. 4 lb.

Can these be beaten?

THE SUSTAINING POWERS OF BANANA.

One of the most courageous marches ever taken was that of Colonel Wilcocks to Kumasi. We hear that during the march from Kumasi the whole party lived on bananas. On one occasion they even waded shoulder high through a river for two hours. Does any one want a higher test of endurance on a vegetable diet than this?—*Journal of Horticulture.*

A NEW GREEN TEA-ROLLER.

It is stated that a well-known firm of Calcutta engineers will shortly introduce to the industry a new leaf roller, which has been designed by Mr. Perman, an experienced Assam engineer planter. The machine will be called the "Express," apparently the name is justified in view of the fact that 300 lb of green leaf can be efficiently rolled in about 20 minutes. The new roller is circular in shape, occupies a space of about 4 feet square only, and last, but not least, the cost will probably work out less than that of other existing rollers.—*Planter*, Nov. 17.

BRAZIL COFFEE NOTES.

The steamer "Dacia" which left Santos on the 21st ult. carried 100,020 bags of coffee. This is said to be the largest cargo of coffee that has ever been shipped from the port of Santos.

To a circular of the state government of S Paulo asking for estimates of the coffee crop for the year 1900-1901 answers have been received from 71 municipal districts, whose production is estimated at 3,643,867 bags. From 92 municipal districts no answers have yet been received. We presume that in those that have been reported the most important coffee-producing districts in the state are included — *Rio News*, Oct. 2.

UGANDA: A PARADISE FOR COFFEE;

COTTON, RUBBER, EBONY, TIMBER, AND OTHER PRODUCTS.

Coffee grows wild over all the more hilly districts of the Uganda Protectorate. When properly prepared it has a delicious flavour, and is quite fit to be put on the market as gathered from the wild bushes. Coffee yields the most encouraging results under cultivation. Mr. Whyte is of opinion (and from the little I know I agree with him) that the Kingdom of Uganda and the adjoining districts of Busoga, Unyoro, and Toru are destined to be great coffee-producing countries. The soil, the water supply, and the abundance of shade from forest offer conditions and advantages rarely present in equal force. Local labour is almost as cheap as in British Central Africa; but, of course to make coffee-growing possible as a commercial enterprise, the railway must be completed to the lake, and steamers on the lake must gather up the coffee crops for transport to the rail-head and thence to Mombasa. Given the railway and the steamers, and I think no other part of tropical Africa could compete with Uganda as a coffee-country.

Cotton grows wild, or half wild, in many places, and is to some extent cultivated in the Nile Province, chiefly on the sites of Emin Pasha's former settlements. It is of good quality and long staple, but, except for local purposes, it is not worth consideration, as it would probably never pay to export it over the railway to the coast.

The castor-oil plant grows abundantly, and the oil which is very easily obtained by crushing, is very useful for lubricating purposes.

Sesamum seeds yield good oil. They are met with here and there in Uganda, but not so abundantly as in British Central Africa.

Rubber (chiefly from two species of Landholphia, from a *ficus* and perhaps from a tree called scientifically *Tabernæmontana*), is probably abundant in every thicket of the Protectorate below 5,000ft. in altitude. Rubber will probably become a very important item of the Uganda exports; but at present time, although the natives know of its existence, and of the trees which produce it, they make little or no effort to collect it for sale.

The ebony trees (*Diospyros*) grows in the western forests, where also the camwood (*Raphia*) is found. A common tree in Uganda is the "incense" tree, the constantly exuding gum of which is the principal ingredient in increase. I do not remember to have seen this tree growing in such numbers in any other part of Africa, or for it to be so easy to obtain its delicious-smelling gum. As a matter of fact, when ever one wishes to fumigate a house or room, and to replace the mustiness of these dwellings by an agreeable odour, one has only to send a native servant to a short distance to scrape the exudations off the incense tree and place these on hot charcoal, and a delicious smell of incense at once arises.

I should certainly think that the splendid timber which can be obtained from the Mau forests would be an important article in the future exports of Uganda. This timber will be derived from three conifers—a juniper, and two species of *Podocarpus*. I do not suppose that this timber would be worth exporting to England, but it would certainly vie with Scandinavian timbers on the East Coast of Africa, and even perhaps in India, the more so as it is said to be left untouched by the white ant.

All the southern half of the Uganda Protectorate to the south of the 2nd degree of north latitude is a country of forests. The forests of the Mau-Plateau, Mount Elgon, and the Suk Hills resemble in appearance more the woodlands of a temperate country. The trees belonging either to genera or species found in Cape Colony, or else—and to a considerable degree—in the forest of Abyssinia. Some of this—so to speak—Abyssinian forest has rather a European look, and, no doubt, has European affinities. On the other hand, the forest of Busoga, Uganda, and Toru are essentially West African.

All their great timber trees—African teak, *Oldelandia*, *Diospyros*, *Parkia*, *Parinarium*, *Khaya* and *Vitex*—though they are represented to a great extent in East Central Africa as far as Nyassaland, seem to be more closely allied species to those of West Africa. Indeed, on entering these magnificent tropical forests—some of them the finest developments I have ever seen—one might believe one's self in the Cameroons, in the Niger Delta, or in the Liberia. The forests on the slope of Mount Ruwenzori range from a purely tropical character up to the Abyssinian vegetation of the Mau Plateau. A great deal of the local timber, no doubt, would not be worth exporting but it is likely to prove of incalculable benefit to the country itself, as it serves for ship-building, house-building, furniture, and the finest work in joinery. In the forest regions of Uganda below 5,000ft. there are, I believe, only two kinds of palm represented—Makindu or wild date, and a magnificent species of *Raphia*, which, unlike other *Raphia* palms, towers to a greater height of stems. The trunks of the date palms are employed for many purpose in buildings. They make excellent piles for wharves of piers; columns for supporting the verandahs of houses; in fact, they can be turned into a variety of purposes, and there is such a demand for them that some forestry regulations will soon have to be instituted to protect them from undue destruction. The mid-ribs of the *Raphia* palm fronds, which are of enormous length, are also very useful articles as rafters.

I have touched on a few of the native vegetable Products of Uganda, but it should also be borne in mind in considering the resources of the country that the soil and climate of about half of the Protectorate are admirably suited, at different levels, to the cultivation of cacao and tea. Mr. Whyte, who has had considerable experience in years gone by in different plantations in India and Ceylon, considers parts of the Uganda Protectorate as singularly well adapted for the cultivation of the tea plant. He compares such parts of Uganda as are suited for this cultivation to the estates of medium elevation in Ceylon. The rain fall, he remarks, is a little less than it would be in

such parts of Ceylon, but he considers it much better distributed all through the year. There is very great demand for tea amongst the more civilised natives in Uganda and Toru. Mr. Whyte thinks that the local demand for tea (as, indeed, for sugar, coffees, cacao, and other products) is worthy of consideration. No doubt, also, when communication by means of the river Nile is better organised and the sudd cleared away, large quantities of Uganda products could be sent down the Nile to feed the Soudan.

The sugar-cane thrives wonderfully in the better parts of the Uganda Protectorate. It is cultivated in nearly all the native gardens. Individual canes are often met with 15 feet long, robust, and long-jointed, and as well developed as the average cane in the West Indies. The Uganda sugar-cane goes on ratooning for years, and forms a considerable item in the native dietary. We have now got up machinery for crushing cane, and are already turning out coarse sugar, which forms part of the rations of the Indian troops, and enable us to save considerable expenditure, as formerly this coarse sugar (gur) had to be imported all the way from India.

Almost all English vegetables grow and are grown in the Uganda Protectorate with encouraging success. Orange, lemon and mango trees, which were planted a few years ago, have done exceedingly well; but, except on Mau Planteau, it would be impossible to grow stone fruit, apples, pear, or any of those trees which require a real winter.—Zanzibar *Gazette*, Oct. 31.

TEA CULTIVATION IN RUSSIA.

Indian and Ceylon tea growers have not much to fear from competition with Southern Russia. The progress so far made with the cultivation of tea along the south-east coast of the Black Sea is but slow, and it is the opinion of many authorities that the industry cannot possibly assume any very great proportions for a considerable number of years. This information is afforded by the British Consul for the district, who adds that with the exception of the Imperial Domains and the firm of Popoffs of Moscow, no other tea planters of any importance have shown any inclination to purchase lands for tea culture, and that in reality the results obtained up to date are not of such a nature as to inspire would-be tea growers with the necessary confidence to place capital in such enterprises. Messrs. Popoffs, who own three extensive plantations in the neighbourhood of Batoum, are apparently wearied of the results of their eight years' experience in the business, and are, it is reported, negotiating the sale of their property to the Imperial Domain Lands.—*Home and Colonial Mail.*

THE GOURAMI FISH IN CEYLON.—We are reminded that at a meeting of the Fishing Club about a year ago, Mr. W. E. Davidson reported :—

Mr. Davidson said that last week a tub arrived at Colombo with five young Gourami fish from Messrs. Scott & Co., of Mauritius. This was a fresh attempt which Mr. Burrows had made to ntroduce this fish into Ceylon waters by way of an experiment. The fish were now with Mr. Fowler, who proposed rearing it in Colombo, as they only thrived at sea-level. He (speaker) had had a deal of correspondence on the subject with people, who were experienced in the rearing of this fish and had found out that they do not thrive above sea-level.

We have some idea that Mr. Fowler afterwards reported a failure of the Gourami? But one or two trials should not suffice. There is room for another.

PETROLEUM AND KEROSINE OIL IN CEYLON.

Very few, we suppose, have a proper idea of the importance of the Bulk Petroleum Installations in this island, which have been established in connection with the regular visits of the Shell Transport and Trading Co., Ld.,'s tank steamers. This Company is in itself one of the largest in the world, with a capital of two millions sterling, and a fleet of twenty-three steamers, besides numerous small craft. As local agents, Messrs. Delmege, Forsyth & Co., apart from the headquarters' installation at Kochchikade where 450,000 gallons of petroleum can be stored, have now in full working order tank depôts at Galle, Kalutara, Kurunegala, Kandy, Nawalapitiya, Hatton, Nanuoya and Bandarawela. We had the impression that the importation of kerosine oil in cases (oil-tins and cases coming from Russia principally, but a certain quantity from America) was due to the greater convenience of carriage of the case oil to certain districts not at present served by railway; but we learn that the Tin-making Factory at Kochchikade now turns out as many as 1,000 tins a day, to meet the demand we speak of. This industry, together with the other work done at the Installations, altogether requires a staff of 115 men—so that we have, in this entirely new industry, a great addition to the means of livelihood in the Northern division of Colombo where at one time some of our largest and busiest coffee stores were situated.

As regards Liquid Fuel, for which there is also a large Storage Tank Installation at Kochchikade, adjoining but quite separate from the Bulk Petroleum one, although there are now some ten regular local consumers, the demand has not yet developed to the point it may be expected to reach after proper trials have been made by the railway, and other large fuel consumers, and several of these trials, are to be begun very shortly. We learn that the Company's steam-hopper "Attaka" recently made a trip to Jaffna, and on the way up burnt 14 tons of Cardiff coal, and 6½ tons of liquid fuel returning—which at the relative costs of the coal and fuel, shows a very large saving by use of the latter. Up to the present, the Company's own steamers have been the chief sea consumers, but certain other large lines are getting some of their steamers adapted to use it, and the German war ship "Fürst Bismarck" took a supply here on her way to China.

So far, all the Bulk Petroleum imported into Ceylon, has come from Russia but the liquid fuel is from the Company's lands in South Borneo, where a very large amount of capital is being spent in developing the concession which is held from the Dutch Government. As the large refineries erected there get into full work, it is expected that the greater part of the Company's Eastern trade will be supplied with refined Bulk Petroleum from there. Very large shipments of liquid fuel have already been made, from the Com-

pany's South Borneo ports, to Singapore, Hongkong, Bombay, Madras, Calcutta, Suez and London, as well as large cargoes of Solar distillate for gas-making purposes and other petroleum products to London.

The Company has Bulk Petroleum Tank Installations in full work, at Suez, Karachi, Bombay, Colombo, Madras, Calcutta, Penang, Singapore, Bangkok, Hongkong, Shanghai and other China ports, Nagasaki, Kobe, Yokohama, with liquid fuel storage tanks, as well at Suez, Bombay, Colombo, Madras, Calcutta, Singapore, and in process of erection at Sydney, Melbourne and several other ports. Most of these are very much larger than the Colombo Installations.

COFFEE AND TOBACCO.

For the benefit of intending coffee and tobacco planters in Rhodesia or other parts of South Africa, Mr. Jackson, Keeper of Museums, Kew Gardens, has given the following list of books :—"The Coffee Planter of Ceylon," by Sabonadière (Spon) ; "Coffee Planting in Southern India and Ceylon," by Hull (Spon) ; the article on "Coffee" in Spon's Encyclopædia : "Liberian Coffee in Ceylon," published at Colombo by Messrs. Ferguson (1878) ; "All About Tobacco," Messrs. Ferguson, Colombo (Agents : John Haddon and Co., Bouverie-street, London, E.C.) the article on tobacco in Spon's Encyclopædia —*Globe*, Nov. 9. —[Strangely enough Mr. Jackson omits the latest and most complete work on Coffee, namely "The Coffee Planters' Manual" compiled by J. Ferguson (1899 edition) with a special chapter on "Pulpers" and other machinery—copies of which are also to be got at Haddon's.—ED. *T.A.*]

GERMAN RUBBER ASSOCIATION.

The German Rubber Goods Manufacturers' Association held its annual meeting at Frankfort recently. Forty factories are represented in the association, of which sixteen employ under 100 hands, sixteen employ between 100 and 500, and eigth employ over 500. All important German concerns are connected with the institution, which wields a powerful influence. The Association has been consulted by the Government about the new tariffs to be arranged this year.—*Chemist and Druggist*, Nov. 10.

THE LINNEAN SOCIETY.

"PATENAS" (?) IN AFRICA.

The opening meeting of the session was held on Thursday evening, last week, at the Society's Rooms, Burlington House, Piccadilly, W., Professor Sydney Howard Vines, F.R.S., President, in the chair.

The closing paper, Mr. J E S Moore, dealt with the origin and character of the "park lands" of Central Africa, and was illustrated by a series of lantern-slides. These park lands in the Tanganyika have quite the appearance of having been formed by the hand of man, but are really natural growths due to the fact that light surface soil has been laid down over what Mr. Moore takes to have been lake deposits. Any given line of country will show large plantations, with quite a homelike look, separated by grass lands; and, as Tanganyika is approached, they dwindle in size till they consist of a few shrubs, overshadowed by giant euphorbias, cactus-like in appearance. Then come stretches of grass, dotted with euphorbias, and, last of all, the salt steppes by the Lake, which is now held to have had at one time an outlet to the sea. Mr Moore's explanation is that, at first, only the euphorbias would grow on the salt steppes; but as these sprang up they afforded a shade and shelter to self-sown shrubs, each of which, as it established a footing, contributed to the natural planting of the area by the distribution of its seeds, till this process reached its highest development in the large plantations where the shrubs overtopped the euphorbias to which they owe their growth.—*British and Colonial Druggist*, Nov. 9.

TONGALAND SUGARCANE.

Mr. B Colenbrander, Magistrate, Ingwavuma, in his district report to the *Agricultural Journal*, writes: During the summer of 1898, I planted at this Magistracy, which is almost 3,000 ft. above sea level, a small portion of ground with what appeared to me an unknown species of sugar-cane, obtained from Tongaland, as I had never observed the same cane growing amongst the many plantations on the coast. The cane which is very juicy, does not grow to any great thickness, and has a light yellow surface, turning into a deep brown whenever exposed to the sun. It has thrived very well, especially under the unsatisfactory circumstances and in the unsuitable locality in which I planted it, and appears very prolific. I have counted as many as 63 sticks to one stooe.—*Natal Mercury.*

THE GOVERNMENT DAIRY.

The Government Dairy is now in its seventh year. The Dairy herd was free from any form of contagious disease in 1899, and there were but six deaths for the twelve months, three among the cows and three among the calves. This is an excellent record considering the size of the herd. Thirty cows and three bulls were purchased at a cost of R4,564·86, while twenty-nine cows and two bulls and fifty-six young animals bred on the farm were sold for R4,337·26. Milk to the value of R21,895·64 was supplied, of which R4,823·07 worth had to be purchased to meet the demand from the hospitals, which at different periods required more milk than the Dairy was able to supply. The necessity for the purchase of milk remains a serious defect in the management, and the only way of avoiding it seems by the Dairy arranging with the Medical Department to supply only as much milk as it (the Dairy) produces. It should be possible to make a monthly forecast of the milk that the Dairy can supply under normal conditions, so as to permit the hospitals to arrange beforehand for the supply of milk in excess of the estimated quantity.

"VENESTA" TEA CHESTS.

"Venesta, Limited," London, are anxious that it should be known among Ceylon tea planters, buyers, exporters, etc., that a circular recently issued by some large home buyers declining to purchase tea packed in certain "veneer" chests, did not refer to the "Venesta Tea Chest" which is an entirely different package to the chest referred to, and does not resemble it either in lining or construction.

INDIAN TEA ON THE CONTINENT OF EUROPE.

MR. HARRINGTON'S REPORT.

There appeared to be a feeling (in India) that the American tea trade required special efforts no longer, but only ordinary business enterprise; that the Special Commissioner who had worked things up there might now do greater service elsewhere, and that the tea trade of the United States might, without prejudice to the interests of tea-planters in India and Ceylon, be left to the American tea-dealer, aided or encouraged in some particular ways by the Associations referred to above. How far this idea was correct remains to be seen. A change of programme was introduced. The "American Fund of the Indian Tea Association" became the "American and Foreign Market Fund," and the Association declared in favour of the policy of canvassing vigorously for the lion's share of the existing tea-trade of Germany, France &c., and advocating tea in preference to the rival beverages, coffee and cocoa. Accordingly, Mr. John E M Harrington was appointed special "tourist" to the Indian Tea Association (Calcutta and London) and on the 20th March last was instructed to make a tour through various parts of the Continent of Europe with a view to (*a*) ascertaining by enquiry on the spot the present position and statistics of the tea trade in each country visited and (*b*) to report as to the most practical method of developing both the taste for tea in general and the demand for Indian tea in particular. It was a somewhat "large order," but the absolute necessity for some such investigation as was undertaken was shown by the fact that, whereas in the British Empire some 90 per cent. of the tea consumed is British grown, in all the States of Europe practically 90 per cent. is supplied by one or more of the following producing centres:—China, Japan and Java, less than 10 per cent. falling to the share of India and Ceylon.

The space at our disposal will not admit of a detailed review of Mr. HARRINGTON'S interesting and instructive Report on his tour. The route followed included Italy, Turkey, Bulgaria, Austria-Hungary, Germany and Holland, and the time occupied was less than four months. This brief time was evidently fully utilised, for the Report contains a large amount of most useful information. In some respects, it shows previous ideas as to the potentialities of some of the above countries as tea-consumers to be open to revision; but, generally, it may be said to confirm the opinions we expressed long ago, that there is a market to be had on the Continent of Europe, but that it is not to be had for the mere asking. Success can only be achieved by systematic effort and a certain amount of outlay. It is not a case of advocating the merits of British-grown teas in tea-drinking countries where peoples have a natural inclination to give the preference to products of portions of the Empire to which they belong. The work that has to be done is to popularise tea among peoples more accustomed to drink coffee, cocoa, beer or wines; among peoples largely prejudiced against, rather than predisposed in favour of, British products, and in countries where tea is to some extent heavily handicapped by local fiscal tariffs. These are conditions that preclude the hope of more than slow progress even with the most determined effort. Mr. Harrington's Report shows that there is ground for this hope, and on the whole, it may be regarded as more encouraging than it was, perhaps, generally expected to be. Facts and statistics are given, suggestions are made, and the future will depend largely not merely upon the action taken upon the extent to which planters provide "the sinews of war" so essential to success in the conduct of a campaign such as that which the Indian Tea Association has undertaken. Conditions vary not only in different countries, but in different towns in the same country. For instance, Mr. Harrington writes less hopefully about Naples than about Rome, in which latter place there are more English and American travellers and a larger fashionable Society to follow the general example of such Society in other countries and adopt "Afternoon tea" or, as the French say, the "five o'clockie." Turkey offers a fair field, and, moreover, does no small amount of "transit" trade on behalf of Southern Russia and Persia. Low sorts are most in favour and long wiry leaf has a preference in the Persian trade, where Camel transport tends to break up the tea. Bulgaria is mostly a coffee consuming country, the tariff on tea is high, and the language and trade customs are difficulties to the British trader. Mr. Harrington cannot recommend direct expenditure of time or money upon so small a field, but thinks the market may be reached indirectly from Constantinople. As regards Austria-Hungary, various difficulties are pointed out, and it is remarked that "no practical method is apparent by which Indian tea could be rapidly and successfully introduced." Very different is the case with respect to Germany, where Mr. Harrington thinks a good trade might be developed if proper arrangements were made and a liberal outlay faced for the first three or five years.—*Madras Mail*, Nov. 26.

A BRAZILIAN RUBBER PLANTATION

(To the Editor of the *India Rubber World.*)

Is it possible to find in the United States, or elsewhere, some one who would be interested in a plantation of Ceara rubber? In March, 1899, we established a plantation in the state of Pernambuco, about 12 kilometers from the capital, where we now have more than 100,000 trees of *Manihot Glaziovii*, vigorous and growing well. Having now, however, other needs for our capital, we should be willing to sell the plantation, though our preference should be to retain our present interest in it, provided parties can be found to join us as partners, or found a company, with a view to supply the money needed for meeting the expenses involved during the few remaining years, until the trees become productive. The plantation really promises a very handsome profit. The estate is now in fine condition, with laborers' cottages and stables built by us, and pasture land fenced in and stocked with cattle. The location is healthful and only about 3,000 meters distant from a railway station. The extension of the railway past the estate is projected.

Within three or four years the trees are expected to begin yielding from 1 to 3 pounds of rubber per year. The labor of gathering the crop will be slight, because the trees will simply be tapped and the rubber will coagulate on the trunk, when it can be pulled off dry. With the monthly expenditure of $500 to $1,000, not only can the plantation be kept in condition, but, within two years, our original plan of increasing the number of trees planted to 500,000 could be carried out.

We prefer for the present not to publish our names in this connection, but will be pleased to have this appear in The *India Rubber World*, and to have you receive for us any correspondence which may result. M. & Co.

———, Brazil, October 1st 1900.

ESSENTIAL OILS.

From Semi-Annual Report of Schimmel & Co. (Fritsche Brothers) Leipzig, New York, London, for October 1900, we take the following:—

CINNAMON OIL, CEYLON.—There has been an exceptionally large demand for this article, to satisfy which we have been carrying on the distillation without interruption since the beginning of the year. The prices of the best qualities of chips fluc-

tuated between 3½d and 3¾d per pound. In view of the animated condition of the cinnamon market, there is absolutely no prospect of a return to the previous values. The shipments have been enormous, The aggregate for the first seven months of this year comes to not less than 900,672 pounds, of which nearly one fourth has been acquired by our firm. The distillation of the finest quality of heavy, sweet, cinnamon oil is one of our specialities.

CITRONELLA OIL.—Since the publication of our previous Report, the value of this important article has suffered a further decline, and it would appear that the supply exceeds the consumption. The statistics again show an important increase in the production. Recent quotations were a shade under ten pence, and were the lowest on record. This oil is largely employed for perfuming benzin and mineral oils, and it might also be found very useful for lac and oil paint. The Java variety of citronella oil has found great favour, and in fact is fully entitled to be called the elite-quality. Its effect in the better qualities of soap is striking, the natural explanation being its high content of geraniel and citronellal.

CLOVE OIL.—The information given in our last Report, as to the unsatisfactory result of the last clove harvest in Zanzibar and Pemba, has since been confirmed. The total yield is estimated at about 50,000 bales, or say 3,000 tons, as compared with 140,000 bales or 8,400 tons in 1898-99. The cultivation of cloves is also undoubtedly influenced by the state of the labour market, which has gradually taken a very favourable turn since slavery was abolished on both islands. At the present quotations cultivation has become unremunerative, and it is bound to decline still further, so as to harmonise with the consumption, for the lower values are simply due to the continued overproduction and the piling up of non-realisable stocks in Bombay, London and Holland. The latter, taken together, are so important, that it would require several bad harvests to equalise the surplus.

RUBBER PLANTING IN SUMATRA.

In answer to enquiry addressed to the St. Petersburg Company, the following letter has been received from its president, dated in Prussia :—

To THE INDIA RUBBER WORLD—Gentleman : The Russian-American India Rubber Company, of St. Petersburg, Russia, has sent me your favour of August 20th, because it is not my company, but myself who is going to make a trial on a large scale with *Ficus elastica* plantation in Sumatra, east coast. As all experiences are to be made, I am sorry not to be able to give you any further informations for the moment, except that there will be planted about sixty thousand trees per annum, beginning from this year.—I remain, gentlemen, very truly yours,

FRED. KRAUSKOPF.,
President Russian-American India-rubber Co.
Villa Hohenbuchen, bei Schlangenbad Wiesbaden,
September 18th 1900.

TRAVEL IMPRESSIONS OF A JAVA PLANTER IN CEYLON.

SOIL—VEGETATION—PLANTING—CACAO—COFFEE—CINCHONA—TEA—COCONUTS—RUBBER.

Mr. J. Bley writes in *Teysmannia* as follows :—

In journeying to Europe I stayed a fortnight in Ceylon and had, thanks to good introductions, the opportunity of seeing a pretty good number of the various cultures ; the time was too short however to permit of thorough studies. Ceylon is such an interesting island, that I can assure every colleague, that it is well worth the trouble to visit it. Travelling is everywhere united with expense ; if one has not the money to spare for the extra excursion, let him travel in the (very good) second class of the "Norddeutscher Lloyd" or of other good lines, instead of in the first : thereby one saves enough money for the trip. The objects worth seeing in Ceylon are situated comparatively close together, the railway communication is good, and even without being introduced one sees much of interest ; it is only needful to be able to speak a couple of words of English.

COUNTRY.—Ceylon has in the southern portion very few lowlands of importance for cultures, so that there is little land there suitable for rice, native sugar-cane and such like cultures. Travelling by rail from Colombo to Kandy and the terminal station, Bandarawela, one reaches pretty quickly a considerable height (6,300 feet) through difficult hill-country. One misses, however, the volcanoes with which in Java we are so well provided ; Adam's Peak alone has the same form, but does not appear to be of volcanic origin. One might very well think this of the high lying sanatorium, Nuwara Eliya. The country and the kind of soil are there very like the Diëng plateau. The land also has something of the look of the Djampang districts in the Preanger, only it is wilder and rockier.

The SOIL of the districts that I saw consists almost everywhere of granite and quartz rocks with a very thin layer of poor earth above ; the estates near Nuwara Eliya form an exception to this. They cannot, however, be compared with our good Java soils.

From the nature of the case it is not possible in such a short time to form a judgment of the CLIMATE. I was there in the dry monsoon ; according to the rain statistics the rainfall in the southern portion of Ceylon appears to be pretty much the same as in Java ; it seemed to me, however, that it is there hotter at an equal height.

LAND TENURE.—The land is freehold ; consequently there is no emphytensis or ground-tax paid for it, which has greatly facilitated the transition to other cultures. If anyone wishes to have waste-land, he applies for a piece ; it is inspected by the Government and the forester, who fix a minimum price for it, for example *f* 10. When it has been mapped out by the surveyor, it is put up for sale and sold to the highest bidder. If this is another than the first applicant, then he must repay the cost of measurement, &c. Lands belonging in freehold to natives may also be bought.

THE VEGETATION is poorer than in Java ; it is striking that so little bamboo grows there ; that which is found there is almost entirely *bamboo ampel* and *bamboe petoeng* ;* the native houses are consequently built of brushwood and mud.

Woods are seen here and there, but no large trees, so that timber, wood for tea chests, &c., must be imported. Perhaps the Netherlands colonics might be able to find a market there for wood. Good pasture-land is also not readily available, so that guinea-grass and *rocmpoet petoengan* † or *kalandjană* ‡ are planted. Singular

* *Bambusa fera* and *B. nigrociliata*, *B. aspera or B. gigantochloa aspera*.

† Mal. *rumput*, grass ; *petoengan* I cannot explain.

‡ I cannot explain this.

is the contrast, when one comes through one of the many tunnels near the terminal station, Bandarawela, where the drier northern portion of the island begins. In place of jungle and undergrowth one suddenly sees the hills covered with clumps of short grass, which however does not appear to be suited for cattle fodder.

The Botanic-Garden at Peradeniya is very fine, but not what the garden at Buitenzorg is; the European staff then consisted of only two persons and a third was just expected. The grouping of the plants, it is true, appears at first sight very picturesque; but when one looks for a particular plant, one sees at once the great advantage of the systematic method of planting at Buitenzorg. In addition the guides by their English-Sinhalese pronunciation of the Latin names makes them even more unintelligible than the Javanese *mandoer*, * who translated cinchona calisaya into High Javanese as "*kina lepen koelo*."

Very beautiful in blossom certainly stood *Magnolia* sp. (Himalaya) with large white flowers, which should certainly suit the taste of our Javanlings [*Javantjes*]; further *Poinciana regia*, the flamboyant of Madagascar, a handsome blue flowered shrub, as also the "cannonball tree," so named from its shot-round fruits, &c., &c.

POPULATION AND LABOR. — The indigenous population of Ceylon are the Sinhalese, who appear to have just as little inclination for manual labor as for instance the Malays of Sumatra. For the work on the plantations and in the factories therefore Tamil coolies from British India are generally imported. The pay per day is usually for men 35 and for women 25 rupee-cents, equal at the ruling rate of exchange to about 30 and 20 of our cents. The coolies have frequently *f* 50 and more of advance, may leave the estate, but are then obliged to repay the advance, unless according to a common custom it be taken over by another estate.

As may easily be understood, it is in the highest degree difficult to exercise control over them. Their skill and industry appear to be about the same as those of our Javanese and Sundanese. The planters generally converse with the coolies in the Tamil language, but to a strange it sounds unpleasant with an English accent. One finds everywhere however natives, and especially Sinhalese, who know some English, more even than in Java, who understand Malay, which is certainly an advantage for tourists.

The people are more loquacious, more bustling and dirtier, but also more brutal—which generally see, to go together—than our Javanlings.

MEANS OF TRANSPORT AND CATTLE-BREEDING. —The railway transport is both for persons and goods considerably cheaper and consequently the night trains also more comfortable than in Java.

On the other hand, Ceylon has railways and tramways only in the industrial portion. The postal service appears to be cheaper and better managed than in Netherlands India, but of telephone communication, even in the towns, there is hardly any. In the principal places and at the hotels one can hire carriages, drawn by big Australian or Persian horses, pretty much for the same prices as in Java. There are also jinrikshas drawn by Tamil coolies. The typical method of transport for persons in Ceylon is however the little carts drawn by dwarf-oxen.

* Jav., overseer.

One sees big *deelemani* * carts with two oxen, but many more hackeries [*karretjes*] and bandies with one ox in front, which go almost as quickly as horses. The transport carts are drawn by large Bengal oxen evidently imported; on account of the rocky ground all the horses, as well as *sappies* † have iron shoes. A singular custom of the carters is to brand entire designs on the beasts and often to furnish the horns with brass tips. It is said that several planters have tried to breed horses, but the results were bad. All the horses bred there were small, weak and often albinos, which must probably be attributed to the bad food. The horses are fed with feed imported from Australia or with plently of *gabbah* ‡ and some locally grown grass; the *sappies* with paddy straw, pressed cakes from the coconut oil mills and grass, when that is to be had, which is often not the case.

The roads are excellently traced and hardened with broken stone, but sometimes terribly narrow and the turns pretty sharp. It must have cost an amazing amount of work to cut the roads out of the rocks. An interesting and efficient means of transport is on many estates the "shoots"; these are cable lines of the very simplest construction for the hill transmission of produce and firewood. A steel rope of ¼ to ½ English inch diameter is, preferably without any other support, stretched to one post or more, often high above ravines and roads. On this the load is hung by a light pulley, or in the case of a very great incline simply by a hook, and then runs down by its own weight to be taken up below. The pulleys are then pulled up again by persons for further use. This method of transport is not used for fragile articles, but for fresh tea leaves, coffee, firewood, &c. Nothing can be sent uphill by the "shoots"; for that purpose however I saw the well-known cable lines driven by water-power: the contrivance is however very expensive. The firm of Walker Sons & Co. have erected many "shoots" and cable lines.

The fresh tea leaf is also transported in large baskets, provided with divisions to prevent drying, and in open-worked sacks of coco yarn, which are lighter and stronger than gunny bags.

CULTURES.—One stands amazed at the energy with which our neighbours undertake their experiments in cultivation, and one also comes to the conviction that English capital must be much easier or stronger than Dutch, or otherwise it would have been impossible in Ceylon to have been able to go over completely and entirely from coffee and cinchona to the cultivation of tea. One sees now and then indeed just as here and there in Java the "whole grocer's shop" system carried out; I saw, for instance, planted amongst each other—tea, cacao, Arabian and Liberian coffee, two varieties of caoutchouc, pepper, cinchona &c.; as a rule however only tea is planted.

COFFEE.—This culture seems to have pretty well been done with; at least I saw very little Arabian coffee left, and Liberian coffee does not appear to do in Ceylon, which is probably chiefly due to the shallow soil.

CINCHONA I also found almost non-existent, and what I saw was of inferior variety. It is true that there seems to have been a

* I do not know what this means.
† Jav. *sapi*, oxen.
‡ Paddy?

rush to buy good Ledger seed from Java, but the neeessary eare does not appear to have been taken everywhere bestowed upon it, so that very little seed germinated. I certainly saw no soil that I should judge suitable for Ledger; we need not therefore be very anxious regarding the competition of Ceylon; there is, however, much cause to fear that we in Java will ourselves again ruin the market by too great planting. What is still harvested of cinchona bark is for the most part sold in Colombo on account of the German firms and despatched packed in square bales.

TEA is now the chief culture of Ceylon. It is planted from somewhat above sea-level to over 7,000 feet and on every sort of soil, even upon rocks. Only on two places did I see no tea planted, namely on the roofs of the factories and between the railway rails; everywhere else I saw tea on flat ground and on slopes only accessible for rock-goats on pretty deep yellow-brown soil (good exception) and on soils ½ to 2 feet deep above solid strata of granite and quartz, nay even on bare rocks each bigger than a factory, in fact everywhere where there is a crevice of a finger's breadth or a handful of quartz gravel, which has the appearance of the government salt with us, tea has been planted. Each planter has his own opinion regarding method of planting and manufacture exactly as in Java. The most widely planted is the small-leaved Ceylon hybrid; I saw also, however, indigenous Assam or what came very near to it; it is found that a little hybridisation makes the plants stronger. Rust (helopeltis) and other diseases I saw little of, though I understood that borer, red spider, &c., were experienced.

THE DISTANCE BETWEEN PLANTS varies from 3 into 4 to 5 into 6 and 7 feet; on high-lying grounds the conclusion has been arrived at that one must not plant too closely. Planting is generally in strait lines without terraees and without following the configuration of the land. On sloping grounds open drains without banks are cut in an almost horizontal direction. The ground is generally weeded quite clean or entirely surface-worked with the *patjoel**; blind drains or deep working of the soil as in Java I never saw practised. The ground is often therefore as hard as *padas*†; but it must not be forgotten that the large quantity of gravel gives a natural drainage. It seems strange to me, that nearly everywhere rows of SHADE TREES are planted along the boundaries and at distances of 50 to 200 feet throughout the estates, usually *Grevillea robusta*, and on higher lands varieties of *Eucalyptus*. The object of this is to break the winds, and also to obtain firewood, which is very scarce; moreover many planters on low-lands find light shade useful for tea.

Much more care seems to be bestowed in Ceylon than in Java upon systematic pruning; I believe that to this and to the excellent climate must be ascribed the good yield per acre. Pruning is done branch by branch with pruning-knives somewhat larger than those we use for the coffee, and the aim is to cause the bush to increase in breadth from below upwards; knots on the branches are not allowed to remain, but otherwise different systems are followed. On high-lying lands for instance heavy pruning is carried out once in four years and then three months left before plucking; on low-lying lands in shorter periods.

MANURE.—They have begun to recognize in Ceylon, that the very poor soils need manuring, and since stall manure is only exceptionally available, experiments are being made with "*boengkil*,* fish and tea manure." I was shown an old China tea garden, the production of which was, so it was said, brought up from 400 pounds to 1,200 pounds per acre, by putting into the ground every other year 80 rupees worth of manure, beside the cost of transport.

PLUCKING I saw was the three leaves about every ten days; the women have for this a large basket on their back, which is suspended by a string over the head. The plucked leaf is often collected in the garden and then transported to the factory. (See *Means of Transport*.)

The TEA FACTORIES are mostly built with a more liberal hand and more all of a piece than in Java. The buildings are larger and especially higher, often two to three stories. Where it is in some measure possible, water-power is employed and then mostly turbines, so necessary with the help of steam and petroleum machines for the dry season. The buildings and machinery are generally erected by firms like Walker, Sons & Co., Ld., and others, who also supply all other needful appliances. Building oneself is much less in use than in Java. The wood is imported from Canada, Burma, &c., and iron joists are also much used.

WITHERING.—Withering is carried out much more thoroughly here than in Java and generally artificially in lofts. *Tampirs*† are not used for withering; it is done on shelves that are generally filled in with "Hessian cloth," a kind of fine gunny stuff either flat or, for the more convenient filling and emptying, sloping  and also in such a way that one end can be loosened; the cloth is then rolled up each time, and the work goes on in that manner by means of trained labor more rapidly (one woman per 100 pounds leaf). I also saw shelves with their planks and also with loose meshes of yarn. Each one finds his construction the best, if more goes on it.

ROLLING is done twice, thrice or even four times; thrice is the most usual, that is to say, the leaf is first rolled with little pressure ½ to ¾ hour, then sifted in the roll-breaker, the large leaf again rolled ½ to ¾ hour, sieved, &c.; the times for the different rollings varies much.

FERMENTATION is often entirely omitted on low-lying lands, prolonged rolling being sufficient. On higher lands however fermenting is well done and then often in rooms that are kept cool by means of ventilators and wet curtains.

RE-ROLLING after fermentation seems to be no no longer usual, only on a high-lying estate the tea is first rolled for half-an-hour (in the dry season ¾ hour), then fermented 1½ to 2 hours, and after that only the coarse leaf re-rolled ¾ hour (in the dry season one hour)

FOR DRYING all kinds of dryers are in use; I saw mostly the "Paragon." SIFTING is mostly

* Jav. *pachal*, hoe, mamoty.
† Solidified earth.

* Oil-cake poonac.
† Jav. *tampah*, fan.

done with the oscillatory sieves of Jackson or Walker, the coarse leaf is cut with various sorts of "cutters," mostly "Parnalls" and "Jackson's." The usual mechanical packing is done to a small extent in chests made by the natives, for the most part in chests half an Eng. inch thick of so-called mommi [*sic*] wood, imported from Japan, sawn to scale and provided with dovetails. Chests are also imported from Canada ⅝ inch thick and consisting of three layers of wood glued together, that apparently is cut mechanically and not sawn. They are provided with tin corners, clamps for the lids, etc, and cost in Colombo R1·30 net. Compressed steal chests seem to be very little used now.

PROSPECTS OF TEA CULTIVATION.—I believe that in Ceylon pretty well all suitable ground is planted with tea; it is true that some gardens have hardly come into bearing, but on the other hand many old gardens are retrograding in quantity as well as in quality of crop, so that one would judge that the top point of production has been reached, unless it should appear that manuring on a large scale gives the results that many expect from it. The produce will certainly not, however, be cheaper thereby; and when one sees how readily consumption takes up the large quantities of Indian tea, one is convinced that there will still remain a place also for the product of Java, Whether planting is being greatly extended in Assam and India I could not learn. I was told, that only young men are being engaged as superintendents, who have studied some years as engineers, a hint for our young men, that it may come to that in Java.

CACAO is still pretty largely planted in Ceylon. I visited an estate near Matale, the centre of the cacao industry, and saw also here and there smaller plantations. A red variety is mostly planted, which greatly resembles the Java sort, only the fruit is somewhat darker violet-red and the streaks more greenish; experiments are also being made with other hardier varieties. All the diseases that we have on the cacao in Java I found also here, such as stem-borers, large borers in the fruits, and also stem-canker, which does much harm and which is attempted to be cured by cutting out the bark and by coppicing. What I did not find was the dreaded disease in the fruits, which threatens to annihilate cacao cultivation in Java. I saw cacao being dried in sheds, the drying floor of which was made of laths, covered with cheap coconut fibre stuff, which seems to answer well.

VARIOUS BYE-PRODUCTS.—Here and there one sees pepper, indiarubber, etc., planted, but they seem more to be experiments. Kapok* is everywhere grown by natives, but experiments to plant kapok on a large scale do not seem to exist. The product is bought and exported by European mercantile houses, but the qualitty appears to be inferior.

COCONUT INDUSTRY.—It appears that this industry in Ceylon is on low lands a counterpart of the tea industry on the high lands, but it is extremely difficult to obtain any information regarding it. The nuts mostly grown appear to be the same varieties as in Java, viz. *klappa-idjoe*† and *merah*‡; other kinds are also found. From of old oil has been expressed by the natives from the coconuts in mills driven by *sappies*, of the same system as the *kadjang*§-oil mills in the Solo district, only larger and heavier. Later on hydraulic presses and crushing mills were erected by Europeans and wealthy natives, and copra exported which is generally packed in square bales.

DESICCATED COCONUT.—An entirely new industry has sprung up in the last few years in the manufacture of dried coconut preparations, which seem to be chiefly used by confectioners. I just managed after much fruitless effort to gain admission to one of these factories. The course of manufacture is as follows:—The nuts come to the factory deprived of their husk, are cut in quarters by a circular saw, the flesh of the fruit is extracted with a chisel, then deprived of the brown skin by a kind of plane and further cleansed with a file, and the pieces washed first with warm and then with cold water. The cleaned nuts are then either cut in slices in machines constructed for that purpose, or rasped in another kind of machine. In the first case one obtains slices, in the second case coarse flour; both are dried in a drying-machine just as tea is; the flour is so sifted, that three kinds are obtained and packed in tea chests with tea lead. In the factory that I saw this was done by means of a tea packing machine with a screw-press on it.

COIR.—Another important industry is the manufacture of mats, bags, etc. of coconut fibre (coir), but I was not able to obtain permission to see it; only I heard, that the fibre and the raw yarn are prepared as a domestic industry by natives in the district between Colombo and Point de Galle and sold to the factories, which work it further with hand-looms.

ALOE FIBRE.—I was present at an experiment with a machine for the cleaning of aloe (agave) and other fibres. The machine worked in the same way as the Faure machines, only the leaf was mechanically put into and out of the machine. It appears that this industry is there still in the region of experiments, just as with us. In conclusion a word of thanks to the gentlemen who afforded me the opportunity of seeing so many interesting things in so short a time.

COTTON PLANTING.—With a Cotton famine and its tremendous consequences to British trade and manufactures almost in sight, it is amazing how little is done to attempt to supplement supplies. With the exercise of a little energy and expenditure of some capital there is no reason why Manchester should not emancipate itself entirely from its present state of dependence on United States' supplies, liable to be cut off at any moment. Cotton could be grown in the north of Brazil to clothe the whole world and, if undertaken on a large and comprehensive scale, probably at a much cheaper rate. Labour is certainly far cheaper here than in the States, whilst the advantage of a depreciated currency in such a competition is likewise not to be despised. The cotton growing States are moreover the most densely populated of the country, Alagoas coming second in this respect only to the Capital itself. A powerful association for the plantation of cotton in the Northern States could not fail to be as profitable to planters as advantageous to home manufacturers if properly undertaken, and deserves to be seriously considered.—*Brazilian Review*, Oct. 23.

THE STATE OF AMAZONAS (BRAZIL) AND THE RUBBER INDUSTRY.

The State of Amazonas, the greatest in area of the United States of Brazil, lies between longitudes 74° W. 54° W., and between latitudes 4° N. and 10° S., having a total area of about 600,000 square miles. It is bounded on the north by British Guiana and Venezuela; on the west by Columbia, Peru, and Bolivia; on the south by the State of Matto Grosso; and on the east by the State of Para.

On the north and west frontiers there are some highlands and plateaux, but for the most part the State consists of vast, low-lying, forest-clad plains intersected by the innumerable tributaries of the River Amazon. These rising in the Andes, converge to the main stream of the Amazon, named in this State the Solimoes. Flowing as they do, through flat country, their course is generally extremely sinuous, and their current sluggish. The course of the main stream, on the contrary, is comparatively straight and the current swift, that is to say, about four miles per hour. Flowing from west to east the Solimoes divides the State into two, about equal, parts, and forms a most important highway for commerce between Para, situated at the mouth of the Amazon, Manaos, the capital of the State of Amazonas, and Iquitos, situated in Peru, being navigable as far as the latter part at all times of the year for vessels drawing not more than 12 feet. The distances between Manaos and other points on the Amazon and its tributaries will be found in Tables Nos. 1 and 3.

It is noticeable that the majority of the larger tributaries of the Solimoes, namely, the Javary, which forms the boundary between Brazil and Peru, the Jutahy, Jurua, Purus, and Madeira, flow from south to north, whilst only one large tributary, the Negro, and two smaller, the Japura and Iga, or Putumayo, enter the main stream from the north. Although no mountains occur until the extreme north and west frontiers of the State are reached, yet, on the whole, the part lying to the north of the Solimoes is considerably higher and less swampy than that lying to the south. On the Upper reaches of the Rio Branco, a tributary of the Negro, large grass-covered plains, known ocally as "Campos Geraes," occur, on which a considerable number of cattle are raised. For this very reason, however, that part of the State is at present of less value, and is less explored than the southern part, where the immense tracts of swampy land produce the invaluable "Hevea Braziliensis," from which the rubber is extracted.

The recent report of the British Vice-Consul at Manaos, from which the above description is taken, says that it may indeed be said that the whole commercial importance of the State depends upon the extraction of rubber which is the paramount native industry.

The following tables show (I.) the distance from Manaos to the ultimate ports on various rivers, and (II.) to Para and to various ports abroad, and (III.) an estimate of the total world's supply and consumption of rubber:—

The State of Amazonas (Brazil) and the Rubber Industry.

I.

Consumption of Rubber.

CONSUMING COUNTRIES.	ESTIMATED QUANTITY OF RUBBER CONSUMED ANNUALLY. Tons.
United States and Canada	21,000
United Kingdom	21,000
Europe (excepting United Kingdom)	15,500
Total	57,500

[These estimates are, we think, taken from our "All about Rubber," some of the figures being slightly altered and given in "tons" in place of "cwt."—ED. *T.A.*]

THE SUPPLY OF TEA AND LOW PRICES.

(To the editor of the *Home and Colonial Mail.*)

SIR,—In looking through the market reports of the various chroniclers of current opinion on Indian tea one is struck by the ingenuity displayed in accounting for the depression in market values. "The increase in the duty," "The general knock-out," "Irregularity in bidding," "The burden of 6d per lb duty, whilst coffee and cocoa escape at 1d to 2d," &c., &c., every one of which reasons, I venture to think, would not matter in the slightest if the real reason were not predominant, namely, over-supply. It is quite apparent that the self-denying ordinance of last season, or automatic feed regulator, is out of working order; and the old policy of printing tea for public sale on the principle of "Devil take the hindmost" has again been resumed. One broker's circular recognises this by saying that "the quantity offered was in excess of the requirements of the trade." The total number of packages offered in public sale for the whole fifty two weeks of 1899 was about 1,600,000 packages or, omitting five weeks' holidays, an average of 34,000 packages per week. And as for the last six weeks, the market supply has been over 300,000 packages, or 50,000 packages per week, with every prospect of more to follow; the cause of the depression is not difficult to find. It is a maxim in political economy that "limitation in supply is the most powerful augmentor of

value" ; and surely the converse is equally true, that over-supply is the most powerful depressor of value. What remedy to propose is not my present object. Buyers find no fault with cheap tea ; and if it suits the sellers to let them have it in abundance—well—it's a free country.—I am, sir, yours, &c. D. F. SHILLINGTON.

UNDOUBTED PROFITS ON TEA: WHERE DO THEY GO?

A QUESTION FOR THE "THIRTY COMMITTEE" TO SOLVE.

"Cosmopolite"—an old Ceylon planter—writing on 13th November, says :—

"Glad to see Ceylon is in such a healthy state ; hope tea will go up again ; for it makes no difference to drinkers like myself. I pay just the same price for the same quality of tea, whatever the rise or drop of the market may be. So I always pray for a rise, just as a help to my old friends in Ceylon. Where does the difference go ? Can't the 'Committe ot 30' find that out? Somebody is scooping in the profit that has no right to it."

There can be no question of the great profits attending the distribution and retail sale of teas in the United Kingdom. A minor London Tea-selling Company reports by this mail dividends up to 10 per cent for its last year and from the "A B C" downwards, all such Companies go on prospering exceedingly. Pity that the poorer producers cannot have a share of such profits !

SNIPE SHOOTING BREAKS.

(*To the Editor of the "Asian."*)

SIR,—A certain amount of luck as well as straight shooting is necessary in order to make a long break of snipe. The birds must be collected together in a small space ; rise singly and within easy range for the shooter to make a long consecutive run of kills. Of course no one can kill with certainty when there is much walking between shots.

One man I knew shot seventeen snipe running (near Secunderabad I think it was). Another in the vicinity of Barrackpore killed thirty-four snipe in thirty-four shots : he had one miss in his break, but squared matters by knocking over two at one shot. As far as I remember it was his eleventh shot which was the miss.

I should imagine that there must be several men in India who have killed 20 snipe or more consecutively. As a rule unfortunately, the only people who know of feats of this sort are the men who do them ; and the better the shot, the more modest the man—consequently many a great deed is lost in obscurity ! "FLEUR-DE-LYS."

—*Asian*, Nov. 27.

[The writer of the above we have previously identified with Major G P L Birch R.A., now at Rawal Pindi, stationed at Trincomalee early in the year for a short time.—ED. *T.A.*]

DR. GEORGE WATT'S ANNUAL REPORT of the Economic and Art Section of the Indian Museum for the year 1899-1900—referred to in our Correspondence column elsewhere—contains much useful information respecting cotton, fibres, tea, coffee, timbers, etc., from which we may quote in our monthly later on.

SEYCHELLES WISH TO LEASE ALDABRAS ISLANDS.

The authorities in the Seychelles are desirous of leasing the Aldabra Islands, famous for the turtle, for any period from nine up to thirty years. A few years ago, when Mr. Risely Griffith was Administrator at Mahé, he visited the Aldabras, and found the islands in a very dreary and deserted condition. The turtle reigns supreme there, and grows to an enormous size, and it is not improbable that the islands will be leased by someone engaged in this profitable branch of trade If the consumption of turtle in London is to increase in proportion to the accretion of mayors and aldermen, it may be a shrewd investment for some Leadenhall purveyor to secure the lease of the Aldabras. There is regular communication now between London and the Sychelles.—*Daily Chronicle*, November 12th.

A MEXICAN RUBBER PLANTATION.

The statements printed in our last number under the head "Returns from Rubber Planting," relative to the work in Mexico of La Zacualpa Rubber Plantation Co. have been supplemented by a later issue of *The Rubber Planters' Bulletin*, from the company's San Francisco office. In the first place, their resident director (in Mexico), O H Harrison, writes of a new method of preparing rubber from the *Castilloa elastica*, by Enrique Ampudio Chavero, the plantation manager. It consists of the addition to the *latex* of the juice of a plant found on the plantation, resulting in a more satisfactory coagulation than has before been seen in that country. The result is described by Ashmore Russan, an English rubber expert who carried a specimen from Mexico to London lately, as a "perfectly pure and almost white product." Mr. Ashmore says, further : "I consider it equal to the finest Para, that is worth 4s 2d per pound (or say $1 gold). Certainly no Central American or Mexican rubber like the Zacualpa company's has ever been put on the market. It is worth at least 50 per cent more than that prepared by the Indians."

A letter from Mr. Ashmore printed in this Bulletin states that on July 4 last he saw on the Zacualpa plantation a nursery of three acres, said to contain 2,000,000 plants of *Castilloa elastica*, growing so regularly as to suggest that all the seeds planted had germinated. He inspected 30,000 young trees, two years old from seed, growing amid maize and shaded by it, the majority looking healthy and strong. Planted in other areas, also chiefly among maize, were 270,000 other young *Castilloas*, looking well, and Manager Ampudia expected to plant 300,000 more during the season. On the company's old plantation he saw planted trees ten years old being tapped. Some of these he was unable to span with his arms at four feet from the ground, "and few, if any, were under fourteen inches in diameter."

"The men were tapping the trees in the old Indian fashion, but it was probably the last time they would be permitted to do so. Senor Ampudia and his colleague, Senor Lopez, are experimenting with a view to discovering a less murderous, more economical, and more simple method, and as I am quite as keen as they are, I am going to send out some special tools and knives to further their experiments. I think, though, that they have hit upon a method which will enable them to do without machetes and knives. I have a pretty good idea as to what the method is, but at this stage I prefer to say nothing more about it."

Mr. Ashmore attempted to cure some *latex* from *Castilloa* trees by smoking, using a stove and corozal nuts for fuel. "The milk coagulated, but the rubber was very spongy, and the process terribly slow."—*India Rubber World*, Nov. I.

UNITED PLANTERS ASSOCIATION OF THE STRAITS.

CATERPILLARS ATTACKING COFFEE.—*The Chairman* informed the meeting that after very careful consideration the Committee had come to the conclusion that they were not in a position to recommend legislation, and that the Committee proposed with the sanction of the meeting to forward the following resolution to the Government. "That the Committee of the United Planters' Association do not feel disposed to take on themselves to recommend legislation on their own responsibility, but desire to express their great sense of the interest and assistance which the Government have shown in the matter, more particularly in connection with the remedial measures proposed by the Acting British Resident, Negri Sembilan."—*Carried.*

THE PROPOSED APPOINTMENT OF A RECRUITER OF TAMIL LABOUR FOR THE FEDERATED MALAY STATES.—The Committee propose that the salary should be $500 per month as an outside figure, but that that sum should command a really first-class man. As to the method of contribution to the cost by non-Government employers of labour, the Committee proposed a capitation fee of $2 for coolies recruited by the proposed officer and 5 per cent on cash disbursements; in cases where the officer only acts as Agent, he would only charge 5 per cent on cash disbursements, drawing bills upon the employer, at the common usage. That the officer's headquarters should be at Negapatam. That the Committee are not in a position to name any one in particular to fill the post; but that T Heslop Hill's name has been repeatedly mentioned in connection with the matter, and they feel sure that his appointment would meet with the unanimous approval of the planting community

EXPORT OF COFFEE TO EUROPE—Letters from Mr T H Hill were laid on the Table, also a letter from Messrs Sanderson and Co of London being a report on the samples previously sent home

COFFEE—Mr T H Hill says: It is evident that the Malay Peninsula can compete with the Brazils in the cost of production of coffee. In the interests of all concerned the standard should not be left as it now is, viz:—"Fair average of the Season" and at I have already said it will be seen it is unreasonable to expect any one man to be able to deal with the matter, even if willing to face the delay and expense. I am informed that 24 monthly sales would probably suffice and when it is remembered that the export duty on coffee is fixed on a sliding scale, and that the higher standard would pay the higher duty, it appears equally to the advantage of the Government and the Planter that such further standards should be sought for, and the Government might fairly be asked to grant a sum per cwt. towards the expense of the coffee shipped as indicated. The value is advancing and if such should be the case in the future each shipment would result not ouly in benefit to the members of the Association but possibly in actual cash profit as well. If the two standards are now established in future I believe it would be a step in the right direction to make Liberian Coffee more popular and enable estates to carry on better in times of depressed markets.

SANDERSON & CO.—The chief thing to bear in mind is to take out all the broken and black berries and keep the sample as even as possible in colour, viz. a bright golden yellow or brown, but not dingy and dull. Our present quotation for our fair average picked standard, is 38/—c & f.

THE COMMITTEE had decided to send 5 piculs of coffee to Aden, and to keep 5 piculs at Port Dickson: to test the advisability of storing coffee, the samples having been duly passed. That as an outcome of the correspondence which had been read to the Meeting, the Committee with the approval of the General Meeting had decided to follow Mr. T H Hill's advice: and to forward monthly shipments of 100 cwt. at least to Messrs. Sanderson and Co. to be auctioned in the way Mr Hill suggested. That various planters had already given in their names as guaranteeing shipments for one year. That the management of the experiment was to be in the hands of six members to be elected at the meeting—three from Selangor, three from Negri Sembilan. The Committee to pass all samples, and see that they were up to standard. The coffee was to be sized into two sizes: to be sent to the Port Dickson Coffee Curing Co. who would see to the bulking and shipment, and generally act as Agents.

The following Gentlemen were elected: Messrs. Bailey, Toynbee and Prior from Selangor and Messrs Cuming, Coates and Lake from the Negri Sembilan. It was further unanimously agreed to send a special letter expressing the gratitude of the meeting to Mr T H Hill for all his efforts and recording a vote of thanks passed at the meeting.

EXPERT.—A semi-official letter from the Secretary to Resident General addressed to Mr Carey was next read announcing the appointment of Mr Stanley Arden to superintend the proposed experimental planting, and requesting the opinion of the Committee as to where his headquarters should be, and what suggestions the Committee might wish to make for carrying out his duties. The Chairman reported that the Committee had decided to name Kuala Lumpur as Mr. Arden's headquarters, and that for the present the best that could be done was to carry out the suggestions contained in the semi-final paragraph of the letter of the Secretary to Resident General, which read as follows: "That he (Mr. Arden) should I think, visit all the estates where Para Rubber is largely planted and advise the planters on the subject, and should, later on, experiment with the cultivation of other products."

TAMIL COOLIES.—During the last year, some $15,000 have been expended by the Selangor Government in bringing Tamil labourers into that State. The Chairman stated that the Committee after discussion suggested, with the approval of the meeting, replying as follows:—"That this meeting thanks the Secretary to Resident General for the information, but cannot realise that the sum mentioned represents the total sum expended on the number of coolies recently brought into Selangor by that Government."

JAVA produces some 80,000 tons of teak timber per annum of which, however, only 10,000 tons are exported, chiefly in the shape of railway sleepers. At present the transport of long logs and squares is attended with difficulties which have not as yet been met; and though the annual possibility of the teak forests of Java is estimated at some 150,000 tons, no rivalry with Indian and Siam teak need be apprehended for some time at least.

FOWL MANURE.—A poultryman, who is noted for success in producing vegetables, states that he grows twice as much on an acre as formerly. He keeps 100 fowls, and has two lots of ground, one being given up to the fowls while the other is used for a garden. the lots being about 1¼ acres each. The next year he turns fowls on the garden plot, and uses for a garden the plot that was vacated by the fowls. By thus giving up his garden plot to poultry every alternate year, he keeps the soil very fertile.—*Texas Stockman and Farmer.*

THE FUTURE OF TEA AND COFFEE :

THE CRY FOR IMPERIAL FISCAL FEDERATION—"PROTECTION."

The circular letter from the United Planters' Association of Southern India given in our Correspondence, appears at an inopportune moment; for the news has only just been published that the "sugar bounties" of the Continent—the most notorious and obnoxious form of differential treatment—are about to be abolished and it is not likely, with that fact in view, that the British Government would enter on a policy so opposed to the principles of political economy which are now-a-days accepted by nearly all schools of statesmen. Not only so, but the Chancellor of the Exchequer, in a recent speech in Lancashire, specially denounced the suggestions he had seen made in certain quarters, respecting differential duties; and it is, therefore, in our opinion, a mere waste of time to try to move the Government of which Sir Michael Hicks Beach is so prominent a member, to listen to the prayer of the circular before us. A united memorial on the part of all British tea producers against the "sixpenny duty" on tea is far more desirable and likely to bear fruit, though, we fear, not in the approaching budget. How then is "tea" to get relief from the accumulation of stocks and consequent low prices now threatening if not prevailing? The first lesson surely to all producers both here and in India is to strive to the uttermost to pluck and manufacture better teas—no longer to sacrifice quality to quantity; but to pluck finer and aim at a higher standard of outturn. Native growers and makers of tea are not likely to take such a hint and we must, of course, recognise the fact that a certain quantity of cheap common tea is bound to be manufactured both here and in India; but we think there is encouragement to anticipate a new outlet for much of these cheaper teas in the movement now actively commenced by the Indian Association, Calcutta, to spread a taste and demand for tea among millions of the native community who can well afford to buy and use such teas. There can be no good reason why the vast population of India, Burma, the Straits and Ceylon should not follow, to some extent, the example set them in China and Japan in regard to the drinking of tea, morning, noon and night, albeit in the form of a very weak infusion. The custom cannot, of course, be expected to prevail generally for a good many years to come; but we hope to see each year make a difference in the local consumption of cheap teas. In this connection we draw attention to the article from a Calcutta paper on another page entitled "the slump in tea."

At the same time the manufacture of "green teas" must go on, and the fight to win over fresh consumers for our teas on the Continent of Europe and America be strenuously maintained. There is still another means of affording possible relief to the local market, of making Colombo more than ever the great tea port of the East, and certainly of increasing the trade and business of this port. That is to be found in the abolition of the local import duty on tea. We are convinced that the sooner this is done, the better for our tea interests all round. For one thing, it must at once meet the convenience of our Russian friends and encourage them more and more to concentrate their business at this port. If it further induced a local manufacture of "brick tea," there would be a distinct gain through the proportion used of our cheaper teas; while as to "blending," as it is notorious that Ceylon teas are blended at every port to which they are exported, we cannot for the life of of us, see why the blending should not be carried out in Colombo, rather than, or just as much as, in Melbourne, Sydney, New York or London. As for the risk of China, Japanese or Java teas being re-shipped from Colombo as "pure Ceylon," we have frequently pointed out that some of our Ceylon tea shipments have already done us as much discredit as any lots from other countries under our name, could possibly effect, but as a matter of fact, experts in the different ports and countries could not be deceived by any "pure ceylon" label, while fraudulent attempts of the kind might be penalised at the same time that the import duty was abolished.

BRITISH NEW GUINEA.

INTERVIEW WITH MR. C. E. KENNEDY, MANAGER OF NEW GUINEA DEVELOPMENT SYNDICATE.

THE COUNTESS OF HOPETOUN'S BROTHER—A COLONIST OF THE NEW COUNTRY.

We had an interesting conversation last month with Mr. C. E. Kennedy of New Guinea, who was on his way home and had spent nearly a month visiting Ceylon, up-country for the most part. Mr. Kennedy is a colonist of ten years' standing in the comparatively new tropical colony, part of which is the same latitude south of the equator as Ceylon is north of it, and part of which reaches even to the equator itself. When Mr. Kennedy first went to New Guinea (as a lay worker for the C. M. S.) he was warned that it was a dangerous fever-stricken country and that he would never come back. After ten years' residence, Mr. Kennedy is now taking his well-earned furlough, determined, like others who know New Guinea, to remove the impression, wherever possible, that the conditions of life in his adopted home are anything but unfavourable to white men who are careful and temperate.

LABOUR

which we believed was one difficulty, is really very plentiful and obtainable for the equivalent of 1d a day! Amongst the independent Colonists, however, there is a feeling that Government is spoiling the labour market by offering too high wages—in some cases as much as 3d per day. This is no doubt so as to secure permanent workers, in a place where living is so cheap for natives that they are not likely to work except when inclined. Skilled labour moreover is very difficult to get, but there are enough hands for the mining schemes on foot;

no less than four companies for Gold Mining in New Guinea have already been floated. The country, Mr. Kennedy tells us, will grow anything that Ceylon will grow, from cocoanuts to tea. He himself has been growing coconuts (100 acres planted—1,100 acres reserve) with considerable success, and cacao also is making a start. Asked as to

TEA

Mr. Kennedy thought it was unlikely that tea would ever be grown in New Guinea; it was already overproduced in Ceylon and India—not to mention Java or any other place. The Far East New Guinea Colony facing the Pacific, Mr. Kennedy is quite sure, will one day become one of the most prosperous, as it is one of the most fertile and extensive, under the British Crown; it only requires that prospectors should get over their prejudice, visit the place and introduce more capital, for it to progress very rapidly. An instance of this shyness was found in the case of Messrs. Lever Bros., of "Sunlight" fame, who were urged by Mr. Le Hunte, the present Governor (successor to Sir Wm. Macgregor) to take up a tract of 5,000 acres for coconuts, to supply the oil needed in their soap manufacure. Mr. Kennedy himself was ready to take the charge, and, indeed, had been asked to inspect the land—the 5,000 acres were offered without limitation as to locality—but after considerable consideration the offer was allowed to slide! Land may be had for 2s 6d an acre and only the diffusion of greater knowledge as to the resources and climate of the country is required before settlers will come in their numbers to add civilisation and wealth to a new portion of the ever-growing Empire of Great Britain.—Coffee had been tried with success:—both Arabian on hill sides at considerable elevation and Liberian in the lowcountry grow well; but the plantations ,Mr. Kennedy said, had been neglected. They are now likely to be taken in hand by a Sydney Mercantile house bent on developing a planting industry. A ready market for "coffee" is available, and, indeed, Australia will take off a considerable supply of coconuts, coffee, cacao, &c.

THE HOPETOUN INTEREST IN NEW GUINEA.

From Mr. Kennedy, we further learnt an interesting bit of information. It appears that the Countess of Hopetoun's brother, the Hon. Edward Dayrolles Evelcigh de-Moleyns, 4th son of Baron Ventry. has taken a liking to the country and intends to settle there. He has for some years been working in Queensland; but hearing of the further Colony, chartered a yacht last year and took a nine months' tour cruising round the coasts of New Guinea, and landing at various points, made several trips inland to explore the territory. He has now taken up 2,000 acres in the Kearns district which, with his brother (the Hon. Richard Andrew (?) 3rd son of Lord Ventry), he intends to cultivate. It is satisfactory that a scion of a family which now has an increased connection with Australia should thus be settled in New Guinea—not only on account of the force of attraction that such a circumstance contains for new and hesitating colonists; but also because it may prove useful in arranging for the amelioration of the laws and regulations prevailing which are as yet to some extent subject to the approval of the Governor-General on the mainland, as they have hitherto been to that of the Governor of Queensland.

VARIOUS NOTES.

It was interesting, and amusing to us, to see how much Mr. Kennedy knew about planting operations in Ceylon in a variety of products, until we remembered that he had been a regular student of the pages of the *Tropical Agriculturist* as well as of several of our Planting Manuals. We began to tell him that one of the finest plots of coconuts in the island was opposite Mount Lavinia Hotel, and how it got planted, when he replied, "by Dr. Macvicar—I've read about it in your book and have already inspected the garden with interest."

Mr. Kennedy's description of the growth of his palms on the shores of New Guinea in three years, shows that good seed nuts, careful planting, rich soil and a suitable climate must all have been available We hope Mr. Kennedy will be able to visit Goluapokuna and some of Mr. Jardine's work on coconut plantations in the Kurunegala district.

Our visitor's "forbears," of course, hail from that part of Galloway where the people used to declare:—"We're a' Jardine's, Johnstone's and Kennedy's here;" but he —like his father before him—was born in Staffordshire, and never left it till he started for New Guinea.

CACAO IN CEYLON.

Our notice of the large cacao pods which we received the other day from Katugastota estate and sent round the Fort offices has attracted the notice of an authority on the subject, who says it is important from an economic point of view to have the number and weight of the seed, as the fruit wall might be very big without corresponding size of seeds. Fortunately the seed were still available:—44 from the one pod, and 36 from the other, the 80 seeds weighing as nearly as possible a quarter of a lb. As regards the characteristics of the pods, we think they were more typical of the Forastero than of the Criollo variety

"TRAVEL IMPRESSIONS IN CEYLON OF A JAVA PLANTER."—The interesting paper under this heading translated from the Dutch by Mr. D. Ferguson will be found on page 470. It is useful to see how a practical planter from another and foreign colony regards the country, soil, climate, land tenure, vegetation, labour, &c., in Ceylon. As might be expected Mr. Bley makes mistakes which will be obvious to Ceylon readers.—We also expect to give shortly the report by Mr. Treub of the Java Botanic Gardens on his visit to Peradeniya and the other Gardens. This has been translated for us by Mr. Barrister de Vos and Mr. D. Ferguson and will be found both instructive and interesting.

FARMER'S EVERY-DAY LIFE IN SCOTLAND.

No. 16.

(By Cosmopolite.)

In a former paper I expressed views anything but favourable to the value of

ARTIFICIAL MANURES IN FARMING

and as special attention was drawn to my opinion by the editor of the *Observer*, I may be permitted to supplement what I wrote then with a few remarks. Of course, I know that the vendors of artificial manures are about the best customers any news paper has, as they advertise wholesale, and so naturally editors are chary of putting anything into their papers likely to be prejudicial to their customers' trade. I am not, however, wishing the proprietors of the *Observer* to adopt my views, at the same time I must be permitted, in these papers to tell what I have proved conclusively in my farming operations. When I say that my artificial bill on my first few years' farming in Buchan amounted annually to over £200, and at the present time it amounts to nothing, it shows that I am at least, a believer in my own views; and when I add that my crops only averaged 4½ to 5 quarters per acre, during the years when I used artificials, and now when using cattle and sheep manure only, they average 6½ to 7½ quarters, I think I have good reason to compliment myself on the policy I have adopted. But although I am a non-believer in artificials, it does not follow that I take no interest in the investigations carried on at Rothamsted and other experimental farms, so that reading the exciting letters of Messrs. Talbot and Melville White, lately appearing in the *Observer*, has afforded me much pleasure. Of course, when a sufficient amount of cattle manure cannot be obtained, as so often happened in Ceylon, some sort of artificial has to be applied and I observe that sulphate of ammonia and nitrate of soda are specially selected by the gentlemen named; but it appears to me that they have not taken enough of trouble to learn what is the best time to apply these manures, but have done so in a somewhat haphazard style. With regard to nitrate of soda, for instance, it is readily absorbed and passes into the plant; so, in farming, it is always applied after the corn blades are well developed. If I was a tea planter and was applying nitrate of soda to my bushes, I would wait until the flush of leaf had got a good start before doing so. Sulphate of ammonia on the other hand is not available until the ammonia absorbs oxygen and therefore does not come into action so quickly; consequently it should be applied to the land sometime before the plant is ready to absorb it. It may interest my readers to be told that nitrate of soda applied to hay increases the bulk of crop very much, but makes it so rank and disagreeable to the taste that animals will refuse to eat it unless compelled by hunger to do so. Would not the same effe be likely to occur in the case of tea leaves and if so what would the tea-taster say about the flavour? I gather from Messrs. Talbot's and Melville White's letters that the ject they have in view is not only the increase of crop, but the upkeep or restoration of fertility to the soil. I may mention therefore that so exhausting to the soil is nitrate of soda, that many landlords prohibit its use altogether, and I don't blame them, for I know that sometime ago it became quite a custom with farmers whose leases were drawing to a close to manure with nitrate of soda for the last two or three years, and this took all the fertility out of the soil and left the incoming tenant some years of heavy expenditure in order to get the place into a productive state again.

PAPER MAKING LECTURE.

THE POSSIBILITIES OF BAMBOO.

Mr. Ainsley Walker, in his lecture on paper-making delivered at Croxley Mill, Hertfordshire, recently, dealt with raw fibres, and the sources from which they were obtained, and described the machinery employed to cleanse esparto grass and straw from dust and other impurities. Speaking of straw, he pointed out its curious property of producing a greasy effect after having been put through the beater. This enabled them to produce a sheet which had more rattle, or to use the paper-makers' phrase "tinny effect," than could be secured from grass. Straw gave a very hard fibre, and as it consisted of parenchyma cells, which, however, served as filling the proportion of bass fibres was small, and a sheet of less strength was obtainable than from grass was the result. Bamboo was introduced in 1870 by Mr. Routledge who was also the means of bringing esparto grass to the notice of paper-makers. So enthusiastic was Mr. Routledge over bamboo that he published a pamphlet on the subject, printed from bamboo fibre, and excellent paper it was too. Mr. Routledge predicted that in years to come bamboo would be the most prominent fibre used in industry. So far that prediction had not been fulfilled, because wood had in the meantime played such an important part in paper-making. Bamboo had been described as a gigantic straw, with which its physical and chemical properties were closely allied. It therefore happened when they examined a sheet of paper under the microscope, that they found it no easy matter to differentiate the two classes of fibre for both had in considerable quantities the characteristic parenchyma cells and the cuticular cells. To this day the problem of readily and satisfactorily resolving bamboo into fibre remained unsolved. The difficulty he believed, was in knowing just how to boil it. He had experimented himself and though he had obtained fairly good results, he had not really succeeded. The subject thus presented a great opportunity to those students who desire to obtain honours for original research. Mr. Routledge stated that

THE BAMBOO YIELDED AS MUCH AS 40 TONS

of green stem per acre, and that these when dry were equal to six tons. The bamboo also grew at an almost incredible rate. It was said that it would grow to a height of 40 feet in 40 days, which was actually one foot a day. Here were possibilities for paper-makers in these days of keen competition. Paper-makers had been told that they had a sad state of things to look forward to in the future, but, if suitable means could be found for its treatment, they had bamboo to fall back upon. Therefore if the worst came to the worst, they could go to the wilds of India and establish the industry where the raw material would grow at their doors. The stems of the bamboo were cut before the plants arrived maturity, and that was all the treatment that was necessary before boiling. This brought them to those great sources of fibre—mechanical and chemical wood. Mechanical wood was obtained mostly from white pine, the poplar, and the aspen. These woods produced a fine, bright and white effect. They were cut into lengths equivalent to the width of the

stone against which they were to be pressed by hydraulic pressure. The rough sand-stone tore the fibres asunder, and a stream of water, flowing over the stone, carried the fibres into a trough, from which they were passed forward to a series of cylinders, arranged with sieves of meshes of progressive sizes, by which the fibres were sorted according to their coarseness or fineness. At different stages the pulp was run into large vats with revolving cylinders, the idea of which, he believed, was taken from a machine invented by Mr. Dickinson. The pulp adhered to the revolving cylinder, and when a sufficient thickness was wound round it it was taken off. This then was known as mechanical wood. Chemical wood was obtained by the use of certain liquors and boiling. Great care had to be taken that no knots were allowed to go through. Some authorities said they should be drilled out, while others said that all the hard knots should be removed from the soft pulp after it had been run from the boilers. He was a believer in this plan. All, however, were agreed that any rotten wood or stained portions should be removed before boiling. The wood in some mills was carried on an endless revolving belt along which boys and girls were stationed in order to pick out the undesirable parts. Then the wood was crushed. The adherents of another process objected to this. They sawed the wood into inch discs, which were carefully packed in the boiler with a view to getting in the greatest amount of wood, and they also claimed to get by this plan a finer circulation. The great objection to this method was the loss by sawdust, which some declared amounted to 10 per cent., a serious item. In this country the pine and the fir were the sources from which mechanical wood was supplied, but in America it was obtained from 25 different varieties, the chief of which were spruce and poplar. As showing the great interest taken in the supply of wood for pulp, he mentioned that about 50 years ago, Mr. Young suggested the use of poplar in this country, saying that it was the coming wood fibre. He even went to the length of planting poplars for miles upon miles on the banks of the Dee in Scotland, but the climate and the soil were not suitable, and much to everybody's regret, the trees died off. Mr. Walker afterwards instructed a number of students in the use of the microscope.—*Home paper.*

ELEPHANT BREEDING IN MALAYA.

Through the kindness of Sir Frank Swettenham the Resident-General of the Malaya States, a correspondent of *The Asian* has been given some interesting items of information concerning the breeding of elephants in captivity. It may be remembered that over two years ago we discussed the "Domestic affairs of the elephant" and the information now placed at our disposal considerably amplifies the facts set out under that heading. The breeding of elephants is a question of little practical importance; so high an authority as the late Mr. Sanderson stated that even if elephants did breed in captivity, it would not pay to begin stud operations as the youngsters are of no use for working purposes until 15 years of age; and this being so it was cheaper and more satisfactory to catch and tame. From the naturalist's point of view the matter is full of interest, and it would appear that the sources of information Sir Frank Swettenham has made accessible to us, will provide answers to many debated questions. From the fund of information presently furnished we select a few of the more important items. The Sultan of Perak, whose mahouts have supplied answers to the questions put for our correspondent states that the pairing of tame elephants as a rule results in the birth of a calf. "The birth of calves can be regarded as a matter of certainty." This disposes of any idea that the production of calves in Malaya is only occasional or accidental. The young ones are taken in hand to be broken when about four years old, and are apparently used for light work at a much earlier age than the limit named by Sanderson. But there is probably a wide margin of difference between "work" as understood by the late Superintendent of Kheddas, and as understood by the not very energetic Malay. We had, we confess, gained the impression that the domestication of the elephant in Malaya was complete, but our illusions are dispelled by the information now before us. The question was asked "whether a bull born in captivity has been successfully put to a cow born in captivity?" And the answer disposes of the "complete domestication" theory in very few words:—A bull born in captivity has never been successfully put to a cow born in captivity. The fact is curious, and opens up a large new field of enquiry. No enquiry was made as to whether a cow born in captivity had been known to throw a calf to a wild bull; but there is little reason to doubt that the cow, which has never known freedom, proves equally fertile with others when served by wild males in the jungle. The query "Can you say whether a bull born in captivity has been successfully put to a cow caught and tamed?" was, unfortunately, left unanswered. The point is an important one, involving, as it does, the question of respective effects of captivity on the reproductive power of male and female. The opinion that tame tuskers do not more commonly exhibit desire because hard-worked, is, we believe, pretty generally accepted; two answers to leading questions are answered by the Sultan's mahouts in terms which strongly confirm this belief. "The bulls which cover most freely are those which are in the best bodily condition and which do not perform hard work;" and again "the bull which has been longer in captivity, has the stronger sexual inclination." In regard to the latter, it must be born in mind that the work performed by tame elephants in Malaya is extremely light compared with that demanded of elephants in military or civil employ in Burma and in this country. None we are informed, work all the year round, and most are worked for only a few months out of the twelve. Further, the Malay owner, when his elephant shows signs of failing condition, turns him out in the jungles for a considerable period to regain flesh.

Sanderson's dicta concerning elephants in connection with breeding have been proved erroneous in some respects, and the Malay authorities confirm the more modern views. Sanderson, it will be remembered, favoured the theory that the period of gestation varied according to the sex of the calf. The Malay witness is not altogether satisfactory in his answers to questions concerning the length of the period of gestation, but as regards the length of period in connection with the sex of calf, he is quite definite—"It is the same whether a bull or cow-calf is produced." Of this matter, however, we shall speak again. In considering the points in which Sanderson's informants differ from our Malay informants, the difference in the conditions of the life led by tame elephants in this country and those surrounding the tame elephant in Malaya must be borne in mind; the latter far more nearly approximate to the conditions of jungle life and therefore we may conclude that natural habit and tendency is less disturbed. Therefore while Sanderson's informants may have been perfectly

correct in many of the statements which are at variance with those made over the Sultan of Perak's signature, the seeming contradiction may probably be explained by the widely differing conditions prevailing in each country. Thus, Sanderson stated that *musth* is not of regular occurrence in the tame bull, which statement, everybody knows, is perfectly correct; the Malay authority says: "With bulls in sound and full condition which are over twenty-five years in age, the periods of *musth* recur every year when the 'sependurian' is ripe in the jungle." He does not mention the season at which the fruit referred to does ripen, but he makes it perfectly clear that the bull elephant goes *musth* at a recognised season in each year. This does not controvert Sanderson. On the contrary there is a negative confirmation of it in his remarks that *musth* rarely appears in animals much below par. Difference in conditions of life cannot explain so radical a physiological difference as the following—Sanderson says: "There is ample proof that it is not the male elephant that comes in season. In following single males with a view to capturing them with trained females, they may always be relied upon to make advances to the females usually to some particular one." This is not very convincing evidence though it bears the stamp of observation for which Sanderson has deserved reputation. The Sultan of Perak's men say that bulls *do* show signs of *musth* in the presence of a cow in season, and that the cows have no regular season, "but merely follow the conduct or inclination of the bulls." Sanderson, if we read him correctly, did not admit any *correlation* between *musth* and sexual excitement, adducing in proof that on four occasions on which he had opportunity of judging the bulls showed no sign of *musth*. We think, however, that Sanderson's judgment on this point is now generally admitted to have erred.

It is curious that the answer to our correspondent's enquiry concerning the length of the period of gestation should be qualified. "Those who are experienced with regard to the habits of elephants put the period of gestation at twenty-four months." Inasmuch as opportunities of ascertaining the correct period are as frequent as those offered by other domestic animals it is somewhat strange that no Malay expert has taken the trouble to observe this point. There is no doubt that the period varies considerably in length, the recorded cases range from 19 months to 20¼ months, and in contradiction to Sanderson's native informants the calf born after the longest period was a female. There is evidently something to be learned from the Malay experts, as, in reply to the question whether the presence of man deterred bulls from leaping, the answer contains the statement "Others (elephants) again can be deterred by those men who have learnt the art of the elephant doctors of old times." We have "elephant doctors" on this side the bay, but their practice of necessity lies in a groove different from that of the Malay who for centuries has had dealings with "breeding stock" if we may apply the term to animals whose state of domestication is so incomplete that the union of two born in captivity is infertile. It does not appear that enquiry was made concerning the maximum age attained by the elephant, or if made no answer was given. The point is one which has been much, and sometimes fiercely debated, but facts worth recording are practically non-existent. From the circumstance that the bull elephant, according to our Malay informants, reaches maturity at the age of twenty-five, we might speculate from this basis on the limit of age attained, but see no particular end to be accomplished by so doing. There is no good reason for indulging in conjecture now as our correspondent informs us he is preparing a fresh series of questions for submission to the Sultan of Perak and hopes thereby to obtain light on this and several other points.

AN ORCHID FROM CEYLON.

PRESENTED TO THE R B S., LONDON.

A meeting of the Fellows of this Society was held yesterday, Mr. Andrew Clark in the chair. Mrs. Scharlieb, M.D., was elected a Fellow, and the names of ten candidates were read. There were shown specimens in flower of the lily of the valley orchid from Ceylon, presented by Miss Drage, and a flower of the Victoria Regia water lily now in bloom in the Gardens.—*Daily News*, Nov. 16.

RUBBER FROM TOBAGO.

An item which is likely to be of great importance in the future exports of Tobago is rubber. The only rubber which has hitherto been exported is the gum of the indigenous balata tree. This has been done on a very small scale, and could not be extended without rapidly exterminating the finest timber tree in the colony. Many cocoa planters, however, are now experimentally planting on selected parts of their estates the more profitable sorts of rubber trees, and two large estates are now devoted almost entirely to Castilloa. On one of these, in Tobago, seventy thousand trees have been planted but, of course, some years must elapse before th, produce is put on the market.—*Chemist and Druggiste* Nov. 24.

ARTIFICIAL INDIGO had long been known as a laboratory product, costing far too much to be made upon a commercial scale. No one in this country thought of improving the process or inventing a new one, everybody being well content to be practical and to make the things he was accustomed to make. A large staff of trained chemists, maintained for purposes of practical research by the Badische Anilin and Soda Fabrik, turned their energies to this problem. It was, no doubt, a costly investigation, but not an unremunerative one, since many good things were discovered by the way. At last the triumph of theory was reached in the perfecting of a process, which practical ability, combined with vast knowledge and enterprise, has made a great commercial success. The output is now equal to the indigo crop of a quarter of a million acres in Behar; and, as will be seen by another communication which we print today, the planters are now appealing to the Indian Government for aid in setting up a supplementary sugar industry as the only chance of competing with the German factory. It would be easy to give other illustrations of the truth Professor Perry wants to drive home—that our education is not sufficient to enable us to hold our own, that our adhesion to antiquated methods is forfeiting our industrial advantages, and that it behoves the whole community, through all its enterprises, whether private or Government, to awake to the necessity for a more strenuous pursuit of that organization and co-ordination of knowledge which is called science.—London *Times*, Nov. 9.

TEA MANUFACTURE: SUITED TO REQUIREMENTS.

In discussing this question, the *I. P. Gazette* has the following:—We have been manufacturing, in bulk, a class of teas which cannot possibly compete in price with Chinas and Ceylons, Dealers at Home can get common and medium low class teas, just as good as ours, from China and Ceylon at a figure considerably below ours. Therefore, for that very simple reason, they are not wanted. A drug on the market, they are only saleable at a sacrifice; at a figure in fact which cannot possibly cover cost. The worst feature about the market is that even our better quality medium teas are now selling at prices which, in former years, were realised by our commons; the whole-sale dealers and blenders are now using these in their 1s canisters. The tea drinking public are thus getting better value for their money; and, acquiring a taste for our higher class teas, will always demand the same quality for their shilling. Thus, whilst the price of teas is going down to the detriment of the producer, the wholesale dealer and blender and consumer are more and more getting their money's worth, in that they are obtaining for the same money superior teas to the common qualities with which they were satisfied in years gone by. We do not appear to comprehend this very apparent fact, that our common low grade teas are altogether going out of fashion. At present there is not a sufficient supply of the good liquoring quality teas to meet the demand, wholesale dealers and blenders have, therefore, perforce to take the less desirable kinds, but at their own prices: whilst they get better value for their money than they have hitherto got, the producer suffers heavily in that his product goes for a mere song. The chief cause then for the present slump in prices is undoubtedly over-production of common and poor medium kinds. This is due in a measure to coarser plucking this season, for a large proportion of the current season's crop has been of very indifferent quality; attributable partly to climatic causes and partly to a coarser system of plucking. There was, unfortunately an altogether abnormal market last year for common teas, and although a note of warning was sounded by all the Brokers in this city it was unheeded, and orders were issued that quantity, and not quality, was to rule the roost. The inevitable result has been that we have just played into the hands of the wholesale buyers at home. The next cause for the slump in prices of most importance, we think, we may safely assert is the shipping of teas to the home market direct, instead of selling in Calcutta. It has now become an unmistakably patent fact that if the Indian tea industry is to survive, and animation is to take the place of depression, Calcutta must take the place of London as the chief mart for the sale and distribution of our teas. Mincing Lane has not the diversity of buyers which our local Market has.

PLANTING NOTES.

GOURAMI FISH IN CEYLON.—We are much obliged to Mr. Fowler, Government Agent, Southern Province, for the information which he gives us in a letter we publish elsewhere. It is extremely satisfactory to note that Mr. Fowler's last attempt was so far successful, that two of the fish are flourishing at Galle, and that he is interesting himself in further introductions. We trust his example will be followed by some enterprising pisciculturist in Colombo or its neighbourhood.

CASSAVA OR MANIOC.—We direct special attention to the letter of the Curator of the Botanic Gardens on this subject and we trust that intelligent cultivators in different districts will at once comply with Mr. Macmillan's request, by forwarding to him specimens of the leaves and roots (flowers and fruit if possible) of the Cassava grown in the neighbourhood.—Mr. Jardine and Mr. W H Wright ought to be able to help the Gardens in this matter.

THE KANAN DEVAN DISTRICT.—We quote elsewhere a stout defence by Baron von Rosenberg, of the Kanan Devan District in South India, against an article which recently appeared in the *Investors' Review* which he thought was calculated to harm the prospects of the district generally, both as regards its credit and its position towards the Madras and Travancore Governments. His opinion is that before many years Kanan Devan will be one of the most flourishing among Indian planting districts.

PROSPERITY FROM COTTON-GROWING?—The last product we should think likely to afford a promise of profit to planters is "cotton." The price has fallen so greatly in India that we doubt if any European could make the cultivation pay. No doubt where there is rich soil, a favourable climate, and above all a local demand, the cultivation of one or other of the superior kinds might prove profitable. But Sir W. W. Mitchell did a great deal by introducing new seed into Ceylon, without being successful in getting native and other experimentalists to make much out of cotton. Here, however, is a paragraph from the *Egyptian Gazette* (Nov. 14th) which indicates that the American cotton plant is to be tried in German West Africa and is expected to do well:—

AMERICAN COTTON PLANT IN WEST AFRICA.—If the Germans do not attain to success as colonisers it will not be the fault of the "Colonial Economic Committee" in Berlin. By the help of generous expenditure they are now enabling Germans in West Africa to make a most interesting experiment. They have made an agreement with some American planters, to be accompanied by a hundred and fifty workmen, to introduce the American cotton plant into West Africa. It is anticipated that the plant will flourish well, and in that case the commercial prosperity of the district should be assured.

No doubt soil is rich and climate favourable in West Africa; and if labour prove abundant and cheap, the comparative proximity to the Liverpool market ought to tell. But abundant production will render competition keener than ever.

"PLANTING IN MEXICO"—is the heading of a very full letter by an ex-Ceylon Planter given in our daily and *T.A.* It contains a greater amount of practical information than has hitherto reached us, more especially as regards "labour supply"; and it will be seen that the report given is not very favourable. On the whole, for the British capitalist and planter, the advice of our correspondent is to follow the flag, either in British Honduras or the Malay States. But "Planter" affords a great deal of miscellaneous information regarding Mexico and its sub-tropical industries.

SNIPE.—An interesting letter to the *Asian* regarding snipe-shooting in breaks, is quoted on another page. The idea of such rapid and increasing destruction may jar upon non-sportsmen; but the capture of live snipe apparently leads to far more pain to the birds Live snipe, tortured by being tied together by the legs in bundles, are being exhibited for sale in the Calcutta Municipal Market, says the *Asian*. Taken up and swung about in the faces of customers and thrown down dozens of times a day, starved and maimed, the spectacle of the sufferings of these little creatures is a disgrace to those who have the power to put a stop to it.

JAVA CINCHONA SEED.—In connection with an advertisement of Java seed, we had the following note a short time ago:—

We used to consider bark analysing up to five or seven per cent as valuable; but the advertisement from Java which we publish in our daily indicates trees with bark up to 17 per cent! The seed from such trees, if carefully plucked and transported, must be very valuable. The prices fixed are from two to five guilders (each about 2s in value, we believe,) per gram, of which about 200 go to the ounce. The seed is, therefore, priced very high, undoubtedly; but we suppose an appreciable quantity is found even in each gram, or the 200th part of an ounce. Can there be any mistake in our calculation? This was translated and copied into the Amsterdam "Indische Mercuur" of 25th September and has led Mr. H. Vaupel of the "Preanger Culture Company," Java, to send us (November 4th) a letter of correction in Dutch, the substance of which (through the kindness of Mr. Advocate de Vos of Galle) we are able to give as follows:—

"Now, without discussing how the advertisement in your various issues, works out, I take it that you, in Ceylon, are not up to the mark as to the number of plants to be got from a gram of cinchona seed. For this reason I to convince, you, send you a gram Ledgerseed, derived from original mother-trees with a standard of 17 per cent z.w.k. and of which the price is 5 florins. The number of seeds in this gram is 3,700. In Java, it is expected that by careful cultivation of this amount of seed the yield should be 1,200 at 1,000 cinchona plants for the 5 florins, making at most half cent the plant-which surely cannot be called dear."

We are much obliged for the correction and also for the gram of this very valuable Ledger seed, to which a careful trial will be given in a Nuwara Eliya nursery; while the resulting plants can be tried at different elevations as the Sanatarium is perhaps too high for pure Ledgerianas.

PEPPER AND CARDAMOMS.—These two products are doing well in Southern India though the former does not realise in England anything like the prices that are paid for Singapore pepper. Why? —*Planting Opinion*, Dec. 8.

PARA IN BRAZIL.—The output of Para rubber this season may possibly be augmented (says the *India Rubber World* of Nov. 1.) by the fact that the drought in the state of Ceara has become so excessive that the governments of the Amazon States have been defraying the expenses of the famine-stricken Cearense peasants to Para and Manaos, whence they would be likely to proceed to the rubber fields to find employment. During the first six months of this year the rainfall at the port of Ceara had been less than one-tenth as much as during the same period in 1899. For the same reason, a falling off in the production of Ceara rubber is to be expected.

PRODUCTION OF IPECACUANHA.—One of the most widely used of all vegetable drugs is the powerful emetic, ipecacuanha, which is obtained from a Brazilian shrub. The French *Conseiller de Commerce*, at Cuyaba, in the State of Matto Groso, gives in a recent report an interesting account of this plant, which has in that State and the neighbouring districts its only habitat. The drug is obtained from plants which attain a height of from 12 to 16 inches. The leaves are oval, dark green, and sharply ribbed, and the white flowers give place to an ovoid fruit containing black seeds. Besides the *Ipecacuanha Cophoelis*, or the "white ipecacuanha," as it is generally known, there are several other varieties which are somewhat different, but all are used for the same purpose, and are distinguished as brown, black and striated ipecacuanha. The drug is obtained from the root of the plant, where it occurs in quantities about the size of a quill, between the layers. The taste is acrid and bitter, and the odour is nauseating That found next to the bark is most active in its effects, having in the highest degree the emetic property, due to the active principle known as "emetine." The State of Matto Grosso which as before observed, is the habitat of the plant, is one of the richest in Brazil, among its many natural products being gold and diamonds, rubber, sarsaparilla, jalap, jaborandi, copaiba, various drugs and gums of several kinds. Ipecacuanha is found in the north and north-east of the San Luiz-de Carceres, formerly in the Vila Maria region, and its habitat covers an immense area comprised between a network of rivers in Brazil, Bolivia and Paraguay. The dense foliage of the forest of this region provides the dank and humid conditions which favour the growth of the shrub. The Brazilian product is known as Rio Ipecacuanha, and the product secured from different shrubs in other countries passes under the name of the port from which it is shipped. Attempts have been made to transplant the shrub and to cultivate it in British colonies in various parts of the world, but without success, and Brazil continues to be the only source of supply for the best grade. The process of gathering the plant is perfectly simple, and during the rainy season, when the ground is soft, is very easy. A stick is inserted under the root, and while this is raised with one hand, the entire plant is pulled out with the other. As little care is given to the protection of enough plants to secure a future supply, the output is growing smaller, and the price consequently higher each year. The scarcity of workmen is a great difficulty. In the dry season the roots cannot be gathered, and it is at this season when anyone adapted to the work is engaged in gathering rubber. During the rainy season, from October till April, when the plant may be easily drawn from the ground, women are usually employed for the work.—*Scientific American.*

GOLD IN TREES.—The impecunious man may soon be seen grappling with the monarchs of the forest for the wherewithal to pay his way. In the "Zeitschrift fur practische Geologie" Herr Lungwitz writes of the gold in trees. It only amounts to from about 5d to 5s per ton of ashes. The metal tends to collect in the trunk near the roots. Of course the quantity is greater according to the auriferous character of the soil, and probably, too, the intensity of growth, so that in tropical countries gold may exist in many plants —*Daily Express.*

A BOTANICAL ACQUISITION.—Botanists will be interested to learn that the important cryptogramic herbarium of M. Bescherelle, a well-known French botanist, has just been acquired by purchase for the Department of Botany in the British Museum This herbarium which is one of the most complete of its kind in the world, consists chiefly of mosses, lichens and liverworts, collected in great part in the French colonies, where M. Bescherelle has practically had a monopoly in this respect for the last 30 years. The *Manchester Guardian* (Nov. 23rd) understands that there are 15,000 specimens of mosses and nearly 4,000 specimens of liverworts in this fine collection.

LIMITED COMPANIES.—From "Notes on the Companies Act, 1900," by L Worthington Evans, we learn Directorships will certainly not be so popular in the future as they have been in the past, especially (let us hope) among incompetent nobles sometimes called Decoy Ducks. The Act contains restrictions of the power and additions to the liability of a director as well as "a formidable list of fines and penalties." The responsibility and duties of the secretary are also increased; and these additional requirements, as well as others in regard to registration, apply to all companies registered under the Companies Act. After the first day of January, 1901, no new company having share capital may proceed to allotment until the minimum subscription has been subscribed, and not less than 5 per cent. of the nominal amount of each share has been paid in and received by the company as application money. And both these conditions must be fulfilled within forty days after the first issue of the prospectus. In default of compliance with these and other conditions an applicant is entitled to receive back his application money in full; and unless it is repaid within forty-eight days after the first issue of the prospectus the directors become jointly and severally liable for the amount. For all companies registered after January 1, 1901, quite a number of new requirements are introduced, which, as Mr. Evans truly observes, will tend to make the statutory meetings of the company (ordinary and extraordinary) exceedingly important instead of the often useless formalities to which we are accustomed. The power of control possessed by the shareholders is vastly increased. At an early stage in the company's existence a shareholder will be able to test many of the statements in the prospectus and ascertain officially the facts about the allotment, as well as the names of his fellow shareholders with whom he can combine for protection. The book contains an interesting chapter upon the duties and responsibilities of the auditor, whose appointment has now at last been rendered compulsory, and is to be made not by the directors, but by the shareholders.

A NEW GOANESE INDUSTRY.—A contract has been entered into for the construction of an edifice for the Bombay and Goa Trading Company in the New City of Vasco de Gama. The firm consists of Mr. S J De Souza and of the representatives of the late Mr. Goculdass Tejpal the Bombay millionaire. The principal object of the firm is the erection of a coir and rope factory together with the utilisation of the other products of the coconut palm. The firm who are building the coir factory are in a position to operate in this commodity on a large scale. It is calculated that the company will require from 24 to 30 lakhs of coconut husks annually for fibre and coir yarn, and it could easily convert the coconut into copra and export the same or convert this last into oil and export it. It is in contemplation to order out the latest machinery for this purpose.—*Pioneer*, Dec. 3.

OSTRICH FARMING IN AMERICA.—We call attention to Mr. T. A. Cockburn's chatty notes in another column. From a circular he sends us, we quote as follows:—

The Ostrich Farming Industry has been begun in San Antonio, Texas, by Mr. Thomas A. Cockburn, for some time the proprietor of the famous South Pasadena Ostrich Farm, of Southern California, in the hope of establishing this peculiar industry as successfully in Texas as has been done in California. Fifty of these magnificent birds have been transported across the continent to their new home near San Pedro Springs, where there is every prospect of their settling down to regular Ostrich ways. Compared with the imported South Africa article, the local product is considered by connoisseurs much superior, and after a careful examination of the large and varied stock of boas, capes, collars, tips, plumes, fans, etc., at the San Antonio farm, this opinion will be upheld by the general public. The birds vary in age from a few weeks to eight and ten years of age. A full grown ostrich weighs about 275 pounds, and stands nearly eight feet high, both sexes are a brownish color until eighteen months old, when the males turn black and the hens grey. At four years old the selected birds are paired off, and soon the male bird digs a hole with his feet, in which the hen will lay an egg every other day, until from twelve to fifteen are in the nest, when they begin setting, the hen in the day and the cock in the night; in from forty to forty-two days the chicks should hatch out. In this country they are immediately taken away from the nest and raised by being fed on cut up green alfalfa. They will then grow at the rate of a foot a month until six mouth old. The average life of an ostrich is about seventy years. The food consists mostly of alfalfa hay, cut up small, sugar beets, cabbage and corn. Bones and shells are occasionally given to help digest their food and form the shell, coarse gravel is also kept in the corrals for the same purpose. The eggs weigh three pounds each, the unfertile ones are blown and obtain a ready sale as souvenirs of the ostrich farm. The feathers are plucked every nine months and are graded into their various lengths and colors. These sell in the markets at prices varying from $5.00 to $100 per pound, the latter from the long white plumes taken from the wings, only those feathers from the wings and tails are plucked, the body feathers are shed once a year and are gathered up in the corrals. Every feather has a selling price. Many and varied are the products of Texas, but the industry of Ostrich Farming is possibly the most interesting and peculiar to the general public, and no tourist should consider his trip complete until he has paid at least one visit to the San Antonio Ostrich Farm. There is no more pleasing or suitable souvenir to take back or send to some eastern friend than a feather boa or a bunch of tips manufactured from a Texas ostrich. Prices of birds of all ages on application to the proprietor. Feather goods of all descriptions for sale on the Farm, at producer's prices,

Correspondence.

To the Editor.

PLANTING IN MEXICO.

(By an ex-Ceylon Planter.)

The Editor, *Tropical Agriculturist*, Ceylon.

Mexico, Sept. 9, 1900.

DEAR SIR,—In the *T. A.* for January (which went amissing and only reached me in August) and for July, I notice a couple of letters from Mr. E O Darley on "Planting in Mexico," also your note on the same, asking for information *re* labour, taxes, police etc. In the July number, Mr. Darley has given you some information, and I now take the liberty of supplementing the same. It must be remembered that Mr. Darley writes from the State of Tabasco, whereas I am in the State of Oaxaca, and therefore my remarks and statements mostly apply to this State, and to the district I am in. But at the same time there is little or no difference between the States as regards taxation, communication, etc. I have now been nearly 18 months in Mexico, and have had ample time and opportunity for going fully into every matter that affects planting and give my actual experience. I may preface my remarks by stating that I was planting in Ceylon from January 1877 to May 1880 in Udapussellawa and Maturata, and from May 1880 to December 1898 in Johore, the Federated Malay States, and West Coast of Borneo. I arrived here at the end of March, 1899.

SOIL AND LAY OF LAND.—Beyond any doubt the soil of Tropical Mexico is exceedingly rich and of vast extent, and, in what I may call the low country, is of a rolling character with large areas of almost level country, generally along the rivers, and between the spurs of the main ranges, these spurs generally being of limestone formation. Taken all round, however, the country is badly watered. For instance, in the whole of this Company's lands extending to 111,000 acres, there are three large streams, miscalled rivers, two of which form the North, East, South and South-Western boundaries, one running through the centre of the block. There are only ten other small streams running into these, and yet our land lies at the foot of the "Sierra Madre" mountain. Soil suitable for atmost any kind of tropical cultivation can be purchased for from $3 to $50 the acre, anywhere in the best part of Mexico. We sold for tobacco for the latter price here.

CLIMATE AND RAINFALL.—Once outside the range of yellow fever "vomito" which roughly is confined to a distance of about 60 miles inland from the sea, from Tampico to Coatzacoalcos, the climate for the Tropics is remarkably good and perfectly healthy. The rainy season begins about June and ends in September, but during October to end of December there is generally a fair amount of rain. From January to May the weather is fine with occasional showers. March, April and May are the hot months, November, December and January the cold; and even at this elevation, 615 feet, fires are often necessary at nights, and a couple of thick blankets. The rainfall has been systematically kept only since my arrival, but commencing from 1st July, and I append it:—

1899.	Inches.	Rainy days.	Heaviest fall inches.
July	21·30	19	3·40
August	25·48	17	4·30
September	17·31	11	6·00
October	5·05	5	2·00
November	3·52	2	2·72
December	3·55	5	1·58
1900.			
January	3·23	9	1·30
February	1·83	2	·92
March	2·04	5	·72
April	1·30	2	1·00
May	6·80	6	2·50
June	13·83	11	3·75
July	25·51	25	2·77
Aug.	18·94	12	3·15

On the 18th February, the thermometer registered in the office 55° Fahr. at 11·30 a.m., about the lowest it has been since my arrival.

COMMUNICATION all over Mexico is by means of railway, river and tracks. Metalled or unmetalled roads outside the cities (and few even there) do not exist. The rough jungle tracks, worn down by the feet of man and animals, that were in existence in, or perhaps before, Montezuma's time, are the only ones that are available, and as these go up hill and down dale, one can fancy what the travelling is like, especially in wet weather. As far as I am aware, the Government has not even commenced to think about road making. I will confine myself to the Railways serving the tropical portions where plantations are mostly being opened. First there is the line from Vera Cruz to Alvavado, some 40 miles. It now belongs to Sir Weetman Pearson, a bad line, badly managed. Ordinarily it takes four hours to do the journey. Another line runs from Coatzacoalcos to Salina Cruz, across the Isthmus of Tehuantepec, and a branch line from the main line to the San Juan river. Another line is now under construction from Mozorengo to Santa Lucrecia on the Tehuantepec railway. All these are either under the management of Sir Weetman Pearson or are being constructed by him. On paper, this seems to give ample communication, but one has only to look at the map to see what a small portion it serves, especially as there are no roads to serve as feeders. The lines, too, are chiefly strategical ones, as President Diaz does not intend to allow revolutions to grow unchecked. Now as to the rivers. Stern-wheel shallow-draft steamers run all the year round from Alvavado up the Papaloapam river to Tuxtepec from Tlacotalpam (two hours steaming above Alvavado) up the Tesechoacan river to Tesechoacan, and during the wet season up to and a little above Playa Vicente. There is also regular steamer communication, all the year round up the San Juan river from Tlacotalpam, up the Coatzacoalcos, and some of the other rivers in the more Southern States, but how far the boats can go during wet and dry seasons I do not know. What I do believe is that these rivers only serve a small part of the lands suitable for cultivation, and here again there are no roads as feeders. In the section I am in, during the dry season, we have to depend on canoes for transport, and as the "canoeros" as a body are a drunken lot, we are at their mercy. It has often taken three months to get goods up from Tlacotalpam to where I am (just above Playa Vicente) during the dry season. Freight from Tlacotalpam to here, by canoes, is paid for by the piece of 200 lb. and costs $28 (twenty-eight) the ton up and $17

down if you have return cargo. By steamer it costs from $28 to $31 the ton both ways, the distance by river being about 120 miles. Freight from Tlacotalpam to Vera Cruz has to be added, but I have not the figures by me. There are besides handling and storage charges first at Playa Vicente (12½ct. a package) Tlacotalpam same, perhaps at Alvavado, and finally at Vera Cruz, and I am much better off than the vast majority in this section. The freight from Vera Cruz to London is about the same as from Singapore to London. The next "revolution" has got to come from the Government in the shape of roads, and by that time our grand-children will be old men and women. Private enterprise will, most likely, have to undertake road-making, and pay Government for doing so.

LABOUR.—All who have gone in for Tropical Agriculture in Mexico have, with a strange unanimity, avoided this most important question and for very obvious reasons. First, the large holders have lands for sale, and soon, if I am not mistaken, the small buyers will be sorry they ever bought. There are four classes of labourers employed in estates in Mexico :—1st labourers recruited from Oaxaca, Mexico and other cities and surrounding villages on a 3, 4, 6 or 180 days' contract ; 2nd Serranos, 3rd, prisoners, 4th, villagers living in the vicinity of plantations. The 2nd and 4th class are by far the best labourers, but will not go far afield for work, and will only leave their villages for crop time (generally end of October to end of December). In fact unless the estate is in the hills or near their villages this class of labour can only be depended upon for crop, but will not stay and work steadily all the year round. The 3rd class are taken out of the prisons on payment of $5 to $10 a head, and this forms a more or less regular income to certain Government officials, not leaving out the highest in each State. This labour has to be worked literally as prisoners, and as regards treatment, wages, etc., the slave was far better off. They are generally the greatest scoundrels in a country that produces a good many. I have seen them brought up on a steamer, bound together and guarded by armed police. They are invariably locked up at nights and when not working. There is a good deal of this class of labour used on the tobacco plantations. They cost anything from $15 to $35 landed on the estate per head and work from three to 12 months getting 25ct. a day and food, but in the majority of cases get nothing when leaving, and if they do have a balance are given every opportunity to abscond. Personally I have never worked this class in any of the estates under my charge. The 1st class is the one generally employed. My experience is with Oaxaquenos chiefly. They are recruited on a "180 days' work" contract, the longest term they will agree to. This is illegal, as according to the Mexican constitution, no Mexican can contract his time. In practice the law is not enforced, but still it exists. The average advance comes to $16 for a man, and $9 for a woman, all recoverable. The recruiter gets a commission of $10 for a man and $5 for a woman which is not recoverable. Wages : men 37 cts., women 20 cts., boys and girls, 10 to 15 cts., a day, with food. My average rate of wages from June 1899 to end of August this year, works out on all the five estates under my charge to ·6518 cents per working labourer per diem. This includes wages, food, commission, cooks, watchmen, water-carriers, cabos (kanganies) wages and food and loss on absconders. Per contra the credit balances of absconders are also credited to the average. Working with class Nos. 2 and 4, the average would be perhaps 5 cents less, and in the Sierras perhaps 10 to 12 cents less. Nearer the coast the average would come to about 80 cts. As to the labourer himself, I will sum up his chief characteristics—laziness, stupidity, carelessness, drunkenness, callousness, self-conceit and an utter absence of ambition and thrift are the chief, lying and dishonesty coming a good 9th and 10th. When he first arrives, his chief idea is to abscond, but when treated fairly, he soon settles down. I am not judging him from a European standpoint, but in comparison with Tamils, Sinhalese, Chinese, Malays, Javanese, Banjarese and Dyaks, all of whom I have worked during my 21 years in the East. As regards work ; in heavy weeding, he will do about 15 per cent more than a Tamil, but not as good work ; and in clearing with the "machete," he is as good as the Malay with his "parang ;" but in every other respect he is 10 to 50 per cent behind the Tamil as regards estate work. What can be expected from labour 10 per cent of which are field hands, and the balance loafers, gaol birds, tradesmen, artisans, clerks, etc. No wonder they have to be constantly watched, and often as not locked up when not working and at night. Beyond weeding and using the machete, they know nothing about estate work, and by the time you have taught them something of their work, their contract is up and away they go and you have to begin again. By taking advantage of his thriftlessness, I have kept a good many of the best men in the place for a year by advancing them goods from the estate shop, thus keeping them in debt and raising their wage to 50 cents a day. None, however, will stay beyond the end of crop *i. e.* 18 months from date of contract. When they get a craving for change nothing will keep them. Labour, such as it is, is scarce, and some Americans are beginning to introduce Chinese at a cost of $75 to $100 a head and $1 a day wages without food, In the first place they are making a mistake by getting them through the San Francisco "Societies" and unless Planters and Government combine and get Chinese direct from China, they will end by being at the mercy of the "Societies," as the Sumatran planters were ; but under existing circumstances such a combination is very unlikely to come about. The present labour is bad, expensive, and insufficient and Chinese are the only ones that can be got. My experience of 18 years with them is that they work splendidly on contract, but on day wages are very unreliable and do as little work as they can.

TAXES.—Mr. Darley says : "Taxes are low enough." This being a country with a Protective Tariff disproves the above. The import duties are heavy, running in some cases to 75 per cent and 100 per cent. This fact makes living expensive, even plain living. But leaving out import duties, the following are the duties we pay in this state,

INCOME TAX on incomes over $15 a month 4·33 per cent per annum.

POLL TAX on labourers (recoverable) 21 cents a month, payable by estate.

TAX ON GROSS SALES ESTATE SHOP 1·90 per cent per annum.

LAND TAX $13 on every $1,000 value improved or unimproved land or other property.

PROPERTY TAX (readjusted every five years.)

CATTLE TAX, if over 10 are kept for breeding purposes. I do not know the tax.

STAMPS ON INVOICES OR BILLS. 3 cts. on every $5 (or part of $5) value of goods bought.

STAMPS ON CHEQUES 5 cts. Do on draft or bills $100 2 cts. $500 5 cts. beyond $500 1 ct. for every $100 or fraction.

STAMPS ON LEDGER $14 95, cash book $9 90, Journal 75 cts, all liable to Government Examination, a very good thing too.

LEGAL RATE OF INTEREST 6 per cent. The usual rate charged is 12 per cent.

EXPORT DUTIES on coffee remitted, cacao nil, Rubber nil, Tobacco nil, Vanilla nil, Sugar nil, and Aguardiente, none,

IMPORT DUTY has to be paid on all Tools, Machinery, Ploughs, Harness, Bags, (if good ones are wanted) etc, that are used on an estate. (See enclosed letter from Mex. Commercial Company).

POLICE.—I maintain that Mexico is not well policed. I except the capital, towns and large villages. The nearest village to me is some 25 miles off and has two policemen. Being in Vera Cruz state, they are useless to me. The capital of this district is about 60 miles off, and takes three days, over a fearful track, to reach. These are the nearest police that I can call upon. Since my arrival there have been four murders (two of which were by my own discharged men) that I have heard of, and one arrest, and this last duo entirely to my action. As to minor offences, such as brutal and serious assaults, no notice is taken. Prisons are an absolute disgrace. Hanging is not allowed and imprisonment, no disgrace. The worst punishment is to send a man to the Army. A criminal or absconding labourer has only got to get into another state and is practically free from punishment and arrest. Certainly every estate can have its own police, but has to pay $20 a month per man, feed and house both himself and his horse.

GOVERNMENT.—As in the United States, there is no "covenanted" Civil Service in Mexico, but unlike the United States, though a mock form of voting is gone through. Practically all the Governors of the States, the Federal officials and the members of the Legislature are nominated and appointed by the President, and it is lucky for Mexico that President Diaz still remains at the head of affairs. I consider him the ablest man in America. Every State official is under the thumb of the Governor, and as their appointments only rests on favour, they with few exceptions do his bidding, and all hasten to make "hay while the sun shines." They are all badly paid. Each State is sub-divided into districts at the head of which is the Jéfé Politico and with him the Juez, or Judge, both responsible to the Governor. Each district again is divided into municipalities under an "Alcalde" and "Agente Municipal," who are responsible to the Jéfé and Juez. Until we got our own "Alcalde" and "Agente Municipal," whom, of course, we have to pay, we were under two Indians who could neither read nor write a word of Mexican. I will give two examples of the result. Two of my house servants in a drunken fit, broke into the dispensary and drank some carbolic acid that was in a used whiskey bottle. One died and was buried next day. I notified these officials and three days after they came down, and I was informed by the Secretary that I was liable to a heavy fine for burying him before the officials had seen the body. Backsheesh smoothed everything. Case No. 2. One of my men whilst bathing in the river was drowned, though his wife and several others saw what was happening and never said a word or tried to help. This is not singular, for they all have a dread of anything that has to do with their courts of justice. On Monday evening his body was found half a mile down the river and on Tuesday morning I notified the officials, leaving his body where it was found. Four days after they came down, only to examine a skeleton, as in the meantime the carrion eagle had done the work for which it is protected in this country. The machinery of the law is slow beyond all imagination, and justice, to quote Kipling, is "to him who holds the longer purse" as regards the state courts. I have had a simple case on a pro-note going on now for a year and we are just as we started, the Judge having taken one year to discover that the case was a "civil" and not a "commercial" one, and there is every appearance that this decision was given under instructions. The Supreme Court of the Republic is, I believe, beyond reproach. I quote the words of an influential and well educated Mexican merchant to me:—"In the matter of justice we are far behind in Mexico, and General Diaz seems to be more bent on material progress than upon moral advancement."

PRODUCTS.—Cultivation as understood in the East is quite unknown as yet in Mexico, unless amongst the few men of Eastern experience. From what I have seen, there is a want of even elementary knowledge of planting. Once the plant is planted (often as not "stuck in") three to four weedings or cutting down the weeds with a machete a year is all the cultivation that is given. The soil and climate do the rest. This want of knowledge is due in my opinion to the following causes:—1st. The want of "go" and education amongst the vast majority of Mexican planters. 2nd. The bad and costly labour. 3rd. The richness and productiveness of the soil. Whether in the face of costly transport and the labour conditions, cultivation will pay, remains to be proved. What I do know is that at the present moment there are very few solvent coffee and tobacco planters in Mexico, and a large number of estates of the former have been abandoned and of the latter put out of cultivation. Estimates coming from Mexican or American sources I entirely mistrust; first, because the Mexican as a rule only calculates the amount he spends on labour, and the American estimates come from men with land to sell. Crop estimates are more reliable, but even these should be discounted considerably. I have carefully worked out the cost of properly opening, cultivating and bringing into bearing the following products under existing circumstances in this section and append the same. If I have erred at all it is on the expenditure side, as of course, every planter has his own ideas of how a work should be done. I have taken the acreage of each estate as 500 opened.

COFFEE.—To bring into bearing, say 4th year $300 per acre. Returns in full bearing 8 cwts. the acre, Cost of cultivation $120 the acre. I have seen absolutely no disease.

TOBACCO.—The first year will cost $15 the arroba (25 lb. Spanish) value $18 the arroba. The 2nd year will cost $10 the arroba value $20 to $25 the arroba. Only under expert management. The yield here for the 1st crop is an average 2½ arrobas

per 1,000 plants. The following year 1½ to 2 arrobas. This is far under the Sumatran yield.

RUBBER.—Planted 14′ × 14′ will cost to bring into bearing (*i.e.* full 8th year) and if regularly weeded $150 the acre.

Yield 8th year 1lb. per tree cost per acre including gathering $95.

Yield 9th year 2lb. per tree, cost per acre including gathering $150.

Yield 10th and following year 3 lb. per tree, cost per acre including gathering $200.

CACAO.—Will cost to bring into bearing $250 the acre. Yield in full bearing 8 cwts. the acre cost $100 per acre.

SUGAR AND AGUARDIENTE.—It is generally calculated that in this part the same field will go on yielding from 10 to 22 years (a pretty wide margin) and the profits range from $600 to $800 the "heetara" (2½ acres). In my opinion, as I know nothing of sugar, a good deal of salt would mix well here.

RICE DRY.—This is a crop that for years to come will pay, I believe, better than any other. Very little labour is required. There is a large local demand and prices are good. Rice costs us here 12 cents the pound.

VANILLA.—This is its home, but I can gather no information about it. It grows wild in the forests here, as does rubber. On the Tobacco lands, crops of Maize and Beans are raised, but I do not approve of this mode. There is a large local demand for CACAO, Mexico even importing it, hence the local high prices which Mr. Darley correctly quotes. There is also a good local demand for sugar, maize, beans, tobacco. The local demand for Aguardiente is enormous as the Mexican mozo or peon cannot do without his one, two or three "copitas" (glasses) a day, and they begin drinking as children and gulp it down almost raw without a wink. It is their one remedy for almost every ill. When, however, this local demand is met, and the planter has to compete in the open markets against countries with cheaper and better labour, cheaper transport and light taxes, how will he fare? Time alone will tell. In the meantime he has magnificent soil in his favour and a large and close market in the United States and Canada. It is true Americans are rushing in and taking up large tracts of lands. There are a few exceptions, but the majority are buying only for a deal. They will dispose of these lands in small blocks to would-be planters, and I prophesy that these will be "lett." What Company can deal with 100,000 acres of land and over; certainly not open it themselves? In my immediate vicinity there are 588,000 acres of magnificent land for sale. The truth is there is still a large land boom on in Mexican tropical lands and, what goes hand in hand with land booms, a plethora of exaggerated estimates like the one you published on page 36 of the July *T. A.*

LIFE ON A PLANTATION.—As I have said previously, living, even of the plainest, is very expensive, unless one lives like a Mexican on dry beef, chickens, beans, rice and tortillas and coffee. If you offer a Mexican tea, he will decline saying that he is not ill. Such a thing as a good cook or house servant is not to be found in Mexico, taking the standard of upcountry in Ceylon or in the Malay Peninsula. A plain cook, generally Chinese, will demand $30 to $40 a month and food and a house servant of the same nationality $20 to $30 and food and get it too. Mexican cooks (women) get $12 to $15 and food and house servants $15 to $ 20 and food. The Mexican servant is the most hopeless, lazy, ignorant and dirty brute I have ever come across. He has no idea of waiting, or general house work, and the cook is of the same class. Their worst point is that they will not learn, they have too much self-conceit; and if you get one who is willing to learn, they will not stay long enough to be taught, and if they do, will only learn up to a certain point. I answered a cook's advertisement in the *Mexican Herald* and enclose his reply. $100 a month and food is not bad for a "Mussleman from Conpore" calling himself "Charles Sherman."

The other delights consist of insects called "rodadores" that torment and bite one all the day and all the year round, sandflies that do the same at night during the wet season, and mosquitoes (these only bad in some places). During the dry season one cannot walk through the grass without getting covered more or less with ticks and lice. Of sport of any kind there is none, nor recreation nor society. If one is surrounded only by Mexicans, all idea of civilized society and sociability has to be given up. To compensate for the life one would have to lead, would require larger profits than I am afraid any estate would yield.

For rubber and coconuts, Mexico and adjoining countries will have a formidable rival in the Malay States where labour is from 100 to 125 per cent cheaper and far and away better, transport better and cheaper by at least 100 per cent, taxes 2½ per cent *ad valorem* duty on produce. Any one thinking of investing in Mexico, I should advise first of all to visit British Honduras. I see no reason why British Honduras should be worse than Mexico as regards soil and climate. It is a British colony and labour can be got from India under a five years' agreement and for 50 cts. a day without food, cost landed £10 a head, but irrecoverable.

"PLANTER."

CASSAVA OR MANIOC.

Matale, Nov. 26.

SIR,—With reference to the poison of the cassava or manioc referred to in your issue of the 25th, the natives hereabouts believe that some of the poison in the cassava is communicated by snakes who are said to be very fond of this vegetable and nibble at the roots whenever opportunity offers. Further as the manioc is planted as a fence tree along with the "endaru" which is supposed to be poisonous, the "endaru" is said to have infected the manioc with its poison. All careful housewives as previously stated, cut out the poisonous part of the cassava before they begin cooking. I understand that manioc is very extensively eaten in the Eastern Province and doubtless some of your correspondents there will be able to give valuable tips about the way to avoid the bad kinds.

S.

IMPERIAL FISCAL FEDERATION—FOR COFFEE AND TEA.

United Planters' Association of Southern India,
Incorporated.
Madras, Nov. 29.

DEAR SIR,—I beg to enclose for your information and for the favour of such comment as you may deem fit, a copy of a letter that has been despatched to a very large number of

Chambers of Commerce and other bodies concerned with trade in various parts of the British Empire. Trusting that you will view favorably the action that my Association has taken in the hope of bringing a very important subject under discussion,—I am, dear sir, yours faithfully,

HARRY ORMEROD, Secretary.

Madras, 11th Nov. 1900.

DEAR SIR,—At the annual meeting of this Association on 8t August, 1900, the following resolution was unanimously adopted :—

" That considering the critical condition of the tea and coffee industries, this Association do communicate with the Indian Tea Association, the Ceylon Planters' Association, the Indian Chambers of Commerce and the leading firms of merchants and brokers interested in tea and coffee, etc., in this country and in England and her colonies with a view to ascertaining whether a movement in favour of a commercial combination of Great Britain and her Colonies and India against the world (which would by a system of differential duties afford some protection to British-grown products and manufactures) would receive support."

This resolution may be said to have resulted chiefly from the recent revision of the French Tariff in regard to Imports of produce from (*inter-alia*) India, and the British Colonies and Dependencies. You are doubtless aware that the French Parliament, as an act of reprisal against Brazil, voted recently a law doubling the duties on coffee, tea, and spices imported from countries not having Treaties of Commerce with France or not enjoying Most Favoured Nation Treatment, among which are India, the British Colonies and Dependencies (with the exception of Canada). The French and Brazilians have made up their quarrel, but the French Tariff law, which was really directed against Brazil, still subsists. There appears to be reasonable ground for hope that it will not be put into force, but if it should, the consequence would be,—to use the words of the " *Economist* "—that the prohibitory tariff for Colonial produce would only be applied to countries, British Colonies among others, for which it was not intended.

Although it is possible that the French Government may be induced to reconsider the action referred to, yet what has been already done serves as an unmistakable warning of the grave risk to which British trade is at present exposed, and the burdens, it may at any time be called upon to bear.

It is felt that there is a strong and growing feeling in England and her Dependencies and Colonies, in favour of what may be termed an Imperial Fiscal Federation for the protection of British interests as against those of the rest of the world. The Association is desirous of eliciting your views on the subject, to co-operate for the purpose of submitting memorials to the Home Government and other Governments concerned, and would be glad of your advice as to the precise form such memorials should take.

If you have already made any move in the direction indicated, a copy of your proceedings would be welcome.—I am, dear sir, yours faithfully,

H. PERCIVAL HODSON, Chairman.
Harry Ormerod, Secretary.

GOURAMI FISH AND ITS SUCCESSFUL CULTURE IN CEYLON :

Galle, Dec. 1.

DEAR SIR,—I wrote an account some time ago of the various attempts that have been made to introduce Gourami into Ceylon, but I do not recollect stating that they would only thrive at sea level. I think that they would probably do well up to 1,000 feet in this climate.

Nuwara Eliya has been proved to be too cold, as a large consignment of healthy fish died during the first night in their new quarters. This happened in 1893 or 1894.

Of the five fish which arrived last year, three died, mainly, I think, for want of suitable food. Though they fed greedily, they fell off in condition, and eventually died; while the two survivors, when turned out into a small pond where they could find their own food, throve well. I brought these two down to Galle, where, I believe, they are still flourishing. I have written to Mauritius for a further supply; but have had no reply yet. I hope that other attempts will be made to introduce this fish; but it is important that a suitable pond, well protected, and free from other fish, should be ready to receive the new arrivals. The difficulty in finding such a pond in Colombo is greater than would be imagined, and the best way would be to construct one specially for the purpose.—I am, sir, yours faithfully

GEORGE M. FOWLER.

HOW TO CHECK OVERPRODUCTION AND SECURE QUALITY OF TEAS —A PRACTICAL SUGGESTION.

The Laboratory, Hyde Park Corner,
Colombo, Dec. 7.

DEAR SIR,—Might I suggest the following partial remedy to minimise the *present* production, and improve the general quality of the tea coming into the market. It has been long known, and proved, that the young shoots after a medium or heavy pruning contain little material in their sap to produce a good liquor, and this is perhaps equally the case even when manure has been applied, especially if of a forcing character.

By leaving these shoots unplucked for a few extra weeks and then cutting back, the bush would have a much better chance of forming good wood and *root* grown and the temporary loss of leaf would be made up by the steadier flushes of better quality plucked at a later stage. As pruning is being carried out practically during every month of the year, there must be a constant supply of this immature leaf going both to the local and home markets, which can but do harm to the name of Ceylon tea.—Yours faithfully, M. KELWAY BAMBER.

CASSAVA AND ITS POISON.

DEAR SIR,—It would appear that the " poisonous " variety of cassava is harmless enough—and is in fact the better of the two—if properly treated. Dr. Alfred Nicholls, in his text book of Tropical Agriculture, says " sweet cassava may be used as a vegetable without preparation: but bitter cassava contains juice of a very poisonous nature. This poisonous juice, in which there is much hydrocyanic or Prussic Acid is fortunately dissipated by heat, and so the bitter cassava is commonly cultivated as it gives much larger returns than the sweet kind."

The same author goes on to show that there is a use even for the " poison," for he says, " The poisonous juice of the tubers of the bitter variety of the cassava plant should not be thrown away,

as it can be converted into a valuable product known widely as cassareep. The juice is simply boiled down until it becomes of the consistence and appearance of molasses. In this condition it is a powerful antiseptic, and it is capable of preserving all kinds of meat in a fresh condition for considerable periods. It is the basis of many celebrated sauces, and of the well-known *pepper-pot* of the West Indies. Thus by reason of the boiling process, this highly poisonous juice is converted into a wholesome food product, for which there is usually a ready sale in England and elsewhere."

We then have a reference to the carelessness by which deaths are caused through bitter-cassava poison, and the following valuable hint is given: "The Indians of Guiana use red peppers (chillies) steeped in rum as an antidote to the poison."—Yours faithfully, C. D.

"INDIAN TEA FOR INDIA" (AND CEYLON TEA FOR CEYLONESE?)

DEAR SIR,—With over two hundred millions inhabitants, fully seventy-five per cent of whom are capable of being converted into habitual tea drinkers, it seems absurd that India should still go on flooding the London Market with her teas without making any effort to capture the local market. No doubt a few futile attempts have been made by the Indian planters at odd times, but they have always failed for the simple reason that the tea was not presented to the natives in a way to suit their habits and requirements. The common idea seems to be that the natives will only buy the very cheapest low grade teas and these have been presented either in large packages or *not packed at all*, and then people wonder that so little Indian tea is consumed in the country. What is wanted is to study the native character and then to supply the market in the way best suited to their habits.

I remember writing on this subject more than 20 years ago, giving my own personal experience in selling teas amongst the natives in the rural districts, but little or no notice was taken of my letters. At that time, however, India was not turning out much more than half her present crop, and Ceylon had only just commenced to produce tea and the idea of over-production was scoffed at by most, if not all those engaged in the industry; but, now that we are actually face to face with over-production, my words may have greater effect.

If you will allow me the use of your columns I would like once more to give an account of my own attempt to introduce tea into the native bazaars which extended over two seasons and which though productive of very little good at that time, sufficed to convince me that an enormous trade might by done be supplying the article in the way best suited to the wants of the native community; and had I remained in India, and been given the opportunity, I felt sure of success. But let me give me a brief account of my experience and I will then endeavour to show what is needed.

My first attempt was made somewhere in the seventies entirely with black teas; and as cheap travelling was absolutely necessary, my arrangements were of the simplest. After loading several large bullock carts with about 10,000 lb. tea of all grades in one and two lb. packets, 5 and 10 lb. boxes and large quantities of *Bohea*, simply packed in bamboo baskets with paper lining, I hired a small single bullock hackery for myself and set off to traverse the rural districts and purely native towns, merely passing through the larger cities and perhaps halting for a day or two to rest myself and cattle. I generally took advantage of this halt to send a few hundred lb. of tea to an auctioneer (one or more of whom are to be found in every large city in India) and attending the sale myself (unknown even to the auctioneer) I would bid for the tea till it reached a reasonable figure and then step out. This was perhaps a bit of sharp practice and scarcely honourable; but I always stopped bidding as soon as a fair price was reached, and did not often buy in any quantity. Of course, some of the tea sold at these auctions was bought by residents for their own use, but most of it went to the native shop-keeper to retail to their customers. And now for my experience in the purely native districts.

Firstly, I soon found that the idea that natives would only buy the lower grades, was a great mistake. Nearly all the well-to-do native gentlemen would look at nothing but the very best tea, paying R2 per lb for O P rather than buy good *soo* at eight annas or *Bohea* at four annas. 2nd,—One lb. packets were easily disposed of, but 2lb packets were sold with difficulty and at a reduced price, while five and 10lb boxes could only be got rid of by bartering for goods to sell again upcountry. 3rd,—Most of the Muhammadans preferred *green* to black tea. They say that green tea is less heating than black, and therefore better suited for hot weather; how they got this idea I cannot say. Probably from the Afghans and Persians who all drink green tea. Acting on the above information, I took care to have a proportion of green tea the second time, and this sold readily, and I might have sold double the quantity of greens if I had taken it.

To capture this valuable market which might result in more than half the tea produced in India being consumed in the country, all the I P A have to do is to start a Company to make up small paper packets of tea to be retailed at one anna and half annas the best grades at one and the lower grades at half, the quantity of tea in each packet being made to suit the above prices. For instance the best O P could be put up in one-ounce packets to be sold for one anna, and the *Bohea* in two ounces to be retailed for half an anna—the other grades in proportion to their market value. These little packets should be enclosed in lead packets containing one dozen each or in air-tight tins. Then one or more travelling agents should be sent to scour the country and place these packets on commission sale with every respectable native shopkeeper all over the country. The Company should not rest till their packets are on sale in at least 50,000 shops. This would not be a difficult task. In every case where I tried them, I found the Bunniahs always willing to take tea on commission sale and render monthly accounts and write for more tea when they wanted it. They are generally honest enough in these matters and I don't think the Company would suffer much loss through them nor would the business be expensive in other ways, as little or no money need be spent in advertising and as soon as a demand sprang up, no doubt many of the shopkeepers would buy their requirements from the Company rather than take it on commission; but they would not do so at first.

In almost every large city in India, China tea is sold in small paper packets, for a few pice and this constitutes the chief supply, so far as the

natives and Eurasians are concerned, and is the sole reason why China tea still holds its own in the Indian bazaars. Neither the natives nor Eurasians keep tea caddies and object to buying even a lb. of tea at a time, hence the necessity for these small paper packets. And I am positive the Indian market will never be captured in any other way, but a one-anna packet Company worked as suggested above would be sure to succeed and work wonders in a few years.

I give the advice for what it is worth and the I. P. A. must be mad indeed if they do not give it a trial. If Ceylon had had such a promising market at her door we should never have heard of the tea cess or the XXX Committee; but even Ceylon need not send an ounce of dust or fannings out of the country. If a three-cent packet Company was started in Colombo on somewhat similar lines and it would put a stop to the sale of *rubbish* in the harbour, as the Company would naturally get the whole of that trade in their own hands. To start such a Company would not take a large capital and I should say any planter would be glad to take a ten-rupee share in it.—Yours faithfully, G. S.

TEA AND MR. BAMBER'S SUGGESTION.

DEAR SIR,—That was a very sensible letter of Mr. Kelway-Bamber (see page 490.) I agree with him, the temporary loss in manufacturing rubbishy tea from tippings would be more than made up by the extra root growth and good wood for pruning if the bushes were allowed to run. I had practical demonstration of this many years ago in the Kelani Valley when I knew very little about tea, and allowed the bushes (in about thirty to forty acres) to run and then passed the knife over them. The following year I had splendid wood to prune on and I am sure more than made up for the loss.—Yours faithfully,

WESTERN PROVINCE.

FLOWERS AND FLOWER-GARDEN.

DEAR SIR,—I enclose a cutting from an old *Magazine*, about the "Civilizing Effects of a Taste for Flowers."—Yours truly,

LEISURE HOUR.

Extract from "Civilizing Effects of a Taste of Flowers":—"The Parish of Arncliffe, near Skipton in Yorkshire, situated in a very wild part of the country, and inhabited by a wild and lawless tenantry, had been for many years without a resident clergyman, the living being a very poor one—not over £30 a year. The present incumbent, the Rev. Mr Boyd, determined, however, to set himself down among them, and to use utmost exertions in bettering their condition. To this end he surrounded his house with a fine garden, well stocked with lovely flowers, and induced his peasantry—but with great reluctance, to come in one by one to see and admire his flowers, and to take them home and to cultivate them. Now, for the first time they had light in their dwellings, and ultimately, through the kind and personal care which was bestowed upon them, they have become the most contented and happy set of villagers in all Yorkshire."

NEW GUINEA RUBBER.—I am glad to hear that the natives of New Guinea are beginning to understand the collection of raw rubber. At first they were inclined to cut down the trees in order to obtain the milk. They are, however, doing better now.—*Indiarubber Journal*, Nov. 26.

PLANTING NOTES.

RUBBER IN SANTA CRUZ.—A great discovery of india-rubber forests of vast extent has been made in the Department of Santa Cruz de la Sierra, and on the Magdalena in the Department of Beni, and also some exceedingly rich gold deposits. This confirms the traditions of the Jesuits, who knew something of that region, and who even worked its resources to some extent. In the Province of Caupolican, Department of La Paz, there have also been discovered some splendid forests, in which there have been found some rubber trees of a species not before known. In Bolivia the only species of rubber trees hitherto worked are those known as "Hevea," or "Siphonia Brasiliensis," but lately the species known as "Castilloa," which exists in Mexico, Colombia, Ecuador, Central America, etc., has been discovered. In the Province of Caupolican gutta-percha has been also discovered, which is very important. In order to facilitate shipments for the products of Santa Cruz and Beni, the Government has decided to open a port, with a national custom-house, on Laguna Gaiba, a beautiful creek of the river Paraguay, on its right bank at 17 deg. 43′ S. latitude. The prolongation of the North Central Argentine National Railway from Jujuy to the frontier of Bolivia, and thence to the city of Potosi, is an enterprise which London capitalists might undertake to their advantage, as they could obtain very advantageous concessions from both Governments. —*India-Rubber Journal*, Oct. 15.

BANANA FLOUR.—The banana, which grows in almost all tropical countries, is very nutritive, and forms a nearly perfect food. It contains more than 25 per cent. of assimilable organic matter. According to Humboldt, it is forty-eight times more nutritious than the potato, while Crichton Campbell has stated that the banana is twenty-five times more nutritious than the best wheaten bread. The analysis of Thoms shows the presence in the flour of banana of 9·01 per cent. of nitrogenous matter. The best wheaten flour contains no more than 9 to 11 per cent. It is preferable to manufacture the starch from unripe fruits, because the starch is converted into sugar in ripening. In Venezuela the flour of the banana is given especially to children; it is equally good for aged people, convalescents, nursing women, and is of great service in the feeding of those suffering from complaints of the stomach. In Central America, Columbia, and Venezuela, the banana flour is prepared on a large scale, and sold under the name of Musarina. The flour of the banana may be used in the same way as wheaten flour, except for the preparation of bread, for which it is unsuitable, inasmuch as it contains no gluten. Various formulæ are taken from the *Tropenpflanzer* for preparing banana flour for dietetic use. Thus, a teasponful of the flour in a cup of chocolate or cocoa facilitates the digestion of these drinks, and renders them more nutritious. This addition enables cocoa to be taken by those whose stomachs are in a weak state. A sustaining drink may be made by adding a teaspoonful of the flour to an egg yolk beaten up mixed with milk, and sweetened with sugar. The sale of banana flour in London is insignificant, on account of its high price, and the fact that its uses are not yet understood.—*Revue des Cultures Coloniales.*

TEA COMPANIES' REPORTS.

CENTRAL TEA COMPANY OF CEYLON, LIMITED.

The Directors have the pleasure to submit the General Balance Sheet and Profit and Loss Account for the year ending 30th June, 1900, duly audited.

	£.	s.	d.	£.	s.	d.
The net amount at credit of Profit and Loss Account, including the balance brought forward at 30th June, 1899, and after providing for General Expenses, Directors' Fees, Income Tax, &c., is ...				2,867	0	2
Dividends on the 6 per cent preference shares were paid for 1899/1900 (less Income Tax) amounting to	1,299	7	6			
It is proposed to pay a dividend of 6 per cent (less Income Tax) on the Ordinary Shares which will absorb	1,054	10	0			
And to carry forward to next year a balance of ...	513	2	8			
				2,867	0	2

The Directors trust the results of the year's working of the estates will be deemed satisfactory by the shareholders, considering the fall in the market value of tea.

The gross average price realised for the tea was 7·03d per lb. as against 7·87d per lb. last season, and the rate of exchange was 1s 4 31-64d as against 1s 4 13-64d.

The yield of tea was 406,646 lb., being 454 lb. per acre over a plucking area of 895 acres.

The acreages of the estates are as under :—

Estate.	TEA. In bearing.	New clearings.	Cardamoms.	Forest Grass and Waste.	Total acreages.
Kabragalla ...	508	...	49	380	937
Somerset ... (Including Easdale and Loxa)	387	13	...	33	433
Total ...	895	13	49	413	1,370

Under clause No. 24 of the Articles of Association Mr. H. K. Rutherford retires on this occasion from the Board, and being eligible, offers himself for re-election.

THE GANGWARILY ESTATES COMPANY OF CEYLON, LIMITED.

REGISTERED OFFICES :—BILLITER SQUARE BUILDINGS, LONDON, E. C.

DIRECTORS :—Sir John J. Grinlinton, C.E., F.S.A., F.R.G.S., H. L. Tottenham, Esq., Theodore Stretch, Esq.

FOURTH REPORT OF THE DIRECTORS.—To be presented at an Ordinary General Meeting, to be held of the Offices of the Company, Billiter Square Buildings E. C., on Tuesday, the 16th October, 1900, at 3·15 o'clock in the afternoon.

The Directors submit herewith Balance Sheet and Profit and Loss Account for the twelve months ending the 30th June, 1900.

A new clearing of 27 acres has been made on Yelam-Mallai Estate and is being planted with Cardamoms. This will be increased to 40 acres, making the total clearing 100 acres and the cultivated area of all the Company's Estates 1,017 acres.

The crops of all the Estates have been in excess of estimates, but the advantage thus afforded has been almost dissipated by a further fall in prices. The total Tea made in the Season amounted to 499,029 lbs. costing 26 cents. per lb. free on board Colombo.

The total quantity of Tea sold amounted to 527,139 lbs. including 28,110 lbs. of bought leaf. Of this 126,264 lbs. was sold in Colombo at an average of 27¾ cents. and 400,875 lbs. in London at an average of 6·06d per lb.

The Cardamoms on Yelam-Mallai are reported to be growing well and a small picking may be looked for in the new season.

Estimates for the Tea Crops for the twelve months ending 30th June, 1901, point to a yield of 475,000 lbs. Every effort is being made to keep down cost and at the same time maintain the Estates in good cultivation.

The Profit and Loss Account, after paying Dividends on the Preference Shares to 31st December, 1898, shows a balance of £84 17s 9d brought down. The profit for the year, after writing off £382 16s 11d from buildings, machinery, &c., amounts to £974 9s 4d, which added to the above gives an amount of £1,059 7s 1d. Out of this the Directors have paid a half-years' dividend on the Preference Shares to the 30th June, 1899, leaving a balance of £740 17s 6d ; they now recommend that a dividend be paid on the Preference Shares to the 30th June 1900, which will absorb £636 19s 2d, and leave a balance of £103 18s 4d to be carried forward. J. J. GRINLINTON, Chairman.

4th October, 1900.

THE CEYLON LAND AND PRODUCE COMPANY, LIMITED.

Report of the Directors, to be submitted to the Sixteenth Annual General Meeting of Shareholder' to be held at the Registered Office of the Company-Nos. 353 and 354, Leadenhall Hall House, 101, Leadenhall Street, in the City of London, on Monday, the 12th day of November, 1900, at 2 o'clock p.m.

Your Directors have the pleasure to submit the Annexed Profit and Loss Account and Balance Sheet for the Crop year ending 30th June, 1900, duly audited.

1,103 shares of £5 each, being part balance of the 6 per cent Cumulative Preference Capital, were allotted during the past year, and the premiums received, less cost of issue, transferred to Reserve Fund in the sum of £675.

The amount at credit of Profit and Loss Account is £8,262 17s 10d, which, with the sum of £986 3s 10d brought forward from last year, leaves £9,249 1s 8d to be distributed.

On the 21st July last an Interim Dividend of 7½ per cent. on the Ordinary Shares and 3 per cent on the Preference Shares was paid, and your Directors now propose to pay on the 15th day of December, 1900, the balance of the fixed Cumulative Dividend on the Preference Shares, 3 per cent, making 6 per cent for the year, and 7½ per cent. on the Ordinary Shares, making 15 per cent. for the year, all free of Income Tax. It is also proposed to transfer £1,825 from Profit and Loss Account to Reserve Fund, increasing that account to £20,000, to set aside the sum of £100 as a provision for possible losses on Coast Advance Account, and carry forward the balances of £1,473 1s 4d, subject to the Directors' remuneration for the year under review and to the payment of Income Tax, &c.

A sum of £1,575 spent upon permanent improvements during the year has been debited to Revenue.

Your Directors are pleased to report that the total Crop of Tea for the year exceeded the Estimates by 64,518 lb. ; there were also increases of 64,091 lb. made from purchased leaf, and of 43,486 lb. made for others, the total excess amounting to 172,095 lb. It is a matter for regret, however, that the general

net average of the Company's Teas has fallen from 6.78d. to 6.21d. per lb.; during the same period exchange showed an advance, and Freights were on a par with those of 1898-99.

Your Directors have to report a shortage in the crop of cocoa marketed from the Alloowiharie and North Matale Groups. The estimates framed at the commencement of the season for these properties provided for 2,400 cwts., but the intake therefrom amounted to only 1,436 cwts. This shortage, in the opinion of your board, is mainly attributable to the abnormal weather experienced, but there is no doubt that "canker" is also responsible in a measure. Every precaution is taken to prevent the disease from spreading, and latest advices from the affected properties (North Matale and Alloowiharie) are to the effect that it is becoming less prevalent; the Cocoa on your other properties is, so far, quite free from disease.

During the financial year a total sum of R28,000 has been spent on Manure and its application to Tea and Cocoa, the whole of which expenditure has been charged to Revenue; it is intended to continue generous treatment.

A census of Coconut trees was taken at close of the year, shewing a total number of 40,195 planted amongst other products; this is equal to 530 acres at the rate of 76 trees per acre.

TEA.—The Market opened after the turn of the year, with a good general demand, and steady prices for nearly all descriptions. In the early spring months the Trade were much engaged with clearances, in anticipation of a rise in Duty. This actually took place, to the extent of 2d per lb, in March, after which there was less disposition shewn to purchase, and as supplies at Auction continued abundant, with a large percentage of poor liquoring and and unattractive parcels offering, the average gradually declined until June, when it stood at 6¾d per lb; by that time the value of common leafy kinds had from January 1st fallen from 6d to 5d per lb. Later on some improvement was discernible in quality, and although Public Sales remained heavy, this, together with actual reduced shipments and smaller telegraphic estimates, somewhat restored confidence, so that the result became gradually more favourable, the average being 7½d per lb for the month just ended.

From 1st January to 31st ultimo 1,111,700 packages of Estate Tea passed through the Mincing Lane Sale Rooms, realising 7¼d. per lb., against 8d. per lb. for 964,500 packages, and 7¾d. per lb. for 984,300 packages, in the corresponding ten months of the two preceding years.

The most noticeable feature presented by the Market throughout a great part of the period under review was the depressed condition of medium grades quotations for which, at times, were but little removed from those current for good common and fair, partly attributable to the unattractive selection sent home. For really choice flavoured invoices there was a good enquiry throughout. In view of the anticipated increase in the year's output to 142 million lb., contrasted with total shipments from the Island in 1899, which were 129 million lb., it is satisfactory to notice that the growing demand from outside quarters has induced larger shipments from London to meet it, and also brought about more direct business from Colombo with Australasia, Russia, and America, the amount sent from the Island to these countries for the first nine months of the year being—

TO AUSTRALIA.		
1900.	1899.	1898.
12,894,000 lb.	11,967,000 lb.	11,259,000 lb.
TO RUSSIA.		
6,657,000 lb.	2,719,000 lb.	1,915,000 lb.
TO AMERICA.		
3,463,000, lb.	2,344,000 lb.	1,870,000 lb.

COCOA.—It is gratifying to report that prices this year have attained a higher level than those of any time since 1893, the advance having been gradual and continuous, mainly attributable to the increasing general demand, and the falling-off in supplies from the island which have been about 40 per cent less than last year, and about 30 per cent less than 1898. The quality has shewn no improvement upon last year's out-turn, parcels of good and fine bright red being again in small proportion to the bulk of the crop, and consequently the attractive lots have realized good prices. A parcel from the Company's Alloowiharie Estate obtained 102s 6d per cwt, being the highest price of the season, and above any secured since 1893. The future of the article appears favourable, consumption shews a continuous improvement, and a further increase in production would not materially affect values.

ACREAGES.—The following Statement shews the approximate acreage of the Company's Properties at date:—

Name of Estate.	Tea.				Cocoa.	
	1 yr.	2 yrs.	3 yrs.	Over 3 yrs.	Bearing	Not bearing.

N.B.—In the absence of detailed surveys these figures, as mentioned above, are approximate only.

The Estimates for current year provide for a Crop of 945.5 0 lb Tea from the Company's Estates, and 265,000 lb from bought leaf and Tea made for others, totalling 1,210,5 0 lb. The Crop of Cocoa is estimated to be 2,1 5 cwts. At the higher elevations the intake of Tea at date shews a marked falling-off as compared with last year, but your Directors trust the present shortage will be overtaken It is too soon to speak with any certainty regarding Cocoa, but, given favourable weather, it is hoped that a fair Autumn Crop will be harvested.

By Order of the Board, JAMES WILSON, Chairman. ALFRED E. LOCK, Secretary.

PEPPER, COFFEE AND TEA IN THE WYNAAD.

THE WYNAAD TEA COY., LTD.

The ordinary general meeting of the Wynaad Tea Company, Limited, was held at the office of the company, 7, Mincing Lane, E.C., on Monday last. The chair was occupied by Mr: J C Sanderson, chairman of the company.

The CHAIRMAN, in moving the adoption of the report and accounts, said: When the directors had the pleasure of meeting you last year I remember I told you we thought the prospects for the then current season, viz., 1899-1900, were encouraging, and that we looked for a crop of 78,000 lb. of tea, 20 tons of pepper, and 18 to 20 tons of coffee. Unfortunately, these crops were not marketed, so our hopes have been disappointed. Had we secured those crops they would have given us within about £200 to £300 of the working expenses of the season, which was all the board looked for. The pepper and tea crops turned out fairly well, but coffee failed us, and we picked barely ten tons, while the price realised was very low in consequence of the state of the market; hence the deficiency of £1,446 17s 4d, as stated in the accounts. I would, however, like to point out that this deficiency is so large because £1,266 18s 5d has been credited to the block account, being the proceeds for the tea from the acreage which is not yet in full bearing. The latter part of the season was a most trying time for both coffee and tea, as they had the longest drought in the Wynaad experience for many years, which drought injured the coffee trees to such an extent that we picked, as I have already told you, half our estimate, and it was only very late in the season that the board was aware of this serious deficiency. With regard to the tea crop, up to the end of October we were fully 7,000 lb. ahead of the estimate, but the long drought stopped the flushing of the bushes, and the final outturn was about 2,000 lb short of what we had expected. Our pepper crop turned out larger than the previous year, although rather below the estimate. To turn to a more pleasant subject, I am glad to be able to report that the outlook for the current season is so far satisfactory, although the past monsoon has been an exceedingly heavy one, indeed so heavy that some miles of the Ghat (the Government road) was washed away. (This damage has since been repaired.) Mr. R K Walker still considers his estimates are fairly safe. At the date of the last letter from our superintendent, viz, October 13, he reported that the quantity of manufactured tea was 67,453 lb. which was 27,266 lb ahead of last year, thus we have received nearly half our estimate, and we have the heaviest months to come. He said that although some little injury had been done to the pepper vines by the excessive rains, he did not think it necessary to revise that estimate. I have, however, the pleasure to report that we have just sold the crop at the price of 6½d. per lb. being ½d. per lb, more than last year. As to coffee, the latest report is, they were expecting to begin picking the crop about the end of October, and hoped to get the estimate of 35 to 40 tons, but as every coffee grower knows, there are always so many surprises in store for him up to the very last hour of harvesting his crop, that it is quite impossible to depend upon estimate. I do not think the directors will sell this crop for arrival, as prices ruling are so low that it is better to take the chance of the market improving. I should like to call your attention to the fact that we have planted a further fifty acres with tea, making the area now opened up to 630 acers, so that year after year we may expect an increasing yield of this product, Our cost of production is, I am glad to say, very moderate, and compares favourably with other tea-producing countries. At present we estimate we can put our tea, f.o.b., at slightly under 4d per lb, and as the yield per acre increases, that figure will, of course, be further reduced. You will notice from the report that the policy of the board will contin to be the development of this tea industry indeed, we would have liked to have planted a further fifty acres during this season, but, in in face of the deficiency for the working of 1889-1900, the directors decided to await the result of this current year's trading, before any further capital expenditure was authorised. The directors, however, after having consulted Mr. R K Walker, decided to plant, as a catch crop, a certain area of the Adelaide Estate with chillies, and also to put out a small quantity of ledger bark seed which they were able to procure from the Government gardens in Java. The cost of this work will be trivial, so you see, gentlemen, your directors in England, and Mr. R K Walker in India do not allow the grass to grow under their feet; indeed, they watch the welfare of your company with the greatest care, and at the same time endeavour to work the estates with every possible economy compatible with efficient management and sound cultivation. —*Home and Colonial Mail*, Nov. 9.

THE UKUWELA ESTATES COMPANY, LTD.

ANNUAL REPORT.

Report of the Directors, to be submitted to the shareholders at the second annual general meeting to be held at Ingram House, 165, Fenchurch Street, London, E.C., on Friday, the 16th day of November, 1900, at 2-30 p.m. The Directors beg to submit herewith the accounts of the Company and their report for the year ending 30th June, 1900, showing a balance at credit of Trading Account of £2.373 1s 9d.

After payment of Debenture Interest and Establishment charges, there remains a disposable balance, including £37 12s 7d brought from last year, of £1,190 11s 7d, and which the Directors have dealt with as follows:—

One-third of Preliminary expenses written off ..	£226	15	11
Depreciation of Machinery, Plant, &c. ..	100	0	0
Preference Dividend for Year	567	0	0
Dividend on the Ordinary shares at the rate of 3½ per cent. per annum ..	264	5	0
Balance carried forward to next year ...	32	10	8
	£1,190	11	7

Owing to the very dry weather which prevailed during the greater part of the year, the crop secured amounted to only 273,510 lb. Tea, being equal to 790 lb. Tea per acre over the plucking area of 346 acres (33 acres of which were plucked for the first time), against 927 lb Tea per acre, from 313 acres plucked during the former year.

The net average price of the Tea was 5·02 pence per lb. against 5·12 for last season. Cocoa and other credits amounted to £478 0s. 11d, against £201 3s. 3d. secured last year.

The Trading account shows a working expenditure of £3,710 16s. 8d. This includes a sum of £415 0s. 5d. spent on manuring 166 acres of Tea, and from which little return has been secured during the year under review. The Estate, however, will reap in a larger measure the benefit of same during the current season. The cost of production works out at 3·13 pence per lb. Tea, which includes cost of manuring, also £85 18s. 3d. loss on exchange, but excludes £233 9s. 8d. the amount spent on Cocoa and securing other credits. Last year's cost of production was 2·87 per lb. Tea. The increase arises entirely from the smaller crop secured, as compared with previous year, and the cost of manuring as mentioned above.

The accounts are worked out at an exchange of 1/4 per rupee. The actual rate of exchange averaged 1/4 23-64, thus accounting for the difference of £85 18s. 3d. as per Trading Account.

The prices secured for the Teas during the Autumn and Winter were satisfactory. However, since then there has been a considerable fall and at present prices continue at a low range for common and medium quality Teas.

Yonr Director in Ceylon estimates for the present season 300,000 lb. of Tea, which should be secured if weather continues of normal, as up to the end of the first quarter of the current year 82,160 lb. Tea had been secured, whilst the amount for corresponding period last year was 56,476 lb. The Cocoa crop is estimated at 90 cwt.

Capital expenditure for year endiug 30th June, 1900, amounted to £429 9s 11d ; this sum includes cost of a new roller £172 14s 2d, the balance, £256 15s 9d, having been spent on factory and on oultivation of the Tea not yet in bearing.

The present acreage is as follows, viz. :—

Tea in full bearing	..	346 acres.
Do to be plucked during season 1900-1901	..	19 do
Do not in bearing	..	33 do
Cocoa	...	74 do
Grass Land	...	7 do
Reserve Land available for cultivation	..	79 do
Total	..	558 acres.

Mr. W B Anley, Director, retired in June last Mr. J P B Anley, Director, retires in accordance with the Articles of Association, but being eligible, offers himself for re-election. Messrs. Woodman Tullouch and Edds, the Auditors, retire, but offer themselves for re-election.

F. G AMBROSE and J. P. BENTLEY ANLEY, Directors; T. W. PALMER, Secretary.

London, 7th Nov. 1900.

THE CEYLON AND INDIAN PLANTERS' ASSOCIATION, LTD.

THIRD ANNUAL REPORT, 1899-1900.

The Directors beg to submit their Report and the Audited Accounts for the year closing 30th June last.

TEA.—The crops have exceeded the estimated yield by 67,009 lb., and show an increase over the corresponding twelve months of 135,204 lb. of made Tea. Markets have, however, been lower owing to increased supplies, and no doubt the higher duty has also to some extent had an adverse effect on prices, the result to this Company being that profits earned during the twelve months show a decrease of £631 15s 5d, which, however, is more than counterbalanced by profits on Plumbago, detailed below.

The crop has weighed out 807,009 lb. of made Tea, and the estimates for the current year are 850,000 lb. The Kandaloya Garden still gives a very disappointing result, but the Directors are hopeful that as more Tea comes into bearing this year, returns from this place will be more satisfactory.

The following table gives full information as to cost of production, &c., &c. ;—

PLUMBAGO.—The discovery of this mineral on Laxapana, which was notified to the Shareholders under date of the 25th January last, has proved of much importance to the Company, and the Directors are able to add a sum of £1,585 1s 4d to the profits from Plumbago mined and sold up to the 30th June last, and showing the result of seven months' work. Mining is being carried on, and about 15 to 20 tons a month are now coming in. The Company is endeavouring to engage a competent miner so that the works may be developed to the best advantage, for up to the present there has been but little more than surface work done. Mr. George Greig reports that there is evidence of large deposits, and is sanguine that the veins will improve at depth, and that an increased ontput will be secured during the current season.

The Accounts show that after paying interest on debentures, interest to agents, preference share dividend, and Manager's commission, Directors' fees, etc., there is a balance at credit of Profit and Loss of £2 413 4s 8d. The Directors propose to write off £300 from Machinery Account; £950 from Preliminary Expenses; and £348 16s 3d from Debentu e Issue Expenses Account, and to pay a dividend of 2 per cent., free of Income Tax, on the ordinary shares. In appropriating an amonnt equivalent to more than 3 per cent on the Ordinary Share Capital to the extinction of the two latter accounts, the directors believe that they are acting in the best interests of the Company, and they trust that in future years they may be able to recommend larger dividends.

The directors desire to record their thanks to Mr George Greig and the Staff in Ceylon for their care and attention to the business of the Company during the period under review.

DIGALLA CEYLON TEA ESTATE, CO., LTD.

Report of the Directors to be submitted at the fourth annual ordinary general meeting of shareholders to be held at 20, Eastcheap, E.C., on Tuesday, 4th December, 1900.

The Directors herewith submit the general balance sheet and profit and loss account for the year ending 30th June, 1900 duly audited.

	£ s. d.	£ s. d.
The net amount at Credit of Profit and Loss Account, after providing for General Expenses, Directors' Fees, Income Tax, &c., is ..		500 0 8
Dividends on the six per cent Preference Shares were paid for 1899-0 (less Income Tax) amounting to	346 10 0	
Leaving to carry forward to next year a balance of	153 10 8	
		£500 0 8

The Directors again regret that the year has not been a favourable one on the Digalla estate.

The crop has turned out 8½ per cent under the estimate which was formed at the beginning of the year, but this can be fully accounted for by the fact that the rainfall has been 26 per cent under the average of the past eleven years, the average fluctuation from year to year being only 10 per cent. The shortage of crop has rendered the expense of cultivation much greater than would otherwise have been the case, and this, coupled with a decline in the market value of the produce, places the Directors again in the position of not being able to declare a dividend on the ordinary shares.

The acreage of the Company's property is as follows :—

Tea in bearing	550 acres. s
Tea not in bearing	50 do
Jungle	151 do
Total ...	751 acres.

The gross average price realized was 6.26d per lb., as against 6.84d per lb. last season, and the rate of exchange 1s 4 15-32d, against 1s 4½d. The total crop amounted to 201,622 lb. plucked off 550 acres, of which 32 acres are in a partial bearing, giving an average of 366 lb. per acre.

PLANTING NOTES.

CULTIVATION OF EGYPTIAN COTTON IN INDIA.—An experiment which gave definite results in Betul (Central Province of India) during the year, was the cultivation of Egyptian "Abbasi" cotton as an irrigated *rabi* crop. A small crop was raised by one *Motilal, Patel of Badora*. The crop was valued by the Manager, Empress Mills, Nagpur, at R96 per *bhoja*, as against R65 ordinary *bani* The seed was sown at the end of September in light black soil, and watered about once a week till the end of the cold weather, after which it was irrigated once every three or four days. The amount of watering was excessive, and had the effect of shrivelling the bolls so that although the plants were strong and flowered freely, the outturn was small. Farm experience has shown that one, or at the most two, waterings a month are ample for this cotton even in the hottest months. The Deputy Commissioner considers that this cotton can be grown in Betul as a rabi crop with irrigation, and that it would be exceedingly interesting so see the effect of less watering. The Deputy Commissioner is of opinion that if a fair outturn can be obtained, the crop should be of the greatest use to cultivators. This experiment will be prosecuted further.—*Egyptian Gazette*, Nov. 28.

IN DIAN CATTLE-BREEDING SCHEME.

THERE is a tendency at the present day to follow the example of India, and even in the case of education Ceylon is about to adopt the Indian system. We should like to see, however, the spirit of liberality and philanthropy, so much in evidence in India, infecting the people of this island. Owing to the appalling loss of cattle in Guzerat there is a great scarcity of animals there for agricultural purposes. In order to supply this want, a scheme (which originated with the Governor of Bombay) has been set on foot for preserving that excellent breed of both draught and milch cattle. The scheme provides for the lease of 2,000 acres of grass land, for the procuring of 400 of the best cows, for ring-fencing the land, for a supply of fresh water and constructing yards and shelter sheds. The farm is to be under a superintendent, and the cattle-keepers of the district who have lost nearly all their animals, will be employed as herdsmen. The male calves will be disposed of as yearlings to the natives for breeding purposes. According to the estimate made, a sum of at least half a lakh is required to start the scheme, and an annual expenditure of R4,000 is anticipated for the first four or five years, after which the farm is expected to be self-supporting. The absence of any expectations of *profit* is indicative of the liberal principles on which the scheme is based. The sordid element of a return in revenue for money expended (an element which, we regret to say, is apparent in nearly every local measure intended for the good of the people) does not mar this scheme, the highest hope of which is that after some years the farm will support itself. The details of the project are in the safe hands of Mr. Mollison and Mr. Leley, and the funds for working the scheme are being provided by voluntary subscriptions, the Governor of Bombay heading the list with R1,500 and a number of others —Civil Servants, Merchants, etc.—following with R1,000 each. It is intended to form a trust for the administration of the fund. A letter signed by the Governor's Private Secretary commends the scheme, on behalf of His Excellency, to the favour of the public. We quote the final paragraph from this communication :—

"His Excellency, in now placing the scheme before the public, is confident that its objects are such that it cannot fail to command widespread sympathy and hearty support. He desires hereby to thank most cordially those gentlemen of Ahmedabad who have in so practical a manner testified to their agreement in the benefits which it is to be hoped will be derived from the scheme and so generously contributed towards its funds, besides agreeing to make over their cows for breeding purposes at less than market rates. His Excellency feels assured that this is a scheme which must appeal most strongly to all who are interested in the welfare of the country, and it will be a matter of the deepest gratification to His Excellency if he can hereafter feel that he has been personally connected with a measure to promote the well-being of a Province which has been so terribly afflicted by the recent famine."

COFFEE PLANTING IN COSTA-RICA. WALKER'S PULPERS.

(By the son of a Ceylon Missionary, born in the island.)

Extract from a letter lately received from archi Costa Rica, Central America :—"It is not too much to repeat my thanks for the 'Coffee Planter's Manual' (Ferguson's) which you sent me. I consider that the mere perusal of the articles relating to artificial manuring, which are really only summaries of planters' experiences in that part of the business, influenced our proprietors to adopt the practice on their estates, the result being that in August, I received a shipment of 30 tons of a well-known coffee fertilizer (Ohlendorffs's) from London, and a confirmation of a previous order to pick up or purchase all such manures as cattle-dung and cane trash that can be got cheap and handy, without limit.

"When the Boston people come down next month, I will draw their attention to Walker's Pulpers and shall be very glad if you will send me one of their catalogues with prices. There is a probability of a further extension of our business operations in the near future in the shape of the introduction of new machinery of larger capacity and greater working power and of making advances to the native farmers for the delivery of their coffee to us. We have lately imported a monster turbine for the—station where improvements on a large scale have been projected."

RIVAL FERTILISERS.

NITRATE OF SODA AND SULPHATE OF AMMONIA.

The rival claims of nitrate of soda and sulphate of ammonia as fertilising substances for agricultural land have for a number of years been the subject of much spirited debate. There are many experienced farmers who pronounce unreservedly for sulphate of ammonia as the best nitrogenous accompaniment to mineral manures, while the majority perhaps hold as firmly to nitrate of soda as the more effectual dressing. This sharp conflict of opinion is not surprising in a sense, for the acute dissension that exists on almost every point connected with the wide subject of manuring is one of the most remarkable features of modern farming. A closer examination of the testimony arrayed on either side of this long-standing debate, however, reveals traces of argument somewhat removed from the region of practical and unbiased evidence. The peculiar circumstance connected with the use of the rival nitrogenous manures is that the respective sides rigidly adhere to the substance of their fancy, whatever may be the character of the crop or of the soil. Unprejudiced discrimination seems to be conspicuously absent, for the two materials seem to be seldom found on the one holding. A searching investigation of the relative merits of the two manures does not confirm the wisdom of the exclusive use of either of the invaluable materials. The substances are really less antagonistic than is usually supposed. They are similar in their chemical contents but essentially different in their fertilising effects, and consequently the one substance is often incapable of economic substitution by the other, as is intelligently shown by Professor Warrington in the paper that appears over his name in the Royal Agricultural Society's journal. Nitrate of soda is, of course, the more speedy in its action, and is thus peculiarly adapted for application as a top dressing when the established plants appear to need encouragement. It is also more effectual in dry seasons than sulphate of

ammonia. The latter, however, is a highly advantageous manure for spring application, along with phosphatic and potassic materials, and while nitrate of soda usually gives the better yield as measured by bulk, sulphate of ammonia is the more efficacious in improving the quality of the crop. The selection of the nitrogenous dressing is distinctly a matter for careful and intelligent discrimination, and not, as is often supposed, one on which the fancy of the individual may be humoured with impunity.—*The Field.*

SUNSPOTS AND RAINFALL.

Among the papers presented at the meeting of the Royal Society, was one by Sir Norman Lockyer and Dr. W. J. S. Lockyer on "Solar changes of temperature and variations in rainfall in the region surrounding the Indian Ocean."

PULSES OF RAINFALL.—The authors' object in studying rainfall was to ascertain whether the *plus* and *minus* temperature pulses in the sun were echoed by *plus* and *minus* pulses of rainfall on the earth.

INDIAN FAMINES.—Unless the pulses either overlapped or became continuous, there would obviously be intervals between the ending of one and the beginning of another. The *plus* and *minus* pulses, to which attention had chiefly been directed, were limited in duration, and when they ceased the quantity of water falling in the Indian area was not sufficient without water storage for the purposes of agriculture. They were followed, therefore, by droughts, and subsequently, at times, by famines. Thus, taking the period from 1877 to 1889, there was rain from the *minus* pulse in 1877-78-79 (part); no rain pulse in 1879 (part)-80-81 (part); rain from *plus* pulse in 1881 (part) 82-83-84 (part); no rain pulse in 1884 (part)-86-87; and rain from the *minus* pulse in 1887 (part) 88-89. All the Indian famines since 1836 had occurred in these intervals, carried back in time on the assumption of an 11 year cycle. Thus, taking 1880 as the central year on the ascending curve, it was itself a year of famine in Madras and the North-West Provinces; also

1880 minus 11=1869, N.W.P. famine (1868-69)
1869 minus 11=1858, N.W.P. famine (1860)
1858 minus 11=1847,
1847 minus 11=1836, Great famine in Upper India (1837-38). Again, taking 1885-1886 as the central years on the descending curve:—

1885-86, Bengal and Madras famines (1884-85)
(1885-86) minus 11=1874-75, N.W.P. famine (1873-74)
Bombay famine (1875-76)
Bombay and Upper India famines (1876-77)
(1874-75) minus 11=1863-64, Madras and Orissa famines (1865 66)
(1863-64) minus 11=1852-53, Madras famine (1854)

It was clear from this table that if as much had been known in 1836 as was known now, the probability of famines at all the subsequent dates indicated might have been foreseen. The dates might also be carried forward from 1880; thus—

1880 plus 11=1891, N.W.P. famine (1890)
Madras, Bombay, and Bengal famines (1891-92)
(1885-86) plus 11=1896-97, General famine

Famine years in India were usually years of low flood in Egypt, and it might be pointed out that the highest Niles followed, at an interval of one or two years, the years of the *plus* and *minus* pulses. As to the great Indian famine of last year, the widened line curves, so far from having crossed in 1897 or 1898, as they ought according to the few precedents available, had not crossed even now; in other words, the condition of ordinary solar mean temperature had not even yet been reached. Now India in a normal cycle was supplied from the southern ocean during the *minimum* sunspot period, and the rain was due to some pressure effect brought about in high southern latitudes by the sun at *minus* temperature. But as this temperature condition was not reached in 1899, as it would have been in a normal year, the rain failed. Thus the only abnormal famine recorded since 1836 occurred precisely at the time when an abnormal effect of an unprecedented *maximum* of solar temperature was revealed by the study of the widened lines.—London *Times*, Nov. 23rd.

INDIAN TEA ON THE CONTINENT.

Turkey.—Mr. George Gatheral has been engaged as the Agent of the Association in Constantinople, as suggested by Mr. Harington. I would suggest consignments be sent to an address I would give in Syra, where the tea would lie in bond, and we would then avoid paying duty and being forced to sell to save such duty while I could direct such sales as made to Trebizonde or Russia.

Holland.—The London Committee have resolved to assist the National Tea Union, as recommended by Mr. Harington, by contributing an equal amount of money to that fund by them for the purpose of advertising in Holland, up to a sum of £300. [Surely this is a mistake! We have always said that the Java tea-planters should exploit Holland and send none of their teas to London.—ED. *C.O.*]

Italy.—The London Committee have authorised Mr. Harington to suggest to Miss Babbington (English Tea Rooms) a grant of a sum of £50 towards advertising and pushing Indian tea in Rome.

Germany.—The London Committee although they fear they cannot start a tea house as proposed by Mr. Harrington, are willing to subsidise a firm which might be prepared to initiate one. The matter is still engaging their attention.

My own wish and aim is—

1. To secure a General Agency in Germany for the Indian Tea Association.

2. To establish an "Indian Tea House" in Berlin where tea can be sold both in cup and packet.

3. This to form a distributing centre for all Germany, opening branch agencies in all chief towns, and being charged with care of extensive advertisement, supervised by myself.

4. The cost of such advertisement up to a sum not exceeding say £500 per annum for a fixed period of three to five years to be paid by the Association, subject to conditions. The founding and first year's cost of the "Tea House" in Berlin also to be borne by the Association up to a lump sum not exceeding £1,500.

5. Supply of tea, chiefly Indian, and in any case British-grown only, to be arranged through myself, who will undertake all working details and be responsible to the Association—

(*a*) For quality of tea supplied submitting sample.

(*b*) For control of advertisement and general supervision in the Association's interest.

I regret that up to the present no arrangements on these lines have been completed; further negotiations can, however, be carried on and may be brought to a practical result in course of time. —*Indian Planters' Gazette.*

SOURCES OF TEA SUPPLY.

(To the Editor of the *New York Herald*).

The news from India of a short rainfall in the tea districts, published and commented upon in the *Herald* is of considerable interest to the public as well as to the trade.

The trouble in China is likely to affect the next season's supply more than it has this year's, as the China season happened to be an early one. The movement of the crop was further accelerated by the troubles, and it was rushed down to the coast ports very early. The pinch will probably come next season, and no doubt the market here will respond before spring.

The other sources of the world's supply of tea are Japan, which last season sent about forty-one million pounds to North America (the amount given in the *Herald* as the entire crop of 1888), and India and Ceylon. The crop in the latter two countries in 1888 was about one-third of the quantity now produced.

India shipped about one hundred and eight million pounds last season and Ceylon about one hundred and thirty million pounds. Increasing quantities of these teas are coming to both the United States and Canada, and if the troubles in China are not soon settled we may see the tea from that country entirely displaced here and to some extent in Russia.

WHITTALL & Co.

New York, Oct. 9th, 1900.

MICA AND GRAPHITE IN ZULULAND.

The following are extracts from an official Geological report, published in the *Natal Mercury* of Nov. 22:—

MICA.

The mica properties in the Nkandhla district, near Fort Yolland, are still held, but no work of importance has recently been done on them.

GRAPHITE.

It will be noticed that the prospecting areas in the Impetyini Forest, in Alfred County, have been given up. The prospectors found they could do nothing with them.

All officers returning from South Africa have received 61 days' leave. *Reuter*—in *Egyptian Gazette.*

NOTES FROM THE STRAITS.

MR. STANLEY ARDEN'S FIRST IMPRESSIONS.

Dec. 6th.

Mr. Stanley Arden, recently appointed Superintendent of Government Experimental Plantations in the Federated Malay States, who stayed a month in Ceylon (chiefly at Peradeniya) on his way out to the Straits, writes as follows to a friend in Ceylon:—"Since my arrival, my time has been taken up with travelling in this and the neighbouring states, so as to gain a knowledge of the chief requirements of local agriculture. Everywhere I have been, coffee is by far the largest crop grown. Its cultivation, however, is being gradually abandoned, not by any means on account of disease, but because of low-prices. Many planters go in largely for rubber planting, which with cocoanut cultivation is well suited to large portions of land here. In many cases rubber *Hevea* and cocoanuts may be seen planted among the coffee, thus ousting the latter as did cinchona and tea in Ceylon. Tea would no doubt grow well here on the higher lands, but evidently the present price of labour would not make its cultivation profitable. The Agricultural labourers are nearly all Tamils imported from India, the natives being quite in the shade and devote their time to fishing, boating and other indolent pursuits. The Chinese, who are employed almost exclusively on the tin mines, form by far the largest portion of the population. Tin-mining is at present the chief source of revenue.

I was struck with the excellency of the roads here, which are almost everywhere like cycle tracks. In some places they are metalled with marble, a luxury which not many countries can boast of. The railways are also good, though at present rather disconnected, being in sections which are sometimes separated by lagoons, ravines, etc., over which one has to cross in a boat or otherwise to join a train on the opposite side. In other cases a long gharry ride is necessary from one station to the next. The durian fruit is now in season, and its effluvia seems to pervade everywhere."

PLANTING NOTES.

A FLORAL DISPLAY—of a striking character—is to be seen at present on the very fine specimen of *Alstonia scholaris* in Canella Villa, Turret Road. The tree for height and general appearance is one of the handsomest in Colombo, and its crown and higher sides today have been one mass of greenish-white flowers, highly odoriferous and not at all unpleasant. There ought to be a rich crop of seed after so much blossom. The *Alstonia scholaris* is counted among the rubber-yielding trees; but Trimen does not refer to this. Here is what he says in his "Flora" of Ceylon:—

Lowcountry up to 3,000 ft.; common. Fl. April; greenish-white. In the Eastern Tropics generally. The follicles hang in pendulous clusters, and the whole inflor. falls together. The wood is very light and soft, pale yellowish-white; its principal use is for coffins. The bark is a valuable stringent tonic, much used in fevers; it is an official drug in the Indian Pharmacopœia. The explanation of the name is as follows:—

Charles Alston was Professor of Botany in Edinburgh University from 1719 till his death in 1760. The *Lignum scholare* of Rumphius, the light wood being used to make 'slates' for school children.

THE THEORY OF MANURING.—Plants required about a dozen chemical elements for their healthy nourishment, but in practice it is only necessary to supply three or four of these in order to make up for the requirements of ordinary crops. The plant food constituents in which soils are most deficient are nitrogen, phosphoric acid, and potash, and it is these which it is the aim of the farmer to supply in such manures as he uses from year to year. The other food constituents required by plants, and including magnesia, lime, iron, chlorine, are usually present in most soils insufficient quantity to supply the requirements of the plants growing therein. It is different, however, with the nitrogen and phosphoric acid and potash. Analysis may show all or some of these to be present in fairly large quantity, but, says the *Farmers' Gazette*, the form or condition in which they exist is such that they are of no practical value to the plant because of the latter's inability to assimilate them. The object of applying manure, therefore, is to supply these constituents in a form in which the plants can soon take advantage of them. The proportion in which these ingredients are required in the soil is, after all, but very small, as is shown by the fact that a ton of farmyard manure supplies only from 9 to 10 or 12 lb. of nitrogen, about the same quantity of potash, and only from 5 to 7 or 8 lb of phosphoric acid.—*Journal of Horticulture.*

SPORT IN B.C.A.

SOME REMINISCENCES OF LEOPARDS IN BRITISH CENTRAL AFRICA.—I.

(By an ex Ceylon Planter.)

In 1891 I had the good fortune to possess a donkey who was not much use to me, for I never rode him; so he was allowed to go about the estate at the freedom of his own will, affording much amusement to the natives who used to watch him braying in solemn silence and awe, till the last note of music ended, when there was a stampede with shouts of laughter from the much amused crowd. One afternoon about three o'clock my cattle keeper turned up with the information that my donkey was found dead at the river, and that no one had gone near the beast for fear of being blamed for causing the death by witchcraft; this sounded strange for it is said a dead donkey is never found.

I proceeded to the spot and found the animal lying amongst the boulders in the bed of the river quite dead and a piece taken out of his flank; some claw marks were visible on the neck, so I concluded it was

THE WORK OF A LEOPARD.

The carcase was quite warm and the fresh foot-prints of a large leopard were visible on the sand. I got some men and beat the bush round about to try and get a shot at the leopard but failed; he had evidently cleared right away upon hearing the sound of human voices.

MY PREVIOUS EXPERIENCE

of leopards led me to know that moving the carcase would not prevent him returning for a feed during the night, and as there was danger of the river rising at any hour and carrying the carcases away, I had it dragged above flood level and soon got to work, setting a spring gun with the string attached in such a way as to cover the approach to the carcase. Two friends who were living with me at the time suggested setting a shot gun loaded with No. 5 shot, as the distance was only five yards, and that it would be more certain to bag our game; so I adopted their suggestion and put a shot-cartridge into the gun instead of a bullet. About 8 p.m., bang went the gun and we then, armed with a double ·577 express and a lantern, set off in great haste to see the result of the shot. After a bit of a search however without success, although there was plenty of blood, we retired, deferring further search till the morrow.

After some early tea, soon after dawn, with half-a-dozen natives, we set off in great glee

EXPECTING A GRAND TROPHY

in the sneaking carnivor who killed my donkey. We found upon examination of the spot plenty of blood, and that the leopard after receiving the full charge of No. 5 shot into his side had made one bound of about 20 feet on to the top of a large flat rock where he had evidently stood for some time, and left a pool of blood behind him. Beyond this not a trace of blood was to be seen. After tracking till 9 o'clock we gave up the pursuit, disappointed and disgusted, offering a reward of 10s to any native who would find our game dead or alive. I had not the slightest notion that the leopard would come back to the carcas, but expected hyenas would and set a rifle covering the quarry, about 10 p.m. Off went the gun again; I decided this time however to wait till day-light to make our search in case of accident and, as events will prove, it is as well be did for it is not a nice thing to find a wounded leopard springing upon a person in the dark.

After the first peep of daylight shone through my window, I was up and called W— and M— and off we set to the scene of slaughter, to find the gun had gone off and

LODGED A BULLET SOMEWHERE IN THE ANIMAL

but there was no sign of him anywhere about, dead or alive.

After an hour's search, we discovered by throwing stones into the bush grass, as we followed the blood tracks, the leopard lying in a flat hollow amongst large boulders and thick scrub, evidently alive, for every time a stone was thrown in, he began to growl. Now to oust him out of his lair, came the job, for see him we could not. I had a dog who had often a narrow escape from leopards, and he stood on the top of a rock (right over where the beast was lying) barking most furiously. I managed with the assistance of a nigger to scramble up to where the dog was and I gave the cur a lift with my foot sending him right into where the leopard was. This had the desired effect, for like lightning he

MADE ONE BOUND AND STOOD WITH THE DOG UNDER HIS FORE-PAWS

with his claws firmly set in the neck and ribs. My gun was at my shoulder in a minute and as I saw the snarling mouth and flashing eyes looking the picture of ferocity, I covered the latter and let drive. He let go his victim and made for me but was unable to ascend the rock as his spine was broken, although his fore quarters were strong. My second barrel was discharged at his head as he endeavoured to climb the rock. It was without much effect, for he turned tail to me and made off back to where I roused him from. Being anxious to secure a good skin, not riddled with bullets, I ceased firing and induced a native, rather bolder than the rest, to get on to a small rock close to where the leopard was lying and pelt him with stones, so that he would either die or give me a shot which would not damage the skin. This had the desired effect, although it took a lot of stones. After a tremendous amount of snarling and growling, out the beast rushed, and made straight for the nigger. Both rolled headlong over the other side of the rock and

DISAPPEARED IN THE LONG GRASS

before I had time even to bring my rifle to the shoulder. As quick as my legs could carry me I was on the top of the flat rock and overlooking my prey on the other side, crouching low; covering the poor boy entirely with his long body; snarling and looking savagely at me on the rock. How to shoot the beast without the bullet going through the native, was my study which seemed impossible from my elevated position, and to descend from the rock would be useless, for I could not see the beast without getting right on the top of him; so my only chance was to fire from where I was and risk damaging the boy. So I let go and sent a bullet through his shoulder and had the satisfaction of seeing the leopard let go his hold and sink quietly down beside his quarry,

DEAD.

Neither the dog nor boy was much mauled, and their wounds were soon healed ; they both doubtless owe their life to the badly wounded and weak condition of the leopard. He proved a full-grown male, measuring 6 ft. 10 in. in length and 2 ft. 7 in. in height, weighing 140 lb.

The following night I set a spring-gun again and shot a hyena, standing 2 ft. 10 in. at the shoulder and weighing 150 lb. Leopards are said not to be scavengers, but this I proved not to be the case, for I have known them, take a bait of dead poisoned fowl, and upon this occasion I set a spring-gun over the carcass of the leopard we had secured, and another one came to have a feed off his probable brother and was shot dead. Although the gun was set for hyenas, we secured another fine specimen of a leopard. I have had

VARIED EXPERIENCE OF THE CEYLON AND AFRICAN LEOPARD

and I am satisfied that the African one is by far the most daring of the two, not hesitating to enter a native hut, but through the roof, lifting its occupant in thedead of night or lifting a watchman from the verandah of a house, even after being fired at.

AN AFTER-DINNER ADVENTURE.

One evening about seven o'clock, just as my cook had dished the dinner in the back verandah leaving no one in the kitchen, my two dogs lying near the fire, raised a fearful howling. Thinking it might be a leopard, and as it was bright moonlight I seized my rifle and ran out just in time to see a leopard carrying away one of my dogs. As he was getting up the bank, I fired and hit him, for he dropped the dog and made off with tremendous bounds before I had time to fire another shot. Upon examining the spoor we found blood tracks for some 500 yards up through the garden, but owing to the want of a good lantern, and knowing the danger of following a wounded leopard at night (even with a good moon) we returned to attend to the mauled dog who was found crouching by the dining room fire, evidently suffering from a severe fright if nothing more, for he would not even answer to his name Chekumba (by the way a name given to him by myself as he was captured and taken prisoner at a war against a slave-raiding chief of that name). Upon examination of the wounds we found two holes, one on each side of the neck, and the skin broken on the top of the head, evidently made by the brute's canine teeth. The wounds, however, did not appear to be serious. Hot water was freely used to wash and cleanse the wounds well, after which strong carbolic oil and wadding was pushed well home in the sores, and Chekumba sent to bed with a bowl of milk beside him. My other dog had evidently a narrow escape too, for he was also lying by the kitchen fire at the time the leopard entered, but how he escaped a mauling no one knows; his voice was however audible enough howling all the way down to the niggers' huts where it seemed impossible to restore him to his natural peace of mind, for he continued barking all night, and never came near the house till daybreak, when he was discovered sneaking into my bed-room with his tail well between his legs. Poor Chekumba next morning began to stagger about with his head down, and at 7 a.m. succumbed to the fatal poison, with a neck swollen to twice the size of his natural one.

ON THE TRACK.

Soon after this we (a party of three), my native overseer, a shikari and myself, set out to track the leopard. From the trail left the beast seemed to be bady wounded, for he was evidenly dragging his tail and hind-quarters on the ground, possibly injured on the spine. Although the African native is not such a good tracker as the Indian shikari, when a white man is behind him with a loaded gun, his natural apathy disappears and the savage can and does track well, notwithstanding his natural inclination to cave in, because he firmly believes that master's gun has got the proper medicine to lay the beast *hors de combat* within 100 yards of the place where he was shot at.

Up to about 11 o'clock, we followed those wearisome footsteps through grass, scrub, and village gardens until the virgin forest was entered and further tracking seemed impossible, and we were just about to return home, wearied and disappointed. After some cold fowl and biscuits and a drink of clear cold icy-water, from the mountain plateau stream, a desperate barking of baboons was heard on some large trees, just behind us, some 300 yards up the valley.

BABOONS.

As the barking of the baboons continued without intermission for about 20 minutes, I asked my men what it all meant, and was told the leopard was the cause of all the row ; and that those fierce members of the monkey tribe always bark when a leopard is in sight, and even go the length of killing their bitter enemy by attacking him in large numbers. This latter part of the yarn, I didn't believe; but the former, I proved beyond a doubt. Off we went to where the noise proceeded from, and found a herd of baboons showing their teeth and making awful faces, bobbing up and down, evidently in a most fearful rage. To stop their row, I fired at the biggest fellow I could see, and brought him down, but off he went as hard as he could scamper, and was out of sight in a minute. I fired at a second and broke his arm ; off he went with his broken limb, dangling in the air, with any quantity of blood spurting down on the leaves of the lower jungle trees. This shooting had the desired effect, and the whole herd made off, leaving us to look after the big fellow who tumbled down. We found him sitting under a huge tree, apparently in the last stage of life, indifferent to all around. In fact, one man ran up to lay hold, but only to find there was still life, and asked me to shoot; I didnt care to do so, if the animal was really dead : but I introduced my gun barrel to his side. Before I could withdraw the weapon, he had it in his teeth and was gripping it like a vice. I pulled the trigger and finished off the monster. To show the powerful canine teeth that a baboon carries, my gun barrel bears the marks (large dents) to this day. After shooting the baboon the second time, and he released my gun, I stood away a little distance and was thunder-struck to see the beast take the blood from his bleeding side with his hand, look at it, and then at me, as much as to say, "You have murdered me," and then expired. I vowed in my own mind, that I would never shoot another baboon, and I have not done so to this day, although I have had many opportunities since. Upon resuming our search for the leopard, I found close by a small cave, where he had evidently lain all night, for there were splotches of blood on the dry ground, but beyond the cave, no trace could be seen. The baboons again began to bark some distance up the hill and we made

tracks in that direction. This time, however, I determined not to fire a shot at the monkeys, but reserved it for better sport. We soon discovered the leopard who seemingly saw us coming, and was skulking away looking over his shoulder at us, but turn round; he would not or give me a decent shot. On the beast went very stiff apparently, with his hind quarters now and again giving way under him. Another rock cave came in sight, and we lost sight of our game for a minute, till we got pretty close up to the entrance.

DONE FOR.

My courage at this instant seemed to fail me, for I stopped dead to think for a minute what I was about. Gaining my presence of mind, I looked back for my tracker with my spare gun, and was not a little surprised to find I was alone. All was quiet and still as night in the dense forest; the baboons even had stopped their hideous noise. I grasped my rifle firmly although my legs were a little shaky. Just at this time, I heard the crackle of dead twigs behind me, which made my heart thump against my side, at a furious rate. Upon looking round I found to my surprise and no little delight my men with the spare gun.

A dozen or more paces forward brought us in full view of a handsome leopard lying on the ground, patiently waiting our approach at the mouth of the cave, just in the same attitude as a cat assumes when watching a rat, before the final spring. The position was a bad one, as I was below the level of the animal, but to go nearer was too risky, for I was only twenty paces or less away; so no time was to be lost, and I fired, aiming right between the eyes. No sooner had my bullet been felt by the brute then he bounded out of his lair right towards us, giving me no time for a second shot. The niggers were gone like a flash of lightning in one direction and in another. I pulled up after reaching the nearest tree and looked round to see if I couldn't get a second shot, and saw my tracker aiming at the leopard about ten yards behind me; the beast had pulled up, whether from exhaustion or funk at being between two guns I don't know; but he had the contents of both my trackers' and my gun simultaneously and rolled over down the hill between us, now and again giving a bound in the air till all signs of life had gone. When we got up to the carcase I found my yesterday's bullet had gone right through his back close to the spine. My shot in the cave had torn a piece out of the side of his head, and my last bullet and my tracker's had both gone clean through his lungs. The overseer was despatched to bring men to carry home our quarry. I was soon at the bungalow, and after a bath and a change, was as fresh as a daisy. The baboons were not heard again that day, although many a time both night and day, too, afterwards I was tempted to go out in search of leopards, presuming that I would get some sport. I never again succeeded in seeing a leopard being bayed by baboons again. I found on one occasion, however, the hind quarters of a baboon that had fallen a prey to a leopard who had just left it on my arrival.

LEOPARDS AND TRAPS,

Leopards are very cunning, and dubious about going into a trap. I have frequently had a trap built of logs with a bait of a goat or dog in it, but never induced one to go in, although they have often enough walked round about the trap. On one occasion I had a dog put in the trap every night for about a month as a bait for a leopard, and the beast often enough walked round about the house and had a look at the dog. One night, however, the leopard, very hungry evidently, began by biting and clawing at the far end of the trap (although the trap door was open he would not enter and be caught) until he managed to introduce his forearm, and frightened the dog, so as to force him to make a most desperate effort to escape—till he did manage it, and came home in the middle of the night in a terrible state. Upon my examination of the surroundings next morning I found the leopard had hunted the poor cur at full speed from the trap to my very door, about half a mile.

The African leopard is not destructive to cattle establishments and I have never heard of one entering a cattle kraal, although often enough a stray calf has fallen a prey to their cunning in the bush without even the herd boy's knowledge. Goats and pigs' houses are often entered by leopards, as also native huts, and the occupants carried away for a midnight meal. When hungry the leopard will eat almost anything, even to mulberries on a road-side, till he nearly dies from diarrhœa. This fact once came under my personal observation with an old leopard of mine.

A TROUBLESOME BEAST.

I was very much troubled by a most daring leopard who baffled all my attempts to capture or destroy by any means in my power. He was always about the neighbourhood, catching stray fowls in the forest, or on the estate round about the buildings, or in the surrounding villages. My dogs also became a prey to this determined robber. Fowls accustomed to be hunted by a leopard are grand watchmen, and make the most awful row you ever heard when their enemy arrives in the vicinity at night, rousing a whole household. One night about 1 o'clock, my fowls made such a row that I thought the leopard had got in amongst them. I seized my Lee-Metford, and a lantern and made tracks for my fowl-house, my dog Dan leading the way, making a rush through the garden gate in front of me. I found upon reaching the fowl-house that all my servants had congregated ready for any sport that might turn up; but, alas, to our disappointment, after a thorough search, no leopard was to be found. Neither was my dog Dan; call as we might, he didn't turn up; so I went off to bed, much disappointed and disgusted. Next morning the dog was nowhere to be found and upon examination of the premises, I discovered that he had been caught and carried away by the leopard just outside the garden gate. We followed the track into the neighbouring forest for about half-a-mile and came upon half my poor dog's carcase, but no leopard could be seen anywhere; so the only thing left for us to do was, after considerable search, to retire and leave him his tit-bit, well primed with arsenic, in case he should return to finish the remainder of his meal during the night. Next morning at dawn all were astir, and trackers with flint-locks and myself with a double ·577 express set off in great haste, each one more eager than the other to get a close view of our troublesome robber. Upon reaching the remains of the dog, we found all the remains were finished except a foot. Silent and diligent search was made all round the spot till we found that the arsenic had taken effect: about 100 yards off. Vomiting of dog meat, and much rolling about, was evidence of the arsenic causing much pain and trouble in several places, but the leopard was no-

where to be seen, and it was evident he got away after discharging the contents of his stomach, the dose of poison having been too much. He lived to give us some more annoyance as the following yarn will show. [Strychnine is a much safer poison than arsenic to administer to an animal as they never vomit it.]

FEEDING ON FOWLS.

My fowl-house being well built with strong logs of timber,—in fact a regular American log house that no animal could get through, was a puzzle to Master Spots for many a day when he was on his midnight rounds. His foot-prints bore evidence of his having many a look through at the Kukus fowls, he was so anxious to reach, but could not. Although many a stray fowl sitting on eggs, as was their wont, fell to his lot in the surrounding bush, he seemed to fail to enter the house where the herd of hundreds were visible.

One night, after everybody had retired to rest, a fearful racket got up amongst the fowls, each one trying to croak louder than another, like so many huge frogs at work. All the household were soon on the move, and tracks made to the house to see what was the matter, all making sure the leopard was apparently killing Kukus by the dozen inside. Upon mustering at the door, cook, house-boys and everybody else were very brave, but to go inside and shoot the leopard was more than their feelings would stand; so the door was most carefully opened a bit, and the lantern introduced to see what could be seen. I, holding my rifle half in at the door, expecting a charge every minute, determined to do for the beast. I was much disappointed to find a hole in the thatched roof with the moonlight shining in on the floor, where the leopard had evidently gone in by, for a lunch, sneaked a Kuku or two and evidently made his exit at the same hole, for search in every nook and corner failed to find him. Upon searching outside we discovered footprints quite deep in the earth where he had jumped off the roof with his prey.

ON THE WATCH.

Judging that one or even two fowls, which was as many as could be carried away at that time, would not suffice for a meal but quite enough to prepare an appetite for a substantial meal, I offered a reward of 5s to anyone who would sit up and watch for the leopard, and shoot him, as I felt sure he would return later on in the night. My cook and another domestic volunteered to sit in the adjoining room, partitioned off from the fowl-house. The dividing wall only being six feet high the leopard could be seen and shot when entering his hole in the roof without much danger of a personal attack upon the watchers who considered themselves pretty safe and were quite jubilant at the prospect of being considered by all the neighbouring people brave, lion-hearted men who were brave and courageous enough to shoot a leopard which had a reputation not only for killing domestic animals but human beings also; for it was known to have the daring to carry away a boy and kill and eat him in broad daylight.

About 9 30 p.m., just as all the household were retiring for the night, the shot of a rifle was heard and out everybody bolted to see the result. Upon interviewing the watchmen and examining the hole in the roof and outside of the shed for some distance around we concluded that Somewa, the cook, had missed; for there was neither blood nor leopard to be seen anywhere about. How the watcher could have missed the animal (who according to his own story, was half through the hole in the roof when he fired) seemed a mystery to all. The leopard, however, left marks of his having been there beyond a doubt.

WANTING TO CATCH MEN.

All the household had gone to rest again and were sound in the arms of Nod, when all were roused at 12·30 a.m. by the loud report of a gun, the hoarse growling of the leopard and the yelling of men, as if a fierce battle was raging between man and beast. I could hear distinctly "Mpalugwe afmia cughura enza,"—"leopard wants to catch men." Of course, no time was lost in seizing my rifle and hastening to the spot to find no one any the worse of the scare. So I may as well tell my readers in my cook's own words what actually transpired.

We were dosing, but not actually asleep when my companion roused me up with a nudge on the side with his fist; and upon looking up, I saw the leopard's head and neck through the hole in the roof. (Not a Kuku was on the "prareh" for him to seize, for they had been all knocked down on to the floor during the previous attack and were as quiet as mice, not being able to smell the leopard in his elevated position.) I let him get in his fore-arm and fired. No sooner had I done so than he made a dive through the hole on to the fowl rack, and one spring right into the room where we were lighting in the middle and just as he reached the ground, my friend and I plunged through the door, both leopard and ourselves, howling our very hardest; both of us fell heels over head outside the door, and to the right of it the leopard followed like lightning, but fortunately for us turned to the left and left us alive, and—well, this is all I know!

I examined my men who were more frightened than hurt, and found some spots of blood on one of their cloths and on the side of the door some leopard's hair and blood, evidence of the beast being severely wounded; but how the nigger escaped without a scratch seemed to me a mystery. Well, upon following up blood marks on the ground, we found that the brute had gone right through a well-secured double bango end fence across our tennis ground, and through the fence on the other side, leaving ample evidence, in bloodstains and hair, on the fence to show that he was mortally wounded. A little further on about 100 yards, in all, from the fowl house, groaning was heard, and my dogs began to bark furiously. I knew by this time, if the leopard had strength enough left in him, he would go for the dogs, so we got torches of dry grass and approached the spot where the groans were heard, to find the beast lying on his side, breathing hard, but making no effort to move. He gave one or two kicks and my rifle was up to shoot. But I didn't—he was dead in a second, and I was not called upon to spoil the skin with more bullet holes.

I have not related half the depredations of this scourge of a leopard, for fear of wearying my readers, but suffice it to say that he was the most daring, impudent beast I have ever heard of and my reward was paid, and my cook who shot the brute was never afterwards called chicken-hearted. My readers may be surprised that I had not courage enough to sit up for the animal myself. My reason for not doing so was because my wife was ill with a severe attack of pleurisy, and it would not be right for me to do so under the circumstances. It would not be the first leopard I sat up for and shot however.

The daring of the beast to return a couple of hours after having been fired at within 10 paces, seems incredible.—H. B.

HOW TO DEAL WITH "TEA" NOT FITTED FOR EXPORTATION?

We are reminded by an upcountry correspondent that when rinderpest was bad in Scotland (and we suppose in England) a fund was formed, whereby the owners of any cattle that had to be slaughtered, were indemnified for their loss. The question is, can the principle be adopted and a fund formed to deal with teas which ought not to be exported from this island to the detriment of the good name of Ceylon teas and to the injury of the London market? Naturally, and equitably, the money to form such a fund should come out of the Tea Cess; but for the present all the available collection has been voted away. Nevertheless, if any feasible scheme were formulated for buying up what are talked of here as "rubbishy" teas—all produce sold below a certain fixed limit and thereby considered to be unsuited for exportation—we cannot believe that the Government would make much difficulty in allowing the Cess collection to be forestalled in order to deal with an emergency like that which has been disturbing the Tea Market lately. At the same time, it is possible such a lesson has already been taught and learned that the crisis may be said to be over, and that a continuance of 10 cents-a-lb. teas is not to be feared in the local market. We should like to be assured of such produce and prices being things of the past. But wise men should act against the risk of recurrence, and in order to prevent any possible chance of the further exportation to London, Australia, America—in fact, to any of our customers—of anything like 10 cents-a lb. tea. The parallel of "rinderpest" would point to the destruction of the condemned tea; but might it not be dealt with chemically to some useful purpose for the extraction of the tannin and perhaps of a useful dye? If this could not be done in Ceylon, some precaution would have to be taken to ensure that only for chemical (and not for food) purposes was such tea sent out of the island.

PRODUCE AND PLANTING.

TEA AND COFFEE.—Some interesting and suggestive facts are contained in the Board of Trade report on tea and coffee just published. The English people and peoples of English descent are still the greatest consumers of tea among the Western nations. The average consumption of the home-staying Englishman is six pounds a year, while the Australian colonist consumes as much as seven and a half pounds. Why the fragrant leaf is less popular in the United States it is not easy to say. The Americans and the Russians are conservative in their taste, and continue to prefer China tea, but the work of pushing British-grown tea goes on steadily. The tea consumed in England is nearly all grown in India and Ceylon. The production of coffee, like that of tea, is largely increasing, and may be said, speaking generally, to have doubled in the last ten years. The chief producing countries are all in America, Mexico being the most northern and Paraquay the most southern of the countries of that continent where coffee is produced. The chief countries of production, in the order named, are Brazil, Venezuela, the United States of Colombia, Mexico, Costa Rica, Guatemala, and Hayti. The United States holds a very similar place in the coffee trade to that held by the United Kingdom in the tea trade, the relative consumption in each case exceeding that of all the other countries of the civilised world put together. The coffee trade of the United States, therefore, may be said to virtually control the trade, as well as to a certain extent the prices, of coffee throughout the world.

FIJI AND ITS PRODUCE.—A paper on "The Islands and the People of Fiji" was read before the Royal Colonial Institute on Tuesday by Mr. Morgan L. Finucane, Provincial Inspector of the Provinces of Tailevet and Ra, and medical officer of the colony. Referring to the industries of the colony, Mr. Finucane pointed out that the wealth and future prosperity of the colony undoubtedly depend on the output of sugar, and it has been shown that in the Fiji Islands sugar-cane is capable of high cultivation and growth in nearly every district with profit to the cultivator in spite of the falling prices in raw sugar. The sugar industry is entirely in the hands of the wealthy Colonial Sugar Refining Company, who possess practically the monopoly for the supply of sugar in the whole of Australasia, and are even now sending Fijian-grown sugar into Canada. The system adopted is that of local planters—European, Indian, and Fijian—cultivating areas of cane land and selling the product to the central mills of the company; proper cultivation of the land is brought about by the terms in the company's contracts with growers by which they are paid, not in accordance with the quantity of cane grown and delivered to the mills, but on the percentage of raw sugar obtained by analysis of the cane supplied with a sliding scale. Coffee grows well in Fiji, both the Liberian and Arabian varieties, and does best in shaded mountainous districts, such as are found in the upper reaches of the Wai-ni-Buka in Viti Levu; large areas have been put in by the Fijians as an addition in future years for the payment of their taxes and self-betterment. Vanilla grows well, and has realised good prices in the open market. Tobacco, ramie fibre, cocoa, cinchona, tea, and india-rubber are all to be found in Fiji. Tea does exceedingly well, and has a delicious flavour, says Mr. Finucane: There were, when I went to the colony, two flourishing estates with a perfect soil and altitude for the growth of this beverage: at present the local consumption of the product is entirely drawn from the group, and it is also exported to New Zealand and Australia.

ABYSSINIAN COFFEE.—A Consular report from Harrar says: "The Harrari coffee is of a very good quality, known in the London market as 'Moka long berry,' where it is preferred to the real Moka. Occasionally its price in London is higher than that of Moka. Plantations of coffee are increasing slowly, because the natives prefer to cultivate the Kiatt (Celastrus edulis) as more lucrative, 1 lb. of leaves of which are sold for 1 dol., and sometimes 2 dol.; the natives, as in Arabia, are eating these leaves. Nevetheless, more than 150,000 coffee trees have recently been planted, especially in the districts of Chercher and Itto."—*H. and C. Mail*, Nov. 3).

SPORT IN BRITISH CENTRAL AFRICA.—The second letter of the interesting series of letters we have been publishing on leopard-shooting in B.C.A. appears on page 501. The sport appears to be full of variety, the article describing the despatch of a leopard that raided a fowl-house through the roof and made its exit by the same route! We look forward to further "experiences" from "H.B," whose adopted country evidently abounds in sport of a hazardous nature.

FROM A FRENCH HORTICULTURIST.

TO THE EDITOR OF THE "INDIA RUBBER WORLD."

I have read in your instructive journal several times references to the extraction of rubber by pressure from young Calisaya elastica plants. I do not know what this means. I have twice sent one of my agents to America for the purpose of studying the extraction of rubber from the leaves of plants, but gained little information thereby. I believe that this is something to be developed in the remote future, if ever.

But the extraction of rubber from the barks of trees I consider more practicable. I have been successful, it is true, with one American species, Hancornia speciosa, or "Mangabeira" rubber, which is the easiest of all sorts to try by my process. Its bark is very friable, like sugar so that it is easily disintegrated. Ficus sorts from the Guianas give rubber, but in small quantity. How many species there may be that I have overlooked I am unable to say. But, curious to say, I could do nothing with Hevea or Castilloa, though these are precisely the species in which my agent was interested.

Forsteronia gracilis, of British Guiana, is a member of the same family as Landolphia, Vahea, Urceola, etc., which proves its richness in rubber, and it should be susceptitble to treatment of the bark for rubber. What a beautiful climber, by the way, is this Forsteronia! My agent brought home only stems without any roots, but after six weeks I had stems two and half yards high.

Success ought to be attained in tropical America with the Landolphia Hendelotii, which thrives in a sandy soil as well as loam, and yields a good rubber. Landolphia Owariensis, L. Klanei, and L. Kirkii, want more water and shade. These and various other creepers or climbers producing rubber ought to be grown in America with more profit than anywhere else, as experience will prove. They are easily propagated by cuttings and be utilised for rubber far earlier than any American species.

Can you tell me what is the plant from southern California, yielding a good rubber from stems which can be cut yearly like asparagus? I have several stems, which look like Euphorbia, but I believe these are composite.

A. GODEFROY-LEBEUF.

Etablissement d'Horticulture, Paris, Sept. 13, 1900.

LAGERSTRŒMIA INDICA.—Among the many tropical and subtropical plants which are said to make a very fine display in their native places many prove disappointing when grown under glass in this country. This, however, cannot be laid to the charge of the plant under notice, for it is said to flower quite as well here as in India, where it is one of the most favoured garden shrubs. To grow it well it should be planted in an intermediate house in loam, given a sunny position, and dried off in winter. On the approach of spring all the previous year's wood should be shortened to get good strong young shoots. If a lot of growths are made, all the weak ones should be removed when a few inches long, by which means the inflorescences will be greatly improved. Flowering will commence about the end of July, every shoot being terminated with large panicles of pretty fringed blossoms. The flowers of the typical plant are pink, but variation may be had by growing the purple, deep red, and white varieties. It can be readily rooted from cuttings of half-ripe wood, and can be grown and flowered as a pot plant. If grown in the latter way it must be well fed and thinned to encourage strong shoots.—D.—*Journal of Horticulture.*

SHARE LIST,

(Not made up during Holidays.)

THE LOCAL MARKET.

(By Mr. James Gibson, Baillie St., Fort.)
Colombo, Jany. 8th, 1901.

COFFEE:—		
Estate Parchment per bushel	None	
Chetty do do	Nil.	
Native Coffee do F. O. B per cwt.	Nil.	
Liberian coffee:—per bushel	Nil.	
do cleaned coffee:—per cwt	Nil.	
Cocoa unpicked:—per cwt	R41·00 to 44·00	
do cleaned do	R44·00 to 52·00	
Cardamoms Malabar per lb	R1·20 to 1·30	
do Mysore do	R1·70 to 2·00	
RICE:—

The TROPICAL AGRICULTURIST
MONTHLY.

XX. COLOMBO, FEBRUARY 1ST, 1901. No. 8.

CEYLON: ITS BOTANIC GARDENS; VEGETATION AND SHORT REPORT ON A JOURNEY TO CEYLON.*

As above mentioned, I was afforded the opportunity in the year under report of an official journey to Deli and Ceylon, in the company of the hortulan.

After a ten days' stay on the East coast [of Sumatra], we crossed over to Penang,.....in order, after a short delay there, to embark on board one of the P. & O. steamers bound for Ceylon.

The visit to Ceylon had quite a different object from that to Deli. Agronomic questions were only of secondary importance: the main object being a proper acquaintanceship with the organization and working of the botanical establishments of Ceylon, consisting of the famed garden at Peradeniya—four miles from Kandy—and its four branch-establishments.

In the afternoon of 22nd June we steamed alongside the island in squally cloudy weather. About sunset the vivid lightning over the land reminded us of the old stories according to which the Arabian mariners sailing in those waters considered the incessant lightning as a sure sign that they were near Ceylon. At about half past one a. m. we were in the harbour of Colombo.

Scarcely had we landed the following morning when we were agreeably surprised to find that Mr. J. C. Willis, Director of the Botanical Establishments of Ceylon, had taken the trouble of undertaking a fairly long railway journey from Peradeniya to the low-country to welcome us at once on our arrival in Colombo.

During our whole stay in Ceylon Mr. Willis always had the kindness to spare no pains in arranging to make our journey as instructive, profitable and pleasant as possible. This is therefore also the place to warmly repeat our gratitude to him, the assurance of which, of course, we had before given him verbally. We desire further to tender our thanks to Mr. MacMillan, the Curator of Peradeniya Gardens, and Mr. Nock, Superintendent of the Hakgala Garden, for all they did for us.

Mr. Willis returned at noon to Peradeniya, where we were to follow him the next morning, having spent the night in Colombo, about which place, so far as they are appropriate in a report of this kind, will be found a few remarks at the end of this paper.

If there is no call to deal here in detail with the capital of Ceylon, it were right to begin by considering for a moment the climatic conditions of the island and the nature of its soil. This is necessary to a good understanding of what follows, as also to make a comparison between the conditions of primitive vegetation and husbandry in Ceylon, on the one hand, and Java on the other.

In the centre of the lowest and broadest portion of Ceylon one meets with a great network of mountains running pretty steeply to the South, and more to a level to the North, and quite flat in the Northern half of the island and the South-Eastern parts of it. The south-west monsoon which lasts during four or five months of the year, especially in May, June and July, brings with it much rain. On account of the configuration of the island these rains however affect only the south-western part of the island. When once the Monsoon winds have passed over the tops of the hills (7,000 feet, and higher) they are robbed of their moisture and changed into dry winds which cause, during the south-west Monsoon months, the northern and south-eastern parts of the island to suffer from terrible drought. Indeed in the mountain regions situated behind the high tops and ridges the drought is severely felt.

* Translated from *Verslag omtrent den Staat van's Lands Plantentuin te Buitenzorg over het Jaar 1898 by* Advocate F. H. de Vos and Donald Ferguson.

In October, November and December there is the north-east monsoon which causes rain all over the island, so that there are two rainy seasons a year in the south-western parts of the island. During these months of the north-east Mousoon the rainfall at a time is so heavy in the north-west and east of the island that there is relatively little profit to vegetation thereby, the country being completely under water for a few weeks and parched with drought for the remainder of the year, as Dr. Trimen, the late Director of Peradeniya Gardens, who died some two years ago, puts it.* Therefore one has, as Trimen says, to distinguish between a wet and dry Ceylon. The wet portion, which is specially regarded in cultivation, of any importance, is indeed the best known, but it only includes on an average a third part of the island, and the dry part—generally adopted for the cultivation of products of little value—the other two-third parts. By this alone it can at once be explained how it is that Ceylon, with an area of about one-half of that of Java, has only 3 million inhabitants against the 25 millions of Java. There can be also really no analogy between dry Ceylon and the ceutral and eastern parts of Java where a pronounced period of drought is felt.

Not less great are the differences between the soil of the two islands. The entire country of Ceylon cousists of iroustone, chiefly gneiss. The weathering product of this hard sort of rock has a peculiar copper or almost tile-red colour which caused the ancient Sinhalese to call this island "Copperland"†. Although here and there, rarely, hot springs are found in Ceylon, yet nowhere is the brittle volcanic stones found—a stoue which generally provides in Java a soil with such favourable physical qualities. Finally it appears to me, that—although in a much less degree than both the other factors—the violence of the winds in Ceylon as compared with those of Java, must be regarded. That these winds must be often heavy there, is apparent, in view of the lay of the island from a glance at the chart. If one stands on the high cliffs from which Point de Galle derives its name (*Gala* in Sinhalese is hill or rock‡) between that high-standing place and the distant unknown regions which surround the South Pole no more land is to be found.

Although, especially on a brief visit, from the nature of the case, oue does not at once perceive the influence of these violent winds on plantations, yet in this connectiou may be mentioned the large number of wind-breaks which they are obliged to plant in many places between the tea, for which purpose the *grevillea robusta* is generally used.

This influence, as it seems to me at least, is more apparent on the primitive vegetation of the hills. As I desire to avoid the reproach of being led by passing, and therefore false impressions made on me by this vegetation, let me again cite Trimen in his remarks on vegetation at the altitnde of 5,000 ft. and above. With the exception of certain grassy tracts.....all the hills are forest-clad over their summits—so he says. "The climate is generally very wet, and the forest has special characteristics. All the trees are evergreen, *for the most part rather small,* hard wooded and of very slow growth; they stand close together and form a very dark jungle"——The dense under-growth is very largely made of gregarious plants known by the Sinhalese nnder the name of *nilu*. These are a species of Strobilanthes.

The hypothesis seems to me not too hazardous that the character of these Ceylon hill jungles, so different from similar high-lying virgin forests of most of our Javanese hills, must be attributed to, not only, the difference in the soil, but partly also to the frequent heavy winds that rage there. Setting aside this hypothesis, it is a fact, that, on the hills, *even of the most humid parts of Ceylon* no vegetation is to be met which can be compared with that on our Javanese hill-tops in moist districts at an elevation between 5,000 and 6,500 feet. This great difference in character strikes one forcibly, coming from here, especially on account of the dearth of the large number of huge high trunks found in our, as regards humidity, similar hill forests. As a whole it lacks further the peculiar *cachet* of equational luxuriousness so very characteristic of most of our hill-tops, at least of West Java. On the other hand, indeed, the same characteristic appears in the primitive forests of the low lands of the south-west wet Ceylon. This appears clearly from the description of Trimen at p. 328 (*loc. cit.*) of such jungle.

On 24th June early in the morning we set ont on our journey to Peradeniya, which is 3½ hours' journey by rail. Going to the Fort station, situated in the centre of the city, we made two observations, which may be incidentally set down here. The first is that Colombo creates a much pleasanter, one might say a homelier, impression than Penang or Singapore, because in both these, as it were improvised cities, the original native population is supplanted by others, whilst in Colombo, as in our Dutch-Indian cities, they hold their own. The secoud is that the Chinese element is entirely absent, not, as it was told to us, because the Chinese are systematically kept out, but as traders they cannot cope with the specially cunning "Moormen," the descendants of the Arabs and natives. The absence of Chinese artizans is not however explained by this reason.

For the first three stations, Heneratgoda amongst them (of which hereafter), oue continues in the flat country. Only after 40 miles by rail the country begins to be hilly. Small hills appear covered with vegetation from top to bottom. After this one arrives in a more and more beautiful and grand mountain district, and one climbs over a mountain pass of about 1,700 feet in elevation to descend again to Peradeniya about 180 feet. Although very fine and often indeed impressive the character of this landscape is quite different from that along one line of hills in the Preanger-Regencies. Instead of the relatively great and broad foreground surrounded from behind by high volcanoes with their peculiar shapes, not only are the shapes of the mountains and hills yonder different—fantastic and often cupola-shaped—but there is a lack of much foreground generally when once one gets into the mountain districts, since the levelling process is so much more gradual than with us. The smallest hills are so many hard masses of gneiss which require ages and ages to experience any deterioraton of consequence by the gradual weathering. It will strike anyone who knows the *Sawahs* of Java how much lower is the state of rice cultivation in Ceylon. The rice-fields seem to be badly cared for, in disorder and generally poor. The reason is chiefly because no nursery beds are used, but the grain is sown direct on the field. But in other respects there is by far not that trouble bestowed on rice-fields which our natives take over their *Sawahs*. The Ceylon Goverument has taken enough trouble for the improvement of rice culture, it has however not succeeded in overcoming the peculiar psychical bond that exists between husbandry and the conservative proclivities in the sinhalese husbandman.

There is another matter, and that is to our eyes the relatively little significance attached to the bamboo Almost exclusively one sees the yellow variety o

---

* H Trimen, "On the Flora of Ceylon; especially as affected by climate." *Journal of Botany*, Vol 24, 1886.

† See the introduction to that splendid work of Messrs. Sarasin, *Engebnisse naturwissen-schaftlicher Forshungen auf Ceylon*, Wiesbaden 1893.

‡ But the Sinhalese name is *Gálla*, not *Gala*, and has nothing to do with rocks.—*D.F.*

Bambuse vulgaris, which is considered there to furnish only moderate building material. Indeed bamboo, as such, does not by any means play that important part in Ceylon which it does with us. This is one of the reasons why the native villages there, appear so dirty and unsightly. As regards cleanliness and neatness they cannot compare with our West Java villages.

Having got out at Peradeniya station at 11 o'clock, we were, a few minutes later, hospitably entertained by Mr. Willis in his house.

We owe a double debt of gratitude to Mr. Wills and his wife for their friendly hospitality, as Peradeniya is indeed a station but no town; there is only the little native village Iriagama on the other side of the river directly one crosses the satin-wood bridge. There are no lodgings to be had there for the public; and had it not been for the very much appreciated hospitality extended to us we should have been obliged to have often been on the run between Peradeniya and Kandy, a distance of about four miles.

The Botanical Garden at Peradeniya was established in 1821, thus only four years later than ours at Buitenzorg, and managed by A. Moon, who was an ardent student of Ceylon flora, and in 1824, published a catalogue of Ceylon plants. Unluckily Moon died in 1825 of fever.

For Twenty years the institution was left to take care of itself, and coffee, breadfruit and coconut were cultivated for the Government, "whilst botanical science was completely neglected." It is difficult to avoid the reflection in passing, in how many respects the history of the garden at Peradeniya is similar to that of our establishment at Buitenzorg: similar conditions resembling each other have had most prejudicial results at the beginning. In 1844 there was much improvement in the condition of Peradeniya by the appointment of Gardner, a capable botanist and energetic traveller, who went all over the island and, as a result of his travels, obtained a number of new plants for the garden. After Gardner's death in 1849 Dr. Thwaites was appointed Director. It was under the directorship of Thwaites, extending over a period of thirty years, that a series of improvements were introduced, and the institution acquired not only the necessary stability but a world-wide reputation. With his great merits, Thwaites had however also peculiarities in the catalogue of his time not quite inexplicable—of which I received assurances some years ago from very trustworthy sources. Himself thoroughly knowing Ceylon plants, he thought that what was not serviceable to him was of no use to others, and labels on plants in the garden were considered quite unnecessary. Moreover he had conceived the idea, more inexplicable, that a botanical garden in the tropics ought to be a small edition of the primitive vegetation with all its capricious varieties of forms. As a result of this way of viewing the matter, he not only did not strive to follow the principle of arranging all plants resembling each other according to the natural system, but purposely rejected the same. During this period we entertained and carried out diametrically opposed ideas.

Although there perhaps lurks just a spark of exaggeration in this proposition, it is certain that Dr. H. Trimen, who succeeded Thwaites, as Director, found it necessary in 1880—when the undersigned came to Buitenzorg—to cause some modification in both these said views, and many improvements were also introduced by him. When this amiable savant honoured us with a visit to Buitenzong some years ago, he was suffering with deafness; but we had then no idea that this was only the premonitory symptom of a serious illness, which ended in total deafness and partial paralysis, and a couple of years later brought this excellent and highly-qualified man to the grave. If the garden at Peradeniya is under a debt of gratitude to him, he has moreover built a lasting monument to botanical science by the compilation of his *Flora of Ceylon*, of which the greater part was published during his life-time. The publication of the rest of the work was due to the zeal of Sir James Hooker. Our hospitable host, Mr. J. C. Willis, M.A., succeeded Dr. Trimen.

The choice of a site for founding the garden at Peradeniya was specially fortunate. On three sides it is bounded by the windings of the Mahaweliganga, the broadest river of Ceylon, which forms as it were an eye in which the garden is enclosed. The banks of this splended river, in comparison with which our Tjiliwong is a little mountain stream, are for the most part planted with a luxurious growth of bamboos and create a deep and regal impression, especially when seen from the satinwood Bridge (a, from a technical point of view, fairly long suspension bridge built entirely of wood) on the south-west side of the garden.

On entering the "Royal Botanic Gardens" of Peradeniya one passes round a beautiful grove of palms and reaches the commencement of a long straight road which runs to almost the back of the garden. The first part of this road is adorned on both sides with a large variety of bushes and low flower-plants, standing partly along-side and partly under various fine trees. The attentive upkeep of this approach at once creates an agreeable impression.

About half-way up the road it runs right through a very large lawn with a collection of palms in the centre surrounded by a circular path: "the great arch." The whole of this lawn and its surroundings are laid out in the well-known broad English park-style. Conceived in the same spirit, but still prettier are the surroundings of the "monument road" (loading to the "Gardner monument") with fine specimens of various trees (*Pometia eximia, Terminalia Belerie, Terminalia Catappa*, *Ficus Sacrifera*.) Between this "Monument Road" and the aforesaid "great arch" but closer to the latter there are the places which serve as the office, museum, herbarium, library and laboratory. The herbarium is of course of much value especially for the original specimens of Ceylon plants which it contains: there is besides a very interesting and beautifully executed collection of coloured drawings of plants made in the institution itself. For the rest, to one from Buitenzorg, as regards the appointments there is not much to be said. It would be a break of that courtesy which demands that a guest should be no critic, to say that the arrangements as regards the laboratory were wholly inadequate, so that at the instance of Mr. Willis it was intended to build a special and properly equipped laboratory which probably is now in use. It is not without a feeling of perhaps well-grounded satisfaction, that one sees the idea, carried out in Buitenzorg 15 years ago, to have laboratories attached to the garden, adopted now in another botanical garden in the tropics.

As the part of the garden where a systematic grouping of plants is adopted is still new and not extensive (behind the Director's residence), and as in the greatest portion of the garden such an arrangement is not adopted—as appears from what has been said already—the principles followed at the foundation call for no special remarks. This is not the place to give a list of plant-names taken from our notes or from the "Hand guide to the Royal Botanic Gardens, Peradeniya." However we ought to mention some strikingly interesting or specially well-developed specimens, and especially, in the first place, a male specimen in flower of *Lodoicea Sechellarum*, somewhat older than ours, and flowering and fruit bearing species of *Couronpita Guyanensis*, the remarkable West-Indian cannou-ball-tree which quite recently blossomed in our garden for the first time. Among the really fine specimens found in Peradeniya must be mentioned *Pterocarpus indica*, *Amherstea nobilis*, *Schleichera trojuga*, *Artocarpus nobilis* and *Pericops Mooniane*. The same remarks applies to the remarkably large and robust collection of Burmese giant-bamboos, *Dendrocalamus giganteus* (the same kind of which a

large and small specimen are to he found at the entrance to our botanical gardens), which heing present in large numhers constitute one of the heauties of the garden at Peradeniya. Finally I cannot leave unmentioned a peculiarly pretty, although not long, lane of relatively still young specimens of *Corypha umbraculifera*, the justly famed *Taliput* palm.

Although the nurseries have heen lately improved they are as yet not to be compared with what one sees at Penang and Singapore: From that part where the nurseries are, when one goes along the broad way which runs right through the garden parallel to the river, one comes on to a plot that is specially set apart for *culture plants*. To us with our extensive culture-garden at Tijkenment, this gives no occasion for a special visit inside. It should only be remarked, as regard *Cephaelis Ipecacuanha*,—as lately attention has been directed to the cultivation of this plant—that its cultivation in Ceylon has not been attended with much result as the *Ipecacuanha* plant, according to the statements of Mr. Willis, "seems to need some special conditions of soil or climate". That the land cannot he succeessfully cultivated in the open ground has heen repeatedly demonstrated first in Java and lately again in the Straits Settlements. It is only by garden culture in covered plots as evidenced hy practical experience that any results can he expected. It is evident that the portion of ground reserved for culture-plants now in Peradeniya cannot be compared with a large garden specially set apart for cultivation. There appears to he however in this respect a project of great and interesting changes now in contemplation. During the latter portion of our stay in Ceylon, rumours reached us of a serious intention to transfer the seat of a languishing Agricultural College now in Colombo, to a large tract of ground close to Peradeniya, to serve as an experimental garden and place for instruction in agriculture. At the same time, so the rumour ran, the arrangements devoted to pure and experimental botany and its allied hranches should together form a special branch of the service—an "Agricultural Department" in the spirit of the homologous establishments working under expert direction and with a specially trained expert staff, such as work so usefully in the other British colonies, and especially in North America.

How far these remours will become definite plans, and what are the chances that these in their turn will reach fulfilment, the writer of this, speaking of his own knowledge, cannot say. Should the plans however he carried out, they would create a *rôle* of great importance at Peradeniya, of much use to agriculture in a colony where, just as in ours, though it may he in a somewhat less degree and certainly on a very much smaller scale, agriculture is the chief source of revenue.

The hotanic garden at Peradeniya issues annually a detailed report of its operations, hesides, at indefinite periods, according as occasion demands, small "Circulars." The little *brochures*, the publication of which was begun hy Mr. Willis (they are somewhat like our "Korte herichten uitgaande van den directeur van's Lands Plantentium" which are puhlished in *Treysmannia*), relate exclusively to practical experiments of value to the colony.

The annual reports also include the reports of the "Honorary Entomologist," Mr. Green, who in a general way by his meritorious publications on the injurious insects of Ceylon had already heen ahle to furnish very useful advice to agricnlture there.

On 27 June we set out on a journey, with the ohject of going to visit, under the guidance of Mr. Willis, one of the four branch estahlishments of Peradeniya, namely Badulla. For that purpose we had to travel by rail until evening as far as Bandarawella, where the night was passed, in order to reach Badulla hy the mail coach the following morning. In this expedition we had the pleasure of being accompained hy Mr. J. Parkin, a young English botanist, who was engaged at Peradeniya in very interesting experiments with caoutchouc.

In spite of the fact, that all the lower and medinm sized mountains that one passes are equally entirely denuded of jungle on behalf of cultivation, this railway journey is nevertheless from the point of view of natural heauty really astonishing. Again and again the eye is struck hy the frequently impressive beauty of the environment. To attempt, from a tourist's standpoint, to give some idea of the landscape, would he a very difficult task, and one that in any case would be out of place here. The two principal impressions of those made upon us during this journey belong however to categories *certainly* coming within the scope of this report. The one is of an agronomic, the other of a hotanics nature.

Everyone acqnainted with Ceylon knows that hy the influence on agronomic grounds can only he meant the extent and importance of the tea cultnre.

The tea district begins near Peradeniya. Immediately opposite to the garden, at a distance of a couple of paces, are the gardens of the "New Peradeniya" estate, which yields about one per cent of the whole tea product of Ceylon.

Shortly after leaving the station of Peradeniya Junction, as far as and even above the station of Nanuoya situated at 5,300 feet, one rides literally continuously through tea plantations. I do not helieve that one will anywhere else—unless indeed in the wine-growing districts—meet with a cultnre, carried on upon so large a scale, predominating so greatly in a whole stretch of country.

When one considers, that, as I found stated, in 1875 only 282 pounds of tea were exported from the whote of Ceylon, and the export in 1898 amonnted to nearly 120 million pounds, then one must have great respect for the energy of the Ceylon planters. The more so when one also knows that just in those districts great losses were suffered through the coffee-leaf disease. On many places where tea now stands coffee was earlier found, and partly also cinohona; in addition many waste lands were also cleared and planted with tea. It was originally attempted to ohtain these lands at as high an elevation as possible, it being known that a high situation above the sea has a favourahle influence upon the quality of the product. Estates are even met with going up to 7,000 feet; among others a well-known estate ahove Nuwara Eliya famed for its good product. During the past few years the Government have, in order to prevent further devastation of the forest jungle, given no more permission to denude lands situated higher than 5,000 feet of jungle and hring them under cultivation.

When one sees tea planted everywhere and everywhere, from the immediate neighhourhood of the railway to as far as the eye can reach, on monntain and in valley, npon the steepest slopes and the most unlikely-looking places, there involnntarily arises, with all respect for the strength of spirit developed hy the Ceylon planters, the question, whether the praiseworthy energy has always gone accompained hy a corresponding caution; and whether, with falling prices, hy means of increasing competition and other operative factors, the plantations formed on less favonrahle lands will, in comparison with the favourahly sitnated estates, not have a very hard strnggle. In very many places the soil of the tea gardens possesses extremely little humus, belonging in general to what one calls a poor soil. According to what Mr. Willis told me, this is met by some hy means of manuring with able manure and guano.

Whilst those persons living in Java who have a direct concern in tea cultivation are naturally in the highest degree interested in Ceylon tea statistics, it is at the same time perhaps not unimportant to refer to

the really enormous increase that the export of tea from Ceylon to Russia has undergone in *one* year. In 1897 that export amounted to 439,349 pounds and in 1898 2,714,005 pounds: thus nearly seven-fold. This in truth agrees with what I learned four years ago more than once in Russia, and what has since been repeatedly asserted to me by Russian visitors here, uamely, that the non-Chinese teas will find a great sale in Russia.

Before concluding these short incidential remarks regarding the tea culture, there is yet another question that deserves to be touched upon, even though it be with a single word. It is that of labor. The person engaged in agriculture in Ceylon does not find as do his colleagues in Java (excepting the employment of Madurese labor in East Java) the needful laborers amongst the population of the island itself. As a rule there is no Sinhalese labor, but Tamil coolies obtained from British Iudia, from the Madras Residency.* Accordiug to what I was told, these coolies are mostly easily to be obtained, at wages of 30 to 37 (as maximum) rupee-cents per diem. If the fact that the indigenous population counts for nothing or at any rate for very little as a labor force, does not seem to cause the Europeau agriculturists very much trouble and loss, it must certainly be without the condition of injury to the country itself. The Tamil coolies however—not to be confounded with the Tamil families living in Ceylon (comprising some 440,000 souls) in the uorth in and near Jaffna, and in the east in the regiou of Batticaloa—do not remain in Ceylou, but generally return after a pretty short time to their houses in British-India. The earned and saved sums of money, reaching, as I was assured to pretty considerable amounts, are carried home with them, or are often sent from time to time by post. All this money leaves the country and thus does not contribute to the increase of the welfare of the population in the districts where the European agriculturists carry on their occupation. This evil, there unavoidable, is not to be reckoned too lightly; let one only think—to make a comparison with an equal tea-growing region of Java—of the evident welfare in our villages in the Preanger Regencies where the people work on aud for the tea estates.

Between the Nanuoya station and the small stopping place situated at the highest point of the railway (6,300 feet) the land under cultivatiou becomes steadily more infrequent and the natural vegetation in direct ratio comes more and more, and at last entirely, into the foreground. And it is in that sphere that the great botanic—or more strictly speaking vegetogeographical—peculiarity falls to be uoticed to which reference was made above.

The mountain slopes are only partially covered with jungle. Among the woods, forming large complexes and strips, and bordering immediately upon them, one sees grass-covered lands, which either form great bays in the jungles, or in the fashion of broad passages separate extensive forest-complexes from each other to assume elsewhere the character of enormous accidented grass-fields. These lands, whose prominent charaoteristic is, whatever in addition their form may he, that they are so remarkably sharply divided from the neighbouring pieces covered with jungle, bear the name of "patana." Looking at a distance like rather short-kept lawns, these patanas are in reality formed of pretty high and coarse grasses (species: *Andropogon, Arthistiria, Pollinia, Garnotia, Arundinella*), amongst which occurs a peculiar flora, consisting of pretty numerous ground-orchids, immortelles (*Anaphalis* and *Helichrysum*), gentians, wahlenbergias, &c; besides some low-growing bushes of the families of the Leguminosae, Rubiaceae and melastomaceae. As a further peculiarity of these patanas it is to be noted, that, at least in the high-lying ones, literally only *one* variety of tree occurs, namely *Rhododendron arboreum*. Very scattered in the large grass-plains, standing alone, these rather low trees with short, mostly crooked, branches have as such no handsome appearance; covered, however, with masses of large blood-red rhododeudron flowers they form so many brilliant bouquets standing out gloriously from the monotonous brown-green under-layer of grass.

The whole landscape in the high patana region is *so* singular and the demarcation between grass and jungle so abrupt and always *so* sharp, that one can hardly believe that one sees before one the work of nature alone, and one is constantly inclined to ask who can have been the genial designer, who had the audacity to cover the mountain slopes aud tops with a park on a gigantic scale, wherein woods and enormous *pelouses* [lawns] leaving open bold perspectives, alternate with one another.

Rightly says Trimen, in his article already quoted from on the flora of Ceylon: "A curious phenomenon, which strikes every traveller in the mountains, is the very abrupt line of demarcation bet- the patana aud the forest; so sharply defined is this that it is hard to persuade oneself that nature alone has had a hand in it. The explanatiou appears to be that iu the course of vast ages a perfect equilibrium between the two floras has been arrived at, so that now neither can encroach on the other: the patana plants are unable to exist in the dense shady forest, whilst the seeds of the forest trees never get a chance even of germination in the closely occupied grass-land, so far as can be observed, this balance is now maintained without change."

That the equilibrium is formed and at the same time, so far as one can judge, maintains itself unaltered is a fact that is indisputable. Nevertheless it is quite enigmatic *how* it has arisen and also to a certain extent how it endures. Especially is this an enigma, for the time being totally insoluble as it appears to me, since the patanas certainly are found rather on the dry side of the mouutain range, hut hy no means exclusively. On the wet side of the mountains they also occupy large stretches; it was just there that we saw them for the first time, going up from Nanuoya. In this relative iudependence of the climatological conditions the patanas differ from the llanos of Venezuela and the savannas of Guiana, to which they otherwise have a resemblauce.

It was certainly wet enough at 6,000 feet elevation. Clouds, mist aud rain all together, caused cold shivers, to run through one's limbs.

But, in the strict sense, as by the stroke of a magician's wand, all was changed.

A few moments after one has passed the highest point, one comes through a long tunnel, followed by several smaller ones, and suddenly one is in dry Ceylon. By the landscape, by the uniform tints, hy the feeling, in short by everything one recognizes, that one has been at once transported into a district as dry as a cork. And that, when only half-an-hour previously one's teeth were chattering. This extremely remarkable contrast also forms not one of the least of the surprises in which this journey so rich.

The brief details given above, having reference to the chief causes that distinguish the climate of Ceylon, makes the rapid transition intelligible; only a personal view, however, can convey a just conception of the striking effect of this unprecedented change of climate between the two sides of one and the same mountaiu range.

Before the falling of the evening we reached the terminal station Bandarawela; under the impression of the selfsame panorama formed hy hundreds of hills and mountain tops, all shining in those uniform red tints peculiar to arid and dry regions of

* *Sic.—D.F.*

warm countries. And notwithstanding one finds ourself in the midst of a tropical island lying seven degrees from the equator.

At Bandarawela we spent the night at a small but well-arranged hotel. It is thongbt of making of the place a kind of sanatorium later on, just on account of the drynesss of the climate. If the place is to become really habitable then the great difficulty of the production of shade will first have to be overcome. As it is now——we experienced it the following morning during a little botanizing expedition on the patana—althongh one is at a height of about 4,400 feet, after eight o'clock in the morning it is so scorching hot, that one hastens to flee indoors, where the cold, in contrast with the terrible heat ontside, does not feel pleasant, as being too great a contrast.

By a difficult but excellently-made mountain road a mail coach brought ns, over a distanoe of 18 miles, from Bandarawela to Badulla, the identical first object of our expedition.

The garden at Badulla, or rather the gardenette, since the surface comprises not more tban 11 acres, was founded in 1886 by the former Director, Trimen, with the object of there trying tho cnlitivation of various usefnl plants, in order to find out which of those plants were adopted for the particular climatological condition of the province of Uva, of which Badulla is the capital.

(To be concluded.)

SUGAR ITEMS.

During the past seven years Queensland has sold sugar to the value of £6,500,000. Last year £1,163,010 was paid into the colony for this single article of prodnce. The loss to the working classes by the destruction of this industry would amount to the wages at the fifty-eight mills and ten juice-extracts plants alone, of nearly 4,000 white men. There are in addition some 3,000 farmers, who grow cane for the mills. Probably 8,000 Europeans are employed outside the factories pretty well all the year round, besides some 10,000 indirectly engaged in the industry. Thus they are actually some 25,000 white men employed to 9,000 kanakas, the labour of one of the latter enabling employers to employ nearly three whites. The 9,000 kanakas are employed in the field, bnt it is with great difficulty that the number can be kept up to the figure.

In 1899 Qneensland exported 109,045 tons of sugar to Europe, the Australasian colonies, China, and Japan, &c. Does it ever strike any of tbose who cry aloud again black labour to try and calculate how many white men earn bread for their wives and families by means of this annual output of sugar? Do they ever consider the operatives in British factories who make the linen for the bags, the twine and the needles, the men wbo navigate the ships which carry it, the engineers who make the machinery—worth in Qneensland probably some three millions? Again do they consider the numbers of horses and teamsters employed in the industry both on plantations and in the cities? Wharf labourers have to haudle very once of sugar. How many comfortable homes are the direct result of the sugar industry? For every coloured labourer sweating in the canefields there are a dozen white men and women earning good wages, which they would not be able to earn where it not that there employers enaled to pay them those wages tbrough the means of these reliable, yet not too cheap, coloured w orkers. Every ton of sugar produced in the colony is worth from £4 10s. to £6 to the cane-producers, mostly hard-working men who, by sugar-growing alone, provide comfortable homes for their wives and families, and indirectly for thousands of wharf labourers, teamsters, and draymen's families.

Such an industry is well worth fostering, not by bonuses, but by assistance to introduce superior methods of cultivation by which heavier crops and a higher sugar content may be obtained. During the present season a Fine engaged in sugar-growing took 70 tons of cane off 1 acre of his land, where otbers were only getting from 17 to 20 tons. It may be presumed that the land was rich, new, scrub land; but is it not within the power of science to put even worn-out land into the same condition by means at once cheap and effective? This is what it is hoped that Dr. Maxwell will bring to pass. He will be here by the time this *Journal* goes to press, and he arrives at the right time to at once put existing and intending planters on the right atrack. Should his work have the result of increasing the sugar output by 9 tons of cane or 1 ton of sugar, the black labour question would cease from troubling. It would gradually die out, especially if it should come to pass that the work of "trasbing" is found to be superfluous, and an effective cane-cutting machine be invented. We have seen in tbe introduction of a very useful cane-planting machine, and there is little donbt that ere long some inventive genius will discover a means of mechanically cutting and tropping cane plants in whatever condition tbe crop may be, whether uneven in height blown over by the wind. When that comes to pass the need for the kanaka will pass away, and the Nortbern canefields will no longer be the terror of the white man.—*Queensland Agricultural Jounral.*

HOW MUCH SEED TO USE

Last month we gave the quantities of seed o various crops required per acre broadcast or in drills. To this list we may add the quantities required per acre in hills:—

Maize, 8 to 10 quarts; cucnmbers, 2 to 3 lb, climbing beans, 8 to 10 quarts: rock-melons, 2 to 3 lb.; squash 2 to 3 lb. pumpkins, 2 to 3 lb.; water-melons, 4 to 5 lb.

The quantity of seed reqnired to furnish a certain number of plants, approximately, and allowing for seeds which do not germinate, is—Asparagus, 1 oz. to 500 plants; cabbage, 1 oz. to 1,500 plants; cauliflower, 1 oz. to 1,000 plants; celery, 1 oz. to 2,000 plants; egg-plant, 1 oz. to 1,000 plants; endive, 1 oz. to 3,000 plants; leek, 1 oz. to 1,500 plants; lettuce, 1 oz. to 3,000 plants: pepper, 1 oz. to 1,000 plants; tomato, 1 oz. to 1,500 plants.

Quantity of seed required for a given number of hills—Maize, 1 quart to 200 hills; cucumber, 1 oz. to 125 hills; musk-melon, 1 oz. to 60 hills; climbing beans, Lima, beans, 1 quart to 100 hills; climbing beans, wax, 1 quart to 150 hills; pumpkin, 1 oz to 50 hills; squash. 1 oz. to 50 hills; water-melons, 1 oz. to 30 hills.

Quantity of seed required for a given length of drill —Asparagus, 1 oz. to 60 feet of drill: beets. 1 oz. to 50 feet of drill; beans, dwarf, 1 quart to 100 feet of drill; carrot, 1 oz. to 100 feet of drill; endive, 1 oz, to 100 feet of drill; okra, 2 oz. to 40 feet of drill; onion, 1 oz. to 100 feet of drill; onion sets, 1 quart to 50 feet of drill; parsley, 1 oz. to 125 feet of drill: parsnips, 1 oz. to 200 feet of drill; peas, 1 quart to 75 feet of drill; radish, 1 oz. to 100 feet of drill; salisify 1 oz. to 70 feet of drill, spinach, 1 oz. to 100 feet of drill; turnips, 1 oz. to 150 feet of drill.—*Queensland Agricultural Journal.*

POLISHING RICE.—There is a great deal in the style in which any product of the soil or manufactured article of food is got up for market. Coffee, rice, arrowroot, honey, ginger, preserves, and many other articles produced and manufactured in Queensland, have often suffered in competitive markets in consequence of being either carelessly prepared or badly packed, or put up in unsightly vessels and packets. The *Grocer*, an autbority on such matters, says that fashion demands a brigbt lustre in rice, and this is secured by rubbing off a dull outer coating of the grain, which has been shown to have a food

value nearly twice as great as the rice grain after polishing. The polishing process, however, greatly improves the appearance of the grain, and it is now almost universally practised in cases where the rice is intended for occidental markets. The material scoured off is preserved and sold under the name of rice flour. The polishing is effected by friction against the rice of pieces of moose hide or sheepskin, tanned and worked to a wonderful degree of softness, loosely tacked around a double revolving cylinder of wood and wire gauze. From the polishers the rice goes to the separating screens, composed of different sizes of gauze, where it is divided into its appropriate grades. The rice is then packed in barrels or sacks and is ready for the market.—*Ibid.*

Destruction of Moths.—At Aigle (Switzerland) little boys armed with glued rackets go at dusk into the vineyards and catch the night moths, the eggs of which would produce the devouring worms which cause there such havoc amongst the grape-vine leaves (*Chochylis).* This new way of hunting was quite successful. In a few days, and on a few acres only over 20,000 moths were caught, representing millions of eggs and worms. [We believe that the experiment of catching fruit-flies by means of butterfly-nets was tried with good results by Mr. C. S. Voller. How would the sticky racket answer, fixed to handle? —Ed. *Q.A.J.*

THE EFFECT OF SCIENTIFIC INVESTIGATION UPON AGRICULTURE.

The *art* of agriculture is as old as man, but the *science* of agriculture has not yet completed its first century. It seems at first thought impossible to believe that, before the nineteeth century dawned, agricultural science was, to even the most advanced scientific workers and explorer, a—"dark continent." In 1804, De Saussure published a work entitled, "Recherches sur la Vegetation," in which he gave the analysis of the ashes of many plants, and contended that they were absolutely essential to the growth of the plant, that they must be derived from the soil, and that probably these ash or mineral constituents that the plant derived from the soil were the source of those found in the animals which fed upon the plants. From 1802 to 1812 Sir Humplirey Davy delivered several series of lectures, which he published in 1813, under the title "Elements of agricultural Chemistry." To him is due the credit of making the first attempt to reduce agricultural knowledge and investigation to a scientific basis. The work of these two men, together with that of Thaer, Sprengel, and Boussingault, prepared the way for the magnificent work of Liebig, whose publications appeared in 1840 and 1842, since which time many of the brightest minds in Europe and America have been investigating the composition of the soil, plant, and animal, and their relation to one another.

Davy said. "Discoveries made in the cultivation of the earth are not merely for the time and country in which they are developed, but they may be considered as extending to future ages, and as ultimately tending to benefit the whole race, as affording subsistence for generations to come; as multiplying life; and not only multiplying life, but likewise providing for its enjoyment."

Liebig, in one of his productions, wrote: "I shall be happy if I succeed in attracting the attention of men of science to a subject which so well merits to engage their talents and energies. Perfect agriculture is the true foundation of trade and industry—it is the foundation of the riches of states."

Chemistry was the first science that came to the assistance of agriculture, and ever since agricultural science has been largely built uodn agricultural chemistry as a foundation.

Its application in connection with soils and fertilisers, foods and feeding, and with dairyings is readily comprehended. A large portion of the work in other sciences could not be carried on without the assistance of the agricultural chemist. Perhaps one illustration of the value of chemistry may be sufficient for our present purpose. The beet sugar product in Germany has increased from 360,000 tons in 1876 to 1,620,000 tons in 1896. The average product of beetroot is about 10 tons to the acre. In 1876 the 10 tons produced less than 2,000 lb. of sugar, whereas in 1896 the same weight produced 3,000 lb; in other words, the beet-root of to-day contains over 50 per cent. more sugar than it did twenty years ago. To the agricultural chemist belongs the large proportion of the credit for this marked improvement.

Botanists are at work studying the plants of the world, and helping in the production of new varieties and the improvement of old varieties. Let me give you but one example of the value of this. About 6,500,000 acres in Ontario are devoted to grain-growing. If by selection and cross fertilising we could obtain seed grain that would add only one bushel per acre to the crops, the annual grain product would be increased by 6,5000,000 bushels. The grain crops, of Ontario in 1897 were worth over $50,000,000. An improvement to the extent of 25 per cent. is quite within the range of possibility. The President of the Agricultural College, in his report for 1897, referring to this work in improving varieties of grain, says:—"In this way some excellent foreign varieties have been introduced, tested, and distributed throughout the province—varieties which yield from 6 to 8 bushels per acre more than any varieties previously grown. In oats and barley alone, the varieties introduced and distributed by the experiment stations have, within the past four or five years, paid to the province a good deal more than the entire cost of the College for the last ten years."

Entomologists are studying the thousand-and-one insects and diseases affecting our grains and fruits. One practical example will perhaps best illustrate the value of Entomology. About ten years ago the complete destruction of the orange groves of California was threatened by the spread of an insect known as the "cottony-cushion scale." The vitality was being sucked out of the trees by millions of tiny insects that literally covered them. The pests got completely beyond the control of the fruitgrowers of that country, and in their despair they appealed for help to somebody or anybody. Professor Riley, who was in charge of the Entomological Department at Washington and who unfortunately met his death in 1895—one of the greatest benefactors the American people has ever known—at once began the investigation of that question. Being an expert entomologist, he knew practically every country in the world where that scale insect was common, and he knew that the place from which it had most likely come was Australia. It had probably been introduced, some twenty years before that, in bringing fruit trees or vines. He, however, knew it had never become a pest in Australia. Now if it is found in Australia and later found in California and had not become a

pest in Australia, he concluded there must be something in Australia that will stop it, so he despatched two assistants to Australia to investigate it, and they sent back consignments of lady-bug beetles or lady-bugs as they are commonly known. You have seen these running back and forth over the leaves and branches of the fruit trees, doing great destruction to the other insects. Within a very short time, less than a year, although these scale insects had been increasing for twenty years and practically had the product of California by the throat, and, in fact, had taken possession of the country; in less than a year, this little lady-bug had increased to such numbers that it swept the scales out of existence, or got it into such control, that the fruit interests of California were saved. I do not suppose that anybody could sit down and readily figure up the amount of money that was saved or made for the United States, by that simple little insect brought in by a man known to very few present. You do not see his name prominent in the newspapers. The fact was not heralded broadcast in great flaming type. He was not given any great ovation. It is a question whether any monument will be erected to him by the United States, yet it is doubtful whether the United States has had any greater benefactor than that man and his associates. The importance of economic entomology to the farmer is thus referred to by the late Professor Panton, of our Agricultural College, in an article contributed to the Farmer's Institute report for 1896-7 ;—

"The study of insects in relation to man has of late years commanded much attention, and is usually referred to as economic entomology. While there are some insects beneficial to man there are many injurious. Some destroy his food, some injure his clothing, and others attack the animals that are of use to him. Nearly 100 species have been found preying upon his grain and forage crops; upwards of 40 upon his vegetables; 50 upon the grape; 75 upon the apple. The pine has 125 species as enemies; the oak, 300; the elm, 80; the hickory 170; the maple, 75; the beech, 150; while the unfortunate willow battles against 400 insect foes. The following statistics show what an immense loss is sustained by man from insects :—

1854—The United States lost $15,000,000 by wheat midge.
1857—Canada lost $8,000,000 by the wheat midge.
1864—The United States lost $75,000,000 by the chinch-bug.
1870—New York State lost $5,000,000 by the cabbage worm.
1873—The Southern States lost $25,000,000 by the cotton worm.
1874—United States lost $356,000,000 by the grasshopper.
1884—Canada lost $5,000000 by the clover midge.

The average loss of the United States from insects during 1884 is calculated to have been $400,000,000, and for 1391 $300,000,000. With such figures before us, in most cases under the mark, we must conclude that the study of a subject that will enable us to lessen this loss is of great importance."

The biologist is studying the microscopic forms of life that produce plant food in the soil, that bring about the changes in stored foods, that control the fermentation in milk, butter, and cheese, and that cause the many diseases in our live stock. The debt that the whole world owes to the great Pasteur should not be forgotten. He established the principles of winemaking, and saved the vineyards of France ; he laid the foundations for dairy bacteriology : he mastered anthrax, the terrible disease that threatened the annihilation of the herds, not of France alone, but of all Europe as well. He was one of the greatest geniuses that the world has ever known, and agricultural science received a wonderful impetus from the labour of his head and hands and heart.

So important is scientific research in connection with agriculture that one noble-minded English man set apart a great estate in England for that work, and endowed it with £100,000. For about half-a-century the work has been carried on at Rothamsted, and the Queen has recognised it by knighting its donor and assistants. Sir John Bennett Laws and Sir Joseph Gilbert are familiar names in the higher agriculture of the whole world.

One of the hopeful signs of the times is that agricultural scientific investigation is attracting more and more attention on the part of our Governments, young men of promise are being drawn into its ranks, splendid opportunities for research are being provided in many countries, and we may confidently look forward to a great advancement in the next quarter of a century. The probable effect upon agricultural life of the application of scientific investigations and discoveries may well attract your careful attention —*From Appendix, Ontario Bureau of Industries.*

Sir Joseph Hooker has been elected one of the Foreign Associates of the French Academy of Sciences, Institute of France.—*Gardeners' Chronicle.*

Linnean Society.—The last meeting of the Society was held on Thursday, December 20, at 8 p.m., when the following papers were read:—Mr. Arnold T. Watson, F.L.S., "On the Structure and Habits of the Ammocharidæ;" Mr. I. H. Burkill, M.A., F.L.S., "The Flora of Vavau, one of the Tonga Islands;" Prof. Poulton M.A., F.R.S., "On warning Colours in Insects." Exhibitions—Dr. J. W. Cornwall, F.L.S., two photographs of composite flower which appeared on a white Foxglove growing in a garden near Godalming; Mr. B. Daydon Jackson, Sec. L.S. two editions of Hills *Flora Britannica* with a note on the species of Statice included in them.—*Ibid.*

They Never Drink.—An exchange says:—There are hundreds of horses and thousands of cattle in the Hawaiian Islands which never take a drink of water throughout the whole course of their lives. On all the islands the upper altitudes of the mountains are given up to cattle ranges. The cattle run wild from the time they are born until they are sent to the slaughter-house. Except possibly two or three months in the rainy season, there are no streams or pools of water in any parts where the cattle range, but everywhere there grows a recumbent, jointed grass known by the name of maninia. This is both food and drink. Horses and cattle grazing on it neither require water, nor drink it when offered.—*Journal of Western Australia.*

CANNA OR INDIAN SHOT.*

General Characters.—Canna is a genus of the natural order Scitamineæ, to which belong the Plantain or Banana, the Cardamoms, Arrowroot, &c. It contains upwards of sixty species and innumerable varieties. The great majority of the former are natives of South America, only one species, *Canna indica* ("Butsarana" of the Sinhalese), being indigenous in Ceylon. Ordinarily they are characterized by a tuberous perennial root-stock; herbaceous leafy stems, 3 to 6 feet high; large oblong Plantain-like sheathing leaves, green or bronze, with a strong mid-rib and prominent parallel veins; the inflorescence being a spike or raceme produced at the apex of the stem. The flower includes three small greenish sepals which remain attached to the fruit or ovary after the rest of the flower falls away; three narrow petals which are somewhat showier than the former, and within these again a number (one, three, four, or even more†) of other petal-like brightly-coloured leaves, which constitute the most showy part of the flower. One of these bears an anther and is the stamen of the flower; the others have no anther, and as they are usually supposed to have been derived from stamens which, as in double roses, have lost their anthers and become petals, they are often called staminodes. The only fertile (anther-bearing) stamen is situated in the middle of the flower, next to the petal-like stigma, the anther being attached down its edge. From this petaloid character of the stamens the flower may be considered to be naturally "double." The fruit, persisting on the flower-stalk, is round and oblong, with a warty surface; in the young or ovary state it contains many ovules (potential seeds), but even when growing wild only one or two of these become developed into fertile seeds. The latter when ripe are round, black, of the size of a pea, and very hard: hence the name "Indian Shot." The disposition to produce seed is still less in cultivated varieties, and, in the case of the "Orchid-flowering" class and some others, seed is seldom or never yielded. Thus the increase gained by the hybridist in size and brilliancy of flower may be said to be at the expense of the reproductive functions.

Barrenness in the fruit may however arise from other causes. Seeds never seem to be produced here by *Canna edulis* ("Butsarana"), this being no doubt due to long cultivation and to the practice of propagating the plant exclusively by means of its underground tubers.

As regards modes of propagation, infertility in Cannas may not be considered a disadvantage, except from the hybridist's point of view, as the quickest and best means of increase is by division of the crowns ("stools"), the seeds being so hard that, even if steeped for some time in boiling water previous to sowing, they usually take several months to germinate; consequently filing the outer coat of the seeds is occasionally resorted to, whilst burying them for six months in a manure pit is also recommended.

The beauty of these plants is not their only feature of interest, for some are also of economic importance on account of their underground tubers which yield an article of food, being ground and made into a flour. The well-known arrowroot "Tous-les-mois" is furnished by *C. edulis*, a native of the West Indies, but introduced and cultivated in most tropical countries. Of less utilitarian value, however, is *C. indica*, the real "Butsarana" of the Sinhalese, who gave it this name, which means "help from God," on account of the seeds being used in rosaries by Buddhist worshippers.

History.—The introduction of the first Canna (*C. indica*) into Europe dates back to about 1570. With the exception of this no other species seems to have attracted notice until about the beginning of the 19th century, when several species were introduced for the first time into European gardens. At that time these were grown chiefly for the beauty of their foliage, and on this account became, and are now, much in favour in temperate countries for planting out in groups in the open during the summer months for sub-tropical effect. Therefore the larger and more robust the plants the more effective were they for this as well as general decorative purposes where foliage only is concerned, and clumps growing 10 to 12 feet high were no uncommon occurrence. Consequently any improvement attempted by the cultivator was directed towards the increase in size of stems and foliage. Since 1863 a great gain in size and brilliancy of flower has been gradually gained by the hybridist, which has resulted in the modern varieties of Cannas—a most showy class of "flowering plants," very different in the form and appearance of floral characters from those of their progenitors. Few productions of recent times have created more general interest than the advent of these, or have proved a more valuable acquisition to floriculture. Robust growth of foliage may now be regarded rather as a disadvantage than otherwise, as plants of a dwarfish habit are the most satisfactory for general purposes. In the Tropics, where Cannas have their natural home, probably the most popular class at present are the "Orchid-flowered" forms, a designation which has been applied on account of the general resemblance of the flowers to those of a Cattleya. They are readily distinguished by their large and usually widely expanded and flat-surfaced flowers, which have invariably a rich velvety tint. These date their origin from 1893, being the result of crosses obtained by Messrs. Dammann & Co., of Naples, between *Canna flaccida* (a red flowered species of the Southern United States) and garden varieties. Many of the older so-called "Gladiolus-flowered" type are not however to be despised, and in some respects are even preferable to their more recent congeners, especially for use as cut-flowers or for growing in pots or boxes.

Cultivation.—Few plants are more easily grown than Cannas, or more satisfactorily repay cultivation for ornamental purposes. Their evergreen foliage and perpetual habit of flowering render them exceptionally useful, particularly in tropical gardens, where the variety of suitable-sized and showy flowering plants is comparatively limited. Though in Europe Cannas have an enforced period of rest in the winter months, during which time their tubers are stored away and kept dry, here they can be grown all the year round, especially at elevations below 4,000 feet. They are naturally suited to a hot moist climate, and it is under these conditions that their ornamental character is best developed. Their cultivation is very simple, the chief requirements being rich open soil and a liberal supply of farmyard manure. In this they do well, and require but little attention beyond watering in dry weather and occasional mulching and forking up of the surface of the soil. Before planting, the ground should be deeply dug or trenched and heavily manured near the surface, Cannas being essentially surface-feeding plants young off-shoots or small divisions of the crowns ("stools") may then be planted out 2 to 3 feet apart. Any portion of the crown will grow and rapidly form new plants, provided it is furnished with a bud or a short tuberous root-like structure; this is really an underground stem, bearing rudimentary scale-like leaves, and will in due course develop into an ordinary stem with foliage, &c. In about six weeks after planting, the plants will begin to yield a display of flowers, which will be continued for several months. They quickly form clumps and gradually spread over the ground, becoming in time overcrowded; they exhaust themselves, so to speak

* Circular Royal Botanic Gardens, Ceylon December, 1900.

† Usually fine in cultivated varieties.—Curator.

the flowering stalks becoming tall and bare by their continuous habit of flowering, and the flowers smaller and scanty. It is therefore advisable to lift the plants at least once a year, replanting them as already advised, the process of digging and manuring being repeated each time. When grown in pots or boxes the plants should be allowed as much light and air as possible, as otherwise they will become too tall and lanky. Those most suitable for such culture are probably the "Gladiolus-flowered" varieties, which are included under Class II.

Cannas will thrive at practically all elevations in Ceylon, though they are best adapted for the low-country, where, up to 3,000 feet altitude, their flowers will be larger as well as more plentiful and effective.

As regards arrangement in planting out this is entirely dependent on local conditions and individual taste. Cannas are, however, especially adapted for planting in groups or masses, or at the back of borders; whilst they are also effective when planted amongst a mixed border or against a background of shrubbery; but in pots, tins, or boxes they are seldom satisfactory except as "foliage plants" when in healthy growth. The bronze or purple-leaved kinds, apart from their flowers, may be made to afford a pleasant contrast with green or variegated foliage, and are worth growing on this account alone. It may be stated that an open, sunny situation, away from the shade of trees, is the most conducive to a floriferous habit.

Classification.—For botanical purposes Cannas are divided into four sub-genera, based on scientific distinctions in which the average grower is not much interested; nor are these really of importance from a horticultural stand-point. In any case, with the garden varieties it is practically impossible to follow specific distinctions and, it being difficult to place these plants in any order of merit, an arrangement in accordance with the purpose they fulfil in the garden will be of the most practical guidance to persons making a selection. Thus considered, height of stems with foliage is probably of the first importance, next to this being respectively colour of leaves and flowers. The "Orchid-flowered" class are easily distinguished, as already stated. They have large and usually flat-surfaced flowers, borne on spikes which become very elongated, and are generally coloured with rich velvety tints. In the purple-leaved section of these the flowers are generally smaller and more or less funnel-shaped.

The "Gladiolus-flowered" varieties however do not seem to be so well defined. These are generally of a more compact habit of growth than the former, their form of inflorescence (usually a branched raceme) also being shorter, but more spreading, and forming round heads. Though these include some of the best of the newer varieties raised, most of the older varieties which are not of the Orchid-flower-type may also, apparently, be classed under the same head.

In regard to the following order, in which the different varieties are arranged according to height and colour of leaves, it must be remembered that only the height of the foliage is taken into account; even this will be found to vary in different soils and under dissimilar conditions, so that the figures given should be considered only as an approximation. In the case of colours—which most people describe differently—these are given in accordance with the opinion of the writer. The following selection includes what are considered the most distinct and best varieties at Peradeniya, where, however, several more are grown. When known the date of origin or introduction to horticulture is given in brackets after each variety.

ORANGE-CULTURE IN SOUTH CALIFORNIA.

By D. Wingate.

The following excellent article on citrus fruit culture in California is taken from *Chambers's Journal*, and may *ipso facto* be taken as authoritative. We have frequently been indebted to that journal for reliable information on various subjects, which are obtained from the best sources, and are treated in a manner at once clear and intelligible to all interested in the subjects dealt with:—

The culture of the orange-tree has greatly increased in South California within the last few years, despite the many difficulties the growers have had to contend with. Florida was once the largest orange-producing State in the Union; Riverside, a county in South California, is now the largest orange-producing district in the world. Even Covina, a comparatively new orange section, also in South California, last season (1899) shipped 100,000 boxes more than the whole State of Florida. Given suitable soil and plenty of sunshine, irrigation and cultivation have done the rest; and the result to-day is thousands of acres of beautiful trees in bearing, averaging about a hundred trees to the acre.

The celebrated "seedless navel orange," first produced in Riverside, practically gave South California its world-wide reputation for orange-growing; and this orange has completely thrown into the shade other varieties—such as Mediterranean Sweet, Valencia, Ruby and Malta Bloods, St. Michael's, and others less known. Growers have discovered that, for size, flavour, and steady bearing, no other orange can compete with it.

The first year of the orange-tree's life in the orchard is a most critical period in its existence, because it has just been transplanted from the nursery, in which, during its growth for three or four years from the seed, it has been carefully nurtured, and is then worth from 50 cents to 1 dollar—that is, 2s. to 4s. The young trees are planted in the orchard in rows accurately measured off, 18 by 20 feet apart.

The Washington navel orange-tree fruits the first year in the orchard, but it is only said to be in bearing the third year; and from that time it must be fed and watered with the greatest care if, at the age of twelve years, it is to produce 700 lb. or 800 lb. of fruit. Many of the most successful groves are of comparatively old growth, planted some twenty-two to twenty-five years ago; but the health and productiveness of these trees have been maintained by the generous expenditure of fertilisers—often amounting from 1 ton to 1½ tons to the acre, consisting of guano with necessary proportions of potash and sulphate of iron—and also by the regular irrigation in summer every thirty days, and by incessant cultivation or breaking up of the soil, which is so apt to become baked by the sun. In the first instance the virgin soil is extremely fertile, but it cannot be drawn upon year after year with impunity; and the pioneers discover this, to their loss, when the decadence of their orange-trees become evident. Young orchards pay while the soil is virgin: but it is no economy to spare either water or manure after the first year or two of bearing, if the orchardist wishes his trees to maintain their productiveness. Some growers state that slight blemishes on oranges denote too rich feeding of the trees; but I believe this opinion is held only by a minority.

The grower has practically nothing further to do with the oranges after they leave his orchard; the sorting, cleaning, grading, and final packing for the market, are in the hands of the association packing-houses—unless, of course, the grower himself has been able to establish a brand and a packing-house of his own. Usually the grower is supplied with boxes by the association, and into them the oranges are loosely packed by his pickers, piled up on wagons, and taken into the packing-house. There the teamster

receives a cheque or credit note for the the owner, and these are kept three or four months, and used to check the amount then receivable from the association. The price depends upon the kind of season, also upon the grade of orange, and runs from about 90 cents (3s. 7d.) or 1 dollar (4s.) up to 2 dollars 50 cents (9s.) a box, the average being 1 dollar 15 cents (4s. 7d.).

The first process at the packing-house is to weigh the fruit, and label it with the name of the owner, then put it aside for the brushers. In large houses the brushing is done by a machine; in smaller houses by boys and girls, who use small hand-brushes. Generally the packing machine is conveniently placed so that the oranges roll down an incline to the sorters' table. Here imperfections only are noted, the quick and critical eye of the sorter rapidly rejecting the "culls" as they are called—namely, those oranges even slightly discoloured or blemished. Great piles of these "culls" may be seen in labelled bins ready to be sold to the peddler for 10,25, or even 50 cents (5d., 1s., 2s.) a box; if totally unsaleable they are returned to the owner, and scattered over the orchard and ploughed in as a fertiliser. The next process is that of grading, by which the oranges are sorted according to size. The grader is a somewhat intricate machine. From the hopper at one end, the oranges roll down an incline, by the side of the revolving cylinder, along each side of which are two long slits widening towards the bottom, each size falling through its own special chute into a box below. The three grades of marketable oranges are the fancy, the choice, and the standard. After being graded, the oranges next come into the hands of the packers, who are marvellously dexterous in their handling. They stand in front of the box to be packed, with the bin of oranges on the right and a bunch of tissue-paper wrappers on the left. Swiftly the right hand takes an orange, simultaneously the left hand seizes a wrapper, a sound of crumpled paper, and—hey, presto!—the orange is in the box. The last layer is left slightly protruding above the side of the box; over this are nailed three or four thin laths, with a space between so that the air may have free access; and from the nailer the box goes direct to the railroad car. Many houses have a siding to the warehouse door. About 360 boxes, weighing 13 tons, are piled carefully into a car; the car is then sealed up, ventilators only being open; a large ticket is tacked to the side to tell where the fruit came from; and at last the oranges are ready for the swift freight train to carry them eastward.

The packing-house are extremely interesting, and in many instances have cost from 10,000 dollars to 15,000 dollars (£2 500 to £3,750) each, being equiped with the the latest machinery, run by electricity, gasoline, or steam-power.

Quoting from the annual midwinter number of the *Los Angelos Times*: "Last spring the assessment returned 2,072,417 bearing orange-trees and 1,227,397 trees in their first year's growth. These citrus trees produced in 1897, in car-loads of 336 boxes each, 7550; 15,1 2 car-loads in 1898, and 10,350 car-loads in 1899. The value of the output of 1899 is given by the Chamber of Commerce as 7,000,000 dollars."

Lemons are always included in these assessments, as the railroad lines make no difference between the two shipments when reporting for the trade; as a rule the shipment of oranges is nearly double that of lemons. To the uninitiated there is little difference at a first glance between an orange orchard and a lemon orchard; there is the same precision in planting, the same glossy leaves, the same fragrant white blossom; but, unlike the orange, rarely does one see the lemon in its yellow rind, for it is picked green, and thus the tree is divested of its beauty, for the green lemon is an insignificant object. Latterly the orange, owing to the rivalry among the growers to be the first to ship oranges from California, has been gathered unripe but these early shipments have brought so little profit to the growers that the fruit is generally allowed to remain three months longer until it is ripe and luscious for the table. Lemons are picked every month in the year; while oranges blossom in April, and the fruit ripens and is shipped from December of that year to June of the following year.

As yet nothing has been done to utilise the large numbers of "culls," but as in France and Italy, manufactories will, no doubt, be started to obtain acids and essential oils from these "culls," when the enormous water-power available in the mountains, at whose feet so many orchards lie, has been fully developed.

Many difficulties have been encountered in the orange-culture of South California, of which not the least has been the white scale, an insect pest which threatened at one time the entire destruction of the orchard. Hundreds of acres were ruined; the trees seemed to be covered with snow, so greatly infected had they become. The climax was reached in 1388 89, when meetings were held by the growers, and the idea was mooted that some parasitic insect should be found to wage war upon this white scale. Half-a-dozen ladybird beetles were imported from Australia by the Agricultural Department, and liberated in an orchard, and in about a year the white scale totally disappeared. Other scales have caused trouble, but to no great extent. Fumigation is successfully resorted to each tree being covered with a tent, inside which is liberated cyanogen gas. The fumigation is done at night to prevent ecomposition of the fumes by the sunlight. It is a curious sight to see a whole orchard enveloped in these coverings, like a huge encampment on a field of battle. Frost, too, is an always expected danger, but it is not experienced to the same extent as by the Florida growers, and frequently two or three years will pass without any damage being done. Wind is almost as great an enemy as frost, for the waving of the branches causes friction between the leaves and the oranges, the latter being more or less scarred thereby, Great loss, too, is caused by the windfalls, hundreds of oranges being lost to the grower before they have come to perfection. Frost, however, may be considered an insidious enemy, and on that account it is more difficult to fight, for its effects are not immediately apparent, instances have occured in which the oranges have actually been shipped eastwards in good condition even to the eye of the grower and the packer, only to be declared unsaleable, as, on being cut open, the pulp was found almost rotten. An experiment to obviate the action of wind and frost has been tried—to house the treef collectively under one immense frame-work of wooden laths, so placed at intervals as to admit sunlight and air, but sufficient to break the force of the wind. This scheme has been carried out successfully on the Everest Ranche, Riverside County, with such good results that the production of 17 acres thus covered in has far exceeded that of any previous year. The more common expedient is to plant eucalyptus trees in long rows across the general direction of the wind, thus forming a breakwind, much in the same way as the tea and coffee plants in Ceylon are protected.

Notwithstanding all drawbacks, orange-growing is a pleasant and lucrative occupation, especially when carried on in such a health-giving and equable climate as that of South California.—*Queensland, Agricultural Journal.*

THE MANURE HEAP.

WHAT MAY BE LOST BY INCOMPETENT MANAGEMENT.

It is of the utmost importance to retain all the fertilising elements of the manure heap. In spite of the knowledge gained by experiment of the losses which accrue from an ill-protected manure heap

it is to be feared that much yet remains to be done before farmers are brought to a knowledge of the appalling loss that takes place annually through careless and indifferent management. Experiments have beeu made to compare exposed and unexposed manures. It was demonstrated that there is a greater loss of nitrogen and organic matter from exposed manure than from that protected. The former lost one-third of its nitrogen and the latter about one-fifth. Ten per cent more organic matter was destroyed iu the exposed than in the protected manure There is practically no loss of potash and phosphoric acid from protected manure. Exposed manure that is rotting may lose about one-sixth of its phosphoric acid, and somewhat more than one-third of its potash. The chief changes, due to fermentation, take place within the first months of rotting, and experiments show that there is no apparent benefit in rotting the manure longer than for a period of three months. When gypsum was used, 3 tons of horse and cattle manure, mixed in equal proportions, were allowed to ferment without the addition of any preservative, by way of comparison with an equal weight of the same kind of manure intimately mixed with ground gypsum (land plaster) at the rate of 50 lb. of gypsum to every ton of manure. These lots were fermented at the same time, in separate bins, inside of a building, the manure being fresh and compacted as closely as possible, being undisturbed for four months (July to November), when they were weighed and analysed. The results showed that gypsum retarded, to a certain extent, the destruction of animal matter. The amounts of nitrogen in both lots were the same, no useful result from the application of gypsum being observed. The proper place to use gypsum is in the stable, as it is in the stable that a great loss of ammonia occurs.

MANAGING THE HEAP.

When manure is kept moist, the loss of potash cannot be prevented without a water-tight, non-absorbent floor, but when the manure heap is kept compact and moist there is not any considerable loss of ammonia. It is evident that if manure is exposed to rains, no matter what the absorbent materials may be, the water cannot pass down without carrying soluble matter with it, and when the water reaches he bottom it must either go down into the ground or flow off in some direction. Whatever substance has been dissolved out of the manure remains in the water and passes off with it. The remaining materials of the heap may be almost worthless, but they receive just as much attention, and as much abonr is bestowed in hauling and spreading the snbstances as though the loss of soluble matter had not occurred. It has been shown that when manure is compacted, and the air kept out, the fermentation of the mass is not so rapid, but when loosened and the air admitted, fermentation begins, because the oxygen of the air influences chemical action. When manure is under shelter the rains do not dissolve the plant food from the heap, and when the liquid manure is thrown upon the solid portions by pumping or otherwise, the solids become absorbent and assist in retaining the liquids. All locations for manure should have water-tight bottoms, for then any accumulations of liquids can be retained and added again to the heap, and tanks should be arranged into which all liquids from the stable shonld flow, so as to save the soluble matter. If the heap is then too wet, more absorbent material of some kind should be added.—*Farmer and Stockbreeder.*

COOK ISLANDS.

In a recent report on the trade prospects and social condition of the Cook Islands, the British Resident, Lieut.-Colonel N. E. Gudgeon, says that during his late visit to the outlying islands of the Federation, he found it necessary to comment in strong terms on the fact that at least two-thirds of the area of the group was practically unproductive, owing to the owners of the soil having neglected to plant the coral formation with cocoanuts, and to their having done comparatively little to improve even the most fertile lands. He also pointed out that, in the event of a hurrieane, many of the old cocoanut trees would be destoryed, and therefore the islands would have absolutely no export for the ensuing eight or ten years, since they had no young trees planted to take the place of those that would be destroyed. He could not say that he expected any good result would follow his remarks, inasmuch as the Cook Islanders were too easy-going to take into consideration prospective privations or benefits. But he was now in a position to report that his view of the situation had impressed the native owners of the soil to this extent, that they were planting both cocoanuts and bananas in very large quantities, and therefore there was a prospect that at no very distant date the trade of these islands with New Zealand would be very largely increased, for there was no reason why the export should not be fivefold the present quantity.

He regretted that he had to report that the coffee crop of last year, which at one period bade fair to be abundant, had proved almost a failure. Late in the season the trees were attacked by the Ceylon leaf blight, which it would seem was introduced by a Mr. Dodge, who, about the year 1896, imported several hundred coffee plants to this Island; the result had been that Raratonga was not likely to appear as an exporter of coffee for many years to come, since the whole of the old trees had been entirely killed. Fortunately, this blight had not reached the Islands of Mangaia or Aitutaki, but that was of small moment as compared with Raratonga, since the last-named island had always exported ten times the weight of coffee produced by the two former. The failure of this important item of export had made it imperative that copra should as much as possible take its place, and, therefore, that coconut planting should be encouraged.

There was at present every prospect of a very large orange crop, and he confidently anticipated that the amount available for export would be at least twice that of last year. That was a position which might easily be maintained or exceeded, if the native owners could only be brought to see the necessity for pruning and artificial manures. At the present moment the natural impression on the mind of any stranger would be that orange trees were grown in Raratonga not so much for their fruit as fo timber purposes.—*Imperial Institute Journa*

THE RUBBER INDUSTRY OF SIERRA LEONE.

The Kewattia, or rubber tree of West Africa, is one of the most beautiful trees of the forest, growing usually to the height of from forty to sixty feet. Its leaves are from four to nine inches in length by from one to three inches in width, oblong and tapering towards the ends, supported by a stem from eight to nine inches long. There are several species of vines which yield a grade of rubber inferior in some respects to that obtained from the trees; however, when gathered with care, this commands a ready sale. The United States Consul in Sierra Leone says that the supply of Freetown market for the most part comes from the hinterlands of Sierra Leone and from the Foulah country in the French protectorate farther in the interior. That which come from the Foulah country is limited, owing

to the export tax of about three half-pence per pound placed by the French upon all rubber sold by natives outside their protectorate. Notwithstanding this prohibitory restriction upon the native rubber vendors, there are several regular traders who furnish to the market a good quantity of Foulah rubber every season. This rubber is almost invariably adulterated with clay, yet it grades well in the local market, and brings a better price. In former years Freetown was a better depot for rubber than at present, but since the establishment of the French protectorate, which controls the output of the valleys of the adjacent northern rivers, the trade has been directed to the French port of Konakry, seventy-two miles distant from Freetown. The dry season from November until May is the gathering season. Native chiefs supervise and control the sale of the output of their respective territories.

The method of gathering the sap is very simple. The body of the tree is tapped and the juice flows until it is exhausted; later, new incisions are made. The juice is usually caught in cups or calabashes attached to the tree, so as to prevent impurities appearing in the rubber. The neglect of this precaution is responsible for a percentage of the incidental adulterations, of otherwise good rubber, frequently found in the local market. The native, in his efforts to increase his stock, frequently bleeds the root as well as the body of the tree; this is fatal to the tree. The product is known as "root rubber," and, besides containing large quantities of impurities, is very inferior to any grade of tree rubber, and would be refused altogether by local buyers in order to discourage the destruction of the forests, were it not for the sharp competition for export trade. The rubber is brought to market overland by caravans of natives, or most frequently by canoes. These cargoes are generally consigned to some particular agent, though they are often sold to the one making the best offer. For convenience rubber is arranged in three classes or grades, known as No. 1, No. 2, and No. 3, the character of the tissues and freedom from impurities being the determining factors, as well as the kind of adulterants. Considerable ability on the part of the agent is necessary to enable him to properly assort and select the rubber and to detect adulterations. There are two classes of these—incidental and intentional. The former is the result of carelessness on the part of the gatherers who do not use proper receptacles for the juice. Intentional adulterations are due to efforts to increase volume and weight by use of dirt, sand, bark, and sometimes stones. Another species of fraud is the mixture of other non-elastic gummy substances with pure juice; still another is to soak rubber by placing it in pits close to the water for a long time. Rubber so treated is seriously injured in quality, and at the same time increased in bulk and weight.

The Colonial authorities, as well as the Chambers of Commerce, are endeavouring, by proper instructions to those concerned, to discourage these abuses and to emphasize in every way possible the importance of improving the quality of the rubber brought to Freetown market. There is being inaugurated by the Governor and officials a plan to foster the planting of rubber trees and vines in the colony. To this end they have caused to be issued pamphlets of instructions in regard to seeding, transplanting, etc., through the departments of agriculture and horticulture. It is hoped that there will be a decided improvement in the quality and quantity of the exports in the near future. The value of the rubber exported from Sierra Leone in 1898 was about £51.000, of which the amount shipped to Germany was £6,700. The remainder went to England. —*Imperial Institute Journal.*

THE SUGAR INDUSTRY IN INDIA.

[The Profits of Sugar-cane Cultivation and of Cane-Sugar Manufacture in India By F.N.G. Gill.]

Now that the indigo industry of India is in such a depressed condition, and it has become a question with the planters of adopting cane cultivation more or less, the writer's experience may be of interest to them and others owning suitable land.

The sugar planter's business should be separate from that of the manufacturer, and where it is not it would be well if the planter treated the two branches of the business as separate businesses, each with its own account. In the present paper this course will be adopted.

Making jaggery will not pay if the planter can sell his cane to a central factory on the basis of R16·8 per 500 lbs. of jaggery yielded by it. Results of ryots' milling in South-Arcot was found to be 72 tons of cane crushed by two mills in twenty-four hours and obtained 18,744 lb. of jaggery, equal to 3 75 candies of 500 lb. (11·62 per cent on cane):—

	Rs.	A.
3·75 candies of jaggery at R16-8	61	14
Feed of 12 pairs of bullocks at 6 as ..	4	8
15 candies firewood at R1-4	18	12
4 men to mill, 8 men to boil, 2 men to collect bagasse, and 2 sundry men, day and night working	3	0
12 gunnies at 3as 3p	2	7
Sundries, repairs and interest on capital say	4	7
	R95	0

making cost on spot R25 5·3 per candy of 500 lb.

And to make the concrete with large steam mill, crushing one ton of cane in four minutes, and Fryer's concretor, the writer found the cost of the concrete R24 per 500 lb. bagged and on the spot. The ryots' working shown above is unnecessarily wasteful in fuel, even for open boiling; but as the jaggery in quantity would probably not fetch more than R18 to R22 on the spot, there is little hope of a margin in any case in such system of work.

The following are the results for 18 years 1879 to 1896, of cane cultivation in the South Arcot district of the Madras Presidency, obtained by native ryots with "Ribbon" cane grown under channel irrigation, and manured chiefly with ground-nut oil-cake, and by the richer ryots with indigo trash. The cane suffered considerably from water logging through neighbouring paddy cultivation, and its seasons of planting and cutting were forced into unfavourable seasons of the year by the requirements of paddy cultivation. The whole of the cane of the area of cultivation referred to was sold to the sugar-mills on the basis of the weight of jaggery (concreted juice) yielded by the cane. It might be good or it might be indifferent—really bad cane

was rejected—jaggery, but the system was very much better than that of buying the cane outright, as it gave the ryot a strong, though not a perfect all-round, interest in the quality of his cane. The juice of each ryot's cane was accurately measured, and 15 gallons of it were boiled down to concrete over an open fire, in the country fashion, and the weight of concrete obtained, together with the gallons of juice measured, afforded all the data required for the settlement of the party's account. Such a system as this, however, would not go far enough with European sugar planters, even though they were the owners—as they should be—of the central factory. Nothing short of the measurement of the juice and its polarization (to arrive at the quotient of purity or per cent of sugar in apparent solids) would be found to be satisfactory to all interests

Results of Cane Cultivation in South Arcot for 18 years during which the extent of the cultivation and the results varied :—

	From	To	And averaged
Extent of cultivation ...	129 acres	1,728	806½
Density of juice ...	9 Baumé	10·2	9·4
Cane crushed per acre ...	9·8 tons	18·2	15·0
Jaggery, concreted juice per acre ...	1·167 tons	2,189	1·754
	5·23 candies	9·80	7·86
Jaggery, per cent on cane	11·9	11·6	11·7

The weight of cane shown above is a closely approximate figure, arrived at on the basis of the jaggery being 11·7 per cent of the weight of the cane, the juice being of a density of 9·38 Baumé and being obtained at the rate of 140 gallon per ton of cane, equal to 66·7 per cent of juice.

If R 16-8 per 500 lbs., say R74 per ton, be received for the jaggery in the cane, the gross proceeds per acre, it is seen may vary from R 86-6 to R162 with R129-12 as an average. What the cost of cultivation, cutting and carting-of the crop are, and thence what the profit is, must depend entirely on local circumstances of distance of the cultivation from the factory, cost of land-rent &c., labour, manure, and seeds. On the average, cane cultivation pays well if the jaggery in the cane can be sold for R16-8 per 500 lbs. delivered in the factory, supposing that the cartage to the factory does not cost too much. With yield of 11·7 per cent jaggery on the cane, the ton of cane will give only 262 lbs. jaggery, and therefore 4 annas per cart load, and with three cart-loads to the ton, will make a cost of R1 per 500 lbs. of jaggery, or R7-14 per acre of average cultivation. The profits of the central factory should be very considerable, buying the cane from the planters on the above, or somewhat analogous terms; and working with multiple effect evaporators, vacuum pans, crystallizers in movement and quick-speed centrifugals, and with the factory designed for the conditions of the country. For a factory capable of dealing with 400 tons of cane a day and working for 100 days, equal to 2,666 acres of cultivation cleared in the season, probably 5 lakhs of rupees capital for building and machinery would be sufficient, and such a factory working an inferior cane with a refining value of the contained jaggery of 62·3 would turn out the bagged dry sugars at about R34 per 500 lbs.; valuing the treacle made at R6 per 500lbs. and allowing 7 per cent on the capital for interest and depreciation, and including cost of permanent establishment for the remaining 265 days of the year. The cost would run out :—13,083 candies sugar, and 7,560 candies treacle.

	Rs.	A.
Materials (21,000 candies jaggery) R16-8 and yield 62·3 per cent ...	26	8
Repairs and renewals	0	8
Establishment	2	0
Fuel	2	6
Gunnies, inner-bags and twine ...	1	3
Filter-bags and sheaths	0	2
Oil and sundries	0	4
Charring	0	8
Permanent establishment (in slack season) and insurance	1	5
Interest (5 per cent) and depreciation 2 per cent on R5,00,000 at 7 per cent	2	11
	37	7
Less 1,560 candies treacle at R6 ...	3	7
Net cost...	R34	0

The sugars would realise on the spot a minimum average price of R48 per 500 lbs., leaving a profit of R14 on 13,083 candies equal to R1,83,162. The realisation of the treacle, however, is a difficult matter, and is generally impossible in the working of an inferior cane without a distillery, which to deal with the 7,560 candies treacle would have to be capable of turning out about 20,000 gallons proof-spirit a month, and an outlet for this spirit would have to be found. The alternative, which would still leave a very good profit, of throwing away the treacle, in part or in whole, is not always possible, as there may very well be no place into which treacle in quantity can be run without causing a nuisance. If a distillery can be worked it can make its own profit out of the R6 per 500 lbs. treacle paid the sugar house, the spirit costing only between 6 annas and 7 annas per gallon proof, including 10 per cent 5 per cent depreciation, as it would work all the year round interest and depreciation on 1½ lakhs of distillery building and plant.

If the "Ribbon" cane be not water-logged, be planted seasonably in favourable soil, and be sparingly manured, its jaggery contents may have a refining value of over 74 per cent as also may the "Dikchan" Dr. Leather's analyses of Shahjahanpur, and the soft green cane turning mellow-yellow when dead ripe of Coimbatore; and then while the weight of cane per acre may be considerably less than more stimulated growth the greater value of the jaggery contents would permit of the central factory paying a proportionate price for it. Thus: 15,540 candies sugar and 5,040 candies:—

Gross cost would be—

	Rs. A. P.
R37-7@ × 62·3 ..	31 8
74·0	

And treacle credit—

7,560 × 6	
15,540 ...	2 14 8
Nett cost ...	Rs. 29 9 7

The difference between this and R48, R19-6-5 would be the profit per candy of sugar working the better cane—

		Rs.
15,540 cds. of sugar at Rs. 19 6-5	...	3,01,491
5,040 cds. of treacle at Rs. 6	..	30,240
		3,31,731
13,083 cds. of sugar at R14	...R1,83,190	
7,560 cds. of treacle at R6	... 45,360	
		2,28,550
Difference	...	R1,03,181

equal to R4-14-7 per candy of the 21,000 candies of jaggery which the sugar works can afford to pay the planter for such cane.

On the other band, the planter can afford to grow as little as an average of 11 tons of cane per acre at R21-6-7 per candy of jaggery, as against 15 tons with the jaggery at R16-8.

There is another possibility with the better cane—that of working the treacle for its sugar through a preliminary treatment of the cane juice and a final treatment of the treacle, and so being entirely independent of a distillery for the realisation of the treacle. As regards the preliminary treatment, the writer has not worked it on cane juice, but has worked it on several thousand tons of jaggery in refinery blow up and scum liquors and with glucose content of 4 and 5 in the 100 apparent solids, equivalent to, in the case of ordinary constituted cane juice, $\frac{3}{4}$ to 1 per cent glucose in the juice, and with the result that the treacle contained only 1-4 glucose in the 100 solids, or 1-2 per cent and accordingly quite fit to be treated by the final—the Steffen Lime Separation—process. The writer has not worked this process but he went to Germany to inquire about it in 1885, and in 1891 he went to Europe specially to go into the question of the advisability of its adoption in consequence of the oppression and vexation to which the business was subjected by officials through the distillery. The result was that the writer could not recommend the immediate adoption of the process which would have involved the outlay of $1\frac{1}{2}$ to 2 lakhs of capital, and with a distillery already on hand; and when, too, it was found that what was urgent was the adoption of crystallisation in movement. In the end this view was not justified and with his experience now the writer would not recommend the investment of capital, under any circumstances, in a business dependent on official sufferance in India, where the revenue official of heterogeneous origin and early training is invested with absolute power in anomalous capacities and is free from the restraints of public opinion.

From the foregoing it follows that the writer would strongly recommend the adoption of the Steffen separation process in sugar making in India, where possible. Applied to sugar-cane juice with the preliminary destruction of glucose referred to, the position would be as follows, working the better cane with juice containing a maximum of one per cent glucose.

Crushing 400 tons a day and obtaining 66·7 per cent juice* containing 1 per cent glucose there would be obtained 8·7 tons of treated treacle, requiring 5·6 tons of lime for its treatment, and giving in the saccharate formed—and which would be used for the destruction of the glucose in the following day's cane juice—rather more than twice the lime required for such purpose. Under the circumstances the lime expense is limited to the treatment of the treacle.

The following would be the cost of treating a day's out-turn of treacle:—

	Rs.	A.	P.
39 candies treacle at R6 ...	234	0	0
Establishment: 30 men at 3as. R5 10			
Supervision 10 0			
	15	10	
Fuel, 10 cwt. coal (only pumping, stirring and lime-grinding required, decomposing the saccharate in the cane juice) at R15... ..	7	8	0
Filter-bags	9	0	0
Lighting and repairing	10	14	0
Lime, 5·6 tons at R11-8	64	6	0
40 I. H. P. for cooling machine, at 4lbs, coal per hour, for 10 hours	10	11	5
Labour, oil, and sundries ...	4	8	0
Fitting etc.	1	8	0
Interest and depreciation (7 per cent on R10,000)	70	0	0
Rs.	428	1	5
Value of 16 candies rough sugar in the cane, which if separated would have an average polarisation of 94·7, at Rs. 35-8 ...	568	0	0
Value of 5 candies of treacle, say, nothing			
Rs.	139	14	7

or, say, R140 per day, R14,000 for the the season, but from which has to be deducted the cost of the preliminary process of the destruction of the glucose in the juice, beyond the cost of the lime met in the final process. Plant, consisting of two large gas pumping engines (to take this boiler-flue gases), and gas-scrubbers, three large tanks pipes &c., and more filters would be required, involving a capital expenditure of about R30,000 which at 7 per cent is equal to R2,100 debt which on 15,540 candies of sugar.=R0-2-3; and labour, fluel for gas-pumping, and more filter-bag wear, R0-1-9 total R0-3-0; per candy or R2,913 12, making a nett profit on the process of R14,000 less, say, R2,814. equal to R11,086.

The Steffen separation process, it may be mentioned, consists in combining the sugar of the molasses with lime to make an insoluble saccharate which can be washed free from impurities in a filter press. It necessitates the employment in the tropics of an ice machine, used simply as a cooling machine for keeping the temperatures of the liquors and water in use within 60° Fahr, but as ice machines are at present made this is not a serious matter, and the cost of it has been fully provided for in the above statement.

It will be noticed that a large quantity of lime is required. Further, the limestone burned must be very pure, and it must be burned on the spot. A very good source of lime would be cockle or such shells, washing them before burning if sea shells.

Summary of profits: Working 400 tons cane a day for 100 days

1 Taking the inferior cane with its contained jaggery of 62·3 refining value, costing R16-8 and

(*a*) Supposing the whole of the treacle is worked

* This was the yield ascribed with a density of juice of 9·3° B, but the juice of the better, non-stimulated growth of cane would have a considerably greater density, and hence, probably, the yield of juice would be greater; but this is a detail that need not be considered.

in a distillery, and the spirit sold at 1 anna profit per gallon proof, equal to a selling price on the spot of, say 8 annas.

(*b*) Supposing there is no distillery, and that the treacle can be, and is, thrown away.

	(*a*)	(*b*)
13,083 cds. sugar at R14	R1,83,190	R1,83,190
216,000 gals proof spirit at 1 anna	13,500	..
Less value of 7,560 cds. treacle credited		45360
	R1,96 690	R1,37,830
On capital of 6½ lakhs=30 2%		5=27 5%

2 Taking the superior cane with its contained jaggery of 74 refining value, and supposing that the treacle is worked by the Steffen process as described :—

(*a*) Paying R16·8 for the jaggery in the cane.

(*b*) Paying R21-6·7 for the jaggery in the cane.

	(*a*)	(*b*)
15,540 cds. sugar at R19·65	R3,01,491	R3,01,491
Profit of the Steffen process ...	11,006 ,,	11,086
	3,12,577	3,12,577
Less R4-14·7 more paid on 31,000 cds.		1,03,181
	R3,12,557	R2.09,396
On a capital of R6,30,000 ...	49·6% ,,	33·2%

It is a question whether, in regard to the profits shown in working the Steffen process, if the treacle ultimately left would not have a considerable value for mannrial purposes, and certainly the lime sludges (and wash waters) under favonrable conditions of elevation of factory in respect to neighbouring cultivation would have such a valne beyond the cost of their distribution.

All said and done, however, no process for the profitable absorption of treacle can beat that of the human stomach and it would be of immense valne to the sugar industry of India; and to the working classes of India, if the popnlar consumption of treacle could be brought about: Cane treacle at 5 pies a seer (2·05 lbs) on the spot, would be a remarkably cheap food stuff, and would give a realisation to the sugar works of R6-8 per 500lbs. for its treacle.—*The Indian Agriculturist.*

ARROWROOT.

The plant is propagated by division of the tubers, or by means of seeds. The sets are planted in rows 3 feet or 4 feet apart and 3 feet apart in rows; the drills 6 inches deep. The crop matures, say, in ten months. The bulbs may, however, be left in the ground for a moderate time without losing their qualities, but if to left too long, especially if rain has fallen, the plants begin to grow, and from that time onwards the quantity and quality of the arrowroot obtainable from bulbs then used may be expected to diminish. The land should be ploughed and subsoiled and thoroughly tilled, for though very easily grown, like many other economic plants, the better the treatment it receives the better are the eventual results. The manner of treating the tubers is to firstly place them in a large revolving washer so constructed that the tubers are always gradually passing onwards to a grater, from whence the material passes into a long shoot, the bottom of which is practically a long sieve, being constructed of line wire meshes. As the material passes along with the running water, the starch or arrowroot is gradually falling through this sieve on to a sloping wooden shoot below, whereby it is graduallly run off into wooden troughs and allowed to settle. As the arrowroot settles, the dirty water is run off, and fresh, clean water run into the troughs, in which the arrowroot is again stirred up. This process is repeated several times until the arrowroot is sufficiently clean and white. It is then taken from the troughs and laid out on calica dryers in the sunlight, and here it remains until completely dry and fit to bag as marketable arrowroot. Ordinarily, it takes two days of good sunshine and wind to dry the product, which is not spread too thickly on the dryers. Troughs of galvanised iron should not be used if bright, white, marketable arrowroot is desired. On 26th August, 1897, a small area was planted with *Canna edulis*, at farm in New South Wales. The plants appeared above ground on 18th September, 1897, and grew vigorously from that time until harvested on the 8th August, 1898. The crop raised was equivalent to a return of 33 tons per acre of tubers. One ton of these tubers was taken to the mill and there treated, the result being 240lb. of good, clean, white arrowroot. Some growers of arrowroot do not attempt any deep cultivation for the arrowroot plant. In the case of the experiment mentioned, the land was subsoiled and deeply ploughed, and the bulbs were cleaner, heavier, and larger than tubers ever seen elsewhere locally, and contained more starch, judging by the amount of arrowroot abtained. Probably, it is a satisfactory and payable crop where the methods are modern and complete, not crude makeshifts, especially in the matter of washing and drying the arrowroot. The result of this experimental crop would work out as follows :—

33 tons tubers to the acre. One ton of tubers gave under treatment, 2 cwt. 0qrs. 16lb.

33 tons of tubers equal 3 tons 10 cwt. 2qrs. 24lb., which, at £14 per ton, is equal to the sum of £49 10s. per acre.

So far as Jamaica is concerned, it would all lie in the making of a fine enough and white enough arrowroot that people might try as being at least as good as St. Vincent or any other arrowroot imported here *Journal of the Jamaica Agricultuarl Society.*

Extraction of Rubber.—A novel process was described recently before the Society of Civil Engineers of France for the extraction of india-rubber from the tree. The bark and roots are cut up and soaked in dilute sulphnric acid. The effect of this is to decompose the woody portions without affecting the india-rubber. In this way a division is made between the valuable rubber and the rest of the bark and roots, and it is claimed that the rubber so produced it quite pure. It was stated by the author that 1 lb. of india-rubber could be produced by the process at a cost of about 2½ l.—*Engineer.* Two French chemists have discovered a process by which rubber may be obtained from Landolfia vine, which grows wild and luxuriantly in all parts of Africa The process of tapping the Landolfia is impracticable, as the flow of rubber hardens too quickly. By the process of M, M, Arnand and Verneuil, the vine is crushed in hot water, by which means all the rubber which it contains is extracted —*Queensland Agricultural Journal,*

OUR PEARL FIRHERIES: MR, SAVILLE-KENT, F.L.S., F.Z.S., TO THE RESCUE.

We direct attention to the long and interesting letter (on page 541) with which Mr. Saville-Kent has favoured us by a late mail. It explains the circumstances under which his telegram was forwarded to our office ; and we are glad to see that he had previously addressed the Governor, sending His Excellency full particulars of his capabilities and experience with reference to the undertaking of an enquiry into, and, if possible, resuscitation of, the Ceylon Pearl Fisheries. There can be no doubt of the unequalled position held by Mr. Saville-Kent in reference to exploration in this direction (Pearl-yielding and Pearl-shell oysters) outside of the United Kingdom and of Europe. No other scientist of the day—English or foreign—has had the same experience. This is testified to by the couple of elaborate and splendidly illustrated folio volumes issued by Mr. Saville-Kent giving the result of his labours, these being entitled :—"The Great Barrier Reef of Australia" (a copy of which is in the Colombo Museum) and "The Naturalist in Australia" (a copy of which is possessed by Mr. Oliver Collett, of Watawala, and also by ourselves). We suppose that the scientific world fully admit the great value of these two books and of the prolonged abours, keen observations and successful experiments recorded in them in connection with Pearl and other oysters. Why then, it may be asked, was Mr. Saville-Kent's name not forwarded to the Secretary of State by Professor Ray-Lankester? This, we think, is partly explained in the letter before us, and it is for that reason that we have thought it wise to give certain particulars which the writer intended more especially for our own information ; but which we think, in Mr. Saville-Kent's own interests, had much better be made known, since already we had heard remarks made about his having fallen out of sight in the scientific world of late years. This is explained by his unfortunate connection with a syndicate started for commercial purposes to exploit a portion of the Australian Pearl Banks—which project, after much trouble and expense to Mr. Saville-Kent, entirely collapsed —and also to the fact that the younger generation of scientists are not so well-acquainted with him and his work as were Sir Wm. Flower and Mr. Huxley, both, of course, deceased. It seems to us that Mr. Saville-Kent has a plain, straightforward story to tell us, and that it will be a pity if his claims to service in the Ceylon Pearl Oyster Enquiry were put entirely on one side. At the same time, we are by no means blind to the special qualifications and great scientific authority of Professor Herdman of Liverpool ; and in the interests of the Colony we should feel quite safe if he were offered, and accepted, the appointment. But there are certainly two points to bear in mind :—(1) that Professor Herdman has had no previous experience of the Pearl-Yielding Oyster or of Oyster Fisheries outside of Europe ; and (2) that he is not likely to be able with his other engagements, to give continuous time or attention to the Enquiry in Ceylon. In other words, he cannot give up his University duties which occupy, perhaps, six months of each year, apart from other engagements. It is quite possible, therefore, if Mr. Saville-Kent be eager for the Ceylon appointment—as after his Australian experience, he may well be expected to be—and will make known his claims in the proper quarters at home, as he has already done to the Governor of Ceylon,—that Professor Herdman would himself support the appointment, or withdraw in favour, of the gentleman who has made a name as the "Naturalist in Australia."

It will be seen that Mr. Saville-Kent is prepared at once to apply his past experience to the work required and feels sanguine that fisheries of the larger Australian mother-of-pearl oysters (which often contain valuable pearls) could be established in our waters ; while he has also dealt successfully with the smaller oyster, *M. imbricata*, which is closely allied to our *M. fucata*. We have suggested the shores of the outer harbour at Trincomalee—or Tamblegam Bay—as a suitable spot for experiments in Pearl Oyster culture. But Mr. Saville-Kent's practised eye, in conjunction with the great local experience of Capt. Donnan, would speedily decide which was the best site, whether in the Gulf of Mannar or on the Eastern side of the island.

It only remains to mention that if, as we suggested at the local Asiatic Society's meeting, the Indian authorities would agree to join with the Ceylon Government in this Pearl-Oyster Enquiry and Experimental Culture, it might be possible to secure the counsel and aid of both Professor Herdman and Mr. Saville-Kent,—to have the former as Consulting Naturalist, coming out for a few months each year ; while Mr. Saville-Kent remained continuously in charge of the work undertaken. We think the interests at stake would fully warrant such a course. Ceylon has had as much revenue as R860,000 nett in one year from her "harvest" of pearl oysters, and that so recently as 1891 ; and India has also had handsome returns in the past ; while there are incipient fisheries at more than one point, besides the Gulf of Mannar, in her wide-extending coast between Kurrachee and the Malay Peninsula. Indian trade also benefits by the Pearl fisheries in the Persian Gulf and any good results from the proposed Scientific Enquiry could be freely utilised. If his Excellency the Governor can only succeed in interesting Lord Curzon in the matter, an investigation on the wider and more satisfactory scale might well be arranged for ; and there can be no doubt that conclusions arrived at by Professor Herdman and Mr. Saville-Kent in conjunction, would be accepted by the whole scientific world as well as by the Governments concerned, as final—more especially as, we should hope, these results or conclusions would justify the outlay incurred by pointing to a revival of prosperous Pearl-oyster fisheries in Gulf of Mannar and at other points.

IVORY CARVING IN ASSAM.

Mr. James Donald, I.C.S., Assistant Commissioner, Golaghat, in the course of an interesting monograph on this subject says :—Once an important art in the days of the Ahom rajas, ivory carving has since Assam came under British rule gradually declined. In those past times industry throve, the workers patronised by the rajas and leading men of the court reserved, as a return for their work, free grants of land and labour. In consideration for these privileges, a special class of workers known as Khanikars worked solely for the rajas. This would seem to indicate that the work in those days was much valued.

In 1891, the census showed four ivory carvers in the whole of Assam, three in Kamrup, one in Sibsagar, while the Deputy Commissioner of Sylhet now states—"Ivory carving is a practically extinct art now in Sylhet."

Bringing the information up to date we might safely say that there is but one man in the whole of Assam whose occupation can be described as "Ivory carver," Fiznur, Mussalman, of Jorhat. From an important flourishing and honourable industry, it has, in the space of 70 to 80 years, been reduced to the work of one man, and that spasmodic.

But there are others who, while dependent for their living on other occupations, still possess a knowledge of the art. In the case of all, however, the work is spasmodic, and entirely dependent on occasional orders received—generally from Europeans—which orders they do not always take the trouble to execute. The ivory carver in Sylhet (his principal occupation is that of "goldsmith") whose speciality is fans, has received but one order for fans during the last ten years. No other order has he received either from Europeans or Natives. And the others are in a similar position, although in the case of one or two more frequent demands have been made for their work.

The number of persons in Assam, who are acquainted with ivory carving, may be roughly put down at fifty. Of these about forty depend for their living on agriculture, while the others have become carpenters or brass-workers.

The nature of the articles turned out depends on the demand. Practically the whole of the work done is the result of special orders, and generally any article ordered can be executed, The representative of the industry in Sylhet makes a speciality of fans, while the Jorhat worker has a preference for salad spoons and forks and back-scratchers. The latter carver, however, confines himself slavishly to these three articles and will not execute orders for other than these. Small boxes, paper knives, dice, chessmen, combs, handles for knives, umbrellas, &c., bracelets, rings, and models of animals represent the general nature of the work. In these articles there is generally some ornamentation. Figures of animals as elephants and fish, and drawings of creepers and flowers, are common objects of ornamentation. Rubies and emeralds of a cheap nature adorn many articles as spoons, forks and bracelets and are used for eyes in the case of animals. Silver and gold, and brass, too are occasionally employed. In Fiznur's case there is little or no variety in the ornamentation.

Ivory carving once flourished because nurtured and, as I have pointed out, because not altogether an optional industry. It decayed when both these influences ceased. It has now reached the point of extinction, not so much because there is no demand, but rather because the workers, from want of energy or material, have so hidden their talents, that but few know of their existence.—*Pioneer*, Dec. 12.

PLANTING IN PERU:

COFFEE AND OTHER PRODUCTS.

(From a Planting Correspondent.)

Oct. 27th, 1900.

We are fully 4,000 feet above sea level, with a perfect climate ; neither wind nor great droughts to contend against. The roads are pretty good and are improving and a railway is expected to be laid soon to come within a short distance of this valley. To the European markets we have very low freights, and as Peruvian coffee has taken second place in name, and first price in the German markets, and first place and first price in London, namely, an average of 70s. per quintal (100 to 112 lb.) this gives general satisfaction. Also by this mail came *from the Paris Exhibition—2* awards of gold medals to the Haciends, *La Perla and St. Olaya*, on either side of this one. These are now in their sixth year, giving full crops of 1,000 quintals. This estate is in its third year, and great expectations may be realized if the weather keeps favourable, such as we now are enjoying. There are many questions I would like to ask, but especially these two :—Have you seen the results of the trial of Jadoo fibre, and is it such a marvellous factor ? I would like to see a Company formed to take up land just here, or alongside of the Peruvian Corporation. Their land is a day's journey farther inland. It would open up this country, as labour is cheap and sufficient, and the Indians and Cholos are strong, healthy and active, and very peaceable, and with the courtesy of the Spaniard. Their daily pay is 50 and 60 centavos ; all, or nearly all, are contracted by regular contractists (engauched) whose commission is 10c per tarea that they contract to work. We will employ from 15 to 40 men and 20 to 30 women during harvest.

Readers of the *Tropical Agriculturist* might and it to their advantage, to come and invest in this neighbourhood again.

BAMBOO MANNA.

One of the last numbers of the Agricultural Ledger contains an interesting description, by Mr. D. Hooker, of bamboo manna, and a report by Mr. A. E. Lawrie, a Forest Officer in Chanda, of its discovery in the Central Provinces. Mr. Hooper points out that bamboo manna has been known for many years among native physicians in India, but the term is generally accepted to represent the silicious concretion found in the culms of the bamboo and called *banslochan* or *tabashir*. This, he adds, "is a peculiar substance, and its origin is not satisfactorily determined. It occurs inside the stems of various species of bamboo, either in thin fragments or in masses about an inch thick. It is often mixed with dead insects in the stems, but when calcined it becomes opaline or pure white. Extraordinary properties have been attributed to it, and it is said to be tonic, cooling, aphrodisiac and pectoral, but from its composition it would

appear to be quite inert as a medicinal agent. At any rate, the trade in the drug has decreased within the last few years, and its collection by wild tribes is not by any means so active as it formerly was." The Sanskrit name for *tabashir* is *trakkschera*, or bark milk, an exudation on the outside of, whereas *tabashir* is always found inside the stem. Besides *tabashir* is quite tasteless, whereas the bark milk is sweet, so that the two substances are not identical, the confusion, Mr. Hooper suggests, being due, probably, to *tabashir* being called *saccharon* by Dioscorides and Pliny, the substance to which the ancients gave this name having none of the properties of sugar, and being used in quite a different connection, especially as a medicine. The bark milk exudes from the modes of certain species of bamboo and becomes solidified into pure sugar. Mr. Hooper adds that "Indian travellers, and the most recent writers on the subject of bamboo, have never recorded the spontaneous excretion of a substance similar to manna appearing on the stem." Mr. Lawrie, in his report, states that in November last the entire bamboo (*Dendro calamus strictus*) areas of forest for some miles along the Wardha river flowered, and shed ripe seed from early in January, a very unusual occurrence. This seed—which has been known to sell for 40 to 50 seers per rupee while wheat was selling for 12 seers—was a great source of food for thousands of poor people during the famine, and kept them alive for about three months. In February, Mr. Lawrie noticed that the culms of the clumps of bamboos growing in poor soil in the drier portions of the forests were streaked all the way down with what appeared to be a white, brittle gum, similar to what which exudes from *Odina Wodier*. The Gonds had never seen it before, so Mr. Lawrie collected some, and tasting it found it to be perfectly sweet. "On reaching camp, I got hold of a number of villagers, both Gonds and others, and on enquiry they told me they had never seen or heard of this gum. I passed through a number of similar stretches in which the bamboos were covered with the gum. This sugary deposit only extended for about five feet along the culms and was entirely absent towards the tops. It was found both at the nodes of the bamboo as well as on the stems between the nodes." Some of this manna was sent to Mr. Hooper, who found on analysis that it contained 95·63 per cent of sugar related to, if not identical with, cane-sugar, was quite wholesome, and might with impunity be used for cooking or making sweetmeats in the place of ordinary sugar. Similar saccharine exudations are afforded by many other trees in the East, while three descriptions of manna are imported into Bombay, one obtained from the camelthorn, one from the tamarisk, and one from the shrub *Cotoneaster nummularia*, all of which grow in Persia. Manna is also obtained from the *Eucalyptus viminalis*, which grows on the Nilgiris.—*Madras Mail*, Dec, 14.

SEYCHELLES AND MAURITIUS TRADE.

The prosperity of the Seychelles, as is well known, practically depends on vanilla, the exports of which to Great Britain in 1899 were valued at 873,728r, against 460,320r in 1898; France, 464,992r, against 271,320r in 1898. A rough estimate places the area of land under Vanilla at about 2,000 acres. Nearly all the vanilla is now cured in properly constructed drying-rooms heated with hot air. The French method of steaming the freshly picked pods has been tried, but the boiling water process is generally adopted. In 1899 fine prepared pods fetched 16r to 18r per pound (1r equal to 1s 4d). This year the price is from 14r to 16r. Green pods are now being sold at 10r per one hundred pods. The Administrator gives some hints concerning the method of planting, but similar information will be found in recent volumes of the *Chemist and Druggist*. The exports of vanilla from Mauritius in 1899 were 3,709 kilos, against 4,042 kilos in 1898, or a decrease of 303 kilos.—*Chemist and Druggist*, Nov. 24.

PROFESSOR KOCH ON MALARIA.

FINAL REPORT ON THE GERMAN EXPEDITION.

[TRANSLATED FOR THE *Pioneer* WITH HIS CONSENT.]

On the 6th of August, 1900, we left Herbertshöhe (in New Guinea) for home. The North German Lloyd's new line of steamers, plying between Sydney, New Guinea and Hongkong, and touching at the Caroline and Mariana Islands afforded us an opportunity of visiting these islands and obtaining, so far as the shortness of our stay permitted, a glimpse of their hygienic conditions. Mainly for this reason I chose this line for the voyage home, and was able to make investigations in Ponape on the 12th and 13th of August, and in Saipan on the 17th, in which I was assisted by Dr. Girschner, a medical man in the service of the Government.

In Ponape (in the Carolines) we examined 79 children, some of whom were from Colonia (the seat of the Government), the rest from six other places, some of which are pretty distant from there. In none of them did we find the swollen spleen and the malaria-parasites in the blood which are the characteristic symptoms of malaria. This proves beyond doubt that the island of Ponape is free of malaria. A case of dysentery was said to have occurred a good while ago. From what Dr. Girschner told me I judge that the skin-diseases which are so extremely frequent in the South Sea, and the disease called yaws, which is often mistaken for syphilis, play no great part in the island.

In Saipan (one of the Mariana Islands) 24 children were examined, and neither swelling of the spleen nor malaria-parasites were found; whence we may infer that this island too is free of malaria. Among the many other people who were shown to me as suffering from syphilis, lupus, and leprosy there was not a single one who really was suffering from one of these diseases. Their disease was framboesia, which the English also call yaws. It seems to be very frequent in Saipan, and is extremely widely diffused in the South Sea. I have seen places in the Bismark Archipelago, where almost all the children had it; and it is said that the children of Europeans are sometimes attacked by it too. It is often mistaken for syphilis by non-medical and also by medical men, and I am inclined to believe that the statements about the wide prevalence of syphilis in the South Sea and particularly in the German Colonies there, are due to this fact. It is highly desirable that a physician well acquainted with syphillis and diseases of the skin (a specialist, if possible) be sent to German New Guinea to make a more exact study of these diseases.

A peculiar disease was said to occur at Saipan, the course of which, with fever and lasting paralysis of certain limbs, could not but awaken the suspicion that it was beriberi. Of the patients of this kind who were shown to me one was suffering from hemiplegia, others from articular or muscular rheumatism. There was not a single indubitable case of beriberi. On the whole I got the impression that, as the islands of Ponape and Saipan are free of malaria and also of other tropical diseases except yaws, their hygienic condition is very good. From Hongkong we went by the main line of the North German Lloyd to Suez, where we broke our journey, in order to make a short stay in Egypt. The purpose of our visit to Egypt was to find some explanation of the contradictory reports about the malaria there. This purpose was partly gained, for we found in Alexandria several cases of malaria which had indubitably originated in or near that city, and genuine foci of endemic malaria at Heluan near Cairo and at Wadi Natrun, west of the Delta, in the midst of the desert. According to the last news I have received from Stephansort, dated the 8th of August, the favourable state of malaria there described in my reports had remained unaltered. In order to pave the way for the repetition in Germany of the experiment that succeeded so well in New Guinea, Professor Frosch, who was at one time a member of the malaria expedition, has visited many apparently suitable districts in North Germany, and made careful investigations with a view to ascertaining whether there is any malaria there. He found everywhere that malaria is rapidly dying out. At many places which used to be notorious malaria-foci the disease has almost entirely vanished; at others (in the marshy lands on the North Sea coast for instance) only isolated cases occur; nowhere could a malaria-focus suitable for my purposes be found.

Under these circumstances nothing remained but to conclude the work of the malaria expedition for the present.

Berlin, Nov. 17.—On the 15th instant Professor Robert Koch spoke to the Berlin and Charlottenburg section of the German Colonial Society on the results of the malaria expedition sent out by the German Empire. The meeting took place in the hall of the Kaiserhof (one of the biggest hotels in Berlin), and consisted largely of medical men, officials of the Colonial Department and officers of the army and navy. Koch was welcomed with loud applause. He began by thanking the Colonial Society for suggesting the malaria expeditions, and then stated what is now known about malaria. The gist of his lecture was this:

The germ of malaria, first seen by Laveran, is an animal organism, which lives in the blood of the malaria-patient and is so characteristic that the discovery of even one such parasite in a person's blood justifies the opinion that he has malaria. There is a whole group of malaria-parasites, and a corresponding group of malarial diseases. Germany has two kinds of malaria, Italy three, and a fourth kind, tropical malaria, is found in the tropics. The parasite can live long in a human body. Malaria reveals itself in a series of attacks each of which is the consequence of a fresh proliferation of germs. The violence of the attacks diminishes in the course of the disease, but relapses take place, sometimes even after the lapse of years. The question how the parasites get into the blood used to be answered in several very different ways. Now it is known that they are conveyed from one human body to another by gnats. This discovery is due to an observation of Ross, who demonstrated that the germs of malaria undergo a long process of development in the stomachs of gnats. The microscope shows that the developed germs meet in the poison-gland of the gnat. When a gnat sucks a human being's blood it empties its poison-gland, and thus introduces the parasites into his blood. In August, 1898, a German expedition was sent to Italy to test Ross's statements, and was soon able to confirm them. It was also ascertained that the apparently different Italian forms of malaria are really one, that Italian malaria is identical with tropical malaria, and that, apart from quartian and tertian which occur among ourselves there really is only one form of malaria, namely tropical malaria.

In the spring of 1899 the German expedition went to Italy again, and took up its abode at Grosset, in the Tuscan Maremmae. Spring was chosen, because it is in spring that malaria breaks out afresh in Italy. At first there were few cases, and these were relapses of cases of the year before. Not till the weather became warmer did the first fresh cases occur, but then their number increased very rapidly. They were uncommonly severe too, but the patients were taken to the hospital so promptly that the systematic treatment with quinine could begin in good time, and consequently the number of deaths was comparatively small. In autumn, after raging for four months, the malaria died out. Now, why is it that no fresh cases of malaria occur in Italy in winter, though there are gnats there in winter too? The reason is that the real home of malaria-germs is the body of a malaria-patient; they winter there. But the human body is not only the real home of malaria-parasites, it is also their only home. In the blood of monkeys, birds, and bats, indeed, organisms strongly resembling malaria-parasites are found, but closer examination shows that they differ from them. That the malaria-parasite thrives only in the human body is also proved by the fact that malaria is not transferable to anthropomorphous apes. The way in which malaria is propagated is this: a human being with malaria-parasites is stung by a gnat, which thus imbibes malaria-germs, which then develop in it, and are introduced into the blood of another person whom it stings. The anopheles is the chief bearer of malaria-parasites, but it is probable that other kinds of gnats (the pulex for instance) play a part in the business. It follows that in the battle with malaria the point of attack must be the malaria-patient.

The expedition then went to Java, and from there to New Guinea. Notwithstanding the great resemblance between the physical and biological conditions of those two islands, they differ most strikingly. Wherever you go in Java you see the fruits of prosperous human labour; in New Guinea hardly a trace of it. But the history of Java teaches that New Guinea too may be made to blossom like the rose. All that is necessary is the judiciously managed colonisation of the country, and the only hindrance (but it is a most formidable one)

is malaria, which sweeps away men, women, and children. One most important hint for the combating of malaria is furnished by the discovery made by the expedition in New Guinea that malaria is at bottom a children's disease. If you examine the children at a place where malaria is endemic, you find every one of them under the age of two suffering from malaria. In the older children, up to the age of ten, malaria parasites are found but not so frequently. The best way to ascertain whether a place has malaria is to examine the children. This method was employed in New Guinea and in the neighbouring islands, and it was found that there is only one point on the coast free of malaria, and that some of the islands are free, others not. The combating of malaria must begin with the children, but it is also of paramount importance to attack all mild or latent cases. The latent cases play the same part in the combating of malaria as in the combating of cholera.

That this is not mere theory was signally proved by a practical experiment made by the expedition on the plantations at Stephansort. Of the 700 inhabitants 137 were ill of malaria and all but a few isolated cases were cured. Special attention was paid to all new born and newly arrived children. Those children arrived remained in good health, whereas till then it had been impossible to keep children alive there. The experiment which succeeded there on a small scale will succeed elsewhere on a large. The great decrease of malaria in Germany is significant in this connection. The draining of the swamps alone does not account for it. Gnats, and in particular the various kinds of anopheles, are everywhere to be found. The real reason is that quinine has become accessible even to the poor. In the marshy lands of North-West Germany everybody now keeps quinine in his house, but thirty years ago a doctor had to think twice before prescribing quinine for a poor patient. The dying out of malaria in Germany is strikingly reflected in the statistics of the army. In 1869 the number of cases in the army was 13,500, in 1879 9,000, in 1889 1,500, and in 1896 only 230.

How is it with other proposals for the combating of malaria? One of them is to annihilate the gnats. Here and there perhaps this may be done by pouring petroleum into swamps, but on a great scale it is impracticable. Another proposal is to protect people against gnats by means of ethereal oils; but the effect of such oils lasts only a short time. Another means of protection is the mosquito-net; but such nets are seldom worn after sunset, and they often let mosquitoes through. The mosquito-proof house is open to similar objections. All attempts to confer immunity from malaria have hitherto failed. The prophylactic treatment with quinine, on the other hand, is of value, but it cannot be carried out generally and long.

How, then is malaria to be combated in our colonies? We must send out medical men trained to work with the microscope, and follow the example of the Dutch Colonial administration in giving the people quinine gratis. The first thing necessary is to send some medical men, especially to New Guinea and South-West Africa, as malaria-doctors. This measure, based on the new knowledge we have gained of the manner in which malaria spreads, would afford the prospect of our getting the upper hand of malaria ere long in the colonies, which is the preliminary condition of their prosperity. Professor Koach's lecture was received with loud applause and Professor Gerhardt (one of the medical luminaries of Berlin) delivered a short speech, in which he praised Koch as an investigator who not only brought new facts to light, but also taught how to turn them to practical account.—*Pioneer*, Dec. 23.

THE DATE PALM IN SOUTH ALGERIA.

I have been reading a little pamphlet in French on the cultivation of the Date Palm in South Algeria by the Agricultnre and Industrial Society of Sonth Algeria. They have been exhibiting dates, and also *Eau-de-vie* made from dates at the Paris Exhibition. As the French mode of cnltivation may interest anyone in India who may be inclined to try date plantations, I give herewith a translation of their method.

The pamphlet says that when date seeds are sown they produce a preponderance of males and inferior varieties, although sometimes new varieties occnr. *En passant* one might note that the trees which now produce the finest dates in the world could not have originated *except from seeds*. In Algeria they plant the offsets of the best sorts of secure the same kind of fine date trees. The nativte plant their offsets out at once, bnt this method gives usually only 40 to 45 per cent that strike and grow. The South Algerian Society have adopted another method, which is the following:—They plant the offsets in mannred soil in pots abont 15 inches in diameter and as deep. Then they plunge the pots in a nursery, where they can be easily tended and irrigated. When they root, they are lifted out of the pots with their ball of roots, and planted in the form of a plantation. While the tree are growing, they take catch-crops from between the rows, snch as lucerne, barley and other low crops. Great attention is paid to the date palms by regular irrigation from artesian wells. By this method of striking the offsets, they secnre from 90 to 95 per cent of rooted plants. Their best sort is called *deglet nour*. They have also what are called *dry* dates, I suppose similar to those bronght down to India by Afghan traders nnder the name of *chohara*. The latter sorts never ripen into the transparent sweetmeaty sorts, such as those we see in the London shops. E BONAVIA, M D.

London, 28th Nov. 1900.—*Indian Gardening*.

DR. WATT'S LATEST ON TEA PESTS.

Dr. Geo. Watt, Reporter on Economic Products to the Government of India, who, with Mr. Harold H Mann, has been on a tour through the tea districts, has returned to Calcutta, and has brought away with him a very large mass of material in the shape of specimens of pests and blights which attack the tea bush, and which will require much time and labour to investigate and ideutify. Dr. Watt's *Pests and Blights of the Tea Plant* will have to be revised and considerably enlarged after he has worked up all the specimens he has brought away with him. It should be noted that the specimens he has now brought with him, and which are being added to almost daily by Mr. Mann (who is still touring in the tea districts) are nearly all new. During Dr. Watt's travels among the tea gardens of Assam he found himself on one estate on which a certain kind of caterpillar was devastating the entire garden. The Manager told him that he had been capturing these caterpillars at the rate of *eight* "Acme" chestsful every day, and on counting up his bag, found he had slaughtered 2,700,000 of them! Had he not done this little

bit of *shikarring* on his own account, he would, at a moderate computation, have had to contend against 90,000,000 of these pests next year, with the result that his tea bushes would have been wiped out, and would have gone to manure the land on which they stood. The caterpillar is a peculiarly destructive one, and cunning, for it builds itself a round cocoon of the size and shape of an ordinary marble, and buries it in the soil, where it remains, and comes out in due course as a moth, which in its turn lays its eggs, which hatch out into the little caterpillars. Dr. Watt has brought away a number of these marble cocoons, and is cultivating them in the soil in which he found them, and will thus be able to study their life-history. Dr. Watt also found the little brown bug, that devastated the Ceylon coffee bushes, on a jungle creeper. The bug has commenced to attack the tea bush, and we have now to learn what it will do if allowed to increased and multiply. It is as destructive to tea as it proved itself to coffee. Truly, the tea bush is proving itself a veritable host to all sorts and conditions of insect and fungoid pests; yet it flourishes and "over-production" is the watch-word of tea men just at present. There is yet another interesting discovery made by Dr. Watt. He has found that several of the scale insects are attacked by certain fungi, and killed. He thinks that in such cases the fungi should be employed to inoculate the scale insects, and thus destroy them. He is therefore making cultures of these fungi, and we may expect some nteresting results from his investigations.—*Indian Gardening and Planting*, Dec. 20.

RUBBER AND ITS PRODUCERS.

We direct attention to another interesting letter from Mr. Godefroy-Lebeuf of Paris, on this subject. Our correspondent writes wonderfully goodEnglish,—we only wish we could write French as well—and if he would only make all botanical and unusual terms very clear, the printers would rejoice in his letters. The bark we sent him from a planter, we understood to be from young "Para" trees?—but we may learn more about this. Meantime, there is a good deal of interesting information in the letter before us; and in regard to the "Sapium" we quote as follows from the "Treasury of Botany":—

Sapium.—A genus containing about a score of trees or shrubs of the order Euphorbiaceæ, found in the tropics of both hemispheres, and all of them yielding a milky juice, which in some is very acrid and even poisonous. The leaves resemble those of the willow, the poplar, or the laurel, and at their point of union with the stalk are furnished with two round glands; while the small greenish flowers are disposed in terminal spikes, the lower portion bearing the fertile, the upper the sterile flowers.

S. indicum, a widely distributed eastern species, is known under the name of Boroo, where, according to Mr. Motley, the leaves are largely used for dyeing and staining rotang of a dark colour. The acrid milky juice produces a burning sensation like that from a capsicum. The young fruit is acid and eaten as a condiment, while at the same time the fruit is one of the ingredients used for poisoning alligators. The ripe fruits are woody trilobed capsules, about an inch across, with three cells, and one oily seed in each.

The Milkwood of Jamaica, S. laurifolium, receives its name from the milky juice which abounds in the stem, and is a source of annoyance to sawyers and others when the wood is green. S. salicifolium affords in Paraguay a bark which is used instead of that of oak for tanning. Most modern authors unite this genus with Stillingia, from which there are no reliable characters to distinguish it.

If anything is to be done with "Chonemorpha" for rubber purposes, we may be sure the Director of our Botanic Gardens will see to it:—

Chonemorpha.—A genus of Apocynaceæ, closely allied to Echites, and differing from it principally in the funnel shaped corolla. The species are, moreover, Indian not American. The root and leaves of C. malabarica, a plant of Malabar, are used medicinally by the natives

FIBRE EXTRACTION.

Bahamas—The factory for extracting and preparing the fibre of the pita plant or agave sisalana contains machinery driven by an oil or gas engine and the press for baling. The machine is placed at one of the extremities of the building with free communication to the outside, where there is a mound or raised stand from which the operator feeds the machine, a continuous thin stream of water being conducted to and flowing into the machine, so that the fibre is washed clean during the process of extraction. The leaves are carried by strong "grip" chains to large scutching wheels, which have brass knives passing across the periphery, and these knives scrape the vegetable matter from the fibre against brass or wood curves. At the other end of the machine, and inside the factory an operator is seated to receive the fibre as it emerges white and clean and from thence it is carried by other working hands to the outside, and is there hung out to dry in the sun across posts and rails erected for the purpose. When thoroughly dried, the fibre is brought back to the factory and packed in bales by means of a press exactly similar to a wool press, care being taken to turn in the ends of the fibre so as to give a smooth exterior surface to the bale when it is turned out of the press. Uniformity in weight is not attempted, they vary from 350 lb. to 500 lb. The maximum capacity of the best machine is about one ton of fibre per day. The following is a list of the machines which are or have been in general use:—*Prieto.*—A machine made in Barcelona and in use in Yucatan. *Todd.*—An American patent. Several of these machines are in use in the Bahamas; it may be consider fairly satisfactory, but not so good as the Villamor, of which patent there is one in use in the Island of New Providence. *Villamor.*—A better machine than the Todd in the amount of work done, and is not so liable to break down. It is an American machine, but is not being made at present. It has hitherto been used a great deal in Yucatan. *Torvella.*—A machine made by the same American firm that brought out the Villamor. The Torvella is now replacing the Villamor in Yucatan, and is very highly esteemed there. *Stephens or Theband.*—This is a large and expensive American machine. It is reported that a new machine is coming out on a new principle and probably cheaper.—*Colonial Office Report from the Bahamas.*

Tobacco Cultivation in Jaffna.—In some places the planting of the fragrant weed has commenced, while in others the preparing of the soil and manuring it are going on preparatory to planting. All kinds of manures have gone up considerably in value. The area which will be under tobacco cultivation this time will be much larger than it was in previous years.—*Hindu Organ*, Dec. 19.

THE SCIENTIFIC CULTURE OF TEA AND ITS CRITICS.

It is extremely like "teaching one s grandmother how to suck eggs," to find our evening contemporary attempting to instruct veteran planters and visiting agents in the rudiments of their profession! The process also of trying to discredit and repress scientific cultivation in respect of our Tea planting industry, so frequently attempted in the same columns, bears a close resemblance to Dame Partington's vain attempts to drive back the Atlantic! Cultivation according to scientific principles is acknowleged to be the only means to maintain and render permanent—rather than to injure or destroy—an agricultural industry. The existence of Rothamstead and the life-history of Sir John Lawes and Sir Henry Gilbert testify to this fact, and it is eminently satisfactory to know that Mr. Joseph Fraser has returned from his visits to Rothamstead and from interviews with the greatest agricultural authorities of the age with a clearer grasp of the principles and means to be followed; but without any conviction as to mistakes in the past, such as Mr. G. A. albot supposed he had discovered. It is abundantly evident that tea on old coffee land may as well be abandoned if it is not liberally supplied with fertilizers and nutriment; while it is quite as evident that tea on many younger estates with poor soil, must be aided judiciously and scientifically if its heart is to be maintained.

That means the use of "forcing manures" according to the ordinary but ignorant critic. "Give a dog a bad name and you may at once hang him" is the equivalent vulgar adage. But by following scientific teaching and at the same time watching the result of experiments—"science with practice" in other words—the planter can settle for himself what is best for his plantation, his tea bush and his pocket. This is exactly what has been done, for instance, on Damboolagalla and Pitakande. These estates are, we suppose, open for inspection—we write without any communication from Mr. Fraser who has a far greater stake in the permanent health and prosperity of the Ceylon Tea Industry than most of his critics, and who has verified again and again the truth of the adage that "the proof of the pudding is in the eating thereof," while he can show his tea to be in better heart and greater vigour now than when he commenced his operations.

But does all this not mean an encouragement to overproduction, and especially to the overproduction of cheap teas? We answer by enquiring who can be more interested in doing the right thing for himself, or for his employers or Directors, than the average Ceylon planter. He is by no means the shortsighted worker or downright idiot that some people would think him to be. Last year, it paid well to manufacture an abundance of tea of a cheap grade; and this year the same course being followed, a similar good return might have been experienced, were it not that Indian planters (see the editorial from a Calcutta authority we gave yesterday) abandoned their usual course and, thinking to follow the example of Ceylon, rushed at the supply of cheap teas, so that the market was entirely overdone, and the finer teas have become scarce in proportion to demand. Now, there is the risk of another swing of the pendulum; but the average Ceylon planter has a level head and he will give due consideration to the best course for him to pursue as to "plucking" and "manufacture," while keeping up cultivation and utterly ignoring the ignorant or prejudiced cry about "forcing manures." Even for returns of 450 to 600 lb. an acre, Ceylon tea requires a regular supply of fertilizers if the bushes are to be kept in heart and not worn out prematurely, and we suppose not all the critics in the world—even though led by a contemporary who knows nothing of planting and backed by Mr. G. A. Talbot—would keep the Directors and Manager of Mariawatte—to take only one instance—from following the same course of liberal cultivation which they have proved to be right, as well as successful, in giving handsome financial returns, for the past eighteen years; and we trow that in point of health and vigour, Mariawatte tea will compare with any in the island?

THE FUTURE OF TEA:

HOW TO DEAL WITH THE RISK OF OVER-PRODUCTION.

The proceedings of the Planters' Association in Kandy last month may for once be criticised by onlookers as more of academic than of practical interest. "What is the use," we may be told, "of agitating for the removal or reduction of an Imperial duty when Sir Michael Hicks-Beach has just been assuring a Deputation that there was more likelihood of it being increased rather than reduced?" Nevertheless, we consider Mr. Metcalfe (whom we congratulate on a first appearance and an able maiden speech), Mr. Westland and their supporters most amply justified in the course they have pursued. In the first place, the very best way to destroy the least chance of an increase in the tea duty is to send on Saturday's Resolution urging a reduction; and in the second place, even in the present House of Commons, we are not sure if the question of reduction were taken up on next Budget by some good speaker and leader, that the division would not show a very respectable if not considerable minority. But most important of all is it to begin an agitation now, and to continue it at intervals, if fruit is to be borne in the Budget of fifteen months hence, or in March 1902 when the impost should be reduced not to 4d, but to 3d per lb. So mote it be.

But now to turn from the speeches given elsewhere with their serious tone as to the risk of over-production and of non-paying prices, we direct attention to the deliverance of the Chairman of the Planters'

Association as to the best remedy for an admitted evil, which is contained in the letter he has addressed to us (see page 544). This letter will be read with the greatest possible interest both here and in India, It proposes a heroic measure, and Mr. Rosling deserves a high degree of credit for coming forward at this juncture with what must be regarded as a self-denying ordinance. For, we think there will be no difference of opinion as to the greater part of any loss falling on the higher districts and estates if Mr. Rosling's proposal takes effect. In many of the older and lower districts, it is not too much to say that in a number of cases, not 10 but 20 per cent of the cultivated area might well be given a rest with advantage to the purse of the proprietor; while even with the present reduced grade of prices, ten per cent less of plucking in the higher districts must mean a real loss in itself to owners. Still, there are cases where "the common good" calls for united action, and it is very commendable that the Chairman of the Association should make himself the mouthpiece of the community and come forward with a proposal to deal with an admitted evil, which is practicable and sufficient on the face of it, *if* only unanimity and a sense of honour in its support could be calculated on to prevail throughout the Tea Districts of India as well as of Ceylon. There lies the difficulty. Did the issue depend on Ceylon alone, Mr. Rosling could make quite sure at once of his 80—nay 90-per cent. But how is it possible, in view of past experience, to expect any such result in the case of India? Surely, a far simpler demand on the Indian tea garden owners was the call for subscriptions to the fund for winning new countries to the consumption of their teas. But although this has been pressed year after year in the most urgent fashion and by incontroversible arguments, have 80 per cent, of the owners been gathered in as supporters of the Fund? We trow not. We doubt if one-half, or at most 60 per cent, of the estate owners have responded; and that would lead us to fear an even less proportion of responses to the present appeal. Nevertheless, we think it only reasonable and prudent that such an appeal should be made. If the failure be as we fear, in India, it will more and more show where the blame lies of doing nothing to prevent a crisis. First, Indian proprietors have never moved as they might and ought to secure the imposition of a Tea Cess after the pattern set in Ceylon. Secondly, they have failed to subscribe voluntarily to a Fund, the utility and advantage of which have been universally admitted; and now, thirdly let us see what they have to say to Mr. Rosling's appeal? To bring it formally before the Calcutta Tea Association and the various district bodies throughout India, would it not be well for the appeal to bear the *imprimatur* (as a passed Resolution, say) of the parent Planters' Association in Ceylon. Perhaps, this is Mr. Rosling's intention and that his letter in the first instance is put forward as a "feeler," to educe the opinions of representative men among the planters?

PLANTING NOTES.

Mr. Saville-Kent's recent address at the Royal Colonial Institute in regard to Westralian Pearl Oysters and Pearl Shell and other Fisheries is given in full on another page, and makes good and interesting reading. We have a letter by this mail in regard to the Ceylon Pearl Fisheries from Mr, Stanley Gardiner, the Naturalist from Cambridge University, who has done so much work in regard to coral reefs, etc., in the South Seas, Maldives, etc. It will appear in an early issue.

Volatile Oils.—We have received with the compliments of the world-wide-known firm of Messrs. Schimmel & Co., Leipzig, a copy of a beautifully-printed, well-bound volume * on this subject. There are several maps indicating the pathways of commerce (grocery and spices especially) in ancient, middle age and modern times. There is also a map of Sicily and Calabria showing the Districts of Production of Orange, Lemon and Bergamot Essences in Southern Italy, Calabria and Sicily. There is a chapter on "the Oils of Ceylon (Cinnamon), oil of Cinnamon leaves and root" and of course the oils from grasses—citronella oil, etc.—are largely dealt with, a map of our Southern Province with the Citronella Oil Districts being given.

* The Volatile Oils, by E. Gildemeister, Leipzig, and F. R. Hoffman, Berlin, written under the auspices of the firm of Schimmel & Co., Leipzig. Authorized translation by Edward Kremers, Madison, Wis. With four maps and numerous illustrations. Milwaukee, Pharmaceutical Review Publ. Co., 1900.

The Sisal Industry in the Bahamas.—The Colonial Secretary of the Bahamas, reporting on the pita plant, or *Agave sisalana* of the Bahamas, says it is not identical with the agave, or henequen of Yucatan, though closely allied to it. The henequen has long been known in various West Indian islands as the dagger plant, and has been used for hedges and by the country people for making rope for domestic use. The Bahamas plant is generally unknown in the West Indies. Six years ago it was imported to St. Kitts, and was planted in the island of Anguilla, where there were large areas of waste land. It is not known when it was introduced to the Bahamas; it is certain that it is not indigenous there. It is superior to the Yucatan plant, and in the hands of Bahamas planters gives fibre of better quality and greater market value, while possessing all the powers henequen to withstand drought, its hardihood, immense fecundity, and small demands on the labour and care of the grower. The name Sisal seems to be derived from the port in Yucatan from which henequen was formerly exported. The Bahamas plant is of a darker green hue, and there are no thorns along the edges of the leaf, but in other respects it resembles the Yucatan variety. The most suitable land in the Bahamas is that called coppice land, which is chiefly vegetable mould deposited over soft limestone on which the plant feeds largely. After four years' growth, or less in very favourable conditions the leaves are fit for cutting. They weigh from 1 lb to 2½ lb, and are scraped by machines which take off all the vegetable matter, leaving only the fibre, which emerges white and clean and is hung out across posts and rails to dry in the sun. When thoroughly dried it is placed under pressure and packed in bales 350 lb to 500 lb in weight, and is then ready for export. The quantity of the fibre exported last year from the Bahamas amounted to 1,358,682 lb., valued at £16,942. There are about 14,400 acres under the plant, and factories for extracting the fibre are on all the small estates.—London *Times*.

REPORT ON THE RESULTS OF TECHNICAL TESTS OF THREE PLANKS SUPPLIED BY THE GOVERNMENT OF CEYLON TO THE IMPERIAL INSTITUTE.

(In continuation of the report published in the Imperial Institute Journal, Vol. VI., p. 124. *By* Herbert Stone, Esq., F.L.S., *one of the Expert Referees of the Institute)*

Del. *Artocarpus nobilis, Thw.* A large tree belonging to the Artocarpaceæ or Nettle and Bread-fruit tribe, confined to Ceylon. There is another Indian tree bearing the vernacular name of Dél, *i.e. Bombax malabaricum*, D.C., the Cotton tree, but the anatomical structure of the wood is so different that there can be no question that our sample is Artocarpus nobilis.

The plank was in a bad condition. Decay had commenced in the heart and the sapwood was quite rotten. The heartwood, which was hardly distinguishable from the sap except by a greater depth of colour, had a beautiful metallic green colour, which shows in vertical patches where the wood is hard, but, as there are alternate strips of hard and very soft wood, the appearance is not beautiful. The pores are very striking, being large and filled with a white substance. The wood saws moderately easily, but will not plane in any direction, as the soft parts "pick up" in large furry patches with which nothing can be done. It turns a little better but only the hard parts cut smooth, and the softer ones, even after being well glass-papered, are unsatisfactory. The same may be said of it when turned in the machine. A good finish can be obtained upon small pieces free from soft wood; as the latter keeps absorbing the polish it is extremely troublesome and presents a poor appearance under the best conditions. The characteristic green colour becomes changed to yellow when polished. In Ceylon it is employed for furniture and canoe-making. Weight 39·3 lb per cubic foot.

Jak. This is the jak-fruit tree, *artocarpus integrifolia, Linn.* A large and important tree belonging to the same genus as the foregoing. It is cultivated in India generally, except in the north. The wood is used for carpentry boxes, and furniture, and is exported to Europe for cabinet work, turning and brush-backs (Gamble). It yields a yellow dye which is used to dye priests' robes. I have not heard of its use in England and presume it has not succeeded in gaining a footing in our market. If the present sample is a fair one it scarcely appears to merit a place among furniture woods, though it might have other virtues which would make it useful for building or engineering work. This wood works in almost every respect like Del, but not quite so bad. Before going into the question of its scientific name I was much struck by the similarity in the working of the two, and suspected their relationship. The colour of jakwood is brown, otherwise its structure and physical characters are very much like those of Del.

The sample plank was very sound both as regards decay and cracks. The wood, according to Watts, is of a yellow or yellowish brown colour darkening on exposure. He considers it one of the handsomest furniture woods of India, an opinion which is scarcely borne out by our specimens. Weight 38·5 lb. per cubic foot.

Satin-wood. *Chloroxylon Swietenia, D.C.* A moderate sized tree of the Mahogany Family (*Meliaceæ*) growing abundantly in Central and Southern India, the Deccan, Ceylon and Coromandel. This is so well known in England that it is almost superfluous to enter into detail concerning it, unless the sample planks are more characteristic of the Ceylon-grown Satinwood than of East India Satinwood generally.

There were three planks of this species. Two were of a bright canary yellow colour with the characteristic smell of coconut when being sawn, sound and in good condition; the third, a badly shattered plank, was rich yellow in colour and had a less agreeable smell. Although there was no other evidence of decay I conclude that this latter plank was partly gone. All three planks cut up readily and well with the saw, but planed execrably, worse even than Del, the soft bands being very broad and rough. It yielded, however, to glass-paper, and smoothed fairly well. The wood turned very well indeed by hand and machine, and took an excellent polish without trouble. Compared with the Satin-woods commonly met with here, these samples are decidedly inferior to either the East India (as commonly known) or Tamil Satin-wood, having none of the beautiful mottle or fire of these, but it is very much like the West India wood. According to Watts it is very durable and stands well under water. The Peradeniya bridge of Ceylon, which has a single span of 205 feet, is made of this wood. Weight 56·5 lb. per cubic foot.

It is much to be regretted that more care was not exercised in selecting and seasoning these specimens. If an examination of a species of timber is intended to assist possible users in the choice of woods for special purposes, it is a matter of primary importance that the samples should be average specimens, sound and in good condition when felled, and treated with the utmost care possible, having regard to the peculiarities of each species. Some will stand exposure to sun or damp which may be ruinous to others, and I strongly suspect that when these various series were got together they were practically subjected to identical conditions, hence the large proportion of decayed or shaken logs. Except in the case of those which have been reported sound, the tests merely amount to a criticism of a number of individual logs which may not have the least bearing upon the timber they represent. I trust that if the agents of any of our Colonial Governments have similar tasks to perform in future they will observe this simple rule:—Let the timber be properly seasoned before it is shipped.—*Imperial Institute Journal.*

PLANTING IN NYSSALAND.

(By Mr. Henry Brown.)

DIFFERENT PRODUCTS.

There are several products well suited for cultivation in B. C. A., other than coffee, such as sugar, tobacco, arrowroot, ginger, turmeric, cotton, chillies, etc. These I dispose of (although they may pay very well) because the land requires to be prepared for them every time a new crop is required, and they are not permanent products.

From what I know of cacao cultivation, and judging from the appearance of the solitary plant as far as I know in existence in B. C. A. at Lauderdale estate, Mlanje, this tree is not to

succeed well in Nyasaland. The plant at Lauderdale is now about five years old, about four feet high, with a diameter of about three feet. A cacao tree in its proper climate should be from six to eight feet in height with a spread of branches about five or six feet and in partial bearing at five years of age. For cacao Nyasaland has too great extremes of cold and heat to thrive well. During the winter months the tree looks wretched and suffers much from cold and during the dry season from September to December the air appears too dry for the tree to flower freely or set any fruit.

Cinchona being a drug the market can be flooded any day, and the price reduced to a non-paying level.

Rubber.—It is long before the tree yields enough to pay and a cheap substitute is likely to be found which will reduce the price.

Vanilla and Pepper.—Although permanent occupiers of the land the consumption is limited, and they for various reasons are better suited to native gardens or small cultivators.

For the reasons given above I select tea as the most suitable product other than coffee for the consideration of planters, as it is in my opinion the best suited for European cultivation, being a permanent occupier of the land. Consumption is likely to keep pace with the production and the price cannot go below that which will yield a profit to the cultivator; otherwise the production must be reduced, when the natural consequence of higher prices would ensue as it is consumed by the masses.

The general opinion of planters whom I have met in B. C. A. is that tea requires a heavier rainfall than we have here. To dispel this idea, however, I would point out that tea has a wider range of cultivation and can be grown under more varied conditions of climate than any other product. Further, tea is grown as far north as the Caucasus in Russia and in Natal, our near neighbour in the South, and in both countries the cultivation of the plant has passed the experimental stage.

Natal where tea has been successfully grown has a similar rainfall to the drier parts of Nyasaland, viz., from 40 to 48 inches per annum. In winter the temperature is at 6 a.m. from 50 to 56 degrees Fahr. and at 11 a.m. rises to 80 and 84 degrees. In summer at sunrise 64 degrees to 70 degrees are registered and at 11 a.m. 92 to 96 degrees, which is very similar to our own climate. Some of the Indian districts where tea pays well have a very limited rainfall and badly distributed, as there are four to five months during which no rain falls at all. From official reports in the following tea districts the average for five years is as follows:—Dhubri, 70·37; Ganhabong 59 26 inches and Nowgong 77·68.

The elevation at which tea can be grown is from sea level to 5,000 and 6,000 feet. At extreme elevations a comparatively dry climate is an advantage.

A period of rest for tea such as some of the Indian districts, Natal and Nyasaland have during the cold season (three to four months), when pruning can be done, is considered beneficial.

Experience of tropical agriculture in other countries as well as here should lead one to the conviction that B.C.A., judging from its soil and climate, is more suited to be a tea than a coffee-producing country chiefly because there is a very limited area fit for coffee growing. Coffee requires either primeval forest or very rich virgin soil to prove a paying investment, with even greater advantages in cheap land and labour than we possess. . . . . Any soil in B.C.A. that would produce leaf may be reckoned good enough for tea. Tea does not suffer much from weeds and bad cultivation. I have known tea clearings abandoned for a year or more and when cleaned up the tea seemed to have grown apace with the scrub and had only to be cut down and the flushes plucked as if nothing had happened to retard its growth. Indeed I see nothing to hinder Nyasaland from taking a place amongst the tea-producing countries of the world.

PRODUCE AND PLANTING.

Shareholders and Their Grievances.—We have received a letter from an Indian subscriber of many years standing who, in calling attention to the apathy prevailing amongst shareholders in tea companies, and advocating certain reforms in the management of these concerns incidentally frames an indictment against the agency system. His charges amount to this—viz., that owing to the apathy of shareholders who fail to attend meetings, those who have the financial control of tea companies are able to do as they please. He quotes an instance in India where managing agents have charged commission upon gross expenditure, have supplied stores which were not ordered, while drawing agency salaries and directors' fees. He asks how long shareholders will be content to suffer these things. So far as the apathy of shareholders is concerned, we may remark that when joint stock companies are prosperous shareholders in them are usually indifferent about details, accepting their dividends as a matter of course and taking very little interest in the proceedings which led up to the profitable result and we fear, caring less. When times are bad they clamour for reforms, condemn the management and are generally on the rampage. Shareholders in tea companies are not exceptional in this respect as some directors can testify and they can cry out about over-capitalisation and false promises with sufficient emphasis to create an impression. There are some things in connection with the tea enterprise which certainly need reforming. If we may judge by correspondence in the Indian and Ceylon newspapers the condition of the industry demands numerous reforms, but so far we have seen few practical suggestions on the subject. Amongst such reforms should certainly be included the effacement of all managing officials who act in the manner described by our correspondent. But we presume that he does not imply that the abuse of the system in the particular instance he mentions is a good and sufficient reason for promoting an agitation against managing agents generally or endeavouring to introduce a system which would mean the risk of (to use the expression of one of Mr. Kipling's heroes) a "blooming republic" in tea. Such conduct as that referred to by our correspondent is surely quite exceptional. As a rule tea companies are managed by those responsible with unusual care, attention, and integrity. If abuses have crept into the managerial system of any particular company conducted on the joint stock system, either in London or Calcutta, the shareholders have it in their power to look into them, and they are not backward in demanding investigation, especially when dividends are not forthcoming. Shareholders in tea companies, we take it, are not specially lacking in common sense, and are as capable as any other body of shareholders of looking after their own interests. When they have quite settled amongst themselves the direction reform should take, their apathy will doubtless give way to a lively interest in the whole situation. They will then set themselves to earnestly consider the importance of those adverse factors so frequently referred to by experts, which are mainly responsible for glutted markets and the inevitable depression which ensues.

THE LATEST TEA ROLLER.

TRIAL OF PERMAN'S EXPRESS.

There was quite a large muster of gentlemen interested in the tea industry, who were courteously invited at noon on Saturday by Messrs. McLeod and Company to witness a public trial at Messrs. Jessop & Company's Works in Clive Street of Perman's "Express" roller. Among those present were Mr. Ormiston, of Messrs. Balmer Laurie & Co.; Mr. Macdonald, of Messrs. Duncan Brothers & Co.; Mr. Walker, Mr. Milne and Mr. Horne, of Messrs. Finlay, Muir & Co.; Mr. Danby, of the Planters' Stores; Mr. Kingsley, of Messrs. Shaw Wallace & Co.; Mr. Traill of Messrs. Octavius Steel & Co.; Mr. G F Playfair and Mr. F H E Lamb, of Messrs. Barry & Co.; Mr. Hall, of the South Sylhet Tea Co.; Mr. G Jamieson, Mr. Staples, of the Carron Tea Estate, and numerous other planters. Perman's "Express" roller claims to be the latest and most improved addition to tea machinery. The special advantages claimed for it are that it is simple in construction and easy to work efficiently, rolls 300 lb. of leaf in twenty to thirty minutes, occupies small space in the factory, and requires little driving power and attendance. Perman's "Express" roller has been designed by a well-known Assam Planter Engineer, and it is justly claimed by the Inventor, after series of exhaustive trials, to be the only machine on the market, which combines rapidity of work, a perfect roll and a moderate cost. The whole construction is extremely simple, merely consisting of a stationary table, to which is bolted a circular leaf box, the bottom of the latter is a revolving disc, and at right angles to same there is a fluted cone. The leaf on being emptied into the box from the top is immediately carried round by the revolving disc, the cone in the centre which, turning in an opposite direction, causes the leaf to climb the middle and side of the box and to fall again to the bottom, keeping up a continual ebullition, by which means the leaf is thoroughly aerated and heating effectually avoided. No pressure cap is required, as the weight of the leaf naturally causes it to fall to the bottom of the box. where the diameter of the fluted cone is greatest, and thereby gives the necessary twist and pressure effectually breaking the cells of the leaf, the most important function in rolling. The "Express" does not "ball" the leaf, consequently the above object is attained completely. The time occupied in rolling is from 20 to 30 minutes, thereby enabling one roll extra to be completed within the hour. The leaf is readily discharged from the door on the side of the leaf box. The roller has been inspected by Planters of repute, and in all cases results proved most satisfactory, the machine giving the leaf a good twist in a shorter time than is taken by other machines now on the market, costing nearly double the price of an "Express." The trial on Saturday proved eminently satisfactory, and several questions put by the gentlemen present anent the working of this new and latest machinery elicited a ready response by the inventor. Two hundred and twenty pounds of leaf were emptied into the box, and within half an hour were turned out with a pucca twist and quite cool. Considering that the leaf had to be brought from the Dooars, and that it was hardly in condition for rolling, the trial was very satisfactory indeed under the circumstances.—*Indian Daily News*, Nov. 19, 1900. [Messrs. Brown & Co. have been appointed agents for the above roller which will shortly be on view at Hatton—ED. *T.A.*]

TEA AND CACAO ESTATES COMPANY.

COOPER, COOPER & JOHNSON, LTD.

DIRECTORS.—Hector F Monro (Chairman), Hamilton A Hancock and William Johnson. Managing Director: Edward H Hancock.

REPORT OF THE DIRECTORS

to be submitted to the Ordinary Annual General Meeting to be held at 2 o'clock on Thursday, 20th December, 1901. at Winchester House, Old Broad Street:—

The Directors beg to submit to the Shareholders the Report and Balance Sheet, together with profit and loss account for the year ending 30th June, 1900, also the revised accounts to 30th June, 1899. They much regret that the results are so disappointing, but they feel confident not only that the revenue should not be taken as an index of future profits, but that the expenditure also will be very materially reduced. With regard to the estates, the crop of tea, which is about 2,450,000 lb., has exceeded the estimate of 2,322,000 lb., and is about 350,000 lb. more than that of the previous year; it has also been produced at a less cost than the estimate of 28 cents per lb. and at about ½d per lb. less than the previous year. It is anticipated that the production for the current year will be 2,550,000 lb. at a further reduced cost. Shareholders are, of course, aware that prices have been abnormally low, probably lower than they have ever ruled before, and when it is pointed out that 1d per lb. means £10,000 to the Company, it will be seen how much depends upon the expected improvement in the market. The cocoa crop was not a heavy one, and the board are advised that larger results are already assured for the current year. The same applies to coffee and other products. Fresh arrangements have been temporarily made for the management of the wholesale and retail departments, and the Board are advised and believe that, if further capital is provided to extend these businesses, substantial profits will bb released. The Directors have also re-sold to Mr. Johnson the greater part of the business purchased from Messrs. Johnson, Dodds & Co., they have closed the American business, and have sold the Irish Branch, both of which were purchased from Cooper Cooper & Co. The above changes in these departments have been made with the approval of the Committee, and they not only do away with the recurrent heavy losses, but they have also given the opportunity of effecting very considerable economies in the working. There is no doubt that Trading Charges, as well as the Establishment Charges, will be very materially reduced in the future. In September the Board and Committee asked Messrs. Jackson, Pixley & Co. to investigate the books from the inauguration of the Company; they have in consequence prepared amended accounts for the period ending 30th June, 1899, which they think show more accurately the position of the Company on that date, the chief differences being on technical questions (whereby £9,830 3s 10d is brought forward to the debit of Profit and Loss Account instead of £2,005 4s 3d to the credit) relating to purchases of businesses acquired—which will be explained to the share-

holders at the meeting. In the arbitration with Messrs. Vanderspar, an award was given in their favour. The cost of this action appears in the accounts. The Directors are now consulting with the principal shareholders and with those interested in the Company, to devise a scheme for placing the Company's finances upon a sound basis, which must necessarily be taken in hand at once. This would have been proposed before had it been possible to have the revised accounts earlier. Mr. G L Davies has retired from the board since the last meeting. Mr. William Johnson retires in rotation and offers himself for re-election. Messrs. Jackson, Pixley & Co., who were appointed Auditors, offer themselves for election.—By order of the Board.

Hector F. Monro, Chairman.

London, E.C., Dec. 10th.

PEARL SHELLS AND OYSTERS OFF WESTERN AUSTRALIA.

At the meeting of the Royal Colonial Institute where Sir Gerard Smith read a paper on "Recent Observations in Western Australia," —(at which among others Mr. R. B. Heinekey, Mr. G. B. Leechman, Sir Walter Sendall, G.C.M.G., and Sir E. Noel Walker, K.C.M.G., were present,) the following speech was delivered :—

Mr. W, Saville-Kent, F.L.S., F.Z.S.:—While some few years of residence and travel in the country enables me to endorse much that Colonel Sir Gerard Smith has deposed to and described in his admirable address concerning the natural and industrial wealth of Western Australia, I must honestly admit that I should find myself very much "at sea" if I were to attempt to enter into an elaborate criticism or enlargement of the facts and figures that he has so lucidly brought before us. On the other hand—if I may be pardoned the Hibernianism —I shall feel very much more on *terra firma* if I may be permitted to supplement Sir Gerard Smith's discourse with a few words concerning both the actual and unearned increment of wealth that awaits exploitation and development in the waters that intersect and lave the Western Australian coast-line. Colonel Sir Gerard Smith has incidentally, and by quotation only, mentioned pearl shell as being included among other articles of export. As a matter of fact, that marine product represents one of the most valuable assets of the colony. Even worked on the primitive lines of simply collecting it from the natural fishing-grounds, pearl shells to the value of from £60,000 to £100,000 are raised and annually shipped from the Western Australian ports. There can be but little doubt, however, that in the near future the systematic cultivation of pearl shell on lines parallel to those pursued in connection with ordinary commercial oysters will become a yet vaster and far more valuable industry. During those years in which I enjoyed the privilege of acting as Commissioner of Fisheries to the Queensland and Western Australian Governments experiments were initiated by me with the object of proving, that this shell, like the ordinary oyster, was amenable to artificial cultivation. These experiments were successful, and as an outcome of them the systematic commercial cultivation of this valuable shell has already been established, but most notably in Queensland. Furthermore, at the instigation of that progressive statesman, Sir John Forrest, experiments were successfully made by me in the direction of acclimatising this valuable pearl shell considerably to the south of its natural habitat, that is, outside tropical waters. This means that very extensive areas on the Western Australian coast-line can be devoted to this industry with the advantage of its prosecutors being free from that stress and strain upon the Anglo-Saxon constitution that is almost inseparable from prolonged labour within the tropics. As an indication of the intrinsic value that would be attached to such a suggested industry, it is sufficient to mention that the cultivation of ordinary commercial oysters, as prosecuted in British waters, yields highly remunerative returns upon a capital that must be assessed at several millions sterling. These commercial oysters, having a gastronomic value only, obtain a maximum wholesale price of no more than one or two shillings per dozen—mostly much less. The Australian pearl oysters, on the other hand, while propagating as abundantly, and in ever-increasing demand for the manufacture of all articles composed of mother-of-pearl, realise in the wholesale market no less a price than from £7 to £10 per cwt., or on an average, say, thirty to forty shillings per dozen for well matured shell. It is obvious, I think, from this brief reference to the subject, that a big and prosperous future awaits the scientific development of the pearl-shell cultivation industry in Western Australian waters. Now, in the matter of ordinary oysters, Western Australia, in company with other of the Australasian Colonies, originally possessed what, with due care, would have constituted an inexhaustible stock of an oyster indistinguishable from our own world-famed British native. Over-fishing, however, with no provision of reserves for future propagation, has almost, if not altogether, exterminated that much-esteemed species. Time was when the Swan River estuary upon which Perth is built was one vast oyster-bed. The salt water, however, has retreated, leaving the oyster defunct, and high and dry in such abundance that, at the time of my last stay in Perth, some four or five years since, they were being extensively employed for the groundwork of the new roads and streets that were being so rapidly constructed. With the completion of the new harbour works at Fremantle, and the clearance of the river's mouth by extensive dredging, it is quite possible that conditions may be again made favourable for the growth of oysters in the Swan River estuary. And at all events a very favourable area for the re-establishment of extensive oyster fisheries exists in the neighbourhoods of Albany and King's Sound, where they formerly abounded. Ordinary descriptions of commercial fish teem in Western Australian waters, and I will merely draw attention here to the circumstance that a species of pilchard and other members of the herring tribe are included among them. It has been referred to as a matter of reproach by Sir Gerard Smith that both butter and cheese have still to be annually imported into Western Australia to the extent of several millions of pounds. The same reproach must be attached to the fact that, with the live fish in vast shoals on their coast-line, preserved herrings, sardines, and anchovies are likewise annually imported in increasing quantities from Europe. And this reproach applies not only to Western Australia but to all other of the Australasian Colonies. With the newly-accomplished federation of the Australian States, we may now, however, hopefully look forward to an immense impetus being given to the fisheries, agricultural, and all other industrial enterprises

throughout the Commonwealth in general and in Western Australia in particular, since the levelling of the Customs schedules, and of the high and uneven labour rates that have hitherto prevailed, cannot but exert a most beneficial influence on all the indigenous industries. I may, finally, mention that much has been done already in Western Australia towards providing attraction to the sporting and leisured classes in connection with the fresh water fisheries. The Colony possesses but few indigenous fresh water fish of any value within its southern and more thickly populated districts. Certain of the rivers, however, such as the Preston, Collie, Blackwood, and others, were recognised by me as possessing conditions that were apparently favourable for the introduction of English trout and other desirable varieties. Here, again, Sir John Forrest took the initiative by providing a suitable location for a trout hatchery on his estate at Bunbury, and the fry hatched from ova imported from Tasmania have now been distributed throughout a very considerable area, with the prospects of yielding very gratifying returns in future years. Murray cod, perch, silver eels, and other species have likewise been in a similar manner imported to, and distributed among other rivers of the Colony. These were mostly transported by myself from the Murray River in South Australia as small immature fish, special accommodation being provided for them for their thousand miles voyage from Adelaide to Albany on the Orient and Peninsular and Oriental mail-boats; and, according to the latest intelligence to hand, these fish have already established themselves and commenced to propagate. These few remarks will, I trust, conduce towards endorsing and further emphasising the conspicuous merits and advantages that are so amply possessed by Western Australia, and that have been so ably championed by Colonel Sir Gerard Smith in the lecture we have listened to with so much interest."

CHINA TEAS IN LONDON.

(From a Correspondent.)

I enclose a cutting from the Army and Navy Stores' list. Note what they say *re* China tea. Their sales are very large, and you might pass this on to 'Thirty Committee:—

"In calling attention to the following, Members are reminded that the use of of China Tea is *Strongly Recommended* by the Medical Profession, in preference to the Strong and Pungent teas now so much advertised.

PLANTING IN PERU.—A couple of Scots are busily engaged as planters in the valley beyond the Andes in Peru, which was reported on by Messrs. Arthur Sinclair, the late Alex. Ross and Mr. D. Clark, of Balangoda; and one of them sends us a brief letter given elsewhere, showing that great progress has been made and that coffee crops are satisfactory. There is plenty of good land ready to be opened up, and we are told labour is cheap; but our correspondent should tell us the cost per day in the equivalent of English money? Is the "centrado" a hundred reis and how stands exchange? Then what is charged for land and how are the taxes? Are there any forests of rubber-yielding trees near?

MARIAWATTE ESTATE, CEYLON.

THE HEAVIEST YIELDING TEA-GARDEN IN THE WORLD!

1900 A FAVOURABLE YEAR.

A YIELD OF 1,357 LB.—OR OVER 16 MAUNDS—MADE TEA PER ACRE!

We are much indebted to Mr. Salmond, Superintendent of Mariawatte, for a statement showing the yield of the estate to the end of 1900. As Mr. Salmond says, last year has been an unusually favourable one, the yield being (with the exception of 1890's) the maximum one in the record. We embody Mr. Salmond's figures with those given in our "Handbook and Directory," so as to make the return complete:—

MARIAWATTE ESTATE.

YIELD FOR THE WHOLE ESTATE,

Actual area in bearing: 458a. 1r. 17p.

Year.	Rainfall.	lb.
*1892	95·74	643 per acre.
1893	86·22	817 "
1894	72·00	750 "
1895	100 28	886 "
1896	115·41	896 "
1897	111·25	926 "
1898	79·90	738 "
1899	106·81	749 "
1900	114·63	996 "

Average for above nine years 822 lb. per acre.

(Oldest and Special field:—Yield of 101¼ acres of tea:
N. B.—Plucking began in October, 1880.)

Year.	Made tea. lb.	Yield per acre. lb.
1880	911	8
1881	10,451	100
1882	30,207	300
1883	55,031	529

Statement of Yield of Mariawatte old tea from 1884 to 1900 showing average per acre:—

1884	109 230	1,078
1885	117 842	1,163
1886	105 925	1,046
1887	115,996	1,145
1888	106,410	1,050
1889	113,834	1,124
1890	140,144	1,384
1891	120,366	1,188
1892	119,909	1,184
1893	115,440	1,140
1894	110,448	1 090
1895	118,560	1,170
1896	113,360	1,119
1897	105,729	1,044
1898	108,423	1,073
1899	112,987	1,108
1900	137,066	1,357

D. M. SALMOND, Superintendent.

Mariawatte Estate,
Gampola, 3rd Jan. 1901.

[Average for 17 years from 1884 = 1,144 lb.]

It will be observed that over the whole estate of less than 458½ acres, the crop last year is the largest per acre—996 lb. made tea—ever gathered! It is in fact not only a "record" for Ceylon, but also

* Atgalla crops having been included; prior to 1892 figures are not available.

for "the world." Nowhere in India or Java, we suppose, have 996 lb. (nearly 12 maunds) made tea, been harvested over so large an area as 458 acres? If we turn to the oldest field of Mariawatte, planted in 1879 and therefore in its 22nd year, we find the crop shews a large increase on the previous year, reaching the almost unprecedented figure of 1,357 lb. per acre for the 101¼ acres, against an average for 17 years of 1,144 lb. The average for nine years over the whole estate is 822 lb.

THE TEA TRADE.

IMPORT AND CONSUMPTION—CEYLON PLANTERS' ENTERPRISE.

[By An Expert Correspondent.]

INCREASE IN CEYLON YIELD.

As regards Ceylon, owing to favourable flushing weather during October and November there will be a small further increase in this year's crop. The import, it will be seen, is 9,500,000 lb. over the eleven months of last year. On the other hand, home consumption and export account for 8,500,000 lb. of this, leaving the small surplus in production over consumption of 1,000,000 lb. As I have said before, England will this year receive its maximum share of the Ceylon crops, because it is probable our colonies and foreign countries will take direct from Colombo all the increase that may be expected from newly-planted lands. For instance, according to "Ferguson's Directory," there were in 1897 350,000 acres planted, the whole of which will be in full bearing next year; and as the average Ceylon yield per acre is 425 lb. the 1901 crop will be about 148,000,000 lb. Of this our colonies and other nations will take direct 38,000,000 lb. calculated on the present rate of progress, leaving for export to England 110,000,000 lb. In 1898 the planted area was increased to 364,000 acres. The crop in 1902 will, therefore, probably be 154,000 000 lb. and the direct export to places other than England may be taken at 44,000,000 lb. Ten years ago, if any person had predicted that the export from Colombo to other countries than England would add up to 32 000,000 lb. he would have been put down as a lunatic: yet shipments to this extent will be a fact by the end of this month. It is now generally admitted that when consumers acquire the taste of Indian and Ceylon they cease to appreciate the peculiar flavour of Chinese tea.

DEVELOPMENT OF FOREIGN BUSINESS.

Australians, following the example of the British, have almost ceased to use the latter, and now the Russians are beginning to try the former. This year they have taken from Colombo 8,000,000 lb. as samples. Ceylon planters have for some years past, as is well known, spent much money in trying to induce Americans to use their tea. Wearied at length with their tortoise rate of progress, they are trying to force the pace by manufacturing and shipping green tea to compete with the Japanese, and, to encourage the business, are paying substantial bounties on its manufacture. If previous experiments in the same direction did not succeed when the relative conditions of the two producing countries were equal, how can they expect to be able to undersell the Japanese now that they are handicapped with a 30 per cent. difference in the exchange, when the bounty funds come to an end? I think the tortoise pace is, as in the fable, the one to win the race. By the Board of Trade Returns it will also be seen that this country has secured 10,500,000 lb less from China this year, and has exported 6,500,000 lb. more. Home consumption has dwindled down to 12,500,000 lb. As far as we are concerned, it would be a matter of indifference if we did not get any more tea from China, but to the British planter the duration of the present deadlock is of vast importance. If it lasts a few months longer Russian dealers may have to take precautions against being left in the lurch. Where will they get what they require?—*Financial Times*, Dec. 14.

PLANT LIFE CURIOSITIES.

(Aberdeen Diocesan Association.)

There was a very large attendance at the weekly meeting of the Diocesan Association last night the large hall of Kennaway's rooms, being crowded in every part. The lecturer was Mr Arthur Sinclair, F L S, Oults, and the subject of his lecture "Some Curiosities of Plant Life" was one on which he spoke from personal observation while travelling in Ceylon, the valley of the Amazon, etc. The chair was occupied by Bishop Douglas, who breefly introduced the lecturer. At the outset Mr Sinclair spoke of the importance of a knowledge of botany especially in these days of globe-trotting; and remarked that the ignorance of that subject which was a characteristic of Scotch children, was not found in Eastern lands. The youngest Hindoo child knows the name of every plant and flower around him; the Aberdeen child if asked the name of the commonest plant would probably say, "I dinna ken, an' I'm nae carin'!" The luxuriousness of the tropical vegetation, might to a certain extent account for that The Hindoo children were brought up in the open air, and cradled among the plants and flowers, and very soon became aware what plants and fruits were poisoned, and which were wholesome. Speaking of the effects of a want of botanical knowledge, Mr. Sinclair said tons of good food were lost by the neglect of mushrooms, caused by the inability to distinguish between the real wholesome mushrooms and the poisonous toadstool. He went on o speak of fungus, and described the coffee blight in Ceylon and the fungus on the potato, adding some general rules by which poisonous fungi might be avoided. He spoke in passing of the greenhouse plants imported from the tropics, and now familiar in our gardens and greenhouses, and described some huge tropical trees, pointing out that a very high value is placed by the Indian on the coconut palm and the plantain or banana trees. The bread-fruit tree and milk-tree were also described, and the lecturer said that a few of these trees would support families of natives, who sought no other food. The same class includes the famous upas tree, which, he said, was now proved innocent of the many baneful qualities once attributed to it. From the valley of the Amazon comes the rubber and the gutta-percha, the uses of the former steadily increasing, while without the latter, Mr. Sinclair said, ocean telegraphy would have been well-nigh impossible. To see nature in all her glory, it was necessary to go to the tropics, and especially to the western tropics, where the luxuriance was oppressive. He spoke of the dangers and diseases to which orchid hunters were subject, and extolled the merits of cinchona bark or quinine as a remedy for malaria, referring to the fact that that dread disease was now proved to be caused by the mosquito. The strange flowers of tropical lands were graphically described, and, speaking of the "Venus Fly Trap" and the "Pitcher Plant" which is also a fly trap, he mentioned the "Sun-dew," which is found in abundance in our own marshes at Scotston, Belhelvie, and which is a well-known fly-catcher. Mr. Sinclair, who enlivened his lecture with anecdotes and personal ex-

periences, was listened to with rapt attention, and at the close was warmly thanked for his most interesting lecture on the motion of the chairman, who, in the course of his remarks, spoke of the value of mushrooms as food, and said he had in vain tried to persuade the inhabitants of Orkney and Shetland to use the multitudes of mushrooms growing in their fields as a change from the monotony of their daily menu. In Russia, he said, mushrooms grew luxuriantly immediately after the melting of the snow, and were eaten with avidity by the natives. Dr. Ogilvie, in seconding the vote of thanks, spoke of the great value of the discovery that mosquitos caused malaria, and said it ought to be of special interest to Aberdonians, because Dr. Manson, who discovered it, was an Aberdonian. The lecture was illustrated by beautiful lantern slides, supplied by Mr. Sinclair.—*Aberdeen Free Press*, Dec. 18.

GAME PRESERVATION ON THE NILGIRIS.

(*From a Correspondent.*)

I referred the other day to the trout breeding experiments of the Nilgiri Game and Fish Preservation Association, but the Association's operations were not confined to these during the past year, a good deal having also been done by way of protecting and increasing game.

The local magistracy appear to have supplemented the efforts of the Association in this respect by inflicting substantial penalties when cases of illegal shooting were prosecuted. For instance, a fine of R50 was levied for a flagrant violation of the rule against trespass in a reserve, and R30 in the case of shooting a doe ibex. Illegal fishing was let off with moderate punishment, never in any case exceeding a fine of R10. The Association attribute success in carrying so many cases to conviction to the appointment of two competent game watchers at the foot of the Nilgiris, but they acknowledge, at the same time, that a great deal remains to be done on the plateau to stop poaching among some of the bill tribes, more especially the Bodagus and Kurumbas who inhabit remote and unfrequented parts of the district.

The destruction of vermin, as a means of game protection, has not been neglected. Jungle cats, mongooses, and wild dogs are great enemies of game and play much havoc among them. Sportsmen will therefore, be glad to learn that no less than 279 cats, 65 mougooses and 13 dogs were accounted for during the twelve months ending on June 30th last. The Game Association have a difficulty to contend with, when they give good rewards for vermin destroyed, as these rewards tempt persons to go outside the limits of the Association's jurisdiction, kill the animals where they have no value, and bring them to the office of the Association and claim the reward. During the year under notice, this difficulty was still experienced, but it is hoped surmounted by the *bona fides* of each applicant for a reward being examined before it was paid. Eagles, which destroyed large amount of feathered game, and others which catch and devour imported fish, when they can get them—were also disposed of in numbers.

A very useful record, which the Association have been labouring to set on foot for some considerable time past, was started during the year. This is the Nilgiri Game Bag, to which the local taxidermist is almost exclusively the contributor on the present occasion. Mr. Van Ingen supplied what licensees were backward in communicating, and informed the Association that 11 sambur were killed, seven on the Kundahs and two on the slopes, which proved to be the largest, the spread of their horns measuring 34 inches each. The biggest Kundah sambur measured an inch less. One spotted deer fell to the gun of a sportsman on the Westbury Estate, which lies on the northern slopes of the Nilgiris overlooking the Mysore plateau, two black bucks were also shot in the unfrequented forests conserved between the Nilgiris and the highlands in the north of the Coimbatore district. Among dangerous carnivora Mr. Van Ingen states that three tigers, two males and a female, and four panthers, all males, had been killed, five bears, all males, were also shot. The two male tigers measured 9 feet each from tip of tail to nose while the female was only three inches shorter. The largest panther was killed in the Westbury Estate, while the biggest bear was met with in Wynaad. Although hyænas are known to abound on the Nilgiris only one was destroyed and that a male at Kotagiri.

With the very limited resources at the disposal of the Association, falling short annually of R3,000, it is very satisfactory to find that more than a third of that sum was spent in rewards for vermin killed, and as much as half the rest was laid out in experiments with imported fish.

It cannot be denied that the measures of protection already adopted by the Game Association have had a most beneficial effect in preserving game, and that the future visitor to the Sanitarium may look upon good sport as certain, if he will only seek for it in likely places, when he goes to the Hills for a holiday.—*Pioneer*, Jan. 3.

CARBIDE OF CALCIUM AND ACETYLENE GAS.

A gentleman, who seems to be well up in the subject, writes to us by last mail from home :—

"I am amazed to see Carbide of Calcium pronounced by His Excellency the Governor in Executive Council to be a dangerous article on account of its being *explosive*, and therefore classed with dynamite and gunpowder! It is an article of domestic and everyday use here, and is destined within a short time to revolutionise the lighting of towns, houses, factories, etc., etc. The Germans are making rapid strides with it, see British Consular Report from Stuttgart. I fancy your Executive will hear more on this subject before long.

"*Re* Acetylene Gas from Carbide of Calcium, see the lectures by Prof. Lewis at the Society of Arts. This article should be brought very prominently to the notice of the Ceylon public as being of great utility, as soon as the mischievous notions of the Executive of this *highly dangerous explosive*(!) have been dispelled."

Acetylene gas we see very highly praised for isolated installations, such as Railway stations, and the like. Should not Mr. Pearce give it a trial?

From *Indian Engineering*, Dec. 29, we quote as follows :—

Carbide of Calcium is now being retailed in India at the rate of four annas the pound, or about half the price it can be bought at in this country. Inasmuch as India at present produces no carbide, it would be interesting to know where this supply comes from. The English Company cannot be suspected of any rash enterprise in that direction since it takes it all its time to attend to its own British customers. But the field in India for acetylene lighting is such an immense one that it may possibly have occurred to some German producers of the chemical to attempt its cultivation and to spread acetylene lighting by delivering quantities of carbide upon the market at a price that would offer what are naturally a very conservative class of buyers some inducement to experiment with it.

RUBBER IN BRAZIL.

Remarking upon the steady increase in recen, years in the production of india-rubber in Brazil *La Gazette Commerciale* casts strong doubt upon the need for any further increase for a long time to come. The total quantity exported in the year ended June 30th, 1897, was, says *La Gazette Commerciale*, 22,216 metric tons of 2,205 lb. each; in 1897-8 itwas 23,439 tons, in 1898 9 24,000 tons, and in the ten months ended April 30th last 23,439 tons. Probably, therefore, the exports for the whole of 1899-1900 will reach 26,000 tons at least, and they may substantially exceed this amount. Any further increase of moment is, however, very doubtful. No doubt the forests from which the gum is derived are still of vast extent, and on the score of available supply it is admitted that there is no calculable limit to the production of india-rubber in Brazil. The practice of exhausting and destroying the trees which prevails is not, therefore, for the present likely to have any effect upon the supply. But it is to be hoped, having regard to the future, that steps will be taken, even in Brazil, to provide for replanting. The important consideration in so far as the immediately prospective production is concerned, lies in the limited quantity of labour available for gathering the gum. Trained labourers are very scarce owing to the unhealthiness of the forests and the difficulty of the work, which puts a limit to the number of natives willing to undertake it. As for European immigrants, they are not to be looked for, because they are even less capable than are the natives of sustaining the fatigue and the risk of malarial disease incident to the climate.—*India-rubber and Gutta percha Trades' Journal*, Dec. 10.

RUBBER.

The German consul in Payta Piara (Peru) reports the discovery of large rubber forests on the Niera river, a branch of the Amazon, which can be reached from the middle of the tobacco plantations by eight days' journey. Several German firms organzed a large expedition to start for the interior and to secure the right to collect the rubber. As the natives are very poor, it is expected that cheap native labour will facilitate the collection. A special road is projected, which will touch Iquitos, by way of which town it is considered best to send all material, as it would be difficult to find a route which is shorter through the Piara district.—*N. Y. Journal of Commerce*, Oct. 18.

COFFEE CULTURE ON THE CLARENCE, N. S. WALES.

Mr. John Ball of Chatsworth Island, reports that his coffee crop this year is a great success. His last crop returned 1,694 pounds, which sold at 1s to 1s 3d per pound. This year the crop is expected to amount to something like 6,000 lb. Mr Ball has mastered the manufacture of coffee of the highest quality, and finds a good demand for it. His trouble is to secure sufficient quantities of beans. In reply to inquiries made of Mr Holmes, a planter in Fiji, Mr Ball has been informed that, owing to unsatisfactory price offering in Sydney for the Fijian bean, the growers there were abandoning coffee-growing. Mr Holmes forwarded Mr Ball some seeds of the Liberia coffee, which is a sturdy-growing tree with deep tap root, and which bears a larger berry than the ordinary Arabian variety. In Fiji, even at the extremely low prices (3d to 5d per pound) paid for the beans, this variety returned 4s 7d per tree. Mr Ball finds that he can pay ten pence a pound for good beans. His harvesting is done by lads who are table to earn 15s a week at the work.—*Agricultural Gazette* of New South Wales, Dec. 1900.

BRAZIL COFFEE NOTES.

The Municipality of Cravinhos is small, but it is very fertile and favourable for coffee production. It posseses eight millions of trees under production, and three millions of young plants, and has produced an average of 151 arrobas (4,880·32 pounds) per thousand trees. This is equivalent to 4 88 pounds per tree, which is considerably above any average we have thus far seen.—*Rio News*, Nov. 27.

PLANTING NOTES.

Coconut Oil Scarce and Higher—is the heading of an article in the latest "New York Oil Reporter":—

The soap trade has been quite active this fall. The consumption of coconut oil has been steady offerings have been light and short interests have been called upon to cover. The market from these very natural causes has reached a most interesting stage. It is so bare on spot as to cause considerable anxiety on the part of consumers and to those importers unfortunate enough to be on the short side. A fair estimate of available Ceylon oil at the time of writing places the stock at but fifteen tons. There is considerably more Cochin, probably one hundred and twenty-five tons, but this is barely sufficient to keep a fair parity of price between the two grades.

Bolivia is a country of vast latent resources, possessing even at the present time a very considerable trade. Its products, exported through Chilian, Peruvian, Brazilian, or Argentine ports, are generally credited to one or other of those States; as a silver-producing country it ranks third as a tin producer second; its output of indiarubber—a comparatively new industry—was valued in 1898 at £1,300,000; it possesses valuable copper mines and borax deposits, while the gold mines of Tipuani are probably not inferior in richness to those of Klondike. As a consequence its import trade is by no means insignificant, but, under existing conditions, it has a tendency to drift into the hands of our German competitors, who are more alive to its importance, and who leave no stone unturned to extend their influence and their mercantile operations. —London *Times*, Dec. 19.

Inferior Seeds—A strong light has been thrown on the preparations now being made by unscrupulous merchants in Germany and America for supplying the simple-minded peasants of South Africa "with shiploads of the veriest rubbish imaginable" as soon as the war is over. A contemporary says:—"Articles of such vital importance as grain for sowing and vegetable and other seeds have been manipulated by the German adulterant in a shameful manner. Husks, dirt-sweepings, weed seeds, and every conceivable kind of refuse have been done up into packets with a sprinkling of the genuine seed, packed in covers printed in the English language, and labelled in a cruelly sarcastic manner, 'Specially selected for South African cultivation.' Fertilisers, composed principally of coal dust; ready made clothes, rotten with dye; hunting knives made of scrap iron; gilt clocks, warranted; German concertinas with paper bellows, are a few of the other articles which are to flood our newly-acquired territory as opportunity may offer.—*Commercial Intelligence*.

Correspondence.

To the Editor.

THE CEYLON PEARL FISHERIES AND THEIR RESTORATION.

The Elms, Croydon, Surrey, England, Dec 6.

DEAR SIR,—I am, presumably, indebted to you for the copy of the *Ceylon Observer* of October 29th, containing a very interesting and important leading article on the subject of the Ceylon Pearl Fisheries, and in which you have been pleased to make sundry references to my work and experiences connected with cognate industries. I anticipate that it was your desire in forwarding me this copy to elicit my opinion regarding the prospects of resuscitating the depleted fisheries of the indigenous pearl-producing shell *meleagrina fucata*.

I have much pleasure in stating that I consider that it would be perfectly feasible to establish, as you have suggested, fisheries of the larger and more valuable Australian mother-of pearl shell, *meleagrina margaretifera*, in Cingalese waters. Respecting the resuscitation of those of the indigenous species, I should feel scarcely justified in pronouncing a decided opinion without having a personal acquaintance with the conditions and environments under which that pearl-shell grows upon your coasts. At the same time the species is so closely allied to one of the smaller Australian varieties, *M. imbricata*, with which I have successfully dealt in the matter of re-establishing depleted fisheries, that I should anticipate no very serious obstacles in the accomplishment of the task.

It would afford me the greatest pleasure to contribute some practical assistance towards the restoration of your fisheries and I greatly regret I was not made aware earlier of the existing position of affairs. I gather from your leading article that negotiations are in progress if not completed for securing the assistance of Dr. Herdman of Liverpool to investigate and report as to the best plans to pursue. As indicated in your leader Dr. Herdman, should he come, will approach the subject as an entirely new one and will be dependent, for preliminary information concerning it, on the recorded experiences of the very few previous workers in this field and notably my own. In consequence, moreover, of Dr. Herdman's important University engagements he will be unable to devote more than a limited time to his investigations and it will necessarily have to be left to others to carry out the most desirable subsequent operations that may be decided on.

It has occurred to me that under such circumstances the Ceylon Government might like to avail itself of the opportunity of my assistance and practical experience towards the realisation of the objects in view. In anticipation of such a contingency I have addressed a communication to Sir West Ridgeway stating that I should be pleased to place my services at the Government's disposal and have at the same time remitted to His Excellency copies of my reports made to the various Australian Colonial Governments and other pamphlets testifying to my practical acquaintance with the subjects of Pearl and Pearl-shell Fisheries. I have also referred more particularly to my two published volumes, "The Great Barrier Reef of Australia" and "The Naturalist in Australia," in each of which I have included a chapter specially devoted to these important subjects. These volumes being too ponderous to transmit by post I have suggested that they will be found in the Colombo Public Library or in that associated with the Museum.

In the event of my services being engaged, I may add that my familiarity with the Australasian Pearl-shell grounds and past relationship with the several Australian Governments would prove of material assistance towards obtaining supplies of the larger and more valuable Australian shell for the establishment of fisheries of the species in Ceylon waters. I may remark finally that my previous inurement to, and predilection for, a tropical climate should serve me in good stead and greatly facilitate the execution of the work that may by confided to me.

I have no doubt, in conclusion, that the communication and documents I have addressed to Sir West Ridgeway will come under general notice, and if in addition there are any points in this letter that you may like to, and think desirable to, make use of, you are welcome to do so.

Thanking you again for the copy of your paper and its interesting and important contents, I remain, Yours very faithfully,

W SAVILLE-KENT, F.L.S, F.Z.S.

Late Commissioner of Fisheries, Tasmania, Victoria, Queensland, and Western Australia.

P.S.—Since writing the foregoing letter, I have made the discovery, that in addition to your leading article, your paper contains a full account of the meeting of the Royal Asiatic Society, at which this most important question of the Pearl Fisheries was discussed. His Excellency's speech clearly sets forth that no definite arrangements had been arrived at with Prof. Ray Lankester or Dr. Herdman, Prof. Ray Lankester, in fact, having, as H E. put it, "opened his mouth too wide." The chances of my being permitted the opportunity of coming to your assistance are consequently increased, and I have deemed it worth while to eable out a few words to you intimating that I am at liberty and prepared to take up the work. A year or so ago when my great friend, Sir William Flower, was at the head of the Natural History Museum (to which I was originally attached) the matter would have been referred to him and he would, I think, have indicated myself as the one man possessing the practical knowledge and acquaintance with the subject of Pearl-shell cultivation that could most naturally assist you at the present juncture. Unfortunately, both he and Prof. Huxley—my original teacher and scientific sponsor who sent me out to Australia—have passed away and those new to power are either Pharaohs that "knew not Joseph" or have other views. I am enclosing you in separate packet a few duplicate and additional reprints of my reports and papers that have turned up since I despatched my batch to Sir West Ridgeway. One of these—"The Oysters and Oyster Fisheries of Queensland"—is rather scarce and in demand. Please have it placed with the others. It would no doubt be welcome, after service, at the museum Library.

Though to some extent lost sight of during the past two years, I have been by no means idle. The fascinations of the newly-developed science of Natural Colour Photography and its application to Natural History subjects, has "commandeered" much of my time with grati-

fying results and I shall hope to make some important scientific use of the process it afforded the opportunity of its practical utilisation amid tropical surroundings. I have also in hand a scientific description or revision of the many species of commercial pearl and mother-of-pearl shells, concerning the correct identification and nomenclature of which there is almost inextricable confusion even in the most widely-accepted text-books and well-appointed museums. Another circumstance, however, has more particularly tied my hands and compelled me, like Brer Fox, to lay low this past couple of years. A syndicate of would-be company promoters approached me with the object of obtaining large concessions of suitable pearl shell cultivating areas on the Western Australian coast line, and of which they wished me to undertake the scientific direction. I went to the trouble of using my influence with the W. A. Government to get a special Act passed (which did not exist) and have paid several hundred pounds out of pocket in securing the requisite leases, etc., and now after letting the matter drag on for all this time, they have failed to raise the capital which they said they could command, and left me with all the time and trouble wasted in addition to the cash.

RUBBER:—PRODUCERS AND NEW SOURCES.

Paris, Dec. 7.

Dear Sir,—I am very obliged to you, because you open so liberally your columns to my bad English and my worse writing. I am nearly sure that all—readers, collaborators, printers, etc.—obliged by duty to make the light shine through my prose will, in a better life, receive superior encouragement!

I send you one fruit of Castilloa Tunu * and you will see that all the seeds are sunk in the support. In Castilloa elastica the seeds are exerted. I do not know if you understand well what I write! I will ask for a botanical analysis to M. Posijor from museums and send to you.

With same post I send you a little part of a young stem of Chonemorpha Macrophylla which is an Indian plant. If you look at one end of this you will find a little part of rubber and very fine rubber! Certainly, it is not much, but the stem is a very little part of the plant and the plant is a very robust one. Why don't you pay any attention to so good a producer of rubber? In many plants rubber is found between the bark and the wood, or more properly in the inner part of the bark. In Chonemorpha the rubber is found in the marrow.

New sources of rubber are discovered every day. I have just received from a friend two tons of a rubber from one particular species of Sapium from Ecuador. I know that the plant is similar to Sapium biglandulosum var. Solimanæ, but I have heard such fantastic reports of that last plant that I cannot believe it is the same.

Consul Patin, the introductor of Sapium Solimanæ, says that that tree gives up to 40 English pounds of rubber every year!!! Mine from Ecuador gives four to six pounds and the tree must be felled (cut down). The sap begins to flow, only two or three days after. My friend has collected this year 13 tons of rubber in the country; but the trees are so abundant that nobody can say when the rubber has been taken. In the main country lives the black rubber, Castilloa species. I do not know exactly the name. The rubber badly prepared does not reach so good a price as Sapium rubber or white rubber; but gives regularly by tapping.

About tapping (*saignée*) my friend told me a thing that I have heard from others. The tapping must be made quickly, several cuts at once, for after four or five cuts made in the tree, the sap does not flow, the tree retains its sap!

Sapium biglandulosum is a very common plant on all the American continent; you can find it from Mexico to the Argentine Republic; but the form varies considerably; therefore the two plants which have motived the name *biglandulosum* are more or less apparent. In some parts as in Ecuador, Columbia and Peru, the rubber is good; in other parts it is considered to be very bad. The good rubber plant is always found at 2,000 feet high. I wait for enough from cooler countries.

Did you hear of rubber made from sage bush from Mexico? This plant is extremely common in all the dry region of San Luiz Potosi, and an American Company has started a manufacture. It is a small ligneous plant, two feet high. The rubber is obtained by a very curious process. The plant is boiled with soda? But I will be soon in a situation to give you particular information about the botanical name and the process.

The bark I received from you does not contain any rubber: kindly tell this to your correspondent. I have always been unsuccessful with Euphhorbeaceous plants, but you will see by the different sorts of barks I send you by this mail how rich are the barks of Mascarenhosia, Landolphia and Hancornia. Break the parts and you will see the rubber very apparent.—Believe me, Sir, your most truly servant,

A. GODEFROY-LEBEUF.

* Not yet received.—Ed, *T.A.*

"FOXINESS" IN COFFEE.

Fairlands, Sidapur, Coorg, Dec. 29th, 1900.

Dear Sir,—Can you inform me of any publication dealing with the foxiness in coffee, and would you kindly insert the following in an early issue of your valuable journal, and send me a copy and also further copies by V. P. P. should any answers appear.

Can you, or any of the numerous readers of your valuable journal, give me any information regarding the cause, prevention, or cure of "foxiness" in coffee.—I am, dear sir, yours faithfully,

PERCY G TIPPING.

[We can find no reference to "foxiness": does it not mean a deficiency in the beans, due to drought, poor soil, or some such cause?—Ed. *T.A.*]

REH AND IRRIGATED LANDS.

30th Dec.

Dear Sir,—With reference to an article of yours on irrigation, I believe you have taken too serious a view of the matter, regarding which I have reason to think that you are mistaken in supposing that the condition referred to is due to exhaustion of the soil. For instance, I have seen lands that have been under cultivation for ten and twelve years giving good crops as a result

of irrigation; while in the case of other lands that have developed, irrigation, after three or four crops, was discontinued. As I mentioned in my previous letter, it is the position of the channel and the soil that it runs through, that has great influence in producing this condition. I believe I can accurately say whether, after a channel has been cut, the land below it would be affected or not. Besides, irrigation is not necessary for the production of *reh*, as I will point out. There are many sheets of water in this district called "wilas" and "kalapus" and in every case the banks of these sheets of water have *reh*. I shall send you by next post the *only* plant that grows on lands affected, and which the Sinhalese call "Lunu-palá" or salt herb. The leaves are made into a curry, but they have to be well boiled and the juice expressed or it would be too saltish for the palate. I have eaten the boiled article and even then found much salt in it. This plant also grows on the edges of salt pans, and, I believe, nowhere else. It would be beneficial indeed to the goiyas of this district if Mr. Elliott had a few of his numerous acres affected by *reh*, as in that case, you may be sure he will not be long in consulting a scientist and finding out its cause and cure.—Yours faithfully,

A. D.

THE TEA PLANTING INDUSTRY AND OVERPRODUCTION: SUGGESTION TO GIVE A TWO YEARS' REST TO 10 PER CENT. OF THE PLANTED ACREAGE.

DEAR SIR,—It is generally admitted that the present position of the Tea Planting Industry is, owing to overproduction, very unsatisfactory; and unless some action is taken to curtail supplies, we must see the painful and prolonged process, "The survival of the fittest," gradually force some of the poorer properties out of cultivation.

This process must necessarily be a prolonged one as there are many estates which can just pay their way and which will continue to produce so long as there is no actual loss.

It has been suggested by certain gentlemen, amongst others Mr. A. Thomson, of Messrs. Whittall & Co., that, in view of the enormous quantities of tea being produced, we should endeavour to from a combination by which the requirements of the various markets may be met, without making any one of them the dumping ground for our surplus crops.

It is necessary that any steps taken by Ceylon should receive the full support of India otherwise curtailment of shipments from here would merely allow of increased exports from Calcutta.

The three possible methods suggested for reducing our crops are :—

(1) Finer plucking which would tend to reduce the output whilst giving a better quality of tea.

(2) Making a certain percentage into green teas.

(3) Resting a certain percentage of the acreage in bearing.

The objection to No. 1 is that we should probably have too much fine tea produced with a corresponding fall in its value; and directly the better and poorer classes of tea approximated in value, there would be a tendency to pluck coarse again.

The objections to No. 2 are (*a*) the green tea market is not as yet sufficiently developed to afford material relief, and (*b*) the difficulty of making both black and green teas in the same factory.

The advantages of No. 3 are that if you do not pluck a field for a certain number of months, you rest your bushes and you can hardly bring them into plucking again without pruning, thus doing away to a certain extent with a possible temptation to break out of the combination. The net result would be a reduced yield and improved bushes.

I propose that all estate proprietors or their agents in Ceylon and india be asked to rest 10 per cent of their acreage in bearing for two years from the 1st April, 1901, to 31st March, 1903. This arrangement to be subject *to at least* 80 per cent of the acreage in both countries, agreeing to it in writing.

An arrangement such as this should ensure a reduction of from 15 to 20 million lb. and I feel convinced that with this quantity taken off the market the rise in price would more than compensate for the amount of leaf lost.

At the end of two years the green tea market should be largely developed, and in the black tea market consumption may have once more overtaken production.—Yours faithfully,

EDWARD ROSLING.

TEA OVER-PRODUCTION: *RE* MR. E. ROSLING'S LETTER OF THE 29TH DECEMBER

SIR,—The success of Mr. Rosling's proposition to curtail supply is entirely dependent upon the "full support of India." A very large order!

Few Ceylon men nowadays belong to "the fugitive, flying community" and members, as we all are of one central, integral Planters' Association, and resident in a small island, it is perhaps a little hard for some of us to understand the extreme difficulties of united action among tea proprietors in India. The vast distances, extending from the extreme north of one Indian Presidency to the south of another, separating even one tea district from another; and the varying conditions and capacities of each district, have only to be realised to be appreciated. The apparent supine lack of combination amongst Indian Tea Planters, in such matters as voluntary assessment, exploitation of new markets, &c., must, in my mind, be attributable to geographical disability. It would be hard to comprehend that a body of British colonists could otherwise be satisfied with so suicidal a policy as that of inaction during the past and the present. What Indian men have failed to accomplish for themselves, would, I imagine, be an *ultra vires* task for Ceylon. On the above premises, the success of an appeal from Ceylon to disunited India, would, I fear, be very dubious. Combination with India is in my opinion chimerical.

The present "very unsatisfactory" condition of the tea industry, *taken as a whole*, demands however that any agitation, the

larger it is supported the better, that will convince British tea-growers of the necessity for concerted action, for the common good, is most desirable.

Such an agitation would also sustain our right to relief, in reduction of the Home Tea Duty, and in Ceylon, of surplus revenues *i.e.* of railway rates, of upkeep of grant-in-aid roads, &c., &c.

Were finer plucking generally adopted, the higher cost of production, consequent on a lower yield, would partly equalize the possible extra profit per acre. Supposing, however, a glut of fine teas on our markets, prices for such would certainly come toppling down and further minimise such looked-for profit. Nonconforming members to a general scheme would then score heavily by supplying the demand for common teas.

High estates should now at least, with advantage to themselves, be able to adopt a policy of finer plucking. Medium to low estates, where teas with any special point cannot be turned out, would not, I believe, secure any much better price by plucking finer. It would be insufficient to compensate for the loss in yield and the extra cost. In other words, finer plucking, is not I think a remedy for the bulk of Ceylon.

Green tea manufacture appears to me to be the present solution to this very difficult problem. The development of the green tea market is what we should devote our energies to. I would suggest that approximate statistics be obtained and a tabulated statement be published of the green tea consumption of the world: 1, Name of country, amount of consumption. At present supplied by. 2, Standard samples, methods of manufacture of such. Prices, equivalents in sterling, &c. 3. Freights, dues, duties, &c., and any other information which would lead Ceylon and Indian men to see the possible scope that may exist for an invasion of the green tea market. This, however, would take time to accomplish. It does not afford any immediate relief.

My experience of "resting" a certain proportion of an estate would lead me to expect a subsequent *increased* yield. Supposing a 10th of our acreage were rested for twelve months, then brought into bearing, another 10th in the following year and so *ad infinitum*, the result in the third year and on would I believe be an increased yield and the last state of the colony would then be worse than the present. Estates would certainly rest their weakest tea first. Would then the reduction in supply amount to 15 or 20 million lb.? and *would* such curtailment, by India and Ceylon combined, ensure a sufficient, compensating rise in price?

But Mr. Rosling suggests, as a palliative only, an absolute rest of ten per cent of an acreage for two years, to enable us to tide over our present difficulties by curtailing supply. This is only possible, as he says, with the "full support of India." How to ensure unanimity and a sense of honour in such support is the question.

R. K. C.

II.

Hiralouvah, Haldummulla, Jan. 2.

Dear Sir,—I was very glad to see in your paper of 31st, how energetically the subject of over-production was being taken up, and that the remedy I suggested in my letter to your paper dated June 29th. "That all planters should not pluck from a certain acreage each year, say one-eighth or whatever amount would be considered best, so as to reduce export by 13 million pounds or so,"—is considered the best method of improving our position. A tenth will no doubt be better than one-eighth and I hope Mr. Rosling will be well supported in his scheme by all proprietors and agents. I should think the Indian Planters would be only too ready to join a plan, so certain to be of benefit to the majority of them, especially when we can show them that we in Ceylon are practically unanimous.

The only pity is, that it was not begun earlier.—Your faithfully, H. H. KIRBY.

III.

Dear Sir,—I am very glad to see by letters in *Observer* lately, that the Chairman Parent P. A, has taken up the suggestion I made in June last, in mine to you; only, as stated before, there must be some inducement, such as a refund of the individual estates contribution towards the tea cess, *i.e.* pay back the 10 ct. per 100 lb. or say for an estate producing 100,000 lb. tea pay the proprietor who stops plucking 10 per cent of his average in bearing, R100 per annum, which would practically cover half cost of weeding that portion of the estate resting. What would that leave our American Commissioner? Not much, I fear; but, if we raise prices by my suggestion it would pay us—if India will only join—to increase the cess so as to keep our good friend W Mck. going. Either that, or reduce his advertising bill for a couple of years and get him to push his own hobby, Ceylon Green Teas.—Yours faithfully,

SYN AR DY HUN.

P.S.—How much longer are we to keep on advertising in America in the face of an actual falling-off in the consumption of our teas there?

IV.

Jan. 3.

Dear Sir,—Mr. Rosling's letter is good, but he should, when he went in for yearly letting slide one-tenth of tea area, have gone further and written one-fourth. One-tenth will not make sufficient impression. One-fourth would at once establish a large reduction and bring the buyers to their senses. India has been too hard hit in 1900, to go in for coarse plucking again, and no increase of tea area would arise, as capitalists would know Ceylon had the one fourth of her area up her sleeve as it were, to pour in extra tea three months after pruning down their area allowed to go fallow.

The cornering crew will, of course, object to Mr. Rosling's views as their wish is to let the weak go to the wall: a most cruel and abominable course to pursue either as against India or Ceylon. Why should not

the man who made his R30 an acre be allowed to live because the man who makes R70 wishes to make it R100?

LIVE AND LET LIVE.

NO. V.

Jan. 3,

Dear Sir,—If I was quite sure it was Over-production that was all the mischief, Rosling's proposal would appeal to me more. At any rate I hope his letter will do good.

ANOTHER V. A.

PLANTING NOTES.

The Fauna of British India, including Ceylon and Burma.—We have to acknowledge receipt of a copy of the volume "Arachnida," by R. I. Pocock, published under the authority of the Secretary of State for India in Council, edited by W. T. Blanford. (London: Taylor and Francis, Red Lion Court, Fleet Street; Calcutta: Thacker, Spink & Co.; Bombay: Thacker & Co., Ltd.) —It is a most useful compilation with numerous illustrations.

Bananas as Sick Diet in Typhoid Cases. —An American doctor—says the *British and Colonial Druggist*, Nov. 30th—has lately confirmed the belief, accepted in some medical quarters, in the value of the banana as a food for typhoid patients. It is now positively asserted that the banana is both safe and beneficial, the stomach practically absorbing the fruit owing to its nature. It contains only about 5 per cent of waste matter, 95 per cent possessing nutritive properties.

Tea Growing in Burma.—A very interesting note concerning the tea grown by Kachins in the Myitkyina sub-division of Burma is supplied by the Deputy Commissioner to the last Report of the Department of Land Records and Agriculture, Burma. We learn that tea is grown in three hills Mangin, Watu, and Panle, in the Sinlu circle. The seeds are dried and stored in September, and after the jungle has been cleared are sown in nurseries in May. Holes are drilled about four feet from one another and two or three seeds on germinating are dropped into each hole. Germination is said to take about one month. The plantation is carefully weeded and, after a lapse of three years, in the month of April the tender leaves are plucked. The leaves are either boiled or steamed. Steaming is only practised by those who have the necessary steaming-pots, called in Burmese, *panug gyaung*. After the above process, which softens and imparts a yellow tint to the leaf, the leaves are taken out and spread on a mat for a night; next morning they are put into bamboo tubes or in baskets lined with green leaves. The above tea is known as pickled or wet tea, and is sold at R2 per 10 viss. If the tea leaves are not sufficiently softened by boiling or steaming, they are rolled by hand on a mat before being put into the basket. To make dry tea, the leaves, after being boiled or steamed, are pounded tight into a green bamboo tube. The thickness of the latter is then reduced as nicely as possible, and the tube is kept over a slow fire. Dried tea sells at R1 per four tubes, each weighing from 20 to 25 ticals. The Deputy Commissioner, Myitkyina, estimates that 300 to 400 square miles are available for tea cultivation in his district.—*Pioneer*, Dec. 1.

Rubber Estates of Para.—Those who entertain ideas respecting the collection of raw rubber should (say the *India-Rubber and Gutta-Percha Journal*, December 24th,) study the report and the statements of the chairman of the Rubber Estates of Para, Limited, respecting the working of the company which was formed in April, 1898. During this time the company had only carried on business for about eighteen months, but had succeeded in sustaining a loss of nearly £24,000. Some of this, as the Chairman explained, should really be placed to capital account, as the business necessitated getting a number of labourers on to the estates and establishing factories, workshops, etc. The return of rubber for the past twelve months of the report amounted to 27 tons, against 11 tons 12 cwt. in 1889, more rubber having come into the possession of the company, although the number of collectors had been reduced from 250 or 300 to 170 or 180. The collectors had, of course, advances and stores to be afterwards paid for, but found that when they got into debt, they could collect their rubber and sell it elsewhere, so that the amount advanced was lost as well as the rubber, but Mr. Jacques hoped that this robbery had now been stopped; so that we cannot altogether say that india-rubber collecting is a bed of roses.

The Eucalpytus: Among the Berbers of Algeria: By Anthony Wilkins.—Here is a striking passage from this book according to the *Spectator*. Around Constantine the eucalyptus had been introduced about seven years back from Australia:—

"Already magnificent groves of these quaint yet graceful trees had grown up as if by magic. Last winter came the snow,—heavy and deep. It blocked the railway not once nor twice, and trains had to be dug out. It killed every gum-tree and every cactus for fifty miles round. All are bare and dead, and the groves are littered with the sawn limbs and logs of young giants, who have thus disappointed the hopes of those who have striven—not without success in less bleak provinces—to acclimatise them in a strange hemisphere. These trees come from a land which contains a British population, a good part of which is nearly four generations old, and a population which has begun to count itself by millions. Constantine was too cold for the trees of this land. How shall the French say that Algeria is too hot for them and for their children?

The French make bad colonists; that is a truth which Mr. Wilkin recognises, and he indicates readily its causes,—the limitation of progeny, and also the *nostalgie du boulevard*, that craving for the familiar social life of the café which is in every Frenchman's bones, but not a whit more strongly than in the bones of Cicero and every Roman of his day. In spite of it, Rome made an Empire by utilising other populations; and Frenchmen are, as Mr. Wilkin emphasises, excellent administrators. In Algeria they have cleaned up an Augean stable; in West Africa, as Miss Mary Kingsley testified, their work compares very favourably with ours. For the moment, and possibly for an abiding future, progress in the centres of commercial life is checked by the madness of Anti-Semitism, concerning which Mr. Wilkin is eloquent; but take the French where their work is merely in ruling a half-subdued and alien people, and they are admirable.

THE TEA CRISIS:
OVER-PRODUCTION AND THE REMEDY.

From one of the most experienced Inspectors of Estates in the island, wa have the following:—

"Mr. Rosling's proposal to 'rest' ten per cent. of the bearing tea on every estate for a couple of years should be dismissed for the reason that it would be impossible to get it carried out in practice. In many instances the poorest fields on the estate would be selected for such treatment, and probably any loss of crop that might thus be sustained would be made up the better cultivation and manuring of the balance. Others might select young tea just coming into bearing, and in both cases subsequent returns would be all the heavier. Another and very serious objection to 'resting' teas is that the further the bushes get away from pruning, the more liable they are to blight, and we should see this made the excuse for cutting down the tea before due date.

"My view of things is that both here and in India it will resolve itself into a question of the 'survival of the fittest,' and rightly so too. It is not the smallest use taking any *general* steps for the purpose of bolstering up rotten concerns. The sooner they go, the better for the enterprise though not perhaps for the individual. Philanthropy is all very well in its way, but it is not business. Why should a proprietor of a good estate sacrifice his yield because his neighbour has got hold of the dirty end of the stick and planted tea on unsuitable land? It is contrary to nature to expect him to do anything of the kind, and does away at once with all the principles of competition. If my neighbour is fortunate enough to be on the back of a winning horse in a race, would he pull up in order to give a broken-down old crock on three legs a change? Tea estates which do not pay, and cannot be made to pay, must in time drop out of cultivation; it will be a tedious process, but the sooner it *commences*, the better for those who are associated with sound concerns.

"When coffee went down in price many years ago to figures which made it impossible to work a number of estates to a profit, the acreage under cultivation was lessened, and production increased again with more prosperous times. So it will be with tea, and any attempt to interfere with the laws which govern supply and demand will, in my humble judgment, result in failure."

The above letter and that of Mr. Melville White, elsewhere, following up that of the Chairman, C. P. A., provide much food for thought and—action? Further correspondence and our comment on the same must be held over for the present.

PEARL OYSTERS AND PEARL FISHERIES OF CEYLON.

We direct attention to the following useful contribution to the subject of a development of our Pearl Fisheries, with remarks on pearl and pearl-shell oysters. Coming as it does from a Cambridge scientist, Mr. J. Stanley Gardiner, whose recent valuable investigations at the Maldives have aroused much interest and whose work upon the results of these will occupy a space of four or five years, we need hardly express the hope that his words will receive due notice.

Mr. Gardiner commences with reference to the three species of pearl oyster fished for in the tropics. Two of these, pearl-shell oysters, have a steady market, but fetch poor prices as compared with the third, the true pearl oyster—valueless for its shell, but fished for its pearls. With regard to Ceylon Mr. Gardiner agrees with Captain Donnan as to the importance of currents and would support the plea for selection of sheltered reefs, if actual experiments are to be undertaken here; if these are found, Mr. Gardiner is of opinion that the cultivation of the pearl oyster could be successfully pursued. The conditions attaching to the formation of pearls in the oyster around the coast of Ceylon require to be somewhat more carefully considered than off Westralia, for instance; and we have little doubt that the risk of unsatisfactory results can be reduced to a minimum. Meanwhile we urge upon Government that there should be the least possible delay in securing the services of some duly qualified scientist—Professor Herdman's name was uppermost at the end of October last—to undertake the organisation of the work, in order that local experience may be availed of to the full, as Mr. Gardiner points out. This should be preceded, we are told, by one, two or three years' survey of the coastline by a competent marine zoologist. Whether by themselves or in conjunction with South Indian and Westralian experiments, we hope that the Ceylon pearl fisheries which have proved so remunerative to the Ceylon Government in the past, are not to undergo a very much more extended period of unjustifiable neglect.

PEARL OYSTERS AND PEARL FISHERIES OF CEYLON.

Dear Sir,—A report of a meeting of the Ceylon branch of the Royal Asiatic Society held on Oct. 27., reprinted from the *Ceylon Observer*, has recently been placed in my hands. The paper of the evening was by Mr. Collett on "Pearl Oysters and Pearl Fisheries," a subject in which I in common with all marine zoologists am much interested. Indeed the economic importance of the pearl industry in the eyes of man adds a great dignity and anthropological interest to the subject, which will always preserve it from the sneers of true men of science,

In view of my work round the coasts of Ceylon, the Maldives, Australia and various island groups in the Pacific Ocean, I have been asked to send to you any comments I may have to make on the subject of general interest. So far as I am aware there are three species of pearl oysters largely fished in the tropics:—

1. The true pearl-shell oyster of Torres Straits, characterised by its large size, edge or lip of shell, colourless inside or slightly yellow.

2. The black-lipped pearl-shell oyster of almost universal distribution in the tropics; size same as the last, but differing from it as its name implies by having a markedly black edge or lip to the shell.

3. The pearl oyster of the Ceylon fishery, almost valueless for its shell, but fished for its pearls. Marketable pearls are found also in the two pearl-shell oysters. They are, however, seldom as lustrous as those of the true pearl oyster, and indeed are merely a bye-product, the shell being the chief thing.

The value of the shell varies considerably, good shell of the first or true shell species fetching about £100 per ton. This is a fairly constant price, as the demand for white buttons scarcely alters. At present the black lipped species is worth rather more, as fashion now demands a button of a mixed colour. Its average price is perhaps £80 per ton. The true pearl oyster of the Ceylon banks is worth from £2 to £5 a ton for its shell, but the market is very small. The value of the oyster banks depends on the value of the pearls obtained, and while varying with the market must always be very much greater than that of either of the shell species. This result is very largely due to the fact that the pearl oyster is a social beast, *i.e.* that thousands and even millions attach themselves to a single reef, while the two pearl-shell oysters are found scattered here and there, never, except formerly in a few areas of Torres Straits, in any very great quantity on any single area. It would be obvious however that the cultivation of either of the above three species would be, even if but very partially successful, extremely profitable, and from my experiences elsewhere, there would seem to be no good reason why it should not be quite successful on Ceylon reefs. I have indeed seen very many reefs round the coast of Ceylon, apparently absolutely identical in their physical conditions with reefs in the Pacific Ocean, and in the Maldive Group on which the black-lipped pearl shell abounds. Many quite protected shoals also to the north, east and south of Ceylon, appear to me eminently suitable for the growth of the true pearl oyster.

In Ceylon I had the pleasure on several occasions of discussing the matter with Capt. Donnan. My experience agrees with his as to the immense importance of the currents of any area. Indeed, in considering the fauna of any single reef in reference to neighbouring ones, the physical conditions are the most important factors to be taken into consideration. I would suggest, then, that the first thing to be done is to have made a thorough survey for 12, 24 or even 36 months, if necessary, of the physical conditions of the reefs in the Gulf of Mannar by a competent, practical and, if possible, experienced zoologist. The life history of the oyster can then be thoroughly worked out. The effects of currents, silt, etc., will be known as also the physical conditions of the reefs. Suitable reefs in more protected situations could then be searched for round the coast of Ceylon. On these, cultivation on a large scale could be tried, and I have little doubt would be successful. Further the reefs and waters of Ceylon have immense possibilities for the cultivation of the two pearl-shell oysters. Great areas are exceptionally favourable for sponge planting, an industry, as experiments in the Adriatic have shown, not attended with any great difficulties.

Capt. Donnan has immense, long-continued and unique experience of the pearl industry of Ceylon. Should there be any intention to appoint a scientific man to the work, it should be done without delay, so that he may have the benefit of Capt. Donnan's knowledge to the very fullest extent. He should, too, be in close relation to the museum, as he would doubtless require to refer to it constantly for literature and special information as to the fauna.

I may take this opportunity to thank all, with whom I came into contact in Ceylon, for their courtesy, kindliness and sympathy.—I am, sir, yours obediently,

J. STANLEY GARDINER.

Cambridge University, Dec. 16.

RUBBER IN EAST AFRICA.

Mr. Marsden, the British Vice-Consul for the East African Protectorate, in his report on the trade of the country, again emphasises his conviction, previously expressed that there is money for the private individual and for the Government if the rubber industry in the Protectorate were more systematically worked. "Rubber," he says, "shows an advance of 40 per cent on the previous year, but is still far below what it should be and what the country is capable of producing. This is due in a large measure, to this industry being left to take care of itself, and no properly disciplined or organised effort made to assist it. In times of drought and bad harvests the natives fall back on the rubber-collecting industry to keep themselves from starvation, but in times of plenty the industry is more or less neglected, and only vines which grow in those places easiest of approach are tapped, and in many case ruined by being cut to the ground instead of tapped. It is somewhat surprising that the attention of planters has not been previously drawn to the systematic cultivation of the rubber vines. Through out the territory the soil is sufficiently rich to grow rubber vines in perfection without artificial aid, the only requisite being water, and on the banks of the Tana and Sabaki rivers that can be obtained all the year round. With irrigation and under proper management the results should be as satisfactory as coffee growing."—*India-rubber Trades' Journal*, Nov. 26

INDIA-RUBBER PROPAGATION.

Colonel A. Bloomfield, writing to the *Pioneer* (Dec. 20) about the propagation of the India-rubber tree, remarks that the simplest method of propagation is to strike cuttings made of a leaf of the tree cut off with about an inch of the twig above and below. Every leaf will strike readily. All the piece of twig must be underground.

OUR TEA EXPORTS.—A Calcutta merchant in a private letter to the Editor of the *Tropical Agriculturist*, writes:—"I have been indebted during the past two years to your annual supplement for the figures giving the Monthly Exports of Tea to Great Britain and elsewhere. These cannot, however, be tabulated during the course of the year owing to the way in which the export statistics are published *viz*: to week ends instead of for the calendar month. I feel sure that, were the export statistics published in some such form as annexed, they would be of added interest and value to many who like myself try to follow the development of our Indian and Ceylon Tea Trade; and I trust it may be possible for you to give them in the suggested form."—We referred this letter to a member of the Chamber's Committee and we are glad to learn that it has been agreed to adopt the suggestion for the present year.

RUBBER ESTATES OF PARA.

STRANGE EXPERIENCES.

The ordinary general meeting of the Rubber Estates of Para, Limited, was held on the 17th inst., at Winchester House, London, E.C., the Hon. John de Grey, the chairman of the company, presided. In moving the adoption of the report, which included complete accounts from the inception of the company down to June 30th, 1900, since the total loss, as stated in the accounts amounts to £23,769 12s 3d. This, the Chairman explained, should not be treated as a total loss, because, by the initial expenditure, they had established 170 to 180 men permanently upon the estates, so that a considerably amount of the apparent loss might be reasonably called capital invested in putting the estates in working order, and establishing rubber collectors upon them, which expense would not have to be incurred again. Turning to the result of the first season's working, the Chairman had to deplore that it was of a most unsatisfactory nature, and the board, since the last meeting of the company on June 1st, had given the matter its most earnest attention, with a view to ascertaining the cause which had led to that state of things and remedy them so far as lay in their power. The report stated that Mr. Milne, the Estates Manager, had resigned, and there was little doubt that he had tendered his resignation because he had found himself unable to cope with the difficult problems that he found in managing the estates. Mr. Jacques, the Para agent of the company, had been asked to proceed to the estates and report fully upon the situation and had been appointed general manager. The Chairman stated that Mr. Jacques had given the board entire satisfaction, and had furnished them with a most valuable report upon the property and the business, which shows he has a full grasp of the situation.

In proceeding to summarise the difficulties to be encountered, first the indebtedness of collectors; secondly, robbery by them to avoid paying their debts, and also robbery by private hoats; thirdly, and most important of all—the badness of the labour system.

Mr. Jacques reported as follows:—

"Admitted on all hands to be one of the wealthiest in the district," and which, he says, worked by suitable labourers, would be worth a fabulous sum, and would give ample employment to 1,200 hands, capable of producing 100 and 150 rubber trees, where it only produces one at present. "Solve," says he, "the labour question, and the company can be made a prosperous one indeed." He says also that he considers that apart from rubber, cocoa, sugar cane, bananas and plantains, timber and wood could be cultivated with good results; indeed, that there are no tropical trees or fruits but can be readily cultivated on the estates. These are all matters to which we shall direct our attention with a view to future developments. (Hear, hear.) Turning back to the balance-sheet, under profit and loss I should like to show you what economies we have been able to effect up to the present time. You will find put down in the second part of the profit and loss account, from March 25th to June 30th, 1900—taking these two dates—the salary of the London manager, £2,200; that was at the rate of £1,200 a year, so I have put it down in my notes as salary, £1,200; at the present date that is wiped out altogether. Then secretary and rent of offices appears at the rate of £550; that has been reduced to £450. Directors' fees appear as at the rate of £1,400; that has been reduced to £550, and it will interest the shareholders to know that since the meeting of June 1st, the directors have not drawn any fees, because they wished to delay doing that until the company is in a better position. (Hear, hear.) Then salaries of estate manager, accountant and inspectors were at the rate of £1,836 (£3,367); they are now reduced to £1,500 a year. The special remuneration to Para agents, £650, comes out altogether. Then with regard to the Para agents' commission, that would come under the second item of estates trading account, consumable and general stores, and we estimate that to have been about £2,000 a year; against that we have by our own Para establishment, under Mr. Jacques, a total expenditure which, including office and clerk, comes to £1,000.

REDUCTION IN ESTATES MANAGEMENT.

Then there is that very heavy item of estates management, £11,478 for eighteen months. Now, that would be at the rate of £7,600 a year, and we estimate—I cannot give you this figure exactly, but we know that great reductions have been made, and as nearly as we have been able to estimate them, they amount to £4,000, against £7,600 a year. I should now like to call your attention to the returns of rubber. The total returns of the whole season, so far as we have gone, to December 19th, are 27 tons, and last year they were 21 tons, and when you come to think that the collectors at the same date last year numbered between 250 and 300, and this year they are between 170 and 180, you will see that with a much less number, the directors have got considerably more satisfactory returns. Then I should like to mention that at this time last year we had received no remittances of the moneys of the estates, but this year, either in hand or on the sea in the shape of rubber coming to us, we have a total amount of £1,200, which is sufficient to pay one year's interest on our debentures, the first half-year of which will be due in January. I should also like to read you a telegram which we received on December 15th from Mr. Jacques. He says: "Shareholders will be glad to hear that we do not give any further credit." The meaning of that is that he has been able to stop that detestable system of indebtedness which has been—I will not say the ruin, but which has militated very greatly against the success of the company. You know that according to the system which has prevailed up to the present, when you sent a man up to the estate as a collector, you were asked to equip him with stores, cash and various advances. I do not know whether it will be possible, from what has taken place, to completely change that system, but at any rate, it can be greatly modified, because our great cause of trouble up to the present time has been that collectors great advances far in excess of what they should do, and when they become so indebted, rather than liquidate their indebtedness by giving their rubber to the company to reduce it, they sell it elsewhere. Mr. Jacques is endeavouring to do away with that system altogether, and that telegram means that he is not going to make any further advances. In conclusion, I will only repeat what I said on June 1st, 1900, and which I think is borne out by what I have now stated to you. I said on that occasion: "We are not going to try and make a large profit in the first season. We do not want to run any risks. We want to confine our efforts to building up a proper system of management which shall bear fruit in the future, so that by gradually extending our operations in future seasons we may develop the undoubted resources of our property." It is our confident hope that in time we may be able to carry out that policy with success.

Questions on details of the accounts were put by Mr. Wilkinson and replied to by the Chairman, after which the motion was put and carried.

The retiring directors, the Hon. John de Grey and Mr. E. T. Wolseley, were re-elected on the motion of Count de Torre Diaz, seconded by Mr. H. M. Baker.

Messrs. F. Davies, Meredith & Co. having been reappointed auditors,

Mr. Leach Barrett moved a vote of thanks to the chairman and directors for the able manner in which they had conducted the business of the company.

The motion was seconded by Mr. Woodrow and carried unanimously, and, after a brief acknowledgment from the Chairman, the proceedings closed. —*The India-Rubber and Gutta-Percha Trades Journal*, Dec. 24.

CAMPHOR MANUFACTURE.

Formosa.—The so-called "camphor factory" built by the Government at the capital, Taihoku (Taipeh) is the most imposing in appearance of any of Formosa's industrial establishments. It consists of one main building containing the distilling apparatus for grade A camphor, one building equipped with the necessary apparatus for the extracting of camphor from camphor oil, a large warehouse for storing the drug, a packing house and numerous out-houses, including barrack-like quarters for the labourers, and neat little cottages for the skilled workmen, officers, &c., connected with the factory. The factory buildings are big, solid structures of brick and stone, and provided with not only the latest hydraulic and steam-pressing machinery, but with much apparatus specially designed for the work. The grounds and buildings are illuminated by electricity supplied by the factory's own plant. The buildings impress one as having been erected with the idea of permanency, and the Formosa Government evidently hopes to control the camphor situation for many years. The preparation of the two grades, A and B (crude) camphor, is as follows:—The camphor is obtained by steaming camphor-wood chips in roughly built furnaces set up on the hill districts. A vapour arises from the steaming wood, and condenses in cooled wooden receptacles forming a snow-like deposit of camphor, containing, however, some quantity of oil. After removing the camphor from the condenser, it is allowed to drain in tubs, until a considerable portion of the oil has run off. The camphor is then packed in canvas bags, and transported to the central office at the capital. The camphor destined for shipment as crude is not subject to further treatment after leaving the country districts. For shipment it is packed by hand in zinc-lined cases, holding about 1 picul (133 pounds). This grade is similar in form to the crude camphor exported prior to the establishment of the monopoly, although the Government has been able to improve it somewhat in quality. The camphor for grade A blocks is treated at the factory described above. The plant possesses six large distilling furnaces measuring some 24 by 12 by 5 feet, and two crystallization chambers some 30 by 24 by 24 feet. Several thousand pounds of the crude camphor are placed in one of the large iron retorts, and, after the openings in the latter have been closed and sealed, air is forced in to hasten evaporation. For the first forty-eight hours a slow fire is maintained, which is sufficient, however, to drive off the water and oil, these passing through a pipe leading from the top of the retort into a tank cooled by water. The heat is now increased, and the above pipe having been shut off and a second one opened, the camphor fumes pass through the latter into the crystallization chamber the roof of which is cooled by running water. Here it crystallizes as flowers of camphor. The camphor is now ready for pressing. This is accomplished by first shaping the camphor into the form of a block by the use of wooden moulds. The block is then pressed by steam power, and, lastly, is subjected to a very high hydraulic pressure. The result is a hard, almost opaque bric of practically pure camphor, weighing 10 kin (13¼ pounds). These blocks are now wrapped in oiled paper, and packed in zinc-lined boxes holding ten, and, after receiving the Government label of "crude camphor, pressed by the Formosa Government," are handed over to the selling agents. The Government factory has at present a yearly capacity of some 2,700,000 pounds of grade A. The total Formosa Government expenses, including cost of camphor, are given in the Budget for 1900 as 2,127,611 yen ($1,063,805), and the receipts as 3,455,035 yen ($1,727,512). This leaves a profit of 1,327,424 yen ($663,712), or about 34 (yen $17) a picul (133 pounds). This is taking the maximum production for the year at 39,000 piculs (5,187,000 pounds). Some 2,000,000 pounds of camphor are consumed in the United States yearly.—*United States Consul ta Formosa.*

COFFEE NOTES.

Less than five years ago the first coffee seeds were introduced into Uganda by missionaries. Now there are extensive crops under cultivation. Last year 100 tons were exported from Uganda, and this year this amount will be greatly exceeded. The quality of Blantyre coffee is said to be the best in the world, superior even to the famous Mocha.—*Commercial Intelligence.*

The heavy receipts of coffee at the port of Santos in Brazil are attracting attention in the trade, as well they may. Notwithstanding that the arrivals are much below the normal volume, the total for the two ports is not far below the figures a year ago, when prices were at about their lowest point. The effect of these heavy receipts on prices has been helped by the receipt of estimates pointing to a liberal crop of Rio and Santos coffee the coming season.—*Merchants' Review*, October 5.

INDIA AND FRENCH IMPORT DUTIES.

Calcutta, Dec. 22.—A Press *Communiqué* issued here today by the Finance Department, states that the enhancement of French Import Duties on Indian coffee, pepper, etc., has been postponed for six months, till the end of June, 1901.—*Madras Mail*, Dece. 24.

MICA.

The mining community is much exercised at he determination of the Bengal Government to enforce the rule for the exaction of a royalty of 2½ per cent on all rough mica taken from the mines. The royalty clause has always been inserted in the leases, but hitherto it has remained a dead letter, owing to the difficulty in determining the precise output of the mines. Not long ago Mr. Wild, the Conservator of Forests, Bengal, was round inspecting the mica properties within the forest area with a view of settling this question, and later on Mr. Grundy, the Inspector of Mines, made an exhaustive examination of all the mines now being worked and collected data regarding the output of rough and dressed mica, average value of merchantable mica etc.; and it is believed that his report will embody the opinions of the chief owners as to the manner in which the royalty should be levied. The consensus of opinion is against the royalty being levied on the gross output, since much of the mica that comes to the surface is thrown away as being useless, and it is unfair to demand royalty on what is of no value. The better plan would be to exact a royalty on all mica conveyed to the dressing floors. The amount and value could easily be arrived at, as it is well known that each maund of rough mica yields only one third of a maund of dressed mica. The average price of mica (big and small) is R60 a maund in Calcutta. The cost of dressing and transport may be set down at R10, which would leave R50 as the net value of one maund of dressed, or three maunds of rough, mica at the pit's mouth. This would mean a royalty of 7½ per cent on each maund of dressed mica despatched from the mines. —*Indian Agriculturist*, Dec. 1.

BURMESE GOVERNMENT'S RUBBER PLANTATION.—The Government of Burma proposes starting shortly an extensive rubber plantation on King's Island, the principal island of the Mergui Archipelago.—*Hongkong Weekly Press*, Dec. 29.

THE CORPORATION LIMITED.

(OF CEYLON).

Directors.—Alfred Bull, Cyril Gurney, E H Hancock, T J Lawrance, R R G Norman, V H Smith.

Managing Director in Ceylon, Frederick Tatham.

London Agents, Antony Gibbs & Sons.

Report of the Directors, and Accounts for the year ending 30th June, 1890, to be submitted to the Annual General Meeting of Shareholders on the 6th December, 1900.

The Directors beg to submit herewith the Accounts of the Corporation for the year ending 30th June, 1900, which, they are sorry to say, do not show the results reasonably anticipated, owing to the abnormally low prices which have prevailed in the tea market for a considerable time past.

The following figures indicate the results during the past three years:—

	Crop. lb.	Cost of Production.	Average Sale Price Nett.
1897-98...	1,112,606	31 cents per lb.	5d.
1898-99...	1,234,442	26·10 ,,	5 15-16d.
1899-00...	1,276,139	25·60 ,,	5 3-16d.

From these particulars it will be seen that the estimate for the past year, 1,250,000 lb., has been more than secured at a reduced cost; only normal prices are required to enable the Company to show much more substantial profits.

In view of the present relations of supply and demand it has been decided not to develop the property on the lines roughly sketched in the last report.

Economies have been effected by a reduction in the agency charges and in management; the inclusive London charges on the tea are now considerably under 1d per lb.

The total profit for the year is £6,037 6s 10d. After deduction of Debenture Interest, London expenses, etc., there remains a balance of £1,646 14s 9d.

The Directors have paid a further half-yearly dividend on the Preference Shares in addition to that mentioned in the last report as having been paid on 1st August, 1899, and regret their inability to further reduce the overdue Preference dividend at present.

Mr. Tatham hopes to secure about 1,300,000 lb of tea for the current year at about 26 cents per lb and advises the Board that a fair cocoa crop is practically assured.

Forty tons of plumbago have been won during the year. The Directors have employed an Engineer to advise upon and assist in the mining operations, and much had been done by the 30th June. Since that date there has been a substantial output, and it is hoped that a further profit may be shown this year after writing off a considerable portion of the amount which at present stands in a suspense account.

VITICULTURE IN TRANSCAUCASIA.

According to official figures supplied by the Department of Agriculture at St. Petersburg, the area of land under cultivation of the vine, and the production of wine in Transcaucasia are as follows:—The Government of Tiflis 65,516 acres, and 6,750,000 gals.; the district of Zakatal 1,938 acres, and 22,000 gallons; the Government of Kutais 94,277 acres, and 4,050,000 gallons; the Government of Elizaretpol 33,701 acres, and 2,700,000 gallons; the Government of Baku 27,283 acres, and 2,160,000 gallons; the Government of Erivan 19.926 acres, and 675,000 gallons; the Government of Daghestan 6,420 acres, and 540,000 gallons; the Government of Tchernomoria 1,493 acres, and 135,000 gallons; and the district of Kars 121 acres, and 11,000 gallons, making a total area under cultivation of 250,675 acres, and a production 17,043,000 gallons. The figures given above according to Consul Stevens do not include the grapes grown for sale in the markets of the Caucasus, and the quantities consumed by the distilleries, the total of which amount was as near as possible 108,900 tons. Although viticulture in the Transcaucasus is by no means a new industry, it has, nevertheless, not yet been able to reach that state of prosperity which could entitle it to be classed amongst the industries of the country that form one of the mainstays of the population. This, of course, is due in a great measure, to the ignorance of the inhabitants, and the lack of the knowledge necessary to carry on the cultivation of the grape in a systematic manner, and on principles which would be more or less in keeping with the climatic conditions and varied soils of the different altitudes at which the vineyards are situated. Grapes grow in a wild state almost throughout the Caucasus, and with a little pains there is no doubt that the industry might be raised to a state of efficiency which would considerably enhance the revenues of a large majority of the population of the Caucasus, and thereby increase the prosperity of the country. Although the production of wine has attained figures of fairly large proportions, most of the wine is consumed in the country, and only a very small quantity finds its way to St. Petersburg and other Northern Russian markets. The greater part of the wine made is very inferior in quality, and in most cases is "heavy" and "heady." With a very few exceptions, owing to the poverty-stricken condition of the wine growers who have no possibility of keeping their wines for any length of time, it is sold and consumed as soon as it is made. This, in itself, does not give an opportunity of properly testing the wine, which, if kept long enough, would doubtless undergo a complete change for the better, as has been proved by the wine made on the estates of the Imperial Domains and those belonging to the wealthier wine-growers of the Caucasus. Other drawbacks in the shape of phylloxera, black-root, oidium, mildew, and the diseases of a fungoid nature which have become chronic, continue to cause havoc among the vines, and are a constant source of trouble and anxiety to grape-growers. In many parts of the Caucasus severe local rain and hail-storms have also ruined extensive areas of vineyards.—*Journal of the Society of Arts.*

PARIS EXHIBITION: SECTION OF CEYLON.

MUSEUMS AND NATIONAL INSTITUTIONS TO WHICH EXHIBITS HAVE BEEN PRESENTED IN THE NAME OF THEIR EXHIBITORS.

1.—Philadelphia Commercial Museum, U. S. A.—Plumbago, Mr J W C De Saysa; Cinnamon, Mr Jacob de Mel; coconut products, Messrs Vavasseur & Co.; coconut oil, Mr Arnold Dias; tanning products, Mr W D Carolis; coffee and cacao, Lipton Ltd.; coffee, Mr Gibson; coffee, Mr G H Barber; cardamoms, Mr J Westland; cardamoms, Mr J A Spence; bixa

seed and paste, Anatto Dye Works; banana flour, Mr C Stouter; white pepper and cloves, Messrs Darley, Butler & Co.; arecanuts, Mr J H Meedeniya, R. M.; nutmegs, Government of Ceylon; pepper, Government of Ceylon; copra, Government of Ceylon; rubber, Government of Ceylon; cardamoms, Government of Ceylon; wild fibres and ropes, Government of Ceylon.

2.—Stadisches Museum Bremen.—All the following exhibits of Messrs Darley, Butler & Co.:—Plumbago (in case), coconut oil, poonac, copra, fibre and yarn, kitul fibre, palmyra fibre, cinnamon, essential oils, Mr Jacob de Mel; mica, Mr Kuruppu.

3.—Jardin Colonial, Paris.—Coconut and copra, Mr W H Wright; plumbago (part of), Mr U D S Goonesekera; cinnamon (part of), Mr Jacob de Mel; coconut oil, Mr A P Goonatilleke,

4.—Agricultural Museum, Berlin.—Plumbago (part of), Mr Jacob de Mel; collection of wild fibres, Government; collection of medicinal plants, Government; coconut fibre and cord, Messrs C P Hayley & Co.; cardamoms, cocao, &c., Mr J H Renton.

5.—Field Colombian Museum, Chicago.—Plumbago (part of), Mr U D S Goonsekera.

6.—Museum d' Histoire Naturelle, Paris.—Plumbago (part of), Mr U D S Gunasekera; plumbago (part of), Mr Jacob de Mel; Fauna collection, Government; elephant and skeleton, peacock, 14½ pairs of birds indigenous to Ceylon, two wild boar, one axis deer, one cobra, one tiepolonga, five flying foxes, group of wanderoo monkeys, two flamingo, and two juule fowl.

7.—Australian Imperial Museum.—Plumbago, Messrs Clark, Young & Co.; fibre, Horrekelle Estate Co.; cinnamon, Mr Jacob de Mel.

8.—Musee des Collections, Manufacture Nationale Severs.—Seven pieces Kandyan pottery, Government.

9.—Imperial and Royal National Museum of Hungary, at Buda Pesth.—Five life-size figures in plaster, Government; Model of a Tamil house, Government.

10.—Musee Industriel, Rouen.—Plumbago (part of), Mr U D S Gunasekera; cinnamon (part of), Messrs Miller and Branwell.

11.—Musee Industriel, Lyons.—Plumbago, Mr H B Fernando; cinnamon, Messrs Miller and Branwell.

12.—Royal Botanic Gardens, Kew.—Sample of tea, furnished by Mr J H Renton; coffee, cacao, coffee and cardamoms, specimens of medicinal plants, Government.

13.—State Museum, Hamburg.—Plumbago, Mr L B A de Silva; fibre, Mr U D S Gunasekera; Cinnamon (part of), Mr J de Mel; coconut oil, Mr G C Warr.

14.—Industrial Museum, Bonn.—Plumbago (part of), Mr Jacob de Mel; mica dust, Mr W Kuruppu; coconuts, Messrs Murdoch and Branwell.

15.—British Chamber of Commerce at Paris.—Plumbago, Messrs Delmege, Forsyth & Co.; mica, Government collection; mica dust, Mr W Kuruppu; all pamphlets and reports available on Ceylon Tea and other industries, from the Chamber of Commerce and the Planters' Association.

16.—Imperial Art Galleries, Vienna, (Dr. Eder.)—Two landscapes, Mr W D Bosanquet.

17.—Imperial Institute, London.—Collection of products of the coconut palm, Messrs G and W Leechman; cardamoms, Mr J A Spence; cinnamon, Mr. J W C De Soysa; vanilla (part of), Mr Vander Poorten; cinchona, Mr F G A Lane; cinchona, Mr G S Anderson: cinchona, Mr G B Christie; arrack (collection) (with model still), Mr Arnold Dias; plantain flour, Mrs Arnold Dias; anatto (complete collection), Mr A VanStarrex; plaintain flour, Mr W D Carolis; various flours, Government; pepper and cloves, Messrs Darley, Butler & Co.; sugar, Jayasinha Mudaliyar; resin (collection of), Government; various preserves, Ponnan Nendali and K A Perera; bêche de mer, Government; metal cleaning-powder, D Johannes; dubbing, J Baptist.

KOKARI FISHING IN THE ANDAMAN ISLANDS.

BY MAJOR G. MASSY.

(*Badminton Magazine*, January.)

A somewhat novel methods of handline fishing may frequently be seen in the Andaman Islands by those whom fortune (or misfortune) should take to that little-known penal settlement in the Bengal Ocean. The fishing is carried on during fine weather by certain native convicts of 'self-supporting' class, *i.e.*, men on a short of ticket of leave, who earn their own livelihood; and, as they can generally get a ready sale for their fish, the pursuit is a fairly profitable one. They fish from dug-out canoes, in handling which they are very expert. The crew, as a rule, consists of a steersman, one paddler, and the fisherman, who sits in the bow and is in command of the boat. They carry a good-sized casting-net, similar to those used in England, for catching bait with, and a large wicker basket for keeping live bait in. When required for use, this is slung overboard, and is provided with a canvas flap over the top of it, to prevent the bait from jumping out. It corresponds to the 'courage' which is employed for a similar purpose in sea fishing on some parts of our coast. In lieu of a gaff, a long-handled spear, with a small barbed head, is carried. The fishermen say that it is much easier to use than a gaff, and certainly I never saw one of them miss a fish with one.

The handline, which is a fine one, made principally of silk, is about 150 yards long, and is kept carefully wound round a stick or in a ball, to ensure its running easily when playing a fish. I believe these lines are procured from the east coast of Madras. A medium-sized hook completes the tackle. From this it will be seen that, though a hand line is used, it is no means the pull-and-haul kind of business one generally associates with that kind of sport. Far from it. The line being very fine, a light hand and considerable skill are required to ensure success.

This fishing is usually carried on near the jetty on Ross Island. The water there is deep, and, except, of course, during bad weather, of crystal clearness. Standing on the jetty, one can see countless numbers of fish of all kinds in every direction, and in the clear water every moment can be distinctly traced. Large shoals of sardines disport themselves on the surface, occasionally making frantic dashes for safety under the wooden piles of the jetty, as the hungry kokari pursue them and reduce their num-

bers; other enemies, too, are on the look-out for them—amongst them being barracouta, garfish and horse-mackerel; and further out to sea seer-fish—but the kokari are the most numerous. But here come some of the fishing-boats, paddling as if for dear life now that they see the fish are on the feed—so we will watch one of them at work. Arrived near the jetty, the fisherman slings his basket over the side of the boat, prepares his net for a cast, and looks out for a good shoal of sardines. As the sea is teeming with them this does not take long, and in a few minutes the net is hauled on board with a goodly supply in its meshes; these are quickly transferred to the basket, all hands working busily at the job. One or two more judicious casts, enough live baits have been caught to enable a start to be made, and our fisherman begins business. Squatting down in the bows, he uncoils some twenty yards of line, and baits his hook with a live sardine by hooking it carefully under the back fin. Keeping his baited hook in the water alongside him, he throws out two or three sardines about twenty yards from the boat to attract the kokari. These are taken almost immediately, and out go a few more, followed this time by the hooked one, which is dexterously cast into the midst of the others; there are several boils and splashes on the water, then the line tautens, our friend strikes, but is too late, and his bait is gone. He hauls in the line with feverish haste and repeats his cast; this time with more success, and is at once fast in a good fish which dashes madly out to sea as fast as it can go.

The canoe follows as quickly as the paddlers can make it travel. The fisherman, holding his hand well up, lets the line slip through his fingers, feeling his fish all the time, and not letting him take out line too easily. At the same time he excitedly screams contradictory directions to his crew, and curses them freely for not going fast enough. His object is to peep over his fish as much as possible. After going about a couple of hundred yards or so he gets a pull at his fish, and begins to recover some of his line, the boat still following every movement of the quarry, and, when skilfully handled, doing half the work of killing it. After another good run or two the fish shows signs of being done, and he is gradually brought gasping to the surface. The man in the centre of the boat drops his paddle and takes up the spear—a sharp stab and a hoist, and the fish lies quivering in the bottom of the boat, . . . a grand fish he is, too, close on 20 lb. weight. Locally called a kokari, he belongs to the Caranx family, has a large deep head and powerful jaw armed with numerous teeth; he is deep and somewhat flat-sided in the body. His pectoral fins are peculiar, being long and curved, and shaped somewhat like a sickle; he fines off very much towards the tail, which terminates in a large fork, and in some species the root of the tail is armed on either side with a sort of sharp bony ridge. The colour varies, a silvery hue predominating, but some are of the most beautiful ultramarine blue. Altogether he presents a very game and handsome appearance, which as far as his fighting qualities go he does not belie, as harder running fish it would be difficult to find.

The boat is soon back at the jetty again ready to recommence operations, and with decent luck our friend will have two or three more fine fish before he leaves off, varying in size for 7 to 20 lb. It was very entertaining to watch them at work on a day when the fish were taking well, and I need hardly say that some of us who were keen fishermen were not content with watching only, but soon followed their example, using rods instead of handlines, but otherwise fishing in the same manner; and very good sport we frequently had, which made amends for being stationed in such an out-of-the-way part of the world.

COFFEE PLANTING IN SUMATRA.

We are always pleased to hear from our old friend "W. T. McK." who, after leaving troops of friends behind in Ceylon, has been so many years now in Sumatra without making a fortune. He sends us as usual a graphic letter (given in our daily and *Tropical Agriculturist*) with some useful statistics, showing that his district of "Serdang" has about 10,000 acres under Liberian coffee. The photograph he sends, shows magnificent giant coffee trees (backed by Albizzias) laden with crop; for, of course, the soil is superior to anything we have in Ceylon. But then the market price of "coffee" has, for a long time, been even more disappointing than that of tea!

ELEPHANTS IN BURMA.

The year 1899 was a most disastrous one for the Government elephants in Burma, numbers of which died from an outbreak of a disease believed to be anthrax; contractors and others suffered similarly, and elephants to replace losses cannot now be easily purchased. Several officers have therefore suggested instituting Keddah operations in Burma and the Local Government is now in correspondence on the matter with the Suprintendent of Keddah Operations in India. It seems clear, however, that operations in Burma will not be easy to arrange as there is no chance of success, unless trained men are employed on the work and money liberally spent.

The Forest Officer in charge of the Mu Division writes:—

"The Bombay-Burma Trading Corporation, Limited, increased their stock of elephants in the division to almost 100 beasts. Contractors and licensees, however, are unprovided with these useful beasts, and cannot always pay R3,500 for a tusker and R2,500 for a cow, which are the present prices. Advances might do something in improving extraction, but one looks with longing at the three or four herds of from 40 to 80 beasts each which roam over the division, and which are rapidly being shot down by Burman hunters for the sake of a few rupees worth of flesh. Kheddah work, too, would be especially easy in this division, as for instance in the Thaw basin, where heavy forest is not continuous and the herds are often restricted to small isolated areas."—*Forest Administration in Burma for the year* 1898-99.

OUR EXPORT IMPORT AND SHIPPING TRADE FOR 1900.

The Export trade of 1900 compared with 1899 must be recorded as not altogether satisfactory. For some products, prices were maintained; for a few prices were dearer; but against this, two of our most important exports fell seriously in value, and one further fell off in volume considerably.

CARDAMOMS.—The export to India increased last year 100 per cent, but prices generally were lower both locally and in London. A slightly firmer tendency was noticeable as the year closed. The total exports exceeded those for 1899 by 37,496 lb. More land is coming into bearing and a heavier export must be looked for in 1901.

CINNAMON.—The crops for 1900 were good, the result being an increase in export of quills to the extent of 163,080 lb and of chips to the extent of 34,279 lb. Prices, notwithstanding the increased production, have been maintained. Quills (taking usual assortment as average) have not fluctuated locally during the year more than 1½ cent per lb and values in London have not shown much rise or fall. Chips have fluctuated between R87·50 and R92·50 per candy. Both quills and chips are more and more being shipped direct to the consuming countries, and the result of getting at the consumer direct is very clearly shown by a perusal of the following figures :—

	Quills lb.	Chips. lb.
In 1890 the exports were :—	1,894,514	441,447
1900 „ „	2,678,111	1,863,406
Increase	783,597	1'421,959

In 1890 usual assortment was worth 30 cents per lb. Chips R60 per candy.

In 1900 usual assortment was worth 57½ cents per ⅝lb. Chips. R90 per candy.

Notwithstanding that during the decade we have increased our exports of quills by 35 per cent and quadrupled our export of chips, the value of quills has advanced nearly 100 per cent and chips about 35 per cent.

The export of wild cinnamon, which for a short time threatened to injure sales of plantation and garden cinnamon, has now practically ceased. The value of wild cinnamon in London is barely sufficient to pay the freight and dock charges there. In one or two instances wild cinnamon chips have been mixed to a small extent with usual chips, and exporters will have to very closely watch deliveries.

CINCHONA.—This bark continues to decrease as regards quantity harvested and shipped; and some years must elapse before recent plantings, tell.

COCOA.—The export for 1900 (33,476 cwts compared with 42,745 in 1899) shows the lowest record in volume since 1896. Prices in Europe ran high for good bright beans, and for really fine bright bold beans extreme prices were realised, the latter were worth R57·50 per cwt. locally at the close of the year, compared with R47 at the same time 1899. It is hoped this year's crop will be a larger and a better one.

COCONUT PALM PRODUCTS.—All the products of the coconut palm :—coconut oil, copra, poonac, desiccated coconut, coconuts, coir rope, yarn and fibre exported—show a material increase in volume and prices have been fully maintained. Everything points to a continued good demand for these products, and coconut land may be looked upon as one of the soundest local investments.

A., COCONUT OIL did not fluctuate as much as usual during the year, prices in Colombo varying from R315 to R330 per ton f. o. b. Shippers have practically ceased sending oil to London and New York for "spot" sales, and the almost entire absence of unsold stocks at these ports has kept exporters in Ceylon well supplied with orders. Exports show an increase of 2,149 tons over 1899, the increase being principally for U K and India. As the year closed, value of f.o.b. oil was R325 per ton. 1892 still remains the record year for export of coconut oil.

B., COPRA.—The increase in export for 1900 was 1,853 tons, principally for Germany, Austria and Italy. Russia and United Kingdom show a falling-off. Prices generally have been good, and during the last three months of the year ran very high, the arrivals not meeting the demand for export. Extreme prices led to eagerness on part of growers to get copra into Colombo before reaction set in. This led to imperfectly dried copra arriving, the loss in weight on which must be a serious item for shippers.

C., POONAC.—With an increased export of oil, we must of course, be prepared for an increase in shipments of coconut cake. The export for 1900 was 9,299 tons against 8,739 tons for 1899. Prices dropped during the last six months of the year from R80 to R70 and the outlook for 1901 was not very promising.

D., DESICCATED COCONUT.—The export for 1900 was 13,604,913 lb. against 13,571,084 lb. for 1899.

E., COCONUTS.—A large increase in nuts exported took place last year, the figures being for 1900, 14,995,909 nuts against 11,723,392 nuts for 1899, the increase being practically divided between U. K. and Egypt.

F., COIR ROPE, YARN AND FIBRE.—All these show an increase in volume exported, and prices have also been well maintained.

COFFEE.—This product in 1899 had improved somewhat over 1898, but figures for 1900 show even smaller exports than for 1898.

ESSENTIAL OILS.—There is not much change to record in these oils.

PLUMBAGO.—The fall in values indicated as taking place at the close of 1899 continued steadily during last year, notwithstanding a large decrease in quantity exported. In 1899, 30,819 tons were exported against only 19,167 last year. The principal decline in offtake was to U. K. 2,821 tons, Germany 1,159 tons and America 6,905 tons. The restricted local demand led some dealers to consign portions of their stocks to London and elsewhere for sale, a course of action more than any other calculated to depress the market and force prices down. Shipments of an article like plumbago

unsold, generally mean sacrifice, and only form a lever for buyers to force down prices. Values still paid locally are, however, good when compared with those ruling some three and four years ago, and many pit owners must still be getting good returns.

The extreme prices paid for plumbago towards the close of 1899 and early in 1900 led to a rush after plumbago land, resulting in absurdly high prices being paid for land and leases, and to pits being opened up recklessly. In many cases efforts have not only been unsatisfactory, but in some instances have had disastrous financial results. Quite a number of pits were abandoned during the latter half of 1900.

The following comparative table of quantities and prices at close of last two decades are interesting :—

In 1890 exports aggregated 19,287 tons, in 1900 19,167 tons and the following were respective values per ton.

	In Dec. 1890	In Dec. 1900
Large lumps	R170 to R250	R400 to 650
Ordinary lump	125 to 225	200 to 600
Chips lump	60 to 130	125 to 400
Dust lump	30 to 85	75 to 225

TEA.—This staple article is kept so constantly in print, that all our readers must feel well nourished. so far as "facts and figures" are concerned. A return to better teas from medium and low-country estates will, in course of time, remedy the disastrous state of affairs ruling as the year closed. Closer supervision is wanted in many factories as the samples of "estate bulking" go to prove. If one portion of the factory work is not carried out properly, it is natural to conclude the manufacture of the tea is not receiving proper supervision.

The following are Exports for the year 1890 and for the past three years :—

	U. K.	Continent.
1890	43,756,912	92,839
1898	96,133,833	3,591,106
1899	103,948,124	4,835,938
1900	113,760,193	10,213,169

	Australia.	America.	Other ports.
1890	2,559,901	204,223	287,679
1898	15,126,891	2,180,188	2,737,053
1899	15,606,833	3,080,002	2,423,259
1900	17,606,912	3,980,680	2,870,685

	Total.
1890	46,901,554
1898	119,769,071
1899	129,894,156
1900	148,431,639

EXCHANGE did not fluctuate suddenly during the year. The following is range of quotations.

6	m/s	credits	1/4 23-32	1/4	1-4
3	m/s	do	1/4 5-16	1/4	5-32
3	m/s	D. P. Bills	1/4 5-8	1/4	7-32

IMPORTS.

Exchange fluctuated to some extent during the past year, demand remittances ranging from 1/3 15-16 to 1/4 5-16 and 30 d/s paper London on Colombo ranging from 1/3¾ to 1/3 7-8. Money was easy most of the year, local discounts ranging from 4 per cent to 9 per cent. As the year closed discounts were firming up and with large crops to finance in India and Burma during the next few months, we may expect money locally to be very dear.

COTTON GOODS.—The American cotton crop of 1900 fell far short of expectations, resulting in dear cotton all through the year. Mid Uplands ranged from 4d 13-32 per lb in January to 7d 3 8 in September. As the year closed, the price had gone back to 5½d per lb.

Dear cotton means dear cloth, and prices for all grey, white and coloured goods advanced with the rise in cotton. The higher the price, the more restricted the off-take, and 1900 was no exception to this rule. Only 3,088 packages cotton goods were entered for home consumption during the first eleven months last year, compared with 3,821 during the corresponding period of 1899. Locally, prices were generally unsatisfactory compared with costs laid down at Colombo.

The following figures show the importation for the first eleven months of 1900 and 1899 :—

	1899.	1900.
Grey cottons, bales & cases	2,628	5,198
White do do	2,259	4,135
Printed do do	1,142	835
Dyed do do	91	1,720
Coloured woven do	9,572	7,441
Sundry	112	81
Yarns, plain	1	30
do dyed	171	102
	15,976	19,542

WOOLLEN GOODS.—There is a growing tendency among the European as well as among the better-off Natives and Burghers to discard the time-honoured white drill suits for flannel clothes. This change has led to a large importation of coloured flannel. The initial cost to the buyer is greater, but in the end the flannel suit is perhaps the more economical and the better.

TOBACCO.—The importation of manufactured tobacco has increased considerably, due no doubt to a great extent to the influx of Boer prisoners and their guard.

MALT LIQUOR AND SPIRITS.—The following figures show the quantities bonded and entered for home consumption during the first 11 months of last year compared with 1899.

Bonded.	In 1899.	In 1900.
Malt Liquor, in wood, h'hds	1,615	1,223
do glass, cases & casks	545	130
Brandy cases	1,962	1,741
Gin do	7,296	5,986
Whisky do	5,671	5,437
Entered for consumption :—		
Malt Liquor, in wood, h'hds	1,692	875
do glass, cases	205	482
Brandy cases	2,055	1,881
Gin do	6,056	5,349
Whisky do	5,362	4,255

It will be gratifying to those who are interested in temperance movements to note the large decrease in quantities of all spirits entered for consumption last year compared with 1899. The free consignments of cheap unmatured whiskies which were made some years back are gradually being liquidated, and whisky exporters of any standing are devoting their energies to the sale of the better brands.

MATCHES.—The quantity imported last year exceeded requirements and prices obtained locally were frequently under laid down cost,

CEMENT.—Owing to rise in freights from Europe eastward, prices of cement advanced about 1s per cask. With an article like cement freight is perhaps the chief factor in quotations.

METALS.—A fair business has to be recorded in most of the standard importations. Prices gave away considerably for all iron and steel goods, chiefly due to drop in prices in U.K. following an exceptional output in the United States. The following show some of the chief fluctuations in prices laid down Colombo Harbour.

	Jany.	July.	Dec.
Scotch iron	R165	175	150
4 oz. tea lead	„ 370	375	380
Hoop iron	„ 240	230	220

RICE.—Prices ruled high during last year. In January good Soolye could be got for R3 to R3-10 per bushel, but prices rose gradually, and as the year closed the value of this rice was from R3-50 to R3 75 per bushel. Bumper rice crops are expected in Burmah, and Bengal, and if anticipations are realised prices will become easier. Cheap rice will be welcomed by all Tea Estates, many of which cannot now afford to write off monthly "losses on rice."

COALS.—The "Chinese Embroglio" led to a large number of warships and transports from Europe calling at Colombo to coal last year. The extra demand coupled with a rise in value at home led to exceptional prices being paid for ready local delivery. Prices eased off towards the close of the year and are now quiet but steady. The imports of Indian coal still continue to increase. In 1899 there were 151,468 tons of Indian coal shipped from 1st January to 30th November from Calcutta to Ceylon, whereas last year for the corresponding 11 months the quantity was 297,803 tons, showing an increase of nearly 100 per cent in one year.

SHIPPING.

CEYLON EXPORTS IN RELATION TO FREIGHT AND TONNAGE—1890-1900.

The following figures—compiled from the Chamber of Commerce annual returns of exports and shipping—give the quantities of cargo exported from Ceylon, and the number of vessels by which this cargo was shipped. The figures for cargo exported are however reduced to "shipping tons" according to the Ceylon Tonnage Scale.

Readers will bear in mind that cargo transhipped at Ceylon is not included in these returns.

In	Vessels cleared with cargo.	Shipping tons cargo taken.	Average tons taken per vessel.
1890	698	156,159	223
1891	872	174,316	200
1892	871	200,986	230
1893	848	197,823	233
1894	808	200,489	248
1895	784	213,843	272
1896	830	216,844	261
1897	756	245,830	325
1898	773	297,211	384
1899	856	293,507	343
1900	826	316,004	382

The net increase in shipping tons of cargo exported last year over 1899 and 1898 was 22,497 tons and 18,793 tons respectively. It is gratifying to note that since 1890 the tonnage of cargo exported has increased by 100 per cent. The following are the more noticeable fluctuations last year compared with 1899:—

		Tons.
Tea	shows an increase of	18,537
Coconnt oil	do	3,070
Copra	do	3,088
Coconuts	do	3,273
Coir rope, yarn and fibre	do	5,958
Cocoa	shows a decrease of	659
Plumbago	do	11,652

Grouping together the products of the coconut palm—coconut oil, copra, desiccated coconut, coconuts, poonac, coir rope, yarn and fibre—we find last year shows an increase of 15,983 tons, and the figures following are those for the last decade:—

	Tons.		Tons.
1891	69,879	1896	80,570
1892	94,550	1897	100,614
1893	79,935	1898	139,334
1894	85,711	1899	119,154
1895	84,567	1900	135,137

Of the total exports last year—

Tea gives	47 per cent.	of shipping tons
Products of the Coconut palm	43 do	do.
Other products	10 do	do.

These figures very clearly show how important the Tea and Coconut plants are for the shipping of Ceylon. If the Planting community have suffered from over-production of teas, they have provided shipping with a large increase of fine cargo.

The number of vessels which cleared *with cargo* last year was 826 compared with 856 in 1899. The supply of tonnage has been ample during the year to all countries, with the exception of Australasia. The carrying capacity of vessels running on regular lines touching at Ceylon continues to increase as new steamers replace those taken off.

Freights ruled low all the year round except to Australasia, as will be seen from the following table:—

	Rough Cargo		Tea.	
	Max. rate s	Min. rate s	Max. rate s	Min. rate s
London	25	15	30	25
Antwerp	20	15	30	20
Hamburg	22-6	17-6	30	20
Marseilles	20	12-6	30	20
Genoa	25	20	25	20
Trieste	27-6	25	30	30
Odessa	40	35	40	40
New York	35	32-6	37-6	35
Melbourne	R50	R40	R50	R40

The raising of rate of freight from R40 to R50, combined with want of regular space available to the main Australian ports, has had a depressing effect on many of the local tea sales. Australian markets require Ceylon tea to arrive regularly, not occasionally in excessive quantities. Every effort should be made by exporters to secure a resumption of regular tonnage for tea to Australia. The following are fluctuations in rate of freight on tea to London during the last decade:—

	Max.	Min.			Max.	Min.
1891	45	27·6	..	1896	25	7 6
1892	35	15	..	1897	35	10
1893	30	12·6	..	1898	40	20
1894	35	20	..	1899	30	25
1895	30	17·6	..	1900	30	25

Native vessels and vessels which cleared without cargo from Ceylon are not included in these returns.

EXTENSIVE COCONUT PLANTING IN THE MALAY STATES.

Messrs. Price, Boustead & Co., of London, who have taken up 5,000 acres of land at Kuala Pahang for coconut planting, have had a large area cleared and nurseries laid for 20,000 plants. —*Perak Pioneer*, Jan. 3rd.

THE RIVAL CLAIMS OF TEA CHESTS.

The following is the full text of the letter addressed by the Tea-buyers' Association, London, to the Indian Tea Association, London, relating to Patent Tea Boxes :—

I am instructed by my committee to call the attention of your Committee to the very undesirable packages in which Indian and Ceylon teas are being packed.

They believe that arrangements are now being, or are about to be, made by the gardens for next season's crop, and they feel that now is the time to put on record their opinion as to the most desirable package.

No doubt merchants are entitled to pack their teas in any kind of package they like but, nevertheless, my Committee think that buyers are entitled to say what in their opinion is the most suitable.

At present there are several kinds of package in use, viz , wooden chests with leaden linings, Venesta chests, Colinda chests, Esma Colinda chests, and Acme metal and Acme veneer chests. There may be others. Of these mentioned my Committee are of opinion that the old wooden chest, with a good lead lining, is the best. None of the others are free from serious objection. Metal chests, they consider, are the most unsatisfactory. It is a well-known fact that metal is a good conductor of heat and cold, and tea packed in metal chests is subject to every change of temperature. There is a certain condensation on the metal at times which tends to give the tea a weathery flavour.

The tops and bottoms of these metal chests are very easily knocked out and; very frequently, buyers find several pounds of tea wasted in their vans. Neither are they good for repacking, and they cannot be cut down, or made smaller.

The Acme Veneer chest has, my Committee believe, been condemned, and will not be used after this season, but they understand those who are using it at present propose using the Acme metal chest instead.

The Venesta, Colinda, and Esma Colinda are very much alike, being made of three Plywood and having a thin lead lining. They are much too weak, and are easily broken and punctured. If they were made of stouter material and stiffened at the corners with battens inside, they would be much better. The leads used are frequently so thin, as to be of no protection, and my Committee are confident that the interests of the importers are considerably damaged by the use of such.

The reason why merchants are using these patent packages is, my Committee believe, because of the difficulty of getting wood; but they are assured that an unlimited supply can be obtained from Sweden, and it would cost no more than the patent packages.

I therefore desire to reiterate that the most satisfactory package is the old wooden chest with sufficiently thick lead lining, and some members of this Association have informed the Committee that they will not buy tea packed in any patent package, if they can possibly avoid it.—(Signed) J A Brown, Secretary.

UNITED STATES TEA EXPERIMENT.

For three-quarters of a century, attempts have been made to make tea-growing a profitable industry in the United States. At the South Carolina Experiment Station, Doctor Shephard is endeavouring to utilize the labor of idle colored folk, including children, with fair success. In his annual report to Congress, Secretary of Agriculture states that the experiments so far conducted have shown that tea may be produced in the United states in two ways: First, by families in their gardens, as was demonstrated years ago to be entirely feasible; second, on a commercial scale, after the manner followed by the British East Indian tea establishments and the beet-sugar industry.

In the future special attention will be given to manufacture of pure green tea. This subject is now claiming the attention of both inventors and planters in the British Colonies, as they begin to realize the hopelessness of bringing American tea drinkers to use the black tea instead of the green. The manufacture of green tea in the United States can be made successful only by the invention of machinery which shall take the place of expensive hand labor and prevent the waste which accompanies the latter. The questions are all being investigated by the Department, and, in addition, it is giving special attention to a study of the conditions in various parts of the South, with reference to determining the localities where tea can be grown to best advantage. Experiments have been inaugurated by some of the experiment stations, and plants distributed with a view of putting the work on a substantial basis. Much need is felt for young men capable of taking up this important problem, and it would be well for the agricultural colleges of the South to bear this matter in mind.—*American Grocer. Dec.* 12.

GOOD WISHES FROM A PLNTER AT HOME.

Glasgow, Dec. 6.—I see by the weekly *Observer* which reached me a couple of days ago, that you have been celebrating your 40th year of work in Ceylon, and that appreciative notices have appeared in the local press. I am not a whit behind anyone in my high estimate of the value of these services, and though late in the day would desire to add my voice to the general acclaim. A lot of the time you have been in the island I also cover, and all during that period I have always held that the *Observer* whose, free public life-work is most prominent has been consistently a high-class paper—with a conductor that had a conscience. May you have many more years ahead of you to continue your good work for the public weal, and may the public appreciate it in the form of supporting the journal—as it ought to do.

SPORT IN THE SOUDAN.

NOTABLE HUNTERS GOING OUT AFTER BIG GAME.

Paris, Dec. 28. Now that the Soudanese Government have afforded facilities for transport to Khartoum, several noted sportsmen are preparing expeditions to hunt and shoot over the territory bordering the White and Blue Nile. Big game such as elephants, rhinoceroses, and buffaloes are plentiful in this region, and French sportsmen are keen on being among the first in the field. One notable sportsman, Prince Peter of Arenberg, [who came to Ceylon on a shooting trip a little over a year ago.—Ed. *C.O.*] has already arranged to go out to the Soudan with several friends and proposes starting immediately for Cairo.—*Daily Express.*

SNAKE POISONS AND ANTIDOTES.

Captain R. H. Elliot, I M S, delivered an interesting lecture a few days ago on "Snake Poisons and their Remedies" to the members of the Madras Young Men's Christian Association. In the absence of Dr. J. R. Henderson, of the Madras Christian College, Mr. G. Benton Smith presided. Dealing with antidotes to snake poisons, Captain Elliott said that the fallacies that occurred in connection with snake poision antidotes were innumerable, almost unbelievable, almost every village claimed to have unfailing remedies, most of them vegetable preparations for snake poison! People were never in doubt as to their efficacy; in fact they represented that they had tried and tested them and effected several cures with them. Several natives had come to him with such preparations and he found them all, by repeated experiments, absolutely worthless. The several so-called cures they had effected with the preparations had either been scorpion stings, pricks by thorns or by sharp stones, or bites by harmless snakes. He invited the many natives who came to him with "unfailing antidotes" to submit themselves to an injection of a dose of lethal poison and then prove the effect of the cures on their own persons. Needless to say that the invitation was never accepted. In this connection he dealt with Professor Muller's strychnine cure. He pointed out that Muller talked nonsense when he spoke of strychnine being an unfailing cure. From hundreds of experiments he (the lecturer) had made with strychnine on different animals, he found it to be absolutely useless. Professor Muller's remedy had now been exploded altogether. In fact it was found that, in a large number of cases, victims of snake poison had been killed more by the administration of the strychnine than from effects of the poison itself. An injection of ammonia as well as the swallowing of it were also spoken of as antidotes, but he was convinced that this was also useless. Alcohol was equally useless as an antidote; on the other hand it did harm. Referring to the immunity of snake charmers, he was inclined to think that some of them had obtained a certain amount of immunity by rubbing small quantities of poison into abrasions in the skin. They had a wonderful control over snakes which had, like horses, to be approached and treated gently if they were to be kept under control. The mongoose had a very large amount of immunity. He was not then sure of the exact figure, but he believed that a mongoose, weight for weight, would require, to kill it, 25 times the amount of poison which would kill a rabbit. The pig also was somewhat resistent to snake poison. Peafowl and guinea-fowl which were commonly credited with immunity, were no more so than other animals. Cats and dogs, which were also credited with immunity, owed their reputation to the same cause as snake-charmers, namely to their wonderful dexterity.

The serum of the Russel viper was to some extent antidotal, but its antidotal powers were not sufficiently powerful to make it a marketable product. Besides there was a certain amount of risk in obtaining serum from snakes. The same was the case with the mongoose which was a very difficult animal to deal with. The serum of the horse contained certain protective properties out of which was prepared the anti-venine which was tried and found to be a good antidote against snake poison. But to his mind the hope of the future in this matter lay in separating from the snake poison itself its own antidote. It would be difficult to tell them exactly how he thought it could be done. He thought it was possible that in snake poison itself there was not merely a lethal matter that killed, but side by side with it, at all events separable from it by heat and chemical processes, there remained a remedy which would be very powerful as an antidote. He thought that possibly one might be able by very careful experiments to separate such a remedy from the bile of the snake. There was quite enough to encourage them to think that there was a possibility that either from bile or serpent serum, or possibly by inoculating these into a resistent animal, they would be able to obtain a body which would be more powerful and stable than anything that they possessed at present as an antidote.

Captain Elliot then exhibited to the audience snake poison in a small bottle; which, he said, was the largest collection of snake poison in the world.—*Pioneer.*

RAMIE FIBRE.

A PLANTER ON A BIG SCALE.

Among the passengers stranded in Ceylon for a fortnight or so, by the break-down of the French steamer "Sydney," is Mr H. C. Bluntschli, of Siak, Sumatra, who for seven years has been giving his attention to the cultivation of fibre-yielding plants, chiefly Ramie, and the preparation of the fibre therefrom. Mr. Bluntschli (who has, for many years, been a reader of the *Tropical Agriculturist*), has just returned from Europe, where he has been making a systematic study of fibres in many of the Continental centres of manufacture as well as in Bradford and other places in the United Kingdom, and he has entered into an advantageous contract for a steady supply of his raw product. Mr. Bluntschli says the great matter is to get the right plant to grow (and he purposes visiting China to see some of the fibre plants there, specially China Grass.) He cuts a crop from his Ramie fields every six weeks—save that twice a year or so there is a rest from growth during the dry weather. The machines he uses gives from 1 to 3 per cent of clean fibre fit for shipment, while some use is made of bye-products. Mr. Bluntschli has experimented with pineapple fibre, getting £30 a ton for two tons to Europe, with an order for any quantity; also with Aloe and other plants. But he deems Ramie, so far, the best and most profitable—the drawback, however, for the planter being that there are at present so few buyers, most of the Bradford spinners, after certain unfortunate experiences, refusing to touch Ramie. Mr. Bluntschli is to send us his latest report on the subject. He is to visit each of the local Botanic Gardens and Kandy and Nuwara Eliya, and we bespeak attention, hoping he will have a pleasant and interesting time. Our visitor, who is a Swiss, speaks English well; and we only wish we had a capitalist of his calibre to develope a new industry in fibres in Ceylon.

OUR TEA EXPORT FOR 1901:

CEYLON LIKELY TO SHIP LESS THAN IN 1900 BY 5 OR 6 MILLION LB.

SUCH is the belief of Messrs. Forbes and Walker (who estimate our total export of tea at 142 million lb. of which only 100 millions are likely to go to London) and this, we think, is a very reasonable calculation, considering the general determination to be more careful about plucking and the probability of poor fields being abandoned, apart from the proposed "ten per cwt." reduction taking effect. Our leading Colombo Tea Brokers deserve credit for the promptitude with which they put forward their Tea Exports Estimate each year; and it will be seen from the following table that, although on the whole they have been farther from the mark than the Planters' Association—due perhaps to any revision on their part not being taken into account,—yet, in two seasons at least, their estimate was nearest to the actual result. In the following table we cannot give the P.A. estimate for 1901, because it will not appear for some days yet:—

CEYLON TEA EXPORTS.

	Estimated by Planters' Association.	Estimated by Messrs. Forbes & Walker.	Exports as per Chamber of Commerce Returns.	Exports according to Customs Returns.
	lb.	lb.	lb.	lb.
1901	—	142,000,000*	—	—
1900	142,000 000	125,000,000	148,431,639	—
1899	125,000,000	124,000,000	129,894,156	129,661,907
1898	120,00 ,000	120,000,000	119,769,071	122,113,573
1897	119,0 0,000	105 00 ,000	116,054,5 7	114,466,318
1896	101,000,000	89,000,000	108,141,412	11,0095,358
1895	90,00 ,000	90,000,000	97,939,871	98,581,060
1894	88,000,000	90,000,000	84,991,714	85,376,322
1893	77,000,000	78,000,000	84,406,064	82,269,353
	"Observer" Office Estimates:			
1892	80,000,000†		71,153,657	72,279,984
1891	68,000,000		68,274,429	67,719,371
1890	46,500,000		46,901,554	45,799,512
1889	32,000,000		34,048,085	34,345,859

It may be explained that the Customs enter the exports as each shipment is put on board a vessel in the harbour: while the Chamber only takes cognizance of the vessels and cargoes as they clear from the port.

Seeing that 34,671,446 lb. of our crop in 1900 went to Other Countries than the United Kingdom (or an increase of 8,725,414 lb. over 1899), it is a very reasonable estimate to put down 42 millions as going to Other Countries in 1901. But that would leave only 100 million lb. for London against 113,760,193 million lb. sent in the past year—or a decrease of nearly 13¾ million lb. So mote it be; for certainly that would be a great relief. We see the next Indian Tea Crop is spoken of as likely to be 5 million lb. in excess from new acreage in hearing; but that more than this is likely to be reduced through careful plucking, so that the London market in 1901 should see no surplus of tea supplies from either Ceylon or India.

* Of which 100 million lb. to United Kingdom; and 42,000,000, to Other Countries. † Planters and merchants whom we consulted were greatly out in their anticipations, for this year.

THE PAST YEAR'S TEA TRADE.

In Messrs. Gow, Wilson and Stanton's circular which we issue as a Supplement, some interesting observations are made regarding the progress of the Indian and Ceylon tea trade during the past year. The total crop for export is estimated to reach 325,000,000 lb. (183,000 lb. being from India and 140,000 lb. from Ceylon) as against 305,000,000 lb. in the previous year; while the consumption at home and abroad was 310,000,000 lb. so that there was a surplus production of 15,000,000 lb. or two millions less than in the previous year. Reference is made to the adverse effect which the increase in duty has had upon the industry, and on the other hand to the satisfactory increase (13,000,000 lb.) that has taken place in the quantity taken by new markets, the greatest expansion being in Russia, and to the relief afforded by the reduction in warehouse charges. Dealing with Ceylon teas in particular the well-known Rood Lane brokers express the opinion that the heavy crop was due to the unusually favourable weather for flushing and the extensive use of manure, and while they admit that the quality from some estates has been very good, they show that on the other hand there was a larger proportion of poor liquoring teas. The manufacture of green tea is considered likely to afford much relief to the industry by reducing the production of black tea. Planters are also counselled to avoid coarse plucking. Figures are given of the imports, deliveries and stocks since 1897-8, and those for last year are given up to November.

CONTINENTAL MARKETS FOR INDIAN TEA.

(To the Editor of the *Home and Colonial Mail.*)

SIR,—A good deal of interest attaches to the recent resport by Mr. Harrington on "The Position and Prospects of the Continental Markets for Indian Tea." The real hope for the future of Indian tea lies in those markets. I have been a planter in India for many years, and have watched with much interest the gradnal development of the market for our teas in England itself. One thing which has all along struck me forcibly is that our Indian teas cannot force any market by a direct frontal attack. In England we had from the first a great deal in our favour, from the mere fact that Indian tea is grown by our own countrymen and with our own capital, but for all that it took many years to educate people up to the fact that the Indian article was better than the China. People now fully acknowledge that it was only by *blending* Indians with Chinas that the market was captured at all; so that until about eight or ten years ago it was practically impossible to buy pure unmixed Indian tea in any town outside London.

It was the same with the American campaign: no success attended the efforts of the commissioners for India and Ceylon until they worked through the *existing trade*, and subsidised the *dealers* who were already in possession of the market for Chinas, when they made purchases of Indians, either for selling pure or for blending as they might think fit.

The frontal attack is an old mistake, but it is still being repeated. The Indian Tea Association is attempting to force the consumption of our tea on the Continent in direct opposition to the merchants engaged in the China trade; even Mr. Harrington still clings to the idea, although he admits that the only progress made hitherto has been by blending, and, what is more, that the only hope in the future for strong Assams is by blending. Then further on in his report he makes a sort of forced admission that "blending with Ceylon or even China leaf should not be entirely barred."

In the Continental market we have to face three things:—

1. The general dislike of everything British, and the jealousy generally regarding our Colonial possessions and trade.

2. The existing taste for China tea, as distinguished from Indian.

3. The merchants engaged in the China trade.

The third item is by far the most formidable, if we attempt to set up an "opposition shop."

Let the committee of the Indian Tea Association modify its policy. Don't *push* the establishment of separate houses for the supply of pure Indian tea, but work mostly through the merchants already in the tea trade; bring persistently to their notice the *fact* of the superiority of our teas for *blending* purposes. In doing this a double purpose will be served—the consumer will be gradually trained to appreciate a stronger and better tea, and the merchant will gradually use a larger proportion of Indian, until in course of time there will be no China left in his canister; our tea will beat it purely on its merits.

This has been exactly the course of events in Great Britain, in the Colonies, and will be everywhere.—

Yours faithfully,

C. B.

—*H. and C. Mail*, Dec. 28.

TRAVANCORE GREEN TEAS.

TO THE EDITOR, "INDIAN GARDENING AND PLANTING."

Sir,—As I have just despatched a small invoice of green teas to America I send you as promised a set of samples. Of course the teas are by no means extra fine, being made from ordinary medium pluckings, and as the hot weather is somewhat against manufacture of green tea leaf are almost certain to get a small amount of fermention while in transit from the field. Of the quality of the leaf there is little to be said, as it is very ordinary, but I venture to say the teas have the characteristics of true green teas of Mysore character.

One set of samples are plain, the other set of *the same tea* but slightly glazed. We are shamefully treated I consider, in that owing to the red tape rules of the I P A we are in practice debarred from getting "the grant-in-aid." Theoretically we can do so by sending samples to Calcutta from our shipping agents at Cochin, but we are told that the teas must *not be shipped* until the samples have been reported on and results made known, otherwise we lose the grant: this would mean a delay of three weeks at least and, if a steamer was missed during the interval, perhaps seven or eight weeks.

Common sense, one would think, would suggest that, the samples having been drawn and despatched to Calcutta by the Cochin agents, the teas might be allowed to depart by first steamer, the grant-in-aid being sent to the shipper if the teas passed the standard. Unfortunately, no one here but myself takes any interest in the question, and I am looked on as a sort of lunatic with a fad, but I venture to prophesy that within two years (unless prices mend, many will be making green tea for sale, of which there is a considerable scope in Canadian, American, and Russian markets. Later on, when the rains commence, I hope to go regularly at it, and then I shall send you samples of some really fine teas for price.

H. Drummond Deane.

Stagbrook, Peermaad, Travancore, S. India; 2nd Jan. 1901.

REPORT ON MR. DRUMMOND DEANE'S GREEN TEAS.

TO THE EDITOR "INDIAN GARDENING AND PLANTING."

Dear Sir,—We have the pleasure to hand you our report, on your samples from Stagbrook Estate.

(Glazed) Young Hyson.—Well twisted greenish glazed Pekoe leaf, fair tip, pure pungent flavoury liquor, valuation nominal.

(Glazed) No. 1 Hyson.—Well curled glazed Orange Pekoe leaf, good tip, pure pungent flavoury liquor, valuation nominal.

Imperial.—Rather flat greenish Pekoe Souchong leaf, pure pungent flavoury liquor, colour of infused leaf is good.

No. 1. Hyson.—Well twisted greenish wiry Pekoe, fair tip, pure pungent flavoury.

Young Hyson.—Very well twisted Pekoe leaf, good tip, pure pungent flavoury.

(Glossed) Imperial.—Flat greenish Pekoe Souchong, leaf pure pungent flavoury, colour of the infused leaf is good.

These are as fine samples as we have seen of true *Namuna* green teas. They have not the appearance of green teas, as manufactured in China, but in our opinion, it is a matter of future experience whether the American market will take such teas on their merits in preference to teas made on the old fashioned China methods. The only way to arrive at this is by selling an invoice in America, and we are confident such pure liquoring teas would meet with a favourable reception.

MORAN AND CO.

3, Mango Lane; Calcutta 9th Jan. 1901.

TEA-GROWING IN HUNGARY.

The example of Russia has inspired Austria-Hungary with a belief that she can "grow her own tea." On the initiative of Count Zichy, who recently returned from a tour through Asia, the Hungarian Minister of Agriculture ordered that trials should be made in various parts of the country with tea plantations. With this in view, large quantities of seeds, together with about one thousand tea plants, were imported from Shanghai; but, notwithstanding the utmost care, the plantations have been failures. According to exports, when the selected plants arrived at Fiume, they were more fit for burning than for planting. The Agricultural Department has not yet given up the hope of obtaining favourable results, and has decided to make fresh attempts; for which purpose plants have been brought over from Tiflis. These have been distributed throughout Hungary to the State nurseries.

—*Planting Opinion.*

CARDAMOMS IN INDIA.

A report by Mr. J. W. Mollison, Deputy Director of Agriculture, Poona, according to an Indian contemporary, claims the cardamom plant to be indigenous to Western and Southern India. It is found in abundance in Kanara, Mysore, and Travancore, and as here, affects rich, moist, forest soils—the essential conditions for successful cultivation being "a soil of loam or clay loam consistence, kept moist by favourable position, but not wet at all seasons; and the garden should by

its natural situation be protected from strong winds, and shade trees should be provided." We suppose there is nothing new in this description; and Ceylon Planters have little to learn from it, and must only wish that they could always command the above conditions. They have, however, succeeded with much less, though always appreciating sheltered nooks and shady ravines for the cultivation. The cardamom is not a product about which much is written now-a days. Its cultivation and preparation do not call for much skill; and those who are in it prefer to keep their own counsel, with their profits! Outside our Executive Council, it would be difficult to find ten men who think that the product is, in any sense, in the experimental stage. Still, it is interesting to learn that in Kanara the crop is chiefly raised from seed, while elsewhere the rhizomes used for propagation are subdivided and planted with their leaves attached in 18 inch pits filled with leaf mould. Little guidance is obtained from the statement that a well-grown plant yields up to half-a-pound of dry cardamoms, as we know what such statements mean with coffee, or any other shrub or tree. It is the average yield which decides the profit and not any exceptional feature.

The statement, however, that the cultivation of cardamoms is attended with considerable risk, is one which it is well to bring to the notice of our readers, as prevention is always better than cure, and precautions against disease to which all plant life is liable can be taken without feeling or causing alarm. Our readers will please note that: "In most of the Kanara gardens a so called disease has appeared in the cardamom crops and is restricting cultivation. The affected plants do not present any particular indications of disease, but simply do not thrive. The leaves in parts become yellow and wither. The effect is that the plants have no vigor of growth. It may be taken as certain that the cardamom, like any other cultivated plant, degenerates when grown for long periods under precisely the same conditions of soil and climate and without any change in methods of propagation or reproduction. The vigour of any cultivated plant may be renewed from time to time by change of soil, change of seed, by rotation of crops and by other regenerating influences. The Kanara cardamom crops have for a long period been grown without any changes in the system of manuring, propagation, and general cultivation, and Mr. Mollison is of opinion that the diseased conditions referred to have been induced by these causes. However, within recent years, borers and grubs have caused considerable damage to the cardamom crops, and the cultivators assert as a reason, that they have been prevented by forest conservation from using for leaf-mould the leaves and twigs of certain trees containing astringent properties and incapable of harbouring insect life. It is of interest to note that snakes and rats are particularly fond of the fruit of the cardamom plant." And so are porcupine and Kandyan villagers!

RUBBER.

SUMATRA RUBBER.—I have received a circular from the Tandjong Kassau Estate in Sumatra, giving particulars of the cultivation of rubber on the Bander Betsy Estate. This estate is situated next to that of the Russian American India-rubber Company, and a large number of Ficus Elastica trees have already been planted. Samples of the rubber already obtained can be had from Mr. J. Pot, Almaar, Holland.

RUBBER, IN JAVA.—A meeting of coffee planters has been held at Malong, in Java. A German scientist addressed the meeting upon the subject of rubber cultivation, and admitted that it would hardly pay on a large scale; but mentioned that a factory had been started in Singapore for preparing gutta from leaves on the Ledeboer system. One of the planters at the meeting, however, stated that the company had failed to raise the capital for the scheme, and that no share had been taken.

RUBBBER IN GAMBIA.—The report of the Administrator of Gambia for the past year gives a highly favourable description of the conditions of the colony. The revenue was £46,840, and was the largest on record, while the expenditure was £30,405, so that at the end of the year the accumulated surplus was £43,490. There is a large decrease in the exports of rubber on account of the practical extinction of the rubber plants by ignorant persons who wander about rubber-cutting in the bush.

RUBBER IN WEST AFRICA.—Under the auspices of the African Section of the Liverpool Chamber of Commerce Mr. P. Hitchens, forest inspector Southern Nigeria, read an address at the Sale Room, Exchange Buildings, Liverpool, on the 3rd instant, on the district of West Africa, known as Benin City Territories. In the middle delta there are palm oil trees, cane, etc. In the upper regions there were no forests—there were grass lands, and here and there were to be found patches of rubber trees. In the middle belt also gutta-percha trees had been found, and next year he hoped large quantities would be shipped from the ports near to the Benin City Territories. Having explained the method of tapping rubber trees and the means taken to preserve the trees from destruction, he said that seeds of rubber trees had been planted along four hundred and fifty miles of road and the seedlings were now growing, and would ultimately grow four deep along this length of roadway. The value of the yield at 2s per pound would be about £140,800. This plan would, he thought, solve the problem of the reafforestation of West Africa.—From *India-Rubber Trades' Journal*. Dec. 10.

SNIPE IN BANGKOK.

Let others talk of the glories of grouse and indulge in rapturous talk about the purple heather, and all other delights of Highland shooting. We are satisfied for the nonce with the bonny little snipe. Imagine the holy calm that reigns on a Siamese landscape as the sun, for a few short minutes heralded by the grey dawn, gilds the smiling fields of green rice and the tops of the palms and feathery bamboos. The air is fresh and bracing, and the matutinal cup of coffee and modicum of fruit are eagerly welcomed. Brilliant drops of dew like rare jewels deck every blade of grass and giant leaved shrub; and these brushed by the sportsman's nether garments from the knee-high verdure strike with an icy chill to the skin. No time is lost in sallying forth and before a dozen steps are taken into the paddy the first brown patch, hardly distinguishable in the uncertain light, whirrs up at the sportsman's feet and with a "tweet," "tweet," is soon lost in rapid flight quite oblivious of the ill-directed

storm of pellets that are sent to arrest his retreat. Another few steps and another bird rises and then another, but the eye of the destroyer is too quick for these and a couple of well-directed shots lay them, with wings outstretched, on the water from which they have just risen. The day has now fairly begun and, only diversified with the advent of an occasional land rail, a plump teal, or perchance a gorgeous truncated pheasant, the fun becomes fast and furious and the bright eyed, elegantly marked little snipe plentiful in the hand of the nimble attendant. Indefatigably the work goes in till near noontide when heat and exhaustion call for a halt under some spreading clump of bamboos or peasant's homestead, where, lost in dreamy indolence superinduced by the cool zephyrs rustling through the foliage, the eye wanders over the peaceful picture, the glorious tints of orange, rich brown, and amber. Then, the basket contains the modest lunch, consisting of a little curry, a sandwich and some fruit with a bottle of some innocuous beverage. With such simple fare the true sportsman is content. But a truce to reveries—after an hour's rest he sets forth with renewed vigour until the lengthening shadows remind him of the necessity of returning. Then as the day wanes he can reach home, tired and foot-sore, may be, but feeling brimful of health and spirits, able to do ample justice to his dinner, conscious that he has worked for and shot his game like a man.—*Bankok Times*, Dec. 28.

HOW TO MAKE TEA—AND SELL IT.

A correspondent, writing to a home medical journal, asks how tannin can be eliminated from tea. We presume the inquirer follows the usual method of allowing his view [hrew ?] to draw *ad infin.* When will it dawn on tea drinkers that stewing is not the proper method of treating leaf: despite reiterated advice a cup of drinkable tea is yet unattainable in Calcutta, from the can of the peripatetic vendor of *gurum cha* among the *ghariwans* to that dispensed by fair hands across boudoir tables. A tea kiosk at the Eden Gardens in the evening, and the neighbourhood of the Red Road in the morn, might stimulate consumption and teach our tea concocters a lesson. Have our agency houses ever heard of Lockhart's coffee rooms? or are they too genteel?—*Indian Planters' Gazette*, Jan. 12.

COCONUT OIL INDTSTRY OF THE PHILIPPINES.

ALSO SOAP, CANDLES, TANNERIES, AND OTHER INDUSTRIES.

(*Special Correspondence to the New York Reporter.*)

Iloilo, P. I., Oct. 13. 1900.

The new administration of affairs in the Philippine Islands has brought about many new and important changes in the industries of the former unsettled archipelago. This Spaniards always managed to keep the people of the country in such a turmoil that the owners of

THE LARGE COCONUT GROVES,

never considered it safe to operate anything more than miniature oil-producing plant in connection with their immense groves of coconuts. The proprietors of the plantations and the operators of the plant in which the cocounts were pressed for the purpose of securing the oily materials therein, were subjected not only to heavy taxtation, but were constantly in danger of destruction by raiders, looters and incendiaries. Your correspondent has interviewed very many former wealthy owners of immense cocoonut groves and copra preparing establishments, who are now poor because of various forces of insurgents or revengeful Spaniards who burned the buildings and destroyed the trees. With the advent of the new administration, however, not only is peace assured to these industrial pursuits, bnt the taxation is not so great as before, and the proprietors have some chance to make a good income from the business. In fact, some of the parties who have recently taken hold of the cocount oil industry in the Philippines are well on the way to success and prosperity. Evidently there is a grand opening here for the investment of capital in the immense tracts of cocoonut lands that may be found everywhere in the islands. These lands are often without ownership, and when owners appear, they can be bought off at ridiculously low prices. I have seen miles and miles of coconnt trees, all flourishing in first-class order, sold at the rate of about $1 per acre.

The coconut lands are in the low and rich soil of the island, of which there is an abundance. The trees grow from 50 to 100 feet high, and the natives can depend upon collecting crops frequently for the purpose of securing the meat of the fruit, the milk, the fiber of the husk, or the copra, the latter being obtained by cutting the meat into pieces and drying it. The oil is gotten by subjecting the meat to pressure as will be noted later. On horseback I have ridden for days along stretches of country in which the coconut groves are closely joined, every tree of full size and bearing considerable fruit without any cultivation at all, for the natives never give any time or attention to the trees, and go near them only to gather the fruits.

The natives

GET AT THE FRUIT

by ascending the tall trees by means of notches cut in the sides. They apparently walk up the trees with ease. Parties engaging in the copra or the coconnt oil business in the Philippines make it a point to first hire about ten natives for each grove of from ten to fifteen acres, and these natives are all capable of ascending the trees. They can be secured for ten cents per day. One or two other natives are needed to do a little cultivating and looking after the property.

The process of getting

THE VALUABLE OILS

from the coconuts consists in first procuring the coconuts from the trees. The fruit is made into large piles in the groves and is collected by other natives who operate the bull carts. The nuts are now taken to the bamboo sheds of the groves, and usually an owner of several miles of groves will have the sheds near the centre of all of the groves, and he will there have his office. A number of natives are employed at this point to remove the husks and the husks are by no means wasted, for they are spread in the sun for a few weeks until thoroughly dry, which causes the fiber to open and loosen to such extent as to permit the coconut fibre workers to rip the fibre off and work it into strands for the making of certain native yarns and fabrics. The sale of the husks brings in quite an income yearly. On a few coconut plantations I noticed that the proprietors made quite a side issue by working the fiber themselves, operating several looms weaving fabrics which brought in good profits. After the husks are removed from the coconut the shells are broken and the meat removed by another set of natives, all working for the extremely low price of from ten to fifteen cents per day and doing a good, full day's work at that. Furthermore the natives calculate upon feeding and lodging themselves at this low rate of wages, but a good proportion of their food comes from the coconut meat, of which they are fond. Most of the owners of the large groves also furnish quantities of rice for their help. As to lodging places, the natives drop to the floor or ground wherever they happen to be at dark and sleep

until morning. Some of the workmen have families, and these erect nipa huts in the locality and live there.

After the meat is cut out from the coconuts, it is chopped into bits by hand knives, mechanical devices fitted with rolls and parallelly arranged blades, and spirally fitted knives for accomplishing the same purpose.

THE CUTTING OF THE COCONUT MEAT

involves considerable work, and after it is done right, the meat is spread out in the sun to dry. One may see wide expanses of white surface where this meat is distributed over extensive territory for purposes of drying. The drying is accomplished in a few days, after which the material which is now called commercially "copra," is ready for packing. The copra is usually packed in mats of native make and shipped to Europe, Japan, Russia, and sometimes to America. In nearly all cases the copra is used for manufacture of oils and soaps, although it finds its way into many lines of saleable articles when it arrives at the final markets. Candy makers buy much of it, while bakers and others take certain quantities.

A very large proportion of the cocoanuts and the copra go to waste every seasou and this wastage is equal to good incomes for someone. The writer has seen hundreds of hogs feeding on the rich coconuts in the groves simply because no one cares enough about the product to collect it. There is many more times greater products of the fruit here than is needed to supply the market at the present time, simply because the local raisers of the fruit and the makers of copra do not provide to furnish the demand. If the purchasing agents of other countries could always rely upon obtaining all of the copra they want in the Philippines, a vasty greater number of orders would be placed than at present. I know of many instances where representatives of foreign purchasing concerns have failed to secure the quantity of copra required by them, and of course this sort of thing tends to turn the market to other islands.

THE COCONUT OIL FACTORY OF THE PHILIPPINES

is fitted ordinarily with very crude machinery of ancient type. The principal piece of machinery is the press. In many cases these presses are only of the old screw pattern with a large worm shaft, and the whole force of natives employed in the vicinity of the works is called upon at the time the big levers are operated for turning the worm shaft. I have noticed as many as thirty men on the lever. They work at the lever for hours, pressing the big platen down on the bits of cocoanut, pressing the last drop of oily matter from the same. In other places, they have steam presses, in which case the work is done in more of a mechanical order and on a much larger scale with considerably less manual labour. The steam presses call for the employment of a steam-power plant, and this is one of the reasons why they are not so extentively used. Recently, however, there have been some turbine and other kinds of water wheels shipped here and the writer has observed that a number of cocoanut oil establishments have adopted these forms of power-producing devices for the operating of the presses. Where they can get a steady run of water, they are assured of good and regular service the entire year. Again in a few instances, where they were not required to operate the presses constantly, they were using windmills, obtaining the power from these. Again I saw that they had animal traction employed at other places. In several of the more up-to-date works they were operating hydraulic presses to good advantage. Some of the Americans, who have taken hold of the industry and who are making rich returns, are using the hydraulic presses. As to taxation, factories in which cocoanut oils are made pay $15 gold per year to the Government. For each hydraulic or steam press $6 is charged in addition. Cocoanut oil refineries pay $15 gold. The collections are made quarterly by the collectors of internal revenue of the islands, there being collectors at every port, and at all important interior cities and towns. At present army officers have charge of the collections. Later on civilians will be in charge.

With the general revival of manufacturing and other

INDUSTRIES OF THE PHILIPPINES,

there has come a good demand for all of the products of the plantations and the shops. Oils are in very good demand for the purposes of lubrication, employment in making soaps, candles, illuminating purposes, and many others. There can hardly be enough coconut oil made here during the next five years to be equal to local demand alone, while the exporting demand has not decreased. The result is that oils are coming in from other countries, and these, too, meet with quick consumption. I have been in localities where for weeks the entire oil business is stranded for lack of any supplies. Prices take big jumps under such circumstances. Taking in rotation the various channels for consumption of coconut oils in the Philippines, for the benefit of Americans or others who are contemplating engaging in what is going to be one of the best money-making industries of the new possessions, we find that the oil lamps consume large quantities annually. The shipments of illuminating oils to the Philippines are chiefly kerosene, and the expense is so high by the time the oil is here that domestic oils are sought for. Therefore, many of the street lights and lights for the churches and public buildings, as well as for houses, are made for burning coconut oil. The main consumption for the oils will be for these lights, and the amount consumed will always be large for the reason that, in addition to ordinary lighting purposes, the natives utilize considerable oil in burning lights steadily at church and home altars, besides in the torches of numerous night religious processions. Wakes and feasts are always in progress, at which the burning of oil is large. The result is that the oil manufacturers of the Philippines are constantly doing a lucrative business.

HEMP

has been one of the staple industries of the Philippines since the beginning of the habitation of the country. Hemp manufacturers now manufacture many lines of twines, threads, cords, and fabrics in which the fiber has received a high gloss by means of employing oiled surfaces in imitation of waxed textures. The oil is applied during the processes of winding and warping the yarns, and many gallons of it are consumed annually in the various textile manufacturing districts. After the oils are applied, the materials are subjected to the friction of brush rolls by which the gloss is further heightened.

THE SOAP MAKERS

of the Philippines manufacture little white slabs of soap for use in washing both clothes and persons. These soaps contain large percentages of coconut oils, and some of the fats of animals. The coconut oil refiners sell much oil to the makers of the so-called fancy soaps, which soaps are really dangerous to use, as the native manufacturers employ some of the dye woods for coloring the soaps, which are poisonous. I visited several soap works where they were combining coconut oils with fats, and at certain stages of the operation pieces of dye woods were strewn in the mass, the dye releasing itself and mixing rapidly with the whitish mass of oil and soap. The color was red in one case, in another yellow, while still another was almost green. Then, after enough color appeared, the dye woods were removed and the soaps finished. The soap makers take very considerable quantities of oils, and with the increased additions to the soap making plants and the erection of new works the demand for coconut oils will be proportionately larger.

THE CANDLE MARKERS OF THE PHILIPPINES

do a thriving business, owing to the great amount of candle material consumed for religious purposes in both churches and homes. There are thousands of families who have lost dear ones and who have erected altars in their houses in memory of the departed, at which series of candles are constantly burning. The candle makers buy the lower grades of coconut oils, and, together with fats and greases, manage to turn out some low-grade candles suitable for the purposes of the islands. The best grades of

wax and sperm candles are sent here from other countries, but they cost too much for general service, and usually the home made, cheap candle is used.

The Philippines have in them a great many more

LEATHER TANNERIES

than strangers suppose. There is a large consumption of leather here for the making of shoes for use on Sundays and feast days. Harness leathers are wanted, and belts, etc. In nearly all of the cities or of the country there are leather tanneries in operation, and these have taken new life since American occupation. Your correspondent visited several of these native tanneries and found that in every case there had been increased orders, and that it was the intention to add more machinery and increase the capacity of the work. The native tanners find an abundance of tanning material in the country, and this comes cheap to them. They also use considerable fats and oils in the finishing processes for softening the fibre of the leather and in getting the necessary glossy finish. Since they have tried to make leather belting for the power plants of the islands, considerable oily substance has been called for. The natives formerly turned out belting so stiff and harsh that few would buy it, preferring to pay ten times higher prices for the imported belting that would work well on pulleys. But among the discharged soldiers of the United States Army there were some who were formerly tanners, and these men have seen the money to be made in the business, and they have interested themselves with the native owners, with the result that the belting turned out by the native tanneries is now suitable for the transmission of power on frictional surfaces of pulleys.

It has become a general custom in the Phillippines to always calculate upon certain important portions of articles shipped here from other countries to be missing. Paints have been shipped here from American and other nations in vast lots during the past year, but the necessary oils are often absent, with the result that the native painter uses any available oil. I have seen these native painters dump quantities of coconut-oil into colors so as to thin the colors and make them go over more surface. The oils prevent the drying of the colours for a long time, but no one minds this. The painters of the islands are good customers of the oils, and the coconut oil makers have no difficulty in selling their products, and the chances for additional manufacturers are good.

Americans or others who would engage in the making of coconut oils in the Philippines should calculate upon securing the entire plant for the oil manufacture in America, as there are no presses or refining apparatus here. One can buy the engine here, also the vats, pumps, belting and small devices. All other equipments should be purchased ahead and sent here. The necessary labor can be secured in the immediate vicinity. I know of several Americans who are sitting back in their carriages and riding about, while their newly purchased oil works are paying handsome profits under the superintendence of a Filipino oil manufacturer at wages equal to about $1 gold per day, and a very small commission on profits. This superintendent hires several overseers of departments at 40 to 50 cents per day and no commission, and the overseers get all the labor they want at from 10 to 15 cents per day. The coconuts can be raised or bought outright, or the copra can be purchased ready to crush and refine. There is certainly money in this business now that the soldiers of the islands afford the necessary protection to industries. If need be, soldiers will be provided to guard outlying works.—*Oil Paint and Drug Reporter.*

THE TEA TRADE IN 1900.

In its review of tea for the past year the *Grocer* has the following:—

CEYLON TEA.

This market, as regards priced teas, is ruled by the Indian market, but fine quality Pekoes and all leaf teas suitable for export have a market of their own, more or less, while fine broken Pekoes move up and down 3d and 4d per lb. throughout the year as quality improves or falls off. The enormous extra supply, however, for the first five months of the year greatly added to the collapse of the common tea market. From January 1, 1900, to May 31 we received 11¼ million lb. more than in 1899 to same date, while for the year we shall receive about 112 million lb. against 96¼ million lb in 1899, making a total increase of between 15 and 16 million lb. Deliveries, however, head the list in increases, and are most satisfactory—viz, 11 million lb, or say 105 million lb, against 94¼ million lb in 1899. We have, however, added on to our stock about 6 million lb, and, as we said in our remarks on Indian tea, the outlook for the new year is not a bright one when we consider that India and Ceylon together will add some 17 million lb on to the stock by January 1, 1901. We can only hope that the present ruinous rates will help to curtail any extra supplies we might otherwise get from our "spicy colony." Re-exports are accountable for 1¾ million lb of the increased deliveries. The quality of this year's supplies has been a fair average. The average prices of the fine liquoring leaf teas and brokens until August were decidedly under previous seasons, but since then values have improved considerably, the trade having competed for them, owing, no doubt, to the poor value offering in Indian teas between 8d and 1s per lb. In previous years Russian orders were generally 2d per lb over trade ideas, but of late we find the latter have been willing to take them at even more money. The market opened in January with a very strong tone and a quotation of 6¼d to 6½d for leaf, but prices before the end of the month gave way for the lower grades, and showed small ups and downs for several months, while the better teas rose until May or June. Sweet common broken Pekoes were a feature at 5½d to 6d, and have remained low for the rest of the year, with a rise of ½d per lb about July, only to fall away again later on. In July-August we find quotations of 5d for leaf, and since then there has been a more or less falling market for common kinds until we reached 4¼d and 4¾d for fair leaf teas, and 5¼d to 6d for sweet broken Pekoes. The quality of fine teas was very good in October, and long prices were, and are, being realised. Choice teas have been scarce throughout the year, but as we write we find that the lower grades are nearly 2d per lb cheaper than they were at the end of 1899.

The exports for 1900 from Colombo direct to other countries than the United Kingdom will be about 32 million lb, Russia being credited with nearly 9 million lb, or an increase of more than 5 million lb over 1899; while America and Australia both taken 1 million lb extra.—*Home and Colonial Mail*, Jan. 4.

Artificial Manures.—The *Englishman* understands that a scheme is under consideration for the starting of a company having for its object the manufacture in India of artificial manures. This movement has had its origin in the important part that scientific methods of manuring have been found to play in improving the quality and increasing the yield of indigo.—*Pioneer*, Jan. 7.

Correspondence.

To the Editor.

TAX ON TEA.

[*To the Editor*, "Home and Colonial Mail."]

Sir,—Tea is essentially the beverage of the masses—it refreshes, invigorates, and stimulates, without if properly brewed, possessing any baneful properties ; and it has come into such universal use amongst all classes that it can no longer be looked upon as a luxury, but must be treated as an actual necessity to every man, woman, and child in Great Britain; and yet the policy of our Government has always been to do its utmost to restrict the use of tea by taxing it to a greater degree than any other necessary article of food or drink imported into our islands.

This tax at present amounts to fully cent. per cent upon seven-eighths of the tea we drink,—*i.e.* tea that is sold at 6d per lb in Mincing Lane has to pay a tax of another 6d per lb before it can reach the grocers, and in gross it yields a yearly total of fully £6,000,000, to the Exchequer.

Now your ordinary readers will say that this subject does not affect them, inasmuch as the price of tea retailed to the public has steadily declined of late years, and this in spite of the addition of 2d to the tax made in the spring of last year.

This, indeed, is the case at the present moment; but it cannot and will not last for, as, of course, is not generally known, although none the less an absolute fact, the entire sum produced by the additional tax has come out of the pockets of the unfortunate tea-growers and producers (who for some years past have been working with a very small margin of profit). The result is that much more than half the tea now imported is selling in Mincing Lane considerably below the cost of production, and tea-growers are being ruined. The end is not far to seek—tea plantations or gardens, as we call them, cannot be carried on at a loss and many, if not most, of them will be closed altogether, thus throwing numerless poor natives and many of our own countrymen out of employment in India and Ceylon ; shareholders will be ruined, and the total production will be naturally reduced, with the inevitable consequence that prices will rise again, and the English working man will have to pay probably half as much again for his cup of tea, or go without it altogether. The Government will find, when it is too late, that it has been killing the goose that has been laying the golden eggs, as it will have a very considerably reduced total upon which to levy its unjust tax, and then the only way in which it can recoup itself will be by raising the tax to 9d or 1s, which would in the course of a short time stamp out the industry altogether.

The above is no exaggerated picture, but a plain, bare statement of facts, and of what must inevitably come about unless the masses of the tea-drinking English public bestir themselves, and insist upon this most shameful and oppressive tax being at once very materially reduced, if not removed altogether.

Time was when we heard the cry of a "free breakfast table" ; and we might yet have distant visions of this proof of the freedom and prosperity of our country, if every tea drinker in England, Scotland, and Ireland, would raise a protest against this crying injustice ; and even if necessary make it a party cry. For myself, staunch Conservative as I have been all my life, and had hoped to remain, I would be strongly tempted to vote Liberal at the next election if, failing our present Government, the Liberals would promise to redress this evil before it is too late.

I have spent the best part of my life in growing and making tea, and, if you will believe me, really know something about the subject I have tried to treat of. Everything connected with the tea industry is very dear to me, and it was never in such dire distress before. This is chiefly due to the imposition of that extra 2d on the tax last March. That, at least, was the last straw, and unless relief comes quickly the great Indian tea industry will before long have become in a great measure a thing of the past.

I enclose my card, and remain, yours faithfully,

J. S. H.

London, Dec. 30, 1900.

TEA AND "MANURO-PHOBIA."

Jan. 15.

Dear Sir,—How prejudice can blind one to reason, is finely illustrated in Mr. N. C. Davidson's letter which you published in last night's paper. He has made up his mind against Mr. Rosling's proposal, and bases his opposition to it on the ground that those who have not helped over-production by forcing manures, should not be called upon to suffer for the benefit of those who have, he thinks, brought about all the trouble. I do not say that Mr. Rosling's is a scheme on which there cannot be two opinions ; but it does *not* call for any self sacrifice, as he clearly showed. On the contrary, if his expectations are fulfilled, it is the high estates which will benefit more than those in the low-country from enhanced prices.

Over-production is a fact ; but what is the warrant for the assumption, on which Mr. Davidson builds his opposition—that it is forcing manures which have caused over-production? It is only within the last three or four years at most that forcing manures are alleged to have been used. Assuming the truth of the allegation, what have they forced the bushes to in four years? The exports have increased from 116 million lb. of tea in 1897 to 148 millions in 1900. Is a progressive increase of 32 million lb. in four years anything out of the way, simply allowing for the development of young bushes over about 60,000 to 70,000 acres, to say nothing of extensions? Apply another test, do 148 million lb. represent an excessive yield for about 400,000 acres under tea? It works out an average of only 370 lb. an acre. The theory of forcing manures cannot be supported by statistics. It is a chimera of those who have forcing manures on the brain, and who do not understand manuring with brains. There may be a few hundred, or even a few thousand, acres which have been forced. Others have had only just and liberal treatment to keep the bushes in heart, but for which the acreage abandoned and the drop in exports would have ruined hundreds of stout and willing men.

LIVE AND LET LIVE.

PER CONTRA.

Amherst, Udapussellawa, Jan. 16.

Sir,—In the footnote to my letter (*vide* local "Times" of 14th) it is said that very little manuring of any sort is done in India, and that forcing manures are practically unknown there. If this is the case it only strengthens my argument, as it is quite absurd to think that India will join us in the abandonment of 10 per cent. of bearing tea as long as we go on glutting the market with artificial aids. Why don't people who are crying out against the Over-production, put it down to its real cause, viz., *manure*. I know estates at high elevations (4,800 ft. to 5,000 ft.) that have nearly doubled their yield from fields that would give 450 lb. to 500 lb. naturally and, *pace* Mr. W. D. Bosanquet, there are very few estates that have reached the stage of manuring half every year *of their whole bearing acreage*. A few may be doing so, and they are more than anything else the curse of Ceylon and the tea industry. Mr. Kelway Bamber in his pamphlet page 74 says: "There is little doubt that the present crop of Ceylon could be increased by ⅓ or more, and this without the employment of very expensive, though somewhat stimulating, manures. But prices would drop, &c., &c." With estates at liberty to use manure *ad lib*, the mere fact of abandoning 10 per cent. of our acreage will have absolutely no effect on the present output and we should be worse off than ever. I would suggest:—

1. Put a stop to manuring by a prohibitive duty. *Then* abandon 10 per cent. if necessary.
2. Get Ceylon and Indian Governments to put a stop to further increase of area under tea—Yours, &c.,

NORTH C. DAVIDSON.

THE SILVER OAK—A QUERY.

Delta, Pussellawa, 19th Jan., 1901.

Dear Sir,—Can you give me any information about the silver oak? Is it a quick-growing fuel tree or merely ornamental and about what size does it grow? Yours faithfully, A. L. F.

[In a list of over fifty kinds of oak with popular English names, we cannot find "the Silver Oak." Does our correspondent mean 'the silky oak" of Queensland, which is the well-known *grevillea robusta* that ought to, and no doubt does, grow rapidly to be a very large tree in the delightful climate and soil of Pussellawa? There is besides the "silver tree" (Leucadendron argenteum) or "Witteboom" of Cape Colonists; but it is a small shrub useful for fuel.—Ed. *T.A.*]

OVER-PRODUCTION AND THE REMEDY.

Jan. 23.

Sir,—Mr. Rosling's proposal, which I have written in support of, is certainly not put forward from the altruistic point of view, nor does it ask anyone to give away a part of his profit for someone else's benefit, or it would deservedly earn Mr. Wiggin's title of "Puerile." The essence of the proposal is that the letting of 10 per cent of the acreage of India and Ceylon run unplucked, will reduce the output of tea by 25 million lb., and that 25 million lb., taken off the market, will raise the price of tea 1d per lb. Granted the correctness of the above premises, and the rest is capable of proof, and each estate can work out the result for itself. 25 million lb. is about seven per cent, of the probable yield for 1901. I give a few examples of how the plan would work and each estate can correct the figures in the light of its own estimate. My own belief is that the high estates would benefit more than the low, and that the rise in teas of high quality would be more probably 1½d per lb., as their loss would be more felt in the market.—Yours etc.. faith, fully,

WILLIAM D. BOSANQUET.

Take 3 average estates of 500 acres giving at present 500 lb. of tea per acre at three elevations.

HIGH ESTATE.

500 lb. per acre at 9d nett or 54cts=250,000 lb	...	=R135,000
Expenditure, at 30cts per lb.	...	=R 75,000
Profit	...	R 60,000
50 acres at 400 lb. per acre taken out=20,000 lb. 230,000 lb. of tea at 10d nett of 60cts	...	=R138,000
Expenditure, less saving on 50 acres R5,000	...	=R 70,000
Profit	...	R 68,000

MEDIUM ESTATE.

500 lb. per acre at 6½d nett or 39cts=250,000 lb.	...	=R 97,500
Expenditure, at 26cts per lb.	...	=R 65,000
Profit	...	R 32,000
50 acres at 300 lb. per acre taken out=15,000 lb.; 235,000 lb. of tea at 7½d nett or 45cts	...	=R105,750
Expenditure, less saving on 50 acres		=R 62,000
Profit	...	R 43,750

LOW ESTATE.

500 lb. per acre at 4½d nett or 27 cts =250,000 lb.		=R 67,500
Expenditure at 22 cts per lb.	...	=R 55,000
Profit	...	R 12,500
50 acres at 300 lb. per acre taken out =15,000 lb.235,000 lb. of tea at 5½d nett or 33 cts		=R 77,550
Expenditure, less saving on 50 acres		=R 53,000
Profit	...	R 24,550

FINALLY TAKE THE BEST ESATE I KNOW.

500 acres at 800 lb. per acre at 8½d or 51 cts		=R204,000
Expenditure, at 24 cts per lb.	...	=R 96,000
Profit	...	R108,000
450 acres at 800 lb.=360,000 lb. at 9½d or 57 cts		=R205,200
Expenditure, less saving on 50 acres,		R 90,000
Profit	...	R115,200

The figures are, of course, only approximate.

W.D.B.

II.

Amherst, Udapussellawa, Jan. 23.

SIR,—In a controversy such as is going on, the subject of over-production and its remedies, I am surprised at your admitting remarks like those contained in the first two paras of Mr. A R Wiggin's letter.* They might easily have been deleted. Abuse is no argument, and I do not suppose you are going to add a new suggested remedy to your list, viz., "abuse those who have been deservedly elected as leaders by a plebiscite of planters."

I was one of the first to write in opposition to the Rosling-Rutherford scheme, but I trust I have more sense and better taste than to consider everyone who disagree with me or with whom I disagree, "puerile" and "brainless."

To turn to the object in view:—There is no reason to suppose that India will co-operate with Ceylon in any "curtailments of output" as long as Ceylon goes on using artificial aids to increase her yield, which India does not employ. Mr. Talbot's scheme does not suggest any "curtailment of output," but "an expansion of markets," and is sure to be much more popular than any scheme that means self-sacrifice. I presume that he does not mean that we are to *give* away 5 per cent. of our green, and 5 per cent. of our black, teas. The Indian planters should take the matter up. If there is no caste prejudice against drinking our teas, there must be a vast untouched market in the Indian towns for black teas; and in Afghanistan, Thibet, &c., for green teas, as the Afghans and Thibetans seem to be great green-tea drinkers.

Is it a fact that tippings make as good green teas as leaf longer from pruning? If so, surely it would pay green tea factories to buy tippings from their neighbours at prices that would be profitable to both producer and manufacturer. This alone would reduce the black tea output considerably and improve the quality of the tea at the same time; but I may have been misled on this point, as I have had no practical experience in green-tea making.—Yours, &c., NORTH C. DAVIDSON.

ARTIFICIAL MANURES POISONING VEGETABLES.

Kandy, Jan. 22.

DEAR SIR,—With reference to your extract in *Ceylon Observer*, Jan. 21st, entitled "Suggested Danger from Artificial Manures," I beg to inform you that cabbages and turnips, manured with superphosphates, are surely poisonous; and I estimate the quantity of cabbages or turnips which should empoison a man to be at least *one ton* daily.—I am, dear sir, yours faithfully,

DR. F. W. KOELER.

VEGETABLE SOAP.—There are several trees and plants in the world whose berries, juice, or bark, are as good to wash with as real soap. In the West Indian Islands and in South America (says the "Family Doctor") grows a tree whose fruit makes an excellent lather and is used for washing clothes. The bark of a tree which grows in Peru, and of another which grows in the Malay Islands, yields a fine soap. The common soapwort, which is indigenous to England, is so full of saponine that simply rubbing the leaves together in water produces a soapy lather.

* The letter was signed in full by a responsible colonist: had it been anonymous the case would be different.—ED. *T.A.*

IN DAYS OF OLD.

(By an ex-Colombo-"O.B.C.-eker.")

Sitting by the "ingle neuk" in a long dreary, murky nicht in Auld Scotland, one's thoughts often turn to far off Ceylon, where the best of my years were spent, and an intense yearning for another glimpse of that lovely land creeps in upon one's soul as he recalls the many sporting adventures he had the pleasure to take part in with the many good old friends of his youth, who are, alas, no more!

The writer's earliest experience of

ELK HUNTING

was in 1868 with the late John McLeod while Superintendent of Kadianlena, and to him I was indebted for my first visit to a planter's bungalow in Ceylon.

On arriving from Colombo, it is unnecessary to say, I was received with that open hospitality and kindness, which were in those days extended to every stranger visiting them, by the planters of Ceylon. Their open-heartedness was proverbial then, and, I believe, continues to be so up to this very day. Reclining in a long-arm chair in the verandah after a good dinner, and while enjoying a well-seasoned "Trichi," I can remember becoming much excited by the distant eerie cry of a pack of jackals as they began their nightly round of the Baharundrah slopes, hunting no doubt some unfortunate "moosul," and as their screeching became louder and louder, and the pack came close down through the coffee to within a few hundred yards of where we sat, it took my friend some considerable trouble to check my youthful and ardent desire to be up and join in the hunt, for I recollect it was a lovely moonlight night. Mine host having informed me, however, that he was going to show me another kind of sport on the following morning, and that we should require to be early on the move, I was reconciled to return to my comfortable lounger, finish my smoke with the usual accompaniment, a "peg" of good old Scotch, thereafter to "roost" and dream of the morrow's chine.

We were afloat before daybreak, and, when light dawned, well on our way, with a nice little level pack of hounds to the spot selected for our hunt. Young and vigorous as I was in those days, I soon found out that I was not in good enough training, once the hounds found, to keep within hail of them for any distance. All I can remember at this period is that, after going a couple of miles over beautiful patana land and through stiff jungle, I was quite out-distanced by McLeod and the dog-boys, and left so hopelessly in the rear that I had to succumb and seek mother earth with "bellows no end to mend." How long I lay on the patanas I cannot say, but it seemed hours before the huntsmen and pack returned with a handsome buck elk carried by coolies in the usual manner; and, though I had not the pleasure of being in at the death, I saw and had recounted to me enough of elk hunting to satisfy me that it was about the finest sport extant.

HOW I KILLED MY FIRST AND ONLY SPIKED BUCK.

A goodly number of years had come and gone, and in the interval I had taken part in some very fine runs in and around Nuwara Eliya with the late G A Cruwell, R B Downall, W W Wynn, &c., when in 1875, or 1876, a couple of those gentlemen and the writer received a very cordial invitation from

THE LATE LAIRD OF MATTAKELLE

—than whom there was no grander old huntsman at that time in Ceylon—to have a day with his celebrated pack in Dimbula. Well do I recall that (to me) memorable morning when we turned out on to the large stretch of patanas lying at the back of Mattakelle bungalow. A bright crisp morning in November after the monsoon rains had refreshed all Nature, and "Old King Coffee" looked as if the heyday of its prosperity would never decay—at least over that grand expanse of Dimbula lying betwixt us and the Great Western range—and I had no misgivings then as to the assured fortune of our genial and kindly host—the biggest-hearted soul I ever met. How a few short years changed the circumstances of many hardy, honest, prosperous planters in those days, it would be useless for me to recount in this letter, so I will "hie back" to the subject of my text. In the days of which I write nearly the whole of Dimbula, at least as far up as Radella, was under coffee and there was little jungle to be seen, big enough to hold game. About the far end of the patanas to which I have referred, however, there was a conical hill of forest standing. I should at a rough estimate put it down at 100 to 150 acres, though we could only see the side facing the plains. Into this the hounds were slipped by the "dog boys," while the huntsman, Cruwell, Wynn and the writer squatted on the grass to await results. The Master knowing so well the habits of the elk assured us that when the hounds succeeded in forcing him to vacate his stronghold, the "quarry" would break cover and take to the open on the side commanded by us.

HUNTING THE QUARRY.

"The Laird" had that time in his kennels a magnificent specimen of the greyhound, a half-brother to the famous Irish dog of that breed, "Master McGrath," a triple winner, I believe, for the late Lord Lurgan of the Waterloo Cup at Liverpool. This hound was in leash and delivered over to my care. How long we waited on those patanas, listening to the distant "tonguing" of the pack as they hunted their quarry round and round that jungle, the voices of the hounds every now and then being heard as they approached the ridge and then becoming quiet again as they descended on the other side—it is impossible exactly to say. Keener huntsmen than the trio who accompanied me it would be difficult to find, and yet when 9 o'clock arrived, and seemingly no prospect of any excitement, either their patience became exhausted, or more likely the cravings of hunger led them to make tracks for Mattakelle: for off they went and left me single-handed with only the grey-hound as a companion. I had not very long to wait before the virtue of patience was rewarded. From the far-off corner of the jungle I could see the elk break cover, and come bounding down over those vast and rugged patanas with a couple of small half-bred hounds hanging on to his ears, and in the very direction wished for and exactly as indicated by our huntsman before he left me.

Making the best use I could of my "understandings", and pulled along at a tremendous pace by the straining power of the hound whom I was loath to slip until he had fairly sighted the game, I came almost to mortal grief over a cut drain in the middle of the plain, which was hidden by tall rushes. Unaware of this wretched "man-trap" and going at such speed I tripped over the upheaved earth and stones, and landing full length I came a cropper on some broken metal on the far side, and though clad in a stout pair of English corded "knickers," I received a very severe cut close upon the knee cap (the mark of which I carry to this day) and I was thereafter only able to crawl to where the elk was held at bay by the assistance of the greyhound.

THE "COUP DE GRACE"

followed, and do not wish ever again to hear that "uncanny" cry when my blade struck his heart and he bounded high up into the air, falling dead at my feet. He turned out to be a magnificent specimen of the Spiked Buck very rare in those days in Ceylon. The head was mounted and adorned Mattakelle bungalow along with so many other trophies of the chase; but I was promised that it should eventually find a place in my own house whenever I had the good fortune to settle down in this country; and one of the very latest letters I had from my late noble friend was to the effect that the head of my Spiked Buck would be sent to Scotland by an early opportunity. But it has never reached me.

To finish my story, Making tracks for the bungalow, as best I could in my crippled state, I had not proceeded far, before

ANOTHER DANGER

lay in my path for my attention was soon drawn to the presence of three semi-wild buffaloes who came trotting along in our direction with up-raised heads looking as savage as only those brutes can look when raised. A means of concealment fortunately was close at hand, and into an open drain I dropped unperceived, dragging my grey-hound on the top of me, and with deep feelings of relief allowed these creatures to pass to leeward within about 30 yards of where we lay, and move out of sight. When I did manage to reach Mattakelle, exhausted with pain, I received much kind attention from Dr. D—then resident Surgeon of the district—and who I am glad to know is still in Ceylon. By his orders I was laid up for several days; thereafter when convalescent travelling on to Kandy where I was due to take part in an important Cricket match,—Colombo *vs.* Planters. Thus ended the most enjoyable holiday I ever had in the Island of Ceylon.

"W. G."

BIG GAME IN THE SOUDAN.

A PRICE PLACED ON EVERY HEAD TO BE SHOT AT.

Cairo, Dec 31.—The Soudanese Government, having received numerous applications from notable sportsmen to hunt and shoot big game in the Soudan, have decided to afford sportsmen the desired facilities under certain restrictions. Licences to kill big game will be granted at the following rates:—£25 will entitle a sportsman to kill four buffaloes, two elephants, one giraffe, six hippopotami, two rhinoceroses, antelopes, gazelles, and wart-hogs; in addition to which, for some animals killed a fee is charged—for a buffalo £6, an elephant £8, a giraffe £6, a hippopotamus £1, and a rhinoceros £5. A £5 licence entitles a sportsman to shoot antelopes, gazelles, and wart-hog. In addition to the fees mentioned the duty on ivory has to be paid.

These regulations have been instituted by the military authorities for the purpose of preserving big game, which is plentiful in the Soudan, from wanton destruction. Some of the rare species of antelope will also be protected in an edict shortly to be issned by the Sondanese Government.

Captain Charteris is here, and has made arrangements with the military authorities for a party of sportsmen to hunt and shoot over the territory bordering the Blue Nile. Mr. E N Buxton, a noted English sportsman, is also here, and is arranging a shooting expedition.—*Daily Express.*

COCA.—*Erythroxylon coca.*—It has been ascertained by practical test made in our experimental garden that the coca plant cannot be grown successfully in Madras unless it is partially shaded. Plants put out in the open did not thrive; they grew, but were stunted in appearance, and the leaves were small and scanty; on the other hand, plants grown directly under the shade of a tree, although they grew to the height of 5 feet and looked otherwise in a healthy condition, failed to produce fruit, while plants grown in partial shade grew luxuriantly and bore fruit that ripened in due course.—*Agri-Horticultural Society of Madras.*

The following pages include the Contents of the *Agricultural Magazine* for February :—

Vol. XII.] FEBRUARY, 1901. [No. 8.

THE TEACHING OF AGRICULTURE IN RURAL SCHOOLS.

I

WHILST we have nothing but praise for the excellent system of State school education throughout the colony, whilst we respect and appreciate at their full value the State school teachers, and the splendid work they have done and are continuing to do in the cities and townships throughout this great territory of Queensland, we believe we are justified in saying that there is still one channel through which the stream of instruction has not yet flowed—a channel which, if once filled and set flowing, will carry the beneficent stream throughout the land, eventually bringing wealth, health, and rural comfort to thousands of homes. This so long neglected channel is Agricultural Education. Let us at once say that we do not advocate a systematic course of instruction in the science of agriculture in the State schools. In the nature of things such a course would be impossible—first, because the time spent at the schools by children in the rural districts is of short average duration, hence allowing an all too brief period for mastering the three R's and a certain amount of geography, history, &c.; secondly, because the teachers were never expected to add agricultural subjects to the ordinary school curriculum, and hence went through no course of preparation, nor were they required to pass any examination in agriculture. We may further point out that whatever pleasure the teachers may personally derive from the cultivation of a piece of land in their spare and holiday times, or from the rearing of poultry and cattle, yet teachers are not farmers. The long course of arduous study and training gone through by them during their pupil-teachership, and whilst passing through the various grades to the higher classes, necessarily left them no time to study agriculture in a practical manner. Instruction of a comprehensive nature in the branch of education can therefore only be given in an Agricultural College, or in Dairy Schools, where all the instructors are specialists in their own particular branch of the various industries coming under the head of "agriculture."

But, these premises being conceded, we hold that it is quite within the range of possibility to render the instruction imparted in the schools under notice more consonant with the environment of the pupils than is now the case. It can be shown that without altering the curriculum in any way, without adding one single fresh burden to the teachers or pupils, that carriculum can be so handled as to attain the desired end in a manner not only not burdensome, but rather enjoyable to teachers and taught.

What is one of the most important duties of the teacher? Is it not to train the faculties of observation and research in the child. And how can this be better accomplished than by encouraging the spirit of inquiry—the curiosity, we may call it, so natural to every child?

More particularly should children be encouraged to observe the phenomena of Nature, and the results of her operations in the ordinary events of

daily occurrence everywhere about them. They should be invited to collect specimens of natural history, and to ask questions about all they see. Wherever possible, they should be encouraged to take a share in beautifying the school premises; they should be allowed to cultivate small plots of ground. Whilst doing this, they would soon discover that certain causes produce certain effects. They would find that their flowers, fruits, or vegetables will not thrive except under certain conditions—such as a supply of necessary plant food, manure, water, heat, or cold. Insect pests would also claim their attention, and in a simple way the intelligent teacher would explain how all this comes about, and how the enemies of plant life are kept in check. Then he could cause them to observe the habits of insects and, point out how they act as fertilisers of certain blossoms. The harmless and dangerous insects and animals would come in for innumerable subjects for object lessons. There is no need for any text-books to be placed in the children's hands; no set lessons should be learned by heart. All should be spontaneous on both sides. The teacher himself would no doubt refresh his memory, or gain some useful information from books; but no book should be employed in conversation on any of these little subjects with the pupils.

One valuable means towards inculcating a love of Nature in the youthful mind is the taking of occasional walks into the country. Every one knows how children, both boys and girls, will scatter about, following the bank of a stream, or wandering through the scrubs or fields picking up all kinds of insects, flowers, stones, and fruit. All these they should be encouraged to learn something about, not in a dry-as-dust fashion, but in a pleasant, intimate, conversational manner. There is another way of arousing their interest, that is, by stimulating the dormant faculty of imitation latent in most children, but very apparent in some. They should be provided with pencil and paper, or a slate and pencil, and induced to try and copy such specimens as they might find, but the most ludicrous efforts in this direction should be taken by the teacher as seriously as if they were models of art. Nothing so much damps a child's enthusiasm as a sneer. Every little first attempt should be commended, and the pupil helped to improve.

There are all sorts of other ways in which a painstaking teacher can inculcate a love of rural life in the children entrusted to his or her care, but we have said enough for the present. We may state that the above remarks are dictated by actual experience. They are not theory, for we put them into practice for several years, and always with the most encouraging results. Yet the ordinary work of a school was never for a moment disturbed. We therefore maintain that what has been done successfully once can be done and should be done again.

II.

The idea that the elements of Agriculture should be taught in our rural State schools commends itself to the earnest consideration of all who desire to see a healthy, rural population growing up around us. As matters are at present, there is a growing tendency on the part of the rising generation in the country districts to gravitate towards the towns instead of going on to the land, and by steady application to farming or pastoral pursuits, building up for themselves in the future comfortable homes, where by diligence and economy they may eventually become independent of "billets," either under the Government or in private employ, the remuneration in which is, owing to the severe competition, barely enough to provide food and lodging. On this subject we print the subjoined extracts from the Bulletin of the Agricultural Department of the West Indies. At an Agricultural Conference held in Barbados, one delegate said:—

"The time has arrived when it is absolutely necessary that elementary education should be made more practical, and I feel sure that these West Indian Colonies will do their utmost, with the limited means at their disposal, to make it so. There has been very little attempt made in the past to draw out and train the faculties of children. Our system must be remodelled so as to draw out these faculties.

'In too many cases' (to quote from a paper by Mr. F. J. Lloyd) 'the sole object of education has been to cram a certain number of useless and disconnected facts, or pseudo-facts, into what is termed the brain. Teachers recognise one faculty, and one only, viz., memory; and to train this one faculty to the neglect of every other has been the sole object of education for ages past, and remains so mainly to the present day. It has entirely neglected to develop manual skill; it has neglected to draw out or cultivate any mental faculty save memory; and even for this purpose has utilised subjects, the recollection of which would in no wise benefit the future farmer. But, far worse than this, it has neglected the most valuable of Nature's gifts to all of us, the strongest natural faculty we possess—observation. What is the most striking faculty possessed by a child from three to six years of age? The power of observation. Watch that same child between the ages of thirteen and sixteen, and the power, though at times manifesting itself, is gradually becoming dormant, partly because it has not been cultivated, partly from its constant suppression by the ignorance and heedlessness of those who surround the child. Ten years later the faculty is practically non-existent, lost from neglect of use, as a singer may lose the power of song, or a musician the power of execution. The difficulty now found in improving agricultural education depends greatly upon this failure of the past.'

Be ours the task, as far as lies in our power, to try and remedy this defect in our educational systems in the West Indies."

Mr. H. Collens, Acting Inspector of Schools at Trinidad, in alluding to the objection some parents have to their children being taught to do anything entailing manual labour at school, said:—"If there is an attempt to make a child in the schools do manual labour, the parents state their objections very forcibly. I agree with Mr. Hicks that, if our attempts to teach agriculture in elementary schools are to be successful, the greatest

possible fact must be shown by the officers concerned. We must not drive or coerce the people; above all, we must try and instil into the children's minds a love of Nature, and the necessity of learning Nature's methods. If we succeed in doing that, we may hope in time to turn their attention to field pursuits and to agriculture generally as a means of earning a livelihood. We must, however, proceed cautiously. In Trinidad it has been decided that the teachers should, first of all, have a course of lectures, and, in the event of their showing aptitude in teaching agriculture and passing an examination in the syllabus laid out, they are to be rewarded by receiving a bonus on the results of the examination of their schools at the end of the year.

"That is one encouragement; but we have another. We have made the examination the means for promotion from the third class to the second. That is an important means of influencing the teacher, because it directly touches his pocket. Then with regard to teaching in the schools, we make considerable use of Blackie's Tropical Readers. These are used as alternate reading books. I feel a deep personal interest in this subject of teaching agriculture in elementary schools. I have given considerable thought to it, and I am convinced if we are to do any real good we must exercise great caution, and always place the pleasantest side before the parents and the teachers. Otherwise, we shall fail."

A third speaker took a sentimental view of the question.

"The eyes," he said, "of the country child should be unsealed. He should be made to see the beauties and wonders that lie about his feet, and are to be found in profusion all round him A sympathetic, skilful teacher will invest rural life with an interest that will attract and fascinate. The life that was monotonous, dull, insipid, and purely mechanical will be changed into one full of interest, and with this there will be gained a discipline of the mind, a development of intellectual power which are prominent aims of all true education. The new knowledge and skill will be to the country boy as a new tool, the possession of a new power, and he will be eager to make use of it.

"What is done on a small scale in a corner of the school plot or in the box-garden will be reproduced at home on a larger scale and with added interest. It will be his delight to show what he can do, and the useful results of his doing. He will find use for his knowledge of reading, writing, and arithmetic in connection with his observations and experiments in the study and mastery of some of the secrets of Nature. He will have a desire to read; and, if we are wise, we shall see that he has opportunity by providing the school with a suitable library and some of the books specially applicable to country life."

In France and in the United States, agriculture has been introduced as one of the subjects to be taught with the express view of preventing the constant drifting of the youth into the great cities Illinois has now decided to introduce elementary courses in agriculture into the State public schools with the primary purpose of interesting country school boys in what may be their life work. The course will be adopted especially to the country schools, but it will be introduced into town and city classes in a modified form. One hope of those who have been instrumental in securing the adoption of the study is that it may tend to stem the tide of migration of the boys from the country to the city.—*Queensland Agricultural Journal.*

OCCASIONAL NOTES.

Mr. Kelway Bamber, Agricultural Chemist, has established a laboratory in Hunupitiya Road near the junction with Park Street, and not far from the Victoria Park.

The students for the School of Forestry left Colombo on tour on the 15th. They proceeded to Kurunegala and established their first camp in the Sudugama forest.

We have been hearing from Mr. C. F. Fernando, an old boy of the School of Agriculture, who left for South Africa to seek his fortune. He is still full of hope as to his future in the new country, and we have little doubt that with his ability he will succeed in finding suitable work to do.

Veterinary Surgeon Chinniah's article on Vasectomy, which originally appeared in these pages has been taken over by the *Veterinarian* (London). Mr. Chinniah has repeated the operation on a bull at Grove Estate, Ukuwella, with the same success as before. The after treatment in vasectomy is very simple, and the bull operated on was able to go to work in a fortnight's time.

Mr. Chinniah is reprinting his papers on the Branding of Cattle, and it will shortly appear in convenient pamphlet form so as to be available to all.

The closing of the School of Agriculture has been ordered by Government, and as a tentative measure agricultural work will be carried on though rural schools with connected school gardens. The Superintendent of the School of Agriculture will assume the duties of Superintendent of School Gardens. We are convinced that good results should follow this new departure, and we notice the Ceylon press is of the same opinion.

A gymnasium in connection with the School of Agriculture was opened on the 1st December in the presence of a large gathering, presided over by the Director of Public Instruction.

The School of Agriculture re-opened after the Christmas holidays on the 15th January. On instructions received from Government a new class of students was not admitted this year.

Mr. J. Rodrigo, Manager of the Government Dairy went over to Madras on the 4th December, and brought over 22 cows for the dairy.

A sale of 8 cows and 12 calves drafted from the Government Dairy herd took place on the Government Dairy on Thursday, the 17th inst., with the following results :—

Greatest amount of rainfall in any 24 hours on the 18th, 2·52 inches.

Recorded by C. Drieberg.

COCONUT MANURES.

We are inclined to think that the complete analysis of the coconut made by Dr. Bachofen, the Chemist in charge of Mr. A. Baur's laboratory, established in connection with the latter's manure works, did not, at the time of its publication in the Press—nearly a year ago—receive the attention it merited. We are reminded of this fact by seeing the results of the analysis, as originally published in Ceylon, going the round of the Agricultural press in the various colonies. The analysis referred to is undoubtedly a valuable one, and shows in as definite a way as it is possible for an analysis to show, the actual demands made by the coconut upon the mineral constituents of the soil. On reading through the figures of Dr. Bachofen's analysis, the most remarkable facts are the large percentages (1) of potash (30·7 %) and commou salt (45·95 %) in the ash of the husk; (2) of potash (54 %) in the ash of the shell; (3) of potash (45·8 %) in the ash of the kernel; and (4) of potassium chloride (41 %) and common salt (26·3 %) in the ash of the "milk." Calculating the quantity in pounds removed by a thousand nuts (assuming that the entire nuts are conveyed off the land) we find that the following are the figures for the chief ingredients of plant food :—

Nitrogen	8·6	lbs.
Phosphoric acid	2·4	,,
Potash	18·7	,,
Lime	2·3	,,
Common suet	21·4	,,

It will be readily conceded by any one perusing these figures that, to meet the demands of the coconut, the use of potash manures and common salt together with the nitrogenous and phosphatic fertilizers usually applied, should not be neglected. That well-known authority, Professor Warrington, tells us that neither sodium nor chloride are among the essential elements of plant food, but that they are to be included in a class, which, though not indispensable, yet perform useful functions in the plant economy. But certain plants have, so to speak, a "fancy" for special ingredients of plant food—essential or non-essential, such as that of the glorias and *diatomaceae* for sillica, kumbuk, terminalia glabra, for lime (the bark containing no less than 50 % of the carbonate species of *solsola* for carbonate of soda &c. It may be assumed in the case of the coconut that it has a decided penchant for common salt), and this being so, there is no justification for giving it so niggardly an allowance as finds its way into the palm with the ingredients of wood-ashes and other manurial substances. The very fact of the palm being found growing with impunity with its roots saturated with sea-water—a condition of things few cultivated plants are calculated to tolerate—is a direct enough indication that the coconut revels in well-salted food. We find the coconut has become reconciled to inland sites, where it grows and waxes strong on the rich soils of the interior, contented with a less salted diet that it had on the comparatively barren sands of the sea shore. So, too, cereals which affect sillica will grow even in the total absence of this ingredient. But with the large demands made by the palm, as shown by analyses, for common suet and potash, it is only reasonable that the limited supplies in the soil should be supplemented with *added fertility* as regards these substances. On referring to Mr. Cochran's published analysis of the husk of the coconnt, we find very similar figures given to those of Dr. Bachofen for the percentage of potash and common salt. Mr. Cochran's analysis gives the following percentages for the two salts respectively, 3·45 % and 4 %

those of Dr. Bachofen being 3·7 % and 45·95 % respectively. Mr. Cochran cites the case of the mangel, a plant with a strong predeliction for salt, (its roots containing no less than 45 %, and its leaves 37 % of sodium chloride) as being greatly benefited by applications of common salt together with the fertilizers, and makes the following important statement: "From the evidence before us, I am disposed to consider the coconut trees as one of the special cases in which salt is useful as a manure."

With the opinion of two of the three analytical chemists in our midst to guide him, the coconut planter cannot surely hesitate any further to recognise the importance of using potash salts together with common salt in the manuring of his palms.

It would be interesting to ascertain the views of Mr. Kelway Bamber who has just established himself in a new laboratory in Colombo, as Government-cum-Planter's Chemist. Mr. Bamber has come to us with a made reputation as an authority on the Chemistry of tea, being an Agricultural Chemist of high qualifications, his views with regard to the manuring of coconuts should prove most valuable. Where, we ask, is the Association that can come to the aid of the low-country planters? The consideration of the subjects, as set in for above shows the valuable work that a low-country planter's association, if formed, is able to undertake. We have now a number of technical officers who are capable of giving very good advice. But the coconut planter has no organized body through which he can indicate his wants. This is a state of things that require early attention, and the low-country planters have to blame themselves if they do not utilize the advantages offered to them.—"Ceylon Standard."

INTRODUCTION TO ENTOMOLOGY.

(Miss Eleanor A. Ormerod.)

Insects begin their lives either by being hatched from eggs, or produced alive by the female; commonly they are hatched in the form known as maggots, caterpillars, or grubs, but they are never generated by the decaying vegetables, putrid water, bones, carcases, dung, or any other matter, dead or alive, excepting their own insect forerunners. They come out of these matters constantly, but, if the observer will watch, he may often see the arrival of the insects, the laying of the eggs, and be able to satisfy himself as to the gradual development and the method of breeding, and that the progeny is produced by the female insect.

The eggs are usually laid soon after the pairing of the male and female, and are deposited on or near whatever may be the food of the larvæ. They are laid singly or in patches, and are sometimes attached by a gummy secretion to the leaf or whatever they are laid on; occasionally they are fastened by a short thread, or raised (like the heads of pins) on a stiff foot-stalk of hardened viscid matter. Such insects as insert their eggs in living animal or vegetable matter are furnished with a special egg-laying apparatus or ovipositor, such as a borer, or organs enclosing bristle-like points on saws, by means of which the female pierces a hole, and passes the egg down into the wounded spot.

For the most part insect eggs hatch shortly after they are laid, but sometimes they remain unhatched during the water; and it is believed that, where circumstances are unfavourable to development, they may remain unhatched for years, but this point is one of those subjects on which more information is needed. They have been found to endure intense cold without injury, and, besides some special and extraordinary instances, it has been found by experiment that insect-eggs may be exposed to a temperature lower than that to which they are usually subjected in this country, and cold enough to solidify their contents without destroying their powers of hatching.

In a very few cases insects are partly developed before birth, otherwise, after hatching from the egg, or being produced alive (in the same first stage of development) by the female, insects pass their lives in three different conditions or stages successively.

The first is that in which they are known as maggots, grubs, or caterpillars; in the case of grasshoppers, cockroaches and some other insects, where the young are very much the same shape as the parent, only without wings, they usually go by the parent's name; the young of greenfly are sometimes known as "lice." In this state they are active, voracious, and increase in size; and in this first stage all insects are scientifically termed larvæ.

In the second stage some orders of insects are usually inactive and cannot feed, as is the case with the chrysalis of the butterfly, or the mummy-like form of the beetle or wasp with its limbs in distinct sheaths folded down beneath it; some, however, are active and feed, as grasshoppers, cockroaches, aphides (or green fly) and others, and resemble the parent insect, excepting that their wings and, for the most part, their wing cases are not as yet fully formed; and in this second stage all insects are scientifically termed pupæ.

The thirds tage is that of the perfect insect, in which (whether male or female, or of whatever different kind, as Moth Beetle, Cricket, Aphis, &c.,) it is scientifically termed an imago.

The term Larva is from the Latin, meaning a ask or ghost, and signifies that the insect in his stage gives a mere vague idea of its perfect form.

Pupa signifies an infant, and is fairly appropriate to the second stage in which the insect is forming into the perfect state, but is not fully developed either in its limbs or functions.

Imago signifies the image, the likeness, or an example of the perfect insect. The appropriateness of the scientific names for the first and third stage does not seem very clear, but there is no doubt of the convenience of having some one term by which each different stage of life of any insect may be described; and these are the words that have been adopted; in the following pages some detail is given of these three successive stages of development.

THE CULTIVATION AND CURING OF TOBACCO.

(Continued.)

8. Harvesting.

When the leaves feel thick and gummy, and begin to turn yellow with brown spots, they are considered to be mature and should be cut off. Tobacco should not be cut overripe. Harvesting of a plot should not be done at once; the mature plants are to be gathered first. The best time for harvesting is morning, as soon as the dew is off the plants. They should lie for some time in the sun, say for two hours, to make them sufficiently wilted, so that they can be handled without breaking. Care should be taken not to let them become too much sunburnt. It is better to cut whole plants (close to the roots) than gather the leaves singly. Harvesting should be delayed for two or three days if there be heavy rainfall, which washes away the gummy matter of the leaves.

9. Drying and Fermenting.

Immediately after the plants are conveyed to the house, they should be hung up on strings beneath the roofs of a well-ventilated house six inches apart. They should remain in this state for more than two months, or until they are quite dry. When very hot or strong winds blow, the windows and doors of the house should be closed. In very dry weather, the floor of the shed should be occasionally sprinkled with water, in order to keep the air of the room sufficiently moist. In June, when the rains commence again, the plants are taken down, stripped and handled Best medium and worst qualities should be separated at the time of stripping. 16 to 20 leaves are tied up into one bundle. These are put into large heaps 3 to 4 feet square by 5 to 6 feet high, and well pressed down with hands. The leaves are transferred from one place to another at intervals of about a week or so; fresh heaps being made, top leaves going into bottom, and bottom leaves coming to the top. This transference also involves examination of the leaves. Care should be taken to prevent excessive heating. At the end of the rains the leaves are considered to be fully cured and quite ready for sale. The heat may be broken up earlier, if so desired.

10. Methods of Curing in vogue in Bengal.

The modes of curing differ in the different districts; and it would be well to cite here the systems of curing in Rangpur, Jalpaiguri, Nadia and Tirhut, which are the principal seats of tobacco culture in Bengal.

Mode of Curing in Rangpur and Jalpaiguri.—The methods of curing followed in Rangpur and Jalpaiguri are almost the same. The leaves of mature plants are cut off singly in the morning and are left in the sun for all day long. In the evening small bundles of four leaves are suspended along the roof of the house—generally a cowshed. After two months, *i.e.*, about the middle of June, they are taken down. Eight small bundles are then tied up into a larger bundle. Leaves are not sorted according to their quality, though the tobacco growers are aware that the topmost leaves are the best. The bundles of leaves are then put into a large heap. The bundles are taken out and dusted, and the heaps are made at intervals of eight or ten days, until the tobacco is wanted for sale. It is best to keep on the heap till about the close of the rainy season. Tobacco thus kept is said to bring higher prices.

Mode of Curing in Nadia.—"When cut, the stems with leaves on them are allowed to remain spread out in the sun for two hours. They are then cut into pieces, each of which contains a pair of leaves and a portion of the stem. These pieces are then arranged on the ground in layers of 9 to 10 inches thick, and are allowed to remain in the sun for two days. Rain, of course, at such a time is most destructive. Tobacco in this half-dried state is taken home by the cultivator, who strings the sections together, and suspends them on rows of strings in the longest apartment of his premises, usually the cowshed. The leaves after being thus suspended for about a month are thoroughly cured. They are then taken down on a damp or foggy day when they are a little soft, and made into bundles of about 11 maunds weight each, the strips of leaves being cut into lengths of about a yard, and folded over and laid one on another. The above description relates to the Hingli tobacco of Ranaghat; the inferior sorts appear to be merely made up into bundles and subjected to the alternate action of sun's rays by day, and of the dews at night."—*Vide* Collector of Nadia's Report, 1874.

Methods of Curing in Tirhoot.—"Plants are allowed to be on the ground as cut for a day or two; they are then carried to some grassy spot and laid out to catch the sun during the day, and the dew at night, being turned daily. After this has gone on for eight or ten days, every third or fourth day the plants are stacked together till they get heated, when they are again spread out to cool. If at this time the dew is thought not sufficient to cool the plant, at evening time a little water is scattered over the leaves as the lie; this goes on for twenty days or more. The plants are then brought into cover and stacked; they are changed every third or fourth day, the top going to be bottom, and so on. It is important now to prevent them getting over-heated: if the leaves show a tendency to get crisp, the leaves are covered with plantain leaves or damp grass, over which is put a blanket to make the heap sweat. The leaves are then separated by khurpi or huswa from the stem. They are then tied five or six together with strips of date leaves and piled together. These piles are again watched carefully till it is evident that the leaves will not heat any more. They are then tied up in bundles of four maunds each, wrapped round with straw, and are then fit for the market; if not immediately sold, they are stowed away in some dry place. If the leaves are not of a good colour, the cultivator may, before opening them for sale, get a little good tobacco, boil it, and sprinkle the juice over them after the last process of drying; but this is more a trick of trade than a method of curing, which being really nothing more than a careful alternative of heat and moisture, no extraneous matter being introduced."—Collector of Tirhoot's Report.

11. Seeding.

The best plants are set aside for seeding. They are not topped like others, but the side shoots and suckers are removed from the stems, only the heads or tops of the plants being preserved for seed. The heads are tied to sticks to keep them straight.

As soon as the seed is ripe, the heads of plants are cut off and hung in a dry and safe place. After a few days the seed are rubbed out of the pods by hand and stored. The seed should be preserved from damp and insects.

The vitality of the seed can be tested by scattering some on a piece of hot iron. If a sharp spattering sound is given out, the seed may be considered to be sound.

12. Outturn.

A well-grown crop is expected to yield from 20 to 24 maunds per acre, the money value of which may be estimated at Rs. 100 to 120, Rs. 5 being the average price per maund of country cured tobacco.

13. Injuries.

The chief enemy of the tobacco crop is a kind of caterpillar which eats away the leaves at night and takes shelter in the soil by day. This caterpillar or cutworm causes serious damage to the young plants. They should be carefully looked for and killed when any injury from this source is noticed. Hailstorms often destroy the crop over large areas of the country.

14. Suggestions for Improvements and Conclusion.—Tobacco is one of the most profitable crops grown in tropical and sub-tropical countries. India is one of the important tobacco-growing countries of the world; but as regards the quality, Indian tobacco is very inferior. The only chemical deficiency of the Indian tobacco, according to the results of several analyses, is in carbonate of potash, proving the poverty of Indian soils in this important plant food. It may, however, be supplied by manuring the crop with saltpetre, which is easily obtainable at a moderate cost. Another direction in which improvement is possible is the cultivation of acclimatised foreign varieties, such as Havana, Dindigul, Samatra, Landreth's, etc., which grow as well as any of the indigenous varieties, and are certainly better adapted for cigar making than the latter, which are extremely coarse for the purpose. Seeds of these varieties can be had from the Agricultural Department, Bengal. Defective curing is, however, held to be the chief cause of the general inferiority of Indian tobacco. The curing of tobacco is a difficult art which requires to be learnt by experience. The simple directions for curing given in paragraph 9 will, it is believed, lead to some improvement in the quality of the tobacco. They have been followed with useful results by Mr. B. Pal Chaudhry on his Home Farm at Natuda in the Nadia district.—*Indian Agriculturist.*

RICE AS A FOOD STAPLE.

Rice is becoming more and more an important article of alimentation, as is evidenced by its increased importation. It remains a favourite dish among sweets, is largely consumed in soups, and in madeup dishes, while being extensively utillized along with wheaten flour to secure greater whiteness of the bread. It is also largely used to make starch. The rice emanating from South Carolina and from British Burmah are the two varieties most in request. Japanese rice of late meets with a fair demand. Indeed, when it is borne in mind that rice feeds one-third of the human race, and that it is considerably cultivated in Asia—no less than 100 different varieties alone are peculiar to British India and Ceylon, and Northern and Central America—the importance of the plant of its product will be much better appreciated. Its growth has been attempted in Northern France, and the experiment was tried with partial success of raising it south of the Thames, outside London. Rice exacts a warm climate, but above all, a humid soil; hence, why the growing crop has to be irrigated with so much care. Before being harvested, etc., the soil is freed from water, the crop duly cut with the sickle, and it is next threshed by means of the flail or by machinery; in some cases the grain is simply trampled out by cattle. The rice which has been obtained in the latter way, in the husk, is called "paddy;" the grain adheres firmly to the husk, so much so, that specially machinery has to be employed in order not to injure or break the grain.

The superiority of Carolina rice is due principally to the extreme care taken by the American growers to turn out clean samples. After it is husked, the grain passes through a whitening machine, which removes the inner cuticle or red skin. This done, the rice is fit for sale. Like the potato, rice is largely employed to prepare starch; it is treated with a solution of caustic soda, which dissolves out the nitrogenous matters; the starch deposits, and is weighed and dried. The analysis of Chemist Payen, and that which is generally accepted, gives the composition of rice as follows: Nitrogenous matter, 7·55; starch, 88·65; dextrine, etc., 100; fatty matters, 0·80; cellulose, 1·10; and mineral matters, 0·90. Rice then resembles nearly the composition of the potato, which contains, as will be remembered, so much starch and so little nitrogen, fat and mineral substances. It explains also why rice is not a complete food, and why it is necessary to supplement it with meat, vegetables or fish. But rice possesses the great advantage of being easily digested, and does not fatigue or inconvenience the stomach. Hence, its efficacy as a remedial agent in cases of diseases of that organ, and of the intestinal channels. It exercises no laxative action as other cereals are reported to do, and which explains the efficacy of rice in cases of dysentery and diarrhœa. China is able to procure two crops of rice every year; the Chinese sow it in March and July; the inhabitants of the Flowery Land pride themselves on completely understanding its cultivation, the whole secret of which is to give the plant a great deal of water. It may not be generally known that the Americans were indebted for his grain to a Mr. Dubois, who was treasurer of the East India Company, and who gave a small bag of the said grain to a

merchant of Carolina. This is how Europeans came to be chiefly supplied from Africa with Carolina rice, and which is everywhere accepted as being much the finest of its kind, the grains being double the size of that which comes from the East Indies, and known as Patna rice. Rice is said to be best cooked by thorough steaming; while in case of sickness, rice water can be prepared, sweetened and flavoured in the same way as is barley water.

The rice when being turned out for market is sifted and classified into five categories; one, known as broken rice, which is not to be disdained; if well cleaned, it will form an excellent mucilage, or when ground into flour, it can be mixed along with some wheaten meal, and thus cheapen, as well as whiten loaves of bread. Japanese rice is said to be rich in nitrogenous substance, no matter whether it be the upland, mountains, or lowland varieties. In some districts of India rice is not allowed to be consumed until after a lapse of six months from the time it is gathered, many even prescribe a longer period. A good hour is allowed for the digestion of rice. If the rice be anyway old, it is of course more difficult to digest. A very strong spirit is obtained from rice called arrack, which is partly made from it, being also mixed with toddy, which is the juice of the coconut tree. Sake is another national beverage prepared in Japan from fermented rice. In many countries rice is mixed with bean or pea meal; that combination is recommended to the parched rice travellers that have to secure that kind when on long voyages in unknown lands. South Carolina claims to have obtained the first seed rice from the Island of Madagascar, between 1700 and 1720. The importation of rice into the United Kingdom is nearly 80,000,000 of cwts. annually, and estimated at 3,500,000 of pounds sterling. Strange, though nevertheless a fact, that rice was not known to the ancients, and there is no mention of it in the Bible.—*London Correspondent in Grocers' Criterion.*

PEPPER CULTIVATION IN MALABAR.

Pepper (*Piper nigrum*) is grown in Java, Sumatra, Ceylon, and other Asiatic countries, but that which comes from the Malabar Coast is acknowledged to be the best. The only taluqs in Malabar in which pepper cultivation is largely carried on are Kottayam and Kurumbranad. The conditions most favourable to pepper cultivation are said to be copious rains, abundant dew in the night, and a gravelly red soil. These are found in other parts of Malabar, so it is not understood why the cultivation is chiefly confined to these two taluqs. Two varieties of pepper are produced in Malabar—the black and the white. The fruit is gathered green when intended for black pepper, but must become quite ripe for white pepper. White pepper differs from the black only in being stripped of its covering. After stripping them, the black berries are steeped in salt water, and when they have been exposed to the sun for several days the chaff is rubbed off with the hands. The process of cultivation is very simple. The vine is generally propagated by cuttings. It is usually planted at the base of trees, the most commonly used being *Murikku* (Erythrina Indica); other trees, such as the jack, cashewnut, and mango-tree, may also be used, but they are not in favour with the Malabar cultivators.

The first thing required for forming a pepper garden is to clear all jungle and root out all stumps of trees on the ground. This must be done by the middle of May. The *Murikku* standards, on which the vine is trained, should then be planted, and about half a dozen cuttings of the vine—each about 2½ feet in length—should be planted at the foot of each stem. The soil should then be turned, up by digging, and the cuttings tied with a fibre on to the *Murikku* crop. The tying is necessary to facilitate the growth of the vine, which sends out small roots at every joint, which strike into the *Murikku* stem and enable the vine to climb up the prop. In three or four years the vine attains a height of six feet.

The vines begin to bear in the third or fourth year, and in four years more are in full perfection, and continues so for 20 years, when they die. They blossom about the month of June, and begin to bear fruit in the following two months. The gathering season is January to March. The plant requires constant rains during the blossoming season. The expenses of cultivation incidental to farming and maintaining pepper plantations are variously stated. But it may be stated approximately that a plantation of one acre will not cost more than Rs. 300, together with an annual expenditure of Rs. 10 for its upkeep. The outturns of the pepper harvest are also variously stated. The yield ranges from one to three bharams per acre (one bharam being equivalent to 660 lbs). It is stated that a single vine produces from one edangali to four edangalis of dried pepper. There is no doubt that pepper cultivation is highly remunerative, and it is pity that it is not carried on more exteusively than it is at present.

USES OF SALT.

Most farmers are aware that salt possesses valuable manurial qualities in connection with some soils, but its application has not been nearly so extensive as is desirable. Salt consists of two-thirds chloride and one-third soda, and as the solvent powers of chloride are enormously greater than those of rain water, its ability to break up soil and leave its constituents free and available for nourishing the roots of plants is a highly valuable qualification. Salt absorbs moisture from the atmosphere and helps to retain it in the soil, thus compensating, to some extent, for a deficiency of rain, and it also purifies and decomposes inert matter. When used in connection with stubborn soils they are made easier to work, while, at the same time, it is of material assistance in helping to destroy wireworms, slugs, and other insect pests. Salt is especially valuable for sour pasture lands, its action being to make the grasses sweet and palatable for stock. It also neutralises the injurious effects of rank grasses on new

pastures. For strengthening the straw of cereals the use of salt is most important, owing to the fact that it seems to be the only substance which has the chemical power of setting free the requisite quantity of silica to nourish the stems. Salt, when previously incorporated with the soil, is useful for root crops on account of its powerful moistening qualities and its action in preventing disease. A plentiful application of salt to the manure-heap will not only fix the valuable ammonia, but will destroy millions of vermin, which otherwise would be carried on to the land to the damage of the crops. It is difficult to lay down a hard and fast rule for the application of salt, as so much depends upon the constitution and condition of the soil and on the season. Under ordinary circumstances, from 6 cwt. to 8 cwt. per acre for cereals and about 10 cwt. for roots is generally recommended upon the breaking up of land, or the month before seed time. Salt should not be applied with the seed. Repeated topdressings in small quantities during the spring will be found beneficial, and it may be liberally applied to fallows and on the stubble. The antiseptic properties of salt render it highly valuable for sweetening and preserving fodder and prevent hay from becoming mouldy.—*Australasian.*

POULTRY NOTES.

If eggs are required the best breeds are Black Minorca and white Leghorn. If eggs and flesh, the Orpington stands first. If flesh only the red Indian game is the best. The cross with the Dorking is considered the best table bird in the English market. Enquiry in England, Jersey &c. has brought out the general opinion that the Orpington is the best all-round fowl for a poultry farm. The bird is large, of a good flavour, lays very good eggs, and its constitution is good. But as a rule too heavy birds should be avoided, especially those heavily-feathered in the legs.

There are many forms of the incubator, but among the most reliable are Hearson's "self-regulating," Tamplin's "Gans Parpil" or Harris' American incubator. The eggs in the incubator should be kept moist. This is the great feature of Hearsons, and is covered by patent. The cost for 100 eggs is about £12. Their address is "Chas. Hearson & Co., 225, Regent Street, London S.W. A very useful and practical book is supplied.

Fowls lay more the first year than any other, and in the second nearly as many,—in fact most of the eggs a pullet will lay are laid in the first two years. Fowls should not be kept over two years, as they do not then pay. This entails marking. The simplest way is by rings of aluminium—the first year on one leg, and the second on the other; then sell. For breeding purposes, one cock is required for ten hens.

The outside peel of onions is about as useless substance as one can think of, but when some of it is put into a hen's nest (only the driest parts being used) it makes the nests disagreeable, and thus frees them from fowl lice.

To get rid of scales on hens' legs, mix equal quantities of ground yellow sulphur and good lard well together and apply every day to the legs as an ointment for a week or ten days. Equal quantities of salad oil and kerosine mixed have a good effect in removing the rough scales.

An excellent disinfectant for fowl houses, to be used when the birds are out, is a solution of bluestone (copperas or sulphate of copper), sprinkled by means of a watering can. It removes bad odours at once, and is fatal to disease germs.

A skilled eye can tell the difference between fertile and unfertile eggs in three or four days after setting, but it will be better for you to wait until the eighth night. Go to the sitting-house when it is quite dark, and take with you a candle or lantern, preferably of the bull's-eye type, and a fresh-laid egg. Take the latter between the forefinger and thumb, so that it is surrounded by a dark frame, and hold it up to the light. It will be clear and transparent, nothing dark showing behind the shell. Now take the eggs, whether fowls or ducks, one by one from under the hen, and examine them in a similar way; the unfertile will look like the fresh egg, the fertile will show dark patches behind the shell. The difference should be at once apparent; but if you are doubtful about any, it is safer to mark them and replace, and test again a day or two later. The unfertile should be removed and hard boiled for the future chicks.

GENERAL ITEMS.

The artichoke belongs to the Thistle family (Compositæ). It is botanically known as *Cynara scolymus*. The bottoms of the flowers and the riblike sepals are used as food by man. The so-called Jerusalem artichoke, though belonging to the same family, is a member of a totally distinct branch. It is named scientifically *Helianthus tuberoses*. The name Jerusalem is a corruption of the word Girasole, which is the term applied by the Italians to this plant as well as to the sunflower (*Helianthus annus*). The Jerusalem artichoke is said to possess exceptional drought-resisting properties, which make it an excellent standby for both man and beast during protracted droughts, since it is in many respects a valuable esculent for man, as well as a first-class feed for cattle, horses, sheep and pigs. The green tops or stalks are made use of as green fodder, hay or ensilage; but the main value of the plant lies in its tubers growing like potatoes in large numbers round the roots. These tubers (called in French *Topinambours*) form a very palatable food when fried in butter or boiled, or still better steamed, but best of all baked under hot ashes. For animals their feeding, milk-producing and fattening value is considerable.

The *Cape Agricultural Journal* makes reference to two useful parasites on insects injurious to vegetation: one is the South African parasite destructive to the black or olive scale, a shipment of which has been made to America. The parasites

will be placed on a couple of dozen small-olive trees, planted in pots, and covered with fine muslin so as to prevent their escape, and they will be released. After watching their action on the black scale on these pot plants they will be transfered to the orchard if they do well and permitted to scatter among the trees and propagate,

The other parasite (*Masicira pachytyli*) has just been brought over to California together with dead grasshoppers in the refrigerating room of the steamer to prevent the development of the parasites on the voyage. On arrival they were placed in a glass breeding jar, and after being allowed to issue, they were liberated in localities where the grasshoppers are now breeding. The parasite belongs to the genus Tachina, nearly all the members of which are parasitic or insects injurious to orchards, vineyard and farm products, and it is said that they cannot even be starved to eating any vegetable growth. The parasite resembles a house fly. The eggs of the female are deposited on the grasshopper, and their hatching produce maggots which burrow into the fly. It has been found that from 60 to 90 per cent of the grasshoppers have been known to have been destroyed in districts where the parasite has been introduced.

According to the *British Medical Review*, Dr. Jenni has found that it is possible to free a town from mosquitoes (unless the conditions are exceptionally unfavourable), and that the cost of bringing about such a consummation in a town of 50,000 inhabitants will be from R1,500 to R2,000 a year. The procedure consisted mainly of finding the breeding places of the mosquitoes and destroying the larvae by means of petroleum.

The *New York Merchants' Review* has the following amusing reference to the nutmeg tree :—A peculiarity of the nut-pigeons inhabiting the Indian Archipelago is that they swallow the nutmeg fruit bodily and discharge the nut undigested. This curiosity which leads to the distribution of the plant was formerly connected with the sex as shown in Vogel's remarkable passage: "If the bird that drops the nut is a male, the tree growing from it will be a male too; if the bird is a female, the tree will be a female as well, whilst if the bird happens to be still a virgin, the tree that grows from the swallowed nut will be one of the best in the wood."

The following are as nearly as possible the correct quantities to sow per acre :—Barley, broadcast 1 to 1½ bushels; drilled ½ bushel. Beans (broad) drilled 1¼ bushel; (French) 1½ bushel; (Horse) 2 bushels. Beet (drilled) 5 lbs., Buckwheat, broadcast, 1 to 2 bushels. Cabbage (field), in seed beds, 2 lb. Carrots, drilled, 5 to 7 lb. Clover, broadcast, 12 to 20 lbs. Grasses, prairie, 1 bushel: Italian rye, 4 bushels; perennial rye, 2 bushels; rib,; ½ bushel; couch, ½ bushel; permanent mixed pasture, 3 bushels; imphee, 20 lb.; kohl-rabi, drilled, 2½ lb. Lucerne, broadcast, 20 lb.; drilled 10 lb.; Maize, broadcast, 3 bushels; drilled, ⅓ bushel. Mangolds, drilled, 5 to 6 lb. Millet, broadcast, 1 bushel. Oats, broadcast, 2 bushels. Onions, broadcast, 5 lb.; drilled for setts, 20 lb. Panicum, broadcast, 20 lb. Parsnips, drilled, 8 to 10 lb. Peas, broadcast, 3½ bushels; drilled, 2 bushels. Potatoes 14 cwt. of cut setts; if planted with the American potato planter 10 cwt. Rye for grain, broadcast, ¾ bushel. If for saddlers' use, 1½ bushels. Sorghum for grain in drills 10 lb., broadcast for green fodder 20 lb. Swedes, 3 lb. to 4 lb. Turnips, globe and yellow, drilled 2 lb. Vetches, broadcast. 3 bushels. Wheat, broadcast, 1 to 1½ bushels; drilled, ¼ bushel. Paddy (rice), 30 to 40 lb. Cow pea, 8 lb. Jerusalem artichoke, 3 to 4 cwt. The weights per bushel of the principal farm seeds enumerated above are:—Barley, 50 lb.; beans, 60 lb.; buckwheat, 50 lb.; couch grass, 40 lb.; cocksfoot, 20 lb.; clover, 60 lb.; flax, 60 lb.; grasses (mixed), 20 lb.; oats, 40 lb.; imphee, 40 lb.; prairie grass, 20 lb.; perennial rye grass, 20 lb.; peas, 60 lb.; rye, 60 lb.; rib grass, 60 lb.; sorghum, 40 lbs.; lucerne, 60 lb.; panicum, 60 lb.; maize, 56 lbs.; wheat, 60 lb.

When the bark of rubber-producing trees is soaked in dilute sulphuric acid, it is found that the acid decomposes the tissues without affecting the rubber which is thus got quite pure. This process is maintained by *Engineer* as having been described before the Society of Civil Engineers of France. To French chemists is also attributed the discovery of extracting rubber from the Candolphia vine by crushing the vine in hot-water. The ordinary method of stepping is impracticable owing to the latter hardening quickly.

Mr. C. Staiger, late Government Analyst of Queensland, found the seeds of kekuna (*Aleurites triloba*) to consist of the following :—1. The dry nuts; shell, 70 per cent; kernel, 30 per cent. 2, kernel, free from shell; oil 54·3 per cent; amylaceous and nitrogenous substances, 45·7 per cent.

The TROPICAL AGRICULTURIST
MONTHLY.

XX. COLOMBO, MARCH 1st, 1901. No. 9.

CEYLON: ITS BOTANIC GARDENS; VEGETATION AND SHORT REPORT ON A JOURNEY TO CEYLON.*

By Dr. Treub of Buitenzorg, Java.

(*Concluded.*)

BADULLA, a small inland place, lies at an elevation of some 2,200 feet, on the eastern side of the principal mountain group of the island. It is more dependent, as regards rain, on the north-east than on the south-west monsoon; that is to say, the climate there is considerably drier than that of places at a similar height situated on the western side of the mountains. Messrs. Sarassin call Badulla a big oasis in the unfruitful patana region. The branch of the botanic garden at Peradeniya established there is, consequently, to put it briefly, a kind of experimental garden for the drier mountain regions. When one considers that our visit took place in the end of June (the 28th), and that June and July are the months of the year when the least rain falls upon the place, it is not to be wondered at that the drought, when we were there, had caused its influence to be felt appreciably on the plants. Moreover at the beginning of the year difficulties had been experienced in obtaining the needful water.

A certain number of fruit-trees, for which the drier climate is suitable, were in good condition, namely varieties of *Citrus*; also some ornamental plants and flowering plants looked satisfactory. Among the trees we were specially struck by a fine specimen of *Sapium biglandulosum*. There is in the garden only a Sinhalese overseer; this produces as regards care and upkeep of the plantation, the same difficulties that we know in Java, through exclusive native supervision over places situated too far away for continued European control. At the end of 1899 the present overseer ("conductor") will be replaced by someone else, on which occasion it is intended to effect some changes in the garden and in the method of working.

The garden at Badulla has various fruit-trees available, as well as eight varieties of palms, ten to fifteen ornamental trees and of "economic trees and plants": *Bixa orellana* (*gluigem*), rameh, oils palm, coca, Para rubber, Ceara rubber, and nutmegs.

Before the railway was laid over the high mountain pass, to get from Badulla to the similar mountain garden of Hakgala one followed the post-road Since the distance comprises thirty miles and one has therein to climb 3,690 feet, it is now simpler to return by mail-coach to Bandarawela. From there one goes back over the portion of the mountain railway, that is so beautiful, by train, to the station of Nanuoya situated at 5,290 feet, where one has to get out in order to reach farther on by carriage the justly-famed plateau of Nuwara Eliya.

After only 3½ hours' rail one is again transported from dry Bandarawela to the moist mountain climate of the westerly mountain slopes. In mist and rain we rode in three-quarters of an hour from Nanuoya to Nuwara Eliya, where the weather was much better and at once tempted us to a walk; "walk" in this sense, that, clad in European costume, one had to assume a brisk pace in order to get warm.

The plateau of Nuwara Eliya, situated at 6,300 feet above the sea, is, although a great part of it is quite flat, not entirely horizontal; there are more or less pronounced slopes, without great declivities however. It is a large plateau surrounded for a con-

* Translated from *Verslag omtrent den Staat van's Lands Plantentuin te Buitenzorg over het Jaar 1898 by* Advocate F. H. de Vos and Donald Ferguson.

siderable part by mountain tops, among others by Pidurutalagala, the highest summit in Ceylon (8,280 feet).

With its well-laid-out and excellently-kept driving and walking roads, big lake, wide racecourse, admirably managed hotels and number of villas lying up against the mountain slopes, their roofs modelled after the European fashion with chimneys piercing through the green, the whole aspect reminds one of a small watering-place in Europe. Solitary specimens of the handsome flowered *Rhododendron arboreum*, having their origin in the adjacent patanas, in many places adorn the sides of the roads, in other parts one encounters extensive thickets, composed of the oddest combinations of European, Japanese and especially Australian shrubs and trees (especially many acacias), whilst in the neighbourhood of the dwellings a profusion of European plants (heliotropes pelargoniums, pinks, mignonettes, roses &c., &c.,) blaze with a glory of flowers. Though neither of us very friendly to a stay, such as is usually enjoined in our higher Javanese mountain regions, both my travelling companion and myself were under the influence of the special stimulus of the *ensemble* at Nuwara Eliya, and that although we were not there in the good season. As such however are said to be the months of December, January and February, when it freezes somewhat in the night and is bright sunny weather in the daytime. The mean temperature throughout the whole year varies between 13·5 and 15 degrees c. 56·3 and 59F.)

In the good season a number of visitors come from near and far to Nuwara Eliya, to spend some time there. The growing fame of this plateau must to a considerable extent be explained by this, that the fact has there been grasped, by the building and arrangement of dwellings, clothes, food, comfort &c., of how it is necessary to live, so that one indeed experiences the refreshing, exhilarating influence of the mountain climate, with its surrounding country reminding one of beautiful regions in Europe, but know how to guard oneself against the unpleasant and harmful effects of such a climate, asserting themselves at other seasons and hours, by the mode of living, just as well as one knows how to do at home on bright spring and autumn days.

Although Nuwara Eliya is generally called a "sanatarium," it is self-evident, that the climate there is not suited to some invalids. Indeed I do not think I mistake in saying that the chief value, from a hygienic point of view, of a place like Nuwara Eliya lies in the preventive favourable influence of the climate. It tends to conserve the energy, briskness and love of life of Europeans who for the greater part of the year must live in warm regions, and are only seldom in a position to obtain the desired refreshment of body and spirit by a journey to Europe. That especially in this last respect a stay on a plateau in the tropics, however well it may fulfil all requirements, cannot entirely take the place of a residence in Europe is self-evident. But, when one considers, that in the "season" months at Nuwara Eliya some 3,000 visitors come together from relatively neighbouring countries and not entirely from Ceylon, it is equally evident that one can complain very little of the entire absence of that peculiar psychic stimulus contained in the temporary removal of oneself to an entirely different environment, the meeting of various persons from entirely different countries and with entirely different aspirations, in short a sojourn in a centre not infused with the every-day spirit.

Though the reputation of Nuwara Eliya is now continually extending, it must not be thought that the beginning was not difficult. The contrary is the case. Naturally the difficulties had to be overcome of the site, from the nature of the case, with such a high-lying plateau, not easily attainable. Even more opposition was found in the common human inclination that is *not* diminished in intensity by a residence in the tropics, in the case of every new thing, to look by preference at the dark side, and, by wishing for medals without a reverse, to hinder the carrying out of every new idea.

A former energetic governor, Sir William Gregory, to whom Ceylon is much indebted, among other things, in spite of all real and fictitious difficulties, took vigorously in hand the development of Nuwara Eliya. To him is due the lake, which, by the induction of a stream, was artificially called into life, and which now, perfect as if due to nature alone, adds so much to the attractiveness of the landscape. Sir William Gregory's predecessor, who was pig-headed with regard to the attempts to bring Nuwara Eliya to the front, was, so runs an anecdote, when he heard of the plan of his successor to make a lake there, so convinced of its impossibility that he declared himself ready in his own august person to drink up all the water that should come into the projected lake? And eleven years ago an English member of Parliament, who wrote an account of a journey round the world,—whose style it is true seemed generally to incline towards the pessimistic, —had not a single word of appreciation or praise but only persiflage and ridicule for all that was then already completed at Nuwara Eliya.

That those who, in the matter of sanataria and "air-cure resorts," want by choice "five feet on a sheep," do not allow criticisms of it to be lacking needs no demonstration.

But, in spite of all opposition and criticism, the development of Nuwara Eliya was proceeded with in Ceylon, and, after the overcoming of difficulties without number, one can now point there with pride to the Ceylon "sanatarium." *E pur si muove!* There is business-there; and it is daily increasing. During our stay in the island not only was a proposal of the Governor's, to grant a considerable sum to Nuwara Eliya, for the carrying out of various improvements, unanimously agreed to by the Legislative Council, at its sitting of 29th June, but advantage was also taken of that opportunity by several members to set forth in terms mostly highly laudatory the great importance and utility of Nuwara Eliya.

This somewhat long digression on the Ceylon plateau that is becoming increasingly more famed, is here, inserted purposely, because with us an attempt has begun to bring into existence something like what has taken place there. I lack the qualification and the data both to decide if the plans developed for Java offer more or less chance of success, and if there are present corresponding conditions which should promise as good a result as that attained at Nuwara Eliya. *One* conviction, however, I have brought with me from Ceylon by my own observation and by explanation and information obtained, namely that, whenever it should appear possible to call into being upon a plateau in Java something resembling Nuwara Eliya, the execution of such a plan should be a *blessing* to our colony.

Six miles east of Nuwara Eliya lies the hill garden of Hakgala, the largest branch of Peradeniya. As such the garden has been conducted since 1882 only; before that (from 1869 onwards) the land was occupied by a cinchona plantation or experimental garden of the Government.

The position of the garden at Hakgala, at 5,800 feet elevation, is exceedingly beautiful. The conditions for the growth of most plants from cool climates are there in general favorable. Off and on however they have had to suffer there, now from periods of too great drought, then again from phases when too much rain falls continuously, and there is too little sun. By chance both the one and the other were experienced in 1898. A worse disadvantage—because it happens regularly—to Hakgala as a place suitable for a botanic garden is the constant occurrence of severe winds that cause damage. This evil has under the present conditions been reduced to a minimum by the extraordinary and continuous exertions of the superintendent, Mr. Nock. It is

remarkable what exceptional results have been obtained in the sphere of cultivation by this zealous and capable manager. It is hardly credible that no where else in the tropics will one meet with such a rich collection of flowers indigenous to temperate climates, in number of species and varieties, as that which one is able to see at Hakgala. That the *Eucalypti* and other Australian trees thrive well there is due to the climate; varieties of *Cupressus* also grow well there. Fine specimens of tree-ferns, both indigenous to Ceylon and to New Zealand and Australia, also attract attention. In the lawns stand handsome specimens of *Bocconia frutescens*, whilst a large and well-grown example of *Pinus longifolia* strikes the eye by its dimensions.

In the last annual report the mention of the one that was observed in the botanic garden at Penang gave occasion for a brief consideration of our hill garden at Tjibodas; something similar is now, on the ground of the visit to Hakgala, once more the case.

Both the hill gardens, Hakgala and Tjibodas, are capable, as regards the object aimed at, of only a very limited comparison. The very great importance that, from a scientific point of view, attaches to Tjibodas as a station for the trial of the luxuriant flora of a primeval tropical hill forest is not to be sought after at Hakgala, because in that respect, the conditions there are in no wise so favourable as in our hill garden. Nevertheless the Ceylon hill garden can, in other respects, serve as an example to ours. In the first place there leads to Hakgala a winding carriage road in excellent condition, so that the garden can be reached without difficulty. Herein a comparison with Tjibodas very far from turns in our favour, since we do not even possess an elementary cart road to reach our hill garden. As it is to be feared that even such a simple road must as yet continue to belong to the *pia vota*, we shall have to resign ourselves to the thought that scientific students who visit first the Ceylon gardens and then the Lands Plantentuin—as sometimes happens—will consider the accessibility of our mountain branch as not quite "up to date." Hakgala also surpasses Tjibodas in the state of upkeep of plantations and roads, which is intelligible when one knows that about 11,000 rupees a year are spent on the Ceylon hill-garden, for all expenses inclusive.

On 1st July we returned to Peradeniya, where another couple of days were spent at the head establishment, after which the undersigned, under the guidance of Mr. Willis, set out on the journey to the northern branch, that of Anuradhapura. Of this garden, which truly in comparison with the two hill gardens spoken of, those of Tijibodas and Hakgala, occupies a very inferior place, one can certainly not say that it is easily accessible. In order to get there one must first go in the evening by train to Matale, where one stays the night in an excellently managed resthouse. After this one proceeds the following morning by mail coach in order, if all the circumstances are favourable, to reach Anuradhapura twelve hours later. Indeed we might consider it fortunate that the journey was accomplished in the regulated time, nevertheless the chief impression of that journey may be best expressed by the well-known quotation from the "Camera obscura." "How hot it was and how far."

The first portion of the road goes through a well cultivated and not yet too dry region; one rides, among others, along extensive cacao plantations, that stand under very dense shade. According to what I was told, the planters have adopted that as a remedy against the attack of *helopeltis*; that they had thereby however fallen into the evil—and this view is very plausible—of having by too much shade helped the development of parasitic fungi. On behalf of the Ceylon planters Mr. J. B. Carruthers, a competent and energetic young English botanist, had spent some time in the colony in order to make a study of the parasites of vegetable nature that do harm to the cacao culture. Many a useful hint to the planters has already been the fruit of this investigation.

Further up one comes into the true dry region that embraces so large a part of North Ceylon. Long straight roads over a gently undulating plain lead through a comfortless, monotonous, unfruitful and sparsely populated region, covered with brushwood and low trees. And yet in earlier times this was different. Some 2,000 years ago Anuradhapura was the great and populous capital of Ceylon; in the vicinity were then found gigantic works of art, namely enormous water reservoirs—more strictly speaking artificial lakes—which by means of regular irrigation had to guarantee the fertility of the region. Of all this there remains nothing more than extensive portions becoming marshy or evaporating puddles, where thousands and thousands of herons, storks, ibises, plovers, cormorants and a host of other waterfowl alone have sway.

Towards the fall of the evening we reached Anuradhapura, where, on a large plain, surrounded by strange and fantastic ruins and buildings, no longer easily to be discerned in the gloaming, crowds of pilgrims with hundred of lights and lamps had pitched their camps in the most picturesque confusion near their carts and unyoked oxen. In a resthouse that, as regards accommodation and cleanliness, can easily compete with most of our Java hotels, and far surpasses our *pasangrahans*, we found a very grateful shelter.

The little Garden at Anuradhapura was begun in 1885, with the object of making of it a sort of culture garden, especially for those tropical plants that do not bear a moist climate well and prefer drought and heat. Just in the year in question the drought was so severe, that several plants in the garden died, both trees and shrubs and herbs, which have since been as far as possible replaced by new specimens. A considerable portion of the labor force must be utilized in the middle of the year for bringing water and watering. That under such unfavourable circumstances the condition of the plantation is not flourishing is evident. Moreover the overseer can be but little controlled owing to the great distance—through troublesome communication—that separates Anuradhapura from Peradeniya. The difficult communication carries with it also the evil, that useful plants which, according to experiments made in the garden, will thrive well under the existing climatological conditions, as for example cotton, nevertheless as yet afford no opportunity for distribution for planting on a large scale, because the cost of transport of the product is too high. For the time being there is therefore not much to say about the little garden at Anuradhapura. When however the projected railway connection shall have opened an easy communication with the south of the island, and greater certainty of water supply is arrived at, then it will be possible to propagate a larger number of useful plants, fruit trees and others, in the garden at Anuradhapura and distribute them from there in the neighbourhood.

The place could not be left without a visit to a great botanic curiosity, which, together with the ruins and the dagobas, is the object of the crowds of Buddhist pilgrims, who, especially at certain times of the year, stream towards Anuradhpura. I refer to the sacred bo-tree (*Ficus religiosa*), regarding which its seems to be known with certainty that it was planted 288 years before our era by a certain King Dewanampiyatissa. Of this tree nearly 2,200 years old—probably the oldest of all trees upon our earth of which the age is known—some portions are still, surrounded by a high enclosure and carefully guarded by Buddhist priests, living, whilst in addition several of its off-shoots, also of a respectable age, grow vigorously inside an outer wall that separates the holy place from the outer world.

Had it not been our intention to become personally acquainted with all the branches of the botanic

garden in Ceylon, it is doubtful if the visit to the little garden at Anuradhapura was worth the tedious journey there and back. The expedition however in other respects fully rewarded us. In the first place because the place is so remarkable from an archaeological point of view, that the visit even for a layman is exceptionally interesting. In the second —and this has directly to do with the province of the writer of this—because it affords an opportunity of forming a good idea of the extensive dry northern Ceylon, which differs both botanically and economically so markedly from the better known southern portion of the island.

Yet one last "bye-garden" remained to be seen, namely, that of Henaratgoda, situated at about sea-level, at a distance of 16 miles from Colombo, a twenty minutes' ride from the station of the same name. In my visit to this branch, which thus, in strong contrast with Anuradhapura, has a warm but at the same time equably moist climate. Mr. Willis had the great kindness to again act as my guide by coming down specially for that purpose, some days after our return from the north of the island, whilst I came from the adjacent Colombo.

The Garden at Henaratgoda, which covers an area of 39 acres, was commenced in 1876, specially for the cultivation of caoutchouc-yielding plants imported from South America. Although many other plants worthy of observation are met with in this garden, among others a young but fine specimen of *Lodoicea Sechellarum*, and many cultivated plants grow very well there, still the chief attraction of this branch remains the caoutchouc-yielding trees, and more especially the Para rubber-producing *Hevea brasiliensis*. Of this useful tree one meets at Henaratgoda with such fine and vigorous specimens, that this alone amply repays the trouble of a visit. Here also practice demonstrates the same as on the cultivated plant portion of the botanic garden at Singapore, namely, that the *Heveas* need a warm and moist climate and specially a moist soil in order to grow well and vigorously

An enforced postponement of our return voyage for several days—in consequence of a fear of eventual quarantine in connection with the plague in British India—was utilized by us in obtaining, both by a journey to Point de Galle and in Colombo itself, some data regarding export products of vegetable origin. These data were obligingly furnished, or at least the way indicated how to obtain them, by the Netherlands Consul at Colombo, Mr. Wennink, to whom once more a word of grateful thanks must be offered for the general help and friendly guidance afforded to us.

Especially in the districts round Point de Galle much is done in the culture of Citronella Grass, of the oil of which in the first half-year of 1898 no less than 594,433 pounds were exported from Ceylon. And the cultivation of this grass is further increasing, as was told me on credible authority. For Europeans, in Ceylon at least, the cultivation of citronella grass and the preparation of the oil does not pay. A European proprietor, living 15 miles from Point de Galle, who occupied himself therewith and extracted the product properly, certainly obtained higher prices than the native people for the citronella oil prepared by him, but nevertheless had to give up the business. That locally not much profits is to be made from it is proved by the following figures, which were furnished to me there. In the first two years there is no crop; then every year for a space of ten to twelve years. Then the grass can be cut four to five times a year. From each cutting is obtained 16 to 20 bottles of citronella oil per acre (bottles of 22 English ounces). For this oil the native producer gets 85 cents a bottle, while his total expenses of production come to 70 cents a bottle. Thus under the most favourable circumstances the profit obtained amounts per annum to 15 rupees per acre.

It must be borne in mind, that all these figures as well as the following statement refer to 1898, and that they rest partly upon verbal communications of very experienced persons.

The export of all kinds of products of the Coco palms is very considerable, which is not to be wondered at, since from Colombo to Point de Galle one rides continuously through such enormously extensive and fine coco plantations, that one understands how even a Junghuhn can declare never to have met with anything like it in Java and Sumatra. The shipment of coconuts as such (from the ports of Colombo and Point de Galle together) remained about constant in the years 1895, 1896, 1897 and 1898. In the last half of 1898 there were shipped some 5 million nuts. The export of "desiccated coconut" also remained nearly the same in recent years (with the exception of 1896, when much more was exported), namely 5 million pounds per half-year in the years 1897 and 1898. This dried coconut is packed in tin, in packages of half-a pound. Whilst of coconut oil in the first half-year of 1895 there were exported 143,329 cwt., in the first half of 1898 it had already risen to 177,282 cwt. Nevertheless the comparison of the figures for copra for the same years gives the astonishing result that in the first half of 1895 only 4.692 cwt. were exported, and from 1 Jan. to 28 June 1898, 176,211 cwt. In addition the export of "poonac"—the resultant of the copra after the extraction of the oil, which is sent in cakes to Europe for cattle food—increased in the same period from 83,560 to 101,184 cwt.

Of the fibres of the cocoanut, brought into the market, according to the method of preparation and treatment, under the three categories of "rope," "yarn" and "fibre," there were exported in the first half-year of 1898 respectively 5,785 ; 30,984 and 43,678 cwt ; quantities that, compared with the first half of 1895, taken all together, remained almost the same.

The rope is made by the natives with hands and toes and brought on the market in 14 numbers. Attempts to manufacture this produce by machinery have so far not succeeded; the preparation of the *fibre* however is carried out by Europeans in Colombo.

The coconut oil is prepared by the native people in the most primitive mills, worked by oxen or buffaloes. In the installations in Colombo it undergoes a further purification, by filtration, before being shipped. The careful measures that have to be taken against leakage and also, as I remember well—the higher freights, cause the export of copra and that of coconut rope to be more profitable than that of the oil.

In conclusion it may be mentioned that from the coconut, arrack is prepared (although that article does not appear in the export statistics accessible to me.) At Moratuwa a place situated on the railway to Point de Galle, at about 17 miles from Colombo, is an arrack distillery in which, as my informant told me, millions are earned.

From the very great importance that all these products of the coconut have for the trade of Ceylon it is not to be wondered at, in travelling by rail to Point de Galle and in the vicinity of that place, one is struck by the evident prosperity of the population. Matara, a place yet further than Point de Galle and almost at the southern most point of the whole island, is known as the residence of many rich Sinhalese families of the lowlands.

Of Cinnamon there was exported in the first half of 1898 altogether (in "bales" and "chips") about one-and-a-half-million pounds, that is some four hundred thousand pounds more than in the like period of 1894. In spite of this still fairly remunerative trade, there is, so I was told, only one European who occupies himself with cinnamon cultivation, because it is not profitable enough for the European planter. The prices are on an average about 50 rupee cents per pound, varying between 80 and 35 cents, according to the quality (from No. 1 to No. 5.) In recent years however the price

rose to a maximum of only 68 cents, while sixteen years ago the lowest prices—28 cents per pound—were realized. As has been said, the culture is still possible for natives with prices of 30 cents the pound. One reckons on an average annual return of 100 English pounds per acre and a maximum of 150 pounds. A certain quantity also—which is increasing—of cinnamon oil is exported, whilst from the leaves is prepared the "cinnamon leaf oil" that realizes 22 cents per ounce.

Of Cardamoms there was exported the quantity, that remained pretty constant during the last few years, of about half a million pounds per year, at prices varying for R1·6 to R2·2 per pound.

The export of Cacao, which is increasing, amounted in the first half of the year under report to 27,010 cwt., generally taken at 37 to 38 rupees per cwt., whilst there is one estate the produce of which fetched 55 rupees.

The export of Coffee from 1st Jan. to 28 June 1898 amounted to only 6,560 cwt: against 38,397 in the same period of 1895; that of Cinchona bark in the same time 395,716 pounds against 498,973 in 1895,

Ebony and Sapanwood are still exported, but in steadily diminishing quantities: in the first half of the year of report respectively 1,854 and 2,086 cwt.

Of fibres were also shipped, in the period in question, palmyra fibre (of *Borassus flabelliformis*) 15,768 cwt, and kitul fibre (of *Caryota urens*) 2,181 cwt., more certainly than in both the preceding years, but then somewhat like the export in the first half 1895. There may be mentioned, that the fibre of *Fourcroya gigantea* is not exported from Ceylon, although the plant grows excellently there, because no profit is seen in the prices obtained from the cultivation and preparation.

At the conclusion of these short data regarding the vegetable export products of Ceylon it may be repeated that of the chief of those products, tea, *in the whole year* 1898 were exported a trifle of 120 million pounds, being almost 4 million pounds more than in the preceding year.

Finally there remains just one word upon a subject totally different from the foregoing, namely, a visit to the Museum at Colombo.

It is a handsome building of two stories in front of which is a large lawn with a statue of Sir William Gregory, the former Governor of Ceylon, already spoken of. Commenced in 1877 in the so-called "Cinnamon Gardens," the Museum was reserved for all that Ceylon produces in products of agriculture and industry, minerals and gems, collections of natural history and ethnological as well as anthropological collections, as also for a library.

There is a special reason why the Colombo Museum is mentioned here; namely, the presence on the second floor of an exceptionally fine zoological collection, continuing to remain in an uncommonly good state, also entirely confined to the Ceylon fauna.

The present writer was also previously under the delusion that in a constantly moist tropical climate it is as good as impossible to preserve a Zoological Museum in only a tolerable condition. A visit to the zoological collections of the Museum at Colombo shows, in the most convincing manner, the injustice of this opinion. The collections look so good and well preserved and the mounting is so effective, that one could not find better in any single European Museum. This result, which cannot be too highly commended, was attained by continued expert oversight and particular maintenance. Such a zoological collection must be of specially great use for those that concern themselves in the natural history of the island, either from a purely scientific point of view or from practical interest.

It is certainly a matter of shame to us residents in Netherlands India that we have not been able to produce anything in any way like this.

The hope may perhaps be entertained, that within not too long a period we may get in Java a simple but well-kept Zoological Museum maintained under expert supervision, and in that way, with our rich fauna and our so much more important island, no longer stand entirely behind Ceylon in the matter in question.

Such a Museum would for us be for two reasons of great importance. In the first place, because the number of zoologists that come to Java is steadily increasing; in the second, because a Museum such as that referred to cannot be otherwise than a guide of great value for all questions of practical moment, especially as regards agriculture.

On 15th July we once more embarked, in order to return to Buitenzorg *viz* Singapore, convinced of the great use that the visit to Ceylon had been to us. With the literally daily correspondence that the Lands Plantentuin has with foreign countries and the great number of foreign visitors that come there—both students of nature and persons dependent on or interested in agriculture and horticulture—it is, for him who has the honor to superintend the establishment, of the greatest value *to be able to learn by personal observation* what there is in other colonies in the same or in a similar domain.

Besides: if there is with us much, the superiority of which over that existing elsewhere may with justice be mentioned, that does not prevent the observations made abroad from being in not a few cases of service to our successors also, and the eye is opened to ways whereby and directions wherein service can be rendered in our case also, and to which presumably only very incomplete attention had been paid.

In conclusion thanks are tendered by the undersigned to the heads of the Department for the assistance rendered to him in the compilation of this report.

TREUB,

Director of the Lands Plantentuin.

Buitenzorg, July, 1899.

PLANTAINS AND BANANAS.

By Percy G. Wicken.

Inquiries having been made as to the method of cultivation, and the best varieties to grow in West Australia, the following notes may prove of interest to intending growers:—

The plantain usually attains a height of about 8 ft., and in favourable positions often reaching 12 to 15 ft., and the stalks a foot in diameter, it is one of the most striking instances of tropical fertility, growing in a few months to a size that takes other plants in cooler districts several years to attain. The plantain is to many thousands of people in the tropical islands what rice is to the Hindoos, rye flour to the Russian, and wheaten bread to the Englishman, it is their staff of life. It is claimed as a native both in the old and new world, and has been cultivated for ages in both hemispheres.

The banana is similar to the plantain, but the fruit is smaller. There are several varieties to be obtained in Western Australia, viz., the sugar banana, apple banana, pear banana, Cavendish or Fiji, and the Chinese banana; this latter variety is the one most likely to prove successful in the stretch of country between Perth and Geraldton. It is a comparatively dwarf species, the stem attaining a height of only 5 or 6 ft. Its robust and dwarf habit renders it particularly fit for exposed localities, and this is one of the reasons why it is so extensively cultivated in the South Sea Islands. It is early maturing, is not so exhausting on the land as the taller growing variety, and is very prolific.

This variety, as well as the plantain, should grow very well as far south as the Swan river, but it is not likely to give good results further south. There should be a good opening for several large plantations along the banks of the Swan river or the adjacent country, and having a market close at hand, the cultivation of this crop should prove a profitable undertaking. Between the Swan river district and

the Northern districts of the colony there should be plenty of spots where the cultivation of the banana might be undertaken on a large scale.

It has been found by experiment that the banana will live, if in proper soil, without injury to the roots, at a temperature as low as sixteen degrees Fahr, the stalk will stand a temperature of twenty-five degrees without injury, and the leaves are not wilted until the air is chilled to thirty degrees. Although the banana is stated to live at this temperature, it would not be advisable to plant out on a large scale unless the temperature is considerably warmer than that stated. The site for a plantation should be in a sheltered position, and as near as possible to a railway line or convenient water carriage so that the fruit can be carted cheaply to market, with as little handling as possible. When the site is decided upon the land must be cleared and should then be broken up and subsoiled as deep as it is possible to do it. Strong teams of bullocks are best to use for this purpose, one plough following the other and breaking up the soil in the same furrow without bringing it to the surface. The land then requires harrowing and rolling until in good order. If the land is low, and likely to be covered with water during the rainy season, it will require draining, and if too low for underground draining, open drains should be cut out with the plough at a distance of about one chain apart: the banana likes a rich, moist soil, but will not stand stagnant water.

The land should now be marked out into drills 15 ft., apart each way, and the young plants put in at each intersection of the drills, this will take 193 plants per acre. By planting on the square system we are able to keep the cultivation going between the rows until the plants are fully grown. The banana is propagated by suckers taken from the old plants that have fruited. Holes should be made in the ground deep enough to allow the roots to be placed in as deep as they were when taken from the parent plant. The suckers should not be removed from the parent plant until everything is ready for planting them out in their new home. The roots require planting as carefully, and in the same manner, as you would plant out a fruit tree, and the soil should be well packed round the roots. If the land between the rows is kept free from weeds, the plants will require no further attention except to replace any that may not have taken root. The shoots or suckers should be taken from the parent stem when from 2 to 3 feet high, their bulbs being divided from the principal bulb by means of a mattock. These slips are cut about 8 inches above the next, and placed in a slanting direction in the prepared holes, and covered with earth leaving in sight only about two inches.

The length of time which elapses between the planting of the slips and their fruiting depends on climate, situation, and variety of species.

During the first year a crop of maize, sorghum or other desirable crop may be grown between the rows, and will help to pay the expenses of keeping the land free from weeds; after the first year when the bananas begin to bear fruit, they will require the entire use of the land. The suckers will bear fruit from twelve to eighteen months from time of planting out.

After the bunches of fruit have been harvested, the stems should be cut down to the ground, and two or three of the strongst suckers left for successive cropping, all the weaker ones should be cut out or carefully taken up if wanted for new plantations. If properly cultivated and looked after a plantation will keep in good bearing for about seven years, but after that the yield is noti satisfactory, and it is better to put the land under another crop. It is not advisable to plant bananas on the same land for some time to come, as it is likely to encourage disease, but a system of rotation of crops is always desirable.

The banana being a quick, rank growing plant, is naturally a gross feeder, and requires to be well supplied with manure, it requires principally nitrogen and potash. The best manure to use is well rotted stable manure, dead leaves, etc., that will supply plenty of humus to the soil, it should be applied as a mulch during the summer months to keep the soil moist, and then worked well into the ground with a hoe during the autumn. If artificial manure has to be used, a mixture of bonedust, kainit and sulphate of ammonia would give the best results, it should be mixed in the proportion of 200 lb. bonedust, 200 lb. kainit, and 100 sulphate of ammonia, and spread round the roots at the rate of about 3 lb. per plant; this would take about 5 cwt. per acre. It should be applied early in the spring.

The amount of fruit obtained from a plantation of bananas is enormous, 70 lb. of fruit often being obtained from a single plant twelve months after planting. A statement made by Humboldt, once thought exaggerated, that an acre of good land in the tropics covered with plantain would yield as much nutritious food as 144 acres of wheat, is now no longer denied or doubted.

A Sacramento grower, in recording his experiences as to how to grow bananas in the garden, says:—"My method has been to supply the richest food for this gigantic plant, and force it to its extreme growth. Everyone has old chip dirt, ashes, boots, shoes, clothes and manure which are often a nuisance. Dig a big hole, bury this up, in the centre of the mass place a pailful of sand and plant the fresh bulb. This is to preserve the dormant plant from the wire-worms and insects which will not attack the growing plant. As the plant grows, give it an abundance of water, and all the slops of the house. Any kind of manure, fresh or old, ashes, leaves and vegetables will soon disappear, and be absorbed by this gigantic king of plants. As the rainy season approaches, pile all the leaves and twigs of trees around the plants. It protects the bulbs and makes the soil rich for next season."

In addition to its use as a fresh fruit, the banana is of considerable value as an article of food when dried. In a dry climate, where there is plenty of sun, the fruits may be dried in the following manner:—They are exposed to the sun in bundles, and when they begin to wrinkle they are peeled, for the skin, if left on, causes a disagreeable flavor. They are kept for some time until an efflorescence of sugar appears on their surface, as on dried figs and prunes. They are then pressed in masses of about 25 lb. each and wrapped in leaves or else packed in boxes. These methods can only be adopted in countries where the climate is very dry. In others, recourse must be had to artificial means which are, unfortunately, more costly. There are three distinct ways in which the ripe banana may be dried—1st, exposing the fruit to an atmosphere of sulphric acid gas before the desiccation is begun; 2nd, boiling rapidly very ripe fruit in water which contains sulphate of lime; 3rd, by boiling it in syrup. By either of these, the albumen and caseine of the fruit coagulates, and the tendency of the banana to decay and ferment is stopped at a period favorable for desiccation. Experience shows that the second method is the best to employ in moist climates, without this precaution the fruit instead of drying becomes damp. To expose the fruit to the sun's rays after boiling, trays of bamboo or of any material which permits the free action of the air and light may be used. If rain falls they are dried in a furnace or an evaporator. The bananas when dry are pressed, and packed in boxes. Banana drying has been successfully carried out in Queensland. A meal is also made by slicing the banana,

drying in the sun, and then grinding into flour, it is very palatable, easy of digestion, and suitable for food for invalids and children.

Vinegar may also be made from the banana, when a glut occurs in the market.

The stem of the banana may be used in many ways, cattle and pigs both eat it with a relish, a starch is made from it, but the main use is for making fibre, and this is extensively carried out in Jamaica and other countries, Manila hemp and cordage are made from a species of banana, and over £1,500,000 worth are imported into the United Kingdom annually from the Phillipine Islands.—*Journal of the Department of Agriculture of Western Australia.*

TOBACCO.

A trial was made of a small area planted in tobacco at St. Clair in 1898-99. This produced a crop of tobacco which was of inferior quality, but nevertheless sold at a fair price in the local market. Most of the tobacco grown in the Siparia district of Trinidad, although cured after the Cuban fashion by a native of that Istand, is characterised by the presence of a musty flavour which destroys its value. The texture of the tobacco is good, it burns well, and it would not be deficient in flavour if the musty character could be eliminated. The Cuban leaf, however, appears to be too thin for our climate, for in wet weather, the leaves becomes spotted and useless. Again, many native growers who do not follow the Cuban plan of curing, add to this fault by actually allowing a damp fermentation to take place, which has the result of rendering the tobacco leeves tender in places and generally inferior in quality.

Discarding mainly the Cuban variety in 1899-1900, another kind was planted, which was grown from seed furnished by a correspondent. This variety has proved itself much stronger in habit, and the leaves on being cured have given good sound tobacco of full flavour and aroma. Further experiments are to be carried on next season. The main feature of the experiment was that the seed was sown so that the crop ripened in the dry season of February and March. In these months the euring can be carried on with more security from the attack of mould fungi, and a better sample results.

I am confident if growers could only be persuaded that tobacco does not require a damp fermentation. but should get what is known as fermentation only, a much better tobacco could be put in on the market. As described, our process (which is practically that followed in Cuba) is to cut the leaves in pairs and hang up under cover until the mid-rib of the leaf is well dried and the leaf itself crisp and easily broken if handled in the driest part of the day. When this stage is reached, the leaves are packed into hands of some 10 or 12 leaves together, and again allowed to dry for a few days. This operation should always be done early in the morning when the leaves are limp and soft from the night air, but they should never be handled when crisp dry at mid-day. When all the leaves are ready they should then be tightly packed into a stout box and turned once a fortnight for some three months, when they should be sufficiently cured for manufacture. At no time should the bulk of the package appear damp to the hand, or even to develope heat above the normal temperature, more than by one or two degrees.

Concisely stated, tobacco seed sown in September, planted in November, harvested in February, and dried and put to cure a month later. Turn every two weeks, turning sides to middle each time, cover with dry banana leaves, and put on cover with weights to keep the bulk closely together.

Anyone following this plan will be sure to get a tobacco which will sell and give a good return. Our crop gave 800 lbs. to the acre, and is estimated to be worth not less than 12 cents per pound in the local market. The principal expenditure is for the labour; the picking caterpillars morning and evening being very expensive but a return at the rate of £21 per acre will more than provide for this, and leave a good a good margin for the planter.—*Trinidad Bulletin.*

RATIONAL MANURING.

In our remarks on the above subject published in March last, we dwelt mainly on the value of potash and nitrogen, and stated that a manure containing an excess of nitrogen will unduly increase the growth of leaf and straw at the expense of fruit or grain, and that, in order to avoid such a result, stable manure should always be supplemented by artificial fertilisers containing phosphoric acid and potash. These two ingredients however, should not be applied during the growing season, as their tendency is to injure the young plants and even the seed. We experimented on a bed of beans by applying these fertilsers when the plants were in full leaf, the result being that all of them rotted off at the surface of the soil. To avoid such a catastrophe, phosphoric acid and potash should be applied for some time (several weeks at least) before sowing, in order that their mineral fertilisers may become thoroughly incorporated with the soil. The reason which makes it imperative that phosphoric acid, in some form or another, be applied to the soil is clear enough. All our cultivated plants contain a large amount of phosphoric, acid, which is wholly derived from the soil. If the crops are removed either in the shape of grain, fruit, or green forage, then so much of this fertiliser is irrevocably withdrawn to build up the bony structure of the animals to which the crops are fed. Now, most soils are naturally deficient in the supply of phosphoric acid and what there is is so slowly available for plant food that it becomes an absolute necessity to supply it in a more readly assimilable form and in greater quantity. Seeing that the bones of animals are made up of phosphate of lime, it was concluded and rightly so, that ground bones would supply the want of phosphoric acid in the soil. The effects of an application of bonedust were so apparent that it was universally used by cultivators of the soil. When, however, the discovery was made that certain minerals would supply the necessary ingredient, the consumption of bonedust fell off, as it was found that Thomas's phosphate was not only cheaper than bonedust, but produced better results, and was much quicker in its working. Superphosphates also came upon the scene, and thus bonedust was practically discarded as an agent for replacing the phosphoric acid in the soil. In both these, the latter is very soluble, and is easily absorbed by growing plants. It may be interesting to those who use basic slag, or who see it mentioned in reports of experiments on crops, to know what it is. Steel is made from iron, but if the iron ore contains much phosphorus this ingredient has to be

removed, or the best steel cannot be manufactured. It is got rid of by burning to an acid. Subsequently it was discovered that by combining lime with this acid there was produced a substance called phosphate of lime. Now, this phosphate of lime, mixed with oxide of iron and some other refuse, floats on the top of the molten metal in the furnace, and is named basic slag. When it has been removed and cooled down, it is ground to powder, and thus an excellent fertiliser has been obtained from a substance useless to the ironfounder and the steel manufacturer—the waste of one industry becoming the support of another.

This particular Thomas's phosphate combines lime and phosphoric acid in the proportions of four to one, the lime being very soluble.

When bones are converted, by being dissolved in one-third of their weight of sulphuric acid, a superphosphate of great value is produced, a value such that one bushel of superphosphate is equivalent to four bushels of simple bonedust.

Other superphosphates are the produce of those phosphoric deposits found in the South of England consisting of masses of broken bones and teeth of prehistoric monsters—gigantic sea-lizards, whales, sharks; and also there are vast deposits of so-called *coprolites*, now supposed to be fossilised excrements of the animals themselves. Thousands of tons of these are annually ground up and converted into superphosphates for which there is an immense demand in the farming districts all over the world.

However, it is not our intention to give a list of phosphates or superphosphates, but we wish to impress upon agriculturists the absolute necessity of supplying the phosphoric acid demanded by field and garden crops, and of keeping up the supply. Consider what a quantity of phosphoric acid some crops require. Wheat requires 60 lb. per acre; beans, peas, &c., 80 lb.; some oil-producing plants 90 lb.; and small fruits 100 lb. Now, these quantities must be replaced, and stable manure alone is unable to furnish them; therefore if heavy crops are demanded from the soil, it follows that an artificial manure, in addition to the stable dung, is imperative. Here is a very clear statement showing the comparative phosphoric value of stable dung and Thomas's phosphate: 100 lb of hay demands from 1 lb. to 1¼ lb. of phosphoric acid, 100 lb of stable dung contain only 2½ oz to 4 oz of the ingredient, so that it would require 600 lb of it at least to furnish the phosphoric acid for 100 lb of wheat, whereas, by using the artificial fertiliser-phosphate or superphosphate, 1^0 lb. would be enough for 1,600 lb. of wheat.—*Queensland Agricultural Journal.*

MANGOES.

In article No. 308 published in the issue of the Bulletin for July, 1899, it was stated as follows:—

"There are several other mango trees in the Garden which will probably prove worthy of record later when they have been sufficiently examined."

During the end of last season several mangoes were examined, and out of these seven have been selected for record, the figures and descriptions of which are now given. It has been thought advisable to import, once more, a number of selected varieties from the East, and to this end application was made to the Indian authorities for the best kinds from the various provinces, and cases of plants have been ordered from the Bombay-Bengal and Madras presidencies. It is almost certain that we do not possess all the types of the various strains of mango grown in the East, and although our number of seedling varieties is legion, yet it is probable that the introduction of further East Indian kinds will be of great advantage in the endeavour to improve the strains now cultivated in the Western world.

THE "MAUD" MANGO.—A fine bold dark green mango having a most delicious melting flesh, without fibre, and perfectly sweet. It is a seedling raised by the Hon'ble W. G. Gordon, and named in compliment to Mrs. Gordon. This mango must take its place among the best of our list.

DEUX-DOUX.—This is a pretty little mango, and as its name indicates, peculiarly sweet. It is one of those mangoes which the child needs no teaching to devour, as it only needs to follow on the lines on which it obtained its first nutriment to consume it to the greatest advantage. It is one of those mangoes to cut which spoils it. It has a soft melting pulp which will pass freely through a small hole made in the skin.

ST. JAMES' MANGO.—(Full size.) This is a seedling mango of peculiar form. It has a pronounced turpentine flavour, and a firm and rather fibrous sub-acid pulp, of a clean light yellow colour. The colour of the fruit when ripe is bright yellow. It could never be more than a second class mango at its best.

HONEY MANGO.—Dark green fruit, mottled yellow, with a slight purplish bloom. The flesh is soft and melting, very sweet, having a decided honey flavour. It has no trace of the turpentine taint so common among the mangoes.

THE "CAPTAIN" MANGO.—This is a mango yellowish green spotted with yellow. The fruit has a decided mamillated point on the apex. The flesh is firm, without fibre, but with a decided turpentine flavour, which is more than covered by its extreme sweetness. This tree, though a large one, fruited for the first time in 1899. Being so far unknown to us, it has been named the "Captain" to distinguish it from others.

THE "MARTIN'S" MANGO.—The Martin's mango was first seen in July, 1899, when samples were kindly sent on to the Gardens by the Hon'ble C. Leotaud. It is a pretty fruit with a fine purplish bloom on the check, but in the main the colour is green, dotted with the small yellow spots common to most mangoes. On first taste there may be detected a suspicion of the turpentine flavour, but this is rather agreeable than otherwise, and before the fruit is eaten is entirely forgotten in the sweet and luscious flavour which overcomes it in the mouth. The flesh is bright yellow, melting and rather meaty, with short fibre next the seed. The kind was received through the hands of French cultivators in Martinique.

DR. DE BOISSIERE'S MANGO.—The following description is taken from a manuscript left by my predecessor, Mr. H. Prestoe, dated 15th July, 1869:—"Flesh farinaceous-fibrous, but very tender – strong mango flavour, with only a dash of the turpentine taint; bright orange colour outside as well as inside, round, full and very succulent—a first-class mango—little liable to be attacked by rot or sourness."—*Trinidad Bulletin.*

THE ERADICATION OF LANTANA SCANDENS.

A good deal has already appeared on this subject in the pages of the *Indian Forester*. The question has, however, been re-opened recently by the Inspector-General of Forests, and the conclnsions arrived at during the year may be of interest to our readers.

In May 1900 a snggestion was put forward by the Inspector-General to introduce into the country some well-chosen natural enemies of the Lantana in order to assist in its eradication.

"The *Lantana scandens* invasion of Coorg," wrote Mr. Ribbentrop, "has become a scourge to the conntry, and is spreading rapidly in other parts of Sonthern India.

"Originally, I have heard, introduced by the wife of a missionary as a hedge plant, it has taken rapid possession of open places in the forests, occnpies grazing grounds, and threatens cultivation by spreading over every fallow area, even at a distance from the original stock, the seed being probably carried by birds.

"The eradication of the plant, when once it has taken possession of the gronnd, is an expensive business. It forms perfectly impenetrable thickets in which the sun does not reach the ground and nothing can grow. The *Lantana* takes sole possession. Once such thickets have formed, it is said in Coorg to be more costly to eradicate them than to clear virgin forests. The ryots, looking upon the invasion as an unconquerable pest, do nothing to help themselves and the evil is natnrally spreading.

"In Berar the Forest Department took up the eradication of *Lantana* systematically aud with considerable success. The Municipalities, and lately, I hear, the ryots, have followed suit.

"The first operations were naturally expensive, costing, however, but Rs. 4 per acre, against Rs. 30 estimated by the Commissioner of Coorg, where, however, it is to be said, the evil has taken a mnch longer and greater hold of the country. In Berar we have uot snceeeded in eradicating the plant; but at a cost of Rupees 30—50 per square mile, which is decreasing year by year, we keep it under sufficient subjugation to render it pactically harmless. A pre-considered plan for the work and a carefnl and steady adherence to it are, however, a *sine quanon*.

"Dr. Watt, when in Coorg, was consulted by the Commissioner, and he advised that enquiries should be made in South America (but Mexico I think it is), whence the plant originally came, what its enemies were in its own country and to import them, This plan was considered fantastic and was not acted up to and I think nothing else was done either. I am of opinion that a possibility of snccess underlies Dr. Watt's plan, and I would advise that in the first instance enquiries in this direction should be made from the Kew authorities, who are in touch with the botanists of the world.

"It may be possible, that somebody would have to be deputed to the original home of the *Lantana* to study the question locally, but even that wonld be but a small matter in comparison with the object in hand.

"That it is feasible however, to keep the *Lantana* within reasonable bounds, without introducing its enemies into this country, by unremitting attention towards its destruction, at a considerable cost it is true—but nothing compared with the estimate of the Commissioner of Coorg—has been proved in the Ellichpur district in Berar, where the plague assumed the most threatening appearance; and this might be pointed out to the Coorg authorities."

This view of the matter did not, however, recommend itself to Major Prain, the Director of the Botanical Survey of India, who wrote as follows:—

"I am not favourably impressed by the proposal to depute an officer to America to learn what the natural enemies of *Lantana* in its original habitat are. There are two well-known enemies of *Lantana*: both of them, as cures, are worse than the disease.

"One of its enemies is a Sunflower (*Tithonia*), which is becoming naturalized in many parts of India. It is found in Ceylon that where this runs wild it kills out and replaces *Lantana*. So different is the point of view that Ceylon planters look npon *Lantana* as a 'blessing' aud think nothing has done so mnch as it has to renovate abandoned coffee land. The Sunflower they find, when re-clearing, to be more difficult to eradicate than *Lantana* is, and they believe that in place of renovating the soil the Snnflower greatly exhausts it.

"The other enemy is fortnnately not yet very well known in India. This enemy is a scale-bug (*Orthezia insignis*) originally discovered at Kew, where it was cansing damage in the plant honses It was noticed in Ceylon in 1893 or thereabouts, and was snpposed to have been introdnced from Kew, because it was first observed in the Royal Gardens at Peradeniya, to which place plants are often sent from Kew. Bnt this is not clear to me, because the pest is also known, and gives tronble, in Natal. It was first noticed on *Lantana* in Jnne 1898. By Angust 1898 it had spread, still on *Lantana*, with alarming rapidity, completely destroying, so it is asserted, the patches of *Lantana* it attacked.

"This *Orthezia* is one of the most destructive scale-bngs known. It by no means confines its attention to *Lantana*, but attacks, and is equally destrnctive to, many other species. When it is known that these inclnde Tea; Coffee, both Arabian and Liberian; Cinchona; the Orange and all the other species of *Citrus*; Capsicums; and the Tomato, it will be seen that the alarm with which it snddens appearance on *Lantana* was viewed in Ceylon was a well-founded alarm, and it will be granted that the Government of Ceylon and the planting community there were justified in immediately taking the most drastic steps to stamp it ont.

"Among the enemies of *Lantana* in its native country this or some similar pest may be nnmbered. It may well be that in its natural environment such a pest may cause no trouble. But remedies of this kind are apt to prove double-edged weapons, because there is no possibility of saying that in the new environment to which they are brought these will not get as completely out of hand as *Lantana* itself.

"As regards the methods detailed in the attached correspondence for dealing with the plant, I have little to say. I note that the cost of clearing land of *Lantana* in Berar is given at Rs. 15-8 per acre. This is interesting, because it agrees so well with the estimate given for Ceylon dnring a controversy that arose there so far back as 1881. It was found in Ceylon that land under *Lantana* for 12 years or more, and therefore as thickly covered with the shrub as it was possible to be, could be cleared by contract, the contractor cutting it down, nprooting every plant and burning the roots and stems, for Rs. 15 per acre. I find it stated that at present the plan nsed in Ceylon is to nproot the *Lantana* by bullock teams, and that the method is easy and effective. Its cost I have not seen noted.

"In Honolulu, where the experience has been exactly that of Indiа and Ceylon, it is usually only the *small* plants that are uprooted. Large plants of *Lantana* have their stems cut across close to the ground and kerosine is then poured on the cnt stumps. This is said effectively to prevent any further growth."

As to the steps taken at Chikalda in the Berars, mention of which is made in Major Prain's letter, Mr. Cecil Bagshawe, Conservator of Forests, gives an interesting account.

Lantana (*scandens*) *clearance in the Station of Chikalda and the Melghat Taluq, Ellichpur District, Berar*, 1894-95 *to* 1899-1900.

It seems well to describe the position of the Chikalda station aud the Melghat hill, where the work was carried out.

1. Chikalda is on a plateau 3,600 feet above sea-level with more or less precipituous, dry and rocky slopes to the south, and on the north ravines with easy slopes and good, fairly moist soil, interspersed with steep and precipitous ground. On the north there are perennial streams; to the south torrent beds with waterfalls during the rainy season.

2. The Melghat Talnq * includes a southern extension of the Satpura range, is hilly throughout and varies in elevation from 600′ to 4,000′ above sea level.

The Tapti river and many of its tributaries rise in the Melghat and fall into the Indian Ocean, while the source of a main tributary of the Godavery is also within its limits, so that it forms a hilly well-watered part of the backbone of India.

The average rainfall is 78," which falls mainly from June to September; but the south-east and north-east monsoons sometimes give heavy showers in the autumn and winter.

3. *Lantana* was introduced into Chikalda about 1865, and was largely planted out for hedges. It flowers, fruits and the seeds germinate within a period of some five months and the plants grow freely from cuttings. *Lantana* was not recognised as a pest until about 1889, when it had overgrown the ravines, was spreading on the plateaux and even growing on the steep southern slopes.

In 1893, when the health of Chikalda and apparently any reproduction of valuable forest growth in the vicinity was endangered, the general eradication of *Lantana* was decided on.

4. To facilitate systematic working, the infested areas of the talnq were classed as—

(*a*) Very dense growth, including heavy hedges several miles in length and masses of *Lantana* matted into forest growth in the ravines where it sometimes climbed to the tops of trees 30—40 feet high.

(*b*) Dense growth scattered over extensive areas, but generally more accessible and easily destroyed than the (*a*) area in and near Chikalda.

(*c*) Scattered plots, dense in places, but easy of removal and in connection with which the chief expenditure was incurred in finding the plots.

The method adopted was to cut down † and thoroughly root up the plants, haul them to open spaces, and there destroy with fire. Rootlets left in the ground, it was found, did not shoot up, but plants and branches left lying on good soil readily took root.

This operation was called "clearing" and embraced the 1st year's work in each area dealt with.

In the 2nd year the areas were systematically gone over and all seedings etc., dug up, the operation being called the "1st cleaning." In the case of dense areas cleared, the following rains brought up a most complete crop of seedlings, which by August attained a height of 2—3 feet and flowered.

In the 3rd year seedlings were less plentiful, but the growth from 2nd year seedlings, broken off in the course of extraction in the 2nd year, gave much trouble and another systematic 2nd cleaning was made. In areas of very dense growth a 3rd cleaning was necessary.

Subsequent operations were called "scouring," to carry out which gangs of weeders in lines in open order were taken *rapidly* over the areas, once at the beginning and if possible, again at the close of the rains.

6. It is evident that the cost of the operations described cannot be correctly given by means of the average cost per acre for the whole area, and it is therefore given by classes:—

	(*a*) Areas of very dense growth.	(*b*) Dense but more scattered growth.	(*c*) Scattered growth.
	R. a. p.	R. a. p.	R. a. p.
CLEARING:			
Per acre ...	11 6 0	0 12 1	0 1 10
Per sqr. mile...	7,280 0 0	483 5 4	73 5 4

3RD CLEANING:			
Per acre ...	0 2 5	—	—
Per sqr. mile ..	96 10 8	—	—

The cost of scouring cannot be given per acre, but from 1900-01 about R1,000 a year is being spent in weeding over the whole taluq in areas formerly infested, and destroying any plots that have been previously overlooked. This charge will fall steadily from year to year, but the work must be continued for many years or until the destruction of *Lantana* at sight has become a custom.

The cost of clearing and cleaning operations may seem high, but it is difficult to vividly describe the labour of digging and removing dense masses of prickly *Lantana* from narrow ravines and wooded hillsides.

7. Taking the whole Melghat (1,650 square miles) into account, R24,896 have been spent during the six years 1894-95 to 1899-1900. Acres 32,155·50= square miles, covered with *Lantana*, were cleared at a cost of R8,461 or R169 per square mile, while R16,435 were spent on cleaning and scouring. The average cost of cleaning is put at R54 per square mile, but the cost of the two operations cannot be given separately. It may be said that the eradication of Lantana has been most successfully carried out; the plant is rare in Chikalda, and has to be searched for in other parts of the taluq. Still watchful care is needed to prevent the scattered plants spreading.

8. When work was started in the Melghat, the extirpation of the plant throughout Berar was also aimed at, and a clearance started with fair success in all districts. It may, however, be said that the growth of Lantana is generally only luxuriant in Berar in hilly districts, 1,400 feet and upwards in elevation, and in places with fair soil and moisture.

PRUNING THE TOMATO.—When the fruit-bud appears we want to look out for suckers, which must be plucked off as fast as they appear. Keep in mind a straight, upright stalk, instead of the usual crawling vine we so often see. When the young fruit begins to form, put a stake about 4 feet long down on the opposite side of the fruit-bud, tie a cotton string around the tomato stalk immediately under the fruit-bud, leaving the cord loose, and then to stake, repeating this as the fruit-buds appear. This holds the plant firmly and causes it to grow straight and graceful, instead of falling all over the garden. Keep the suckers off by all means. When from four to eight fruit-buds appear, according to the fertility of the soil, top the plant, and you will have a magnificent crop of tomatoes, whereas if you let them go to vine you will have but very few. If they fail to ripen, a few leaves cut from the lower part of the stalk to admit the air will hasten it. Keep the suckers down, and the fruit will continue to ripen a long time if they have water and attention.—*Queensland Agricultural Journal.*

---

* Area 1,650 square miles, and Chikalda, which is in the South-East of the taluq being about 77·30° E. and 25·30° N.

† Mechanical arrangements for hauling out with blocks and tackle were tried, and failed on score of expense.

ANTIMALARIA CAMPAIGN.

The Roman correspondent of the *Lancet* has sent the following accouut of the systematic action of Italian physiologists in experimenting on the bites of mosquitoes at the cause of malaria

The strenuous efforts now being put forth in Italy to combat malaria and tuberculossis make it necessary to return frequently to these topics iu order to follow the progress of the campaign against them. In regard to malaria the *Academia dei Lincei* publishes the first report of the experiments nndertaken by Professor Grassi and others along the Battipaglia-Reggio line of railway from San Nicola Varco to Albanella, over a distance of some eight miles. The objects aimed at were two: (1) to prove that malaria can be contracted only through the hites of anopheles; and (2) to find means of overcoming the practical difficulties that stand in the way of an efficient prophylaxis. Altogether 104 persons, including 38 children under 10 years of age, were kept under observation, all of them being railway employes with their respective families, living at the two stations and in various honses, 10 in number, along the line. The locality chosen, the Plain of Capaccio, is among the most unhealthy in all Italy. The persons selected for the experiment had all been examined during the non-malarial season—that is to say, before the anopheles had become infected—and those found to be malarious had been treated with quinine. The preventive measures adopted were the protection of the houses from the entrance of mosquitoes by wire gauze over the windows and the wearing by any persons obliged to he on duty outside after sunset or during the night of a simple veil attached round the hat with elastic, and of thick cottou gloves with tight sleeves. All who could went indoors at sunset and did not come out again till after sunrise. It was found very difficnlt, especially at first, to induce the people to observe these simple precautions in the efficacy of which they had no faith, but, nevertheless, of the 104 individuals expcrimented upon, excepting three cases of relapses which had escaped the previous treatment by quinine, not one has so far been attacked by malaria. This is very fortunate, for in spite of all precautions some anopheles succeeded in inflicting their hites, and although the proportion of infected insects is small (1 per cent.) one of these latter might easily have found its way into a house and inoculated some of the inmates. The better to supervise the experiment Professor Grassi spent three days a week on his field of operations, sleeping at the station of Albanella with open windows (covered, of course, with the wire gauze), and the same was done, though for shorter periods by Dr. Martirano and Dr. Blessich who assisted him. While the subjects of the experimeut thus enjoyed a complete immunity from malarial fever the other inhabitants of the same locality, who may be regarded as so many control subjects, not having been protected in any way against the anopheles, fared very differently, having, it is stated, been all attacked, even those living under otherwise superior conditions. Other similar experiments have been carried out by Di Mattei in the Val Savoja* and by Dr. Fermi and Dr. Tonsini on the Island of Asinara,† near Sardinia. The former place is exceedingly malarious, and the mosqnitoes are numerous; nevertheless, by the aid of wire gaze over the windows of the house, and the use of oil of turpentine on the hands and faces of the five inmates who carried out the experiment, the mosquitoes were kept away, and no case of malaria occurred during a period of four months. Elsewhere in the locality malaria was raging. In Asinara the conditions are peculiarly favourable for testing the practicability of entirely ridding a given area of malaria by destroying the mosquitoes infesting it, Dr. Fermi and Dr. Tonsini, hy destroying the larvæ with petroleum, and the adult mosqnitoes by means of pyrethrum, chrysanthemum, valerian, and zanzolina, succeeded in exterminating anopheles in the island, and greatly diminishing the number of culex pipiens. At the same time use was made of wire gauze over the windows of the houses to protect the inhabitants from being hitten, with the result that no fresh case of malaria occurred in the island, althovgh in the previous year 40 persons had contracted the disease there. The experiment was carried out last year from June to November, and is being oontinued this season.

The last number of *Nature* also contains a notice of the work of Dr. L. Sambon and Dr. G. C. Low, of the London School of Tropical Medicine, in a part of the Roman Campagna, near Ostia, where scarcely a person spends a night without contracting a malarial fever of a virnlent type. No quinine or other drug was to be taken as a precautionary measure, but the investigators were to live in a mosquito-proof hut from au hour before sunset to an honr after sunrise, so as to avoid being bitten by mosqnitoes, which only feed during the night. The experiment was planned to test the reality of the connection between malaria and mosquitoes, and the *British Medical Journal* reports that it has heen most successful. On September 13, Prof. Grassi visited the residence of the investigators with several other men of science, and gave his testimony as to the value of the experiment in the following telegram to Dr. Manson:—"Assemhled in British mosquito-proof hut, having verified perfect health experimenters amongst malarial stricken inhabitants, I salute Manson who first formulated mosquito malarial theory.—Grassi." So far as the experiment has gone, therefore, the result is entirely satisfactory, and affords the strongest support to the mosquito theory of malaria. Additional evidence is given by Dr. Elliott, a member of the Liverpool expedition sent to Nigeria some time ago to investigate the subject of malaria fever, who has recently returned to this country. He reports that the members of the expedition have been perfectly well, although they have spent four months in some of the most malarious spots. They lived practically amongst marshes and other places hitherto supposed to be the most deadly, and they attribute their immunity to the careful use of mosquito nets at night.

Another experiment arranged in connection with the malarial investigation in the Campagna is described in the *British Medical Journal*. Drs. Sambon and Low have shown that hy avoiding mosquitoes they avoid malaria; hut this is, after all, only negative evidence, and its full value can only be appreciated in connection with the actual production of malaria in a healthy person in this country hy the bites of mosquitoes containing the germs of the disease. The evidence is now forthcoming. A consignment of mosquitoes which had been fed on the blood of a sufferer from malaria in Rome, under the direction of Prof. Bastianelli, was received in London early in July. A son of Dr. Manson, who offered himself as a subject for experiment, allowed himself to he hitten hy these insects, and, though he has never heen in a malarious country since he was a child, he is now suffering from well-marked malarial infection of double tertian type, and microscopical examination shows the presence of numerous parasites in his blood. Full details of the experiments will be published in dne course; meanwhile, they must he regarded as affording the most striking confirmation of malaria by mosquito bites that has yet been obtained.

The number of the *Lancet* for September 29th also contains a paper by Dr. Patrick Manson on "Experimental Proof of the Mosquito Malaria Theory."—*Journal of the Society of Arts.*

THE CHEAPEST FORM OF NITROGEN.

One of the best authorities on the value and action of sulphate of ammonia and nitrate of soda on certain crops, Professor Warrington, writes to the quarterly *Journal* of the Royal Agricultural Society, England, as follows :—

NITRATE BEST FOR LIMEY SOIL.

On land containing no carbonate of calcium (or, in other words, lime), sulphate of ammonium cannot be profitably used as a manure, though nitrate of soda may.

2. On land containing a large amount of carbonate of calcium (lime) sulphate of ammonium will seldom give its best result if applied as a top-dressing. On such land the proper course is to cover the manure with soil by the plough, and harrow it immediately after being distributed over the surface.

3. Though sulphate of ammonium may often be successfully used as a top-dressing upon ordinary land, it gives its best return when it is ploughed or harrowed in before sowing the seed. It is thus specially suitable for application to spring corn and potatoes.

4, Ammonium salts do not become available as plant food till they have become converted into nitrate of calcium. This nitrification will not take place in a dry soil, but in most arable soils it will speedily occur in showery weather.

5. Nitrate of sodium, being immediately available as plant food, and distributing itself in the soil more rapidly than the nitrate of calcium arising from the nitrification of sulphate of ammonium, this manure is generally more suitable for use as top-dressings to growing crops and for late applications.

SULPHATE HAS MORE GRADUL EFFECT.

6. The effect of sulphate of ammonium is always more gradual than that of nitrate of sodium, and is especially prolonged in soils containing little lime, and in old grass land, or when associated with organic manures. This implies a more gradual or a longer continuance of growth in the crop receiving it, and results in some cases in a better quality of produce.

7. The character of the climate or season frequently determines whether nitrate of sodium or sulphate of ammonium will be the more profitable manure. In a dry season nitrate of sodium always gives a better return for the same quantity of nitrogen applied, while in a wet summer the advantage is frequently with the ammonium salt. This influence of climate is most clearly seen in the case of cereal crops, or on grass land; it is less perceived in the case of crops, like potatoes and mangels, which have a long period of growth.

8. The greater crop frequently given by nitrate of sodium is in part due to the soda which it supplies, the soda acting beneficially both in the soil and in the plant.

PRODUCE YIELDED.

9. The produce yielded by sulphate of ammonium is more dependent on the presence in the soil of an abundant supply of cinereal plant food than is the case when nitrate of sodium is employed. Kainit is an excellent addition to sulphate of ammonium.

10. On an average of ten series of field experiments with cereal crops, continued throughout many years, in which equal quantities of nitrogen in the forms of nitrate of sodium and ammonium salts were applied to soils well supplied with potash, soda, and phosphates, the average return in corn was 93 by ammonium salts for 100 by nitrate of sodium, and in straw 79 by ammonia for 100 by nitrate. The return in corn is thus not very different by two manures, but the return in straw is considerably larger when nitrate of sodium is used. The quality of the corn was a little better where ammonium salts had been employed.

SOME FIELD EXPERIMENTS.

11. In three series of field experiments on grass hay, conducted in the manner thus described, the average return by ammonium salts was 85 per cent. of that given by nitrate of sodium, when the first cutting of hay was alone considered. When the second cutting of hay was included, the return by ammonium salts was in two series of experiments 88 per cent. of that given by the nitrate.

12. In the first ten years of the Rothamsted experiments with potatoes, the produce by ammonium salts was on an average fully equal to that yielded by nitrate of sodium. No dung was used, but alkali salts and superphosphate were applied.

13. The weight of mangel roots yielded by ammonium salts during seventeen years at Rothamsted was on an average only 76 per cent. of that yielded by nitrate of sodium, but when the superior quality of the roots grown by ammonium salts is taken into account, the return by the ammonia is probably 82 per cent. of that given by the nitrate. No dung was used, but alkaki salts and superphosphate were applied.

FARM EXPERIMENTS IN SCOTLAND.

14. The farm experiments made on turnips in Scotland and the north of England, with small quantites of sulphate of ammonium and nitrate of sodium generally do not show any considerable difference in the effect of these two manures.

15. Sulphate of ammonium of average quality will contain 24½ per cent. of ammonia. Nitrate of sodium of 95 per cent. purity will contain nitrogen equivalent to 19 per cent. of ammonia; 19 lb. of sulphate of ammonium will thus supply as much nitrogen as 24½ lb. of nitrate of sodium.

16. If the nitrogen in the two manures produced the same effect on crops, their money value would be determined simply by their contents in nitrogen. Thus when nitrate of sodium was £8 a ton, sulphate of ammonium would be worth £10 6s. Under various circumstances already described, the nitrogen in sulphate of ammonium is sometimes as effective as that in nitrate of sodium, and sometimes gives a smaller return.
—*Queensland Agricultural Journal.*

"FOXY COFFEE."

To Editor "Planting Opinion."

Sir,—With reference to Mr. P. G. Tipping's query *re* "Foxy Coffee" in your impression of the 5th instant, I think he will find the following information of some use. Speaking on the subject at the U. P. A. S. I. Meeting in 1899, Mr. Graham Anderson, C.I.E., said :—"This term ("foxy") denotes a reddy-brown appearance of the seed caused by the adhesion of the silver skin into which the colouring matter contained

in the outer skin and fruity portion of the cherry has infiltrated. *This appearance is undoubted evidence of the fruit having been picked when quite ripe* (italics mine); and nearly all really good, cherry-dried coffee, which is so highly esteemed in France, is thus indelibly marked. The quality of the coffee is in no way injured, the stain being superficial and confined to the silver skin, which can easily be scraped off with a penknife. If roasted carefully, the aroma will be found excellent, which is another proof of maturity. If a quantity of ripe coffee fruit is heaped, or kept in a cistern, fermentation will take place, and the red colouring of the skin and fruity portions will sink into the gummy substance surrounding the "parchment," precisely in the same way that aniline ink penetrates the gelatine slab used for copying letters. If prompt measures are not adopted, not only will the parchment be permanently discoloured, but the silver skin below will be stained and firmly gummed on to the seed. If observed in time, the remedy consists of getting the fruit pulped as soon as possible; in closely watching the subsequent fermentation, and having the parchment thoroughly washed as soon as the gum has changed into a state in which it can be acted upon by water. In warm, rainy weather similar changes occur in very ripe cherry before it is picked from the trees. Some pulpers do not work satisfactorily and allow a large quantity of skins and half-pulped cherry to pass into the cistern along with the parchment. If these are not properly separated, before fermentation takes place the seeds they contain will be more or less foxy. The ripest richest and most succulent fruit is always the first to suffer in this way, or from any delay occurring in "picking, pulping or preparation."

Last season, in his desire to enhance the quality of his coffee, a proprietor hereabouts allowed his coffee to get dead, or purple, ripe on the trees before picking it, and to his thundering surprise, it was reported on from the Coast as foxy. Now his coffee had never before been reported on as foxy. His surprise was even greater when he was told that the "foxiness" had probably been produced by his allowing the fruit to become over-ripe on the trees before gathering it. On the other hand, on a neighbouring estate, the coffee, which had previously to *last* season been nearly always pronounced foxy, was that season singularly free of "foxiness." This was attributed to a uniformity of shade over the place which seems to have been attained for the first time in 1898-99; but the "trick" seems to have been done by washing the coffee twelve hours after pulping it, the pulp-house having a position facing south-west, and the aspect of the estate being throughout nearly the same.

The obvious precautions which suggest themselves from the foregoing are—

(1) To avoid, as far as possible, allowing the berries to become dead, or purple, ripe on the trees. They should be picked as uniformly red-ripe as possible. A spot of green on the outside pulp will make no difference, the bean being nearly always matured before the pericarp has been fully coloured.

(2) To pulp the coffee as soon after taking in as possible. The operations of pulping and measuring might go on simultaneously. Some power more expeditious than cattle-power is desirable in this connection.

(3) To pulp as cleanly as possible. If pulpers are not working satisfactorily, this must be done with the aid of a sieve, the skins and half-pulped cherry being passed through the pulpers a second time.

(4) To wash the coffee as soon as the mucilage is ready to be acted on by water. This can be determined by experiment. For the rest, trust in Providence. I trust that this small contribution on the question will promote a healthy discussion which will lead to the elucidation of a subject which there is no gainsaying is of great importance to the planting industry.—H. G. R.

COFFEE SUBSTITUTE.

Read the following letter from Dr. G. Watt, Reporter on Economic Products to the Government of India, dated Calcutta, 14th June, 1900, in answer to our query about the value and analysis of Spermacoce hispida seeds sent:—"I have the honour to acknowledge the receipt of your letter No. 809, dated the 25th May, 1900. In reply I beg to say the question was referred to Mr. D. Hooper, F.I.C., F.C.S., who reports "that the seeds of *Spermacoce hispida* have the same shape as coffee berries, but are brown in colour and much smaller, ⅛x1-12 inch. The seeds were powdered and analysed with the following results:—They contained a thick greenish oil dissolved by ether; a quantity of astringent matter giving a greenish colour with iron saltf; a bitter principle soluble in alcohol having the re-actions of an alkaloid; a colouring matter giving an orange solution with alkalis; mucilaginous and albuminous matter soluble in water. The moisture of the seeds amounted to 10·75 per cent. and the ash 6·7 per cent. These seeds contain similar constituents to Coffee and afford a substance of similar odour when roasted over a fire. They appear to have nourishing and stimulating properties different to other seeds offered as substitutes for Coffee. Their commercial use depends upon the abundance of the plant and the labour of collecting the seeds." *Madras Agri-Horticultural Society.*

BANANA DISEASE.

The disease, which has been so prominent a feature among the banana family in Trinidad, appeared at the St. Clair Station experiment during of the first year of cultivation, and many plants were killed out by it. This disease is caused by a species of fungi known as *Marasmus semiustus*, which attacks the older leaves eventually causing the whole stem and fruit to decay. From the fact of some plants growing in soil which was of a rich character not succumbing to the disease and developing their fruit in perfection it was inferred that the growth and spread of this disease was in a great measure due to the want of proper manurial constituents in the soil, in which they were growing.

To test this view of the case, a parcel of land was especially prepared by heavy manuring, and suckers from diseased roots were planted therein. The result has been a growth as good as could be wished, and although the fungus can be seen to be present, it is not able to fight against and overcome the "vegetative vigour" of the plants

under these conditions. These results seem to point to the supposition that the fungus is itself really only a saprophyte, (*i.e.*,) living usually upon dead material, but at the same time one able, under conditions of impoverished growth, to attack and destroy living vegetable growths which have been weakened by starvation or other causes, as is probably the case with the cane fungus *Trichosphæria Sachari* in abnormal seasons, and in unsuitable or impoverished lands or where the constitution of the growing plants have been weakened by other causes.—*Trinidad Bulletin.*

CHILE PEPPER CULTURE.

Mr. J. B. Neff, of Anaheim, California, discourses on chile pepper culture in the *Californian Cultivator*, on the basis of his own experience as a successful producer of hot stuff:—

How Plants are Grown.—A hot bed is made by excavating about 16 inches deep; fill in to within 4 inches of the top with damp stable manure, trampling down vrey solidly. Spread about 4 inches of sandy loam over the manure. The seed is sown quite thickly over the loam, and then about ½ inch of loose sandy soil placed evenly over it, and all kept damp. When the plants have two or three leaves, thin to 1½ inches apart each way. The plants must be watered while in the hot-bed by sprinkling. Great care should be taken to protect from frost.

Soil and Preparation.—Rich sandy soil is the best for the chile pepper. It should be ploughed deeply, and be put in a state of thorough cultivation. Ridges should be made 3 feet apart, and the plants set 2½ feet apart on the ridges. All plants must be on a water line, and to get this the ridges should be made, water run down the furrows, and the plants placed about 2 inches above the water-mark. This insures every plant receiving water when irrigated. Plant as soon as danger from frost is past.

Cultivation.—Frequent cultivation is necessary until the plants get too large to allow of a cultivator and horse passing between the rows. All weeds must be pulled out. When the plants are set as before noted, all the ridges will be on one side. This must be worked down with a cultivator, and then a plough used to throw earth on either side of the furrow, so that the plants will be midway on the ridge.

Irrigation.—While the plants are small water will be needed about once in twenty days, but as they get larger it will be needed as often as once a week, though only in small quantities. The plants seems to have no deep roots, consequently the surface soil must be kept damp.

Picking.—The field should be gone over about once a week after the peppers begin to ripen, all that are fully ripe being taken off. Great care must be exercised to pick all the stem with the pepper. They should be allowed to lie in the sun one day after being picked in order to toughen the stems and prevent them breaking during the process of curing.

Stringing.—The common method is to cut strings of strong smooth twine 8½ feet long. Draw this through a needle about 12 inches long, which is often made of a bicycle spoke. Peppers having any breaks or blemishes must be thrown away, as they would decay before drying properly. Of course, where an evaporator is used these can be saved. After the strings are full and tied they are hung on nails driven into a rough pole or other framework standing about 6 feet from the ground, and left until dry; or if shelter is available they may be moved before becoming fully dry and hung closely together until such shelter, but where there is a free circulation of air.

Evaporating.—Many growers prefer evaporating instead of drying. The evaporators used are of various designs and sizes, but they should be large enough when the peppers are dried on strings to hold not less than 500 strings. The usual plan is to have a furnace with several turns of 8 to 10 inch pipe in the basement, the peppers being placed in the second storey over a very open floor and with good ventilation. The temperature must be kept at 110 degrees Fahr., and in this way the house can be refilled about every four days.

Yield and price.—Both of these, of course, vary with the season, soil, and water supply. Two hundred and fifty strings of 5 lb. each is called a paying crop, but with all conditions favourable, including a late, warm season, as high as 400 strings, or even 2,400 lb. per acre, of dried peppers may be grown. Prices range from 35 to 75 cents. per string if sun-dried, and 7½ to 12½ cents. per lb. if evaporated.—*Queensland Agricultural Journal.*

A NEW VEGETABLE.

A new vegetable, and one that promises to be a great acquisition, says the *Australasian*, is the asparagus pea, introduced into Victoria by Lord Hopetoun. It is extremely prolific, and most people would pronounce it a delicious vegetable when properly prepared, combining, as it does, the pronounced flavour of asparagus with the delicate suggestion of the table pea. The method of culture is that of the ordinary pea, and the particulars as to price of seed, &c., can be obtained from Messrs. Adamson and Son. Amongst other places where it can be seen in full profusion is the Leongatha Labour Colony, and the head gardener there states that it is suited to all classes of climate, thriving almost equally well with or without watering. The plant is of a prostrate nature, branching much like a rock melon, and spreading nearly two feet. Stem prostrate, leaves trifoliates leaflets spatulate ovate, an inch in length, two stipules ovate, flower axillary, and of a scarlet red and purple, giving the appearance of a field of red clover. Pod square, with fringe on each side, 2in. to 4in. long, containing six to ten small peas. The pod is cooked and eaten with the fingers, after the manner of asparagus. With reference to the above, Mr. Wicken of the Department of Agriculture, to whom the matter was referred, said:—"I have grown this for several years. When I came over here last March I brought a small quantity of this seed and sent some to Subiaco for trial, and some to Drakesbrook. They both came up, but that at Subiaco has not done very well, while that at Drakesbrook was not sufficiently forward to report on at my last visit."

THE PLANTING OF MANGO GROVES.

The following brief account of the method employed in Thana, Bombay Presidency, for the planting up of open spaces with mango grafts, may interest some of your readers, who have not had experience in such planting.

Pits 4' x 4' are dug and left open for three or four days. Grass and dead leaves are then placed in the pits and burnt so as to destroy the roots of any other trees that may happen to be there.

Fresh earth from the margin and bed of dried-up tanks, and from cultivated rice fields is brought and the pits are then filled up, each with an alternate layer of tank-earth and field-earth. The sites of the pits are well watered daily for about 8 or 9 days.

The mango grafts are brought growing in earthenware pots. Holes 1 to 1½ feet deep are prepared in the sites of the old pits and in them the grafts are inserted. But before insertion a little fresh earth from the spoil bank above is thrown into the holes to render them shallower and a layer of cowdung ashes is spread over this. It is needless, perhaps, to remark that the earthenware pots in which the grafts exist are broken and that the resulting ball of earth surrounding the roots is inserted in the holes.

More earth is then thrown into the holes and carefully arranged with the hands around the ball of earth surrounding the roots. Then a second layer of cowdung ashes is applied, and over this another layer of earth. When the holes are completely filled, a third layer of cowdung ashes is placed at the surface surrounding the stem, and the ground is well watered.

The graft is now established and the grafted portion of the plant is on a level with the surface soil. In order to induce the plant to grow erect, a bamboo support is tied to it.

One month or 1½ months after planting the stock is pruned near the summit, and six or eight months after it is cut off almost down to the point of the graft.

The three layers of cowdung ashes are applied to prevent the roots being attacked by white-ants, etc.

Mr. Jagannath Damajee, an expert in planting mango grafts, for he has established over 2,000 plants successfully in Thana informs me that when the plants are 3 to 5 years old, a layer of salt, about an inch or two deep, should be placed round the stem, commencing at a radius of about 1½ feet from it—to further protect the plants from insects' attacks.

He forms mounds of earth round the stems during the rains at this age of the plants and removes them (the mounds) in the hot weather.—G. M. R.—*Indian Forester.*

PLANTING NOTES.

Animal Manure.—From a series of careful experiments which have been made from time to time, it has been shown that a well-fed horse produces from 5 to 6 tons of manure per annum during the time he is in the stable. A steer of 1,000 lb. produces about 20 tons of manure a year. A sheep weighing 6 lb. would produce about three-fourths of a ton, and a pig from 2 to 3 tons of manure yearly. These amounts include the necessary bedding to keep the animals comfortable—*Queensland Agricultural Journal.*

India-Rubber in Sierra Leone.—The United States Council at Sierra Leone reports favourably on the local india-rubber industry. He states, however, that the native collectors are now frequently bleeding the roots of the tree as well as the body—a proceeding which is as fatal to the tree as to the quality of the rubber.—*Queensland Agricultural Journal.*

Keep them Busy.—Hens that go in the corner and sit down should be put to work. In the morning give them about one-third as much food as they can eat, so as to have them hungry. Then get some leaves, cut straw or dirt, and scatter about a tea-spoonful of wheat, corn, and oats (mixed) through it. The hens will soon get hungry, and finding one grain will hunt for another. That is just what you want. Give them nothing until night, then feed all they want. Do this every day. Keep them hungry during the day, but feed them well before going to roost, and they will keep well and lay.—*Farm and Fireside.*

French Scent Farms.—The flowers mostly cultivated on the French scent farms are the violet, the jonquil, and mignonette, which are picked in February, March and April, though when the winter is mild and rainy, violets begin to flower in December. Roses, orange blossom, thyme and rosemary are gathered in May and June, tuberose and jasmine in July and August, lavender in September, and acacia in October and November. But the most important crops of flowers are the roses and orange blossoms, the others being mostly grown by small cultivators in the rural districts among their vines and olives. One of the largest flower farms is one at Seillans, about 2,000 feet above the level of the sea, and 20 miles from the coast, until the southern slope of the Alpes-Maritimes.—*Australian Field.*

A Rubber Plant for Temperate Climes.—In a recent lecture at the Paris Academie des Science (says *Das Handelsmuseum*), Messrs. L Dybowski and G. Frou introduced a new rubber furnishing plant, a native of Northern China, which is at present cultivated with great success at the Jardin des Plantes, the Paris Horticultural Gardens. Up to the present time rubber has been extracted from trees only, and efforts have been made to acclimatise those from the Netherland East Indies in the French colonies, but unfortunately, without any result whatever. This new plant, called *Encomia illinoides*, whose fruits contain over 27 per cent. of indiarubber, has great economical advantage. It can easily be acclimatised and cultivated in countries of even a moderate climate.—*Queensland Agricultural Journal.*

Germinating Olive Seeds.—The olive tree is, as a rule, propagated by means of truncheons, or cuttings, or from the tips of the branches, but it may also be grown from the seed, the latter being first cracked and well washed. Experiments have lately been made in Italy to determine the effect of different temperatures of water on the germination of the seeds. After removing the pericarp from a number of olives the seeds of eight lots were subjected for ten minutes to the action of water of different temperatures, the initial temperature of which varied from 30 to 100 degrees C. The seeds were then planted, and the germinations for seven months were tabulated. It appears that the germination of the olive seeds was accelerated when they were treated with water heated to from 40 to 50 degrees, and the maximum was reached at 70 degrees C. When the water was hotter than 90 degrees C. there was no germination, the seed having been killed.—*Queensland Agricultural Journal.*

DISTRIBUTION OF OUR COCONUT PRODUCTS.

The Distribution Table compiled by the Chamber of Commerce, showing the destination of our Exports, is of continuous interest to the statistician and the businessman. The figures for last year bearing on the products of the Coconut palm, are, like those of previous years on which we have commented, as puzzling in some respects as they are interesting. There is one circumstance which must strike the observer—the wide distribution of these products, going, as one or other of them does, (several in some cases) direct to 18 out of 19 countries whose names appear on the Export list. And the fact that these countries take up practically all that we produce every year, and that the result has been attained without any special efforts, such as have been found necessary in the case of Tea, is evidence that the supply is not outstripping the demand, and that the Palm holds what may be called a steady market. Our remark applies, not only to the older products, such as Oil and Poonac, in which business has been done with the outside world for generations, but also to more recent exports like Copra and Coconuts in the shell, and to the entirely new industry of Desiccated Coconut which already finds its way direct to twelve countries, most of which are, probably, centres of distribution. The time that the palm takes to bear, has, doubtless, been its chief safeguard against the rush which quick returns provoke in the case of both Tea and Coffee, both of which of late, have had to contend with the problem of over-production, and the inability of the markets of the world to take up all that was being hurried into them.

But to deal with distribution, the United Kingdom was our largest customer for Oil—having taken 257,655 cwt., or nearly three-fifths of the output of last year. In the previous year it took only one-half, though then too, it was the largest buyer, America coming next with more than one-fourth to its credit. But last year America took little more than one-half of the previous year's purchases, or one-seventh of the total exports, and was distanced by India, which claimed 88,148 cwt. In 1898, however, India stood at the top of the list, having taken 125,687 cwt., against 123,316 cwt. by the mother country; while Singapore which has dropped off to 6,052 cwt. in the latest returns, stood third with 91,893 cwt.! What is the explanation of these violent oscillations? The demands of the United Kingdom and America where the Oil is chiefly used for soap-making and candles, are believed to be regulated by the abundance or scarcity of animal fat and the imports of African palm oil; but in India and the Far East the Oil is largely wanted for food and lighting; and it is a puzzle how they can do with so little one year, when so much can be taken off another year. Nor do we find, on the assumption that the Oil taken by Singapore is intended for the American market, any correspondence in the exports to the two countries.

In Copra, Russia stands *facile princeps*, having taken 99,620 cwt. out of 362,467 cwt., Belgium coming next with 77,988 cwt. and Germany third with 65,599 cwt. In 1899, too, she stood (more easily) first with nearly 105,000 cwt., against 76,634 cwt. for Belgium; while in 1898, the year of our largest export, Russia had no less than 143,688 cwt. to her credit, out of 506,000 cwt. The mother country continues our best customer for Desiccated Coconut, having taken nearly nine million lb. out of 13½ million lb. exported; but in 1899 she had nearly 9½ million lb. out of a smaller output. America is the next best with 1,829,280 lb., followed by Germany with 1,149,471 lb. The other countries which take large quantities are Australia, Belgium, Austria, France, Holland, Africa and China; so that, if only quality keeps up, there is no reason why there should not be that steady growth of the trade which we anticipate. Our Poonac is not sought by many countries; but with Germany taking a little more than a half, and Belgium somewhat less than a half of the output, there is not much left for other countries. The mother country stands first again for Coconuts in the shell, having taken over ten million nuts out of less than 15 million sent away. Africa comes second with over 2½ million, and India third with over a million; and almost all the continental nations are among our customers for nuts Ceylon Coir, in its various forms of Rope, Yarn and Fibre, find their way to almost all the countries on the list—Singapore taking all but 1,000 cwt. of Rope, and the United Kingdom almost seven-eighths of the yarn, and more than one-half of the fibres.

"RESTING" TEA AND MINOR PRODUCTS.

A correspondent writes;—

"An idea has just occurred to me that, perhaps, the Hakgalla or Peradeniya people might be able to suggest a Product that we could grow between the lines of our tea, while the fields are *resting*: anything that would pay for the weeding of these fields would be a help; pine apples grow well where the climate is hot and forcing, and pine fibre *might* be of use if machines could be introduced at little cost for its preparation?"

A good authority replies on the above;—

"I am afraid I cannot recommend anything to grow among tea that is likely to pay, as I think the tea plants require all the ground allotted to them. The roots of the tea would not allow anything else to have a chance. Where the tea is widely planted and in good soil, the 'ground nut,' pine-apples and tomatoes may struggle along; but I don't think they would pay, as the tea bushes would soon smother them. I understand the resting of the tea to mean that it should be allowed to run for three years and then to be pruned down and start afresh in general cultivation. In this case if the ground is in fair heart the tea would grow so quickly that few weeds would grow and very little weeding would be required."

THE ENDURANCE OF TROPICAL HEAT.

Dr. William Hunter Workman, M.A., M.D., F.R.G.S, writes an article of nearly six columns in length in the *Pioneer* this month entitled: "The Endurance of Tropical Heat, a Study from Personal Experience," and endeavours to combat, and claims to destroy, some of the prevailing notions regarding heat in the tropics. Dr. Workman is known in Ceylon for his five months' tour here with Mrs. Workman, whose fame, by the way, springs rather from her being the first lady mountaineer in the world than from any cycling achievements. He certainly achieved longer rides *per diem* in our hill and lowcountry than are usually performed by the ordinary resident in this island; but his experiences in India, not in endurance of mere heat alone, but of thirst, becoming continuously more intolerable, which is the outcome of long distance wheeling in the peculiar heat prevailing on the driest routes traversed, certainly surpassed anything undergone in the way of physical hardship in our midst. Here we may quote an interesting passage:—

"We carried four felt-covered aluminium water-canteens, each containing a quart. If the contents of these had been used with any such freedom as thirst demanded, our supply would never have lasted beyond noon, and usually not till then. We found it advisable when passing a railway station at any time during the day to stop to fill our canteens, and drink as much water as we possibly could. Otherwise we replenished our stock as occasion offered at dak bungalows, or failing these, if we passed through a town large enough to have a postmaster, we applied to him, though we drank with misgivings unboiled water obtained from natives. In riding through the Bhil country and other famine districts in February, 1900, we had no opportunity to obtain any water except at an occasional railway station. Nearly all wells, streams and tanks were dry. When all the above sources failed, we had to endure the tortures of thirst, from the time our canteens gave out till the journey's end. On one such occasion when our last drop of water was exhausted at three o'clock p.m. we arrived at our destination in darkness at half-past seven so used up and with throats so parched that we could only with difficulty utter an articulate sound."

Survivors of such hardships, we would point out, must be persons extremely well-fitted physically for the trials of endurance undergone; and we do not hold this to be any proof of what may be done by the residents of longstanding in the country, who bear the heat and burden of the day, working in their offices, and are only able to take comparatively brief exercise before our briefer tropic twilight. The advice Mr. Workman so vividly describes, as warnings to him that he must not do this and that, was, of course, given by people who have become more subject to the effect of the tropical sun; and, even if well meant, has, we admit, proved more than mistaken in the case of this successful tourist over islands and continents of no mean size. What we would emphasize is that Mr. Workman had experienced a good deal of foreign travel, involving physical endurance, before his arduous wanderings in India, and that he was therefore in a condition to stand far more than the Anglo-Indian, however abstemious, who becomes slightly more subject to the effects of tropical *heat*—not necessarily of the sun's rays, for though Mr. Workman half hints that exposure to these in India *need* not do harm, he does not exactly say so—with each succeeding year. Mr. Workman "dodges" this question of sun's rays with the ability of a mountaineer on the prose slopes that correspond to those of Parnassus! In Kashmir he has stepped into the open sunlight with only a cap on his head, *but*—at 5,000 feet above sea; in America, at close on 100 degrees Fahr., he has seen young men expose themselves for hours to the burning sun and done the same himself; but no mention is made of similar exposure in the plains. Even if such was undergone, his subsequent mountaineering feats prove that he and his active wife were persons of no common powers in the endurance of extreme heat and extreme cold, in the art of pedalling an extensive mileage and of making stiff pedestrian ascents.

"Moidart," in the *Pioneer*, writes a witty and useful letter in reply to Dr. Workman, but the record of his far more dependable experience is spoiled by attributing exaggerated conclusions to Dr. Workman's long and, throughout, able article. Nevertheless we give two extracts, the first for its practical worth, the second for the entertaining advice given; and with these we conclude:—

"As to what to do to stand the heat, I say only general rules can be given which each man must adjust to suit his own constitution. Watch your health. Wear what clothes you can. Prickly heat will soon explain if you make a mistake. Wear a hat of thickness which will allow you to stay out from 10 to 3 without a headache, and see that it is well ventilated above the hair. Don't go out, unless obliged, before the sun is up; as nothing gives a headache more quickly than horizontal sunrays which strike your neck below your hat. Take as much exercise as your organisation will permit, as you must never allow yourself to be overtired. It upsets digestion and banishes sleep. Sleep as long as you can. Goodness knows it is little you get at some seasons of the year.

"I presume we shall soon hear of Dr. Workman lecturing in Europe on the failure, through their own bad management, of Europeans in India to enjoy the glorious climate they are privileged to live in: also advice as to how they should bear heat and, I must not forget, quench thirst, this time, I hope, in a temperature above 130 degrees. On the chance of this meeting his eye, I would humbly and with due deference suggest that, to assuage abnormal thirst after a hot day, a more effectual and perhaps more *comfortable* remedy, than pouring gallons of fluid down his throat, would be to soak himself in a warm bath and then sip a cup of boiling tea or, still better, one cold, weak, however pernicious and despised whisky and soda."

THE SISAL MATTER.

(*To the Editor of "the Speaker."*)

Sir—I should like to make a few remarks in reference to a letter signed "Observer" in your issue of the 15th inst. In the first place, your correspondent has misread the report of the Co-

lonial Secretary of the Bahamas, who says "hennequin," or "dagger plant," the fibre of Yucatan, and not sisal, grows all through the West Indies. In Yucatan there are two varieties, the Bahama and another. Mr. Morris imported in error an aloe from Ceylon, which was planted in Jamaica and probably in other islands, but I do not believe it is "hennequin," neither do I believe the dagger plant to be hennequin. As to the statistics referred to, all sorts of mis-statements were made under the "Shea" administration, so Mr. Churchill's estimates may be more correct; but I should mention that an acre of land in the Bahamas must not be confounded with an acre in this country; the first would probably be equivalent to one-fourth of an English acre, probably less, so much of the land being nothing but plate rock. "Observer" is right as to the question of origin: that has been settled in the minds of all truth loving people by the *Refutation of a Romance of a Governorship*, but I have already had my say upon this point. On Mr. Chamberlain's speculation in sisal I need not enter, except to wish for his own sake he had bought the lands I pointed out to him. Results might then have been very different, and the colony would not have lost the great assistance in its development which his investments in the islands would have brought; but under the influence of Sir Ambrose Shea he did otherwise. I wonder if Sir Ambrose's friends give him credit for this disastrous result of his want of judgment and knowledge. "Observer" refers to the "Crown Fund" of the colony. I am of opinion that, under the sole control of many Governors, it has not been properly administered. The "options" given on land, for instance, were without any binding agreement or fine, and so the fund is not nearly so large as it ought to be, if any reasonable foresight had been exercised. Really, this Colony manages its own affairs so intelligently, that it would be well if Mr. Chamberlain turned over the Fund to its Legislature, who are the proper parties to administer it.—Yours truly,

AUGUSTUS ADDERLEY.

SUGGESTED DANGER FROM ARTIFICIAL MANURES.

(A tit-bit for Ceylon's daily alarmist.)

The "Lancet" says:—"During the past week our laboratory commissioners have undertaken the examination of a number of substances, including certain foods and drugs in common daily use, in the preparation of which sulphuric acid is used. It will be found, after a few moments' consideration, that a fairly lengthy list of articles of everyday use may thus be drawn up. The results are not yet ripe for publication, but we feel bound to divulge one important result, since the disturbing announcement has this week been made by the analyst of Manchester that arsenic has been found in malt in a quantity equal to that found in glucose or malt substitutes. Moreover, arsenic was found in beers which were known to be brewed from malt and hops only. Now that this remarkable statement has been made, we may say that we have found, in the course of the inquiry alluded to, artifical manures to be rich in arsenic easily soluble in water. This is hardly surprising, since the basis of artifical manures—namely, superphosphate of lime—is made by acting on ordinary done ash with common oil of vitriol. The important point is that it has been established that plants to which arsenical manure is applied take up arsenic in their tissues. Cabbages and turnips gathered from fields manured with superphosphate have given unmistakable evidence of the presence of arsenic. It is probable that arsenic accumulates in the soil which is constantly being dressed with superphosphates, so that plants raised on such soil would absorb arsenic and exercise an injurious effect on the health of man and animals. The question arises, therefore, may not the arsenic in malt be traceable to the somewhat large amount of arsenic inevitably present in artificial manures? This aspect of the subject is very serious, and needs further inquiry. We shall return to it in a future issue, when we hope also to be able to record the results obtained in an examination of other more or less familiar articles in which arsenic may be possibly introduced through the employment of impure sulphuric acid in the course of the manufacture."

TEA; POSITION AND PROSPECTS AT END OF YEAR IN LONDON.

McMEEKIN & Co.'s NOTES ON INDIAN AND CEYLON TEAS.

INDIAN.—As practically all Teas on which duties were paid in anticipation have now passed into ordinary consumption, the annual summary may be taken as fairly correctly representing the year's trading in tea in the London market.

From the producers' point of view, the statistical position cannot be regarded as at all satisfactory. The imports during the calendar year showed an increase of some 12,000,000 lb., while the deliveries only increased by about 4,000,000 lb., and it must be remembered that of this increase over 2,000,000 lb. went into Export trade. It is evident that Ceylon teas have again gained materially in home consumption as compared with Indians, the reason doutless being the lower level current for the former during a large part of the year. For two months, however, quotations for Indian teas have been very low, and the effect is being quickly seen.

At the close of the year the total of seasonal imports recorded showed an increase of about 3,000,000 lb. only, while up to the same date some 9,000,000 lb. in excess of the 1899 figures had been shipped from Calcutta alone, irrespective of the increase due from Southern India. Besides, the quantity offered to date for the seven months was much below the figure for the same seven months of 1899 and the accumulated stock showed an increase of 8,500,000 lb.

The position is a most serious one to face, as, in addition to the London market being oversupplied, the other important outlets—Australia and America—are in a most congested state owing to the excessive shipments injudiciously consigned to them; and the strong demand from Eastern Europe has been temporarily well supplied.

A proposal is now under discussion to arrange for a voluntary limitation of production during 1901 by a mutual arrangement of producers. Should anything of the kind be arranged an made effective by the conclusion of Ceylo

growers, it must rapidly and seriously affect prices. A reduction of even five per cent in the yield from both India and Ceylon could not fail in present circumstances to lead to a marked advance in the value of the remaining 95 per cent produced.

Ceylon.—The statistical position appears rather more favourable than that for Indian teas. Within 1900 there was an increase of 15,000,000 lb. in the imports, while the deliveries showed the marked advance of 11,700,000 lb., of which under 2,000,000 lb. went into Export Trade. The large advance in home consumption has been bought at a heavy cost in the level of prices realized. The year closed with an increased stock of 8½ million pounds, while the quantity shipped from Colombo to London within 1900 exceeded that received in the latter by fully 3 million pounds. The congested state of other large markets, referred to above, affects Ceylon tea fully as much as it does Indian, and serves to explain the very heavy export from Colombo to London during December. It may also have an important bearing on the volume of shipments to London during the early part of 1901.

The expectations of yield for the new year again point to probable large increases, if no steps are taken in the direction of restricting output.

COFFEE AS A BEVERAGE.

Sir,—I notice that a great deal is being said at the present time in the public Press regarding the remarkably small consumption of coffee in England. It appears that more than 30 times as much coffee per head is drunk in Holland as in England. It also appears that the United States of America is an extremely large consumer of coffee; in fact, nearly half the coffee produced in the world is consumed in that country. As the Americans and the English are practically of the same race one would naturally suppose that the consumption of coffee per head would be about the same in both countries. Various writers have lately been attempting to arrive at the cause of this great disparity in the consumption of coffee. Why is it that England consumes such a small quantity, and Holland, Germany and the United States such an enormous quantity? One writer speaks of coffee in the following language :—"Coffee affords the human frame energy and vigour, and consequently ameliorates the ill-effects of overwork or excessive study, and neutralises the consequences of deficient, poor, or unwholesome nourishment."

The coffee berry in its raw state contains, on an average, about half of one per cent of caffeine. Caffeine acts as a stimulant. It strengthens the action of the heart, and stimulates the whole vascular system. It removes fatigue, and, in fact, has an exhilarating effect similar to alcohol. Caffeine is the only substance known which can produce these exhilarating effects without an after depression. When coffee is well roasted and well prepared drinkers acquire a certain coffee habit very much like that of smoking. In some countries, like Greenland where no alcohol is either imported or made, the natives produce a species of intoxication by drinking very large quantities of strong coffee. If anyone is a habitual coffee-drinker, he feels great depression if he misses having his coffee at the usual time.

In the United States of America there are absolutely no restrictions on the importation of coffee or on its use. Even when coffee was dutiable, after the duty was once paid the purchaser was at perfect liberty to do anything he liked with the coffee. But in England the case is quite different. The Government is not satisfied with simply receiving the duty; coffee is hampered in every way by restrictive laws. No other adulterant is permitted but chicory. In France the children are provided in the morning with a large cup or bowl of coffee and milk, into which they break their bread, and eat it very much the same as they would eat bread and milk. In the United States a very cheap drink is prepared by mixing roasted cereals with coffee, which is practically the same thing as mixing bread with coffee. In this way a very delicious and cheap beverage is produced, which is not only stimulating in proportion to the coffee it contains, but at the same time serves as an excellent food. A cup of so called coffee prepared in this way is quite as good as a bowl of soup, and what is more, it is exceedingly cheap and palatable. It is because the Americans are allowed to use coffee in any way they like, either as a beverage or as a flavouring material, that the consumption is so extremely large.

In England, on the other hand, coffee can be adulterated with nothing but chicory, because chicory pays a duty. Now it so happens that chicory is a root, not altogether unlike beetroot. It contains a large amount of very impure sugar similar to raw beetroot sugar. When this chicory is properly roasted, it communicates to the coffee a great deal of colouring matter. Moreover, the roasted impure sugar which it contains becomes extremely bitter; and as an adulterant of coffee, as far as bitterness and colour are concerned, nothing could be better. When the quantity of chicory is limited to one-third of the whole, it produces a very pleasant drink; but unfortunately chicory has a medicinal effect. It is like a great many other things which may be quite palatable at first; but if chicory is consumed day after day one soon tires of it, as it is like all other impure sugar. It produces slight nausea, and in this way, unless one has a very strong stomach, it soon becomes quite unpalatable. Therefore, as coffee is always associated with chicory in England, coffee is discarded because the consumer finds that chicory causes indigestion, and does not agree with him. As coffee contains only half of one per cent of caffeine, and as a large amount of this is dissipated in roasting, and as the relative amount is still more reduced by the addition of chicory, it follows that the actual amount of caffeine contained in an ordinary cup of coffee, such as one finds in England, is quite insufficient to produce any exhilarating effect. On the other hand, tea contains sufficient caffeine to produce a perceptible amount of exhilaration. The result is that people take to tea and avoid coffee.

If the Government really wished to increase the revenue from the importation of coffee, the best course would be to let people adulterate it with anything they saw fit, instead of confining them exclusively to chicory. In countries where common cereals are used for adulterating coffee people never tire of it, but in England, where only chicory is used, coffee has become very unpopular.—Yours, &c., Hiram Stevens Maxim,

—London *Globe*.

A THRIVING WATTLE PLANTATION.

On the mountains, not far from Maritzburg, in Natal, the Town Hill Wattle Company eight years ago acquired a tract of 3,000 acres, and commenced to plant wattle trees for bark. At the present time 2,400 acres are planted, the trees standing six feet apart in rows twelve feet wide. The soil is poor in quality, of a red colour, and light and porous. A correspondent of the Natal *Agricultural Journal* recently interviewed the manager of the plantation, Mr J A P Ellis, and it is thought the following particulars from his report may be of considerable value to people in New South Wales interested in the production of wattle bark, for which there is so great a demand and so little provision. The land is broken up about Christmas-time and well harrowed. In February the planting is done, and the ground receives no further attention until the autumn of the following year, when the space between the young trees is ploughed to aerate the soil, and at the same time protect the trees from the ravages of fires. Trees in Natal do not reach their prime, either as regards bark or timber (the company have a market for all their wattle timber for mining purposes and firewood) till about the tenth year. Insect pests, in the shape of locusts and bag-worms, do considerable damage to the trees, and grass-fires are a great source of anxiety. "In August and September no plantation in Natal is absolutely safe in the event of fire starting with a high wind, for the undergrowth in most cases is sufficient to feed a fire in hot wind." To protect their plantation, the company have nearly fifty miles of fire-breaks, boundary and dividing. It is costly work, but is regarded as a sort of insurance premium. The stripped bark is brought in by means of a tramway, which also connects with the nearest railway station.

The shed for drying the bark is 250 feet in length, with its back to the weather quarter. From the back, along the whole front of the building, a series of very broad-gauge tram lines, six feet six inches orem the ground, on wattle posts, like an overhead railway, run out a distance of 126 feet. On what may be called these tram-lines there rests a flexible ladder of thin poles overlapping the rails on either side by a foot. The sides of the ladder are light chains, a dog-spike at the extremities of the wire rungs entering the chains at fifteen inches apart. The last rung is a stout pole for the hauling wire, which wire runs over a pully at the extremity of the tram line. As the bark arrives for drying it is thrown over the rungs of the extended ladder. When rain or mist threatens, a wire from the back of the shed is drawn by a couple of oxen, and the flexible ladder with its load comes under the shed, the load of bark hanging from each rung being closed up compactly like the bellows of a concertina or the laths of a venetian blind, if they were run in horizontally from a couple of guides. On the return of fine weather, the ladders are again drawn out. The capacity of the shed is one hundred and twenty tons. At one time there was apprehension that it might become necessary to send the wet bark down the hill below the mist line for drying—for much depends on the proper drying of bark—but this system of shed drying has disposed of the necessity for such costly procedure.

Close by is the shed for chopping the bark, sawing the poles, &c., the motive power being a twelve-horse-power engine. All the machinery is well set on exceptionally solid foundations and the shed seemed advantageously planned for avoiding unnecessary handling, both as regards the placing of the machinery and the run of the tram sidings. In reply to a question, Mr Ellis said he had not been able to do anything profitably with tannage or cutch. The former, as many know, is an infusion of tannic matter derived generally from the waste small branches of the tan trees, and the latter (cutch) is the same inspissated—evaporated to a solid consistency. For making cutch, he said that a plant of vacuum pans, &c., costing £8,000, would be required.

From a commercial point of view the company's operations have been attended with great success.—From *The Agricultural Gazette*, New South Wales, for December.

RUBBER TRADE IN LAGOS.

At a meeting of the Manchester Chamber of Commerce, on the 12th inst., Mr. John Thomson, president, in the chair, the minutes of the African Sectional Committee containing the report of a discussion by the committee on the Lagos rubber-tree regulations, which were recently brought under its notice by the Lagos Chamber, were laid before the Chamber. The "Manchester Guardian," in a report of the above meeting, states that it appears that, with a view to the preservation of the rubber industry, the Lagos Colonial Government has placed restrictions on the "tapping" of trees and the sale and purchase of rubber in certain districts. The Lagos Chamber a few weeks ago addressed a letter to the Lieutenant-Governor of the colony urging that these restrictions should be removed, or at least modified. It was stated that "trade is extremely bad in the colony, and the Chamber is of opinion that it is partly due to the restrictions, which are diverting the rubber industry to other colonies." The African Committee having last week had the advantage of an interview with Sir William M'Gregor, the Governor of Lagos, resolved to recommend to the Board that a letter be addressed to the Secretary of State for the Colonies to the following effect; (1) That the Chamber is not sufficiently well informed to express an opinion on the demand of the Lagos Chamber that the restrictions on the rubber trade should be withdrawn. (2) That the matter is of sufficient importance to make it advisable that the Governor should receive instructions to inquire into all the points raised by the Lagos Chamber, after his return to the colony, so that he may be in a position to judge whether it is possible to modify the restrictions. (3) That in the opinion of the committee some restrictions are needed, and that the best way of making them effective is by securing the goodwill of the chiefs and by working through their agency. (4) That the chiefs should be encouraged to prevent overtapping the trees and to plant young trees in place of those which are killed. (5) That it is desirable to pass an Ordinance making it penal to buy or sell "root rubber." (6) That measures should be taken which will render it impossible for the native police to show the undue harshness to the people which is alleged to have been manifested. The Board sanctioned the despatch of a letter to Mr. Chamberlain in accordance with these suggestions. —*India-Rubber Trades' Journal*, Dec. 24.

HOW MUCH SEED TO USE.

Most people are very indifferent as to how much seed to use. In writing us for seed corn lately, some correspondents thought a quart of corn should plant one acre, others seemed to think that it would require a bushel. From my own experience, I find that four quarts will plant one acre, not more than four grains to a hole, 4ft by 4ft which is a good standard distance to secure a favourable return. Where rats and mice are giving trouble by eating out the seed, it is judicious to steep the seed in a decoction of bitter wood or in water with kerosene added, for a few hours, but even that does not secure immunity from some mysterious pests, (which I know are not rats or ants—the people say the offenders are frogs, but I do not believe it) which scoop out a hole and do away with the grains. For this reason, it is better to drop six or eight seeds in the hole and thus give a better chance to secure

a good stand. It is easier to pull some of the plants out if too many escape harm and come up than to go and plant more seed, for nothing is more annoying than to have to do this; you have to make holes again, even though the ground have been ploughed, drop seed, cover up and after all, these later plants never do well, for they are shaded by the older plants and dwarfed from the start. Therefore in planting six or eight seeds to the hole you would allow eight quarts to the acre. With pumpkins which can be planted through the corn after it has half grown, two to three pounds per acre is the rate for seed setting. As a general rule the following will be found fairly correct:—Beans in drills 1½ to 2 bushels; Peas in drills 2 bushels, broad cast 3½ bushels; Corn in drills ½ bushel; broadcast 3 bushels; in hills 8 quarts; Guinea Corn, broadcast or hilled 1 bushel; Cow peas to 8 quarts; Rice 30 to 40 lb: Cabbage (in seed bed to plant an acre) 2 lb; Guinea Grass 1 to 2 bushels; Turnips in drills 2 lb; Jerusalem Artichokes 3 to 4 cwt. "Red Peas" allow a bushel per acre in holes, tomatoes 1 ounce to 1,500 plants, egg plants 1 ounce to 1,000 plants, onions 5 to 6 lb, potatoes cut in two sets 12 to 14 bushels of whole potatoes or allow 4 to 8 barrels to plant whole or in sets. The weights in lb per bushel of different seeds are:—Beans and Peas 60 lb. Beggar Weed 60 lb. Guinea Grass 20 lb. Guinea Corn 40 lb. Country Corn (Maize) 56 lb. Oats 40 lb. Wheat 60 lb.—*Journal of the Jamaica Agricultural Society.*

RUBBER FIND.

A great discovery of india-rubber forests of vast extent has been made in the Department of Santa Cruz de la Sierra, and on the Magdalena in Bolivia. In the province of Caupolican, Department of La Paz, there have also been discovered some splendid forests, in which there have been found some rubber trees of a species not before known.

In Bolivia the only species of rubber trees hitherto worked are those known as "Hevea," or "Siphonia Brasiliensis," but lately the species known as "Castilloa, which exists in Mexico, Colombia, Equador, Central America, etc., has been dicovered.

In the Province of Caupolican gutta-percha has been discovered, which is very important. In order to facilitate shipments for the products of Santa Cruz and Beni, the Government has decided to open a port with a national custom-house, on Laguna Gaiba, a beautiful creek of the River Paraguay, on its right bank, at 17 deg. 48 S. latitude.—*India-rubber Trades Journal*, Dec. 24.

THE SUMATRA FIBRE PLANTER.

TOBACCO ABANDONED FOR RAMIE.

Mr. Bluntschli, with a friend, visited the Peradeniya Gardens on the 18th and enjoyed a round of the Gardens—being of course chiefly interested in fibre-plants, more especially Ramie, which he grows on a large scale in Sumatra. He has had nearly eight years' experience of Ramie cultivation now, so that he can speak with authority on the subject. It is not however every planter who can afford the patience or means to persist for seven years (!) at a cultivation like Ramie, as Mr. Bluntschli has done, before any profits are reaped. Previous to this he grew tobacco extensively, but becoming dissatisfied with the returns from this he ventured to try Ramie on a large scale, which is the only condition under which it can be made profitable. But it was a case of "out of the frying-pan into the fire." Still, patience has its own reward, and Mr. Bluntschli is now sanguine of respectable and steady returns, for he now employs 24 decorticating machines at his different factories, which are all lighted with the electric light. Mr. Bluntschli grows six distinct varieties of Ramie, though he considers there are no less than thirty more varieties in existence. Yet he was shown a species at Peradeniya which was quite new to him, viz: *Bœhmeria pulchra*, which as the name signifies, has beautiful velvety dark-green leaves. This seems to contain as good a fibre as any of the family, and is easily grown. *B. nivea* Mr. Bluntschli considers the best, and he confirms local experience (in the Gardens) by condemning the variety *tenacissima*, which is often said to be the best variety for high elevations. Mr. Bluntschli purposes a visit to Mr. Power's ramie clearing before leaving the Island. Then he goes on a tour to China and Japan for the purpose of acquainting himself with the methods of Ramie cultivation in those countries and with the different varieties grown.

THE NILGIRI GAME ASSOCIATION.

This Association held its annual meeting on Friday last at the Collector's office. There were present Sir Frederick Price, Messrs. C M and W Mullaly, Colin Mackenzie, H P Hodgson, Herbert Browne, Van Ingen, Wilbraham, Church and Captains Bagnalls, Van Agnew and Swan.

The Honorary Secretary, Mr G Hadfield, presented a Report of the year's operations of the Association, which was recorded satisfactory. Of the prosecution under the Game and Forest Laws detection had considerably improved owing chiefly to the appointment of two competent watchers, at Mettapollium and Satymungalum ranges.

The other measures of game preservation referred to was the destruction of vermin. A schedule of what had been done during the year is appended to the Report and testifies to rewards having been paid for 141 eagles, 279 wild cats, 65 mongooses, 24 cow pheasants, 13 wild-dogs and an otter. These figures were in excess of those of the previous year.

The question whether there had been an increase of game as the result of measures of protection was answered in the affirmative and the amount of success achieved, the Secretary contended, justified perseverance in the course adopted.

Among measures inaugurated during the year was the Game Bag and Shikari Register. Mr. VanIngen was the only contributor to the former and from lists of game shot in the district furnished by him, it appeared that 11 sambur, 1 spotted deer, 3 tigers, 4 panthers, 5 bears, 4 muntjack, 2 black bucks and 1 hyæna, were destroyed.

From the detail's supplied in Mr. VanIngen's list, we learn that the largest stag, with 34 inches of antler, was met with on the slopes of the Nilgiris, while the Kundahs and the Drug furnished two others of 33 and 32½ inches, respectively. The spotted deer was shot on the Westbury estate and the length of its right horn was 32 inches and of its left 31. The biggest tigers killed

were one male on the Kundahs and a female at Westbury each measured from nose to tail 9 feet. Westbury also supplied Mr. VanIngen with the largest skin to cure, which measured 6 feet 8 inches. Nellacotta, in S-E Wynaad, accounts for the largest bear destroyed, which measured 5 feet 11 inches, and was a male,

The meeting then adverted to the trout culture, undertaken by the Association; and to Major Bagnall having taken up the duties so ably performed by Major Grant, V.C. Major Bagnall arranged what he had to communicate under 3 heads—(1) attempts to procure ova, (2) the evidence of the existenee of trout in Nilgiri waters (3) the existence of other fish. Two consignments of ova were sent by Messrs. Andrews and Andrews, of the Surrey Trout Farm, the first consisting of *S. Fario* by the "Golconda," the second of the American rainbow trout or *S. Iridens* by the "Manora." Every precaution was taken this side of Madras, but owing to the apathy and utter want of appreciation of what was required on the part of the individual into whose custody they were delivered on board the ship, both the consignments arrived in a hopeless condition.

H.E. Lord Ampthill, it was resolved, should be asked to become the Patron of the Association, and a few additions were made to the Committee or the year.

CINNAMON IN LONDON.

It was scarcely to be expected that the extraordinary prices which some parcels of fine Cinnamon fetched at the August sales would be maintained. It is not surprising, therefore, that at the last quarterly sale for the year, held in Mincing Lane on the 26th ultimo, prices receded to the extent of 1d to 2d per lb. This falling-off was, however, only on the qualities which had received an abnormal fillip, and it represented a return to the range of prices which had previously ruled. A fictitious or unusual rise generally does harm by inducing illegitimate speculation; and if some people feel disappointed that the August prices were not maintained last month, they should derive consolation from the fact that there was not a serious drop, by way of reaction, and that prices were not forced down by an excessive supply. The finer qualities which are usually "worked" in London, by being unbaled, examined and re-baled, all found buyers at prices which must be considered satisfactory—the difference between the bids for the three First sorts being far less than usual, and one lot of Seconds actually fetching top price! Only about one-half of the offerings of "unworked" spice found buyers in the room; but the drop in their price did not exceed ½d a lb., for marks on which August prices were not maintained. The quantity catalogued was a fair average one, and the leavings need not mean accumulations, as Cinnamon is generally taken off at auction prices soon after the sale. The prospects of the spice may, therefore, be regarded as good, looking both to prices and stocks. Another circumstance which renders the outlook hopeful, is the determination of the trade to have nothing to do with so-called wild Cinnamon. Would that it were possible to secure a similar, effectual boycott for rubbishy Teas, by which we do not mean sound Teas of inferior quality—Cinnamon counts four sorts—but Teas manufactured of coarse leaf, leaf that does not roll, and adulterated with stuff that does not generally enter into consumption as food. We quote as follows from the Cinnamon Report of Messrs, Forbes, Forbes & Co., Ld.:—

CINNAMON.

London, E.C., Nov. 27.

The last series of quarterly sales for this year were held yesterday, when a total offering of 1,587 bales plantation Ceylon quill was catalogued, against 1,141 bales in August, and some 2,900 bales plantation at this period last year. With only a moderate enquiry, about 900 bales passed the hammer at generally easier prices. The exceptionally high prices realised for "Worked" quill at the August auctions were not maintained, as we had anticipated, and prices for these marks then unduly forced up, now gave way to the extent of 1d. to 2d. per lb. The "Unworked" spice realised about last sale prices to one halfpenny per lb. decline. The whole of the "Worked" quill —296 bales—was sold, firsts 1/4 to 1/7; seconds 1/2 to 1/7; (one lot at 1/8; thirds 1/1 to 1/6; fourths /9 to 1/; of the 1,391 bales "Unworked," 601 bales were cleared, firsts 11d. to 1/; seconds 9½d. to 11d; Thirds 9½d. to 10½d; fourths 9d.

A few lots quillings and chips sold, the former at 7½d. to 10d. per lb., and the latter at 2¾d. per lb. 1401 bales and 2,500 bales wild cinnamon and bark were again brought forward and, as before, were totally neglected.

Stock of Ceylon	3,032 bales quill 2, 2,446 „ wild	against	1899. 3,659	1898. & 6,116
Chips	2,743 bags		1899.	1898.
Wild bark, &c.	7.450 „	„	6,705	& 1,920

The next public sales will be held 26th Feb. 1901.

Owing to the strike of Thames lightermen the Cinnamon on board, the SS. "Alcinous" was shut out of the auctions.

SOME NOTES ON CHRISTMAS FRUITS.

By SAMPSON MORGAN.

The present Christmas season will be connected with the fact that it is a record one as far as the supply of fruit is concerned, and that never before has there been such a varied show of festive dainties in the windows of the fruit-shops, not only of London but of the United Kingdom. Until a few years ago the fruit-supply for Christmas was confined to a few well-known fruits, such as the grape, orange and apple; now shippers ransack every quarter of the world for new fruits, so that they may be put on the markets at a time when an insatiable demand and high prices prevail. That is why this Christmastide we have the grape-fruit from Jamaica, the persimmon from the South of France, the custard apple from Madeira, the mango from the Canaries, lychees from China, and golden-skinned apples from the Pajaro Valley. This apple is known on the English markets as the Californian Newton pippin. It is, however, nothing of the kind. It is the Pajaro Newton, and is grown in that fruitful valley from whence it derives its correct name. One fact about the development of the Christmas fruit-trade deserves a special notice. The public is inclined naturally to take it that we are as a nation importers of Christmas fruits, and importers

only. This is a slight error. At the present time English hothouse grapes are on sale in the leading fruit-shops of Berlin, Paris and New York. The English hothouse grape stands above all competitors, and is of magnificent appearance and quality. These grapes will be on the tables of many of the richest families in Germany, France and America, this Christmastide, and the fact, though generally unknown, deserves notice. But things will not even be permitted to stop here. We suggested the development of the export fruit-trade from this country to the Continent many years ago and now a Covent-garden firm has, we believe, opened a shop outside the Halles Centralles in Paris, so that best English fruits will be obtainable in Paris in large quantities for the festive season.

Another important feature of the Christmas fruit-trade is the unique position taken up by the Denia orange. Of course, no city in the world is so well and cheaply supplied with oranges as London is. At one time the flat St. Michael was the Christmas orange; then it gave place to the round Valencia. This in turn was eclipsed by the oval-shaped Jaffa; then the Navel orange surpassed that, for not only was it of a similar shape and size, but contained no seeds. Higher prices in Canada and New York have diverted the supplies of Navels from London, so the Denia enters the list, and to-day holds a foremost position with all comers.

This Christmastide the English hot-house grape-growers have for the first time had to face serious Belgian competition. True, Belgian fored grapes have been sold in previous years, but this season the fruit has been put up in special little wicker-plaited baskets, and by this means have come to hand in perfect condition, with the bloom quite untouched and as fresh as when they were packed by the growers. The quality is not equal to the home-grown fruit, but they are excellent imitations, and few of the public will be able to tell whether they are buying English or foreign fruit. Great expectations had been raised with regard to the arrival of huge quantities of bananas from Jamaica, but the public will have to depend upon the shipments from Madeira and the Canaries for the yellow-fingered fruits this Christmas-time. Without doubt the quality of the Madeira banana is as near perfection as possible. The banana is the coming fruit. It is wholesome, highly nutritious, and when fully ripe may be said to be devoid of starch, hence its great value as a food produet. Among dates those that come from Tunis are immensely popular, and the public prefer them to the Tafilats, which are sold loose, though the latter are twice and three times their size. Then there are the Elvas and Carlsbad plums. These have met a larger sale this season than ever, and have taken a good hold upon the public taste. The American figs in little wooden drums are also highly appreciated. Lady-apples from France, packed with dyed moss and with one layer of crimson-cheeked fruits in a case, have become so much sought after that they will command high prices this year.

Nuts are plentiful—the cokernut (*sic!*) particularly so. What wonder when we know that in Ruatan, off Spanish Honduras, the Carib Indians never work, because the cokernut trees drop their harvest of nuts about them, and repeat the process for half a century before losing their fruitfulness. In other parts of the world it is the same, and the cargoes which reach us from Trinidad and elsewhere prove the prolificness of this wonderful tree. Brazils and almonds are plentiful. Kent cobs are abundant, so are the small Spanish nuts, There are good stocks of chestnuts on sale; the best come from Naples. France sends a good-quality nut to this country. Walnuts are represented by samples from Naples and Grenoble. The former are kiln-dried, and the latter what are termed fresh. In its dried state the almond is known to everyone in this country now. In Italy their culture for commerce receives special attention. Around Catania and Syracuse they are grown in profusion, but the nuts are also eaten when they are soft and green as a dainty by the rich classes. In either form, whether green or ripe, they are a useful article of diet, and always appreciated. The almonds of Catania are well known in fruit-trade circles.

In addition to the other dried fruits that have been named there are huge stocks of figs, and a fine and varied display of fruits in thick sugary syrups.

Possibly in time we shall have the privilege of adding a considerable number of fruits to the extensive list we already possess. Were the fruit-growing centres of India alone exploited by dealers as they should be, we should soon be having a plenteous supply of oranges, bananas, custard-apples, guavas, pomegranates, limes, lemons, dates, figs, and mangoes from that possession alone, and in prodigious quantities too. As to melons, those of India are of the finest quality, and would be prized in this country.—*St. James's Gazette.*

DESTRUCTION OF GAME IN INDIAN NATIVE STATES.

Government would do well to direct attention to the game laws and their administration in Native States. In Mysore it appears that a wholesale destruction of game takes place all the year round, whilst a gun license may be had for the nominal sum of four annas. No animal is spared, whatever its age, sex, or season, and the result will be that eventually not a living thing will be left in the forests. The rivers also are suffering from netting, and representations by the local Government appear to be barren of result. In Hyderabad half the State is annually closed to European sportsmen, but the destruction by native shikaris proceeds apace in a country where every man is armed. The natives, however, destroy only harmless animals, and do not keep down beasts of prey, with the consequence that the latter prey almost entirely on domestic animals and not infrequently take to man-eating; the predaceous animals are thus likely to largely increase in numbers and destructiveness.—*Asian*, Jan. 15.

The Forthcoming Burma Rice Crop, according to the estimate, will be the largest on record. As it is to be hoped there will be no famine in India, prices will probably be lower than those of 1900. In Siam the prospects of the present crop are said to be excellent, and Bangkok and Saigon will doubtless supply a good deal of the demand for China and the Straits. Japan now buys Burma rice pretty regularly, finding it more profitable to export her own grain. No attempts seem to have been made to introduce the Japan variety of rice into the province and it might be worth while to experiment in doing so.

REPORT ON CEYLON TEA, 1900.

EWART MACCAUGHEY AND COMPANY, LIMITED.

The New Year's Auctions opened pretty well on the same lines as Indians. The market was strong up to 7½d per lb while over this prices were irregular, although, where quality was unmistakably good, buyers were prepared to pay up. A fair amount of Pekoe Souchong for price was available at 6½d per lb, and Broken Pekoes generally were relatively much cheaper than leafy grades. The very strong tone died out towards the close of the month and partly owing to inferior quality, but chiefly no doubt in sympathy with Indians, prices fell all round until 6d per lb teas in particular were showing wonderful value.

In February better teas brought a better market, and with both home and export buyers coming in and fine teas in small compass, prices advanced, finer kinds selling up to 1s 7d per lb or 1s 8 per lb, while in Common Leaf there was no quantity to speak of under 6½d per lb. Prices for Common did not, however, remain up very long and the end of the month brought lower quotations for all tea under 7d per lb with a fair number of 5¾d per lb quotations.

The first auctions after the Budget opened with an irregular tone and very shy bidding. Pekoes at 6d per lb, wonderfully cheap, and tea generally a full ½d per lb down from highest point. Quality was improving, and in March we had a strong enquiry for fine teas, while at the other end of the gamut low grades had receded to 5½d per lb. Throughout April and May quality was indifferent, but prices were useful, and with 6d per lb grades showing wonderful value a large business was done, the blenders in particular operating freely as prices exactly suited them. All the enquiry was however for leaf, and Brokens were going anyhow.

May closed quietly with bad tea and easier prices. There was plenty of Pekoe Souchong and Pekoe at 5½d per lb., and a fair amount at 5¼d per lb. Enormous quantities were being offered and this not only killed the Ceylon enquiry but reacted on other markets as well. Poor quality and more tea than the trade wanted at this time of year had brought down the average price to 6¾d per lb. as against 7½d per lb. in the previous season.

In June again the market was entirely overdone with tea and prices receded to 5¼d per lb. for leaf and 5¾d per lb. for Broken, practically the whole weight of tea selling between 5d per lb. and 7d per lb.

Quality improved in July and a better market resulted, and by the end of the month the average price had risen to 7½d per lb., with 5½d per lb. representing about the lowest price for common leaf.

Auctions had been heavy right through what is usually the slack season and this led to a deal of fluctuation in prices, and by the end of August we had a decidedly slumpy market, with a much larger supply of 5d per lb. and 5¼d per lb. tea. This feeling was even more pronounced in September, and the very bad condition in which a large proportion of the tea was landed tended to create a further knock-out in prices.

Quantities dropped off a little in October, and there was rather less 5d per lb. tea, but, except in the case of finest, there was a poor market. Free buying in the upper grades, especially by the blenders, hardened up prices for anything with quality, and to show that fine tea is appreciated, there were Pekoe Souchongs selling at 1s per lb. and 1s 1d per lb. during the brief period in October when really good tea was being offered.

The last two months of the year showed a continuously weak market for Common and unfortunately the very low class of much of the tea offered (the worst ever seen) tended to keep down quotations, and to discredit Ceylon Tea generally. That buyers would rather deal in good articles was shown by the fact that while the grades up to 5d per lb. were neglected, there was nearly always a strong enquiry for useful medium between 6d per lb. and 9d per lb.

During the past twelve months it was more than ever noticeable that the planters are sacrificing quality to quantity, and this is much to be regretted especially as the export branch of the trade has of late years steadily increased. The Continental orders are now an important factor but if Ceylon tea is to hold its position, quality must be considered as of the first importance.

A result of the low prices, and a most satisfactory one, was the very considerable increase in the Export of Indians and Ceylons to other countries and this opening up of new outlets capable of absorbing large quantities must prove of the greatest value in the future.

After the experiences of the past season planters will doubtless see that it is to their interest to reduce production by plucking finer, and we hear that proposals are afoot for combined action by both Indian and Ceylon Garden Owners to bring about this desirable consummation. If carried out efficiently this would be an enormous advantage to every branch of the trade as it would raise the standard of quality all round.

An unsatisfactory feature has been the large proportion of tea which was laid down here in a tainted condition. A certain amount of friction and endless trouble has resulted, and never before have we seen anything like the same number of parcels thrown up or contracts cancelled. Unsuitable packages, no doubt, largely account for the flat teas, but in the case of real taint we are bound to look for other causes, and shippers, rightly or wrongly, are becoming very suspicious of some of the steamship lines.

PLANTING NOTES.

A LARGE AUSTRALIAN PUMPKIN.—Canon Garland has sent to the Minister of Lands a huge pumpkin, of the ironbark species, which was grown by the boys of the Swan Orphanage. This great vegetable when weighed turned the scales at 30 lb. —*Westralian paper*, Jan. 14.

THE SEYCHELLES.—Mr. CHAMBERLAIN has given his sanction to the establishment of a botanic station in the Seychelles, which, with the co-operation of the Director of the Kew Gardens, will be started on the first day of the coming century. Some people have actually assigned the site of the Garden of Eden to the Aldabra group in the Indian Ocean, now famous for little else than the gigantic land tortoises, of which so many have been sent to the Zoological Gardens through the instrumentality of the Hon. WALTER ROTHSCHILD, M.P. Every description of plant which is likely to be of the slightest economic value will be obtained from other countries, and the treatment of the soil will be made the subject of special experiments. The islands are in direct communication by steamer with Colombo, Mauritus, Aden, Zanzibar, and Bombay, a factor which is likely to play an important part in the development of their internal resources. Our contemporary, the *Daily News*, overlooks the famous double-cocoanut, around which so many legends have collected, the most fantastic being the theory of the late Gen. GORDON above alluded to, that this was the forbidden fruit.—*Gardener's Chronicle.*

THE WORLD'S SUGAR.

The map which we print on page 11 shows roughly the area of the world where sugar is produced. It will be seen that the sugar-cane is not cultivated beyond the 40th parallel of latitude while the beet can be grown to the 60th parallel. Until a few years ago sugar was extracted from the cane in the warmer latitudes by an antiquated method of labour and ineffective system of machinery, but as a good price was obtained for the sugar no attempt was made to improve the methods of production. It was never anticipated that sugar could be produced in a comparatively cold climate, and when the beet sugar came in the sugar-cane planters were quite unprepared for the new development. They had to face a fall in prices, the introduction of bounties, and improved methods by capitalists and companies in other hands and they went under.

Beet sugar is now grown in most of the countries of Europe, and the following figures, which are published by the International Union for Statistics on Sugar, show the number of acres that have been planted with beet sugar seed.

BEET SUGAR PLANTING.

Country	1899 Acres	1900 Acres	Increase Per cent
German	1,057,939	1,090,521	3·1
Austria-Hungary	804,063	839,151	4·4
France	626,480	685,391	9·4
Russia	1,261,614	1,356,075	7·5
Belgium	158,235	170,028	15·0
Holland	109,703	112,878	2·9
Sweeden	65,238	71,271	9·2
Denmark	34,594	34,594	—

The beet sugar production of Europe this year is over 5,500,000 tons, while the production in the United States amounts to 73,000 tons. The beet sugar shows an increase over 1899 of 500,000 tons, while cane sugar shows a decrease of 250,000 tons. The Louisiana crop, according to the New York *Journal of Commerce* is put in at but little more than half of what it was last year, the Porto Rico crop is charged with a large ratio of deeline and the Cuban crop is sat down for 45,000 tons less than last year, and at much less than one-third of what it was in each of the two years next preceding the revolution. In Queensland and New South Wales the crop is estimated at very much below last year's figures, the decrease in the former colony being 40,000 tons or nearly one-quarter and in the latter 12,500 tons, or not much less than one-half.

To cope with the unremunerative nature of the cane industry, Barbadoesis endeavouring to obtain the capital to erect central factories which would enable the colonists to extract more juice out of the canes, and also to produce a better quality of sugar which would be more suitable to the Canadian and British markets. At present nearly all their sugar finds its way into the United States.

PROGRESS OF THE EUROPEAN INDUSTRY.

To show the progress of the European beet sugar industry, it may be stated that there are 213 factories in Austria-Hungary alone, the total ontput of raw sugar from this country in 1899 being computed at 1,083,000 tons. The Government set aside a sum of £750,000 for the payment of export bounties. The decision of the Legislative Council in Calcutta—following the example of the United States—to introduee a countervailing duty on bounty-fed sugar imported into India has made no change worthy of special notice in the trade between Austria and India. The chief burden of the countervailing duty, which is equal in amount to the export premium accorded to sugar in its country of origin, is thrown upon the Indian consumer, who has not only to pay more for the bounty-fed sugar, but also for the colonial sugar, which sympathetica ly rose in price.

Russia is now the largest produeer of beet sugar in Europe, there being altogether 23 beet cultivating provinces in this country. The industry in Germany is able to keep going 400 raw sugar works and 150 refiners.

There are about 230 sugar factories now at work in Cuba, which is only about 60 per cent of what there were before the war. Owing to the present competition of beet sugar, it is unlikely that the mills which have been destroyed will be replaced. During 1899 about 324,000 tons were exported.

There has been an improvement in the sugar industry in Jamaica after a persistent decline for many years; 360,748 tons were exported last year. In British Guiana many of the sugar plantations can hardly pay their way, and future prospects are not encouraging. About 100,000 tons were exported from Georgetown, Demerara, in 1899. The whole of the sugar production of the Hawaiian Islands, amounting to 282,807 tons in 1899 went to the United States.

Large quantities of cane sugar are produced in Southern China, Formosa, Java, Philipines, Mauritius, Central and South America and other tropical and sub-tropical countries, but the rise of the beet sugar affects them all. The bounty system has also meant the ruin of more than one commercial house in this country. Bristol, whieh was once the centre of an extensive sugar-refining industry, elosed the last of her refineries a little while since. In this country there are now only about five refineries—two in London, two in Liverpool and one down Greenwich way.—*Homepaper.*

THE REDUCTION OF THE TEA OUTPUT.

(To the Editor of *The Home and Colonial Mail.*)

SIR,—Last week you were kind enough to publish a letter we wrote you on the subject of over-supply and consequent low prices.

We are pleased to learn that this matter is being taken up energetically by influential producers.

Some three weeks ago we wrote a similar letter to that published by you to the Editor of the *Ceylon Observer*, and according to a telegram published in the *Daily Express* this week the idea has evidently caught on in that island, as the telegram reads as follows:—

"With a view to reducing the excessive production of tea, Mr. H. R. Rosling, chairman of the Ceylon Planters' Association, suggests that all Ceylon and Indian tea planters shall leave one-tenth of their tea unplucked for two years."

There can be no getting away from the fact that the law of supply and demand dominates the tea market as it does all others. In other words, the present demand must be increased or supplies must be curtailed in order to beneficially affect prices. The demand, or consumption, has been artificially reduced by the advance in the duty, and if any further change is made at the next Budget announcement the chances appear more in favour of a furthor advance than any reduction in tho tax. There is, therefore, no hope of relief from materially increased demand, so that the question of supplies must be dealt with if the situation is to be improved, or even saved. If nature does not produce a diminished crop then some scheme of artificially accomplishing that end must be devised, and such a scheme must be thoroughly and enthusiastically carried out by all

concerned, whether growers of fine or common tea. It is a mistake to think that all parties are not in the same boat; it is the weight of tea that is crushing the market quite as much as, or more than, one particular class. Certainly the high grown estates are, and should be, getting larger proportionate profits on their smaller outturns, but how badly do those prices compare, speaking generally, with those ruling but a few years back. If there is a demand for 250 million lb. of tea, and 275 millions are supplied, then the market must decline whether all that tea is fine or common.

There is one other point we should like to mention, viz., that the idea of voluntarily plucking finer would not inspire confidence among buyers, as they would feel that in the event of a rise in price the method of plucking might be changed by telegram, and in six weeks or two months the market might be flooded and stocks greatly depreciated in value.

The producer must inspire confidence in the trade, and the same can only be done through reduction in the supply being absolutely assured.—We are, pear Sirs, yours faithfully, BROKERS.

RAISING OUR OWN NITROGEN.

Everybody believes that the soils of California are abundantly rich, yet in a Los Angelos paper, Professor A J Cook stated that the orange growers spend an average of $50 an acre for fertilizers. Florida needs fertilizers even more, but they believe there in raising their own nitrogen, not buying even cottonseed meal, except, perhaps, to get a start. Desmodium (beggar wee) cowpeas, and velvet beans, are legumes, and have power to draw nitrogen from the atmosphere through their rootlets, and transit it to the soil as food for future plant growth. Nitrogen is the most expensive element of our fertilizers, costing 17 cents a pound, while phosphoric acid costs 6 and potash 5. The planter should aim to raise everything that he must have, which he possibly can raise, instead of paying out his hard-earned money for it. No farmer can afford to buy rough nitrogen for fertilizer when he can so easily raise it. Desmodium makes the best of hay, if sown thick, so as to reduce the size of the stalk, and at the same time it enriches the land. If put in tall narrow cocks and capped, and left to cure for a few days without getting wet, then opened and aired for half a day before being hauled in, it makes the most valuable hay the planter can produce. Horses not only relish it, but they actually fatten upon it without oats or other grain. Immediately after cutting, another growth starts up and makes a heavy second crop. Some farmers prefer to save this for hay, because the rainy season is passed, while they cut the first crop and leave it to rot on the ground, as it comes in the rainy season.

The effect of this plant on the soil is almost magical. Not only do the roots draw nitrogen from the atmosphere, but they also run down deep and bring up mineral fertility to the surface. A Middle Florida farmer, a native of the State, and accustomed to Desmodium all his life, has stated that he raised a crop of corn for twenty years consecutively on thin, sandy land, and the yield increased a little every year, with no manuring except that given by a crop of Desmodium following the corn each year. There is something which cannot be explained which makes heavily-shaded soil gain in fertility. It is nature's way of enrichment. After plowing down this dead Desmodium one can grow almost anything with astonishing results; the shading of the land has made it mellow, and it is full of nitrates. Potatoes revel in such a situation; melons, pumpkins, cucumbers and beans grow like the proverbial gourd—Florida *Fruit Grower*.

TEA PLANTS FROM CHINA.

According to the "Annales de la Sociedad Rinalde Argentina," the Department of Agriculture in that country has procured a quantity of tea plants in good condition from China. These have been distributed among the State Agricultural Colleges for purposes of cultivation, and, as in the Argentines there is a choice of climates, it is anticipated that ere long a suitable locality will be found, and that an important development in the direction of tea cultivation may be looked for in the future. But, of course, there, as in most South American countries, the labour question is the lion in the way.

IMPORTANT IMPROVEMENTS IN TEA. LEAF WITHERING.

The results recently obtained in Ceylon from the artificial withering of tea-leaf are of so much importance to the whole tea industry that they deserve some special reference in our columns. Messrs. Davidson & Co., Limited, of Belfast, whose "Sirocco" Tea Machinery for every other process in the manufacture of the leaf is so widely know and highly appreciated, claim the credit of having solved the difficult subject of tea leaf withering. The experiments made by them in this connection extend over a period of fourteen years, during which, and more particularly within the last four years, we believe, that they expended well on to £10,000 in apparatus, plus cost of conducting large scale trials in different factories in India and Ceylon before attaining the present satisfactory results.

These experiments were carried out by Mr. F G MaGuire, under Mr. S C Davidson's guidance and directions, and the resulting outcome is that now, at a small outlay to the tea garden proprietor, thorough control of the wither is, it is claimed, so perfectly obtainable that the quality of the tea produced is equal to that from leaf withered naturally under the most favourable circumstances of temperature and weather; and the time required for producing the wither is greatly reduced, so that the output capacity of the existing withering space is thereby increased to such an extent that in many instances large extensions to withering houses have been obviated.

A cold wither, it is stated, can now be obtained of such satisfactory quality that, if a small quantity of the leaf be pressed between the hands, it will stick together, showing that the leaf has attained that desirable soft and clammy condition which is so conducive towards the production of the best results during subsequent manufacture.

A large number of factories in Ceylon, ranging from sea-level to over 5,000 ft. elevation, have, we understand, been equipped with the necessary apparatus during the past season, and in actual practice, perfect withers have been obtained in twelve to fifteen hours, from leaf plucked on wet days during the rainy season, and which on arrival at the factory was saturated with rain water.

The opinions expressed by the proprietors and managers of the tea factories in which the new system (the principal item in which is the special adaptation of the new Sirocco fans in existing withering lofts) refer, we understand, in the highest terms to the results obtained.

Mr. F G MaGuire is now in this country, and will, we are informed shortly, visit London in the interest of Messrs. Davidson & Co., so that their numerous clients, representative of the important tea industry, will be enabled to gather further particulars from him as to this new system of withering The data and details of numerous trials which have been reported on various estates, where the entire crop of leaf is now being withered on this system, can, we learn, also be inspected.—*Home Colonial Mail* Jan. 11.

CINCHONA AND QUININE IN 1900.

The year 1899 ought to be a memorable one for quinine speculators, as the article has again proved a veritable will-o'-the-wisp. The makers have done their best to stem the tide of speculation by refusing to make contracts with speculators, but they have only been partially successful. At the first cinchona-auction in Amsterdam an average of 8·90c per unit was paid, but at the second one the price advanced to 10·65c, dropping to 10·05c at the third and rising to 10·10c at the fourth. From this period to the eighth auction in September there was an uninterrupted advance to 12·25c (the highest point touched). In November the unit dropped to 10·90c, and again this month to 8c. The gradual advance from 10·10 to 12·25c was due to a falling-off in bark-shipments from Java, but unexpectedly large shipments were made during September, October and November. There was then a deficiency of 1,100,000 Amsterdam pounds to make up before the year closes, of which 470,000 was wiped off in the first half of this month. Meanwhile the second-hand quinine-market has been influenced by every little wind that blew; but makers have been very passive, only raising their price when absolutely compelled, and at one period an advance of half-pence was made when quite two-pence had been expected. Prices are two-pence cheaper today than in January. The notable alterations by makers were a reduction of two pence in April and one of three pence in December. The highest figure of the year 1s 7d, in September, at which time the second-hand market stood at 1s 6¾d spot—also the highest.—*Chemist and Druggist*, Dec. 29.

CINCHONA AND QUININE.

Recent events in the cinchona and quinine markets have rather upset the calculations of those who conceive and act upon short views of the course of these articles. With such an artificial and highly—in fact, one might say, fantastically—sensitive market as that created in London by speculative dealing, the natural trend of things is often obscured and even retarded for a period. It has been our good fortune to point to the promising positions of the market just before each occasion of late when [illegible] advances have set in. These have not been so steady and consistent as natural causes acting alone would have made them. Speculators have paid the penalty for their weakness, or their rashness, or their miscalculations. Many of them have shown again their peculiarity of carefully keeping out of the market until it has sustained several material advances—then rushing in as if believing that quinine only wanted a start to carry it to goodness knows where. They never allowed for set-backs to compensate for the unnaturally rapid advances, and when some of them were involved in disaster the others had to pay a double malty.

But to the men of long views the situation seems only temporarily clouded. They will find their ideas reflected in a letter from a planter which appears in the *Tropical Agriculturist*. Much of what this planter says reads like a re-echo of remarks in former notes of ours. For instance, he leads off by stating that nobody will deny that consumption of quinine has overtaken production. He continues as follows:—

"Nor is there any doubt that it will do so to a far, larger extent during the next five or six years, for that at the least, is the period necessary to bring matters to a state of fair balance again. The reason for this is evident; it takes five to six years under the most favourable circumstances to grow cinchona fit to bark."

Five or six years is the time we allowed for those planters to be ready with, new bark who had perceived the situation and had begun to extend their plantations in view of this. The planter whom we quote is bitter towards the quinine manufacturers who according to him, "have grown fat and sleek" by their manœuvring in the past, though "many cinchona planters have been ruined by it." He believes the move of raising the unit temporarily, in order to stimulate the shipments, is about played out, and he alludes to the low shipments from Java during the first nine months of 1900 to illustrate this. The Java planters, according to this correspondent, have now "probably learnt the lesson that a pound of bark at a two-penny unit is equal to three pounds at a penny unit as regards net results on every four per cent of bark." Turning from bark the planter has next some advice to give to quinine manufacturers. He says he is "one of those whose cinchona prospects have been ruined by the policy of the manufacturers;" yet he does not blame them for doing the best for themselves, but for the way they have done it. Now, he thinks their wisest policy is a generous one. This is to reduce their margin of profit to a minimum and thus by "a good and stable unit encourage the planting of as much cinchona as possible in the near future, and the cultivation of every cinchona tree in existence." It is, of course, impossible, he says, to tell what stock of quinine and bark they hold [all the evidence shows next to none, say we]. They have, however, to reckon on a steadily increasing demand, and "five to six years of decreased production." Any manœuvre tending towards a rapid overthrow of the unit would decrease the amount of cinchona which will otherwise be planted out in the near future. Even with an increase in the plantations, it is pointed out that much will not grow into anything worth barking, suitable land and good seed being difficult to find. Manufacturers are advised to investigate for themselves what is the state of the cinchona districts.—*B. and C. Druggist*, Jan. 4.

New Vegetables.—Were it not that humans are creatures of conventional habits, the probabilities are that our sources of food supply would be very extensive, and we should not be as dependent on certain known and cultivated species as we are. Arguing on this line of thought *La Science Frangaise* puts forward the following suggestion:—"Our present garden vegetables are cultivated varieties of wild species; why do not our horticulturalists seek for other wild plants that could be introduced with profit to our tables? A fortune awaits him who does this successfully. We may be shy, at first, of a dish of iris, or a saxifrage salad, but the papers will relate how Bernhardt or Coquelin ate and liked them, and then the iris and the saxifrage will become popular, like the potato." The possibilities of the vegetable kingdom as a source of food supply are immense, and the suggestion thrown out above is well worth pondering over.—*Indian Gardening and Planting*, February 7th.

CINCHONA IN MYSORE.

The reader will probably smile at this headline, thinking that he is to see something after the style of the chapter on Snakes in Iceland, which read "There are no Snakes in Iceland." We have no such plagiarism in view, however, for there actually *is* cinchona in Mysore. That it is apparently not worth removing the bark from it is quite another matter. Official statistics show the following figures for 1898-99 :—

		No. of Plants.		
		Mature.	Immature.	lb of bark.
Kadur	C Succirubra	49,160	43,200	25
	„ var. Condaminia	9,840	4,500	
Mysore	C Succirubra	1,749	75	
	„ Calisaya	—		
	„ var. Condaminia	502	19	
Hassau	„ „	1,940	120	
		63,191	47,914	

In 1894-95 there were 350 acres under cinchona in Mysore, in 1898-99 only 279 ; in 1894-95 there were 207,783 cinchona plants in permanent plantations in Mysore, only 111,105 in 1898-99 ; the quantity of bark collected had decreased from 160 lb in the former year to 25 lb in the latter. Can any Mysore planter oblige us with a histo riette of the Rise (?) and Fall of the Cinchona Industry in the Mysore State? The above figures suggest that there is something to be told that is worth the telling: 279 acres, 111,105 plants and yield—25 lb!—*Planting Opinion*, Jan. 26

A FARMER'S EVERY-DAY LIFE.

XVIII.

(By Cosmopolite.)

The New Year has begun with a dry change, for which we have long prayed :

THE WEATHER OF THE PAST YEAR

having been the wettest in North East Aberdeenshire, of all the years of the 19th Century, so, at least, says the oldest inhabitant and he ought to know ; and now farmers, when they get the chance of a dry day, can't push fast enough in order to make up lee-way in the work which has been retarded by the bad weather. I have managed to get 300 loads of turnips carted, but it has been a terrible job, the mud up to the box of the cartwheels causing the work to be extra hard both on man and beast. My turnip crop has been an exceptionally fine one, and it gratifies me, when reading the reports of the prize competitions for the growing of turnips with artificial manures, to find that I have beaten the best record by a good deal, although I have only used bulky manure. The best record that I have read about has been

23 TONS PER ACRE

except in one instance when 28 tons were got from a field dressed with cattle manure only. Having sold a few acres of my turnips, as I had such a heavy crop that I was not likely to require them all myself, one of the purchasers, who had bought an acre, carted his to the railway station, where they were weighed and trucked South, and the aggregate was just a few pounds short of 30 tons, and this, I think, may safely be considered one more victory scored to the credit of bulky manure.

I see that many agriculturists are publishing complaints, in the press, about the habit which has been adopted, by the farm-servants, of drinking great

"BLASHES" OF TEA,

not only in the afternoon, but during the forenoon also. One writer, who farms in Peebles shire, tells how his ploughmen's children carry hot tea to their fathers, in the field, at 8-40 a.m., no matter what sort of weather is in evidence ; and again, about 3 p.m., the same arrangement is carried out. He adds that he would not object to this during harvest time, or when work is from 6 to 6, but that surely it is uncalled for at the present time of year, when the work is only of seven hours' duration. This custom on the part of farm-servants has not yet reached our northern counties, so that I cannot speak from personal experience as to the effect which it produces on the men and on the work ; but, no doubt, the habit, will be highly approved of by Ceylon tea-planters, as providing another outlet for the disposal of some more of their staple. Another singular habit obtains in England, which, I am thankful to say, has not yet reached Scotland, namely the

DYEING OF HAIR AMONGST THE LABOURING CLASSES.

The fact is that the working man has, long since, found that, if he looked old or white-haired, persons to whom he applied for a manual job would seldom entertain him if they could get a younger man. Even amongst clerks this habit prevails in a great measure, and some of those, of upwards of 60, are wonderfully made up. Writing on this theme reminds me of the rhyme of one's childhood.

"The sudden fright unnerved her quite,
She fainted dead away ;
Her hair turned white in a single night,
But she turned it brown next day."

THE LONDON CHRISTMAS MARKET.

has been a complete frost this season, the price being very much under what the same class of stock was selling at, in provincial markets. This is easily accounted for, although, I fear, it will take many years yet before the dealers who patronize the London market will learn wisdom and become converts to the well-known fact that London is the city in which the *worst* meat in Britain is retailed. Formerly London was celebrated for its roast beef and Highland mutton but now, owing to the vast quantities of cheap foreign meat at their command, the London butchers do not care to buy the better quality and higher-priced article that Scotch feeders send them. Their customers grumble away at the tough meat they get, and for which they pay top price, but they make no attempt to improve matters, and it never seems to dawn upon them that they are steaks off the gully-rakers of Argentina, and frozen roasts off the working bullocks of Australia that they are eating.

It would be very different if these butchers were compelled to disclose the origin of the article they sell, and foreign meat be sold for what it really is.

THE BEST BEEF AND MUTTON

is now to be got at the small village butcher shops where the public see and take note of every animal that is slaughtered ; where it came from, who bred it, how it was fed &c. And he would be a foolish butcher indeed who attempted to bring into one of our villages a frozen carcase or an animal bought at a distant market. The London Parish Council elected to do away with private

slaughter houses, so the butchers of the metropolis have gradually given up killing on their own account, but purchase their supplies from the freezing depots or the dead-meat market, hence the toughness and the poorness in quality of the meat retailed in the London shops. Now that the Christmas season is past, with its glutted markets and its low prices, I am preparing to send off my usual weekly consignments of sheep to the fat sales. When all the rest of the Agricultural world was flooding the markets with stock,

I HELD MY HAND,

and so, for the past few weeks, I have sent none forward for sale. The price is now going up, however, and as there appears to be a scarcity of stock owing to so much having been sent off at Christmas time, I hope that my patience may be rewarded by a good price. The season of ploughing matches has once more come round, but, as I referred to these entertainments in an early article, I will not again revert to what is undoubtedly of the greatest interest to our farm servants. Horses, with their coats shining like satin, are to be seen at work in every direction, the extra grooming which they are receiving being preparatory to the day when the man who looks after them, is to face the music on the ploughing match field. The harness also shines like enamel and the buckles glitter like silver, whilst the men put in their spare time in plaiting fancifully coloured ribbons into rosettes, with which to decorate their teams.

AN EXHIBITION OF PAINTINGS

was lately opened in our country town, and it has been acknowledged, by good judges, to be by far the best that Aberdeen has ever produced. A singular fact in connection therewith has been commented upon, and, as it refers in a measure to agriculture, I take notice of it. It appears that the best judges of art, the chief connoisseurs of paintings in the Silver City by the sea, are all, more or less, connected with inanimate farming produce. One is a wealthy soap manufacturer, which is made from the fat of stock; another is a felt-monger and tallow merchant, whose stock in trade is all derived from agriculture; another is a miller, whose grain, of course, also grows on farms, and, although he is dead now, the gentleman who did more for art in Aberdeen than any other, made a fortune in the granite trade, the quarry which he worked being on my own farm, and which is still in full swing. Granite, perhaps, can hardly be said to be the produce of a farm, but let that pass; with regard to the other three, however, there can be no doubt. I have never heard it said that agriculture tended to the making of an artist, but, who knows, I may, even at my time of life, break out as a modern Titian or a successor to Sir Frederick Leighton.

PARAGUAYAN TEA FOR WESTRALIA.—The secretary of the Westralian Department of Agriculture is making arrangements to try and cultivate the tree or shrub that produces Paraguayan tea. It has been cultivated successfully in the Botanical Gardens, Melbourne, and it is considered that it should find a suitable home in many parts of Westralia, especially in the north-west and south-west divisions.

THE DEVELOPMENT OF THE TEA TRADE.

We quote the following from Harrison's and Crosfield's Tea market report,—the local branch of the firm being Crosfield, Lampard & Co., Colombo,—dated 3, Great Tower Street, London, E.C., 7th January, 1901 :—

The Statistics just published having closed a Century of remarkable expansion in the consumption of Tea in the United Kingdom, it may not be altogether uninteresting to note the various developments in the Trade, together with the changes in the Duty, market value &c., as they have taken place from time to time. At the beginning of the Century the entire Import of Tea was in the hands of the East India Company; and the Duty was collected through them, by an *ad valorem* percentage on the prices realised in their Public Sales. The monopoly granted in their charter having come to an end in 1833, this method of levying the Duty was no longer found practicable, so a specific rate per pound was adopted instead, and it has continued to be so levied ever since with the undernoted variations in the amount.

Table showing the quantity of Tea consumed in the United Kingdom at the various points in the 19th Century when changes of Duty were made: and the quantities of Indian and Ceylon Teas consumed after their introduction.

Year.	Duty.	Av'rage market value without duty.	Total home consumption.	Indian.	Ceylon.	China and other sorts.	Percentage of British grown Tea.	Percentage of Foreign grown.

c Crimean War Budget.

THE POTATO INDUSTRY IN KUMAON.

The last monsoon of this century must he set down as a rascally bad one for this important crop of the province of Kumaon. I do not remember a more highly promising spring than the last during the past dozen years; the weather was ideal and could not have been better made even in Germany up to the month of May. But after that date and all through the month of June what rainfall there was —and it was very little save in places—came in non-effective driblets, and so progressed the monsoon period until the 11th of July when it did rain in real earnest, but the destructive drought had done its work: and in fifteen days after the real rains had set in it was quickly seen the potato plant had had enough and would do no more in the way of plant-production. Meantime the weather continued exceptionally warm and vapoury, and the great development of the rainfall was not as usual in July but near the tail end of the monsoon. In consequence of the altogether premature closing of plant growth three things ensued. First, there is this year a great dearth of large potatoes compared with normal years. Secondly, there is an excess of small potatoes; but thirdly, and worst of all, potatoes have supertuberated badly—indeed I have never seen this evil so pronounced.

Few people probably out of the province are fully aware of the amount of excitement, speculation, and finesse the native growers impart to the trade of growing and dealing in potatoes. For example one would think the best possible thing for a potato after digging it up was to dry and clean it, to separate bad from good, large from small, and so forth, and so it is in reality. But the native growers do nothing of the kind, but this is what they do. They remove about a foot deep of earth in circular form, the size being ruled by the amount of potatoes to go into this base for a conical pile of potatoes, which may, and does, vary from 5 to 100 maunds. Soon after digging up the potatoes go into these conical heaps, all the sorting being for the veriest mites that grow; these are saved for seed. Now at digging up time it is usually brilliantly fine by day, the sun is hot, and the potatoes damp as they go into the heaps; the moment these are completed a layer of grass is put round them and on goes a pile of earth an inch or two thick. There are here all the elements for keeping the tubers very thoroughly moist, drawing moisture up from the earth in fact, besides that with the potatoes already. The dealers buy from these heaps. The potatoes are lifted and weighed with extraordinary rapidity and a desperate kind of earnestness, dirt, small stones, bad and good, and all finding their way into the dealer's sacks with despatch. The dealer says but little besides seeing he gets weight, but he is, however, far from the apparent fool a casual observer might take him to be. When the weighment is over, he draws out a coil of rupees from somewhere and deals out so many: but the settlement day is at Haldwani, as many a grower knows full well.

The native grower is devoid of any consuming kind of honesty in growing potatoes. I have mentioned that this year potatoes have supertuberated badly: which is to say the crop in large measure, particularly the late-dug-up potatoes, grew again or commenced to grow. Now the effect of this is practically to spoil the tubers for table use, and also to produce seed which when planted shows much irregularity, some coming strong, others weak, and yet a lot more very much behind the rest in growth. The growers however lump them all in and say not a word to the buyers of such a fact. This year, however, there is heart-burning among the wily growers, for the Bengali dealers have come along with a terrible tell-tale weapon none other than a homely knife. With this they slice up samples of potatoes longitudinally; in a very few minutes, your supertuberated tubers tell their own destruction, being either of a congealed watery consistency, or with black markings, in either case they are inedible.

The buyer wants potatoes, the seller wants money, but the advantage is with the buyer, because he has grown more astute than in former years when he purchased direct from the field, whereas now he buys at Haldwani, knowing full well once the potatoes are there none but a madman, and scarcely he even, will take them back again: and so he seizes the bad samples, forthwith quoting terms, which are this year anything but magnificent. I greatly fear Kumaon potatoes will come in for a bad name this year; it is certain many hundreds of maunds are bad—very bad. But I hasten to say it is an entire mistake for any one to assume, and I happen to know some have assumed, that it is the disease. The evil is supertuberation, induced first by the extreme lateness of the monsoon, and its long continuation beyond the usual period. This is quite sufficient to turn many potatoes either black inside, or hard and stony. I believe a normal season will establish the fact that the province is practically if not entirely, free from the dreaded disease known in other parts of India and all over Europe.

I endeavoured to persuade many growers to hurry on with digging up, and mind nothing else for the time being, and pointed out that the late-dug potatoes would be very inferior, but the native will have none of these ideas; he is waiting, watching the Haldwani market, keeping a man there indeed to scent the fluctuation. This year he is being pretty well punished and it serves him right. Two years in succession previous to this the Haldwani market floundered about between R3 and R6 per maund, due in a large measure to astute speculation, and practically false information, for which the dealers were made to pay through the nose; the growers reaped a fine advantage; but the middleman as usual the best of all.

There is no doubt whatever at the present time the Kumaon patatoes for seed purposes are of very material advantage to practically the whole of India. The native with his extraordinarliy cheap way of working the crop makes incomparably the best profits out of potatoes, and for this very reason there is a growing evil which it is earnestly to be hoped Government will once for all put down, particularly at this opportune moment of settlement operations. I refer to the monied speculators—they have become monied solely through this crop. They are in every place where potatoes are grown, andgenerally absolute strangers. These men are the wire-pullers, always prompting a dummy to put in applications for land: and promptly stepping in afterwards. Now my contention is no man has a natural right to land in this way, entirely out of his own *puttie*, and removed from his own village and home. There is a rule in the province now that no man can acquire lands without property qualifications: and I am sure there is no rule that has been during the past seven to ten years more technically observed, but virtually and in reality more absolutely broken. What is required is to kill the speculative part of this trade, and for Government to fully recognise that it requires steady progress and uniformity of grants for potatoes, every man to be limited to his own capacity for production of this crop, and to his own *puttie*, and no bunniahs to receive grants at all. I should suppose 2,000 or 3,000 acres during the past 10 years have been exploited by people who had precious little right to the land since they have done nothing to cultivate it, but brought in the outsiders from distant *putties*. Potatoes are the sum and substance of matter to him. Lest it should be supposed I have some animus against bunniahs I may be allowed to quote a true example seven or eight years ago. A bunniah came from somewhere, not in the immediate district, and obtained a small piece of land for which he paid Government the magnificent sum of R5 per annum. It was to my certain knowledge and direct personal observation, as jungle, one of the finest pieces in the *puttie*. The way that insigni-

fieant beginning grew into a considerable piece many times larger than the original was a marvel. In addition this same man obtained another piece, stuck up a bunniah's shop where one was absolutely not required at all, and thereby annexed a piece of resting land for ponies and Bootias. Further, he hacked the jungle in the barbarous jhooming fashion right up to the Government Road, in flat contravention of another rule about jungle adjacent to Government roads. Yet again this same man in conjunction with another put in application for yet a third piece of land, but the officer before whom it came was one too many for him He has since died, having made a heap of money: since which Government, I believe, has resumed the original grant The wisdom of this sort of thing seems to me conspicuous by its absence. NICOTIANA.

PLANTING ON THE ANNAMALAI HILLS.

(*From a Correspondent*.)

I have on one or two previous occasions given an account of planting progress on the Annamalai Hills, Coimbatore District, and a further report may be interesting. Over 2,000 acres have now been opened, about 1,000 of this being

COFFEE

the growth of which is quite satisfactory. I have picked about 1½ tons of crop from plants, a few hundred of which were put out very late in 1897, the balance in 1898; and at the present time not only all the 1898, but a large proportion of the 1899, planting has a large, even spike, promising a fine blossom after the next rain. Quality of bean looks excellent, and I am having the above small lot cured and shipped. If coffee is to keep down in price (it is useless going into the pros and cons of such a question here) good quality means salvation, and I am trying both the Maragogipe and Costa Rica coffee to get a fine bean; but from experience of various districts I am convinced that however useful careful selection and cultivation are, the natural conditions of soil and climate are mainly responsible for quality. No manuring has been done as yet, but 150 acres of the clearing are being trenched at present. It is worth mentioning that there has been no failure of the S. W. Monsoon during the recent dry years.

CARDAMOM

clearings are doing very well; and though a wary and somewhat pessimistic old planter, who was going round mine a few day ago, remarked that "good growth was all very well, but no doubt cardamoms would be selling at a penny a lb. in a couple of years," it is not an expensive cultivation, and if there must be a survival of the fittest such a natural home of the plant should be amongst the survivals. It must not be forgotten that there is a large market in India for this product, so large that the local price is not dominated by European rates, and the producer therefore does not suffer from the crushing effect which the 1s 4d rupee has on the coffee and tea grower. Over 1,000 acres in all have been opened in cardamoms up to date. Mysore seed has been tried, not all ways with success. I do not know whether it is unusual, but I notice that the short plump Mysore or Ceylon cardamom, and also the long Malabar fruit, are picked from indigenous plants growing side by side, and, I think, off the same plants, but this latter I cannot be sure of as yet. The partial clearing necessary for cardamoms costs us 15 to 18 rupees per acre.

TEA,

2½ years old, covers the ground well. I am not making tea from the few acres which I planted, more to see how it grew and to encourage others than for any other purpose, so the bushes, though they have been cut down, are some eight feet high or so. A planting at stake, on another property, is, I am told, coming on well, and from the great rapidity with which my plants grow and spread I can quite believe that the Annamalai tea-planter will be among the survivals, if quality can be obtained.

CINCHONA

I am very pleased with. Last year I planted C. Ledgeriana, believing that we had just the right conditions to suit this valuable but delicate variety. The plants were very small, too small in fact to put out at all until August and September, 1900, but there are many 15 ins. high now, and their healthy appearance is all that can be desired. A large amount of this variety, from the best Java seed, will be planted this year, the very free, deep soil, with its splendid drainage, appearing to suit to perfection. Some neighbours are giving Succirubra and Hybrid a trial, thinking that Cinchonidine and quantity of bark will yet pay. Personally, if, as seems probable, we eventually settle down to a penny unit, I pin my faith to good class Ledger, as, if it grows as well as it now promises, we shall have no difficulty in holding our own against the Java average of 5¼ per cent S Q. or even the Java Government average of 7·16 per cent. With cinchona also it is very marked how thoroughly suitable conditions tell on the quality of the bark and send up the analysis.

PEPPER,

according to my experience, does not do well, possibly, as has been suggested, because the elevation 3,600', is rather too great, and our evergreen forest climate is not forcing enough.

HEVEA BRAZILIENSIS

is making what I am told is excellent growth, but I know little about Para. I should have thought the elevation too great. Work on the ghaut road has gone on steadily, and we hope this will be completed to the nearer estates in the course of the year. Labour has presented no greater difficulty than in other districts, and the jungle tribe of Kaders has quite taken to long periods of steady work on the estates. Health generally has been excellent. On the whole, in spite of the general depression among planters, I feel sure that the youngest planting district will be by no means last in the race.—*Madras Mail*, Feb. 7.

COFFEE PRODUCTION IN MADAGASCAR.

Recent reports by the French Bureau of Foregn ommerce contains statistics relating to the tea and coffee industry of the Protectorates of Annam and Madagascar. The production of coffee in the eastern coast of Madagasoar isexpected to develop soon into important proportions. In the past it has been insignificant, but the French Government has published figures showing that in a short time an estimated crop of 713,000 kilogrammes (1,568,000 pounds) may be looked for. The receipts of coffee from all the French colonies in 1889 were only 963,000 kilogrammes 2,118,000 pounds.—From *Journal of the Society of Arts*, Dec, 28, 1900.

TEA IN FRANCE.

CEYLON AND INDIAN VERSUS ANNAM.

A recent report by the French Bureau of Foreign Commerce contains statistics relating to the tea industry of the Protectorate of Annam. The year 1894 was the first in which tea from one of her colonies was offered in France. In that year 7,500 lb were received from Annam. In 1896 the receipts increased to 10,296 lb; in 1897 to 13 000 lb. In 1898 the imports of tea from Annam into France were 42,262 lb. The figures for 1899 are not yet available, but it is estimated that the exports will not be less than 54,000 lbs. Up to 1892 Annam tea was cultivated only for use among the natives, and the proposition to cultivate it for European consumption seemed a chimera. But the consumption of tea in France was increasing very rapidly. From 1,447,635 lbs, consumed in 1892, the quantity rose to 1,794,832 lbs in 1898, and increased by nearly another 100,000 lb in 1899. The supply was almost entirely from China an Ceylon. The tea from Annam is said to equal the finest article produced in China. It is in very general use in the French army in Annam, and it is only believed to be a question of time when it will meet the entire demand in France. The production is daily increasing. The old colonists are going into the business of growing tea, finding it more profitable than any other occupation. The above statements, culled from a French report, are not very favourable as to the prospects of Indian and Ceylon tea in France. They must, however, be accepted with a considerable "pinch of salt," as it is highly improbable that Annam tea will ever be able to compete with the British-grown product. It is hoped that the standard of tea will be raised in France and that the Ceylon staple will be supplied to the army. Strenuous efforts are being put forward to achieve these most desirable results.—*I. P. G.* Jan. 19.

OVER-SUPPLY—LOW PRICES.

[To the Editor, *Home and Colonial Mail.*]

SIR,—There is no doubt that the advance of 2d per lb. in the duty was imposed in a most inopportune year for the producers of tea. Even though the duty had not been increased, we should doubtless have had a fall in values due to over-supply, but this fall has been aggravated by curtailment of demand, owing to fictitious or forced increase in the retail or consuming price of the article. The planter is thus smitten on both cheeks. What is the remedy? There is only one: reduction of supplies.

There are various schemes suggested, having this object in view, some more absurd than others. One goes so far as to propose burning or destroying a portion of the tea. To these various suggestions let us add one more. It is this: that every producer should agree, under penalty, to allow 10 per cent of the total area of his estate to remain unpruned and untouched for one year. The area lying fallow would unquestionably be improved by the year's rest, and if the scheme were workable and succeeded, then that particular 10 per cent of acreage could be cultivated the next year, and another 10 per cent could then be given a well-earned rest. The effect should be about 10 per cent less tea, which might mean an advance in London in price of perhaps 1d or 2d per lb., or say, roughly, 20 per cent.

We like to make practical suggestions, but as we think insurmountable difficulties might crop up which would make this suggestion impracticable, we desire to subscribe ourselves.—Yours truly,

BROKERS.

London, January 3, 1091.

PLANTING NOTES.

GOOD PRICES: A HINT TO THE TEA FOLK.

We are interested to learn from Mr. Geo. Christie that the estate, Kanapediwatte, of which he has charge, sold 2,947 lb. cinchona bark in November last, and that it fetched 47½ cents per lb. in Colombo. Better than Orange Pekoe?

ELEPHANTS IN N. SIAM.—Elephants have grown so scarce in northern Siam that a special law has just been passed for their preservation. Any person wrongfully killing an elephant is made liable to fine or imprisonment. Formal permission to catch an elephant must be obtained from the authorities, and one in five of those so caught will be the property of the Government.—*B. Gazette*, Nov. 21.

TREATMENT OF MOSQUITO BITES.—M. Manquat recommends, for the treatment of the bite of the mosquito usually met with in France, the employment of tincture of iodine, formol, or mentholised eau de Cologne. Applying the tincture of iodine on a brush causes the disappearance of the itching at the end of about ten to twenty minutes. Although the iodine acts much more quickly when it is applied at once, still it does not lose its efficacy when the papules are enveloped and inflammed. Using formal, five grammes are taken of a forty per cent solution, and mixed with ten grammes of ninety per cent alcohol and ten grammes of water. This is applied in a thin coat and renewed as it evaporates, care being taken to discontinue on the appearance of any canterising effect. This is said to act even more quickly than the iodine mentholised eau de Cologne, or mentholised alcohol of a four or five per cent solution, also soothes the itching.—*British and Colonial Druggist*, Jan. 25.

EXTRACTION OF RUBBER.—A novel process was described recently before the Society of Civil Engineers of France for the extraction of india-rubber from the tree. The bark and roots are cut up and soaked in dilute sulphuric acid. The effect of this is to decompose the woody portions without affecting the india-rubber. In this way a division is made between the valuable rubber and the rest of the bark and roots, and it is claimed that the rubber so produced is quite pure. It was stated by the author that 1 lb. of india-rubber could be produced by the process at a cost of about 2½d.—*Engineer.*—Two French chemists have discovered a process by which rubber may be obtained from Landolfia vine, which grows wild and luxuriantly in all parts of Africa. The process of tapping the Landolfia is impracticable, as the flow of rubber hardens too quickly. By the process of M. M. Arnand and Verneuil, the vine is crushed in hot water, by which means all the rubber which it contains is extracted. —*Queensland Agricultural Journal,*

Correspondence.

To the Editor.

TEA PROSPECTS AND OVER-PRODUCTION.

Dear Sir,—It is only natural that current rates for low-priced tea should cause producers in India and Ceylon some alarm, and, as many enquiries have reached me regarding the reason for, and probable duration of, the present state of things, I should be obliged if you could find space in your valuable paper for this letter which may interest some of your readers and, at the same time, be a reply to all my correspondents.

The usual London statistics being merely rough estimates based on a supposed average nett weight, I have obtained the official figures from the Board of Trade returns, and they show that notwithstanding the increase of 2d per lb in the Duty, the actual consumption of Indian tea in the United Kingdom during 1900 showed an increase of 4,006,105 lb and of Ceylon tea an increase of 7,332,063 lb or a total of 11,338,168 lb (whilst China tea shewed a decline of 4,106,895 lb) and the export also shows a moderate increase of 2,548,002 lb Indian and 1,631,026 lb Ceylon; so that London practically disposed of a total of 15½ millions out of the 21¼ millions increased shipments from India and Ceylon. These figures, in my opinion, should at once remove any serious cause of alarm; the expanding consumption of the article disclosed by the figures of the Board of Trade being an unanswerable argument as to the inherent soundness of the industry. The extremely high prices ruling for common tea during the latter part of 1898 and the commencement of 1899 induced most gardens to go in for making the maximum quantity at the minimum cost, and of the lowest quality. Helped by an abnormally favourable season and also, to some extent, by the aid of manure, the result has been an increased shipment from Ceylon to the United Kingdom during 1900 of 10,850 000 lb, and from India 10,397,000 lb totalling 21,247,000 lb, thus leaving a very distinct surplus over and above the increased consumption: and this surplus is made up entirely of common tea, which is demonstrated by the satisfactory rates ruling throughout the year for all teas with any pretensions to quality. The theory advanced by some that a large quantity of the tea exported from Ceylon and India this year is too common to be consumed readily may be dismissed; for in 1898, teas which today are difficult to realize at from 3d to 4d per lb were readily taken by the trade at from 6d to 7d; and were the position today the same as in 1898 the same rates would be obtainable. The position, however, is altered. Instead of a scarcity of common tea every market is glutted with it; and as the addition of 2d per lb to the English Duty has resulted in the practical abolition of all the retail canisters under 1s 4d—for which canister competition forces the trade to pay from 6d to 7d per lb. The consequence is that the best value offering at about that range finds a ready market, whereas anything distinctly inferior is almost entirely neglected, its chief outlet being for export.

The duration of present prices rests entirely with planters, and will continue as long as the policy of flooding the English market is persisted in, only more so. Many suggestions have been made to rectify the present state of things, the most remarkable being that 10 per cent of the land under cultivation should be abandoned. This does not, I imagine, come within the range of practical politics, nor, in my opinion, is it necessary. By combination in both Ceylon and India, in three months a totally different range of prices for common tea could be established. Are the Associations in Ceylon and India sufficiently strong to bring this about? An agreement universally to adopt fine plucking for the period stated would have an immediate effect, if it were known in London that it would be rigidly adhered to.

To deal, however, with the output of the increased area under cultivation (which, in both Ceylon and India is as yet not in bearing or only partially so) the further development of the markets in Colombo and Calcutta is essential. Not only should more teas of all descriptions be offered locally, but steps should be taken to make conditions for buyers in the Eastern markets as favourable as those in force in London. All teas offered in Colombo and Calcutta should be more carefully bulked on the estates and more carefully graded and packed even than those shipped to London. The object in selling locally is to develop a foreign trade, where uniformity of leaf, freedom from dust, and good packing are all points of the greatest importance. At present, while care is taken in the bulking and packing, &c., of teas destined for direct shipment to London, this care by many estates is considered unnecessary in teas intended for local sale. As a matter of fact it is more important that care should be exercised there; for in foreign markets we meet in competition China and Japan teas, which, as regards packing, freedom from dust, and uniformity of leaf, are immensely superior to Indian or Ceylon teas.

The chief aim of India and Ceylon should be to avoid sending to England more than she requires; for to do so means lowering the price of British-grown tea throughout the world. London is still the barometer of the world, as far as British-grown tea is concerned, with the exception of Australia; lower that barometer by oversupplying her market, and prices drop all round. Far wiser, in need, to sell a few millions cheap in Calcutta and Colombo and so encourage the development of a foreign trade than send to London a few millions over her visible requirements, which means reducing the price generally on an immense quantity of tea. There are many interests which tend to draw tea to London, but the price obtainable is not always one of them. If, however, the policy of flooding the ruling and most important market of the world is continued, no material alteration or improvement can be looked for until consumption again overtakes production. Apologising for trespassing at such length upon your space.—I remain, yours truly,

ARTHUR LAMPARD.

CACAO

POLLINATION AND 10 CWT PER ACRE.

Dear Sir,—Mr. Carruthers, among other things, I believe, is devoting his attention to pollination of cacao flowers, and I have ventured to collect a few ideas on the subject.

If only a tenth of the female flowers that annually appear on a cacao-tree set, 10cwt per acre would be common. But there are dangers

ahead, and in our endeavours to avoid Scylla it would be well at the same time to have a care of Charybdis.

Thus a tree bearing at the rate of 5 cwt per acre—and this is surely a low estimate in the event of successful pollination—should yield about 50 average-sized pods per annum. But this is reckoning 300 trees per acre.

It is not probable that the average Ceylon soil will stand the drain of 5 cwt per acre for very long, therefore systematic manuring is bound to be more or less generally adopted, sooner or later. Nor can it be expected, however much it may be hoped, that so delicate a plant, as the chocolate tree has proved itself to be, will absorb and continue healthfully to assimilate the concentrated nourishment of impoverished soil highly impregnated with stimulants. Moreover, the best artificial manure for cacao has yet to be named.

Ceylon planters have only to look about them to be fully assured of the fact that 20 to 25 years at a remunerative rate of yield, say 3 cwt. per acre, and a hundred trees for every hundredweight, should be the outside life-limit of the cacao-tree. It is useless to point to individual trees, whose locality is an open secret, whose age may be stated at 30 or 40 years, and whose fecundity is astonishing. The comparison fails (1) because the individual tree in question is not one of a number of others planted at say, 12 feet by 12 feet; (2) because cacao so planted will have been treated far more drastically than the solitary tree which bears so munificently; and (3) because, in the case of Forestero (to which these points more especially apply), there is not in the whole island a field of any useful extent planted up with only one particular variety. Such trees are altogether exceptional. So that every 20 to 25 years the estate will need to be renewed. For canker will help.

Now, the lower a tree, the cheaper the crop-gathering; therefore suckering will continue in vogue. But the tree having been heavily manured there will be an abundance of "suckers," and this means extra expense. But as the tree will achieve a great spread, this need not be taken into consideration, for then 300 trees per acre will become an impossibility. Probably 150 trees per acre would be nearer the mark.

In order to obtain 5 cwts. per acre from 150 trees, each tree will need to bear 100 pods, and there will probably be no decrease in the expense of manure. Being set further apart the trees are likely to live longer, however: and this is already a big step in the right direction.

To qualify this I am personally acquainted (and concerned) with fields of Forestero cacao whose trees have an average perimeter of 25 ft., and they are not yet at their maximum. Let me, therefore, suggest that their maximum spread will be 30 feet—a low estimate—say, therefore, 50 trees per acre. This indicates that in order to obtain 5 cwts. per acre, each and every tree must bear on an average of *300 pods per annum.*

But a tree with a perimeter of 25 ft. must of neccessity be some 15 ft. to 20 ft. in height, and probably much more. The *cost* of pollinating, an expensive process at best, now becomes something that may be felt. Picking will be dearer, for the trees will be very tall. Moreover, the cost of seed, and the planting of it is not excessive, so not much will be *saved* by having fewer trees per acre.

Trees planted at 25 ft, will find some difficulty at first in covering the ground; therefore weeding will become of more consideration than usual. In order to avoid this, the cacao might be planted at 12 ft. or 15 ft. and alternate trees cut out later. It is doubtful whether the crop for a year or two will make up for the trees so cut out. There might be two lean years.

Finally, cocoa will drop to 15s per cwt, through overproduction!

Now, the first answer to all this is that there already exist in the Island fields—few indeed!—which give, or recently gave, up to 8 cwt. per acre. But this does not dispose of what may be condemned as a *reductio ad absurdum.* for such fields are of the red variety of which planters are becoming more and more shy. Morever, any attempt at pollination in such fields would be justified only if the owner were willing and prepared to cut out and replant every 15 to 20 years. Under such circumstances (8 cwt. per acre) even the greediest planter would be inclined, I surmise, to leave well alone.

Manifestly, then, there is a point at which pollination, as fertile as I assume, and apart from the physical capacity of a tree to produce flowers which might set, must cease in order, paradoxically, to become beneficial. So that pollination is to be welcomed more in respect of that cacao which is not giving more than two or three cwt. per acre; otherwise the trees will become worn out in a very few years.

Some may say "What though they do become worn? The younger the trees, the larger the pods (the less, therefore, to the cwt.), and the older the trees the more liable they become to canker. Let us plant up afresh two to three years—(and with *grafted* cocoa it is hoped this will be possible)—before we cut out every 20 years, so long as we get our 10 cwt. per acre." Once recognise the fact that the life of a cacao tree as at present cultivated is as stated, and the answer is obvious.

But if it were possible to obtain eight to ten cwt. per acre without cutting down—if, by means of pollination, a sixth of the trees per acre of a virile and prolific variety of Forestero could be made to bear as well as a Criollo field at 300 trees per acre, can there be any choice as to which of the two methods is to be recommended?

But as there is no field in the island of only one variety of Forestero, so there is no field of Forastero in the Island which gives—I speak under correction—more than two to three cwt. per acre; and on the top of this comes pollination.

But is there any known jât of cacao—Criollo, Forestero or Calabacillo—which can be depended on for 300 pods per tree per acre per annum?

For purposes of argument I propose to halve this figure: 2½ to 3 cwt. per acre show a very decent profit. There are Forestero fields giving that now, and successful pollination should double and treble this yield.

And the second answer is that cacao, like everything else, is worth precisely what it will fetch in the market. *Verb sap.* P O D.

"SILK-WORM SEED" FROM CONSTANTINOPLE.

Colombo, Feb. 11.

DEAR SIR,—I send you herewith for inspection a sample-box of silk-worm "seed," reared in Constantinople, in which, the sender

says, "a large export trade is done, considerable quantities being sent to Kashmir and other parts of India." I should wish to know if you or any of your readers have any experience of the process of "rearing," and if it is done to any extent in this island. I have received also a pamphlet in Turkish explaining how the silk-worms are to be reared from the eggs or seed; but as the language is not familiar here, it will be useless to give extracts.—Yours faithfully,

M. L. M. ZAINU DEEN.

[For a concise account of what has hitherto been done in "silk" experiments in Ceylon, see page 129 of our review in last "Handbook and Directory." The Northern Province is expected to be best suited for the silk-worm and mulberry tree, being so dry. Major Gordon Reeves of Madulkele and Father Palla of the R. C. Mission, Galle, were amongst the most recent experimentalists, and they might be glad to have some of the "seed." We add the following information for the benefit of our correspondent :—

The eggs of the silkworm, called *graine* (seed) are hatched out by artificial heat at the period when the mulberry leaves are ready for the feeding of the larvæ. These eggs are very minute—about one hundred weighing a grain; and a vast number of hatched worms may at first be kept in a small space; but the rapid growth and voracions appetite of the caterpillars demand quickly increasing and ample space. Pieces of paper punctured with small holes are placed over the trays in which the hatching goes on; and the worms, immediately they burst their shells, creep through these openings to the light, and thereby scrape off any fragments of shell which, adhering to their skin, would kill them by construction. The rearing-house in which the worms are fed (Fr. *magnanerie*) must be a spacious, well-lighted, and well-ventilated apartment. in which scrupulous cleanliness and sweetness of air are essential, and in which the temperature may to a certain extent be under control. The worms are more hardy than is commonly supposed, and endure variations of temperature from 62° to 78° F without any injury; the higher temperature is very detrimental. The lower the temperature at which the worms are maintained the slower is their growth and development; but their health and vigour are increased, and the cocoon they spin is proportionately bigger. The worms increase in size with astonishing rapidity, and no less remarkable is their growing voracity. Certain races moult or cast their skin three times during their larval existence, but for the most part the silkworm moults four times —about the sixth, tenth, fifteenth, and twenty-third days after hatching. As these moulting periods approach, the worms lose their appetite and cease eating, and at each period of change they are left undisturbed and free from noise. The worms from 1 oz. of graine —numbering, say, 40,000—consume in their first stage about 6 lb. of picked leaf, in the second 18 lb., in the third 60 lb., in the fourth 180 lb., and in their final stage 1,098 lb.,—in all 1,362 lb., of mulberry leaf; but from that is to be deducted about 590 lb. of unconsumed fragments removed in the litter, giving of leaf really consumed 772 lb. An ounce of graine so treated may yield from 80 to 120 lb. of cocoons, 85 per cent. of which consists of the weight of chrysalides and 15 per cent. of pure cocoon.
—ED. *T.A.*]

KURUNEGALA, Feb. 18.—The weather is hot and dry. We had some most welcome rain on Saturday night—the showers were heavy and lasted some time. Sunday evening looked threatening, but no rain fell. The mornings are misty, prognosticating a sultry day.

PRODUCE AND PLANTING.

IMPORTANT TO MANUFACTURERS OF SUGAR MACHINERY. British Central Africa will soon occupy a prominent position as a sugar-producing country. In the rich, fertile district around the Lower Zambesi and the Shiré rivers the sugar industry already promises to become very important within the next few years. One company alone has 1,100 acres under cultivation at the present time, and shortly inteuds to bring in a further tract of 2,500 acres, while several other companies and private planters are either making preparations for planting sugar or have already started plantations. The land "according to reports recently to hand," is highly suited to the growth of sugar-cane, and there seems to be an ample supply of labour, while the sugar grown is said to be superior to that from Egypt. Sugar-cane growing is an industry, moreover, that gives a good return for a comparatively small outlay of capital, and, with the experience gained in Natal, the district round Chinde "should speedily become one of the great cane-sugar-producing centres of the world." A hope is expressed that British manufacturers of machinery and agricultural implements will not fail to grasp the opportunity which presents itself. As the country is staked out and divided up into plantations the demand for tools and implements will steadily increase, and as the canes grow mills for crushing and refining will become necessary.

RICE-CLEANING MACHINERY.—The British Commercial Agent in Russia has received an inquiry from Samarkand (Turkestan) asking for names of British firms supplying rice-cleaning machinery of newest type of construction, and, if possible, such as have received prizes and awards at the Paris Exhibition. The catalogues would probably be more serviceable if well illustrated, and it would he of advantage if the technical descriptions were in the Russian or German language. Further information may he obtained from Mr. Henry Cooke, British Commercial Agent, 88, Petrovski Bouleward, Moscow, to whom all communications should be addressed.

THE ZANZIBAR CLOVE TRADE.—The "1899" crop of Zanzibar cloves was the heaviest on record, and was 570,600 frazils, or 7,061,250 lb above that in the previous year; but whether this excessive outturn will be equalled in the future is a question which is beginning to exercise the minds of the trade generally. No reliable estimates of the total crops for 1900 have yet beeu published, and it is doubtful if the yield of cloves for the coming season will again be of similarly large dimensions. The grounds for entertaining this supposition are that circumstances in connection with the systematic cultivation of cloves in Zanzibar have considerably altered within the last few years, it being no longer carried on by compulsory slave labour as formerly, and time has not been afforded the planters to recover from the disastrous effects of the severe drought that existed during 1899-1900. Since the importation of slaves was prohibited, and the blacks were granted their freedom in 1897, the scarcity of labour in Zanzibar has been keenly felt. Prospects of a continued abundance of Zanzibar cloves are, therefore, not particularly cheerful, and as this condiment is in universal demand, any serious diminution in supplies would have an instantaneous effect in forcing prices up to a higher point. Speculators have already heen busy enough to send quotations in Mincing Lane up to 4¼d and 4½d, which is 1d per lb beyond what was paid on the spot in January last, and judging from the extensive purchases of Zanzibar cloves to arrive, made from time to time, it is reasonable to anticipate a further improvement in value as the season advances.—*Home and Colonial Mail*, Jan. 25.

OUR PEARL-OYSTER FISHERIES AND MR. SAVILLE-KENT.

Last mail brings us a letter from Mr. Saville-Kent in which he states that he sent in his application to the Colonial Office for the appointment to investigate our Pearl Oyster Fisheries, backed by a strong testimonial in his favour from Lord Avebury (Sir John Lubboek); but Mr. Saville-Kent feared he was too late, though he understood the steps to be taken with regard to our Fisheries had not been finally determined on. Mr. Saville-Kent adds:—

"I certainly feel confident that within three or four years, and with the assistance and support contributed by the local officials, very substantial headway might be made towards both the re-establishment of the present fisheries and the inauguration of new and, what would in all probability eventually prove to be, still more profitable ones. I have read up the pamphlets and reports bearing on the ease kindly forwarded me by Mr. Collett, and was previously in possession of those by Mr. Edgar Thurston and others. Their perusal has still further convinced me that, with the advantage of my previous experience, the difficulties to be contended with are by no means insuperable, and I have in fact already sketched out some of the earliest and most essential steps in my plan of campaign that I should propose to follow or suggest, should the work in any form be entrusted to me."

CAMPHOR INDUSTRY.

One of the chief events of the year has been the fruition of the Japanese Government scheme for the conservation of the camphor-indnstry, which we outlined in March last. As was inevitable, the monopoly which was created has entirely altered the conditions of the market, the speculative market to a great extent having been obliterated. The price was originally fixed at about 180s, c.i.f. in March, but since then values have considerably advanced, 190s spot being quoted in November and "pressed" at 205s. For fluctuations in prices the palm must be given to refiners of German camphor, as no fewer than fifteen alterations have been recorded in 1900. On the other hand, English refiners, who are not influenced by speculators to the same extent, only raised their prices when absolutely necessary, and during the twelve months there have only been four advances, the year opening at 2s and closing at 2s 4½d.—*Chemist and Druggist*, Dec. 29.

PHOSPHATE IN THE MALAY ARCHIPELAGO.

AN IMPORTANT DISCOVERY.

A discovery of considerable importance to India has been made in a remote island of the Malay Archipelago. To make the story plain, it is necessary to go back some years when a party of scientists were sailing the seas in the now famous vessel the "Challenger." Amongst the most distinguished of them was Sir John Murray who has recently been in India [spending a week in Ceylon first.—Ed *C.O.*] This gentleman had studied the question of the deposits of the deep-sea bottom, and when the "Challenger" was off Christmas Island a lovely place in mid-ocean to the South of Java, he found phosphate of great purity in the haul brought to the surface from the bottom by the deep-sea dredger. Now phosphate is an exceedingly valuable manure Treated with sulphuric acid it forms the super phosphate that is in demand for indigo cultivation. Sir John did not let the matter rest. Phosphate on the sea-floor might be valuable but it was not easy of access. It had been formed, he surmised, by the dropping to the bottom. through countless ages, of the remains of dead marine animals from the two geographical zones that here meet each other, the intermingling of water of different temperatures causing the mortality to be excessive; the fish from the waters of the north unable to stand the warmth of southern seas; those from the south similarly discomforted by the colder current. The island hard by might have had an analogous origin, so he examined it. It proved a veritable phosphate heap. Negotiations were commenced for its annexation. But years elapsed before this was affected. The British marine authorities indeed declared, at first. that the place was useless, and at one time mining operations narrowly escaped being undertaken under Dutch auspices. But at last the British flag floated over the possession, and a number of borings were made, the result fully confirming the sanguine expectations of the discoverer. A European chemist was brought out to superintend the the operations, and now large quantities of phosphate are being raised at a profit. The matter is of more than academic interest. Not only does it offer possibilities of supplying an indefinite amount of the dressing needful for the indigo fields, but the process of preparing the raw article for application means a demand for sulphuric acid which may not be without effect on the question of making the mining of the sulphurous copper ores of Western Bengal remunerative.—*Bombay Gazette*, Jan. 27.

TWO ISLANDS SET APART FOR CULTIVATION.

From the *Globe* of December 21st we learn that the United States Department of Agriculture has set aside the islands of Panay and Panitani in the Iolo Islands for the cultivation of India-rubber, as the American supply is failing. On the other hand reports from South America do not indicate any falling-off in rubber supplies from the back country of the Amazon aswell as the Andean Valleys.

NEW TEA MARKETS SUGGESTED.

EAST AFRICA AND FIJI.

There are two possible openings for establishing a trade in our medium teas that should not escape notice, the one in Mombassa, in East Africa, where not only are there many Indian emigrants among whose rations tea might well be included, and another in Fiji, the coolie trade to which is assuming increasing proportions. The rate of coolie pay in Mombassa is, we are informed, £1 per month, but the rations come up to an extra £2, while once out of his indentures the laborer nets a clean £5. It is not only among the imported labor that we may look for consumption but there is a steady influx of people from all parts, and our informant (a ship's officer) says that there is quite as marked a predilection for tea as for the home-grown coffee; the latter, however, owing to the cost of labor given

above, places it beyond the reach of the masses, while the use of the former is confined to the well-to-do. As for producing tea on any commercial scale with the wage rate ruling so high, that is out of the question, although the tea plant, grown as an experiment, has been successful enough. The development of East Africa is proceeding at as rapid a rate as Australia in 1850-51, so those first in the field ought to establish a firm business.

The tea trade with Fiji proper would be of a limited character; but as the coolie vessels subsequently go to the South Pacific ports to load for Europe, we have in these an as yet untouched market, while not far north there are thousands of labourers employed on the western terminus of the Nicaragua Canal in the Gulf of Panama. These small markets are bound to expand into large ones, offering better facilities for introducing a novelty than those already occupied by established rivals; not that we suggest any relaxation of efforts in Europe or America, but merely ask that places at present considered of minor importance should receive a fair share of attention.—*I. P. G.*, Feb. 9.

MEASURING RAINFALLS.

THE WORK OF 3,500 AMATEUR SCIENTISTS.

In every district, in every county, of the British Isles there are amateur scientists who take measurements of every fall of snow or shower of rain that occurs. This work is of immense interest, directly or indirectly, to all classes of the community. It is controlled by the Rainfall Organization. Yesterday Mr. Sowerby Wallis, who has made it his duty to receive the reports of these systematic observations and record them, gave an account of the work to an "Express" representative. "Forty years ago," he began, "my predecessor, Mr. Symons, commenced to study the rainfall of the British Isles, and found that there was very little knowledge on the subject, and even that was in a chaotic condition. In 1861 he wrote to all the observers, of whom he was aware, for records for the year 1860, with the result that 168 were sent in, and afterwards published. This gave a stimulus to observers, with the result that their number now exceed 3,500. The subject has been studied scientifically for the purposes of water supply, flood prevention, drainage, and river conservancy. The great majority of the observers are amateur scientists among doctors and clergymen. A large number, too, are maintained by the engineers of corporations and water companies." As a rule the work is done thoroughly. But that the observers are sometimes slack the following stories will show:—

"A Scotsman religiously kept his gauge out in his front garden during the daytime, but always took it in at night. His reason for this was that he was afraid it might be stolen. Another time a country parson, instead of sending in the record, posted the amount of the previous Sunday's collection."

HOW IT IS DONE.

"How is the rainfall measured? By a gauge costing from 12s 6d to £3 3s. For use in ordinary localities we recommend the Snowdon pattern. This consists of a copper or galvanised iron cylinder 15in. deep and 5in. in diameter, and containing a funnel and jar. Every week or month the jar is emptied and measured in a tube which is divided into 1-100ths of an inch. Snow, of course, has to be first melted. The gauge is placed on a level piece of ground at a distance from shrubs, trees, walls, and buildings. Readings are taken at 9 a.m." "Knowledge of rainfall," continued Mr. Wallis, "is of the greatest importance to the country." All water is rain-water, whether it be stored in tanks, water-butts, wells, springs, or rivers. When a town wants an increased water-supply the first thing to look for is a district where there is a heavy annual rainfall. That information we supply. Again, to agriculturists trustworthy statistics as to the annual rainfall in a country is of the utmost value. To river conservators figures showing the time it takes for a fall of rain over a given area to run off allow precautions against floods, such as the opening of locks and sluices, to be taken.

"In France the various parts of the great rivers are in telegraphic communication with one another. A heavy rainfall in the upper reaches, with its necessary consequences, is known at once lower down. With such a system on the Thames a great deal of destruction of property during storms would be avoided."

The work of the Rainfall Organisation is purely voluntary. The money derived from the sale of "British Rainfall," which is a general summary and epitome of the year's work, supplies the necessary funds. Mr. Wallis calculates that he spends at least six weeks every year in giving evidence before water committees and inquiries. His work is therefore recognised. At every Parliamentary Inquiry or Commission dealing with water questions, since the Duke of Richmond's famous Commission, Mr. Wallis and the late Mr. Symons have given evidence. Among the "observers" have been three Speakers of the House of Commons; the Dukes of Wellington, Westminster, and Argyll; Lord Addington, the late Mr. W H Smith, and many members of Parliament.—*Daily Express*, Jan. 10.

Our Botanic Gardens and Vegetation.—The special feature of February's issue of our *Tropical Agriculturist* is the Report by the accomplished scientist and botanist, Dr. Treub, head of the Buitenzorg Botanical Gardens, etc., in Java, on his visit to Ceylon and its Botanic Gardens over two years ago. It was published in Dutch and translated for us, the first portion by Mr. Advocate de Vos of Galle, and the rest by Mr. Donald Ferguson of Croydon. We regret the delay in giving the translation to the readers of the *T.A.*, but the concluding portion will appear in the March issue. Dr. Treub's observations are full of interest for their realistic freshness, and for a stranger he makes singularly few blunders. He accounts for Java, with only double the area, having eight times the population of Ceylon, by the dry if not thirsty climate over the larger portion of our island and the comparatively poor soil. He shows us how superior is the Javanese system of rice cultivation to that of the Sinhalese; he is delighted with the contrast between patanas and forest; does justice to the work of Thwaites and Trimen; as also to the energy of Ceylon planters, and generally writes a very appreciative notice, at least so far as Part I goes.

ADVENTURE WITH A LEOPARD.

The town of Nagercoil, in Travancore, was thrown into a state of wild excitement on Saturday morning last when it was reported that a leopard had found its way into the town and was hiding in a field near the Ooluganachery bridge. Large numbers of people collected at the spot, and, taking up positions at convenient distances, watched the movements of the brute, which had already attacked two men. Word having been sent to Vadasary, Mr. J Duncan Roberts and Mr. F A Cox hurried to the field, and while they were walking along the bund, without seeing any sign of the leopard, the bystanders called out to them that the brute was lurking in the grass. Turning round and walking a few paces, Mr. Cox's attention was arrested by a low snarl and on looking round he saw the brute spring on Mr. Roberts. A Shanar man who happened to be near rushed forward and diverted the attention of the animal on to himself, while one of the shikaris present fired and killed the brute. Mr. Roberts was badly mauled on both hands and suffers a great deal, but his injuries are believed and hoped to be not dangerous. The leopard is a fair-sized one and well-marked. The presence of mind and pluck shown by the Shanar, in saving the life of another at imminent risk to his own, are beyond praise.—*Madras Mail*, Feb. 14.

PRESERVATION OF THE WILD ANIMALS OF THE SOUDAN.

A CEYLON MAN TO THE FORE.

The Anglo Soudanese Government is forming a "Soudan Wild Animal Department," the object of which is to preserve the wild beasts of the Soudan, which between the time when the country was closed after the death of General Gordon and the capture of Khartoum had greatly increased. Indiscriminate slaughter in this, one of the few preserves left in the world, will be checked and regulated: and one of the branches of the department will be the supply to Zoological Gardens, Museums, &c., of live and dead specimens. The Soudan Government offered the post to Mr. Butler, who,

SINCE HE LEFT CEYLON AND TEA-PLANTING

four years ago, went on an expedition to the Andaman and Nicobar Islands, collecting birds for Mr. Walter Rothschild, of Tring. The work he found delightful, but it was very hard, and he resigned, taking up similar work in Perak. He then obtained under the Selangor Government the curatorship of the Straits Museum, and occupied this position when he received the offer from the Soudan Government. As may be well imagined the number of candidates suitable for such a post is limited, but the offer made to Mr. Butler required his quick decision. He wired assent, threw up his post in the Straits, and booked a passage by the Japanese ss. "Shinani Maru" for Port Said.

The action of the Anglo-Soudanese Government in taking steps to preserve the wild animals of the Soudan is most praiseworthy. It is only necessary to glance at the recent records of travel, not merely in Africa, but in other haunts of big game in various parts of the world, to see that valuable types are following the dodo and great auk into premature extinction. We need hardly dwell on the pity of this event. On the lowest ground it is extremely bad economy to use up in one great battue the sport of generations to come: on higher grounds it is a crime against posterity to deprive the science of the future of the very elements of practical investigation.—*Egyptian Gazette*, Jan. 28.

PRODUCE AND PLANTING.

THE MOVEMENT FOR RESTRICTING THE OUTPUT OF TEA.—The Calcutta correspondent of the *Times* cables under date January 22:—"The Indian Tea Association has addressed a circular letter to all proprietors and agents of estates with a view to limiting the output and consequently enhancing prices. Opinions are invited on the following proposals: The temporary abandonment of 10 per cent. of the area in full cultivation; the fixing of a date for closing manufacture in each district; generally finer plucking; and that a percentage of the crop consisting of low-grade teas be placed at the disposal of the Association, and utilised for encouraging the consumption of tea by the natives of India."

A WISE SUGGESTION.—Mr. Cuthbert Burgoyne, writing from Mount Ophir Vineyards, Victoria, puts in a plea for Imperial products which will specially commend itself to Indian and Colonial planters and producers, and he says: "At the beginning of a new century, when the civilised world is throbbing with the growth of the Empire, a plea for patriotism, even in trade, may not be misplaced. In the daily struggle for existence patriotism should not be lost sight of. If 'self' had dominated our feelings, the British Empire would not hold the powerful sway it does today. By giving preference to Colonial products, the grocer can assist in the augmentation of Britain's power without detriment to his own pocket. The British Empire produces from some corner of her vast dominions everything needful to mankind. Encourage, then, the tea-planters of India and Ceylon, the Colonial cane sugar mills, and push the cocoa of the British Colonies. New Zealand and Australian butters are quickly creeping into favour, and the full-bodied Australian wines have made their mark on French imports, and have come to stay. Spices are, to a very great extent, Colonial, and before many years the grocer will be able to place British dried fruits and coffees before his customer. Whatever is good for the British Colonist is good for the Empire. Let us always bear in mind that Greater Britain has her vineyards, her tea and sugar plantations, her rice fields, and her spice and orange groves, and, that in the present condition of the world, commercial interest are all powerful. Give preference to Colonial products, overrule the Englishman's prejudice against a new article, and the commerce of the Empire will be strengthened. As unity is strength, if we all work to one end, the result must be to the benefit of the empire." This idea might commend itself to the Chancellor of the Exchequer in connection with the tax on tea. While the Government does nothing in particular to foster British-grown produce, we fear that individual members of the great trading community throughout the British Empire cannot be expected to give such evidence of true patriotism as is indicated by the correspondent from Mount Ophir. The prosperity of the British Colonist or the Anglo-Indian weigh very little against the needs of the Imperial Exchequer.—*H. and C. Mail*, Jan. 25.

CACAO CULTIVATION.—We direct attention to a very suggestive letter on this subject by a practical cacao planter. It deserves the careful consideration of his brethren, whose criticism on any of the points raised will be welcomed. The problem submitted by "P.O.D.", as to what could be done with a limited number of trees per acre, specially treated as regards pollination, is eminently one adapted for experiment in the Peradeniya Gardens where the soil is, we suppose, no more than a fair average of our cacao districts.

THE KALUTARA COMPANY, LIMITED.

ACREAGE, 31ST DECEMBER, 1900.

Tea in bearing	518	acres
Tea in partial bearing ..	140	do
New Clearings	24	do
Arecaunts, Grass, Ravines, &c..	10	do
	692	do
Forest	392	do
Total	1,084	acres.

The Directors herewith present the accounts for the year ending 31st December, 1900.

The crop secured (including 4,653 lb. manufactured from purchased leaf) was 292,305 lb. tea against an estimate of 333,000 lb. The average net price realised was 31·32 cents per lb., against 36·89 cents per lb. obtained in 1899. The cost of the tea laid down in Colombo was 26·07 cents per lb. which included a sum of R5,691·75 spent on manuring.

In addition to a fall in price of 5·57 cents per lb. in common with most other low country estates, it will be observed that the crop was 40,695 lb. short of estimate. This most disappointing result was directly due to a local drought of unprecedented severity, experienced in the early months of the year, from the effects of which it took some time for tea bushes to recover. The reduction in amount of crop also added to the cost per lb. of securing it, which was in consequence distinctly high.

The new clearing, 24 acres in extent, planted during the past year is coming on satisfactorily. The growth of Para Rubber is promising and the Directors purpose extending its cultivation on the Company's estates.

After making ample provision for depreciation of building and machinery and paying the interest on the preference shares, there remains a balance at credit of Profit and Loss Account on the the year's working of R1,006·56, to which has to be added the balance of R5,921·79 brought forward from 1899, making in all a sum of R6,928·35 to the credit of Profit and Loss Account, which the Directors recommend be carried forward to the current season's account.

The capital expenditure for the past year amounted to R6,571·61, chiefly on the opening up of 24 acres in tea and for new lines.

For the year 1901 the estimate of crop from the Company's estates is 324,715 lb. Tea, as against an estimated expenditure of R73,693·69 on working and R3,448 on capital account. The latter expenditure being mainly on lines and the upkeep and supplying of the new clearing.

During the year under review Messrs. R S Templer and G H Alston resigned their seats on the Board on their departure for England, and Mr. H Cumberbatch and the Hon. Mr. W H Figg were appointed to fill the vacancies respectively.

In terms of the articles of Association Mr. H Cumberbatch now retires from the office of Director, but is eligible for re-election.

The appointment of an Auditor for the current year rests with the meeting.

THE GANGAWATTA ESTATES COMPANY OF CEYLON, (LTD.)

ACREAGE :

Tea in full bearing	335	acres.
Do partial bearing	2	do.
Do not in bearing	8	do.
Grass and Ravines	10	do.
Total	355	acres.

The Directors beg to submit their Fourth Annual Report and Statement of Accounts for the year ended December 31st, 1900.

The Tea crop amounted to 171,406 lb., against an estimate of 160,000 lb., which was disposed of as follows :—

Sold in Colombo	170,983 lb.	for R61,515·88
Sold on Estate	291 lb.	263·96
Carried forward to next year	132 lb.	—
	171,406 lb.	61,779·84, or an average per lb. of 36·07 cts. as compared with 40·16 cts. last year.

Cost of production was .. 25·65 cts.
including Manure .. 2·95 cts.
As compared with last year .. 27·06 cts.
including Manure .. 2·70 cts.

The season was an undoubtedly favourable one throughout the Tea districts, and is responsible in great measure for the heavy output of tea and the consequent overloading of markets and fall in price.

The area manured with artificial manure was 120 acres, which, with 60 acres manured last year, leaves five acres only untreated on the Gangawatta division of the property.

The working account shows a surplus of R18,001·01, an interim dividend of 3 per cent. has been already paid, and the Directors propose to pay a final one at the same rate making 6 per cent. for the year.

After this payment, interest on mortgage, commission to Superintendent and Secretaries, and Auditor's fees, a balance will remain of R3,190·06 subject to payment of Directors' fees, and it is proposed to carry this sum forward to next year.

A regrettable accident of the year was the loss of the newly-erected wire bridge in the floods of June; half cost of reconstructing this remains to be met in 1901.

Some expenditure will probably have to be incurred for providing the factory with fans. In times of pressure the withering accommodation is at present insufficient. No provision for this is made in the estimate.

Mr. Hayes reports that the property is in good order.

Crop estimate for 1901 is R170,000 lb. Expenditure is estimated at R44,706·50, which includes R425,725 for manure. This will be applied almost entirely to the Bitterne division.

In terms of the Articles of Association Mr. S. H. Hayes retires from the office of Director, and being eligible offers himself for re-election.

The appointment of an Auditor for the current year rests with the meeting.

AGRA OUVAH ESTATES COMPANY, LTD.

THE REPORT.

The Report was as follows :—

ACREAGE, 31st December, 1900.

Agra Ouvah.

Tea in full bearing ..	302	acres.
Tea not in bearing ..	20	,,
Grass and Jungle ..	9	,,
Total Estate ..	331	acres.

Fankerton.

Tea in full bearing ..	15	acres.
Timber clearing ..	10	,,
Grass, Patana and Scrub	18	,,
Total Estate ..	193	acres.
Grand Total ..	524	acres.

The Directors now have to present to the Shareholders the accounts for the past year.

The crop secured amounted to 374,274 lb. (being 84,274 lb. in excess of the estimate) as against 293,908 lb. in 1899.

The average nett price obtained for the tea was 45·02 cents per lb., against 48·90 cents per lb. in 1899. After deducting the cost of manufacturing outside leaf, the cost of laying down the Company's tea in Colombo

was 23·18 cents per lb. The gross income derived from manufacturing tea for other estates was R11,975·90.

Allowing for Depreciation on the same scale as last year, the amount at credit of Profit and Loss Account for the year's working is R79,989·34 equal to 21·30 per cent on the Capital of the Company, to which must be added a sum of R2,794·58 brought forward from last year, bringing up the total at credit of Profit and Loss Account to R82,783·92. An Interim Dividend of 7 per cent was paid on 30th July last, absorbing R26,250. The Directors now recommend the payment of a final dividend of 13 per cent, making 20 per cent for the year; that a sum of R5,000 be transferred to the Reserve Fund for the equalization of Dividends, and that the balance of R2,783·92 be carried forward to the current season's account.

The estimate for this year is 343,750 lb. Tea on an expenditure of R82,092·39, including a sum of R6,220 for manuring.

During the year under review Messrs. Alston and Polson resigned their seats on leaving the Island, and their places were taken by Hon. Mr. W H Figg and the late Mr. A E Wright, at whose loss the Directors desire to record their deep regret. Mr. Jas. Forbes was appointed to fill the vacancy thus caused on the Board.

In terms of the Articles of Association the Hon. Mr. W H Figg retires by rotation from the office of Director, but is eligible for re-election.

The appointment of an Auditor will rest with the Meeting.—By order of the Directors,

WHITTALL & Co., Agents and Secretaries.

Colombo, 25th January, 1901.

CEYLON MINING AND THE GEOLOGICAL SURVEY.

We omitted the other day to refer to the promised Geological Survey of Ceylon as an indispensable preliminary to the development of the mining industry of the Colony. When this Survey is completed, the Government will be much better able to revise and formulate definite regulations. —In this connection we may refer to the discussion following on the reading of a Paper on "Metalliferous Mining in India" by Dr. Evans (ex-State Geologist and Chief Inspector of Mines in Mysore) before the Society of Arts. We quote as follows :--
