Mr. ALEXANDER ROGERS writes :—At the conclusion of the discussion on Dr Evans' paper yesterday I said that I had intended to lead the discussion in a new direction, but that I refrained from doing so because the lateness of the hour would not permit of my expatiating properly on the subject. I now write to explain what my subject was, and to call attention to the subject of the mining regulations issued by the Government of India, which appear to me admirably calculated to crush all mining enterprise, instead of encouraging people to develop India's great mineral resources, as they should do. This is specially the case in the part of Central India which has not been mapped in the Geological Survey map of the country, as it is here particularly that there is the largest field open for research. It is all more or less under the charge or administration of political agents, who, as a rule, are military officers or men whose studies have not led them to inquire into such subjects. The greater, therefore, is the necessity for encouraging the efforts of outsiders to ascertain and develop the resources which at present are lying dormant for want of exploitation. I propose now to give you an instance, which I can personally vouch for, of the method in which the supposed intention of the Government of India to open out the country is acted up to locally. There are two villages on the outskirts of a low range of hills in the Rava Kanta political agency to the north-east of Baroda, which contain extensive deposits of the finest iron. Having discovered those valuable deposits, which are particularly rich in the villages mentioned above, I applied for a prospecting licence in them with a view to temporarily keep other prospectors out of the field, and suggested that a small sum of 50 rupees should be paid in each village. I received an answer that I had not complied with the rules of the Government of India by fixing on the exact spot where operations were to be carried out. I could not have done this without the advice of a mining expert. It was then suggested that the difficulty could be met by taking licences for the whole area of the two villages, which had never been surveyed, at the rate of 4 annas an acre. The estimated area came to 1,800 acres, so that the amount demanded was 450 rupees, in addition to 100 as a deposit on each licence, or a total of 650, which would only have protected me for a single year. I wrote to expostulate with the Supreme Government, and was finally offered by the Government of Bombay licences at 1 anna, in place of 4 annas an acre; that is, for 350 instead of 650. This has been finally declined, and I only bring it forward in order to show the penny-wise-and-pound-foolish policy that is being pursued, a policy which appears to me well calculated to stop all mining enterprise. Prospecting or exploration licences of the protective character asked for should, I think, be granted gratis, some kind of security only being required in order to provide against wilful injury to any property having an appreciable money value on the part of prospectors or explorers. I will not go further at present to inquire into the condition for mining licenses offered by the rules, but would suggest that such mining firms as J. Taylor and Sons should be consulted on the subject, especially with regard to such particulars as that no two shafts should be sunk within a certain distance of each other.

Dr. EVANS :—I cannot concur in Mr. Rogers's censure of the Indian mining regulations. They may not be perfect but compare not unfavourably with those of other countries. If any one interested in mining believes a particular region to possess mineral wealth, he can take out an exploring licence at a cost, which varies in different parts of India, but never exceeds ten rupees. This gives him, it is true, no definite rights, but it is expressly laid down that in considering rival claims for mining concessions, "due regard will be had to operations conducted under cover of an exploring licence." If a valuable deposit is found, but the limit of its occurrence cannot at once be readily determined, a prospecting licence may be taken out over a comparatively larger tract till a proper survey can be made. When this is completed, the licensee is entitled to a formal mining lease of the block he ultimately decides to select. In most other mining countries not only is the amount of mining land which the prospector can take up much less, but he can acquire no rights till he has actually "pegged out" the boundaries of this small area. Mr. Rogers would have been far worse off in Australia, for instance, for there he would have had no means of safeguarding his rights while waiting for the arrival of his mining expert. I cannot regard a penny an acre, amounting altogether to £7 10s., as an exorbitant charge for obtaining preferential rights over nearly three square miles for a whole year. The R100 £16 13s. 4d) is only in the nature of a deposit.

A LABORATORY IN COURSE OF CONSTRUCTION.—"At Hakgala, we have just learnt," a Nuwara Eliya correspondent writes to us, "that a laboratory is being built at the Gardens with a special view to Research work being carried on *there*, as well as at Peradeniya, by Professors who come out to Ceylon for that purpose. Rooms are also to be put up adjoining the laboratory for the scientists to stay in. So far only the timber is being felled ready for the building, but they hope to have the work in hand shortly."

PLANTING IN THE STRAITS.

EXPERIMENTAL PLANTATIONS:—RUBBER, GUTTA, SUGAR, COCONUTS, &c.

REPORT BY SUPERINTENDENT OF EXPERIMENTAL PLANTATIONS.

SIR,—I have the honour to submit a Report of my visit to Penang, Province Wellesley and Perak.

Acting on instructions received from the Acting Resident-General, W. H. Treacher, Esq., C.M.G., I left Kuala Lumpur on 25th October with the object of visiting the Botanic Gardens in Penang and the estates of Perak and Province Wellesley, with a view of obtaining a knowledge of the country and the requirements of the planters, and, at the same time, selecting a suitable place as head-quarters for the Experimental Plantations which Government are about to establish.

In Penang I met Mr. Curtis, the Superintendent of the Botanical Gardens, and with him visited he Gardens, where rubber-tapping was in progress. Although the trees here are not growing under the conditions generally recommended for Hevea braziliensis (Para-rubber)—being planted on a dry, sandy bank—it is interesting to note that the returns are very favourable; the average annual yield for the last three years amounting to rather more than 1 lb. of dried rubber. It appears, therefore, that not only does Hevea thrive under varied conditions, but that it gives a fair return, which statement does not apply to Ficus elastica, the "Gutta rambong" of commerce.

I journeyed to Kuala Kangsa, and, accompanied by Mr. Derry, inspected the Para trees recently tapped by him, and other economic plants growing in the Government grounds. The average yield per tree was 1½lb. of dry rubber, the trees ranging from six to thirteen years of age. As this Officer points out, "the tappings were not exhaustive," and it is probable that more might have been extracted without impairing the health of the trees. What this amount is, has yet to be determined, neither Mr. Curtis nor Mr. Derry having attempted to decide the question.

Kuala Kangsa having been suggested as a suitable place for head-quarters, I made the visit here a special feature of my tour. After duly considering the matter, however, I must say that I fail to see that this district offers any special advantages over other places I have visited. I am of opinion that Kuala Lumpur, or its immediate neighbourhood, would be more suitable, seeing that it is much more central.

From Kuala Kangsar I proceeded to Sungei Siput, and, after visiting the Kamuning Estate, went on to Ipoh, where I had the benefit of an interview with the Acting British Resident, Colonel Walker, C.M.G., who advised me to go to Batu Gajah to see the estates in the vicinity and the Government Plantations at Parit. This I accordingly did, and, accompanied by Mr. Cecil Wray, I also drove out to see the large rambong and Para trees.

In the limestone districts of Kinta rambong grows very luxuriantly; but, so far as I am aware, it does not occur naturally either in the marshy districts or along the coast.

On returning to Ipoh I had a further interview with Colonel Walker, and, acting on his advice, I retraced my steps to Taiping, with the object of visiting the Krian district and the Province Wellesley sugar estates. I might here remark that it is the opinion of Mr. Turner, the Manager of Caledonia Estate, that sugar might be successfully cultivated in some parts of the interior. This is somewhat important, in view of the fact that beet-root sugar cultivation is on the decline in Europe.

From Prye I proceeded to Teluk Anson *via* Penang. Here Mr. Brewster kindly enabled me to visit the coconut estates on the Perak river and the rubber plantations at Setiawin, by placing the Government launch at my disposal.

At Setiawin there are a number of fine specimens of Hevea and Ficus, which would be suitable for experimental work.

In reference to Ficus elastica, I would like to point out that it has been proved in Bengal and elsewhere that "although it grows with undiminished rapidity and luxuriance in districts remote from the hills . . . it fails to produce caoutchoue." Dr. Morris also says that, in spite of the abundance of the tree under cultivation in the tropics of both the Old and the New World, it has nowhere proved so valuable for the production of rubber as in the mountainous parts of Assam.

It seems, therefore, that there is a possibility of this tree failing to come up to the expectations of the planters of this country, and I would advise Government to allow me to proceed to Setiawin, to experiment on these trees with a view to obtaining reliable data concerning their yield. It would be necessary to rent a sufficient number of Ficus from the Penghulu. The Para trees are Government property.

STANLEY ARDEN,
Superintendent of Experimental Plantations.

BIG TEA-GROWING SYNDICAE IN CAROLINA.

A syndicate has purchased 4,000 acres of land 15 miles from Charleston, South Carolina, United States of America, where a tea farm will be started. Unlimited capital is behind the venture and the syndicate will deliver at least 300,000 lb of tea for the American markets annually after the area is in bearing. It is evident that Americans are beginning to look upon tea as a possible industry.—*Indian Planters' Gazette*, Feb. 16.

THE USE OF SORGHUMS.—The use of the sorghums as forage plants is rapidly increasing in all countries which are semi-arid or subject to frequent long summer droughts. As the use of the plant increases there is an increasing desire to use it as pasture, but there is a reluctance to do so from the fact that there has sometimes been a loss of stock fed upon the growing plant which could not be accounted for upon the theory that death was caused by ordinary bloat. While these cases have been rare, yet they have occurred, and the cause is not yet known. The Nebraska Experiment Station has been thorough in its investigations, but so far has learned nothing. Samples of sorghum which had killed a cow within a few minutes after eating it disclosed no trace of any poisonous substance when analysed a few days later. The station authorities are forced to conclude that sorghum sometimes, when growing or freshly cut, contains poison which soon disappears in the process of curing, so that by the time the samples reach the laboratory and are analysed they are harmless. There is at any rate no danger in feeding cured sorghum, and a great deal of sorghum is pastured with no injurious results, and yet the fact that deaths, not from bloat, have sometimes occured from its use makes it an undesirable pasture crop until we know more about it. It is suggested by the station authorities that in cases where poisonous effects followed its use the plant itself was probably unhealthy and yellow, but there are not sufficient data on that point to justify a very strong opinion.—*Weekly Chronicle.*

PLUMBAGO: CEYLON'S ONLY MINERAL OF COMMERCIAL IPORTANCE.

We learn with much regret that the Morgans Crucible Company—represented here by Mr. R. C. Fielding—have decided, after much consideration, to give up mining for plumbago in Ceylon, since neither the laws nor the conditions seem to them to offer any inducement for the investment of capital in the industry. This would be a matter demanding the serious attention of Government, were it not for the undeniable fact that native capitalists seem to prosper and to multiply as miners, under the same laws and conditions as are deemed so inimical by the great Battersea house, so long identified with the purchase and utilisation of Ceylon plumbago. Have we not here another illustration of the fact that there are certain trades and industries in this tropical island in which Europeans are unable to compete with the natives? It used to be an axiom in the Fort, during the "seventies" and "eighties," that no European merchant could successfully compete with the Chetties in the importation and sale of rice. The most notable attempt to develop a rice trade was by C. Shand & Co. who had, for several years, a special Agent (as brewed a Scot as ever did business) stationed at Chittagong to buy rice at first hand, and ship it to Colombo; but after a time, the agency was not found to be profitable and had to be abandoned. The spell has been broken within the past few years by the advent of Calcutta experts in the trade, and here we may speak of an exception to the rule of the previous decade. But again, in regard to "gemming" and Mining for Gems, Europeans have on several occasions entered the field, operating through Syndicates and Limited Companies; but so far without success. And now it would appear as if Plumbago mining were to be added to the failures; for, certainly, no Company or Association in the world could have entered the local field with a greater backing of capital, authority and experience of the mineral sought for, than that represented by Mr. Fielding. At the same time it cannot be forgotten that our plumbago industry has been one of considerable and growing importance for the past fifty, sixty and well-nigh seventy years, though the mining was confined entirely to native hands. So far back as 1836, the export of plumbago was 12,644 cwt.; in 1846 (with many fluctuations in the interval, down to 423 cwt. in 1839) it was 25,037 cwt; in 1857 (again with extraordinary fluctuations between) it stood at 33,497 cwt.: in 1869 there was an enormous increase to 226,131 cwt. which was only exceeded in 1881-2-3- when 262,714 cwt. was reached in the last-mentioned year. Since then, the average annual export for the five years ending with 1888 was 216,472 cwt., rising in the quinquennial period ending with 1893 to 408 418 cwt.; while for the next four years the Export was very steady at between 335,000 and 357,000 cwt. Then in 1898 came a rise to 473,000 cwt. and in 1899 to the exceptional maximum of 616,000 cwt.—falling last year to 383,000 cwt. Now, until about five or six years ago, when the late Mr. C. Tottenham—with the remarkable prescience for which he was distinguished—interested himself in plumbago mining and finally got out Captain Tregay, as a practical Cornish Mining Engineer, to develop the mine on his Monerakande property,—it cannot be said that Europeans took any practical share or much interest in the industry. We have, therefore, a purely native plumbago mining industry which has built up an export of over 400,000 cwt. (it was 427,030 cwt. in 1892) with practically no extraneous help and which may, therefore, be supposed to be equal to the present trade, if not the actual requirements of the European and American markets. All this must be taken into account in dealing with the question as it now stands, as well as the fact of the withdrawal of the great Battersea Company after little more than three years' mining experience.

On the other hand, no civilized, progressive Government can content itself with the actual results we have shown, without taking into account the means by which they were produced. Until of late years, the working of Plumbago Mines in Ceylon was a disgrace to the British Government. There was no inspection, or care for the manner in which the lives of the labourers were endangered, and, if all accounts were true, no reports or enquiries were made in reference to numerous casualties. Even now that we have Inspectors, we have statements reaching us that many of the employees in the pits are little better than slaves, are badly treated and badly paid, and are allowed or encouraged to become demoralised by constant arrack-drinking—an illicit trade (not in the sense of cheating the Government, but of breaking the law) being developed round nearly every large mine or group of plumbago pits. Then again, it is alleged that a great deal of plumbago is illegally dug, and that bribery and corruption prevail to a large extent in certain native districts in connection with the mining. Of course, while failures of Europeans to make plumbago or gem mining (or even a rice trade) profitable, are notorious, one scarcely ever hears of the many native pioneers or capitalists who may have gone under, and whose non-success may possibly be due to causes which ought to be removed by a wise Government. And now we may consider the list of "obstacles," put forward by our evening contemporary, encountered by a European Plumbago-mining Company as doubtless experienced by Mr. Fielding and his principals. These are:—

(1) No owners of lands (whether natives of Europeans) that have ever been transferred from the Crown have any title to the minerals on them, according to the position now taken up by the Government.

(2) A good title to native-owned land, whether originally transferred from the Crown, or not, is practically impossible to find.

(3) The present mining rules do not offer a fair inducement to prospect and mine Crown lands.

(4) The delays in granting prospecting licenses, even after payment of the large deposit (R1,000) demanded by Government, forms a separate and most serious obstacle.

Practically therefore, the opening up of mines is barred in all directions under existing circumstances in Ceylon.

In contrast with these "obstacles" we are told of the much more favourable terms and conditions which prevail in India.* One great difference—and the difficulty which lies at the foundation of most of the "obstacles" above specified—is the absence of a "cadastral survey" in Ceyloh Good titles cannot be got to much "plumbago" land, because the Crown is not as yet in a po-

* The Indian Mining Law is generally condemned by the Indian and English trade papers.

sition to say, definitively, to whom the land belongs. Natives, probably, dig with impunity in many cases, on lands to which they have neither right nor valid title. A cadastral survey is now in progress and when completed—or further advanced—all this could be rectified. But many years will be required before this is accomplished! —unless indeed the Governor gives orders to concentrate and strengthen the survey in the "plumbago" districts as the most pressing claim on official attention.

But apart from this question of survey, and in view of what we have said as to the mode in which Native Mines in many cases are carried on, and still more in view of the great difference between the Mining Laws and conditions prevailing in India and Ceylon, there is a case, in our opinion, for immediate Enquiry and Report. A Commission ought to be appointed, before the European gentlemen who have acquired so much unfortunate experience, leave the Island. Their evidence as well as that of leading native mine owners and managers, ought to be recorded, and could not fail to be valuable to the Government as well as to the public; and we sincerely trust His Excellency the Governor will take advantage of the opportunity now presented, to arrive at a right conclusion in respect of the working of the local Industry in Plumbago Mining.

Finally, we have to notice a letter on our sixth page which may be regarded as, in some sense, a warning to the Ceylon Government. But so far as substitutes for "plumbago" (as also for "rubber") go, we do not think much need be feared. The risk of discoveries of the mineral in other lands must, of course, be faced; but so long as Ceylon can give from 15,000 to 20,000 tons of its mineral to the world at a fair price, we think it should hold its own. Curiously enough last mail brought us a letter from the great American business house of "Joseph Dixon Crucible Co," of Jersey City, in which while anxious to get information on certain points—the request arriving in the nick of time to have the answer embodied in our "Handbook and Directory,"—they say not a word about "substitutes" or new "finds" of plumbago. It cannot be forgotten that the United States is our largest customer for plumbago, its demand far exceeding that for the United Kingdom. We are anxious to compile a reliable list of all the principal Plumbago Mines at present open in the island and trust to have a due response from the owners and managers to whom "forms" have been issued. Meantime, we repeat, the time is ripe for an Official Enquiry by Commission into the working of Ceylon Plumbago Mines, into the nature and effect of local Mining Laws as compared with those of India and as to how "prospecting licenses" can be more freely and promptly granted.

CEYLON PLUMBAGO CRISIS.

IMPORTANT LETTER FROM THE MANAGING DIRECTOR OF THE MORGAN CRUCIBLE COMPANY.

SUBSTITUTE ALREADY FOUND IN AMERICA.—THREATENED REVOLUTION OF THE TRADE.

SIR,—I have read your* articles on Ceylon's mining laws and mineral wealth with great interest, and feel that you have rendered a great public service in calling attention to this subject, which is of such vital importance to Ceylon I consider, Sir, that such serious economic questions should be discussed in an absolutely calm and philosophic manner and free from anything approaching personality. I do not, therefore, endorse your strong strictures on local authorities, as I believe that the official apathy and opposition is due, not so much to any wish to discourage the industry, as to an entire want of appreciation of the risks and cost of prospecting and mining operations, which is, perhaps natural in a Colony whose principal industry is, planting.

It is obvious to anyone that in clearing jungle and growing tea, for example, the planter must spend his capital, and the approximate cost per acre can easily be calculated—what he does is easily recognised. The work of the prospector too frequently leaves nothing to show for itself, and the mining laws now in force in the island are evidence that it is neither understood nor appreciated by Government.

It is well-known that more gold is put into the ground than ever comes out of it as the rare reward of the successful prospector. What is difficult to make clear is the cost of even superficial prospecting in a country like Ceylon, where heat, jungle-fever, etc., are serious factors. Even if, at last, some indications of that most "chancy" mineral, plumbago, are found, expense on a far larger scale must be incurred to prove, in nine cases out of ten, that it is one that will not pay to mine. The Government have dealt with the subject more as if they had well-defined and accurately-located coal measures which they wished opened up by private capital than jungle land in which, possibly, one acre in ten thousand may contain some deposit of plumbago that would pay to mine.

In your first article and at the end of your fourth you allude to the fact that users of plumbago may be forced to find some cheaper substitute. On this point, perhaps, I can give you a little information. In a great measure this is a "*fait accompli*" in that they are learning to do without *Ceylon* plumbago. A great many trades are Ceylon's customers for plumbago. One of her best is the American manufacture of crucible steel. [The Sheffield industry has never used plumbago crucibles for this purpose.] I am well within the mark in putting down this customer for 3,000 tons a year. Just before leaving England I received a letter from America, from one who is in a position to know accurately the course of trade there, telling me that recent enormous prices had set the biggest people to work to do without plumbago, and that the result was a complete success and would revolutionise American consumption of plumbago. Another large customer of Ceylon is manufactured stove polish—a customer extremely useful as it takes the inevitably produced and otherwise unmarketable common dust.

Just before leaving England, again, I saw, for the first time, Chinese plumbago of a new character, and was informed that 1,000 tons of this were imported into the United States last year, and tests show that it will be equally appreciated in England.

The enormous rise in plumbago prices in 1899-1900 has been regarded in the light of a blessing to Ceylon, and as a subject for congratulation by Government, native pit-owners, and owners of estates. But if more were known of the course of trade hitherto dependent on Ceylon

* A local daily paper.

plumbago, it would have filled them with consternation instead of rejoicing. It was a tidal wave which will leave ineffaceable marks in the form of *permanently diminished demand.* In the twentieth century the price of a commodity cannot be trebled in twelve months with impunity and without ensuring that the ingenuity of man will devise a means of defence against a recurrence. The best friend of the Ceylon plumbago industry at the present moment is he who can do anything to assist in *reducing prices.* That the Government have not hitherto realised this, and have failed to appreciate that the interests of Government and plumbago consumers are identical, is, I consider, Sir, a subject of serious regret. The dry logic of facts, in the form of diminished exports of Ceylon plumbago, will, however, inevitably prove it in time.—I am, &c.,

BASIL E. PETO,
(Morgan Crucible Company, Limited, London.)
Colombo, February 11th.

RUBBER AND GUTTA-PERCHA.

East Africa.—An interesting discovery has recently been made that the fruit of a tree which grows principally at Dunga will on being tapped with a knife produce a white fluid, which when placed in boiling water coagulates into a substance closely resembling gutta-percha; this in the process of cooling becomes hard, but can in its previous soft state be moulded into any required shape. The fruit somewhat resembles a peach in shape, but is of the size of a small melon. It was intended that samples of this product should be taken to London, and doubtless by this time expert opinion has decided whether it is actually gutta-percha or not. It is not improbable that it will prove to be an inferior order of that article. Should it be found to be worth anything, however, a large source of revenue may be derived from it, particularly if, as is quite likely to be the case, it is discovered in the sister island and upon the mainland.—*Central African Times.*

WYNAAD PLANTING NOTES.

WYNAAD, Feb. 13—The coffee spike is so well developed upon bushes which yielded only a light crop recently that the recent showery weather, if succeeded by more wet within a reasonable time, will open and set an excellent blossom. A considerable amount of pruning has already been accomplished, but this work will prove more costly and tedious than in 1900, as the quantity of old wood, from the heavy crops borne by estates, is necessarily larger than in the preceding season.

A weeding on weedy estates, if carefully accomplished after the termination of coffee crop work, is a judicious means of keeping down expenditure in weeding during the May and June ensuing, as the weeds do not, in such instances, require further attention till July; and this leaves labour available in the two earlier months for burning borer stumps, handling, and supply pitting. A hot weather weeding, (on weedy estates,) if undertaken in February-March, can be finished for R2 per acre, especially where much local labour is to the fore for the operation. Where funds are available, in addition to the weeding, a light forking and the application of bulky fertilisers is also progressing, and by the end of March nearly the whole of such important operations should have been concluded and low country labour discharged, before the Vishoo festival, generally held early in April.

South Indian planters have every need to be buoyed up by the assurances and views of such as hold optimistic theories regarding the future prospects of coffee and tea, for a prominent London merchant, largely interested in such industries, as well as in Ceylon tea gardens, writing under date the 18th ultimo. holds that "we have a bad time before us which will not be improved by our dear friends the French putting 10d. per lb. duty on East Indian coffee, and letting Brazil in at about 2½d. The only hope is that I cannot conceive anyone drinking Brazil coffee who has ever tasted anything beter, and yet 70,000,000 of Americans drink it; but then their state of civilisation is inferior in all matters of taste."—*Madras Mail.*

INSECT PESTS.

Planters will be interested to learn that Mr. De Niceville, the newly appointed entomologist of the Indian Museum, will spend several months each year on tour, for the purpose of investigating insect pests wherever they occur. He will also deliver a course of lectures annually at Dehra Dun.—*Indian Agriculturist.*

GUTTA-PERCHA.—The exports from Singapore are shown by the following figures to have swollen considerably in the last decade, and those who look with anxiety to the continuance of the supply will be seen to have cause for their disquietude:

1891	...	...	...	...	7,013,440 lb
1897	...	...	...	...	6,437,733 ,,
1899	...	...	...	...	16,178,133 ,,

These figures are certainly somewhat startling in more than one respect, and no doubt the Pacific Cable scheme has had a good deal to do with the conversion of a decrease into such a large increase. How long the producing districts can stand the train is a speculative matter of great importance, and it is regrettable that the system of gathering by natives, as practised in Borneo, cannot be effectively controlled by responsible persons. As things are at present, the natives do pretty much as they like, and there seems to be no way of enforcing the regulations as to cutting down trees which have been issued by the Governor of British North Borneo. We are promised a supply of gutta-percha in the future from French and German colonies where transplanting is being carried out, but it will probably be some time before supplies from the new sources affect the Singapore market—if, indeed, they ever do so. Still, what is being done by France and Germany is worthy of all praise, and our own Government might do well to take some decided action in the matter. Seeing how little success has attended the various schemes for the preparation of gutta-percha from the leaves of the tree, it is somewhat surprising that an attempt was recently made to form a new company for this object. Whether the promoters have succeeded I do not know, but cautious investors will surely take warning by what has occurred in the case of a large London company on the prospectus of which the names of distinguished scientists occurred. There seems to be a great difficulty in getting regular consignments of leaves to Europe, and the idea of successfully working the extraction process on the spot in the forest is scouted by men who are familiar with the country.—*Gutta-Percha Trades' Journal* Jan. 21.

RUANWELLA TEA COMPANY.

THE REPORT.

The report of the directors was submitted as follows :—

ACREAGE.

Tea in full bearing ...	..	358
Tea in partial bearing..	..	16
Jungle and Waste land..	..	199
Total	...	573

year.

The crop secured amounted to 167,125 lb., being 12,875 lb. short of the estimate. The average nett price realized was 27·72 cents per lb., a drop of 6·94 cents per lb. on last year's prices shared by most other estates in Ceylon situated in the low country.

After providing a moderate sum for the depreciation of buildings and machinery, and setting aside R1,000 for doubtful Coast Advances, the profit for the year amounted to R2,073·62, to which has to be added the sum of R73·67, the under-estimated value of tea unsold of the 1899 crop, and the balance of last year's account amounting to R4,635·73. The total now available therefore is R6,783·02, which in the present very uncertain state of the tea market the Directors recommend carrying forward to the current season's account.

The crop estimated for this year is 200,000 lb. tea on an expenditure of R45,851·09, in which is included a sum of R5,828 for manuring.

During the year under review Mr. G H Alston resigned his seat on the Board on leaving the island, and the Hon. Mr. W H Figg was appointed in his place. Mr. Melville White now retires from the Board in accordance with the article of Association, and being about to leave Ceylon does not offer himself for re-election.

The appointmnent of an Auditor for the current year rests with the meeting.

KIRKLEES ESTATE COMPANY.

THE REPORT.

The report of the directors was submitted as follows and adopted on the motion of the CHAIRMAN seconded by Mr. ARMITAGE OGDEN.

ACREAGE.

31st December, 1900.

Tea in full bearing ...	...	310 acres.
Do partial bearing	...	70 ,,
Tea not in bearing ...	...	58 ,,
Timber and Cardamoms, about ...		122 ,,
Uncultivated Land ...	...	157 ,,
Total	...	717 acres.

The Directors have now to present to the Shareholders the Accounts of the Company for the past year.

The crop secured amounted to 148,682 lb. Tea[s] (including 4,526 lb. made from purchased leaf) 1,183 lb. Cardamoms and 19 bushels of Coffee. The prize realized for the Tea was 33·49 cents per lb. as against 39·80 cents per lb. in 1899, while the Cardamoms sold for Re1·32 per lb. nett, as against Re1·49 in the previous year.

The Directors much regret the very disappointing prices realized for the Tea crop, and having provided extra withering accommodation trust that prices for this year will be more in proportion to what might be expected from a district favourable for the growth and manufacture of good Tea.

After making provision for depreciation of Buildings and Machinery and paying the interest on Preference Shares, the profit for the past year amounted to R2,558·23, equal to 2·55 per cent on the Capital of the Company. To this has to be added the balance brought forward from last year, making a total of R3,625·45 at credit of Profit and Loss Account. This sum the Directors recommend carrying forward to the current season's account.

The estimates for this year are 160,000 lb. Tea and 2,000 lb. Cardamoms, on an expenditure of R44,465.

In terms of the Articles of Association Mr. Jno. Gordon now retires from the Board, but is eligible for re-election.

The appointment of an Auditor for the current year rests with the Meeting.

THE TALGASWELA TEA COMPANY OF CEYLON, LIMITED.

THE REPORT.

The report was adopted on the motion of the CHAIRMAN seconded by Mr. CHRISTE.

ACREAGE.

	Acres.
Tea in full bearing	455
Abandoned	135
Cinnamon and Tea abandoned	43
Ravines	113
Forest boundary belts	53
Forest	1229
Total Acreage	2028

Acreage.—Under instructions from the shareholders a detailed survey of the tea has been taken and the above figures represent the actual area, of the estate in cultivation.

The Directors beg to lay before the Shareholders their Thirteenth Annual Report, with a duly audited statement of the Company's affairs to the 31st December, 1900.

The yield for the year was 195,243 lb including purchased leaf and tea sold locally at an average of cents 28·63.

Mr. R Morrison last visited the estate on 18th Jan. and reports that the general improvement of the tea bushes and condition of the estate during the past season is most satisfactory.

The expenditure on manure was R6 000, and is debited to crop account. After paying for this and putting all machinery in thorough order, and writing off the usual depreciation on buildings and machinery, the balance at credit of profit and loss account is R4,991·31 ; out of this the directors propose paying a dividend of 2 per cent per annum, which will absorb R4,000, leaving R991·31 to be carried forward to 1901.

The crop estimate for coming season is 170,000 lb and expenditure during coming season will be kept down as far as possible.

Messrs. J A Henderson and J G Russell resigned their seats on the board when they left for England, and Messrs. Hector Van Cuylenburg and W Rae Sands were elected in their stead.

Mr. W Rae Sands retires by rotation and offers himself for re-election.

The appointment of an Auditor has to be made.

COLOMBO TEA TRADERS' ASSOCIATION.

THE ANNUAL REPORT.

The annual report was then submitted as follows :—

Your committee have now pleasure in presenting their Report for the year 1900.

TEA PACKAGES.—The subject of Tea Packages has again occupied the attention of this Association, which sought the advice of Mr. A. F. Broun, Conservator of Forests, and his Assistant, Mr. F. Lewis. An exhaustive and interesting Report by the latter gentleman upon Ceylon woods suitable for toa boxes, for which the Committee herewith acknowledge their indebtedness, has been printed and circulated amongst members, and a Special Sub-Committee has recently been appointed to report further on this matter.

TEA LEAD.—Severe complaints reached the Committee last October with regard to the inferior tea lead being largely used in packages offered for local sale. The interests of trade were finally protected by a new Rule passed at a Special General Meeting held on the 16th November last. providing that all teas in packages weighing gross over 28 lb. and packsd in lead under 4 oz. shall be so declared by the Selling Broker before selling. This rule came into force on the 1st January.

TEA SALES.—Some confusion having arisen on one occasion through the sale having taken place at 10-30 a.m. instead of 11-30, without apparently the knowledge of the entire trade, your Committee recommended that in future it shall be understood that tea sales are held on each Wednesday at 11-30 a.m. except the first sale after a Tea Trade Holiday, when the time shall be 10-30 a.m. This is now recognized as a custom of the Trade.

AUSTRALIAN FREIGHT.—Much dissatisfaction has been felt for a long time amongst Buyers at the scarcity of tea freight to Australian Ports, and this was intensified by the subsequent raising of freights by all mail steamship lines from R40 to R50 per shipping ton. A Special Sub-Committee was appointed to report upon the subject, and its recommendations were forwarded to the local Agents of the mail steamship lines. Your Commitaee regret to state that no relief has so far been afforded to shippers, though the arrival of a few outside steamers quoting R40 per shipping ton is a satisfactory feature.

GREEN TEAS.—The unsatisfactory state of the black tea market together with the bonus offered to makers of Green teas has caused a very considerable growth in the offerings of these kinds. In order to prevent the bonus fostering the making of inferior teas, a Special Committee was appointed by the "Thirty Committee" under the auspices of your Association to arrange a standard of quality below which no tea would be entitled to receive the special bonus. A standard was agreed to and the grant is to paid ont any teas not passed.

INFERIOR TEAS.—Several complaints of shipments of inferior tea both to London and Australia have reached your Committee during the past year, and attempts have been made to trace them to their original shippers, and through them to the estates, the chief offenders, but so far without success.

The total exports for the year were, as per Chamber of Commerce Returns :—

	1900.	1899.
United Kingdom ..	113,760,193	103,948,124
Australia ..	17,606,912	15,606,833
Russia ..	8,917,185	3,949,740
America ..	3,980,680	3,080,002
Other Countries ..	4,166,669	3,309,457
Totals ..	148,431,639	129,894,156

Totals for 1898 and 1897 :—

1898 ..	119,769,071
1897 ..	116,054,567

The following figures show the quantity offered locally in public sale for the last four years, with the average price obtained for complete invoices sold:—

	lb.	Average cents.
1897 ..	33,886,809	37
1898 ..	35,958,819	35
1899 ...	38,377,318	38
1900 ..	47,681,826	34

The following is the Committee for 1900 :—

THE CHAIRMAN OF THE CHAMBER OF COMMERCE.

BUYERS.—Messrs. Tarrant, Henderson and Company, Messrs. Finlay Muir and Company. Mr. F F Street, S J Tokmakoff.

SELLERS.—Messrs. Whittall and Company, Bosanquet and Company, J M Robertson and Company. Geo. Steuart and Company.

The number of members belonging to the Association is 42, against 43 in the previous year.

The accounts for the past year made up to 31s December, 1900, and submitted to you shew a credi balance of R1,387·61

PLANTING NOTES.

RUBBER-PLANTING has gone ahead in the Kalutara district during the past year, and much of certain tea plantations has been covered with it. Enemies abound, however, in cattle and especially porcupines, for which as much reward as R5 a head is offered.

INTRODUCTION OF TROUT INTO KASHMIR.—A very interesting account of the one experiment made so far, to introduce trout into Kashmir, is given in a recent issue of the *Pioneer*. The preparations were wonderfully elaborate and complete; but as usual the fault lay at the other end, and the recent attempt failed.

BRITISH CENTRAL AFRICA.—"H.B." sends us another useful and chatty letter on the subject of life and prospects in British Central Africa, He is certainly able to present us with several names and residential terms which stand to the credit of the white population there, but in contrast with this we have a comparatively large obituary list, for a brief period, in a paragraph quoted elsewhere from a Central African paper. Nevertheless it is plain that the country has a future before it and that as the land becomes opened up—we hope by the way, to see a B.C.A. railway sanctioned before long—the life of the white man in this fertile territory will be rendered more popular for intending colonists by increased comfort and safety in its conditions.

COFFEE WITHOUT CAFFEINE.—At the last meeting of the Paris Academy of Sciences an interesting paper was read by M. Duclaux on "The Chemical Composition of a Coffee of the Grande Comore," the results of experiments by M. Gabriel Bertrand, of the Pasteur Institute. It appears that this coffee grows in a wild state in an island off the coast of Africa, where it was found by the explorer Humboldt, and is signalised on account of the peculiar fact that it does not contain the slightest trace of caffeine, to which ordinary coffee owes its excitant properties. One quality of this coffee is, therefore, that it can be taken as an after-dinner beverage at night without any fear of insomnia. Referring to it from a scientic point of view, Mr. Bertrand drew attention to the fact that well-known Botanists, such as Professor Frœhner of Berlin, and Professor Baillon of Paris, have not been able to agree as to the specific nature of this coffee. The French Botanist holds that it belongs simply to the same species as ordinary coffee, *Coffea Arabica*, while his German colleague treats it as a new species, and gives it the name of *Coffee Humboldtiana*. As a matter of fact, the botanical characteristics are practically identical with ordinary coffee, but there is a distinct difference in the chemical composition. This is not apparently due to any difference of soil or climate, as an analysis of *Coffee Arabica* cultivated on the Island shows it to contain 13 grammes of caffeine per kilo. M. Bertrand is of opinion that the subject opens a new field of study to biologists.—*Chemist and Druggist*, Feb. 2.

CULTIVATION OF TEA IN THE UNITED STATES.

(*The London Times*, Monday, Feb. 4.)

The possibilities of tea production in the United States cannot fail to be of considerable importance to those who are interested in the tea industry in various parts of the British Empire; in India, Ceylon, and Natal for example. In his recently issued annual report, the American Minister of Agriculture takes a hopeful view of the prospects of tea cultivation in the United States. It appears that for several years Dr. Charles U Shepard, of Summerville, South Carolina, has been experimenting with a view of obtaining information as to the practicability of producing American tea, and his efforts promised so much of value that it seemed proper for the Department of Agriculture to render assistance. To this end arrangements were made with Dr. Shepard, whereby certain machinery, &c., were to be furnished in order to settle some questions pertaining to the commercial production of tea. Throughout the work the question of labour has been an important one; but through Dr. Shephard's efforts there has been adopted a method for utilising the labour of colored children. What he has accomplished in this matter in his region could undoubtedly be brought about in other sections of the south, where much idle labour is awaiting proper utilisation. He has established schools on his place, and in these the children are received and educated, and at the same time are taught to pluck tea and perform other work in connection with the production of the crop. For such work fair wages are paid, and in this way interest is maintained. The experiments have shown that tea may be produced in the United States in two ways:—1. By families in their gardens, as was demonstrated years ago to be entirely feasible; and (2) on a commercial scale after the manner followed by the British East Indian tea establishments and the beet sugar industry. The work at Summerville was started with a view of ascertaining whether, under favourable conditions, tea plantations could be made to yield as much as the average Oriental production, and whether the crop could be marketed at a fair profit. The results obtained have been affirmative; the crop of 1900, although not so large as expected early in the season, exceeding that of any previous year by at least 12 per cent, and the entire product being sold before it was all gathered to a prominent Northern distributing house at a price that gave a fair profit. As further evidence that tea can be profitably grown in the United States capitalists are already making preparations to begin the work in certain parts of the South on a more or less extensive scale. It has so far been shown that a good grade of tea can be grown and put on the market in bulk at a cost not exceeding 15c per lb. Under average conditions an acre will yield 400 lb. of marketable tea, and this at 15c per lb. would make the expense of growing it $60 per acre. The tea should sell in bulk for at least 30c per lb. and the profit on this basis would be 100 per cent. Besides the cost of marketing, however, there are other expenses to be considered, such as the salary of a superintendent and the interest of the money invested in the plant, which would, of course, cut down the profits.

From considerations such as the foregoing it is inferred that the commercial possibilities of tea production in the United States can no longer be questioned, but there are still many points to be settled, especially as regards the improvement of the product. During last year experiments were undertaken for the purpose of determining the effect of irrigation on tea, and also the effect of shading the plants from the direct rays of the sun. Work has likewise been inaugurated with a view of reducing the cost of the preparation of tea, especially the green tea. The experiments in irrigating and shading, which will be continued, have given promising results, the shaded plants affording nearly double the yield of the unshaded, and a much finer grade of leaf. In the future special attention will be given to the manufacture of pure green tea. This subject is now receiving the notice of both inventors and planters in the British Colonies, as they begin to realise the hopelessness of bringing American tea drinkers to use the black tea instead of the green. The manufacture of green tea in the United States can be made successful only by the invention of machinery which shall take the place of expensive hand labour and prevent the waste which accompanies the latter. These questions are all being investigated by the Department of Agriculture, and in addition, it is giving special attention to a study of the conditions in various parts of the South with reference to determining the localities where tea can be grown to best advantage. Experiments have been inaugurated by some of the experiment stations and plants distributed with a view of putting the work on a substantial basis. Much need is felt for young men capable of taking up this important problem, and the subject is especially commended to the notice of the agricultural colleges in the Southern States.

[Dr. Shepard is certainly making a stir; but all the same it is impossible he can compete, commercially, with the cheap labour and teas of Ceylon and India.—ED. *T.A.*]

RAW RUBBER AT BULL WHARF.—We are enabled, by the courtesy of the proprietors of Bull Wharf, to give two illustrations of the method of sampling india-rubber and gutta-percha for the market. The crude material arrives at this wharf, which is one of the most important in the rubber trade, from all parts of the world, and a consignment very often includes a large variety of qualities. These have first to be unpacked and classified; the packages are then tared, and an average sample of each parcel is taken and forwarded to the selling brokers. The firm having been for many years connected with this branch of the Rubber Trade, and having on their staff men who have been used to the work all their lives, they at once appreciate the various points connected with the quality and different features possessed by each package, so that they can at once classify them according to their market value. In dealing with materials like india-rubber and gutta-percha, which have such very varied appearance, and can be adulterated in so many ways, it is important that this work should be done by men who thoroughly understand their work. The staff know approximately what a package should weigh, and if it is either too heavy or too light they would guess that something was wrong, and would immediately investigate the cause, and consequently place the package in a different class to that which its ordinary denomination might entitle it to.—*Gutta-Percha Trades' Journal*, Jan. 21.

THE "TEA" PROBLEM:
THE VIEWS OF THE LONDON BROKERS:

"SWEET CLEAN CEYLON PEKOE SOUCHONGS" SELLING FOR 3¼D.—AND "NOW IS THE TIME TO PAY ATTENTION TO CHINA TEA"!?

WHY ARE AMERICA AND EUROPE NOT SWEPT CLEAN OF CHINA-JAPAN TEAS—WITH "SWEET CLEAN CEYLONS" SELLING AT 3¼D. PER LB.?

"In the multitude of counsellors there is safety"; and surely if the scriptural adage be true, the position of the tea-planters of Ceylon ought to be safe enough! For, apart from the prolonged discussion before and at the Planters' and Merchants' annual meetings, our Correspondence columns shew that there is no abatement in the interest felt in the subject or in the varied advice tendered to the tea-grower. The latest letter of importance comes from a gentleman, who mentions that he has had residence and experience in China to guide him and whose name and firm will be recognised as connected with some very extensive tea interests in Ceylon. The gist of the warning tendered by Mr. M. P. Evans is that the growing inferiority of Indian and Ceylon tea, if continued, is bound to encourage a revival of the China tea trade with the United Kingdom; and, secondly, that in "going for quantity" without caring about quality, Ceylon planters, or certain of them, have taken the surest step to ruin the reputation of their teas and to injure fatally the trade in the same. Now, with *very few* exceptions ("the black sheep" who may be found in every large community) Ceylon planters do not mean this year to go for "quantity" at the expense of "quality." The universal determination, we believe, is to "pluck fine" and to turn out better teas; and if the same is done in India, we may be sure that the overplus of common teas will soon disappear. But why is it that our London friends and advisers do not confess that much of the blame for the deplorable state of things during 1900, lay at the doors of the London tea trade. How long ago was it—during 1899?—that we had the commoner grades of tea so much in demand, that the prices closely approximated to those paid for the higher, that is for the fine teas, and this continued so long that, of course, it set the mass of producers to go in for the very policy of "quantity" latterly condemned. Now, we are bound to have the other "swing of the pendulum," and we shall see how long it will be before there is a cry at home of "too much fine tea"?

But is the mass of the Ceylon tea that has been selling in London of late at 3d to 4d per lb. mere "rubbish"? We have good reason to doubt this; and here is our authority in the report of a London Broking Firm who must know what they are writing about—note the sentence we have italicized:—

I. A. RUCKER & BENCRAFT'S WEEKLY TEA CIRCULAR.

LONDON, THURSDAY EVENING, FEBRUARY 7TH, 1901.

TEA.—CEYLON—Deliveries for January shew an increase of one million pounds over those of same month last year, but as Imports were very large, we are carrying a stock of 28 millions against 21 millions. As the Indian stocks are nearly 75 millions compared with 63 millions, the position is adverse to price, and we are now lower than ever.

The market feels the weight of common tea, which is now at about 3¼d *for clean sweet Pekoe Souchongs with fair leaf, such as were selling at 6¼d per lb. same time in 1900.*

Ceylon Tea is really not doing so badly as Indian, as deliveries in the past eight months have increased by four millions of pounds, while those of Indian Tea are less by nine millions. Very heavy clearances of both kinds are being made, in prospect of a further increase in the Duty.

In the first three working days of February 4,327,000 lb. all kinds were cleared against 2,200,000 lb. last year

Now, here we have a most important admission, and we want to know from tea authorities, both here and at home, why it is with "clean sweet Pekoe Souchongs with fair leaf" selling at 3¼d, there is (1) a single million of lb. of China tea wanted in the London market; (2) why the American market for "black teas" is not swept clear of Chinas and Japans from the Atlantic to the Pacific Coast. [Some years ago we were constantly assured that only the high price prevented Ceylon's superseding Chinas and Japans in America; that the importers and dealers could not get their profits out of 6d to 9d teas. Well now can our "sweet pekoe souchongs" ever be cheaper than 3¼d and why does Commissioner Mackenzie not report that they are clearing out the black teas of the China-Japs? It is all very well to divert attention by crying up "green teas"; but after all America consumes *more* black than it does of green tea and now or never should be the time to get the dealers and drinkers accustomed to the "clean, sweet," cheap machine-made teas of Ceylon. Is the "Thirty Committee" awake to the fact and should not their Agent be even now in New York urging this new phase on the dealers' attention?—That we should have here a splendid opportunity for winning the Continent of Europe is equally true.] But (3) we have to ask, how it is that another London Broking Firm—Messrs. St Rucker, Marshall & Co.—on the same date, 7th Feb., urge on the Trade, that now (with "clean sweet P.S.'s" at 3¼d) is the time to pay more attention to China tea! Here is their report:—

LONDON, E. C., 7th February, 1901.—Business during the past month has been exceptionally quiet, prices for all descriptions showing a heavy decline; the large quantity of Indian and Ceylon Teas offered at public auction, combined with the heavy duty payments made owing to the fear that the Chancellor of the Exchequer may again increase the Tea Duty, has tended to depress the China Trade more and more, neither the Dealers nor Shippers showing the slightest inclination to buy, even at the exceedingly low prices now ruling. In our opinion the Trade would do well to pay rather more attention to China Tea, as in all probability they will never have such an excellent opportunity of securing such good value again.

CEYLON.—During the past month the market for Ceylon Tea has been very irregular. Up to the middle of January it remained fairly steady, when owing to the large quantities brought to auction prices fell away all round, especially for common sorts. Common Pekoe Souchongs have been sold as low as 3¼d per lb., and common Pekoes at 3¾d to 4d per lb. The export trade is quiet. During January 148,520 packages

were brought to auction, and realised the average price of 6⅞d per lb.

Verily, the puzzles of the Tea Trade are interminable: just as we might expect China tea to disappear with our own clean sweet leaf down to 3¼d, sharp city men in the trade, say "Now is the time to pay attention to Chinas." What does it mean?

Next for some more counsel to our planters which we find this time in—

McMEEKIN & CO.'S NOTES ON INDIAN AND CEYLON TEAS, MONTH OF JAN. 1901.

Indirectly the business of the Tea trade has been seriously affected by the war in South Africa. The derangements caused by the large clearance prior to the production of last year's Budget, and by the imposition then of an extra Duty were not fully overcome when another movement to pay Duty in anticipation of this year's Budget set in. During January, the total of the Duty paid on all Tea was £740,000, while the monthly average for 1900, (taking the whole at 6d per lb) was only £520,000. Consequently, £220,000 of the available capital resources of the trade is now locked up in Duties beyond current requirements, and, in addition to that the whole value of the Tea has had to be paid over to the Importers in order to clear it from Bond, as now required by His Majesty's Customs, this would absorb about £250,000 more. The lock-up in question is doubtless responsible for some falling off in the activity of the demand towards the close of the month.

The proposal to restrict output has been seriously taken up by most of the larger producers of both Indian and Ceylon Tea, and if the scheme suggested is carried out there should soon be little excess beyond reasonable requirements to deal with. It is to be hoped that production will not be cut down too much, as anything approaching to inadequate supplies would certainly lead to speculative dealings, which have always proved bad for the trade.

Not only may speculation set in at home if Indian and Ceylon shipments fall off much; but are not China and Java exports to London bound to increase? The really great cloud overshadowing the future in our opinion lies in the area of young tea coming into bearing, especially in India — 11,000 acres in one block on the "Kanan Devan" property in North Travancore; 2,000 acres more in Travancore proper and perhaps between 20,000 and 25,000 acres of tea in Northern India on well-selected soil. On the other hand, many gardens in the poorer parts of Sylhet and other Indian districts must contract their plucking area, and this leads us to consider the case of our older and poorer estates in Ceylon. Well does a London merchant (with no personal interest, we believe, in such poor old estates) write to us by this mail with reference to the "survival of the fittest" theory :—

"Terrible times for tea growers. Combination is not philanthropy and the retention in cultivation of the poorer estates is the safety of those less poor. If poor places shut up there is plenty of good land to be had in India!"

Here is another risk before Ceylon; but surely no capitalist will be so foolish as to put money in opening more tea land during the next three or four years? The supporters of the "10 per cent reduction of area" plan allege that it gives great security against any tea-planting extension; but all the same, we are not convinced that it must be the duty of every proprietor in Ceylon to subscribe to this plan. As we have already indicated, we should like to see tea estate proprietors have an option between the following answers (to the P. A. circular) or something like them :—

(1) We, or I, agree to abandon for the year 1901 one-tenth of my plucking area;—or

(2) I agree to make one-tenth of my output into green tea, in place of reducing plucking extent;—or

(3) I cannot consent to reduce plucking area; but I guarantee that my estate sends one-tenth less outturn or crop into the market during 1901 than in 1900;—or

(4) Inasmuch as my estate gave no more crop in 1900 than in 1899 and therefore did not contribute to the overproduction, I cannot agree to any one of the above proposals, but intend to pluck carefully and get no more than an average crop during 1901.

Surely if the above programme, were universally adopted—that is, if one or other of the answers were sent in, signed and honorably maintained—the object in view as regards "combination" and a reduction in production, especially of common teas, would be attained.

As to Mr. Robert H. Elliot's "currency" remedy, we are quite with him in realizing the great benefit of a cheaper rupee, to producers and exporters; but what about the dislocation of Banking, Trade and Revenue? Is there the slightest chance of reversing a Currency policy so deliberately arrived at, and which from the point of view of the official, the banker and the merchant, has given such special satisfaction? If Mr. Elliot thinks there is, he will agree that the agitation should begin and be mainly carried on by Indian exporters, as little Ceylon is but as "the fly on the wheel" when compared with the exporting interests of all India.

A NEW CEYLON TEA COMPANY.

The *Investors' Guardian* (of Feb. 9.) has the following details of a new undertaking :—

Kobonella Estates Company of Ceylon, Limited, (69,280).—Registered January 29th, with a capital of £30,000, in 1,200 preferred shares of £10 each and 18,000 ordinary shares of £1 each to acquire the four estates known as Deanstone, Kobonella, Horakanda and Meenagella, in the Central province of Ceylon, to adopt an agreement with J Greig and others and carry on the business of planters, farmers, graziers, cultivators and growers of tea, coffee, cardamoms, cocoa and other crops, miners, merchants, ship-owners, agents, etc. The subscribers are :—

	Shares.
J R Hughes, 30, Mincing Lane, E.C., Merchant	500
E B Smith, The Cedars, Norwood, Gentleman, Director of Balmoral Estates Company.	500
E S Anderson, Oak Bank, Elgin, Planter.	500
T J Anderson, Dunster House, Mincing Lane, E.C., Tea Share Broker.	1
J N Layton, 30 Mincing Lane, E.C., Tea Broker.	1
E J Young, 9, Fenchurch Av. E.C., Planter	50
E J House, 66, Old Broad Street, E.C., Clerk.	1

Minimum subscription (if any shares offered to public) 450 preference and 9,500 ordinary shares. The number of directors is not to be less than 2 nor more than 4; the first are E S Anderson, J R Hughes and E Bowden-Smith; qualification £500; remuneration £50 per annum. Registered office, 66, Old Broad Street, E.C.

NEBODA TEA CO., OF CEYLON LIMITED

THE REPORT

was submitted as follows :—

ACREAGE.

Tea in full bearing	..	231 acres.
,, in partial bearing	..	152 ,,
,, not in bearing	..	112 ,,
Total Tea	..	495 acres.
Forest land, &c.	..	240 ,,
Total	..	735 acres.

The Directors submit their Report and Accounts for the year ending 31st December, 1900.

The Crop secured for the year was 194,600 lb., and was sold in Colombo at an average rate of cts. 28·82 per lb., as against 35·09 for 1899. The cost of production, including manuring, was cts. 22,176.

Allowing for area pruned during the year, the Tea in full bearing has maintained the yield of the previous year.

The estimate for 1901 of 200,000 lb. made Tea is based upon the finer plucking already adopted. Compared to previous style of plucking this will effect a reduction of 20 per cent. in yield.

The Directors recommend that the 69 acres purchased last year for fuel be sold, as the completion of the cart road to Neboda renders the ample forest reserve there available for firewood.

The balance at credit of Profit and Loss Account was R13,609·63 which sum the Directors recommend should be disposed of as follows—to place R13,250 to credit of Reserve Account as a set-off against Capital Expenditure for the year, and to carry forward the balance.

In terms of the Articles of Association, Mr. Joseph Fraser retires from the Board, but is eligible for re-election.

The Meeting will appoint an Auditor for the current year.

KANAPEDIWATTE TEA COMPANY.

THE REPORT

The Directors beg to lay before the shareholders their report and accounts for the year ended 31st December, 1900, which they regret are not so satisfactory as in past years.

The usual table shewing the crop, cost and average of the tea for the past three years is attached for comparison.

	1898. Crop in lb.	Cost in Colombo.	Nett Average.
From Estate Leaf..	142,267	23·11	32·71
From Bought Leaf..	30,330		
	172,597		

	1899. Crop in lb.	Cost in Colombo.	Nett Average.
From Estate Leaf..	151,030	21·92	36·16
From Bought Leaf..	38,565		
	189,595		

	1900. Crop in lb.	Cost in Colombo.	Nett Average.
From Estate Leaf..	151,121	2,407	27·72
From Bought Leaf.	52,195		
	203,316		

It may be mentioned that the estate tea by itself cost cts. 23·89 as against cts. 19·94 in 1899 and cts. 20·52 in 1898.

It must be borne in mind, however, that applications of manure cost cts. 1·39 per lb. of estate tea this year, or cts. 1·24 more than in 1899.

The crop was 13,879 lb. short of the estimate, which was in great measure due to abnormal rainfall in July, August and September.

The nett profits for the year amount to R20,065·98, which is equal to six per cent on the paid up capital of the company, as against 13 2-5ths per cent in 1899 and 12 per cent in 1898.

A sum of R660·70 has been written off for coast advances, which unfortunately could not be recovered, leaving a sum available for distribution, after adding the balance brought forward from last year, namely R480·39, of R19,885·67. Of this sum R6,680 was absorbed by the payment of an interim dividend to the 30th June last of two per cent, and the Directors leave it to the meeting to decide what dividend shall be declared out of the available balance R13,205·67.

In February last, Mr. Geo. Christie, one of the Directors (and also Manager of the properties of the Company) resigned his seat on the Board to proceed to England, and Messrs. W P Metcalfe and E M Shattock were appointed to act temporarily in his place.

He has now resumed charge of the estates and taken up his old position on the Board as a Director.

In terms of the articles of Association Mr. W Kingsbury resigns his seat on the Directorate, but is eligible for re-election.

The Auditor, Mr. J D Forbes, offers his services for 1901.

The report was adopted.

THE KELANI TEA GARDEN CO., LD.

THE REPORT.

ACREAGE.

282	Acres Tea in full bearing	
52	,, ,, planted	1896
30	,, ,, ,,	1897
34	,, ,, ,,	1898
10	,, ,, ,,	1899
14	,, ,, ,,	1900
422	,,	
313	,, Reserve	
11	,, Ravines, Waste and Grass	
746	Acres.	

The Directors beg to submit to the Shareholders the accounts of the Company for the year ending 31st December, 1900.

The crop secured amounted to 198,877 lb. made Tea, realizing R55,838·32 or an average price of cents 28·08 per lb., as against an expenditure exclusive of items under Capital Account of cents 20·92 per lb., including R1,843·77 spent on cost of Manure and application.

The balance at credit of Profit and Loss Account after allowing for depreciation of Buildings and Machinery is R6,319·99, which the Directors recommend should be carried forward to next account. The Directors regret the unsatisfactory result of the year's working, which may be attributed to the adverse conditions of the Tea market prevailing for low-country Teas during the latter part of the year.

The manufacture of the Tea also has been seriously interfered with during part of the year owing to alterations and extension in the Factory, but these having now been completed, better prices may reasonably be expected.

The estimate for the current season is 200,000 lb. made Tea, to be delivered into Colombo at a cost including manuring of cents 21.92 per lb.

Mr. Fred. Hadden retires from the Board in terms of the Memorandum and Articles of Association, and being about to proceed to England does not seek re-election. It is suggested that Mr. F L Clements,

who has recently been appointed Visiting Agent to Kelani Estate should be elected to fill the vacancy on the Board.

The appointment of an Auditor rests with the Meeting.

YATADERIA TEA CO., OF CEYLON, LD.

The Directors have the pleasure to submit the balance sheet and profit and loss account for the year ending 31s December, 1900, duly audited.

Including extraneous profit from outside manufacture the profit for the year is R43,575·04 to which must be added R6,405·80 balance from 1899. An Interim Dividend of 12½ per cent. absorbing R23,750, was paid last August, and the Directors propose that a further Dividend at the rate of 12½ per cent. absorbing R23,750 be declared and made payable as the Directors may determine in meeting on 26th instant, leaving a balance of R2,480·84.

It will be seen that the property representing Capital stands in the Balance Sheet at approximately R197 per acre cultivated, as compared with about R197 in the previous year's accounts, and that the profit is R47·72 per acre in bearing, and 22 93 per cent, on the capital.

The total Tea crop was 643,360 lb. or 63,360 lb. more than the estimated quantity, the latter part of the year having been more favourable. The plucking area was 913 acres, in addition to which the 29 acres of 1898 tea was plucked towards the close of the year. The total quantity of Tea for disposal was 660,419 lb. including 17,059 lb. made from purchased leaf, of which 17,805 lb. were sold locally averaging 19 11 cents per lb. and 642,614 lb. were shipped in London, of which 176,342 lb had still to be accounted for; but the average obtained for the 484,077 lb as yet accounted for is 28·14 cents per lb. The cost of the Tea delivered to buyers or put on board ship, including all charges, was 18·95 cents per lb and the nett value realised from sales (a portion being estimated) was 26·43 cents per lb.

The Company's property consisted on the 31st December 1900, of ;—

Acres Tea.				Tea per Acre. lb.
172	planted in	1885	yield in 1900	620
208	do	1887	do	605
100	do	1888	do	570
42	do	1889	do	968
6	do	1890	do	1,009
52	do	1891	do	1,015

68	do	1894	do	697
37	do	1895	do	782
75	do	1896	do	772
33	do	1897	do	299
29	do	1898	do	62
24	do	1899	do not in bearing.	
22	Acres cocoa and Factory site.			
10	Acres cardamoms.			
255	Acres forest, &c.			
Total 1,253	Acres as per last report.			
966	Acres Tea.			

Average yield from 913 acres 702 lb.

The estimated crop for 1901 is 594,045 lb Tea.

Mr. V H Mascfield retires from the Board, and the Shareholders will be requested to elect a Director and also an Auditor for the current year.

THE CEYLON PROVINCIAL ESTATES COMPANY, LIMITED.

THE REPORT

was submitted as follows :—

The Directors beg to present their report for the year ending 31st December, 1900, together with a statement of accounts for the same period.

The tea crop amounted to 506,207 lb. against an estimate of 455,000 lb. for the year, or an average of 562 lb. per acre from the tea in bearing.

The total profit for the year was R91,017·16. The cost of producing the tea was R24 42 cts. including R1·97 cts. expended on manuring as compared with R24·35 cts. and R1·50 cts. respectively for the previous year.

The nett selling price of the teas shews a falling-off from 1899 of R2·06 cts. per lb., the average for 1900 having been R42·56 cts. per lb. as against R44 62 cts. obtained the previous year.

Including the sum of R587·03 brought forward from last year, the profit and loss account shews, after the payment of an interim dividend of 3 per cent, interest on mortgages, bonus to Superintendents, Secretariat and other items, an available surplus of R57,426 31, which the Directors recommend being disposed of, by paying a final dividend of 6 per cent, making 9 per cent for the year and absorbing R39,960 ; by setting aside R10,000 towards the liquidation of one of the mortgages and by carrying forward the balance to next year after providing for Directors fees.

The estimates for the new season point to a yield of 500,000 lb. of tea costing R24·98 cts. per lb., which includes a sum equal to R2·33 cts. per lb. for manuring operations.

A fresh survey has been made of Glassaugh, and the following is the preseot acreage of the estates :—

	Glassaugh.	Brownlow.
Tea in full bearing	452 acres	423 acres
,, partial bearing	20 ,,	80 ,,
,, not in ,,	20 ,,	— ,,
Total in tea	492 ,,	503 ,,
Fuel trees	— ,,	2 ,,
Forest	4 ,,	33 ,,
Grass	1 ,,	27 ,,
Scrub and Waste	22 ,,	20 ,,
Total	519 acres.	585 acres.

Mr. E S Grigson retires from the board in terms of the articles of Association, and is eligible for re-election.

The appointment of an Auditor for 1901 rests with the meeting.

PLANTING IN B. C. AFRICA.

COFFEE AND TOBACCO—OLD RESIDENTS—HEALTH—FEVER—SOIL—MONEY-MAKING—ROOM FOR MEN OF THE RIGHT STAMP—RAILWAY—COFFEE CROPS.

Mlanje, 7th Jan. 1901.

You ask me if I could name half a dozen men who have stood this climate as long as I have, and kept as good health, and if anybody has made money here. I would not go beyond this district itself to answer the first question.

Mr. A C Simpson has been over 25 years in this country, arriving with the first steamer for the Shirè, and has had various ups and downs in the Country ; serving on Lakes and Rivers as engineer, trader, and latterly settled down to planting and trading in Mlanje where he has been for the past eight years or more, and has only been home twice, I believe, during all those years. A.C.S. looks as fit and as well as any man could do at the present time.

J W and Mrs. Moir of Lauderdale, who are at present at home, enjoying a trip to

the old country, have been over 20 years in Africa, and eight years in Mlanje and I can safely say they both enjoyed good health in this country.

Mr. and Mrs. Smith, of the Church of Scotland Mission, have been 12 or 14 years in Blantyre and here, and are also in good health.

Mr. and Mrs Herd of the same Mission have been nine or ten years out and are also in good health.

Mr H B Bradshaw, my neighbour, and Mr. D Ritchie have been in Mlanje nearly as long as myself, and both have only been home for a run once for a few months, and finer specimens of robust planters you could not find in any of your mountain planting districts. I need say no more in response to your query although I could name many in other districts who have been over 20 years in B.C.A. and are perfectly well at the present time.

The fact is, as I have said before, people must learn how to live in Africa as well as in other tropical climates, and those who have been long resident in B.C.A. have done so.

Now that scientific research is bringing to light so much on the subject of malaria it will soon be possible to be perfectly safe from fever in any country. Notwithstanding the mosquito theory I do not think it safe to live here without taking quinine. Mosquitoes are not numerous here in Mlanje, and *one* is only heard and seen occasionally during the rainy season, but I would not like to risk giving up taking quinine in preference to the mosquito netting. I have not had fever for five years now, and do not want to get it.

With regard to money-making in B.C.A. I know of only two planters who have left the country for good having made money at coffee-planting. Messrs J—— and D——, the former some £6,000 and the latter about £3 000. The former was only about six years here, and was fortunate in getting some 10 cwts. per acre from a coffee estate he opened up during that time, and his other investments proved good; so he sold out and has gone to S. Africa to start business in one of the coast towns.

The other was some 25 years in B.C.A. but only about 10 years planting coffee, and he sold out—clearing, I was told, the above amount and is now living with Mrs. D. in Scotland.

It must be remembered that this country is young, and that the agricultural resources of the land have not yet been developed. There are few men with capital to enable them to prove what can be done with the different products which might be, and are, grown successfully here; most private planters have really got very limited means, and everybody knows what uphill work it is anywhere working under such circumstances. We all know it requires money to make money, especially quickly, so give us a chance. I can safely say, however, that there are no planters or others hard up in this country, and all seem able to make a decent living either at planting or trading or something else.

I do not believe there is a single individual out of employment in the country at the present time; and I am quite sure a few more are wanted to take up billets. So it is perhaps a good thing that the country has got such a bad name for sickness, at least it prevents us being flooded with men on the staff, especially those of the loafer stamp who are not wanted.

Any one coming here should be of good character and have sufficient means to leave the country again if need be—but it would be better still if emigrants had the means to engage in some independent industry. The transport and other firms, or companies, are all doing swimmingly well and some of them have paid dividends of 7 and 8 per cent. They have great trouble with their employees, who find when they come out here that they can better themselves, try all sorts of dodges, and do all sorts of things to get sacked; they of course, forget the fact that they were brought out by their employers, and were of little use till they learnt the language, etc. I cover the sketch of a draft prospectus which has been sent home to try and get capitalists to take up the construction of our railway. Comments on the paper I leave to yourself. It may force the hands of our newly-formed home Government to take up the matter. We have certainly more claim on the Imperial Government for a railway than Uganda has, and ours is far more likely to be a paying line.

We are going to have a very short crop in Nyassaland this year; the blossoming season was upon the whole very unfavourable, being too dry. Although we, in Mlanje began well, the latter end of the season was a scorcher, and with the dry heat came on an unusual number of spotted bug, and thrips; the latter is as bad as a severe dose of leaf disease, carrying off the leaves and killing back the branches and withering up the crop, which drops off to single berries. Fortunately this latter pest only comes with a very dry season. I never saw them in Ceylon. Our trees are now making wood fast and throwing off the thrips.

A good many planters are going in for tobacco, &c, not to have all their eggs in one basket. I have grown tobacco here for over two years now, and have at last got a market for it which pays me very well. So there may be money in the weed, if overproduction does not reduce the price.

H. B.

The Effect of Lime.—Lime, though chiefly mechanical in its action, also acts chemically upon the constituents of the soil. One of the great purposes which it serves is that it sets free plant-food which would otherwise remain locked up in the soil.—*The Journal of the Jamaica Agricultural Society.*

Big New Sugar and Paper Company.—An English company has just bought 10,000 acres of sugar lands, and will not only make sugar, but turn the bagasse into paper. The immense reclaimed sugar land areas in Florida below the frost line are now attracting foreign promoters, and with more reason even than those in Louisiana.—*New York Commercial.*

THE EXTERMINATION OF WILD ANIMALS IN INDIA.

The question which is often raised in these days, regarding the extermination of wild animals in the shooting grounds of the world, admits in India, at least, of being examined, to some extent, by the light of statistics. Statistics are proverbially capricious things to deal with, and, unfortunately the records I have at my disposal only go back to 1885, but they may help us a little. Let us commence then with that monrach of Indian big game, the tiger. The number of tigers destroyed and persons killed by tigers since 1885 is as follows:—

	Tigers destroyed.	Persons killed.
1885	1,355	838
1886	1,464	928
1887	1,408	1,063
1888	1,473	975
1889	1,312	985
1890	1,276	798
1891	1,293	979
1892	1,323	947
1893	1,267	969
1894	1,311	864
1895	1,381	909
1896	1,502	944
1897	1,569	1,071
1898	1,257	927
1899	1,570	899

The foregoing figures, it shou'd be observed, deal with Madras, Bombay, Bengal, the N.-W. Provinces and Oudh, the Punjab, Burmah, the Central Provinces, Assam, Coorg, Banga'ore, Hyderabad Assigned Districts, and Ajmere-Merwara. They consequently furnish no *data* regarding Mysore or the Native State of Hy-erabad, nor of other tiger districts, which, though not so important as the two here mentioned, must certainly be regarded as factors of great weight in influencing our general conclusion. If we break up the totals for the whole of British India into Provincial totals, we obtain the following figures:—

TIGERS DESTROYED.

Bengal	N.-W.-P. and Oudh.	Punjab.	Burmah.	C. P.	Assam.	Ajmere-Merwara.	Coorg and Bangalore.	Madras.	Bombay.	H. Assigned District.
674	83	12	83	221	347	4	9	266	122	34
245	74	4	121	253	436	4	4	209	97	17
269	99	4	120	222	438	7	9	149	72	19
376	100	1	74	315	323	6	6	203	57	12
318	83	3	76	231	337	2	12	175	49	26
275	85	—	76	208	384	2	6	150	72	18
239	106	4	87	347	377	6	12	137	49	29
256	69	5	121	274	343	—	10	150	68	27
236	73	11	133	207	367	5	6	132	82	15
271	66	3	141	361	356	1	6	141	49	16
336	77	12	152	225	360	4	6	116	54	39
361	96	15	171	323	353	—	6	105	43	29
546	121	4	173	222	387	2	3	110	22	29
292	112	1	200	262	293	2	1	102	44	48
356	108	5	233	233	411	1	5	129	51	38

The only deduction to be drawn from these figures is that from 1885 onwards there has been no apparent diminution, nothing worth speaking about, in the number of tigers available for killing. In 1885 Bengal, Madras and Bombay returned figures which they have never reached since, but in the North-West, in Burmah, in the Central Provinces, in Assam, and Assigned Districts, a full table of tigers always seems to be forthcoming. The Burmah figures are, perhaps, a little misleading. Up to 1890 the returns apparently date with Lower Burmah only; since that date the whole of Burmah has fallen under the intelligent classification of the Statistical Department. Hence these tigers! Though in Bengal 674 tigers were killed in 1885, considerable circumspection is required in dealing with this total; for the very next year, the Provincial bag dropped to 245, and indeed, from the *shikari* point of view the three years following 1885 were nothing like as good as 1897, and 1898, and 1899. It must also be insisted on that in the last three years of the series more persons were killed by tigers than in the first three, and after all said and done I suppose nobody will seriously maintain the doctrine that men should die so that tigers may be kept alive. Personally I can't see that India would be any worse off if there wasn't a tiger in the country. So far as leopards, bears, wolves, hyenas, and other wild beasts are concerned, the numbers recorded as having been killed since 1885 hardly lead to the conclusion that the stock is diminishing, Hyenas and wolves, perhaps, are the exceptions. The figures for 1885, 1886, and 1899 are here given:—

	Leopards.	Bears.	Wolves.	Hyenas.	Other wild beasts.
1885...	5,466	1,874	6,278	2,238	5,959
1886...	4,051	1,668	6,725	1,630	6,852
1899...	4,548	1,585	2,357	776	7,989

Matters far more serious for India than the extinction of beasts of prey, however much their disappearance might be made the theme of lamentations from sportsmen, are the everlasting slaughter that goes on among deer, the ruthless destruction of Indian wild birds, and the deterioration and diminution of agricultural Stock.

SAMBHUR.

—*Times of India.*

THE INDIAN TEA CROP, 1900.

In September last the Indian Tea Association gave an estimate of the outturn of the present season's crop of Indian tea showing a total of 182,144,874 lb.

The Association now give the following figures showing the actual outturn of the crop:—

	lb.
Assam	... 67,928,770
Cachar	.. 27,299,230
Sylhet ..	... 33,854,808
Darjiling	.. 7,474,098
Terai	.. 3,378,075
Duars	... 29,997,065
Chittagong	.. 1,065,300
Chota Nagpur	.. 185,089
Kangra Valley.. ...	... 3,000,000
Dehra Dun	.. 1,785,000
Kumaon (estimated) ..	.. 300,000
Gardens from which no returns have been received, including Private and Native gardens (estimate)	.. 11,260,000
Total	..187,527,435

The outturn from the Duars district shows an excess of rather more than 7,000,000 lb. over the estimate of September last. This excess is, to a large extent, an apparent one only. Owing to incomplete returns it was necessary when framing the estimate to include about 5,000,000 lb. of tea under the general heading of "Gardens from which no returns have been received," This quantity has now been accounted for by the final returns from Duars gardens and is deducted from the estimate of 16,168,000 lb. for "Gardens from which no returns have been received."

Correspondence.

To the Editor.

TEA OVERPRODUCTION:—JUDICIOUS *VERSUS* INJUDICIOUS (AND "WILD") MANURING OF TEA—AND THE "RESTING" PROBLEM.

Dear Sir,—Your leading article of 21st inst. gives startling figures. I will not repeat them though they look simple enough, but I should think India will pause before agreeing with Ceylon to rest any part of her cultivated area.

17,717 tons manure means 53,151 acres of tea manured. The friend you support—on his style of working—would expect quite 200 lb. per acre as the legitimate extra quantity of tea to be produced by the application of this manure that equals 10,630,200 lb. extra tea. With the present labor supply in the country there is nothing to prevent a still larger increase in manuring operations for 1901. What is the use then of resting one portion while we go on increasing our production in this way from the remaining area. Does not above go to prove that it is not the resting of 10 per cent of our tea that is needed (any benefit from that is doubtful) but an actual reduction in output of say 10 per cent. This could be leased on the actual crop of the last two years; thus an estate averaging 100,000 lb. for the two years should undertake to put only 90,000 lb. on the market leaving it to the proprietor to decide whether he would pluck finer, rest a portion, destroy his low grades, or sell to the natives of Jaffna, Trincomalee or India; just reduce as it best suits his own taste or individual estate.

In some such way only shall we get any reduction in output that will be of any help to us. Still we must support the best scheme that is brought forward so as to make a beginning and do our best to make it workable in such a way as shall benefit us all. I do not think your friend was unjustly criticized. We do not object to manuring, it is fair legitimate cultivation; but we do object to everything being taken that the bush will produce, and this at the lowest possible cost of plucking so making and throwing on the market all unnecessarily increased quantity of low class teas that are spoiling our good name and ruining our industry.

In olden days we made tea so as to get the best price obtainable, the question was not—How cheap are you plucking? or—What is your yield per acre? but—What price did you get for your last break?

If men would work now on these lines, and manure so as to keep their bushes healthy, we should not hear so much about over-production; high and low estates would each in their own line get better prices than even your highly manured old coffee land has given during the last year or two.

Here are figures from a typical old coffee estate averaging over 40 years' cultivation in that product. Not a single acre of new land has been opened for tea and it is not in a favourite district. Area in tea, 356 acres, carefully plucked and manured just sufficient to keep up the fertility of the soil.

Season	1895	1896	1897	1898	1899	1900
Total crop	184,539	182,133	173,000	169,000	175,000	185,000
Spent on manure	R1,982	2,521	2,800	2,149	1,705	2,712

Yours truly,
MANAGER.

THE "OVER-PRODUCTION" DIFFICULTY—AND HOW TO MEET IT:

[A copy of the following letter has been placed at our disposal from London.]

Brookfield, Carnoustie, N. B.,
January 21, 1901.

To the Chairman, Planters' Association of Ceylon, Kandy.

Dear Sir,—I have received copy of Mr. Rutherford's letter to yourself for which I am much obliged. The proposals for reducing our over-production of Tea are very well worthy of consideration, but are quite impracticable, unless it is absolutely certain that India joins with us, and not only joins, but does so exactly to the same extent as we do, and either by the same system as Mr. Rutherford proposes, or in such a way as will in its working show us that a *bona fide* 10 per cent reduction is being carried out by them as well as ourselves. I note that Mr. Rutherford says he has reason to believe that Indian Planters will co-operate with us; this of course must be made a certainty, otherwise they willl walk away with the enhanced price which we hope our reductions will create. I doubt very much however whether our Indian *confrères* will care to fall in with our proposals. We must call to remembrance that Indian men were growing Tea long before us, and that it is we who have done Indian planters much harm, (even though we have opened up new markets, and done such splendid advertising) by growing these enormous quantities of Tea, and not only great quantities of Tea, but poor cheap stuff, that has still more added to the harm, and to the present lamentable state of the Industry.

The greatest injury that has been done to our Industry has been caused by sacrificing quality to cheap production, and this has been done almost without exception by every individual and Company in Ceylon, and I venture to say Mr. Rutherford's own Company is in this respect as great a transgressor as any. My cure for the present poor prices is first—to improve the quality of our Tea, in every possible way, and to do so let us firstly cease to cut our trees to pieces immediately the poor coolie finds it impossible to drag 10 to 12 lb. of green leaf per day out of them: secondly, instead of asking superintendents to pluck for 7 or 8 cents give them 12 or 14 cents per lb. for this work; thirdly, never prune oftener than once in 18 months in the very worst climatic districts, and 2 to 2½ years in more favoured districts. If, as many of my friends tell me, their fields will have ceased to yield before these months have expired, then I say all the better for themselves, their trees, and the general prosperity of the Tea Industry.

Why do fields go so quickly out of yield? Simply by the bad treatment the trees get, caused by this wicked and accursed cheap working, *i. e.*, cheap plucking and pruning. My plucking used to cost 13, and often 14, cents per lb. of Tea, when many of my friends were doing it for 8 or 9 cents or even cheaper, but my profit per acre equalled

some and beat many easily. Cheap plucking means wretched quality and it acts in many ways. First, the coolie has to work so quickly that many mature leaves are missed and when the next turn to pluck them comes these leaves, instead of producing broken pekoe and pekoe, are only fit for making souchong and congou, if indeed they should not have to be discarded altogether; secondly, this cheap plucking means ripping the trees when the shoots are young and succulent, causing the trees to cease yielding much sooner than they would otherwise have done had they been more gently and carefully plucked; thirdly, to secure this cheap working, continual pruning at short intervals is done, adding fuel to the fire in the shape of poor thin weak Teas. Then this pruning must also be done cheaply, which means that the trees are hashed to pieces in the same way as a Sinhalese man cuts *varitchies* with a blunt vettu cattie.

I have only to add further that for the past eight years my prices have kept exactly 2½d above the rate for all Ceylon, with careful plucking and pruning once in two years. The yield has been over 500 lb per acre for these years and for 1900 is 530 lb. without manure. Improved quality means less quantity; the tea itself being worth more money and a less quantity being produced, our position will be thereby doubly benefited — I am yours faithfully,

ROBT. C. BOWIE.

OVERPRODUCTION—AND GIVING TEA BUSHES "REST"?

(THE BUSH MUST AYE BE GROWING AND PRODUCING FRUIT IF NOT LEAF.)

Feb 5.

SIR,—I do not believe in the recuperative effect of allowing tea bushes to remain unplucked. If they ceased to grow, it might have that effect, but as they do not, they draw nourishment from the soil, and as they grow, they become fruit bearers, and require much more nourishment, and the bigger they grow, more fruit do they produce, and naturally require much more food. Just as a cat requires more food than a mouse, and a tiger more than a cat, the larger a fruit bearing-tree is, the more it exhausts the elements that sustain it.

It is the general opinion amongst tea planters, that plucking the bushes exhausts them more or less; they think that, when a bush has been plucked continuously for twelve months or two years, and the shoots get clogged and form what are called crows' nests, and it almost ceases to flush, this is a sign of weakness, or exhaustion. I do not think it is anything of the kind. It is in my opinion simply a sign that the bush wants pruning, if you want it to flush. For when it is pruned, what happens? It grows with increased vitality, and flushes again for another couple of years, when it again calls upon the planter to prune it, if he wants it to flush. At one time, I thought that frequent pruning was injurious, but subsequent observation and reflection convinced me that it was not so.

I have seen Cinnamon bushes cut down annually for cropping purposes, for fifty years, and they grew up again with increased vitality, and these bushes, grown apparently in the poorest soil, had been treated in the same way for fifty years previously by the Dutch. Moreover I have seen yew, privet, and thorn hedges, in England, which had been cut down, and trimmed, for hundreds of years, without shewing any signs of being injured by the operation. I think, therefore, that an exhaustion of the soil, from nourishing the bush, and old age will alone diminish the vitality and flushing powers of the tea plant, after it is pruned. The longevity of the tea plant, in suitable soils and climates, is still undefined.

As an illustration of its vitality, I may mention a surprising incident within my own knowledge. In 1860 the Agent of my firm at Chittagong sent a large quantity of tea seed to Ceylon. This was planted in a nursery amidst coffee plants; the field of coffee was abandoned in 1862 and with it the nursery of tea. Twenty years afterwards the Chena—20 feet high—was felled, and burnt off, and apparently all vegetation was destroyed. With the first rains, wonderful to say, the tea shot up most luxuriantly, as if it had only been cut down, whilst all the other plants burned off were killed!

C. S.

P. S.—I have written the above, because I notice that many experienced planters talk of giving the plants *rest* by not plucking them. If they could send them to sleep thereby, like Rip Van Winkle, it might have that effect; but that sort of rest means increased exhaustion of the soil, by converting a small leaf-bearer into a large fruit-bearer.—C. S.

TEA: OVER-PRODUCTION AND ITS REMEDIES.

HOW THEY ARE AFFECTED BY CURRENCY.

Hill Grove Hotel, Coonoor, Nilgiris, Feb. 23.

SIR,—I have lately visited Bombay, Calcutta, and Madras, and I am now confident from all I have been able to hear that the Government must either sacrifice its Indian exporting industries or its currency policy; and (I say) exporting industries, because an industry like that of coal is not at present affected as it is produced and sold in silver. Were there no artificial rate of exchange the struggle between India and her industrial rivals would be determined by the relative cost of labour, and India having cheap labour would well be able to hold her own. But the Indian Government compels its producers to pay 1s 4d for a rupee while the competing countries can purchase one for 11½d. When prices were high India could still continue to struggle through under a disadvantage of about 25 per cent, but with low prices profits made either vanish or descend to a very low level. Even taking the rupee at 12½d the difference between that rate and one of 1s 4d would entail on the Indian producer a loss of £583 on every £4,000 worth of an exported article. But the producer could live on £583 per annum till better times came round. Without that sum he must starve, or at any rate approach that disagreeable condition. The ultimate point of the struggle between India and her rivals is not one of the comparative cost of labour,

but the comparative rate of exchange, *i.e.*, between the natural state of exchange enjoyed by India's rivals, and the artificial rate created by the currency policy of the Government. And this artificial rate, by much worsening the position of the producer, naturally much lessens his credit. The profits and the credit of the producers having thus been heavily attacked by the Government, the ultimate result of the contest between them and their rivals in the competing countries cannot be doubtful. I do not wish to under-estimate the value of the various expedients which the planters propose to adopt with the view of relieving the pressure of the situation, but I would represent to them that, do what they may, the ultimate result must be dominated by the artificial advantages which the Government has conferred on India's rivals. The planters then should continuously press on the Government that it must either sacrifice its currency policy or its exporting industries; for it is absolutely impossible that it can have both. The planters, too, should practically understand that to move our governing countrymen, two things are necessary:—(1) a long continuous hammering to convince their reason, and (2) a still longer steady course of representation in order to move them into action.—Obediently yours,

ROBERT H. ELLIOT.

P.S.—I think it would interest many of your readers to look at the Silver chapter in my "Gold, Sport, and Coffee-planting in Mysore" (Archibald Constable & Co.). This was written in 1893 when the Currency Act was passed. I may mention that I have no pecuniary interest in the book.—R.H.E.

II—THE SERIOUSNESS OF THE SITUATION.

5, Dowgate Hill, London E.C., 8th Feb., 1901.

SIR,—I have read with interest the various expressions of opinion that have appeared in your local press with reference to the Rutherford-Rosling and other suggestions that have been put forward with a view to help the present unfortunate position of the British tea-growing industry. The majority of correspondents are satisfied to find fault, some even make the position a subject for levity, but very few appear to realise the true gravity of the situation now, and ahead of us, and the necessity there is for organisation amongst those dependent on tea growing for their livelihood. There can be no use in asserting that but for extensions, manure, and the rest, we should all be well off. The extensions have been made, and the results to be obtained by cultivation have been proved, and what we require is a remedy that provides an effective means of controlling the over-production which already exists and promises to increase owing to these causes. Some possessing favored properties at the higher elevations are inclined to the view that the true remedy is to allow natural causes to work a cure, but I venture to think that a policy of drift will in the end prove disastrous to everyone concerned. Financial credit will be shaken. The process of killing out the weaker estates will be a long-drawn one, and before abandonment every device of cheap production will be resorted to, which must tend to breed blight and disease and bring discredit on the whole industry. We have in British-grown tea an industry which has shewn itself so far able to meet successfully all its competitors. The industry, from an agricultural point of view, is thriving and healthy in every respect, the one thing at fault is the price, and that is the one factor that we have it in our power to control.

Surely then it behoves us all to give this matter our most careful attention, to give those who bring forward schemes of relief a careful hearing, and finally to give to that scheme which seems to be the best our heartiest and most loyal support. It must be borne in mind that we have to find a remedy effective both for the protection of high and low grown interests, and acceptable both to Ceylon and India, and this may seem difficult of attainment, but it is by no means impossible if the majority are determined to work together in the matter. The tea growing industry is easy to organise in comparison with numerous other complex interests that have been brought together and now exist as examples of what can be done by organisation.—Faithfully yours,

ALFRED BROWN.

MINES AND MINING IN INDIA.

Writing to the *Journal of the Society of Arts*, Mr. W Sowerby, C.E., says:—

The coal mines are of the greatest importance. Iron mining and smelting is surrounded with great difficulties, though there are vast deposits of iron ore of every kind and very rich in metal, but the climate and labour are unsuitable. Mr Henwood's visit in 1854-5 was on the suggestion of the late Colonel Drummond to establish colonies of iron workers in the Himalyas, but the question of the fuel put a limit to that experiment. The clearances of forest were too rapid, for it takes six tons of wood to make a ton of charcoal, and two tons of the latter to make a ton of iron; so the value of the wood would be about £15 which would be the cost of the iron for fuel only. Of the greatest importance is the development of the coal-mining. Seams of coal were discovered at the foot of the Himalayas, but the geological superintendent, the late Dr. Oldham, and Captain (now Sir Richard) Strachey discouraged the idea of further search. There are also indications of coal in Kattyawar, also oil, which the writer of this noticed when occupied there. While in Scindh, the late Mr John Brunton, C.E., found, mined and used some coal, which was tested on the Indus steamers, but it has been entirely ignored and remains unexploited. It is stated by Dr. Evans that when Lord Curzon visited the gold mines of Mysore he was very pleased to see the work and the forty thousand labourers. What, however, is that to 250 millions to find employment for in India. The occupation of the masses must be agricultural, but on a better system than that which is now being followed. Then so far from the country being over-populated, as suggested in the discussion, double the population might be maintained. Unworked and unproved gold mines can never be correctly valued; the prices asked and obtained in 1882-3 for Indian mines was ridiculous. Gold mining is best in the hands of Government in an old country like India. In new colonies they attract emigrants, but in India no such immigration is either desirable or feasible.

THE TRAVANCORE TEA ESTATES CO., LD

The ordinary general meeting of the Travancore Tea Estates Company, Limited, was held at the offices of the company, 20, Eastcheap, on Monday last.

The chair was occupied by Mr W Mackenzie, Chairman of the company.

The Secretary (Sir William Jonston) read the notice convening the meeting.

The Chairman, in moving the adoption of the report and accounts, said—I do not think we ought to begin the business of our meeting without expressing our deep regret at the death of Her Majesty the Queen and of our sympathy with the Royal Family. Since our last report death has deprived us of the very useful services of our colleague, Mr Tod, and Mr Talbot, another of our directors, is abroad. The report and accounts you have had for some days and, unsatisfactory though they be, may, I presume, be taken as read. The crop was 128,000lb more than the previous year, because of the larger area being plucked. But for the absence of rain, which caused the Indian famine, and the excessive downfall of the last two months of our financial year August and September, when 3in fell daily on an average, the yield would have been considerably larger. In the report you are told that 1,702 acres gave 304 lb. per acre. But as you will see, one-half of that area was immature tea. For the current year the estimate from the same area is 743,000lb. I say the same area, because nothing of any consequence can be gathered this year from the 1,500 acres, more or less, planted in 1898. During the first three months of this financial year to end of December the crop from the 1,702 acres has been 49,000lb. more than for the same three months of last year. More serious even than the falling-off in crop from the bad weather has been the fall in tea prices. In the early half of the year we were doing well, and we were quite justified in paying the interest on preference shares to end of March. But the unprecedented fall which has occurred since then has upset all calculations, and has brought the average price from 7·18d in the previous year to 6·20d, a drop of ·98 of a penny per lb. The average price of Ceylon teas since June has been 7·48d, against 8·42d the previous year, and Indian tea is also all but 1d lower for same period. The yield we anticipated four years ago has been realised, except during the final months of the last financial year, when first drought, causing famine, and then an excessive rainfall lost us nearly 50,000 lb of tea. The cost of production from mature tea has been less than we expected, the price alone is responsible for our present difficulties, Another misfortune we have to record is the loss of about £2,800 in advances to native contractors. This money was given out three to four years ago, when we were preparing for the large development in acreage made in 1898. The acting manager who advanced this money has been resident in Travancore for many years, and was well acquainted with the native contractors. He was home here a year ago, and was then confident he could recover three-quarters of the money on his return. As yet, however, he has not been able to do so. This advance system is universal in the East, but is seldom attended with loss in Ceylon. In some of the great tea-producing districts of Northern India, however, it is quite understood that labour costs R100 per head for a coolie, and it is seldom that any of this is recovered. In Travancore we trust this may be our only loss under the heading The result of the several misfortunes I have mentioned, the loss of crop from bad weather, the fall of 1d in price and the loss on these advances, is a deficiency in our resources of about £6,000. To cover this we propose to issue £7,000 of Preference shares and if your and our property is to be protected something equivalent to this is absolutely necessary. At the present moment the average price of our tea is 1½d less than last year's average of 6 20d, and this means that it is being produced at a loss. How long this is to continue we, as directors, have no better means of forming an opinion than you have. Were it to go on for years, then it were better not to throw away more money but to allow the properties to pass to the Debenture-holders. But, pessimistic as we all are at present, I doubt whether anyone in this room really believes that prices are not to rise within a reasonable time. The laws of supply and demand will assert themselves. Planters will not go on producing 500 lb to 600 lb per acre at a loss of 1d per lb, when they can produce 400 lb of a better tea which may show no loss. The demand is increasing all over the world. The crisis has been brought on us by the great success of the tea-planting industry four to six years ago, which induced companies to open up hundreds of thousands of acres, the produce of which has swamped the market during the last two years. I might say much more in explanation of the position, and as encouragement for the future. But I refrain, as we have no wish to persuade shareholders against their convictions. I do not even wish to advise them. As directors we can merely make suggestions. It is for you to decide. But failing this scheme, the only resource known to us, short of handing over to Debenture-holders, is a reconstruction, or rather a re-arrangement, with a call on the shares. The sum we propose to raise, viz., £7,000, is what appears to us sufficient for the present. But it must be clearly understood that, with a continuance of present prices, the whole of this might be used up in paying debenture interest, and the difference between cost of production and sale prices; but such a condition of things, though we cannot, of course, say it is beyond the range of possibilities, we can only hope may not arise as the enormous tea industry of India and Ceylon would in that case also became involved in a general disaster. We show you in our report what we expect from the working of the company if our teas fetch 6½d per lb. when the land is in bearing. The price is 2d per lb. below that at which the company's teas stood when the company was formed, and if you think that is a fair and reasonable figure to assume when production and consumption have adjusted themselves, then I think you should have no hesitation in subscribing for your share of the extra capital. The matter rests entirely in your hands, however, and you must judge for yourselves. With regard to the debenture issue, I may state that when the company was formed there was not the slightest intention of issuing debentures. It was stated in the prospectus that the first issue of shares was for the purchase and working of four estates, therein named, aggregating 2,371 acres. It was also stated that further lands would be acquired and developed. This latter entailed the raising of more capital, and the total acreage is now 7,163 acres. The directors considered that the issue of debentures presented the best and cheapest form

of raising the necessary capital. The directors were of opinion that the company from the first would be a success, and there would be no difficulty raising ordinary and preference share capital when it was required, but as the price of tea gradually fell and tea investments were not in public favour they saw clearly it would not be possible to obtain the necessary capital from the shareholders. The contemplated acreage of development was very materially curtailed, but what was begun had to be brought to completion. The directors have given constant and anxious attention to the affairs of this company from its inception to the present time, without fee or reward of any kind, and respectfully maintain that as they could not foresee that Travancore teas would fall from 8.50d per lb. (the price when the prospectus was issued) to an average of 6.20d per lb., the present state of the company's finances is solely attributable to low prices. Anyone experienced in tea cultivation knows that £35 per acre is a reasonable price at which to bring tea into bearing with buildings and machinery, so it cannot be said the shareholders' money has been squandered. No new clearings of tea have been made for the last two and a half years, and it is practically three years since the land was opened out, roaded, and drained, for planting up. The properties are good, and have been well cared for, and the whole position entirely rests with the future market price of the produce, which we must all hope will soon take a turn for the better. I now move the adoption of the report and accounts.

Mr. H K Rutherford, in seconding the adoption of the report and accounts, said :—I would add a few words to what has fallen from your Chairman, and to recount the history of this company. It was started in 1897 as a tea company to develop and open out tea estates from jungle lands, having as a nucleus a certain acreage of land under tea. The land was reported on most favourably by the Ceylon manager of the Ceylon Tea Plantations Company, a gentleman of very high standing and experience in tea cultivation—and we have no reason, even at the present moment, to doubt the capabilities of the land to be less than he estimated. The principal vendors were your Chairman and Mr Knight, our manager in India—two gentlemen of the highest probity. The price paid was a reasonable one, and I believe they could, had they been anxious to do so, have sold these properties for cash to others, but they were desirous of retaining a large interest in the concern, as they had absolute confidence in the potentialities of the property. That interest your Chairman afterwards considerably increased by purchasing a large number of shares. Your Directors, from their intimate connection with tea, shared in the confidence of the Chairman, and had not the slightest hesitation in investing and joining in the management of the company. Let us now consider why results have fallen so much under our anticipations. There is one fact very patent, that it is not over-capitalisation that is the cause, as the price at which our estates stand is a fair normal cost for opening out and equipping tea properties, and therefore the company stands at practically bed-rock price without inflation. When we negotiated for these properties exchange stood at 1s 2½d, and the price of the teas at 8½d, and at the present time the former is 1s 4 15 32d, and the latter 6¼d. When I have stated that simple fact I have stated the whole of our case. I do not know if any shareholder has taken the trouble to apply the condition of exchange and the price of tea in 1897 to the accounts in this report, but if so you will find that, had these two factors held good, instead of showing a loss we would have earned Debenture and Preference interest and 7 per cent on the Ordinary shares, and further, if you continue the application to the estimate of crops which it is practically certain the estates will yield, the Ordinary shares would earn something like 50 per cent. dividend. I ask you, therefore, as reasonable men, even if after allowing what one would consider a safe discount in the 1897 conditions of exchange and price of tea, if it can be said any of us—either we as directors, or you as shareholders—went rashly into this venture. Shareholders may complain today of minor matters of finance in our accounts which in a successful concern might have been looked at as virtues, but, believe me, the real crux of our position is the price of tea. If you believe this state of things cannot continue in the tea world very long, then you ought to keep this company afloat. It has potentialities if tea recovers, and if you stick to the ship I have no doubt whatever that you will reap a fair return in due course. So serious is the position of tea producers at the present moment that efforts are being made to bring all into a co-operative movement to reduce the output of British-grown tea for this season in India and Ceylon. If we make no profit whatever out of our estimated crop of 743,000 lb. of tea, then our debit balance, after paying Debenture interest, will be some £8,200, and therefore the £7,000 lb. we ask you for would not suffice, and we would again require to come to you. We do not wish to call upon you for one penny more than necessity demands, and it becomes a question for you to decide whether in the meantime it would be better to make this call in the hope that it may be sufficient to tide us over, or at once re-arrange the company. No one could have foreseen the difficulty, and we must leave the matter in your hands.

Mr. Dangerfield thanked Mr. Rutherford for his remarks, and stated that, although the position was an unfortunate one, the explanations given would, he felt sure, meet the views of the shareholders. He also asked how the required capital was to be raised.

The Chairman stated that that Directors would leave the shareholders to decide how that was to be done. They were, however, prepared to put it, *pro rata*. The position of the tea market was accentuated since the report was drawn out. The market might fall again [illegible]y, and they could not say what might happen. They did not anticipate a month ago what had now happened. That being so, the Directors would not pledge themselves that the amount as stated in the report would be sufficient. The call would be spread over a number of years, and would be made as easy as possible.

The resolution for the adoption of the report and accounts was then put to the meeting, and carried unanimously.

Mr. D Reid proposed the re-election of Mr. Rutherford as a director. He remarked that in doing so it was no easy task he was asking Mr. Rutherford to assume. He had always carefully watched over the interests of the Company, and

had devoted much time and thought to their interests. They had been deprived of the assistance of Mr Mackenzie, the chairman for a greater part of the year, as that gentleman had been travelling in Canada and the States with the object of trying to raise the consumption of Indian and Ceylon tea. He (the speaker) joined the board of this Company four years ago, believing that it had good prospects, and that tea from Travancore would realise a good price. The Directors could not foresee that such a mass of tea would be thrown on the market. He thought it would be very unfortunate for the shareholders to throw up the sponge. He believed the depression would pass away, as a great industry, such as the tea industry, could not go on as now. The Directors were all willing to lend a helping hand. They did not get any fees, and the item for keeping the books, &c., was a mere trifle, so there was no such thing as bolstering up the company.

Mr Dangerfield, in seconding the proposal, remarked that the shareholders could take it for granted that the whole of the board were acting in good faith. He had perfect reliance on them, and believed that if the company could be pulled through they would do it.

The resolution for the re-election of Mr Rutherford was then unanimously agreed to.

On the proposal of Mr Worthington, seconded by Mr Dangerfield, the Auditors were re-elected.

The proceedings closed with a vote of thanks to the Directors.—*H and C Mail*, February 8.

THE LIMITATION OF TEA PRODUCTION—A TEA PLANTER'S VIEW.

To the Editor of the *Home & Colonial Mail.*

SIR,—May I ask your permission to make a few remarks on this important subject, more particularly from a planter's point of view? The various conditions are sufficiently complex to make the problem somewhat difficult of solution. I believe, however, that a means may be devised which may be practicable and acceptable to producers. The following scheme may to some extent, perhaps, assist in the matter:—

ESTABLISHED OR MATURE GARDENS.

1. All factories whose tea crop of season 1900 realised, say, 11d per lb gross be exempt from restriction.

2. A graduated scale of restriction as to yield for all estates whose tea crop of season 1900 realised an average price of less than 11d per lb at, say, from 5 per cent. for the finer, graduating to 12 per cent. for the coarser teas.

3. All five-year-old planting to be classed as mature, and four years and under to be exempt from restriction.

ENTIRELY NEW PLANTATIONS.

4. All new gardens of five years' planting to be limited to the average yield per acre of mature plant of the district.

5. All four years' planting and under to be exempt from restriction.

In making these varying distinctions consideration has to be given to the following:—

a. The makers of high-class teas have not contributed unduly to the present glut and therefore should be exempt.

b. The factories producing low-class teas are mainly responsible for the present over-production, and should rightly be subject to restriction.

c. In the case of new planting of four years and under it would obviously be unfair to tax such planting to repair a difficulty to which it had not contributed to any appreciable extent.

6. In order to calculate quantity to be produced by each garden a return of crop of season 1900 to be sent in to secretary of the respective Tea Association, together with statement of new planting for the years 1900, 1899, 1898, 1897, and in the case of entirely new gardens return of area planted in 1896.

7. All gardens manufacturing a special make of coarse tea sent down under a separate mark, not the recognised mark of the garden. to furnish statement of such teas produced in season 1900 to secretary of their Tea Association.

8. All factory marks to be registered with the Tea Associations.

A form of agreement as between two contracting parties could be adopted by which each producer covenants with the joint Tea Associations as representing the whole or any one of the members of the Tea Associations to carry out the engagement as to allotted output, &c., under pain of whatever penalty may be agreed upon.

It occurs to me that the agreement contracted should extend over at least two years—with provision, of course, for such modification as circumstances may render necessary, for little good will be gained by merely clearing away the present accumulation in order to make room for another. The present producing capacity of Indian and Ceylon gardens is far in excess of requirements. It will be necessary, therefore, that production be controlled until it is overtaken by requirements. This brings me to a subject about which I will, in this letter, only remark that the time has arrived when the scope and sphere of influence of the Tea Associations of India and Ceylon should be extended.—Yours truly, JAMES HODGES.

Erdington, Birmingham, Feb. 12, 1901.

PRODUCE AND PLANTING.

THE CRISIS IN TEA.—The Chancellor of the Exchequer is, we fear, not in a mood to lend a kindly ear to proposals to reduce taxation, but the two members of a sub-committee appointed by the Indian Tea Association (London) have thought it advisable to direct public attention to the causes which have contributed to the present crisis in tea. In the circular issued by these gentlemen, and reproduced in another column, it is mentioned that Sir Michael Hicks-Beach will be asked to reduce the Government royalty on tea from sixpence to fourpence per pound. In the circular it is pointed out that the closing of the mints and the fixing of the rupee at the artificial value of 1s 4d by the Indian Government have increased the cost of production by some 20 per cent, while the addition of twopence to the duty last year, instead of coming out of the pockets of the consumer, has fallen almost entirely on producers. A still more cogent argument is that the home Government reaps an annual harvest of six millions sterling from tea, and the total revenue at home being 120 millions, the impost is out of all proportion to other taxes levied. The object of the circular is to invite all those who are interested in the production of tea to help the movement by at once communicating with their local members of Parliament (irrespective of party), asking them to support Sir Henry Seymour King in his endeavour to get the tea tax reduced to its former rate of 4d per lb. We trust that the statements put forward will direct public attention to the grievances of the tea producer, who sees that unless some remedy for the existing state of things is found the important industry developed with such care, patience, and expenditure of capital is seriously threatened.

A TRADE VIEW OF THE TEA POSITION.—"As a natural consequence of the rapidly increasing production of tea within the last few years—that of Indian alone expanding from 148,252,000 lb. in 1897-98 to 182,144,000 lb as the estimated crop for 1900-01—the market here has been so over-supplied with the article," says the *Grocer*, "that steps have been recently taken by a Select Joint Committee of the Indian Tea Association

to call upon the proprietors and agents of estates to restrict the output of tea in India and Ceylon during the current season, and so bring the general supply more under control than it has been hitherto. Besides attaining unmanageable proportions, the quantities of British-grown tea have contained a much greater percentage of common, spurious, and undesirable qualities than ever before known, and in this respect cultivators of tea in Ceylon have been the principal offenders. In November last it was remarked in our London trade report that 'Some very inferior teas have lately been shipped from Ceylon, and such quality has been termed by the trade a disgrace to the island. It would be better if these teas instead of being shipped were destroyed in Ceylon, as buyers here have refused to have anything to do with them, and the Customs are apparently at fault in allowing this rubbish to pass.' Having seen and examined the teas in question we can vouch for the truth of the above statement, certain samples bearing a close resemblance to cinnamon chips, as coarse as chaff or stubble; and one firm of Mincing Lane brokers advises the planters to 'dig into the ground a large quantity of this common red stuff as withered leaves, or to utilise it, after burning, in the form of ash.'"

AN AMERICAN VISITOR.

LARGELY INTERESTED IN CINCHONA SUPPLIES.

Amongst the most recent arrivals from the Far East is Mr. F. L. Seely of St. Louis, Mo., U.S.A., who has come from America *via* Java, travelling for the Paris Medicine Company of St. Louis and London. Mr. Seely has been spending a month at the Government plantations, Java, and has shown us photographs of some splendid trees of *Ledgeriana* and plantations of *Succirubra* which give no less than 12 per cent yield. Any tree, in fact, that gives less is rooted out from the plantation. In one case as much as 16 per cent was yielded. Mr. Seely is travelling in the East to gain some idea of the quantity of supplies of quinine that are likely to be forthcoming in the future, for the Company of which he is Secretary and Treasurer buys an immense quantity annually. Mr. Seely informed us that the preparations sold by it are advertised in every paper in the States, $225,000 being spent annually on advertising alone. Mr. Seely proceeds to Kandy on Monday, and, after visiting estates with Cinchona here, will proceed to the Nilgiris, before returning to the States.

THE COMMON BIRDS OF BOMBAY

By E H A.*

"Eha" is well-known by the volumes "The Tribes on my Frontier," "Behind the Bungalow" and "A Naturalist on the Prowl"; and this latest volume will be welcomed by all who wish to know about the birds that abound in the land of their adoption. To enjoy this book, one does not need to have previous scientific knowledge; the author has watched the habits, haunts and customs of the birds, and in an easy conversational way he tells the reader enough to enable him to recognise and name the feathered songsters around him. Boys are always ready to hunt for birds' nests. Let them take this book out of doors with them and follow up the mother-birds sympathetically, watch them, their ways, their haunts, and the study may be quite as useful to them in after years as that of Latin or French.

The telling pen-and-ink sketches in this book are an additional help to the identification of birds, while the English names so freely given, make the stories life-like and real. The volume has 195 pages, and the chapters (32 of them) follow the natural orders:—The Birds of Prey, the Perching Birds, the Moaners, the Scrapers, the Stalkers, and the Swimmers. Among the Perching Birds or Insessores, the most interesting and best-known are the Woodpecker and the Coppersmith, the Sunbirds and the Hoopoe, the Babblers (which include The Seven Brothers) and the Bulbuls and Orioles. In the introduction, birds are very sympathetically described, thus:—"Though beasts rank above them anatomically and physiologically, birds have in many respects a higher nature. Their wits are quicker, their thoughts sweeter, their tastes finer, and their passions and appetites less gross. With respect to manners and morals they stand on a higher plane altogether. . . . The great majority of them are monogamous during the nesting season, and many pair for life and become devotedly attached to each other. Brides are won by courtship. . . . Much of their time is spent in the duties, or pleasures, of the toilet. Many of them bathe regularly in water, while others prefer a dust bath. Nature gives them an entire new suit every year, sometimes two, in which case the summer and winter suits are often different. If there is any difference in the sexes, it is the male which is most beautifully, or at least most brilliantly, dressed; as is fit, for he is in the front ranks, fighting and making love, while her place is in the sweet backgrounds of life, and quietness and modesty adorn her best." We must quote the description of the Sunbird:—"Our common Sunbird (Arachnethra Zeylanica) seen at a distance and in a dull light, is a tiny bird of a dull brown colour, except on the breast and lower parts which are yellow. But see it at close quarters, with the sun shining on it, as its admiring mate sees it; the top of its head glitters with a hue which Jerdon defines as 'bright, metallic, glossy green,' while Mr. Oates calls it 'metallic lilac.' Its throat and the whole of its back glow with the tints of an amethyst, the shoulders and wings are of the richest maroon red and the tail is black. The admiring mate is herself dressed in the beauty of simplicity. She also is yellow on the under parts, but paler than her lord, while her head, back and wings are of a greenish dusky colour. They are a loving couple and I think the union is for life, for one seldom sees a single Sunbird. Belt and other observers have stated that Humming-birds frequent flowers less for the nectar than for the little insects in them. I am sure this is not true of the Sunbird. It eats plenty of little insects, especially spiders, but it seeks flowers for their nectar. Sometimes it hovers in front of them, like a hawk moth, exploring their recesses with its long tubular tongue; oftener it clings with its minute black feet, throwing its lithe body into all manner of acrobatic attitudes, while it thrusts its slender, curved bill into each tube in turn. And 'between whiles' it skips about, slapping its sides with its tiny wings, spreading its tail like a fan, and ringing out its cheery refrain, *ching-ching, chikee, chikee, chikee*, as if it could not contain all the happiness that filled its little frame." For the description of the nest and the eggs, our readers must refer to the book itself.

* Thacker & Co., Bombay. Price R4·50.

THE LONGEVITY AND VIGOUR OF TEA.—The veteran colonist who writes above the initials "C.S." has some interesting experiences to relate in the letter which we publish elsewhere. The old Kandyan who declared that the tea-bush was a regular jungle plant, nothing could kill it,—was not far wrong.

IMMENSE RUBBER AREA ACQUIRED IN MEXICO.—The newest company organized to go into the planting of rubber exclusively is the Obispo Rubber Plantation Co., which has been incorporated under the laws of New Jersey. It will acquire a large plantation known as "La Republica," in the state of Oaxaca, Mexico, a property consisting of 9000 acres, of which at least 8000 acres will be planted entirely in rubber, 200 trees to the acre. This will form probably the largest rubber plantation in the world.—*India Rubber World.*

AGRICULTURAL INSTRUCTION FOR VILLAGE YOUTHS.

IN our last issue we took over two interesting articles on this subject but had no opportunity of adding our own views. As might have been inferred, however, from the absence of comment on our part, we are entirely in sympathy with the movement that has found favour in England, as well as the Australian and West Indian Colonies, and do not hesitate to say that the system of agricultural instruction in rural schools may be expected to be as fruitful of good results in Ceylon as elsewhere.

It must be borne in mind that what is aimed at by this new scheme is not technical education in the science and practice of agriculture, but rather the directing of the young mind to the study of nature, so that the natural surroundings of the village lad may present new beauties and fresh interests and possibilities to him and reconcile him to the so-called dull monotony of a country life.

To most of our village population the germination, developement and reproduction of vegetation are a mystery, and the realization that plants are living and breathing organisms performing all the vital functions of such, must come as a great revelation to the majority of our rural friends. A knowledge of the forces of nature as they work through plant and soil, the wonderful adaptations of these forces and the interdependence of the mineral, vegetable and animal kingdoms is what is wanting in the villager who sees nothing of design and recognises little of the sequence of cause and effect in his "common round and daily task." Under such circumstances is it any wonder that he becomes discontented with his lot, which he is wont to associate with manual labour pure and simple? Jerome, in one of his books, has a beautiful passage referring to the companionship of plants. It is this companionship which the new scheme seeks to establish in order that the life of the rustic may present a new charm for him which so long it lacked, and his environment appeal to his instincts in a manner that he has never experienced before.

An intelligent knowledge of nature in her various phases should be so much power in the possession of the youth of the village, which he will be able to use to his advantage. With such knowledge his lot will be infinitely more congenial to him, his prospects more cheerful and (what is devoutly to be wished) his inclination will be to remain amid his rural surroundings and apply himself to the cultivation of the land with a new zest. Thus it is to be hoped will the people of the country be led to develope its agricultural resources, and while the cities are relieved of the congestion of disappointed place seekers, the country be made the home of the industrious and contented husbandman bent on making the most of his newly-recognised opportunities. We trust the hope will be realized.

RAINFALL TAKEN AT THE SCHOOL OF AGRICULTURE DURING THE MONTH OF JANUARY, 1901.

OCCASIONAL NOTES.

The *Agricultural Magazine* for August, 189 , contains an article entitled "The Queen as Agriculturist," in which a short history of Her late Gracious Majesty's connection with the agricultural interests of England was given. In concluding the article we said, "Whatever be the fate of English agriculture in days to come, the Royal family will be sharers in its prosperity or adversity, the bright traditions of the reign of Queen Victoria will be honoured and observed for many a day." King Edward the Seventh may confidently be expected to protect the interests of the agriculturist, for has he not already earned the sobriquet of "the Friend of the Farmer"?

At the great Scottish Annual Show held last year in Edinburgh, Sir John Gilmour speaking at a meeting over which King Edward—then Prince of Wales—was presiding, referred to His Majesty as "a Prince who followed so well and fully in the footsteps of Her Gracious Majesty, our Beloved Queen, and who had so thoroughly gained for himself the title 'The Friend of the Farmer.'"

The following typical little speech by His Royal Highness delivered only a few months ago will be read with interest at this time when the Prince that was is King, and the Duke of York who is about to visit our shores is the Prince Elect :—

The Prince of Wales, in responding to the vote of thanks, said : My Lords and gentlemen—and, may I say, brother agriculturists?—I am deeply sensible of the kind terms in which Sir John Gilmour has proposed the vote of thanks to me. I am also most grateful for this cordial reception and the kind words which fell from the Lord Provost of this great city. I need hardly tell you, as I mentioned to-day already, the great pleasure it gives me to be your President at this great Show at Edinburgh at the close of the present century. One has often heard of walking in one's father's footsteps. Well, in this instance, gentlemen, I am walking in my son's footsteps. In 1893 you kindly elected him to be President for the year. He had a good reason for not coming, for he married a wife and could not come. But he came the following year, and presided at your Show at Aberdeen. I shall always look back to this visit with the greatest pleasure and satisfaction, and for the kind and cordial way in which you received me. I hope before I leave to-morrow to have had an ample opportunity of seeing all that is of interest in this Show. I am glad to think that it has reached already the one hundred and fifteenth anniversary of its existence. At the Centenary Show, I believe, there were the largest exhibits of horses, sheep, cattle, and swine, amounting to 1,536. I think we have done very well this year when we have exhibits in these classes, as I believe, to the number of 1,417. I can only allude for a moment to the Scottish Agricultural Benevolent Institution. It has only been in existence for two years. From what fell from the lips of Lord Mansfield, it is indeed an institution, though young, which is, I think, well worthy of your support. Anything that can be done to alleviate the suffering of the agricultural class, male and female, deserves our sympathy and philanthropic efforts. I need hardly say it will give me great pleasure on this occasion, if I may do so, to give a donation of £50 towards it. I shall not keep you longer, as I think on these occasions that brevity should be the soul of wit ; but I thank you once more for your kind reception, and I can assure you how proud I have been to take the chair to-day.

Veterinary Surgeon Chinniah's paper on the Branding of Cattle—reprinted from the pages of the *Agricultural Magazine*—has appeared in pamphlet form, and been favourably noticed by the local press.

Mr. A. F. Broun, Conservator of Forests, has left the Island on leave, his duties being discharged by Mr. Alfred Clark of the same department. The work of the Forestry School will be in abeyance during the absence of Mr. Broun, who during his holiday, expects to revise his lectures on Sylviculture and Forest Utilization with a view to their publication. The students who have just left the Forestry School are Messrs. D. W. Goonesekere, C. A. Bartlott, S. Lovell, W. Amerasekere, C. S. Fernando and J. T. de Silva. A Syllabus of the School, printed at the Government Press, is now available.

We welcome back to the Island Mr. W. E. Davidson, C.C.S., who proceeded to Paris as the Delegate of the Ceylon Government at the Great Exhibition of 1900. Mr. Davidson has done much to advance the agricultural interests of the Colony, and his excellent handbook prepared for the Paris Exhibition is a compendium of the latest and most reliable information about Ceylon and its industries.

We have to thank Mr. A. Chinniah, Veterinary Surgeon, for a photograph of the Calculus, the operation for the removal of which is described by him in his contribution on Crystology to the present number. Considering the weight of the stone (3⅜ oz.), its circumference (7¼ in.), and the fact that the patient was discharged within 3 weeks, we cannot but commend the skill with which the operation was done and the successful antiseptic after-treatment.

Comparing the rainfall at the School of Agriculture and the Fort, we find a difference of about 8 inches for the year 1900, the larger rainfall being in the Cinnamon Gardens.

Some months ago a question was asked in the Press with reference to the most approved way of placing a thermometer for getting reliable readings, and if we remember aright, it was given as the opinion of an expert that the nature of the shade provided was not of consequence. We should like to state that we have found an appreciable difference between the readings under a Calicut-tiled roof and one covered with the old-fashioned half-round tiles, and we have no doubt that there will be a difference where the roof is of galvanized iron and again of olas. It would, therefore, be as well that there should be a uniformity of conditions, particularly in the tropics, as regards the conditions under which thermometers are kept.

In this connection we might refer to a case where the conditions under which rain was registered could not possibly have helped to give correct readings. The rain gauge, in this case, was so placed that a "Union Jack" fluttered on its pole above with the result that the precipitation of rain must have been seriously interfered with.

CYSTOTOMY.

By Veterinary Surgeon A. Chinniah, Colombo, Ceylon.

History.—A black waler gelding pony about 14·2 high, eight year old, the property of W. W. Kenny, Esq., of Colombo, was brought to my surgery with the history that the animal had been passing highly blood-coloured urine. It was treated by me for some time with palliative drugs as in the case of ordinary Haematuria; but when the case assumed an obstinate nature I suspected that there must be some mechanical agent—such as a Calculus—doing the mischief, as the symptoms suggested. The animal was examined per rectum, and the presence of the Calculus was diagnosed with certainty.

Symptoms.—There was painful straining during micturation, but at times the urine passed was of normal colour and consistency. After brisk exercise the urine passed contained blood corpuscles and pigments in abundance, and the expression of the patient during the passing of urine indicated great pain. The appetite was all throughout good, and there was no noticeable rise of temperature. As soon as the proper diagnosis was arrived at, I informed the owner that the animal must stand the operation, which, if it succeeded, was the only means of saving the life of the beast.

Modus Operandi.—The instruments taken for the operations were scalpels, sharp-pointed bistoury, Symes' artery forceps, bull-dog forceps stone forceps, Gullion's lithotritor, male catheter, and the female washing catheter.

The animal was thrown on the near side and general anaesthesia (chloroform) was administered. The penis was pulled out, washed and lubricated, and the catheter was passed and the penis retained all throughout in this position by an assistant told off for the work. The off-hind leg was drawn a bit in front, I took my position just near the croup. The tail was washed antiseptically and given in charge of another assistant to be kept in the desired position. An incision was made two inches below the rectum along the middle line of the perinium downwards. When the urethra was reached, the sharp point of the bistoury was introduced into the tube (urethra) which was eventually slit open to admit the passage of the forceps. When the forceps were in the bladder the stone was grasped with the, assistance of my left arm in the rectum. Several attempts were now made to remove the stone without performing cystotomy or lithotrity, but they proved futile.

I finally decided to perform Cystotomy. The bistoury was passed along the urethra into the mouth of the bladder, and guided by my left hand per rectum to prevent any rectal fistula, an incision was made dividing the mouth of the bladder, prostrate glands and (unavoidably) the pudic artery. The latter was promptly caught and ligatured. This made the operation simple, and with the help of the hand, per rectum, the removal of the Calculus was easy enough.

The Calculus weighs 3⅜ ounces and its circumference is 7¼ inches. It is not spherical, but convex on both surfaces, and the margin unbroken and round. The outer layer is apparently composed of Phosphate of Lime and the urine of Oxalate of Lime.

After Treatment.—The bladder was washed with a tepid solution of Boracic acid. The wound was antiseptically treated and painted with Iodoform and Eucalyptus oil and left open. The animal micturated soon after the operation and passed urine both through the wound and along the natural passage. The passage through the wound ceased after the first day of the operation, 27th January, 1901. The wound was daily dressed antiseptically with what I call an antiseptic emulsion, composed of Boracic acid, Carbolic acid, Iodoform, Eucalyptus oil, and Glycerine, and satisfactory progress continue to be made. The animal was discharged from my Surgery today, 16th February, 1901.

THE VELVET BEAN.

The following notes from the *Queensland Agricultural Gazette* refer to results of experiments made in Mackay, Queensland, by Mr. A. A Ramsay:—

The velvet bean was planted at the beginning of November, 1899, and the analysis refers to the crop at 31st April, 1900. The crop was sown in drills.

Date of Planting—4th November, 1899.
Date of Harvesting—3rd April, 1900.
Yield in tons per acre—18·250.

The analysis gave of moisture	...	72·370 %

THE "UNCULTIVATED" OILS OF CEYLON.

Among the exhibits sent from Ceylon to the great Exhibition at Paris last year was a small collection of the most useful oils produced by forest trees and uncultivated plants. Some of these from their importance as medicinal agents are worthy of special attention and examination by experts, and it is with the object of bringing them to the notice of medical men and others who may be interested in this subject that we are led to enumerate the oils and write short notes on their medical virtues, as known to the natives of Ceylon and India.

1. DUHUDU OIL.—This is the product of *Celastrus paniculatus* (Celastraceae) sometimes called the oleum nigrum plant, from the dark colour of the oil. The plant is of the nature of a scandent shrub. It is from the seeds that the dark red oil is extracted. This is acrid and pungent in flavour, and has a tendency to deposit a fat when kept. Medicinally the oil is used in India for beri-beri, rheumatism, dropsy, and also as a diuretic, diaphoretic and nervine stimulant. Among the natives of Ceylon it is considered to strengthen the brain, purify the blood and cure internal and external sores and boils, while it is highly recommended for external application in rheumatic and gouty pains.

2. IRIYA OIL.—This is the product of *Myristica irya* (Myristicaceae) a moderate-sized evergreen tree. The oil from the bark is used in the treatment of sores.

3. WAL-DEL OIL.—This is the produce of *Artocarpus nobilis* (Urticaceae) a fairly large-sized tree. The juice of the bark is used to kill maggots and is said to be used in other ways in cattle treatment. The oil which is not made mention of in any botanical works I have had access to, is, as I am informed, extracted from the seeds, and as the outer shell of the seed when roasted is considered good eating, the oil is probably also edible.

4. MAKULU OIL.—This is the product of *Hydnocarpus venenata* (Bixineae) a large tree generally found on the banks of rivers. The seed yields an oil of the consistence of soft butter, known in South India (Kanara) as *Thertag* oil. Externally the oil is used in cutaneoms diseases, and is considered specially valuable in the treatment of leprosy, being recommended as a substitute for the well-known chalmugra oil (got from *Gynocardia odorata*).

5. DIVIKADURU OIL.—This is the product of *Tabernaemontana dichotoma* (Apocynaceae) also known as the "forbidden fruit," and "Eve's apple. The tree is small in size. The oil is extracted from the seeds and is used in the treatment of sores and ulcers.

6. MADOL OIL.—This is the product of *Garcinia echinocarpa* (Guttiferae),—a tall tree of the forests in the lower mountain zone. The thick oil is extracted from the seeds. Thwaites mentions that it is burnt but yields a poor light. The leaves and bark are used in dropsical affections, and also as a vermifuge: no mention is, however, made of the oil being medicinally employed.

(*To be concluded*).

MILCH CATTLE AND THEIR PRODUCE.

The latest volume of Transactions of the Highland and Agricultural Society contains an instructive paper entitled "Lessons of a Milk Record," in which important deductions from a properly-kept record (which every dairy farmer should have) are given by the writer for the benefit of dairy farmers.

In keeping a milk record it is recommended that the milk should not be measured but weighed, and the most conveuient way of doing this is by using a spring balance in which the scale is so set that no deduction is necessary for the can.

There are so many causes that affect the quality and quantity of milk that only a long series of records and tests can be expected to supply data for reliable deductions. Rough treatment, exposure to rain and rough weather, change of diet, change of milkers, rapidity of milking, length of interval between milking, unusual excitement, or sickness, all tend to temporarily affect the richness of milk and the quantity yielded; while it is the case that some cows' milk varies considerably *without any apparent cause.*

Cream tables for testing the percentage of cream in milk are to be at once put down as absolutely unreliable. In testing the milk of 20 cows, it was found that while the percentage of cream as

shown by setting varied from 4·7 to 20·3, the percentage of butter fat varied only from 3·2 to 5·6, these limits being exceptional, the majority of fat records approximating 3·5 per cent, while the cream records were very inconsistent.

En passant, the writer gives his vote in favour of separating over cream raising, in view of the former producing more constant and larger percentages of cream and butter.

The most convenient and rapid way of ascertaining the percentage of fat in milk is by using Dr. Babcock's machine.

The percentage of fat as recorded in the case of a milking herd through a period of 5 years varied from 3·45 to 3·68.

The milk was richest when the majority of cows were pretty far on in the period of lactation, exemplifying the old story that when the quantity decreases the quality increases.

Again, cows were found to give richer milk when young than they did after they reached the age of 8 years or upwards. At the commencement of keeping the record in 1894 it took 25 lbs. of milk to make 1 lb. of butter, and with the same cows 5 years later the quality had degenerated so much, that 27½ lbs. were required for the same result. Such facts as these, it will be admitted, are most important to the dairy-farmer, and prove the value of milk records.

As regards milking we are told that a good milker will get more and richer milk than one who does not put life into his work. Continental experiments all point to one conclusion—rapidity of execution and thorough stripping are essential to good dairying. But, as remarked before, there are cases which baffle the most careful experimenters, where every condition may be favourable and yet the precentage of fat is abnormally low.

With milking records available we have the best means of selecting not only our dairy cows but also (what is of more importance) the stud bulls of the farm. It would, therefore, appear that a little time given to the testing of milk as to quantity and quality (it need not be every day, but regularly) will greatly facilitate our own work and the work of others in the dairy, and help to make dairying a more exact science than it is at present.

QUARTER-ILL.

This is a highly fatal disease that effects the bovine species. It may effect other animals but this must be considered as very exceptional. The cause of the disease is the entrance into the system of a specific germ—the quarter-ill bacillus. The germ is most readily found in the tumours localised in the muscular parts of the body, such as the quarter, shoulder, &c.

Quarter-ill, like distemper in the dog, affects young growing animals. There is a difference of opinion as to a plethoric or non-plethoric condition being predisposing, but the majority of authorities rather incline to favour the former view. Very young calves and full-grown animals are, as indicated above, never attacked except under the rarest circumstances, so that it is to be inferred that the muscular tissues are at a particular age a fit habitat for the bacillus, which thus enters the animal organism from the soil where it first exists.

The most striking symptom is the localised, painful and hot swellings generally about the quarters and shoulder. The chief character of these tumours is the crackling sensation they impart to the touch—due to the pressure of gas within them. As a rule, lameness follows, depending in degree on the localisation and severity of the tumours. Fever and other indications of derangement in the healthy condition of the body are apparent on examination.

There may be said to be three methods of treating quarter-ill :—(1.) The depletory method recognises the use of purgatives, setoning, &c., which are employed also as preventative measures. (2,) Preventative inoculation advocated by French Veterinarians. (3.) Natural prevention, which consists of preserving the surroundings of the animals in a condition that is distateful to the bacillus.

The germ, like most other germs thrives in the soil under certain conditions, and therefore may be said to have a limited existence in it. Contaminated soils would be most prolific in the propagation of the germ, so that it is only reasonable that the greatest precautions should be taken in the disposal of quarter-ill carcases which are best burnt or buried deep with lime.

Land, on which quarter-ill has prevailed, should be well drained and cultivated, though it is problematic whether it is safe to allow the stock to consume the fodder : under any circumstances it is best to prevent all young from grazing on such land.

INTRODUCTION TO ENTOMOLOGY.

(Miss Eleanor A. Ormerod.)

Larva (*Maggot, Grub, Caterpillar, &c.*).—If an insect-egg about to hatch is held against the light, or examined as a transparent object by means of a strong magnifier, it will be seen that there is a speck inside which increases in size and becomes more regular in shape daily, until it is too large for the egg to contain, when it breaks through this thin film which serves as an egg-shell, and often begins life by eating it. This is the larva. It is usually hatched from an egg, but sometimes is produced alive (as some fly-maggots, or Aphides during the summer months). When it is coloured and has many feet, it is usually called a caterpillar; white fleshy larvae, such as those of many Beetles or Flies, are commonly known as grubs or maggots; such as resemble the parent insect are usually known by the name of this insect; but the term of "worm" or "slug" is objectionable, as it leads to confusion.

Larvae differ very much in appearance: some are legless, cylindrical, or blunt at the tail, and tapering at the head end, with the head (which is soft and furnished with hooks by way of feeding apparatus) capable of being drawn some way back into the maggot; many Fly-maggots are of this kind.

Some larvae are legless or with the mere rudiments of a pair of legs on each of the three rings behind the head, fleshy, smallest at the tail, and furnished with distiuct head and jaws; such are some kinds of Beetle—and Wasp-grubs; others are strong and fat, a few inches in length, with three pairs of legs well developed—as the Cockchafer grub.

The caterpillars of the Butterflies and Moths are often beautifully marked, and have for the most part a pair of articulated feet on each of the three segments behind the head, and pairs of fleshy appendages called sucker-feet on some of the other segments and at the end of the tail, not exceeding sixteen in all. These "Sucker-feet" enable the caterpillars to hold firmly to the twigs they frequent. Proceeding onwards still by number of feet, the caterpillars of the Sawflies will be found in every case (Corn Sawfly, *C. pygmoeus*, excepted) to have, besides the three pairs of true feet, five, six, or seven pairs of sucker-feet, and also the pair at the end of the tail (known as the caudal pro-leg).

Sometimes, as with Grasshoppers, Locust, Aphides or Green Fly, Plant Bugs, &c., the young in the first stage—whether produced alive or hatched from the egg—much resembles the parent, that is, has a distinct insect shape, of head with horns, trunk or thorax, furnished with six legs, and abdomen; and differs mainly in size and in being wingless; but, whether in this shape, or what is known as grub, maggot, or caterpillar, or whatever kind of insect it may belong to in this stage, it is scientifically *A. Larva.*

In this larval stage the insect feeds voraciously and often grows fast: the skin does not expand beyond certain limits, and when this point is arrived at, the larva ceases feeding for a while; the skin loosens, cracks, and is cast of by the creature inside, which comes out in a fresh coat, sometimes like the previous one, sometimes of a different colour or differently marked. This operation is known as moulting, and occurs from time to time till the larva has reached its full growth. The duration of life in the first or larval state is various; in some instances it only extends over a week or two; in some (as with the wireworm and caterpillar of the goat moth) it lasts for a period of three, four, or five years.

As far as observations go at present—that is to say, with such kinds as have at present been obscured—larvae are not injured by an amount of cold much beyond what they are commonly called on to bear in this country, but they are liable to injury from over supply of moisture, whether from sudden rain in warm weather or from full flow of sap of their food-plant, and in this point of their constitutions we have a principle that may help much towards getting rid of them.

When the larva has reached its full growth it ceases feeding, and (in the forms known as caterpillar, grub, or maggot) it usually either goes down into the ground and forms a cell in the earth, or spins a "cocoon" (that is, a web) round itself of threads drawn from the lower lip (as in the well-known silkworm-cocoon), or in some way it makes or seeks a shelter in which it changes from the state or *larva* to that of *pupa*. These various changes are not mere matters of curious enquiry, but can be used very serviceably, in prevention of recurrence of attack.

COMPOSITION OF INDIAN COWS' AND BUFFALOES' MILK.

Agricultural Ledger (Calcutta), No. 19, treats of this subject.

The information on the composition of Indian Cows' and Buffaloes' Milk is very meagre. One analysis of cows' and one of buffaloes' milk was published in the Proceedings of the Madras Board of Revenue in 1892 (*vide* Board's Proceedings No. 387, dated 25th May, 1892), and the average composition of each kind of milk is published in Mr. Collins' Agricultural Chemistry, page 28. The latter were deduced from a number of analyses which Mr. Collins made at Poona, but unfortunately the Note Books containing the details were lost in transit by rail in 1898.

The composition of cows' milk has been found in England to be very regular for different breeds, and to possess a relationship between the several component parts for all the breeds. It is of importance to know whether these relationships hold good for Indian breeds of cows, and to what extent they vary in the case of the buffalo.

The analyses published by the Madras Board of Revenue are only two in number, and are therefore quite insufficient for the purpose in any case. In addition, however, they show the proportions of Proteids and Lactose to be altogether different from anything met with in the case of English cow's milk.

Mr. Collins found, on the other hand, that the composition of the milk of the several breeds of cows at Poona coincided with that of English breeds. The milk of the buffalo he discovered was characterised by a high proportion of butter-fat and considerably more Proteids than that of the cow. Owing to the loss of the detailed notes, it seemed to me very desirable that the work should be repeated, and in the following pages I give the composition of the milk of some of the cows and buffaloes at Poona, and that of the cows at the Saidapet Agricultural College Farm. This information is set out in the accompanying Statements Nos. I., II. and III.

It has been found in England that (*a*) there exists a relationship between the Solids-not-Fat, the fat and the specific gravity, and (*b*) between the proportions of Proteids, Lactose and Mineral matter (ash), and that these relationships are constant, within certain limits, for all the several breeds.

Regarding the former, several formulæ exist. That of Richmoud (*vide* "Analyst," Vol. XX., p. 57) is expressed, thus:—$S = 25G + 2F + 14$. Another recently worked out by Leonard is expressed:—$F = \frac{4}{5}(T - \frac{9}{4}) + (0{\cdot}3 - 0{\cdot}004T - 0{\cdot}01G)$ where T = Total Solids; S = Solids-not-fat; F = Fat; G = the excess of gravity over 1,000. The latter formula gives results which differ only slightly from Richmond's. The proportions of

Proteids, Lactose and Mineral matter in English cows' milk has been found to be approximately as 9 : 13 : 2. It is of interest then to consider in how far those relationships hold good for Indian cow's milk.

In the case of the Poona cows' milk, the specific gravity was not determined, but this was done for the milk at Saidapet. The results are set out in the lower part of Statement No. III., from which it will be seen that the relation between the Solids-not-fat, the Fat and the Specific gravity is the same as it is in the milk of English cows, the variation between the proportion found by analysis and that calculated by Richmond's formula lying within the error of experiment. Similarly, in the lower part of statement No. II. is set out the proportion of Solids-not-Fat found and calculated for those buffalo milks in which the specific gravity was determined at Poona, and here also the relationship holds good and is the same as for English and Indian cows' milk.

Regarding the relation between the proportions of Proteids, Lactose, and Mineral matter, Statement No. IV. exhibits it for two samples of the average milk of the Poona cows, for three samples of the average cows' milk at Saidapet, and for the average buffalo milk at Poona.

Statement No. IV.

	Proteids.	Lactose.	Mineral matter.
Cows' milk, Poona, average, 6th February, 1899	9·20	12·86	1·94
Cows' milk, Poona, average, 28th February, 1899	9·25	12·72	2·03
Cows' milk, Saidapet, average, 29th March, 1900...	8·66	12·25	2·09
Cows' milk, Saidapet, average, 4th April, 1900 ...	8·71	13·25	2·04
Cows' milk, Saidapet, average, 7th April, 1900 ...	8·74	13·31	1·95
Buffaloes' milk, Poona, average, 6th March, 1899	10·78	11·33	1·89

From these figures it is evident that in this respect also, the milk of the Indian cow corresponds to that of the English one, and that the proportions of Proteids, Lactose and Mineral matter is approximately as 9 : 13 : 2. In the case of the buffalo milk the relationship is different, that of Proteids being distinctly higher, that of Lactose lower than in cow's milk,

Generally, it may be said that :—(*a*) The milk of the Indian cow containsa high proportion of butter-fat, varying from 4 up to 6 per cent. Buffaloes' milk contains usually much more, varying from 5 or 6 per cent up to as much as 10 per cent. (*b*) The percentage of Proteids (Albumen and Casein) usually varies in cows' milk from 3·1 up to 3·5 ; in buffaloes' milk from 3·5 up to 4·3. The buffalo, Nevasi, was exceptional. Such proportions as 5·0 and 5·2 per cent of Proteids as stated in the Madras publication referred to, are never found ; (*c*) The percentage of milk sugar (Lactose) in the cow's milk varies from 4·4 to 5·0, and in buffaloes' milk it is present in about the same proportion. It is never so low as is stated in the Madras publication ; (*d*) The percentage of Mineral matter in the cow's and buffaloe's milk varies from about 7 to 8 as it does in English milk.

ORIGIN OF THE SEEDLESS ORANGE.

The first seedless orange-trees were apparently freaks of nature. Their counterparts have never been found. In the summer of 1872 William F. Judson, United States Consul at Bahia, Brazil, heard an account from natives of a few trees in the swamps on the north bank of the Amazon, some sixty miles inland, that bore oranges without seeds. He had heard of the starting of orange groves in Florida, and he believed that seedless orange-trees were well worth experimenting with there. So he sent a native up the river to cut some shoots of the trees and get some of the fruit. When the native returned the Consul was delighted with the specimens. Forthwith he sent six of the orange-tree shoots, carefully packed in wet moss and clay, to the Agricultural Department at Washington for propagation. The trees did not excite as much attention in the Department as the enthusiastic Consul had expected. Two of the shoots, which were no bigger than horse-whips, died from lack of care in the Department grounds, and the others were almost forgotten in a few months.

In the winter of 1873, Mrs. Horatio Tibbetts, who was collecting specimens of fruits and shrubs suitable for experimental propagation in southern California, among other things got from the Department grounds the four surviving orange-tree shoots from Brazil. The trees reached Mr. Tibbets safely at Riverdale, Cal., a week later and were immediately planted. That was in December, 1873. Two of the shoots died from neglect and another was broken and chewed up by a cow. Five years passed and the two surviving trees came into bearing. In the winter of 1878-9 they bore sixteen oranges, the first seedless oranges ever grown in North America. The specimens were carried about southern California, and shown to all ranchmen and fruit-growers. There were many who doubted whether the trees would annually bear such royal specimens of orange culture. Nearly everyone believed that the fruit would become coarse and tough in a few years more. So the second crop was awaited with curiosity among the neighbours. There were about a box of oranges in the second yield, and they were even better than those of the first crop.

The planting of groves of seedless orange trees propagated from buds from the two original trees on the Tibbetts' place began in earnest throughout southern California in the winter of 1882.

A year or two after the orange trees that had been propagated from the Tibbetts' trees began to bear, and they themselves furnished tens of thousands of navel buds as good as those from the two original trees. Then the first navel orange groves began to bear fruit, and from that time the boom in naval orange groves has continued.—*New York Sun.*

GENERAL ITEMS.

A curious way of dwarfing plants for table decoration, says an exchange, is to take an orange, and, having cut a small hole in the peel, to remove all pulp and juice, fill the skin thus emptied with some coconut fibre, fine moss, and charcoal, just stiffened with a little loam. In the centre of this put an acorn, date stone, or the kernel of any tree that it is proposed to obtain a dwarf from. Place the orange peel in a tumbler or vase in a window, and moisten the contents occasionally with a little water through the hole in the peel, and sprinkle the surface with fine wood ashes. In due time the tree will push up its stem through the compost and its roots through the orange peel. The roots must then be cut flush with the peel, and the process repeated frequently for some time. The stem of the tree will assume a stunted gnarled appearance, making it look like an old tree. When the ends of the roots are cut for the last time, the orange peel which curiously enough does not rot, may be painted black and varnished. Has any one given this a trial? It is worth trying whether it will succeed with us in a tropical climate.

Mr. Ranglaret, a Frenchman, has discovered a very simple means of stopping bolting horses. It consists of a pair of moveable blinkers fixed with the ordinary blinkers, and connected by means of a string which passing through a ring attached to the collar or saddle is held by the driver. On the horse bolting the string is simply pulled till the false blinkers close up the eyes of the horse so that he cannot see and stops bolting. It is said that experiments carried out before the French Minister of War proved entirely satisfactory.

The imperial cwt. of 112 lbs. may be taken in an average fed animal as representing 64 lbs. carcass or dead weight. Prime animals would give a larger percentage of carcass, perhaps as high as 72 lbs. in very choice bullocks, anp inferior cattle a less proportion down to 60 lbs. per cwt. live weight.

The following is recommended as the best ration for a horse during a sea voyage: 5 lbs. oats, 5 lbs. bran, 10 lbs. (about 3 cubic feet) hay, 8 lbs. straw, ½ gill vinegar, ½ oz. nitre, and 8 gallons water.

To avoid the labour of constantly stirring jam, in the course of preparation, place half a crown in the bottom of the cooking pan, before putting the fruit in. You will find (says the *Australian Farm and Home*) that the trouble will be overcome. The movement of the coin caused by the operation of boiling prevents burning quite as much as stirring will. Remember that the effect will be spoiled if any stirring is done.

The TROPICAL AGRICULTURIST

MONTHLY.

XX. COLOMBO, APRIL 1st, 1901. No. 10.

CACAO PODS AND THEIR SEED.

(By J. B. Carruthers, F.L.S.)

CACAO is grown for its seed, and the value of the fruit depends upon the quality and weight of the seed contained in it.

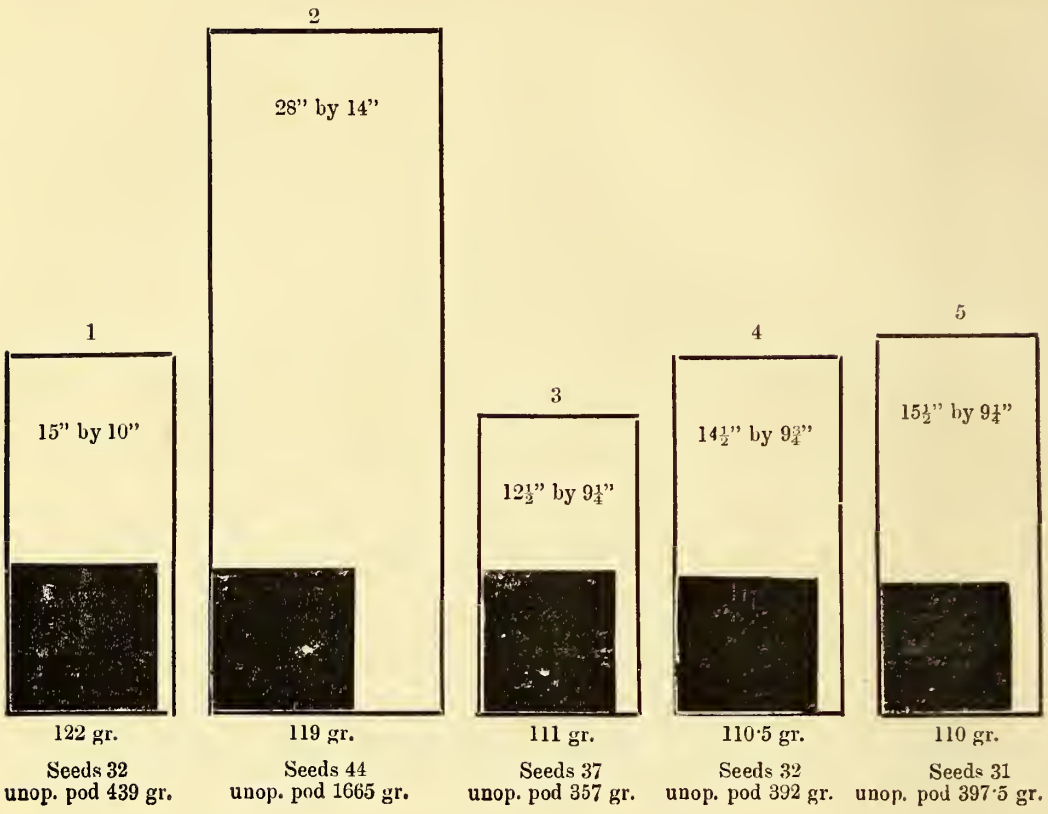
In selecting Cacao pods for seed planting, it is important to know if any external characteristics can be used as guides. As a rule, in Ceylon, Cacao planters have their individual methods of selection by colour, shape, size or other character. Thus, one man chooses the biggest pods, another the longest which have a knobby fruit wall, another those of a certain shade of colour.

In order to test the value of characters such as these, I have begun to measure and weigh a series of pods of different varieties, grown under varying conditions, and so far as my experiments have gone (only to the examination of some two or three hundred), the characters of size and weight of the fruit do not afford any criterion of the weight of contained seed, which is the only consideration to the planter growing Cacao for the market.

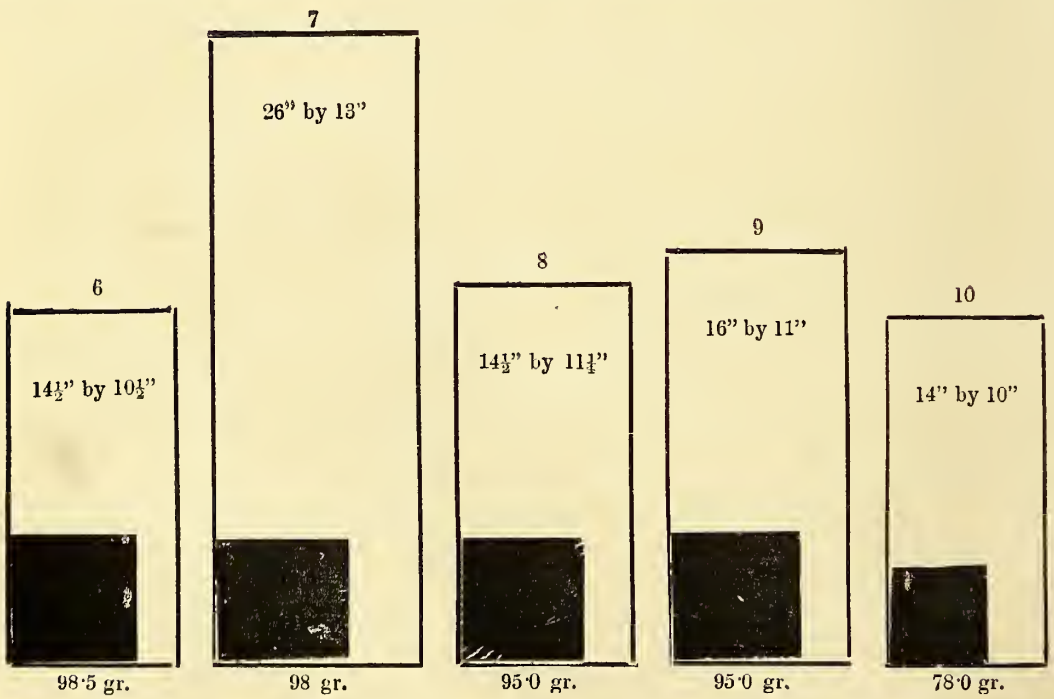
The diagrams (pp. 656-657) are drawn to scale, and they show so far as they go that the size of the fruit is due chiefly to the thickness of the fruit wall and gives no clue to the number or weight of the seeds in the pod.

The investigation of these and other pods points to the uselessness of any selection of pods for seed by external appearance. A more hopeful method and one calculated to improve the Cacao plant, is the selection of seed from parents possessing marked advantages over their fellows, such as abnormally large and regular production of fruit, *i.e.*, large number of pods on the tree or large number of heavy seeds in the pod, hardiness against varying conditions, production of fruit at a suitable dry season of the year, quickness in growing to maturity and the fruit-producing period. These and similar advantageous qualities in parents should by selection be perpetuated as far as possible.

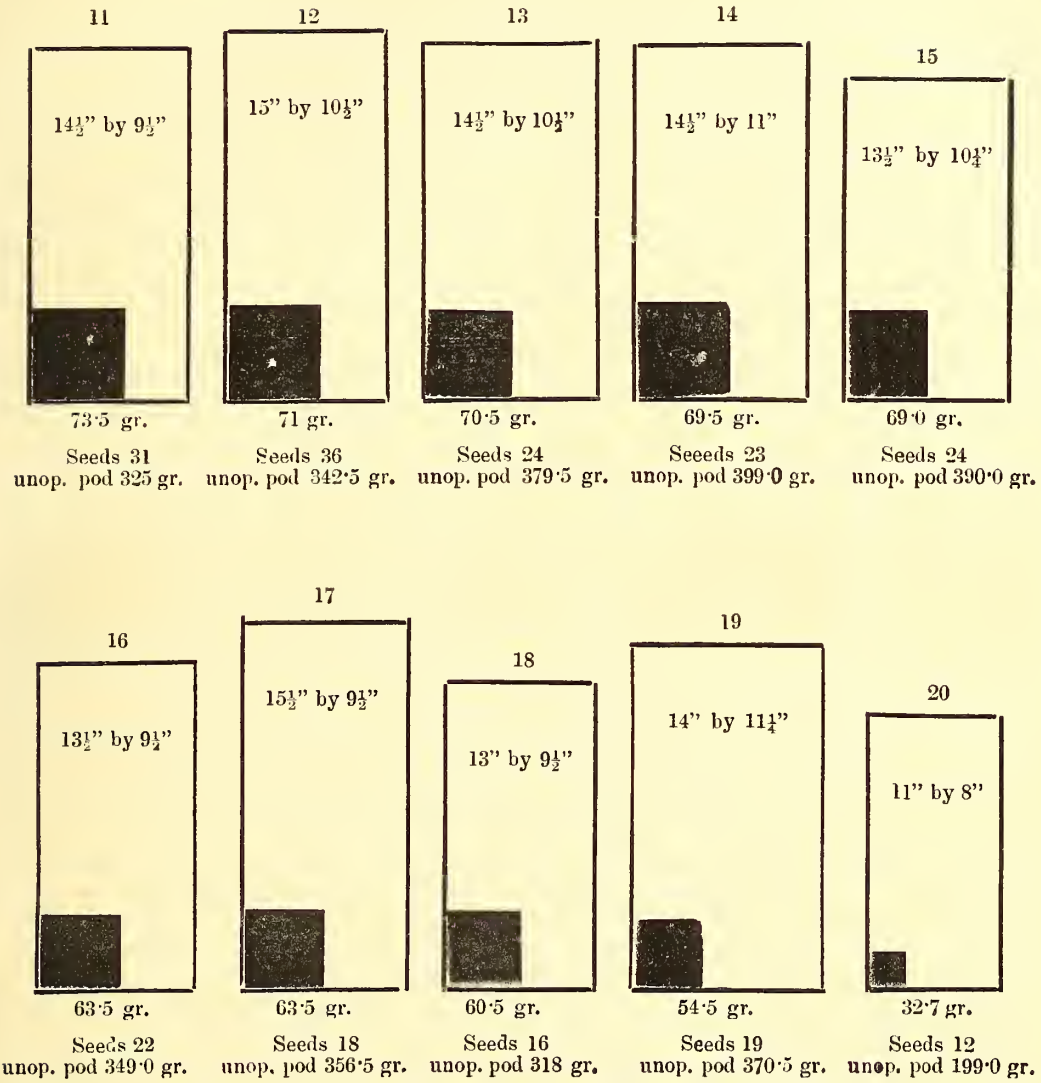
When a larger number of records of these measurements and weights of the fruit of Cacao have been collected, more definite knowledge will be gained as to methods of selection by fruit characters. The diagrams, however, of these twenty fruits will perhaps induce planters to make such observations, and so gain information as to the nature of the Cacao pod which would give the best return to the cultivator and the least waste, so that selection should be carried on in the right direction. The waste material in pods 2 and 7 is in the proportion of 13 to 1, whereas in 1, 3 and 4 it is less than 4 to 1. The magnificent proportions of pods like these two (2 and 7) must be considered in the calm light of the commercial value of the seeds which at once brings them on a level with pods of an average or even diminutive size, and the tree in producing the latter is not using its forces to form so much material which brings no monetary return.



122 gr.	119 gr.	111 gr.	110·5 gr.	110 gr.
Seeds 32 unop. pod 439 gr.	Seeds 44 unop. pod 1665 gr.	Seeds 37 unop. pod 357 gr.	Seeds 32 unop. pod 392 gr.	Seeds 31 unop. pod 397·5 gr.



98·5 gr.	98 gr.	95·0 gr.	95·0 gr.	78·0 gr.
Seeds 30 unop. pod 410·5 gr.	Seeds 36 unop. pod 1462 gr.	Seeds 31 unop. pod 447·5 gr.	Seeds 27 unop. pod 526 gr.	Seeds 37 unop. pod 394·5 gr.



The figures in the unshaded part of the diagrams are the two perimeters, *i.e.*, measurement round lengthways and circumference at the thickest part, in inches. The figures under the shaded part are the weights in grammes of the seeds in the pod. The total weight of unopened pod and number of seeds are given below each figure.

TEA SALES IN COLOMBO LAST YEAR.

The local "Times" has been compiling the estate and total averages for last year's Colombo Sales. On the whole, the result is encouraging for supporters of the Colombo Sales, and we trust the day is not far distant when through the abolition of the absurdly anomalous import duty (accompanied by expert Customs inspection) the business and importance of the local Sales may increase, leading to the arrival of more buyers to what ought to be one of the greatest tea markets in the world. Meantime here are the results :—

THE AGRICULTURAL CHEMIST TO THE GOVERNMENT OF MYSORE.

The following are Extracts from the Report of the Agricultural Chemist to the Government of Mysore for the year 1899-1900:—

LABORATORY.

As a Chemical Laboratory is a matter of prime importance to an Agricultural Chemist, several plans for such a laboratory were prepared by the Agricultural Chemists and State Geologist. The plan selected by the Government provides for the chemical work of the Geological Department being done in the same building as that containing the laboratories and office of the Department of Agriculture. In it the present "Geological Laboratory" is included. The fixtures are being made similar to those of the laboratory of the Central Experimental Farm, Ottawa, Canada, and will, it is hoped, prove as eminently satisfactory as those from which they were copied. Before building the necessary additions, the Department of Public Works are kindly undertaking to make all the changes required in the present building to adapt it to the new requirements. This wil give the Chemist some space in which he can begin analytical work before the entire building is completed—a kindness for which he is very grateful to Goverument and tbeir Department of Public Works. The chemical apparatus has beeu selected from various catalogues so as to get the best value. As always, a portion of it had to be made to order to meet special requirements or to embody improvements which appeared desirable. A large portion of it has arrived.

SAMPLES.

Chemical.—Twenty-five samples taken in connection with the study of various problems of general interest to coffee planters are awaiting analysis. In addition to these, ten miscellaneous samples have been received. To dispose of this work only will require at least three or four months, and numerous other samples are waiting to be sent as soon as there is some prospect of their beiug taken in hand.

Mycological.—Eleven samples of plants affected with fungoid diseases were received and disposed of as circumstances permitted. All that could be done was

to recommend the application of Bordeaux mixture where practicable.

Entomological.—Three parcels of larvæ of injurious insects were received during the year. For leaf-eating insects not protected by a covering, an application of Paris green cannot be too strongly recommended, provided care is taken not to poison domestic animals or men. Paris green is an arsenite of copper which has been largely used as a pigment; and is now one of the most popular insecticides. It may be applied either as a spray when suspended in water (about one ounce to ten gallons of water) or dusted on the plants in the dry condition when mixed with 100 times its weight of perfectly dry fine flour or better still "land plaster" (Gypsum) if it can be got. Since the close of the year, several samples of injurious insects and plant diseases have been received. These made it necessary to visit several fields, and have led to a practical demonstration in applying Bordeaux mixture. Paris green could not, unfortunately, be obtained at the time. In the near future it may be necessary to write a bulletin on the subject. When sending insects it is absolutely necessary to provide them with some of the leaves of the plants on which they are feeding.

Much more important than the correspondence, in the way of giving information, were the interviews in the office; and more important still, the talks and lectures on the estates, the villages, or the fields and gardens visited when on tour. But of these no record is kept. In response to an invitation from the United Planters' Association a general outline of plot experiments and some of the fundamental principles of manuring were discussed at their meeting held in Bangalore.

TOURS.

The three principal tours undertaken during the year were:—

1. To Bidadi and Closepet,
2. To Koppa.
3. To Shimoga District and Mangalore.

A tour to Koppa was undertaken in July to become personally acquainted with the effect of the very heavy rains which usually occur during that season of the year in the Malnad Districts. But owing to the practical failure of the monsoon, not even a moderately heavy shower of rain occurred during the stay of nearly two weeks. The time was occupied in noting what could be seen of the diseases of coffee and arecanut. These diseases are of a fungoid nature. The condition of the moisture which largely influences the growth of the specific fungus, especially Koleroga, is doubtlessly one of the most important factors in the spread of the diseases mentioned. But as the vitality of the trees has doubtlessly something to do with resisting the attack of the disease, the task of finding a remedy is not absolutely hopeless.

The coffee works at Mangalore were visited to see the last step of the preparation of coffee for the European market.—*Planting Opinion.*

RICE CULTIVATION.

(From a Correspondent.)

Some weeks ago you published a letter from your South Mysore correspondent which contained, amongst other interesting details of planting news from that locality, an allusion to the fact that some Mysore planters are embarking in rice cultivation, in conjunction with that of their coffee estates. An agricultural undertaking of this description requires practical experience in order to insure its being profitably conducted, and the following particulars may therefore prove useful to those who have not essayed the cultivation of paddy, or to such as have still something to learn on that subject, the more so, as with the acute crisis through which the coffee industry is now passing, every estate proprietor will hail with satisfaction any facilities for augmenting the revenue accruing from his holdings. There are probably many blocks held by planters which either include lands within their boundaries suited to the profitable growth of paddy, or which, from their close proximity to the latter, can be conveniently taken up from Government, or from private landlords, while the advantages of utilising such areas for raising an article of consumption available for the labour employed, both in the growth of the cereal itself and on that engaged on their estates, are so obvious, that it seems strange rice has not hitherto been more largely tried by European planters.

There are two methods by which paddy can be successfully grown in the planting districts, namely, by indigenous, *i.e.*, local labour and by imported coolies, the former being preferable, as it is continuously available, and better trained to this special work. The scale of remuneration ruling for local labour employed on wet lands usually consists of a daily payment in the form of doles of grain, a man receiving for a full day's work approximately 4 lbs. of paddy, and a woman 3 lbs., while one anna in cash is disbursed weekly to such of the former as may have laboured for not less than five days in each week, and twice a year all hands are presented with a couple of coarse white cloths, on the anniversary of their two principal festivals, in April and August. Imported labour is, however, paid in specie at the rate of 4 annas per man and 2½ annas per woman daily. It may be assumed that, on the average, the value of paddy in the planting districts does not exceed R2 per maund, of 82 lbs, and upon such hypothesis the rate of remuneration earned by imported labour is rather more than twice as high as that paid to local coolies. When, therefore, framing an estimate of the necessary outlay incidental to a paddy cultivation, it will be fairest to strike an average, and charge the account with the labour at an all-round rate of 3 annas per diem. A forty-acre stretch of wet land suffices to grow seedlings raised from 40 maunds of carefully winnowed seed grain, and a herd of 40 ploughing buffaloes are essential to work the block successfully. In addition to the initial outlay connected with the first season's cultivation, the cost of bunding the land may have to be met. Good ploughing buffaloes are procurable at about R15 apiece, so that the outlay on the latter, and on the seed grain, would amount to R680. If, however, the land taken up possesses the requisite bunds, from the last ryot's occupancy, no block disbursements on earth work is required, and as this is the rule on tracts thoroughly suited for growing rice, it seems scarcely necessary to allow for special expenditure under this head. The accruing manure from a herd of 40 buffaloes should suffice to liberally fertilise every portion of the land at least once in two years, or to manure half the extent in each season, while the animals are utilised (1) for ploughing and harrowing, and (2) for threshing, *i.e.*, treading out the grain.

Irrespective of the block expenditure on seed grain and on buffaloes, as well as on a few ploughs and tools, a sum of about R750 would be required to cover the whole of the first season's expenses, up to hulling the grain, while in the following year it would be unnecessary to incur any outlay under the three former headings. Paddy, on an average, takes about four months to mature, and on some lands, where special facilities for perennial irrigation are available, two harvests can be raised annually; but as a rule on hill tracts a single crop of grain is grown in each season. There are a couple of methods of cultivating paddy profitably (*a*) from seedlings, and (*b*) by sowing the seed broadcast; but the yield, where the work is well done, is far more satisfactory from the former than the latter plan, and no weeding is required for seedling planted paddy lands, whereas on areas treated the other way weeds and grass cause some loss and trouble. As regards the

yields from paddy grown from seedling, or under the broadcast system, a crop of from 15 to 30 fold is obtained on liberally cultivated lands of the former, but rarely in excess of 15-fold from the latter. The following details of expenditure connected with cultivating a compact block of 40 acres of wet land are based on actual experience of such work, but the figures quoted as regards yield are slightly below what it has been found that fairly good land will bear in favourable and in bad seasons. Where the area treated is smaller, the outlay under all heads except that of supervision is necessarily minimised :—

Block Outlay.		R.	
To cost of 40 ploughing buffaloes	...	600	
To cost of purchase of 40 maunds of seeds grain	...	80	
To cost of 12 ploughs and tools	...	30	
			710

Revenue Outlay		R.	
To herding 40 buffaloes	...	90	
To ploughing 40 acres of land each square, at least 6 times, before planting, as also cost of repairing bunds	..	270	
Application of manure	...	20	
Sowing seed in seed beds	...	40	
Reaping the grain ..	...	40	
Threshing and winnowing	..	40	
Overseer's salary ...	...	120	
Rent of land ...	...	100	720
			R1,430
Value of crop of 600 maunds of paddy, or 15 fold, at R2 ,, ...		1,200	
Value of straw yielded ..		250	
		R1,450	20
Balance profit	...		R1,450

It will be observed that the first season's operations show merely a nominal profit, because Block expenditure, amounting to R710, is added to current Revenue account ; but the former would not be required in the following year, and hence, the sum so shown would be approximately the net profit on the second season's operations, if the grain is reserved and used as paddy, but a far more lucrative result can be obtained by allotting a moiety of the paddy crop in the husk for the second season's contingencies, and by disposing of the other half as raw rice. The subjoined figures indicate how this scheme works out :—

Cost of hulling 300 maunds of paddy at 3 as per maund ..	R56-4-0	
Value of 7,200 measures of clean rice, accruing from 300 maunds paddy, refined, sold at the rate of 9 measures per rupee ..		R800
Net profit on hulling	..R744-12-0	
	R800-0-0	

The foregoing calculations, which have been framed upon data actually acquired from experience, demonstrate what a highly profitable undertaking rice cultivation can be made when conducted on approved principles, as the value of the produce, that is of 300 maunds paddy, and 7,200 measures clean rice, shows a large margin of profit over working expenditure, irrespective of the value of the straw itself. —*Madras Mail.*

THE DATE PALM (PHŒNIX DACTYLIFERA).

Undoubtedly, next to the cocoanut palm, the date palm is of the most value to man.

It is a beautiful and majestic tree, the stem forming a cylindrical column rising to a height of 50 or 60 feet. From the summit of the trunk it throws out a crown of leaves which are equally graceful in their formation and in their arrangement. We, in Queensland, should ultilise this beautiful palm not only for garden ornamentation, but for its fruits. One reason that this palm has not been more largely planted is that it is dicœcious, having the male flowers on one plant and the female or fruiting ones on another: One male plant will fertilise a number of female plants, but it does not appear that a male plant is absolutely necessary to induce a female plant to bear dates. It is probable that the seeds of the dates will, in such a case, not be fertile, but the tendency of the age is to produce fruit without seed. There are at the present time two date palms growing in Brisbane laden with fruit—one in the Botanic Gardens (an illustration of which is here given), and the other in the garden of the late Dr. J. Bancroft, in Ann street. The seeds of these palms may not be fertile, but that is of little moment—the fact remains that the date palm (*Phœnix dactylifera*) will fruit in Queensland, and that freely. This palm should be largely planted—in suitable districts—around water boxes, where they would in a few years form oases in tracts swept by hot winds, and in time they would become a real boon. They might also be planted on the islands along the coast. Plants can be raised from the seed of imported dates, but it is some years before such plants fruit. Offshoots taken from fruiting plants are best for planting, as these will fruit in about five years. A few years ago a number of suckers were imported and distributed by the Acclimatisation Society. Some of these should now be fruiting, and from them offshoots could be obtained.

There are several varieties of *Phœnix*, all of which are called date palms, but which are useless, except for decorative purposes, so care should be taken to obtain *Phœnix dactylifera*, all other kinds being useless for fruit-bearing.

In South Australia the planting of date palms has proved very successful. At Lake Harry (in the far north) the seedings are now from 3 to 5 feet high, and many plants of either sex have flowered. The Algerian palms have made great progress, and some are quite 10 feet high. There have also developed numerous suckers, such as Mr. Pink describes as best for transplanting. Good fruit has also been produced by several of the trees. The variety planted is the "Deglet Nour." At Hergott Springs the fruit has ripened for eight seasons. Here, there are 277 thriving palms. At Lake Harry there are 2,745, and at Oodnadatta 36. Our illustrations, for which we are indebted to the Conservator of Forests of South Australia, give a good idea of the plantation Hergott. —*Queensland Agricultural Journal.*

A NEW ASSAM TIMBER TREE.

By D. Prain, I.M.S., F.L.S., &c.

In October, 1886, Mr. Barker, of the Forest Department, called attention to the existence of a tree which he was unable to identify, occurring at the foot of the hills in the North Lakhimpur district and known to the Assamese as the "Sia Nahor." He had submitted specimens for identification to the Forest School at Dehra Dun, but having received no definite reply he sent a flowering example to the Calcutta Herbarium. Mr. Barker's specimen was not a very good one ; it sufficed, however, to show that while "Sia Nahor" belongs to the same natural order as the "Nahor" proper (*Guttiferæ*), it is not like "Nahor," a *Mesua* but a *Kayea*. The specimen sent was, as a matter of fact, tentatively referred to *Kayea floribunda*, a not uncommon tree in the lower hill forests of Sikkim, Bhootan, Khasia ! Cachar and Lushai, known in Cachar and Sylhet as "Kurun" (*Wallich*) or "Kurul" (*G. Mann*). The flowers of Mr. Barker's specimen were, however, so much smaller than those of *Kayea floribunda*, that it was clear from the first that "Sia Nahor" was at least a distinct variety of "Kurul."

Nothing further was heard at Calcutta of Sia Nahor for thirteen years when, in December, 1899, Mr. Young, Deputy Conservator, sent a set of specimens, this time in fruit, for identification. Mr. Young writes as follows:—"The tree is to be found on the north bank only, and is most plentiful immediately under the hills in the North Lakhimpur sub-division. This fact probably accounts for its absence from Peal's list of Assam Timber trees, as I understand his collection was confined to the south bank of the Brahmaputra.

"The tree is large, with a straight bole 60 feet and more to the first branches, bark grey, wood close-grained, hard and very heavy. It is said to be very good for structural purposes, but decays rapidly in contact with the soil."

An examination of Mr. Young's fruiting specimens made it clear that the Sia Nahor was not *Kayea floribunda*, but before preparing a formal description, fuller material was desirable. Mr. Young was accordingly asked to send flowering specimens to correspond with the fruiting ones already sent. With this request, Mr. Young very courteously complied in June, 1900. These plainly showed that in "Sia Nahor" we have to deal with a hitherto undescribed species of *Kayea*. To make this absolutely certain, the material now available was submitted to Sir George King, who has kindly compared the specimens with those in the collection at Kew and, in confirming the view that the species has not before been described, has kindly undertaken the joint responsibility as to its name. A formal description of the tree is given below.

Kayea assamica, *King and Prain*.—A tall handsome glabrous tree, bark grey, wood hard, close-grained; young branches pale, slender, cylindric. *Leaves* opposite, firmly coriaceous, entire, ovate lanceolate, base cuneate, apex shortly caudate-acuminate, nerves numerous, equal, slender, one-eighth of an inch apart, not prominent on either surface, upper surface somewhat shining, lower dull; length, 3·5—4·5 in.; width, 1·35—1·75 in.; petiole slender ·4 in. long. *Flowers*, in slender, terminal and axillary panicles, 3—6 in. long, branches of panicle short, slender glabrous, pedicels in flower very slender, ·2 in. long, in fruit elongated and thickened, bracts and bracteoles at base of branchlets, and pedicels 2 opposite small caducous. *Sepals* 4, imbricate, outer pair orbicular ·15 in. long, much enlarged in fruit, inner wide spathulate, apex rounded. *Petals* 4, shorter than sepals, suborbicular, ·1 in. long, thin, white. *Stamens* many, filaments free, capillary, longer than sepals; anthers globose. *Fruit* globose; covered by the thick accrescent calyx, tipped by the remains of the style, ·85 in. across. *Seed* solitary.

Assam; North Lakhimpur, near the foot of the hills, common, *Barker! Young!*

The species is most nearly allied to *Kayea floribunda* which, however, differs markedly in its much longer leaves, narrower for their width, with fewer more arching nerves which are much more prominent beneath; in its more copious racemes with larger flowers and in its much larger fruit which is 1·5—1·75 in. across.—*Indian Forester.*

PLANTING NOTES.

Sisal Hemp.—Some thousands of Sisal hemp plants have been planted round the island of St. Helena, Queensland's penal establishment. The suckers were put in about twelve months ago, and they now average about 5 feet in height, each plant having from 40 to 50 leaves from 4 to 5 feet in length. If any proof were wanted of the adaptability of our climate to this valuable plant, it is plainly furnished here. If the authorities of the island are provided with facilities to clean the leaves and produce the fibre during the ensuing twelve months, there can no longer remain any doubt as to whether the crop would pay or not, especially if accurate records were kept of the actual amount of labour and time expended from the cutting of the leaves to the baling of the cleaned fibre.—*Queensland Agricultural Journal.*

An Inch of Rain.—What does an inch of rain mean? Few persons have a definite idea. An acre, if calculated out, will prove to be 6,272,640 square inches. An inch deep of water on this acre will be as many cubic inches of water, which, at 231 to the gallon, is equal to 27,154 gallons. This immense quantity of water will weigh 228,190 lb. or 114 tons. One hundredth of an inch (·01) alone is equal to over one ton of water to the acre. In forty-eight hours, during the month of January, 15½ inches of rain fell at Geraldton. This was equal to 420,837 gallons per acre or 1,767 tons, or about one-seventh of the total quantity required to irrigate a crop of sugar-cane during the growing season.—*Ibid.*

Caprification of Figs.—The caprification or cross-pollenisation of figs is described in a recent number of the *Californian Fruitgrower*. The work in Smyrna is performed by women and children, who gather the profichi and suspend them in the branches of the Smyrna tree. In the Meander orchards it is customary to string the hard profichi on the ends of rushes, which are pushed horizontally through the sides of the fig; if the profichi are plentiful, two are strung on each end of the rush, which is then thrown up into the Smyrna tree and caught among the branches. The fig wasp, on emerging from the profichi, enters the figs nearest to hand, not discerning any external difference between the young Smyrna figs and the young mammoni, which it would enter if still in the caprifig tree. But, once inside, the fig wasp discovers that something is wrong, for, instead of finding short-styled male flowers in which it could lay its eggs, there are only female flowers with long styles, which are entirely unfitted to receive the eggs; the insect is unable to escape, and, in darting about in vain efforts to find some male flowers, the pollen with which it was so freely dusted in emerging from the profichi is rubbed into the receptive stigmas of the female flowers. The little wasp finally dies in the fig without having been able to provide for the production of its kind, and, on cutting open a Smyrna fig shortly after caprification, one can usually find the dead insect.—*Ibid.*

Conifers as Rain Gauges.—According to a recent number of the *Revue Horticole*, M. Felix Sahut has lately communicated to the Congrès des Sociétés Savantes observations respecting certain plants that act as registering rain gauges:—"Mention has already been made of the influence of certain more or less severe droughts in the French Mediterranean upon *Pinus Laricio* of Corsica, and Cephalonian Fir. The lengthening of the branches of these two species is always proportionate to the quantity of rain falling during those months of the year when it is most profitable to them. Co-efficients have been established indicating what the degree is for each month of the year. These co-efficients enable the relationship that exists between the amount of rain fallen and the greater or less intensity of the vegetation which it has encouraged to be determined. It is shown that, under these conditions, it is possible to judge approximately the quantity of rain which has fallen by measuring exactly the length of the leader, or of the branch produced yearly on these species of pine, and, if the estimate is not absolutely proportionate to the quantity of rain registered by the rain-gauge, it closely approaches to it; and a still closer estimation may be made by taking into account the relative value of the results produced by rain in the several months of the year. It is, therefore, possible, to a certain extent, to use plants specially selected for this purpose as actual registering rain-gauges."—*Ibid.*

SOIL BACTERIA.

(From *Agricultural Gazette* of New South Wales.)

R. Helms.

The discovery of the important part played by certain bacteria within the soil in converting nitrogenous substances into nitric acid, in which form plants assimilate one of their most important foodstuffs, has created a clearer conception of the processes by which such chemical changes are brought about. This, together with the discovery that certain plants by means of similar minute organisms in their roots can utilise the nitrogen of the atmosphere, has opened out new vistas to scientific agriculture.

Besides these oxidising organisms a number of others occur extensively, which act in the reverse manner by reducing nitric acid to ammonia, or even to nitrogen, and thereby play, on the whole, an even more important part in the economy of nature, although in many instances their action is the reverse of beneficial to plant life. These are known as reducing or denitrifying organisms in contradistinction to the first-mentioned, which have been named, nitrifying bacteria.

Anything we can do to increase the development of the nitrifying bacteria, or to design methods for checking the too rapid multiplication of the reducing organisms, will, at the same time, be the means of increasing the fertility of the soil, improving those soils that are poor, and maintaining the productiveness of more fertile ones, since, of all the factors on which the fruitfulness of land depends, the power of nitrification is undoubtedly the most important.

Investigations with this aim in view, carried on during late years in the greater number of countries where agriculture is pursued according to advanced principles and with modern appliances, have led to promising results, and these researches, together with the better understanding of the value of manures, are beginning to produce a revolution in the theory and practice of agronomy.

Since the functions of these organisms are considerably affected by their surroundings, and they behave differently in different soils and climates these differences may prove to be very pronounced in Australia where both soil and climate are so extremely variable and peculiar. It is therefore not possible to accept as conclusive the results obtained by investigators in other countries, and it becomes necessary to study their behaviour under local conditions.

Before further discussing the different groups of soil bacteria and dwelling upon their characteristics, it is desirable to sketch the history of their discovery in an epitomised form, and to present the results hitherto obtaied by different investigators.

Historical.

As far back as 1862, Pasteur surmised that nitrification in soil was due to micro-organisms. Up to his epoch-making investigations, fermentations were considered to be the result of purely chemical reaction, and it was but natural that, after proving the important part played by the yeast organisms, he should go so far as to consider other phenomena involving complex chemical changes as being connected with similar microbes.

Schloessing and Muntz proved in 1878 that the action of minute organisms caused nitrification, or the transformation of ammonium salts into nitrates by oxidation. This fact was confirmed by Warrington in the same year. A definite knowledge of the specific organisms producing the alteration of nitrous compounds were, however, not obtained.

Herœus was the first who, in 1886, applied the modern methods of bacteriological research to this subject. He claims to have obtained positive results. By means of elaborate investigations on a large number of bacteria obtained from soil, water, and air he managed to produce pure cultures. Among them he credited four distinct bacilli with nitrifying power.

Frank soon after made lengthy investigations on bacteria insolated from several kinds of soil, and obtained entirely negative results. In consequence he disputed the vital process in connection with nitrification.

This conclusion was rebutted by Plath and Baumann in 1887.

Celli and Marino Zucco in the meantime had experimented with five micrococci isolated from the highly nitrated water of Rome, but did not succeed in proving that any of these were the specially-qualified nitrifying organisms.

Warrington examined, in 1888, a large number of bacteria obtained from soil for their nitrifying power without arriving at the desired result; but when, instead of his pure cultures, he took ordinary soil for seeding his food media with, he always succeeded in inducing nitrification. These researches led him to the conclusion that the specific organisms had yet to be found.

Further, Percy Frankland and Grace Frankland have paid attention to this important question. Although they experimented with twelve different organisms isolated from soil, the result was in every case a negative one; but, as with Warrington, when using a little of the soil from which the organisms had been obtained, nitrification was readily excited in the culture fluids.

As these many experiments of such able bacteriologists failed to prove a definite nitrifying organism the result of Schloessing and Muntz were attacked anew, and it was again doubted whether organisms played any part at all in nitrification.

At this stage the famous Winogradsky, of Zurich, took the question up, and by his masterly handling of the subject produced definite and important results,

From the experience gained by experimenting with such a large number of different organisms during several years, and by the foremost bacteriologists, it had become apparent that those capable of introducing nitrification could not be numerous, and that probably only one or two might exclusively possess this characteristic. It had, moreover, become plain to him that the organism in question did not thrive on the ordinary nutrient media composed of organic substances in general use for the official cultivation of pathogenic and other microbes. Winogradsky very ingeniously took advantage of this peculiarity. By showing ordinary gelatine plates with cultures derived from various soil bacteria, he induced a vigorous growth of species that flourished in this medium, and then grafted in suitable fluids from the spots which showed no development. Thus he succeeded in separating the nitrifying organisms. Further discussion of the methods, of manipulation is needless, but he ultimately proved a somewhat oval-shaped organism to be possessed of the characteristic power to nitrify ammonium salts.

The puzzle was solved at last, and led to more definite studies being continued by Winogradsky and others. The technique of bacteriology had meanwhile been enriched by the clever invention of Kuhne, who provided a solid culture medium free from organic substances by gelatinising silica. This allowed of reliable work being done in a more rapid manner.

Several species, or may-be varieties, of nitrate-producing organisms have been detected in soils from different parts of the globe, and it seems fairly certain that nitrifying organisms are universally distributed and found in most soils, but are present in greatest number in fertile areas. Less is known of the nitrate-forming organisms, and

it is surmised by some that these many possibly be a modified stage, so to say, of the former.

From experiments made in laboratories it has been ascertained that in cultures seeded with soil the development of nitrites precedes that of nitrates. Thus ammonia is first converted into nitrous acid, and this latter into nitric acid.

This has led to the conclusion that two physiologically distinct organisms are required to accomplish the transformation of ammonia into nitrates. Winogradsky is of this opinion, and claims to have separated the nitrate-forming microbe.

He has proposed for the group of nitrifying organisms the name of *nitrobacteria*, giving the generic term *Nitrosomonas* to the nitrate-forming types, and *Nitrobacter* to those who transform nitrites into nitrates.

Nitrogen-Fixing Bacteria.

Besides the nitrifying bacteria which are able to transform ammonium salts found naturally in soil, or have been added thereto, into other nitrogenous compounds, a number of related organisms are met with in many fields which have the power of utilising the free nitrogen of the atmosphere and drawing from this vast store of almost inert gas considerable quantities for plant-food. These are the nitrogen-fixing bacteria.

On the rootlets of many higher plants, more especially on those of the *Leguminosæ*, small nodules in varying numbers are found produced by and filled with bacteria. It is supposed that by the *symbiosis* (a living together) of these lowest forms of plant-life with the higher plants, the latter derive the nitrogenous food which it is proved cannot have been derived from the soil, and therefore must have been obtained from the atmosphere. The process is not yet properly understood, but the general opinion tends towards the assumption that the bacteria fix the free nitrogen within the nodules and that the resulting nitrogenous compounds are assimilated by the host-plant. By some also it is thought that through the peculiar conditions of "living together" the plant is enabled to fix free nitrogen in its foliage.

Whatever may be the correct theory, the effect of this remarkable inter-action between the lower forms and the higher plants is very striking and very variable in extent. Even amongst the *Leguminosæ*, the plants deriving the greatest advantage from this phenomenon, extremes are met with; some deriving apparently but little benefit from it, whilst on the other hand many may very largely depend upon it. Amongst the Lupines, for instance, the yellow-flowering variety is able to entirely dispense with nitrogenous substances in the soil.

Through the exhaustive investigations made first by Professors Hellriegel and Willsarth; and later by Lawest, Gilbert, and others, on nearly all the cultivated leguminous plants, no doubt has been left that the nodules found on the roots are formed through bacteria, and that these are able to fix free nitrogen for the use of the plant they attach themselves to. Until Hellriegel proved that the presence of bacteria is necessary to enable plants to utilise the nitrogen of the atmosphere, and that, for this reason, *Leguminosae* may almost entirely dispense with nitrogenous manuring of the soil they grow upon, and in many instances even enrich the land with nitrogen, these observed facts were not properly understood.

It is well-known in practice that clover and lucerne would grow vigorously for a period of years without being manured, and when flagging could often be invigorated by a dressing with gypsum. This tends to prove that these crops did not sicken for the want of nitrogenous food, but on account of other elements becoming exhausted or unobtainable for some reason from the soil.

A palpable proof that the help of bacteria is almost absolutely necessary to enable plants to assimilate atmospheric nitrogen is afforded by the fact that seedlings, say, of peas, will not thrive unless the soil contains at least some traces of nitrogenous compounds; but as soon as they have made a start and have sent out rootlets upon which the bacteria can form colonies, they prosper independently of the presence of this food in the soil.

During the experiments carried on in several German agricultural establishments it was discovered that every species of legumes was associated with a specially sympathetic bacterium which would not perform the office of fixing nitrogen for other species. Based upon the acquisition of this knowledge, Professor Nobbe, of Tharand, in Saxony, is now preparing a number of pure cultures of these specific bacteria for the purpose of sowing them together with their respective culture plants. These cultures are placed on the market under the name of *Nitragen*, and for some time have been undergoing and still undergo practical tests regarding the efficacy of promoting the growth of plants.

It has not been definitely ascertained how long these artificial cultures can retain their vitality unimpaired; and, besides, in some instances, adverse seasons have prevented a definite judgment being arrived at as yet, whether the results obtained in trial plots can be maintained on a larger scale in the field. Considerable attention is being paid to this question at the agricultural stations in Germany as well as in the United States and elsewhere.

The De-nitrifying Bacteria.

In addition to the organisms hitherto referred to, all of which are pre-eminently friendly to plant-life, and thus indirectly to man, there are a host of other bacteria met with in soil and water which play an important part in connection with agriculture.

Their action is to reduce the compound organic substances into less complex combinations, or into simple elements, and in this manner make them again available for plants to which otherwise they would be lost, as these can utilise nothing but elements or simple componnds for their nutrition.

It is manifest that, were it not for the decomposition of the many complex substances taken from the earth in the shape of plants and animals, after these have changed from the active state called life to that of inactivity or death, and by this process are redissolved periodically, these substances would be entirely lost to succeeding generations of plants and animals, and this constant drain from the resources now found on the surface of the globe would ultimately exhaust their supply and make life impossible.

That putrefaction and other processes of decompositions are produced by bacteria was suspected for a considerable time, but it was not definitely proved till 1875 by Menzel, and subsequently verified by others. The action of these organisms is so variable that in the decomposition of any given substance probably a dozen species participate.

From this indisputable achievement of scientific research it will be seen that it is in the first instance entirely due to the activity of the minutest organisms that what is of earth goes back to it again by the dissolution into simpler substances of the complex and intricate combinations. Chemical action, no doubt, has also much to do with the redissolution; but it is now accepted that this activity in the generality of instances is secondary to the bacterial, and takes place after these have broken up the compounds.

Without the one process the other would not take place, and from this it is evident that micro-organisms are more closely connected with the productiveness of the soil than was dreamt of less than thirty years ago, and that not only in medicine and industrial pursuits, but also from an agronomic point of view, bacteriology is becoming daily of greater importance.

The organisms intimately connected with the fertility of the soil may conveniently be divided into two groups, namely, assimilating and destructive bacteria.

Under the first group we would classify the nitrifying and the nitrogen-fixing bacteria; and in the second all species which cause putrefaction and decomposition may be included.

The first group, as previously stated, includes nothing but beneficial species which are occupied either in building up nitrogenous compounds in the soil—the nitrifying species—or in fixing nitrogen from the atmosphere—the nitrogen-fixing bacteria—the latter of which, besides assisting plants to use this element, frequently also enrich the soil itself.

Important as is the numerous second group on account of the reducing power of its species, it includes several that act disadvantageously in regard to agriculture.

These objectionable species are the de-nitrifying organisms. By denitrification is understood the deoxidation nitrates and nitrites, which in each case involves a loss by either nitrogen or ammonia being given off. Their activity is perceptible by the pungent smell of ammonia rising from fresh stable manure, particularly from that of horses. Nitrogen being odourless, its loss cannot be perceived by the senses; it nevertheless takes place to some extent during every process of decomposition where nitrogenous compounds are present.

The Aims of Soil Bacteriology.

It now remains to indicate the aims of Bacteriology in connection with agriculture. These are shortly as follows;—

1 To encourage a definite multiplication of the nitrifying organisms found already in the fields, by adding substances that will enable them to retain their vitality and vigour after their activity ceases for the want of nitrogenous material; and in case of their absence from a soil to transplant them thereto, if this can conveniently be done, by adding soil impregnated with the desired bacteria.

2. To secure by the growth of plants favourable to nitrogen-fixing organisms an enrichment of the soil by nitrogenous compounds; and

3. To counteract the sudden and excessive development of the denitrifying organisms, in order to prevent loss of fertilising substances by means of these later.—*Journal of the Department of Agriculture of Western Australia.*

ORANGE CULTIVATION IN CEYLON.

With tea in its present parlous state, it behoves us to look about for some other product to assist the struggling planter and to help him to eke out the lean years. I have seen several references to orange growing in your columns, but do not think the importance of this culture has been sufficiently urged. I am of opinion that orange growing, and the growing of citrus fruits generally, will in many cases not only materially assist many estates suffering from a depressed tea market, but, in suitable locations, lead to the up-rooting of tea to give place to a product infinitely more profitable.

I have found, in course of conversation with planters and others in Ceylon, that they had not seriously looked on orange growing as an industry. For the information of all such I may quote from the Californian State Board of Trade returns for 1898, which gives the value of a year's shipment of oranges and lemons out of that State as $7,226,356, or equivalent to R22,000,000. This is from one State alone, and is exclusive of the consumption of the local population numbering a million and a quarter.

The annual importation of oranges into the United Kingdom exceeds 200,000,000, and this does not include any of the Californian crop already referred to, which gets no further than the Northern States. Two hundred million oranges seems a large numbers, but it is not six oranges per annum per head of the population, a consumption which cannot be regarded as excessive. It has also to be remembered that in the event of importations being made into the United Kingdom from Ceylon, they would not come into competition with the present imports, as the Ceylon crop would strike the market when it was bare of the fruit, viz., from May to September right through the heat of summer, and just when this delicious thirst-quenching fruit would be most appreciated. On a recent visit to the old country I noted carefully the advent of the season's supply. The first oranges to appear were from Jamaica, and came in at the beginning of November, and sold at from 2d. to 3d. each, and these were followed at intervals up to January, by supplies from Sicily, Italy, &c., when they came in in large quantities. I was informed by a leading firm of London fruit-brokers that shipments received from May to October would undoubtedly command high prices.

The Importations from Jamaica, which I have referred to, are an example for Ceylon of a new industry, which dates its origin from the initiative action of Sir William Robinson, formerly Governor of that island, who in 1891 issued broadcast to the agricultural population a printed message urging the wholesale planting of orange trees, pointing out the large trade that lay at their hands, and offering prizes for the best cultivated blocks under that fruit within a given time. The result of these measures is a steadily-increasing trade with the mother-country. What Jamaica has done Ceylon can do.

That the best varieties of the orange will thrive in many parts of the island is now known, as small importations of grafted trees of good sorts have been made during the past few years, and their success has been such as to justify their being planted on a commercial scale.

Trees planted three years ago have already begun to bear, and it is here that the great advantage is seen of planting grafted trees instead of seedlings. Not only can the variety and excellence of the fruit produced be calculated on with perfect accuracy, if the young trees are procured from a reliable source, but, under proper cultivation and attention, the trees will begin to bear at from two to three years from planting, as compared with the eight or nine years one has to wait for fruit from a seedling tree, in addition to which there is the uncertainty as to whether the fruit, when it does at last appear, will be an orange or a worthless throw-back of the sweet lime persuasion,

Wickson, the leading Californian authority on orange culture, states in his official description of the Washington navel orange, which is recognised as the finest variety in the world (and of which there are a few hundred specimens doing well in the island, some having already fruited and been proved true to type) that it begins to bear as early as *one year from the graft.*

The results of the few instances of lemon planting in the island have been even more satisfactory, if possible, than with the orange, by reason of the tree being naturally a more rapid grower. Trees planted three years ago are now bearing well in the Dikoya District. Lemons are always in demand in the London market, and there are periods of the year when high prices are realized for them. The tree is hardier than the orange, and as it apparently does not require such richness of soil and general favourableness of conditions to develop the acid which is the charm of the lemon, as it does for the production of the sugar which is essential to a good orange, the lemon might profitably be grown along with the orange up the inferior portions of a block.

As regards the profits to be made from orange and lemon culture, it would be easy to take the crop produced by a given tree, multiply it by so many trees to the acre and calculate the value according to the present market price. Were I to do that the result would be such as to make the mouths of many a struggling tea planter water with prospects of riches

beyond the dreams of avarice. This is a calculation, therefore, that I prefer not to make in these columns, but I may mention the fact that there are mature orange trees in Ceylon which produce their crops not by hundreds, but by thousands per annum, that the usual number of trees to the acre is from 100 to 150, and that decent oranges cannot be had in Colombo under five cents a piece! In my opinion it will be a good many years before the local demand for good oranges is satisfied. As soon as they are available, I predict that they will displace the present supply of worthless green and sour fruit which is a disgrace to the age of this colony. It is a matter for surprise that up to date so little has been done to introduce the first-class named varieties of the orange which are well-known in most if not all countries where citrus fruit can be grown. Here an orange is simply an orange and nothing more whereas there are about a dozen distinct named varieties, each with its own special characteristics by means of which identification can be made.

I would urge the advisability of making experimental plantings of the orange and lemon as far as possible all over the island, and especially at elevations between 2,000 and 5,000 feet, which so far seem to suit best the kinds that have been introduced. A variety which does well in the low country would be a boon to Ceylon, as suitable land in the shape of rich flats and easy slopes is more plentiful there than in the hill districts. Such a variety will no doubt be fixed upon before long, as plantings were made last year in different parts of the low country. At present all trees have to be imported, but with local nurseries and a few natives trained to graft and bud the seedling trees, a supply of plants could be produced at a slight cost as compared with the expense of importing the trees, and there is a good opening for anyone who cares to take this nursery business up, although two years' time would necessarily elapse before any saleable stock would be available.—Local "Times."

RISE OF THE SUGAR INDUSTRY OF JAVA.

Under this headidg the *Journal des Fabricants de Sucre* prints an account of the extraordinary conditions of sugar production in Java. According to an official report, the production for the last three years has been as follows:—

Year	Factories in Operation	Production in Tons.
1896	187	534,390
1897	188	586,299
1898	188	725,030

Java, therefore, produces as much sugar as France with less than one-half the number of factories.

The astonishing part, however, is in the yield obtained per acre. The figures are these:—

Year	Cane per hectare in kg.
1896	76,900
1897	85,400
1898	98,700

The yields of beets in Europe is about 25,000 to 30,000 kg. per hectare on an average.

If the foregoing figures are astonishing, the following are simply fabulous. They represent the sugar per hectare in Java:—

Year	Sugar Extracts per hectare in kg.
1896	8,100
1897	8,600
1898	10,100

Compare these figures of 8,000 to 10,000 kilogrammes per hectare to those of Germany, where they have only 4,000 kg.

On the other hand, the yield in the factory went lower than Java. The amount of raw sugar extracted from the sugar cane by weight was as follows:—

Year	Field in per cent
1896	10·55
1897	10·06
1898	10·21

The factories which obtained more than 40,000 kg. of sugar per hectare were only 11 in number in 1896, in 1897 they numbered 30, and 1898 they had reached the number of 87.

Die Deutche Zuckerindustrie says in connection with this subject: "This enormous superiority of the cane-sugar industry over the beet-sugar industry would increase still more if the bounty was taken off. The only possibility of keeping up the fight against so privileged a competitor rests in the value added by the bounty to the products of the beet. If by the abolition of the bounty the cane-sugar and the beet-sugar industries were placed on an equal footing from the point of view of realising on their products, the fate of the beet-sugar industry would be sealed. And in considering the foregoing results, one speedily acquires the conviction that the progress of the colonial industry is far from having reached its highest point, whereas one hardly perceives any noteworthy progress to be realised in agriculture and manufacturing in Europe."

The French paper agrees with the idea that the development of agriculture and industry in certain countries affords grounds of apprehension for the beet-sugar industry of Europe, but it differs as to the future of the latter. It believes that under the stimulus of necessity it will make great progress and reduce the cost of production so materially that it will have a long series of years of successful existence.—*Planters Monthly.*

ADVENTURES WITH A BISON.

I had often heard stories of people being charged by bison; but as so many men say it has never happened to them, and that really the bison is a most harmless creature, I thought the stories were "yarns"; but now I am wiser.

About a week ago, C. and I. started forth to try and slay a bull, of which there are a goodly number in the forests which I have to look after. I had been after them a great many times, but had only been able to get one, rather a poor one. Well, the first day, we came up to a herd, and after a lot of crawling (and this is not easy when you have to crawl with a double 8-bore, weighing 18lbs.) managed to see that there was a good bull in the herd. Here let me digress for a minute, to tell you that it is easy enough to shoot a bison, but to get a good bull out of a herd requires an awful lot of stalking as the confounded cows and young bulls always promenade about and offer such easy shots, at the same time getting right between you and the bull. Perhaps, he, being boss of the show, gives them instructions to do it! Anyhow, it is very annoying of them, and in this particular instance they carried out my lord's orders to perfection, and C., whose shot it was, could not get more than a glimpse of him. After about half-an-hour's waiting, during which the cows—who saw, or smelt, that something was wrong—kept walking about and snorting at us, there was a loud snort and away they went. Well, I fear that I am not getting on very well with my yarn, but I am not used to "writing to the papers." Suffice it to say that two people trudged most of that day without food or drink and never saw the bison again. But next day made up for the disappointment of the first.

We started off at some unearthly hour (about 3 A.M. I should think), and when we got out to the swamp, which is a favourite feeding-ground both of bison and elephants, we came on the tracks of a solitary bull. It was my shot this time, and after a very short track, one of the trusty jungle men spotted

master bison lying down about 5 yards off. I went up to the place, but could see nothing, for those confounded Kurumbers (jungle-men) can see in the dark, and while I was "fooling around," up he got; I caught sight of a great black mountain rushing away acros my front; he was so near (about 6 yards) that I could not resist the temptation, and let drive. Snap-shooting, when you have the above-named 8-bore, loaded with 12 drams of powder, is foolishness, but by a lucky chance I hit the beast and knocked him over. In a minute he got up and went off. We waited a bit to give him time to die as the track was covered with blood on both sides which made us think he was very badly hit, and then we cautiously went after him, mounted on my *shikar* elephant, I in front and C. behind. After about half-a-mile we came to a place where he had lain down, so making the Kurumbers walk behind the elephant we went on. I suddenly caught sight of an ear moving behind a bush abont 20 yards in front, and told the *mahout* to stop the elephant, as I wanted to put in a shot where I calculated his shoulder to be. One can't talk out loud to the elephant on these occasions, so the *mahout* touched him on the head. The idiot of an elephant (and really wasn't he an idiot not to see the bison, if I could see it?) stopped and, imagining, I suppose, that we wanted to get off, promptly sat down. This proceeding was a bit too much for our friend, the bison, who came charging out like an express train straight for us. You bet, the elephant got up sharp enough, and as soon as this operation was finished, I let drive as best I could. No effect; the bison came on and went full tilt into the elephant's forehead; what with the smoke and the elephant's swaying up and down, I could not see to shoot again at once. The bison naturally recoiled somewhat (most people would if they had charged an elephant), but he was not going to be put off, and promptly closed again. This time I was able to lean over the elephant's head, and pour the contents of the second barrel into the broad back of the bull. He subsided gracefully, and then (and thank goodness it wasn't sooner) the elephant turned tail, and bolted. It was a nasty place with a lot of dead bamboos sticking up, and one of these caught C. in the back and knocked him off, rifle, hat and all. I was too much occupied with looking out for bamboos and trees, to pay much attention to C. but I knew he must have fallen rather nearer to the bull than was nice. Well, we managed to stop the elephant, and I ran back (nothing would induce the elephant to go back) expecting to find the bull executing a war-dance on the the top of C., but luckily I found him and the Kurumbers all safe and sound. What was to be done now? That was rather a ticklish question. We could hear the bull lying groaning where he had fallen, but I confess we both decidedly considered discretion the better part, as the beast was lying in the middle of a lot of fallen bamboos and long grass, and if he had tackled us at close quarters—well, we might be there now. However, he got up and moved slowly off. We followed at a respectful distance, and though I saw him again I could not get in a shot, and as it was getting pretty late, we decided to leave him to himself for the night. Next day, as we thought he must be dead, we sent the men to see, but far from being dead he charged them twice, they skipping up trees.

Next day I came up to him, but he bolted before I got a shot, and it was only on the fourth day that I found him standing in some thick jungle, and was able to kill him.

Poor beast, he must have had a bad time of it for those four days, He had eaten nothing and must have been in great pain, and I was really glad, both for his own sake and mine, that I managed to kill him,

He was a very big bull, standing 5 feet 11 inches at the shoulder (measure an ordinary English bull and see what that means), but he had not got a very big head. His horns measured 36 inches across the sweep, and were 19 inches round at the base. The points were very much worn; he had lost 3 teeth, and his hoofs were almost worn down to the bone, so he must have been a veteran, and no doubt a very grumpy old chap, too.

I am afraid I have spun this yarn out much longer than it ought to have been, and if it is very dry reading, well, you need not publish it.

Let me, however, give a small parting word of advice, and that is that anyone who is likely to get any bison shooting when he comes out here should not use a pop-gun. I believe if I had not had an 8 bore on this occasion, and that loaded with 12 drams of powder, I should not be inflicting this interminable yarn on the patience of your readers.—*Indian Forester.*

AMOUNT OF FARM AND GARDEN SEEDS REQUIRED PER ACRE.

It may be of advantage to farmers who have only lately settled on the land and particularly to some who may have entered on the business for the first time in Queensland, to know how much seed to purchase for sowing or planting various crops. Although there are certain crops which may practically be sown and raised all the year round in this favoured climate, yet the regular seasons for most crops are quite as clearly defined as they are in other colder or hotter countries. Some modification of the times for sowing and of the amount of seed to sow will have to be made in different parts of the colony, owing to the wide range of temperature and rainfall, and to the variety of soils and their aspect. But as a general rule, the following will be found fairly correct, the quantities in all cases being per acre:—Barley, broadcast, 1 to 1½ bushels; drilled, ½ bushel. Beans (broad), drilled, 1½ bushels; (French), 1½ bushels; (horse), 2 bushels. Beet (drilled), 5 lb. Buckwheat, broadcast, 1 to 2 bushels. Cabbage (field), in seed beds, 2 lb. Carrots, drilled, 5 to 7 lb. Clover, broadcast, 12 to 20 lb. Grasses, prairie 1 bushel: Italian rye, 4 bushels, perennial rye, 2 bushels; rib, ½ bushel; couch ½ bushel; permanent mixed pasture, 3 bushels; imphee, 20 lb.; khol-rabi, drilled, 2½ lb. Lucerne broadcast, 20 lb.; drilled, 10 lb. Maize, broadcast, 3 bushels; drilled, ½ bushel. Mangolds, drilled 5 to 6 lb. Millet, broadcast, 1 bushel. Oats, broadcast, 2 bushels. Onions, broadcast, 5 lb.; drilled for sets 20 lb. Panicum, broadcast, 20 lb. Parsnips, drilled 8 to 10 lb. Peas, broadcast, 3½ bushels; drilled, 2 bushels. Potatoes, 14 cwt. of cut setts; if planted with the American potato planter, 10 cwt. Rye for grain, broadcast, ¾ bushel. If for saddlers' use, 1½ bushels. Sorghum for grain in drills 10 lb., broadcast for green fodder 20 lb. Swedes, 3 lb. to 4 lb. Turnips, globe and yellow, drilled, 2 lb. Vetches broadcast, 3 bushels. Wheat, broadcast, 1 to 1½ bushels.; drilled, ½ bushel. Paddy (rice), 30 to 40 lb. Cow Peas, 8 lb. Jerusalem artichoke, 3 to 4 cwt.

The weights per bushel of the principal farm seeds enumerated above are:—

Barley, 50 lb; beans, 60 lb; buckwheat, 50 lb; couch, grass, 40 lb; cocksfoot, 20 lb.; clover, 60 lb; flax, 60 lb; grasses (mixed): 20 lb.; oats, 40 lb.; imphee; 40 lb; prairie grass, 20 lb; perennial rye grass, 20 lb; peas, 60 lb; rye 60 lb; rib grass, 60 lb; sorghum, 40 lb; lucerne; panicum, 60 lb; maize, 56 lb; wheat, 60 lb.—*Queensland Agricultural Journal.*

THE NAGPUR EXPERIMENTAL FARM IN THE CENTRAL PROVINCES.

It is not stated with what object the Ceara rubber plants are being planted, but the experiment is likely to suceed, as many be gathered from the following

notes on the subject collected by Mr. Reuther, I.F.S., and roprodnced below :—

MANIHOT GLAZIOVII (Ceara).

Climate.—Thrives nnder a very wide range of conditions. *M Ceara*, grows even in desert plains with rainfall under 50 inches, where the vegetation is scorched up during the greater part of the year, and thrives also on mountains up to 3,500 feet elevation, where the rainfall reaches 100 inches and the night temperature falls even below 60°. A rainfall of 60 inches to 70 inches is ordinarily sufficient, but about 100 inches suits the tree better. In Ceylon, thrives up to 3,000 feet elevation.

Soil.—M Ceara, thrives best in scanty soil among granite boulders; never in marshy soil. Though growing readily on hillsides in poor, rocky soil, unsuited to almost any agricultural crop, it thrives best where the ground is covered with shrubs.

In Ceylon, grows on most barren soils.

Characteristics.—A moderate-sized tree, with erect stem 30 feet to 50 feet high and 2½ to 5½ feet girth (at 5 feet from the ground). Rounded crown.

Hardy, adaptable, fast grower; not prone to insect or fungoid attack; requires little or no attention once established.

Readily raised from seed ; can be propagated from cuttings as easily as willow. In every part of the world where it has been introduced, the seed production is abundant, and the seed may be gathered already at 3 to 5 years of age. Large areas could therefore be planted in short time: In Brazil the seed is universally sown directly in the plots which the trees are intended ultimately to occupy (just like teak seed in *taungya* plantations), and nurseries and transplanting are not required.

ARTIFICIAL CULTIVATION.

Spacing.—Recommended to be planted thickly, with judicious thinuing to follow.

Germination.—Seed-coat hard and thick; said to require more than a year to germinate. But germination inducible within two or three weeks by rasping off with a file both edges at the radicular end (recognizable externally by the two-lobed caruncle).

Development.—In Ceylon, attains in 2½ years a height of 25 feet to 30 feet and girth of 1 foot 9 inches at 3 feet from the ground. Flowers at 18 months of age.

Rubber.—Quality excellent: second only to the best 'Para." Yield equal in quantity to that of "Para."—*ndian Forester.*

THE TAPIOCA PLANT.

An interesting correspondence between Dr, Watt, the Reporter on Economic Products, the Secretary of State for India, and Mr. Robert Thomson, concerning the value of the tubers of the Cassava or Tapioca plant, as an alternative food-stuff in seasons of scarcity and famine, has been published as an "Agricultural Ledger." Mr. Thomson urges that the numerous varieties of the Cassava cultivated in Columbia should be introduced to India where, he declares, if widely distributed as a subsidiary crop to rice it would ward off famine. The Columbian varieties of Cassava, he says, flourish with a total annual rainfall of from 14 to 16 inches, while the plant thrives admirably when droughts extend over six months at a time. It is thus pre-eminently a drought-resisting crop, while rice requires from 50 to 60 inches of rain in a year. Some of the varieties grow in rich soil, and some in exhausted or impoverished soil ; and while certain varieties are cultivated on the hot plains others are grown at elevations up to 6,000 feet above sea level. Dr. Watt declared that he had little faith in the value of acclimatisation in the abstract, in the improvement of the resources of a country, and he doubted whether one per cent of the experiments hitherto performed in India of that nature had proved of practical value. The development of the existing resources by selection was, he stated, infinitely more satisfactory. With that object in view, he was endeavouring to obtain information of the extent of the food supplies of India of the nature mentioned. Mr. Thomson replied that Cassava was chiefly known in India as a source of Tapioca, but the Columbian varieties had been cultivated in that country from time immemorial, and they were the result of slow and gradual selection. His experience of tropical planting in regard to acclimatisation differed from that of Dr. Watt. To raise new varieties or races from the existing Indian varieties which are found only in restricted areas would, in Mr. Thomson's opinion, take a long period of years, whereas a score of valuable new varieties are immediately obtainable from Columbia. There is every reason to believe, he observes, that these would readily accommodate themselves to a wide area of India. The last word so far, however, falls to Dr. Watt who, as the Editor of the "Agricultural Leder," remarks in a foot-note that it is probable that a few years would suffice to reduce all the various forms to which Mr. Thomson alludes to two or three, and that these would not differ materially from the acclimatised varieties already met with in India.—*The Indian Agriculturist.*

CAOUTCHOUC PLANTATIONS IN ASSAM.

BY W. R. FISHER, B.A., I.F.S.

I see, in the report on the caoutchoue plantations in Assam, a statement that the Bomani Hill plantation yielded 9·5 lb. of clean rubber per acre, and that the Charduar plantation yielded 9·4 lb., there being 92 trees per acre on the Bomani Hill and 14 per acre on the Charduar. Mr. McKee remarks that this proves that a densely-planted area does not yield more rubber than one sparsely planted, while it must have cost more to plant out originally and to establish as a going concern.

I chose the site for both these plantations in 1873-74, and managed them for about two years. In the Charduar plantation, lines forty feet wide were cut one hundred feet apart in dense evergreen forest, full of cane-brakes, large Ficus trees and other difficulties. Colonel Keating, the Chief Commissioner of Assam, was struck with the waste of timber this involved and the great expense of clearing the line, and directed that an experimental plantation should be made on grass land near the Brahmaputra River. Mr. Mann, the Conservator of Forests, considered that trees grown on grass land would not yield anything like the same supply of caoutchoue, as trees grown in the humid air of the evergreen forest, and his opinion was based on the fact that some large trees that had been tapped in Tejpur yielded very little rubber. The plantation on grass land at Bomani Hill was therefore limited to a small experimental area. The expenditure on it, however, was a mere fraction of the cost of the Charduar plantation, as far as I remember, and it would be interesting if the Assam Forest Department were to publish figures showing the comparative cost of the two plantations per acre, now that it has been proved that they return an equal yield per acre.

If grass land plantations like that at Bomiani Hill will afford as good a yield as the forest land plantations in Chardnar, a great future may be predicted for rubber-planting in Assam, and there are, or were in my time, enormous areas of waste grass land in that Province.—*Indian Forester.*

RICE AS A FOOD.

Dr. John Haddon, M.D, writes to the *Rangoon Gazette*:—

In coming to Rangoon, I noticed that there were two ways of boiling rice on board the ship. The rice for the passengers, boiled by a native cook, was put on with cold water, and poured as we pour potatoes. That for the lascars, also prepared by a native cook, was put into a measured quantity of water boiling very fast, and allowed to boil, until all the water was absorbed. It was not poured. Now some may not know that a large amount of the nutritive material of the rice goes into the water in which it is boiled; but that is a fact well-known to chemists. It is thus evident that pouring the rice we are lessening its food value. Some are inclined to regard rice as of comparatively little value as a food, and it is not uncommon to hear Anglo-Indians saying that the natives, who live mostly upon rice, have to eat an enormuus quantity of it. If it be really necessary, in living upon rice, to eat a larger quantity than the stomach can accommodate with comfort, how careful should those who so live be not to deprive the rice of any of its nutritive material, since it is evident that if a certain quantity of dry rice must be eaten to support life (according to the calculation of physiological, chemists) those who pour their rice will not be so well fed, as those who do not pour it, if they both eat the same quantity of dry rice? And again, if the natives require to take an enormous quantity of rice, to live upon it alone, they will require to take more of that which has been poured, than of that which has not been poured and retains more of its nutritive value. Granting my premises then, the logical conclusion is that rice must not be poured and, from personal experience, I believe it is best to put the rice into the water when it is boiling fast, but I do not wish to say more about that at present.

Perhaps the most important question with regard to rice, is as to its cleaning, or milling. We require, in a perfect food, a certain proportion of albuminoid, carbonaceous, and mineral material. Unless we have these in proper proportions, our health suffers. The albumenoids go to supply the waste of our tissues, caused by the vital processes, and the amount of muscular effort put forth in work. The carbonaceous goes to supply us with energy. It is like the coal in the fire, the combustion of which heats the boiler, and makes the steam, which gives the engine all its power. Starch is one of the principal ingredients in our food for the supply of energy, and it exists in large quantity in all our cereals. The mineral material goes to the formation of bone, and supplies us with salts which are absolutely necessary for health. We are only just beginning to realise that it is the want of these mineral salts in animal food (its sin of omission, as it were) which helps to produce gout in its protean forms, making such ravages, as it does, in those of sedentary habits, who indulge in the pleasures of the table. A London physician, who has been studying the question of diet, in relation to gout, is endeavouring to obtain the ashes of vegetables which contain so largely what we may call these anti-gouty salts in such a form that it could be used instead of our ordinary table salt, but surely it would be wiser to eat such food as contains these salts. If we examine wheat, we find that these salts are contained in the bran, which is entirely removed from wheat by millers in making the fine white flour, and given to cattle. The bran, however, contains not only the salts, but a large proportion of albuminoid material, which we require to build up the waste of our tissues. Such knowledge has induced some doctors to recommend the used of bread made from whole wheat meal, and many who have found the benefit derived from eating such bread keep handmills in which they grind the wheat as got from the farmer, just as they require it; and they find the bread made from such freshly-ground meal much better than that from meal which they can buy, seeing that such meal does not keep well. Dr. Keith, who visited Rangoon two years ago, made some enquiries as to rice, which he put into an article in *Chambers' Journal*. He states that so much as 16 per cent of what is called rice meal is taken from the rice, in the process of milling. An analysis of the rice meal made by Messrs. Duncan and Flockhart, of Edinburgh proves that rice meal (which is sold for feeding cattle) contains 12½ per cent of albuminoids, and 4½ per cent of phosphoric acid, which, in union with lime, as phosphate of lime, makes up the greater part of the ash amounting to 7¾ per cent. Parkes gives 5 per cent as the proportion of albuminoids in white rice. Thus we learn that rice meal has more than double the amount of albuminoids that the best rice contains, and as it has in addition all the mineral salts, which we know to be so necessary for the system, it is evident that rice meal is a valuable food, and that in taking it off the rice we are making the same mistake, as we so long did in taking the bran off wheat and giving it to cattle.

What then is the lesson we should learn from these facts? It is very evident. We should leave as much as possible of what rice meal consists of on the rice, and use it in that state for human food. If we could keep it all, we would have instead of only 5 per cent of albuminoids, and no mineral salts, 17½ per cent of albuminoids and plenty of the mineral salts, so that in that state rice alone would be an excellent food. The natives mix dal with their rice, and in doing so they do well, so long as they use white rice, since the dal is rich in albuminiond material, but if they used the brown rice they would not require any dal. This is a question which ought to interest all who have the welfare of the natives in this country at heart and the Government might do something to encourage the millers to turn out the rice with its invaluable nutritive material retained. If it will not keep long enough for exportation all ground up, as we grind our wheat, when we make whole wheat meal, it might be sent home in the brown state, and ground in mills there, for home consumption. In that state it makes an excellent porridge, and might be used by our

peasantry instead of the oatmeal porridge upon which their foreteathers lived and which their degenerate children have almost entirely discarded. How greatly such a change would increase the consumption of rice at home! I trust that these facts with regard to a food so wholesome and invigorating as rice may reach those interested in that industry, and that brown rice may be properly appreciated in the near future.—*The Indian Agriculturist.*

FLOWERING OF THE BAMBOO IN THE C. P

By A. SMYTHIES, B.A., I.F.S.

A somewhat remarkable event is taking place in the Chanda district of the Central Provinces, and that is the flowering on a large scale of the ordinary bamboo (*Dendrocalamus strictus*). The area over which the flowering extends is estimated at 1,200 square miles, and in this area, although a few clumps here and there have escaped, the phenomenon is universal. But the extraordinary point about it is that clumps of all ages are flowering —not only mature clumps but quite slender seedlings of six or seven years' growth, or even less. I send you some specimens to illustrate this; the rhizomes show that those clumps are quite young. Last year the droughts affected the bamboos in the Dhaba Range of this district, and the bamboo flowered over a small area, and produced a kind of manna, which was described in the Forester (Vol. XXVI., page 363). Many thousands of people were kept alive for some weeks on the seed. This year the area is infinitely larger, and the whole population will, in course of time, flock to the forests to gather the seed.

The consequences to the people in the vicinity of this flowering and subsequent death of the bamboo will be rather serious, as, for many years to come, they will not be able to find sufficient stores to satisfy the numerous wants of the agricultural population to the north and west of Chanda—at any rate, the price of bamboos will be very much higher.

The Government revenue which now amounts to about ₹20,000 from this source will also suffer, as, when the dead bamboos have been utilized, there will be no more available for some 15 years or so. It would be interesting to ascertain whether such a universal flowering of this particular species has been recorded before. Needles to say, the oldest inhabitant has no recollection of such an event, and the flowering of the smallest clumps is believed to be unique.

It is probable that in this district, at least, the bamboo does flower gregariously over fairly large areas, as three of the oldest inhabitants informed me that they had seen the bamboo flower twice: first, when they were about 10 years old. Their ages were probably quite 70. Hence it is not unlikely that this bamboo flowers at intervals of about 30 years.

[*We would refer our readers to Volume XXV. (1899) of the "Indian Forester," pages* 1—25, *and* 305, 306.—*Hon. Ed.*]

PYTHON-BREEDING AT THE CALCUTTA ZOO.

It is not often that one has the opportunity of seeing a pythoness hatching its eggs, and those who were lucky enough to visit the Zoological Gardens last May might have witnessed the unique sight. The eggs are about twice the size of duck's eggs, and exhibit a leathery crumpled-up appearance, as if they were small bladders not properly distended with air, their colour, however, is a dirty white, and their covering might be compared to the skin of a mushroom. The pythoness which appears to be aboutthirteen feet in length, and whose body in its thickest part must be nearly two feet in diameter, is nursing her eggs in a curious manner. She has coiled herself up in a symmetrical heap till she resembles a basket of which the sides and the lid are her coils; and within this arrangement she has piled up the eggs, which she is so assidnously hatching. It will be interesting to see the little pythons when they make their entrance into the world, for to judge from the size of the eggs, they should be quite six inches in length. The poor mother was so stared at by sight-seers that the authorities took pity upon her and covered up the glass face of the cage with a screen.—*Statesman.*

TREE GROWTH ON IRON SOILS.

In the course of examining a forest area for the purpose of marking off areas of approximately equal capability, I had to walk over two large hills from 1,750 to 1,850 feet high. These hills are covered with dense spear grass, about 3 feet high, among which are hidden boulders of various sizes. There is scarcely a tree over an area of 100 to 150 acres, although an adjacent higher hill is well clothed. The very few trees that do exist are evidently not happy, and consist of dwarf, badly-grown individuals of *Anogeissus*, *Lagerstræmia*, *Terminalia tomentosa*, *Schrebera*, and *Buchanania*. The hills have often been burnt, but not more so than the adjacent stocked ones. On examination of the boulders I found that they were full of an ore of iron, and would be interested to learn whether there are other cases which point to soil so constituted being inimical to tree growth. Iron occurs in many parts of this district, but I have not observed it in such large quantities elsewhere, nor any marked effect on the crop. Iron.—*Indian Forester.*

CHLOROSIS IN PLANTS.—Recent researches by Dr. ROUX confirm the notion that the yellow condition of the leaves known as chlorosis is due to some deficiency in the chemical constituents of the soil. The liquid absorbed by the roots has an excess of lime, and deficiency of potash and phosphorous. The consequence is a stoppage of the work done in the leaves, and of transpiration ending in the degeneration and death of the cells from starvation.—*ibid.*

CAPE FRUIT.—Since our last note on this subject, two ships of the Union Castle line have arrived with consignments of some importance, the *Tantallon Castle* bringing 189 boxes of Plums, and 212 boxes of Peaches; and the *Dunottar Castle* with 280 boxes of Plums, 820 boxes of Peaches, and in 18 of Nectarines, from Cape Town. (Since the above was in type we are asked to note the arrival of the *Briton* at Southampton with 2,124 packages of Peaches; 98 of Plums; 120 of Nectarines; and 27 packages of Pines).—*Ibid.*

THE PLUMBAGO MINING COMPANY.

It is refreshing to note the manly enterprising tone which distinguishes the proceedings at this Company's meeting reported on page 762. In the face of multiplied discouragements through unexpected obstacles to work, and repeated disappointments as to "paying veins," there is not a word of idle grumbling in the Directors' Report nor the Chairman's Speech, nor in any of the speakers' remarks. All are determined as plucky Englishmen to persevere and do the fullest justice to the "Kingsbury" mine; and we sincerely trust that this Company may prove a very notable exception to the general rule in Ceylon, that European capitalists do not succeeed in the digging for plumbago; and that worthy, experienced Capt. Tregay may have his faith in the mine amply justified; while Directors and Shareholders may secure a full reward for their courage and persistency.

ARRIVAL OF TROUT OVA FOR THE C.F.C.

FROM WALES.

The N.L. ss. "Prinz Regent Luitpold," which arrived today from London, brought out the first of three consignments of trout ova for the Ceylon Fishing Club for this year. As has previously been stated, owing to the failure of the ova hitherto imported from the Surrey Hatchery of Andrews and Andrews, the Club has indented for the ova from other hatcheries this year; and the consignment which arrived today was shipped on the 30th January last and consists of 15,000 rainbow trout ova and 5,000 brown trout ova from Earl Denbigh's hatcheries in North Wales. Great hopes are entertained of this batch which was received from the ship's hold today by Mr. H D Elhart, who is in charge of the hatcheries and stew ponds of the Ceylon Fishing Club at Nuwara Eliya. He will take the consignment up by tonight's mail train and the boxes will be opened tomorrow morning when the ova will at once be sorted and put out to hatch. It is of course impossible to know at present how the ova has fared during the voyage, but it would appear that great care was bestowed on it while on board and from what Mr. Elhart could judge there would seem to be no smell indicative of decomposition or any such damage and the liveliest anxiety is felt as to the success of the importation. It may be of interest to note that hitherto the P. & O. Company's steamers always brought out the ova and great care was said to have been bestowed on it on the voyage and the C.F.C. has even given gratuities to the stewards of the vessels for devoting such attention to the matter.

THE DELFT BREEDING EXPERIMENT.

RETURN OF DR. STURGESS.

Dr. G. W. Sturgess, Government Veterinary Surgeon, returned from Jaffna this morning by the ss. "Lady Gordon," after a fortnight's absence in the north, on his six-monthly visit to the islands of Delft and Iranativu, where the Government horse-breeding experiment, dating from three or four years back, continues to be carried on with success. Dr. Sturgess, who was seen by our representative this morning, states that there is no disease—either on Delft where the brood mares and foals are kept, or on Iranativu whither the latter are transferred to be reared after reaching a certain age. On Delft there are now about 60 mares and 25 foals, while on Iranativu the young animals number no less than 46. During the present trip 7 three-year-olds (by Raeburn) have been removed from Iranativu to Jaffna, where they are available for sale, and where particulars may be had on application to the Government Agent.

The Value of Ammonia, &c.—Mr. Mitchell Henry (aged 75), trained as a Surgeon and at one time M.P. for Galway, succeeding Governor Gregory when he came to Ceylon, in the course of a letter of reminiscences to the *Spectator* has the following:—"I would ask, what keeps the blood-fluid in the veins and arteries? It is the presence or absence of free ammonia. This remedy was taken up by Mr. Baker Browne, the father of Mr. Lennox Browne, and he discovered and showed that by the administration of ammonia (common smelling-salts) scarlet fever, pneumonia, and other diseases caused by a stasis, or stoppage of the blood in the blood-vessels, could be completely overcome. He wrote a treatise on the treatment of scarlatina, and proved that by the early administration of small doses of ammonia in water, not mixed with anything else, no one need fear scarlatina. I have seen much of this disease, and can confidently corroborate this statement. Any one, however, who goes out of the ordinary line in medicine is called a quack, and that was the fate of Mr. Baker Browne. I learned much from him, and he was the first to perform ovariotomy, which was subsequently taken up by Sir Spencer Wells, who owned Golder's Hill at Hampstead, now bought by the London County Council. But the virtues of ammonia penetrated to Lancashire, and in the large soap factory of the Messrs. Thom, who always kept at their works a large barrel of ammonia and water, every woman used to obtain and keep by her a bottle of this fluid sweetened with a little sugar, to administer to any child who got feverish, a sure sign of incipient stasis of the blood. In my hunting days I have saved several horses, which got pumped out by running and stood breathless with cold ears not able to breathe, by getting some smelling-salts and mixing it with water, and so administering it. Lastly, I will mention another thing that I was taught by Mr. Raetger, a Hungarian. He collected the blood, say of a bullock in a barrel, and when the yellow serum floated on the top, he cut it off and left the black blood corpuscules behind. To those he added a little powdered quicklime, mixed it with bran, and preserved it in brown paper bags hung up in the kitchen like hams, and gave some to his young stock of horses, turkeys and fowls. They throve in a remarkable way, and if others will give some to their domestic fowls with the grain they feed them on, they will see the avidity with which it is consumed and the remarkable effect it has on the birds or on fowls."

THE AGRA TEA COMPANY OF CEYLON LTD.

THE REPORT.

The following is the report:—

The Directors have the pleasure of submitting their report on the transactions of the Company for the year ending 31st December, 1900.

The acreage of the Company's property is as under:—

Tea in full bearing ..	295 acres.	
Do in partial bearing..	27	do
Do not in bearing ..	8	do
	330	acres.
Forest	27	do
Grass, waste land, &c. ..	10	do
Total area ..	367	acres.

The estimated crop for 1900 was 180,000 lb. and the out-turn 203,860 lb. or a surplus of 23,860 lb. This crop realized R80,178·64, equivalent to 39·33 cents per lb. as against 41·79 cents in 1899. The expenditure, as shown in the accompanying accounts, was R57,070·60, or about 28 cents per lb. as against 26·89 cents in 1899.

After deduction of R4,158·58 for depreciation on buildings and machinery, the profit on working account for the year amounts to R18,363·96 representing rather more than 4½ per cent on the value of the property as shown in the Balance Sheet.

The net profit for the year amounts to R9,637·76, to which has to be added the sum of R6,337·12 brought forward from 1899. An interim dividend of 2 per cent absorbing R5,590 has been paid, and the balance now at the credit of the Profit and Loss Account is R10,384·88. In view of the fact that funds will shortly be required for the purpose of paying off part of the Standard Life Assurance Company's mortgage, the Directors do not think it advisable to pay any further dividend now, but they propose to transfer R9,888 97 to the General Reserve Account, thus bringing the total of that account up to R24,000; and to carry the balance of R495·91 forward to next year's accounts.

Since the issue of last year's report, the vendors of the Kalkudah estate have taken back that property for the price paid by the Company, and have surrendered shares to the value of R60,000, and refunded in cash the amount expended upon the property by the Company. Out of the cash so received the loan of R15,000 over the properties of the Company has been paid off.

The estimated crop for 1901 is 200,000 lb. tea, to be produced at 28 cents per lb., which includes a fair allowance for manuring.

The condition of the Sacharawatte estate continues to be satisfactory in all respects.

In terms of the Articles of Association, Mr. Joseph Fraser retires form the Board of Directors, but is eligible for re-election.

The appointment of an Auditor will rest with the meeting.

PLUMBAGO MINING COMPANY.

THE REPORT.

The Directors have pleasure in presenting to the Shareholders their Report and Accounts for Season ended 31st December, 1900, which represents a period of about nine months from the time the Company was incorporated. The Accounts are brought out up to this date so that the 1st January may commence the financial year of the Company.

The new Shaft started on the 26th March, and now called the "Kingsbury" shaft had been sunk to a depth of 78 feet, and the Cornish Pump imported from England had been erected.

Considerable trouble was experienced in getting the Machinery to the Mine and putting it in working order, but things are now working satisfactorily.

It will be noticed that the Accounts shew Cash in hand to be only R3,924·92, and it will probably be necessary to raise more Capital for the further development of the Mine; this matter will be discussed at the Meeting.

As Captain Tregay is going down on inspection in a few days' time and a full Report will be obtained from him for presentation to the Meeting further details are unnecessary.

In terms of the Articles of Association all the Directors retire, but being eligible offer themselves for re-election.

The Auditor, Mr. J D Forbes, also offers his services for 1901.

CAPTAIN TREGAY'S REPORT.

Gentlemen,—In handing you this my report for your General Meeting on the 2nd March next, I cannot help expressing a wish that the meeting had been postponed for a couple of months or so, to allow of more extensive explorations being made from the bottom of the Kingsbury shaft which would, doubtless, have enabled me to place before you more definite information as to your prospects than I am in a position to do at present. As you are aware the mine was floated largely on the strength of the two veins intercepted at the 46 feet level of the old shaft, these being the only veins of plumbago I was able to see at the time of my first visit to the mine.

These veins have not yet been tapped at the Kingsbury shaft, consequently I am unable to give you any further information upon your prospects there than I gave you in my first report on the mine.

In sinking the Kingsbury shaft several small veins of plumbago were passed through and numerous very promising indications were met with, which goes to show that the district is highly mineralized, but the fact remains that the two veins seen in the 46 feet level of the old shaft, have not been touched upon yet at a deeper level, and therefore we cannot say if these veins improve in depth or not. This I need hardly say is a most important question to settle.

Your explorations have now reached a very interesting stage, but, nothing definite has actually been arrived at yet.

A very short time now will bring you into touch with the two veins of the 46 feet level, and it is towards this end all our operations hitherto have been directed, hence the wish I expressed at the beginning of this report, that your meeting had been postponed. For the purpose of this report I visited the Iddagoda Mine on the 16th instant, and I am very pleased to say that I found everything going smoothly. Pump and steam-power working well and keeping the water down with ease. Of the difficulties encountered in getting the boiler to the mine and starting the machinery, &c., &c., you are all doubtless aware, and they need not be repeated here. All I need say is they were many and troublesome, and caused an expenditure in time and money that had not been anticipated or estimated for. At the time of my visit the Kingsbury shaft was down 84 feet from surface and at this level a cross-cut had been put out east to intersect some veins of ore passed through in the shaft. At 9 feet from the shaft these veins were intercepted and driven upon in both directions, north 20 feet, and south 17 feet. There are three veins of plumbago here varying in width from 1 inch to 3 inches wide, on an average, with occasional spots up to 4 or 5 inches wide. These veins are in close proximity and in the northern drive they appear to the converging towards each other, and, should it by come together will, in all probability, develope one a highly productive vein of ore. More cannot be said on this point at the present stage of the exploration.

In the bottom of the Kingsbury shaft directly where sinking was temporarily discontinued, a very promising looking vein of plumbago was met with. This vein is from 3 to 4 inches wide of good quality ore and, I may say here, that all the veins

at this depth show plumbago of better quality than that to be seen in the 46 feet level of the old shaft.

This points to one of two things, either the veins discovered in the Kingsbury shaft carry better ore throughout than those met with in the old shaft, or that the quality of the mineral is improving in depth and I am of opinion it is the latter and that we shall find a corresponding improvement in quality in the veins coming down from the 46 feet level.

In addition to the drivages eastward of the Kingsbury shaft, before referred to, a cross-cut has been started west, and driven at the time of my visit about 5 feet, with the object of intercepting the two veins driven upon at the 46 feet level of the old shaft.

I should have preferred sinking the Kingsbury shaft another 20 or 30 feet before cross-cutting to those veins, as better results might be looked for at a deeper level, but this would take time and I am hoping that, at the level we are now we shall see an encouraging improvement in the veins referred to and therefore I instructed Mr. Hutchings to push on the driving of this cross-cut with all speed and I hope in a month, or less from this, to reach the point aimed at.

The chief object in sinking the Kingsbury shaft was to explore the veins discovered in the old shaft, at a deeper level and at better advantage than was obtainable at the old shaft. Thus will be seen the importance of continuing to a finish the cross-cut now started, and it will not be out of place here to say that unless this is done little will have been gained by the expenditure incurred up to the present.

As I said before I should like much to have gone deeper before tapping these veins, but the cross-cut now going in will show them some 30 feet deeper than where they were seen before and I am not without hope of seeing an improvement even at this depth and if my anticipations prove correct we may safely look for still better things as we go down.

I feel it my duty therefore to advise the carrying ont of the explorations now in hand at the Kingsbury shaft as, with a comparatively small expenditure now you will attain the object sought namely prove, if the mine is likely be a profitable undertaking or not. So far, although the real object aimed at has not been attained the operations have not been without some good results.

New veins of ore have been discovered that, if not of very great value in themselves, show up the highly mineralized character of the district and point to an improvement in the quality of the ore the deeper you go. These facts are important in that when numerous small veins are met with it is usually inferred, and often proves to be true, that a large or mother vein exists somewhere in the near neighbourhood and I can see no reason why this may not be the case at Iddagoda.

Before closing I may say that your prospects of opening up a productive mine at Iddagoda have in no way lessened by recent operations. On the contrary I consider they have been enhanced by the discoveries made in the Kingsbury shaft and I have no hesitation in recommending a vigorous prosecution of the exploration of the mine.—I am, gentlemen, your obedient servant, Leonard Tregay.

Monerakande, February 25th, 1901.

THE HORREKELLEY ESTATE CO., LTD.

The Directors have pleasure in submitting the accounts of the Company for the year ending 31st December, 1900, shewing, after writing off R5,893·57 for depreciation on Buildings, Plant and Machinery, a profit of R25,104·77, which, with the balance of R563·03 brought forward from 1899, gives a total of R25,667·80 available for distribution.

The Directors recommend that a dividend at the rate of six per cent on the Capital of the Company be declared. This will absorb R24,000,—and leave a balance of R1,667·80 to be carried forward to 1901.

The working of the estate for the years 1898, 1899 and 1900 compares as follows:—

	1898.	1899.	1900.
Expenditure on Estate and in Colombo office	37,014·85	R36,754·67	R35,761·59
Number of Coco-nuts produced	1,437,885	1,305,429	1,502,298
Quantity of Coir Fibre made Ballots	35,474	28,324	22,592

Two Directors—Messrs. F W Bois and C E H Symous retire by rotation, and are eligible for re-election.

The Shareholders have to appoint an Auditor for 1901.

The current year's prospects are favourable.

ESTATES COMPANY OF UVA.

ACREAGE :

31st December, 1900.

	Tea in full bearing.	Tea in partial bearing.	Tea not in bearing.	Total Tea.	Other Products.	Timber, Grass, Forest and Waste Land.	Total.
Dammeria	515	60	29	604	30	556	1190
Battawatte and Forest Hill	413	178	...	591	..	164	755
Gampaha	455	78	57	590	45	231	866
	1383	316	86	1785	75	951	2811

The Directors have now to present to the shareholders the accounts of the Company for the past year.

The crops secured amounted to 667,101 lb. tea, 72½ bushels coffee, 167 lb. cardamoms and 41 cwt. cocoa. During the year 95,320 lb. tea were manufactured on Gampaha for other estates. The average nett price realised for the tea was 34·60 cents per lb., and 98·77 cents per lb. for cardamoms, whilst the cocoa realised about R46 per cwt.

After writing off for depreciation of buildings and machinery the sum R13,591·72, the nett profit for the year amounts to R34,720·26 equal to 4·88 per cent on the capital of the Company. To this has to be added the balance brought forward from 1899 of R13,090·04, less the sum of R409·17 over-estimated for tea unsold at the end of that year. There is therefore a sum of R47,401·13 available for distribution.

The Directors recommend the payment of a dividend of 4 per cent, that the sum of R10,000 be placed to credit of an Extension Fund Account, and that the balance amounting to R8,981·13 be carried forward to the current season's account.

During the year under review a sum of R21,228·97 has been spent under capital account, in instalment due on construction of the Battawate Road, additions to buildings and machinery, and upkeep of young tea.

The mortgage of R100,000 referred to in the 1898 report falling due, the Directors have paid this off, and negociated a fresh loan for £7,000 sterling on more advantageous terms.

The crops for the current year are estimated at 632,000 lb tea, 25 bushels coffee, 60 cwt cocoa, and 150 lb. cardamoms on an expenditure of R183,855·35.

During the year Mr. G H Alston resigned his seat on the Board on his departure for England, and the Hon. Mr. W H Figg was appointed in his place. In terms of the Articles of Associa

tion Mr. F G A Lane now retires from the Directorate.

The appointment of an Auditor for the current year rests with the meeting.

CLYDE ESTATE COMPANY.

The report was as follows:—

Your Directors beg to submit their Report and Accounts for the year ending 31 December, 1900.

The quantity of tea made was: from Estate leaf 171,521 lb. and from bought leaf 13,610 lb. The yield for the year from tea in full bearing equals 385 lb. per acre.

The cost of tea, including transport but exclusive of manuring and other extraneous expenditure, was R42,457·26 or say 24·75 cents per lb. The net amount realised for the total crop (185,131 lb.) was R59,476·81, an average of 32·13 cents as compared with 35·73 cents per lb. in 1899.

All expenditure on the young tea has been charged against revenue. The cost of manuring during the year (R1,444·44) has been similarly dealt with. A sum of R7,418·33 has been set aside to meet doubtful debts, and the year's provision for depreciation in value of buildings and machinery amounts to R3,255·52. The available balance then remaining is R2,543·13, which the Directors recommend being carried forward.

Under the Articles of Association, Mr. E D Harrison retires from the Board, and being eligible offers himself for re-election.

The Shareholders have to appoint an Auditor for 1901.

UNION ESTATES COMPANY.

ANNUAL MEETING

ACREAGE.

	Tea in full bearing.	Tea not in bearing.	Cocoa.	Cardamoms.	Total Cultivated.	Grass, jungle & Waste land.	Total.
Hayes Group	518	3	—	25	546	1,665	2,211
Dea Ella	248	—	91	—	339	147	486
	766	3	91	25	885	1,812	2,697

The Directors have now to present to the shareholders the accounts of the Company for the past year.

The tea crops secured were 87,416 lb. on Dea Ella (including 42,330 lb. purchased leaf) and 271,822 lb. on Hayes. The average nett prices realised were R31·44 cents per lb. for Dea Ella and R30·75 cents per lb. for Hayes, as against 36 cents and R38·65 cents respectively in 1899. The Dea Ella cocoa crop amounted to about 100 cwts., which sold at an average of R44·30 per cwt., and the Hayes cardamom crop sold realised R1·21 per lb. nett.

The plant for the electrical transmission of power to the factory on Hayes estate continues to work most satisfactorily.

After making provision for the depreciation of buildings and machinery, writing off a sum of R180·82 cents for irrecoverable coast advances and allowing for the balance of R1,818·86 cents brought forward from 1899 account, the result of the year's working shews a loss of R6,286·26 cents to be carried forward to the current year's account.

The Directors deeply regret this disappointing result which is entirely attributable to the extremely low prices ruling during the year for teas of the description manufactured by the Company's estates. Under the circumstances the Directors and Agents have decided to refund half their fees for the year.

The amount expended upon capital account during 1900 was R13,256·68 cents for instalment due on the construction of Hayes Cart Road, additions to buildings and machinery on Hayes, and upkeep of tea and cocoa on Dea Ella not yet in bearing.

The estimate for this year is 359,250 lb. tea, 120 cwts. cocoa, 12,000 coconuts and 600 lb. cardamoms, on an expenditure of R104,998·60 cents which includes R1,310 on capital account to be expended on upkeep of cocoa clearings on Dea Ella and the planting up of a further 10 acres in cardamoms on Hayes.

In term of the articles of Association the Hon. Mr. W H Figg now retires from the Board, but is eligible for re-election.

The appointment of an Auditor for the current year rests with the meeting.

HIGHEST PRICE FOR CINCHONA SEED.

We are indebted to Mr. Standen, Director of the Government Cinchona Plantation, Nilgiris, for the following memorandum:—

"From the Report of the Director of the Dutch Government Cinchona Plantations for the quarter ending 31st December, 1900, I see that the highest price paid for a packet of 25 grammes of cinchona seed was 555 guilders or 22·2 guilders per gramme. This is equivalent to 10069·69 guilders or R12,587 per pound."

AN EXPERIMENT IN PISCICULTURE.

A recent number of the *Fishing Gazette* contains an interesting account, by Captain Stuart Godfrey, of the attempts made by a small body of enthusiastic anglers to introduce the English trout into Kashmir waters. We briefly chronicled the failure of the initatory endeavour in this direction, the misadventure being due to the carelessness of the agents entrusted with the sending out of the trout ova. But, though disappointed, the promoters have not been disheartened, and we shall hope to hear very shortly of the success of their second experiment. Meanwhile it is worth while glancing at the history of this attempt to improve the sporting qualities of the waters of Kashmir. Experience has proved that trout ova could be successfully conveyed to South Africa, New Zealand, and elsewhere; and there seemed no reason, says Captain Godfrey, why, despite the long road journey from Rawalpindi to Srinagar, the ova should not during the cold season, be brought out by a line steamer to Bombay or Karachi, and thence conveyed to Rawalpindi and Srinagar. Colonel Unwin headed the subscription list which was started for this purpose, and support was also forthcoming from a few others interested in Kashmir. The State authorities approved of the scheme and promised certain assistance, such as a site for the breeding shed, a supply of water, and the setting aside if necessary of a portion of the Dal or some other lake for the purpose of the experiment. The Duke of Bedford also kindly offered a present of 10,000 ova to start the proceedings. Elaborate arrangements had been made in India for the reception of the ova. A railway carriage was sent to the Karachi docks with slings fitted in it to support the ova box. Ice had been got ready for the train journey, and

every possible precaution taken to ensure the safe transit of the future trout from the seaboard to Rawalpindi. Meanwhile, for the road portion of the journey, Mr Dhahjhidboy had prepared a special tonga, and arrangements had been made with the tehsildars all along the road to Kashmir for an ample supply of ice and snow at each halting station. The Collector of Customs, too, at Karachi had also promised to see that there was no delay in clearing the eggs. All these careful preparations were unfortunately rendered useless by the action of the home forwarding agent who actually sent out the ova in a slow steamer, unprovided either with ice or a cool room, so that there was nothing to take over at Karachi but a mass of putrid eggs. The Duke of Bedford, however, has again come forward with a fresh present of ova, which reached Bombay a few weeks since in the *Caledonia*, but regarding the arrival of which in Kashmir we are at present without any information. Pending the receipt of this, however, it may be of interest to consider the chances of successfully acclimatising English or American trout in the lakes and rivers of the Himalaya.

Captain Godfrey thinks that there is every chance of success. He points out that those interested in the present venture have several important points in their favour. These are: (1) water supplied in pipes from a glacier-fed stream filtered in the reservoir; (2) ice and snow within easy reach costing even in summer only two days' coolie wage for a man's load; (3) a community of sportsmen always in the country, from whom assistance may be relied on; (4) a temperate climate little dissimilar to that of Switzerland or Scotland, except for a short hot weather; and (5) the assistance of the Kashmir State officials. There is a good deal no doubt in this list of advantages, but yet the Kashmir Fishing Club would do well not to be too confident. Success in matters of this kind is not to be expected at the outset. We say this, not for the purpose of throwing cold water on the scheme, but rather with a view to encouraging those interested to persevere in their attempts even though they be met at the outset with many unmitigated failures. It was only after numerous failures that the English trout was at length successfully acclimatised in places such as New Zealand and Tasmania. In the Nilgiri Hills, too, there have been many endeavours to introduce the English trout, but so far with practically no real success. A careful examination of all the various ponds and streams in that district wherein trout have been from time to time deposited, lately revealed their almost complete absence. A few unhealthy-looking fish were, it is true to be found, the sole remnant of the thousands imported. But there had been apparently no attempt on the part of these to perpetuate their species, and the Nilgiri attempts, so far as our information goes, must be written down a failure. It remains to be seen what will happen in Kashmir. It would be difficult to exaggerate the nature and extent of the many obstacles to be overcome before trout can be successfully acclimatised. Kashmir presents certain solid advantages for an attempt of this nature but the list of these as presented by Captain Godfrey does not necessarily ensure success. We will assume, for instance, that the ova are landed in Kashmir in a healthy condition, that is, with the usual percentage of bad or unfruitful eggs. This is no small assumption by the way. The next thing to do is to hatch out the eggs. Here undoubtedly the supply of pure cold water mentioned by Captain Godfrey will come in useful. Such a supply is the very first desideratum in trout culture. If all goes well the fish in due course are hatched out. For a certain period after their entry into this world they feed on the contents of the umbilical sac with which nature provides them. There soon comes a time, however, when this source is pretty nearly exhausted and it is necessary for the young fry to obtain other food. The glacier water will certainly contain no food, so that recourse must be had to other means. Artificial feeding is seldom satisfactory, and the difficulties in carrying it out would be enormously increased in the case of a country like Kashmir, especially as there is no skilled professional pisciculturist on the spot. It will be necessary therefore to fall back on the natural food present in minute particles in the water of the lake or some neighbouring stream which runs, not through a rocky channel, but through weeds. There ought to be plenty of such water available for the Kashmir experiments, and no doubt there will be plenty of food in it. The question which remains to be settled, however, is whether such food will be suitable and acceptable to English trout fry. If it is, well and good. The experiment will have advanced to a notable extent, and barring accidents, the young trout will soon grow to a respectable size. Here the temptation to turn the trout at large may be felt, but it is to be hoped will be strenuously resisted. Turning them out at such an early stage would simply mean that they would never be seen again. The Kashmir lakes and rivers swarm with the so-called Kashmir trout, a fish of the most pronounced cannibal tendencies, and running to over twenty pounds in weight. These fish would certainly soon make short work of such interesting strangers as yearling English trout. Even if thousands of two-year-old trout were turned out into unenclosed Kashmir waters, it is doubtful if any of them would be met with again. The extent of water is enormous, and the cannibal instincts of the native fish, together with the inroads of the mahseer during the summer months, would easily account for their early disappearance. No; the only way to go to work with any chance of success is to get out from England relays of ova. These must be hatched out in succession and kept in separate partitions until a respectable size. They could then be turned out into a carefully partitioned-off part of, say, the Dal lake, care being taken that only fish much of the same size were placed in the same position in order to prevent cannibalism. These partitioned-off spaces of natural water could be gradually enlarged as the trout grew larger. In time the fish might begin to breed, and then the success of the experiment would be assured. The management would be able to secure as many ova as they required on the spot, without having to go through the risky and expensive operation of importing them from Europe. It would then be possible to turn out from time to time some of the larger fish into open waters, and as the hatching and breeding operations would be kept up and more and more fish turned out into the open, a time would eventually arrive when it would be possible to truthfully assert that the English trout had at length been thoroughly acclimatised in India.

Exactly what this would mean, it would be difficult to exaggerate. The attractions of Kash-

mir as a holiday resort would be doubled, and it might be quite possible to extend the Indian habitat of the trout to such streams as the Poonch and the Giri. Generally speaking the fish could only be introduced into the Himalayan streams, for in waters whose temperature rises for considerable periods over 60 degrees Fahrenheit, the salmon family do not thrive. Still the success of one serious attempt at pisciculture might give rise to others. Why not try and cultivate the mahseer, for instance? There are not wanting signs that this truly sporting fish, what with the enormous increase of poaching and the greatly extended operations of anglers, will in time begin to get scarce in many of the more get-at-able waters. What has already happened to the salmon in many home streams will in course of time happen also to the mahseer, unless Art steps into assist the operations of Nature. When once a certain amount of practical experience has been gained by Indian sportsmen in the art of fish-rearing as carried out in Kashmir, it would be a comparatively cheap and simple matter to rear young mahseer in suitable localities, and thus add enormously to the sporting value of the selected rivers. The experiment now being carried out in Kashmir is consequently one which is capable of great results, and the progress of the operations will be watched with anxiety by all who take an interest in the improvement of sport. So far the cost of the Kashmir trials has been borne by a few, but we feel confident that if experiments on a small scale give any promise of success, there will be money enough forthcoming from the sporting community to enable them to be prosecuted on a more ambitious scale.—*Pioneer*, February 8.

A TROPICAL BEAT FOR BLACK BEAR IN KASHMIR.

All the arrrangements had heen made the day before by "Whiskers," my *shikari* (so-called because his hirsute appendages stuck out like a cat's), for 50 coolies and 3 tom-tomwallahs to turn up at 6 a.m., which means 8 a.m. Consequently when they arrived talking only as Kashmiris can talk at 9 a.m., it did not matter much, as it is considered rude to disturb a bear in his early morning sleep. As a matter of fact, it is easier to drive them in the middle of the day when it is hot. Off we started —Kashmiris, tom-tomwallahs, hangers-on and swells, *tous ensemble*—to a narrow strip of forest on a steep side of a hill about one mile away. The coolies and tom-tomwallahs, &c., were distributed, according to the drive, at either end of the forest, to beat both ways and eventually meet in the middle. In the meantime after a stiffish climb myself and *shikari*, who was fairly agog with excitement, reached the top and planted ourselves, after much deliheration on my *shikari's* part, by a boundary pillar with a view down either side, along the ridge, for about 100 yards along a cut line, with perfectly dead ground at my feet. This I tried to explain would be very awkward with a lively bear. However, there was no time to change now as the faint sound of tom-toming was heard in the distance. All the rifles and guns were loaded and I tried to get comfortable; but deodar needles are not the best of friends with thin trousers. On came the beat with the coolies whistling and shouting, all making as much noise as an English school-boy does when he gets a half-holiday. Suddenly—"What's that?" from my *shikari*, accompanied by a nudge in my short ribs, as a breaking of branches was heard below us to the left. I grasped my faithful ·500 and waited; the noise came nearer, and then I saw something black. "Shoot, shoot," cried the *shikari*, "Baloo, Baloo"; but I was not such a fool as to do so until I had seen what it was; for to shoot a cow in Kashmir is considered much worse than polishing off a human being; and right enough, after about three minutes, out wandered a small black heifer across the cut line. My *shikari* was quite overcome, wagging his head and clasping his hands and muttering prayers to *Allah* in his whiskers. But there was no time for this, so I woke him up with the butt-end of my rifle. In the meantime the beat had been drawing nearer and nearer, and the whistles sounded like a lot of gallery boys in a theatre on the Surrey side of the river. Suddenly another nudge from my *shikari*, and right enough, in the bushes to my left, about 100 yards away, helow the cut line, I saw something move. I turned round and got into as comfortable a position as I could when out bolted a hear across the line. Bang! I let drive, and what a row he kicked up, which was good to hear as I knew I had hit him as he disappeared down the other side of the hill. The *shikari* was simply bursting with joy, so I had to quiet him again with the hutt-end of my rifle. The heat now was coming to an end, and the *shikari* was thinking of stopping it, when suddenly—"Wough-wough," and a grunt at my feet; of course, just where nobody was looking; and out of a bush from this very dead ground appeared the sleek head of a fine black bear. I don't know who was the most surprised—the bear, the *shikari*, or myself. Anyhow the bear holted before I had time to swing round on deodar needles (a very painful performance) and get a shot. The brute evidently hroke back through the heaters as he never appeared again. This made old "Whiskers" very wroth, and so he hurled invectives at all the coolies' and tom-tomwallahs' grandmothers as they turned up, in which performance the poor man made himself quite hoarse.

The beat being over, great excitement was evident amongst the coolies, especially as my *shikari* had informed them that the bear I had shot was at least 12 feet long. The next business was to track up the wounded bear; and for this purpose village dogs were sent for. These amused themselves for the first half hour in pulling each other to pieces, and judging from the fur that flew, they did. However, with the help of many sticks, they were brought under subjection. In the meantime my gallant *shikari* had disappeared, taking with him, without my knowledge, my 12-bore loaded with ball. Suddenly, bang-bang, far down the hill. I collared my rifle and legged it for all I was worth to where the sounds came from, through thick brushwood, which was almost as nasty as the deodar needles. I came upon my tremhling *shikari*; probably he was in a funk on account of his having disobeyed orders in shooting, and not from being alone in the proximity of a wounded bear. He informed me that he suddenly came across the bear lying down, and that he let him have it, right and left, straight into the brute's back. This evidently woke him up, as he had gone down hill; but the dogs soon rounded him up: so I took the 12-hore and descended to where the dogs were baiting the bear behind a large deodar tree. I could see nothing, so sat down about 20 yards away above the tree and awaited results. Presently a black head appeared round the corner, so I gave the beast a ball in his neck which settled him. The plucky dogs, finding the bear dead, immediately began to maul the carcass and to pull it down the very steep hill side. However, the coolies soon drove them off, and when in about an hour's time 10 coolies came staggering under the load, I had him measured—a full 4 feet ten inches. So much for the 12-footer. I found that my first shot had hit him a few inches behind the shoulder and had torn him about terribly. The *shikari's* shots had further blown great holes into him; and it was a wonder, the animal being so small, that he ever got away at all—a fact which shows their extreme vitality. I had two or three more beats after this with no luck; but as moral: "Keep an eye on the *shikari*."—*Indian Forester*. E. RADCLIFFE.

RUBBER COLLECTION AND CULTIVATION.

The various reports coming from our consuls and agents in different parts of the world contain a large amount of very interesting matter respecting the collection and cultivation of rubber in the various parts of the world where this useful article can be obtained. Considerable attention has been paid to the subject, with the result that the rubber has arrived on the market in a very much better condition and more suitable for manufacture than previously. Where the work has been left to natives, their only idea being to get as much as they can for their work on the spot, they have not troubled much about the future, the consequence of which was that they loaded the raw material with all kinds of sand, stones and rubbish, so as to make their parcels of rubber heavier and so obtain a larger remuneration. Rubber collected in this way has given a vast amount of trouble to india-rubber manufacturers, who have been compelled to inspect every piece of rubber very carefully before putting it into their machines, otherwise great damage might have been done to them. Another difficulty was with regard to the condition in which the rubber arrived upon this market; being badly prepared, it had deteriorated very considerably by the time it reached the rubber manufactnrer, and, consequently, the loss in washing and drying was very considerable, but now that the requirements of the Trade have been more generally known, especially in the foreign countries and our own colonies, the resnlt is that the rubber comes to the market in a much cleaner condition than it used to. Owing, however, to the more speedy means of transit, the rubber, as it now arrives, contains more moisture than it originally did, when it took some months to get from the point of collection to the port of shipment, and some months to the English ports. Now, owing to our ocean greyhounds, the rubber can be brought from far up the country to the English manufacturer in the space of a very few weeks. Mannfacturers must not, however, be led away by the clean appearance of the rubber and should allow for the additional moisture which it contains. It is all very well to take the average of past years as a basis, but we hear on all sides from manufacturers that the loss on washing and drying raw rubbers keeps on increasiug every year, in spite of the improvements which have been made in the condition of the rubber. Experiments are being continually made to find out the best means of curing, and we suppose that it will not be many years before some satisfactory method is adopted whereby rubber can be bonght on theEnglish market, which is practically pure and ready for immediate working without the usual process of washing and drying. The past century has seen vast improvements in the Rubber Trade, but we anticipate that in the early years of the present century much more will be known about this useful material, and considerable strides will be made in the collection of the raw material, especially in those districts where the cultivation has been carried on upon proper lines. There are various processes of coagulation which have been tried, but none seems to have answered so well as the old-fashioned process of smoking carried ou in Brazil; but, still, time will prove.—*India-Rubber Journal*, Jan. 21.

RUBBER PLANTING IN BRAZIL.

An interesting account of rubber planting reaches us from Brazil. The centre of the rubber plantations in the State of Minas is Bagagem where at least 150,000 shoots have been planted during the last two years. On one plantation the trees had already reached the height of 5 metres (16 feet 3 inches) some of them of little more than a year's growth. The trunks, however, have not developed in proportion and only measure, so far about 20 to 30 centimetres (10 inches to 12 inches). This plantation is situated on high gravelly soil and counts some 10,000 trees. The older trees planted two or three years ago show signs of abundant latex, which exudes from the tender shoots and solidifies the stems. The growth of the trees was greatly retarded in the winter months, from June to August, but afterwards the development was surprising, nearly 3ft in three months. The trees were raised from seeds planted three together, the holes being at distances of 12 to 15 hands from one another in regular lines. Only one weeding is necessary per annum. The climate of Minnas is cold, falling below freezing point in some localities during the winter, and as Manicoba appears to be peculiarly susceptible to cold, it is necessary to choose the ground carefully. Within a few years the Manicoba industry may be expected to give important results.—*India rubber Journal*, February 4.

TWO NEW PLANTING DISTRICTS.

We have now decided to separate from the Kurunegala district, the following estates to be included in a

GALAGEDARA DISTRICT,

namely :—Aluta, Betworth (late Isabel), Dea Ella, Greenwood, Malgré Moi, Mousava, Morankande, Nella-Oola, Rockhill, Sunnyside, all of which are served by the Post Office at Galagedara, to which will be added Belgodde (P.O. Rambukkana) and Moorock, Muttettudeniya, Rookgolle and Woodslee (P. O. Weuda); as well as Bollagalla Upper and Lower, with Kandy as post station. We may as well also transfer a number of places which have "Madawalatenne" as post station, though most of these are now "uncultivated": — Ancumbura,, Battagolla, Beragama (Peradeniya), Boccawella, Bon Accord, Dunira Fulton's, Tennekoon's and Wilson's Land, Galanne, Goddehena, Hatbawa, Hingulgalla, Iddegodde, Kallugallatenne (Kandy), Kandewatte (Peradeniya), Mahatenne (Kandy), Palagalla (Peradeniya), Richgrove (Kandy), Riverside, St. Julia, Thornhill and Wattagalla) (Kandy). Any proprietor or manager who objects to such transfer, or any one wishing to include a further estate, will kindly communicate with this office at once.

Then we are urged to establish a

SOUTH MATALE DISTRICT,

as we have Matale North, West and East; and Mr. H. Storey is good enough to suggest the following estates for this new district:—Benveula, Ballacadua, Barton, Duncrub, Goruluhela, Kaduwella, Kotuwagedera, Kuruwille, Marakona, Malvern, Meegastenne, Muwagala, Pansalatenne, Ratwatte, Syston, The Grove, Ukuwella, Vellana, Warriapolla, Warakamure, Wyamita—21 estates all described as truly of "Matale South," taking the town of Matale as a centre. Here again we are in the hands of proprietors and managers. If any object to this proposal, or wish to modify it in any way, let them write at once.

TEA "REFUSE" AND CAFFEINE; ALSO CINCHONA PROSPECTS.

Mr. F. L. Seely,—the very worthy and well-informed representative of a big American drug house—has been giving us some useful information about tea refuse and caffeine. Mr. Seely is chiefly interested in cinchona and quinine, and he tells us plainly that Java commands—and must for many years command—the "bark" market with her 25,000 acres of old trees, chiefly Calisaya, which, if the price justified the export, could supply five or six million lb. in place of the normal one million lb. of bark, each month. Last year Java supplied 12,000,000 lb. of cinchona bark and manufactured one-tenth (one million ounces) of the world's supply of quinine. There is, therefore, no special encouragement to grow cinchona in Ceylon, save as an adjunct to other products; and in this direction, a good deal may be safely done, because the Java planters are bound to keep up the price for their own protection. Mr. Seely ran up to Kandy, Hatton and Blair Athol; but finding it took him four hours to find as many cinchona trees (!), he thought he had better hurry over to India.

But now to turn to refuse tea and caffeine, Mr. Seely estimates that the world's requirements in caffeine equal 50,000 lb. at least and may shortly rise to 100,000 lb. To produce this quantity, chemists require from five to ten million lb. of refuse tea. The firm of Messrs. Bohringer, as representing the great Mannheim Chemical Manufactory, have hitherto been the chief purchasers of such refuse; but they find a difficulty in dealing with planters, because of their fear lest any of the tea should be sold for food consumption. Of course, such an idea is absurd in the case of a house of the standing of Messrs. Bohringer. But Mr. Seely suggests a very easy check. The addition of some lime to refuse tea would prevent its use for food consumption, while it would aid, even expedite, the work of the chemist. If, therefore, the planters consigned their refuse tea to Messrs. Bohringer's store in Colombo, a representative of the Planters' Association or "Thirty Committee" could, once a month or once a quarter, check the consignments and see the lime duly added. We give this suggestion for what it is worth. Certainly the transfer of some 5,000,000 lb. of refuse or rubbishy teas to the chemist ought to be an object worthy of attention from the Association and Chamber's Committees.

COCOA AND CHOCOLATE:

THE NEW LOCAL INDUSTRY.

(*Communicated.*)

Of late years, manufacturers in some parts of the world have complacently claimed the credit to themselves of giving to the consumer an article of diet of great excellence, as if the excellence was not in the bean itself before it went into the manufacturer's hands. Long before the days of elaborate machinery and the necessity for laws against adulteration of foodstuffs the Mexican ground his cocoa paste in the primitive grindstone of the aborigine; and in golden goblets, we are told, did the kings sip this ambrosia of the gods. If, therefore, the manufacturer could take credit for aught he could of a verity only claim credit for leaving well alone. To him, indeed, could a discriminating public say in these days of popularised science—for he can take away much of the purity and strength of cocoa with the aid of starch, as he could increase its solubility by the addition of deleterious chemicals:—"Nothing extenuate, nut down nought in malice." The medical faculty may, in the case of those with a weak digestion, demand a reduction of the natural fat found in the cocoa. But this is readily extracted by the use of a press, while the cocoa is still in a liquid state, as it flows out of the mill, and the confectioner as readily takes it away at double the price paid for the nib. The residuum is what the manufacturer is pleased to call essence! Such is the romance which attaches to cocoa.

OUR VIEW OF BARK AND A BROKER'S.

Readers who have followed our articles on cinchona and quinine during the last three years will be especially interested in a letter recently issued by Messrs. Woodhouse & Co., the well-known bark brokers. There is nothing remarkable in the fact that this firm interprets the figures relating to cinchona as we do, for it is difficult to see how anyone taking a wide survey of the situation can come to any other conclusion. The only people who doubt the evident conclusion are those who expect that if the natural position of an article is strong the article should stand any amount of rushing by speculators without having reactions. Messrs. Woodhouse's way, however, of putting certain points are, perhaps, curiously like ours. As the letter is lengthy, we can only, of course, refer here to scattered passages.

First, the fact is noted that 1900 is memorable as being the first for many years in which the value of the unit in bark did not fall below 1d per pound, and the price of quinine below 1s per ounce. The average units for bark were, for 1900, 10.13 cents in Holland and 2d in London, as against 7.05 cents and 1⅜d in 1899, and 4.78 cents and 15-16d in 1898. One noteworthy point to which we drew attention is here emphasised—viz., that whereas in 1899, at the point when the unit reached 10.90 cents, manufacturers raised quinine to 1s 9d, in 1900 the alkaloid was never above 1s 7d, though 12.25 cents was the unit in September. A calculation is also made, showing cost of quinine in bark, this cost plus that of manufacturing, and the selling price. Taken in the order named these factors are:—1900, 1s, 1s 4d, 1s 5½d; 1899, 8d, 1s, 1s 3d; 1898, 5½d, 9½d, 11d. This reveals at once how the general trend of bark and quinine has been strongly upwards, and how a healthier situation is being promoted by the closer approach of cost and selling price. In the broker's letter the cost of manufacture is put at 4d per oz; we think 3d is a fairer figure.

Turning to the question of consumption and production, some carefully compiled tables are given, which, however, we will leave for later consideration. At present we may simply say that the conclusion from these is the one we have repeated again and again, viz, that consumption has overtaken production. In these tables the production is probably stated rather too low; indeed, alkaloids other than quinine

sulphate are purposely excluded. The figures given for the last three years, set out as ounces of quinine, are as follows:

	1900.	1899.	1898.
Production ...	12,261,000	12,447,000	12,855,000
Consumption ...	14,818,000	14,861,000	14,464,000

Thus we have been drawing on stocks of bark, that in London having fallen from nearly 20,000 packages to less than 10,000. Allowing for the increase in stocks of quinine, the net reduction in the last year of bark and quinine stocks is given as 1,213,000 oz. of the latter.

Moreover, Java bark has been falling off in quality as well as quantity. In 1897, 5,315,000 kilos offered gave 10,256,000 ounces of quinine; in 1900, 5,260.000 kilos only gave 8,735,000 ounces. About 900,000 ounces of quinine have been sold in Java during 1900. This manufacture locally has undoubtedly had the marked influence, as stated, of forcing European makers to maintain a good unit for bark and a low price for quinine. Java planters have thus the matter in their own hands (irrespective of financial obligations) and, if they behave sensibly, we ought to see higher prices still this year.—*British and Colonial Druggist*, Feb. 15.

THE WORLD'S SUPPLY OF CRUDE RUBBER.

NO CHANCE OF A MONOPOLY.

There is no real scarcity of rubber. Vast supplies exist in forests which have never yet been "worked," and there is rubber in warehouses in many markets, and afloat on the seas, for all who have the money to pay for it. Every country that ever yielded any rubber continues to do so; every grade of rubber that ever came to market is still coming; the world's total production, as rule, becomes greater every year. All who have use for rubber goods of any sort find the market amply supplied. Where, then, is the scarcity? It is true that, now and then, consumption gains on the rate of production of the raw material, and prices may rise in consequence, but this very fact starts more gatherers to work, and prices tend downward again. Of course all crude rubber costs more than formerly, but this is true of many other things, and consumers now are as able to pay for the rubber goods they need as people ever were.

No fear need be felt that the supply of rubber will ever be monopolised. Could such a thing be done, the manufacturer, first, and the consumer of rubber goods, in the end, might be made to suffer exactions hard to bear. But a consolidation of all the firms, in various parts of the world, who have capital invested in handling crude rubber, would be out of the question, if only for the reason that the rubber business is as a rule carried on in connection with other trading, from which it would be difficult to separate it. A complete monopoly of rubber, then, would mean a great general trading company constantly liable to competition from new sources, in respect not only to rubber but to all the other commodities. The success of the Standard Oil Co., a notable example of monopoly, is due to their complete control of the natural supplies, confined to a limited and accessible territory, and to handling their products on a very large scale, making great economies possible. Rubber, on the other hand, is obtained throughout a wide belt, extending around the world, but mostly in regions remote from civilised centres, unsuited for white men; it comes in driblets to innumerable initial markets, from millions of gatherers, whose labor practically is beyond control. Moreover, if all the forests now yielding rubber, and all the rubber gatherers at work, and all the houses trading in rubber in America, Europe, Asia, and Africa, were brought under a single control, the possibility would exist of new forests being explored, new workers found, and new trading houses opened, every one of which facts would tend to the overthrow of the monopoly.

As for the future of rubber prices, certain considerations are worthy of attention. In the first place, the great increase in the demand for raw material in recent years has been due both to new uses of rubber, and to the introduction of the use of rubber goods into new fields. In not a few cases the recent rate of growth doubtless is meeting a check for the present, whereas the production of rubber seems likely to continue, in which event it would seem that prices should decline. On the other hand, a very marked decline in prices would lead to still further new uses of rubber, which would prevent the cost from sinking to former levels, or at least from staying there very long. In this connection may be mentioned the widespread interest in planting rubber, the outcome of which can hardly fail to be, within ten or twenty years, a considerable addition to the world's supply of this commodity, which will further enable its use to be extended.

The constant fluctuations in the price of rubber are most inconvenient at times for manufacturers, especially where contracts are made for supplying goods at a certain price, which price may fail to yield a profit on account of a heavy and unexpected advance in the cost of the raw material. Here is involved, by the way, the whole question of speculation in rubber prices by manufacturers, to which a further article will be devoted in a latter issue. But manufacturers have it in their power, to a certain extent, to protect themselves against some of the unpleasant effects of fluctuations in prices by keeping on hand larger stocks of rubber instead of the "hand to mouth" policy of buying that so many of them pursue.—*India Rubber World*, Feb. 1.

TEA PLANTING IN JAVA.

PAYING WELL: BUT EXTENSIONS NOT PUSHED!

Tea-growing pays so well in Java that the area under the staple shows increase. Yet capitalists, as a rule, shrink from investing money in this line of enterprise. The Batavia *Nieuwsblad* deplores this lack of interest at the present time, when coffee is on the down grade and when, owing to the abandonment of many coffee estates, thousands of labourers thrown out of employment can be started on tea-planting. Investors object that tea-growing stands under the disadvantage of no dividends being available in the early years of an estate. The reply is that this is made good by the heavy dividends sure to come once the estate has begun to bear.—*Straits Times*, Feb. 25.

Fibre Production by Indigo Planters.—The cultivation of fibre-producing plants has lately been taken up rather extensively in India, particularly in the indigo districts; and there would appear to be every promise of satisfactory returns being obtained by the planters. A sample of agave fibre, decorticated by Faure's machine, recently sent home, has been valued at £24 a ton, which should make its production a fairly profitable one to the grower.—*Englishman*.

ROYAL BOTANIC GARDENS, PERADENIYA.

The Director and his Staff, aided by the Government Printer, deserve great credit for the promptitude with which their interesting and valuable Reports for 1900 have seen the light. We hope through the courteous aid of the same indispensable Printer, to give our readers the advantage of reading the bulk of the Reports in the very convenient and reliable form in which they are officially issued. And meantime we can only say that it is evident the Staff —Director and Botanist, Mycologist, Entomologist, Consulting Chemist and temporary Assistant, besides the Curator at Peradeniya and the Superintendent at Hakgalla are now in full working order, and that much good should result. "The losses by disease are enormous and to save even 5 per cent of them," it is rightly said, would be "a great gain." Camphor, citronella, tobacco and sericulture are new or minor industries to be investigated. The total cost of the Department for 1900 was R71,740 against R58,822 in 1899; the receipts from sales fell off owing to lower price of rubber seed and aggregated last year R4,659. The paragraph of most general interest and importance at this time is that on our staple from Mr. Willis:—

As the extension of cultivation, though practically over in Ceylon, is still going on in South India, Java, and elsewhere, it is probable that the full effect of overproduction has yet to be felt, and that the tea industry has now to pass through a trying period, which may lead to considerable alterations and reorganisations in methods of working, &c. Greater specialisation, larger factories under specially-trained managers, manuring and plucking for quality rather than for quantity, selection of the best and most suitable jâts as regards quality of tea and power of resisting disease, replacement of inferior bushes and fields by better and by other products, careful precautions against disease, and improvements in methods of cultivation and manufacture, are some of the directions in which relief may be looked for. Tea has been comparatively free from serious outbreaks of blights during the year (see supplements). A commencement, which may lead to important developments, has been made in the manufacture of green teas suited to the American markets. If this extend, it will temporarily relieve the overproduction difficulty.

Mr. Carruthers deals with Cacao and also with Tea Blights; while the list of "enemies" dealt with or described by Mr. Green is very formidable; but it shews how keenly he is on the alert. Mr. Macmillan and Mr. Nock also supply interesting reports; but we must close for the present with the Director's notable reference to Trimen's "Flora of Ceylon":—

The fifth and last volume of the Flora of Ceylon appeared early in the year, written by the veteran botanist, Sir J D Hooker, The Colony now possesses perhaps the best existing Colonial Flora. At the same time, this flora is anything but complete; there are yet many new species to be discovered, and many occur in other localities than those mentioned. For the filling up of the gap we must rely largely on the help of local botanists and an attempt will shortly be made to interest more of the public than have hitherto cared for such things in the study of this most fascinating of the sciences. Suggestions to this end will be cordially welcomed.

MINOR PRODUCTS REPORT.

London, Feb. 14.

Coca Leaves.—Offered, 32 packages. Sold 0. Ceylon leaves of the Huanoco character were bought in at 1s 6d, and broken Truxillo leaves at 1s 2d.

Cinchona Bark.—The London bark auctions for February were held this week. The offerings and sales were rather lower than at the last auction. Out of 1,343 packages offered, 1,132 were sold. The weight offered was 285,394 lb, of which 230,549 lb were sold. The unit was 1½d. The following prices were paid:—Calisaya, cultivated Bolivia quills were sold at 7½d to 8⅝d. Ledger, Java chips were sold at 3d to 4⅝d; branch, at ¾d. East India chips were sold at 4¾d to 4⅛d. Officinalis, East Indian chips were sold at 2½d to 3d. Ceylon, branch, 2½d; hybrid stems chips, 3½d. Succirubra: Ceylon chips sold at 2¾d to 4d; and roots 4d to 4⅝d; Hybrid chips at 3¾d.—*British and Colonial Druggist*,

RUBBER IN MEXICO.

The British Commercial Agent in the United States has sent the following report upon the development of the rubber industry in Mexico by American capital:—

The report states that out of the interest in the subject of planting rubber in Mexico has grown a series of companies operating in the Ubero district on the Isthmus of Tehuantepec, whose prospects seem encouraging. Two companies have existed for some time past having their headquarters at Indianopolis. These are the Mexican Coffee & Rubber Company, and the Ubero Plantation Company, of Indianopolis.

The Ubero Plantation Company was incorporated under the laws of Maine, August 10th, 1900, with 1,000,000 dollars capital. The company owns 3,000 acres, adjoining the original Ubero tract, on which it proposes planting 1,000,000 coffee trees, 400,000 rubber trees, and 1,000,000 pineapple plants.

The Isthmus Rubber Company of Ubero, now being organised, will have a New Jersey charter and its principal offices in New York.

Tehuantepec Rubber Culture Company, Canton Mintitlan, State of Vera Cruz, Mexico.—The personnel of this company were all in the organisation of the Woolson Spice Company. The original stock of the Woolson Company was 37,500 dollars; it paid in dividends in six years over 1,000'000 dollars, and the company was then sold for 2,200,000 dollars. The Dos Rios plantation has also been a marked success.

Mexican Plantation Company, State of Vera Cruz, Mexico.—This company was incorporated under the laws of Indiana on November 20th, 1900, with 10,000 dollars capital, fully paid. It has acquired 600 acres on the Tesechoacon River, 90 miles from the gulf port of Alvarado, and purpose planting 125,000 rubber trees in the spring.

La Zacualpa Rubber Plantation Company, State of Chiapa, Mexico.—A report recently issued by this company states that during the last year 600,000 rubber trees were transplanted, 1,000,000 rubber plants were placed in nurseries for transplanting in 1901, 1,000,000 plants were started in seed-beds for transplanting to the nursery.

The Leavenworth Coffee & Rubber Company, Leavenworth, Kansas, is mentioned as having a tract of 2,000 acres just above the Dos Rios plantation, on the Isthmus of Hehuantepec. Some coffee, rubber, and vanilla have been planted.—*India-Rubber Trades' Journal*, Feb. 4.

AVERAGES FOR TEA SALE.

FEBRUARY 27TH, 1901.

CRUDE RUBBER COMBINES.

There is, perhaps, no cry—says the *India-rubber Journal*, Feb. 4th—which appeals so much to Englishmen in their love of freedom as that of "No Monopoly." It is only necessary to start the cry and immediately all ranks rally round the standard to break down the work of any individual or association who endeavours to monopolise any industry or interest. Monopolies, as a rule, are only short-lived, but they are liable to disturb the equilibrium of trade, and produce results which have a baneful influence upon commercial life in general. A combination formed to control the crude rubber market can only have a result which would be disastrous either to the industry or to the promoters. Considerable excitement has been recently caused by the reports that a combination has been in process of formation in the United States to control the crude rubber market. Different figures have been stated as to the proposed capital, varying from 10,000,000 to 30,000,000 dollars. It is unnecessary to enter into the alleged objects of this combination, and it is difficult to say what the effect of it would be on the British raw rubber market. From inquiries we have made we are left in an uncertain state of mind as to whether this combination will actually come into being, but the majority of firms with whom we have consulted, allege that the whole thing has fallen through. The report on the market that this failure has come about is doubtless responsible for the fall in price of Para rubber by 2d per lb during the last week. We know many rubber manufacturers who would prefer that the price of the crude material should remain fairly stable, so that they can found their mixings and prices upon a firm basis, which would allow them a fair margin of profit should the market rise or fall but slightly. When, as we have seen during the last ten years, the price of Para can fluctuate from 1s 11d to 5s per lb, the calculations of the manufacturers are upset and considerable trouble is caused. The laws of supply and demand naturally affect the price of raw materials, but supply and demand is not responsible for such startling fluctuations as sometimes prevail. Crude rubber will always be the subject of that speculation which is common to all similar articles, and we can indicate nothing which is likely to prevent such speculation. It may be as well, however, to remind the promoters of such combinations as are here referred to of previous failures, and of the fact that the manufacturer is an important factor in the situation and can do much to upset the plans of would-be monopolists.

A LADY BOTANIST FOR KOREA.

TWO YEARS' SOJOURN IN THE INTERESTS OF SCIENCE.

Miss Constance Taylor, a London botanist, will sail for Korea on February 27, and for two years will be semi-officially botanising in Korea. As Miss Taylor explained to a *Daily Mail* representative yesterday, it all comes about through Korea being largely an unknown quantity as far as the botanical world goes. There are not many places so open to civilisation as Korea, the botany of which is so little known, and it is much more important than appears at first sight to have the botany of a place cut and dried and reduced to specimens. Miss Taylor, while travelling for a few weeks in Korea, became enamoured of the land. And as she is a devoted scientist, and has studied botany very deeply at King's College and other places, her present scheme gradually shaped itself. The Botanical Society, the British Museum, the Anthropological Society, and the Linnæan Society welcomed her idea, and have given her something in the nature of commissions. She will work for them. The Korean Government cordially invites Miss Taylor to submit her results to them.

"Of course, I cannot do it exhaustively in two years," said Miss Taylor, "but I can do a lot. As soon as I get there I shall start collecting all the specimens that are to be obtained, and as I collect them I shall paint them in water-colours. That has to be done most carefully. Then all the

specimens will have to be carefully classified, and in the end the Korean Government may publish the results of my work with all the pictures of flowers, etc. Nobody is going out with me. I shall have no assistance, and very little kit is necessary."

And Miss Taylor is delighted with the project of her two years' sojourn among the Koreans.—*Daily Mail.* Feb. 13.

CINCHONA BARK SHIPMENTS.

According to our cable advices the total quantity of cinchona bark shipped from Java to Europe during January 1901 was 500,000 kilos. as compared with 550,000 kilos. during December 1900, and 307,000 kilos. during January 1900. In the following table we give figures showing the quantity of bark shipped during each month since January 1, 1899 :—

	1899 Kilos.	1900 Kilos.	1901 Kilos.
January	255,000	307,000	500,000
February	465,000	320,000	—
March	488,500	325,000	—
April	498,500	265,000	—
May	476,500	403,000	—
June	566,450	433,000	—
July	470,000	314,500	—
August	601,200	488,500	—
September	616,000	683,000	—
October	479,000	550,000	—
November	681,000	745,000	—
December	313,000	550,000	—
	5,910,150	5,389,000	

[Equal to 13,002,330 lb. in 1899 and 12,856,000 lb. in 1900.—Ed, *C.O.*]

During the first half of last month the shipments amounted to about 300,000 kilos. and in some quarters it was expected that the total shipments for the whole month would again be large and on a par with those during the last five months of 1900. It is true that the shipments were larger as compared with the first half of 1900, but, from the fact that since November there has been a slight falling off each month, those who have been of the opinion that all available supplies in Java were rushed forward to take advantage of the high prices which prevailed during the last part of last year, derive some encouragement. Bark shipments, as we have said many times before, are always uncertain, but the opinion is now very general that shipments will show a further falling off during February and also during March, unless there is a substantial advance at the coming Amsterdam bark auction on the 21st Feb.—*New York Drug Reporter.*

THE CAUSE OF YELLOW FEVER

The Liverpool School of Tropical Diseases has received a report from the late Dr Myers and Dr Murham, members of the commission appointed to investigate yellow fever in tropical climates. They say that there are in all cases of yellow fever minute bacilli, and they state that they are of opinion that this is the cause of the disease. They consider that yellow fever is not due to an animal parasite like malaria, nor do they consider that the mosquito plays any very important part in the transference of yellow fever from person to person. —*Daily Mail,* Feb. 18.

IVORY CARVING IN THE PUNJAB.

As the machinery of the administration in India becomes more intricate, the District Officer has less time than of old to study the habits, customs and occupations of the people. It is all the more noteworthy, therefore, to find a young Assistant Commissioner in the Punjab turning aside from the daily routine to trace the development of one of the most interesting of the art industries of the country. Whatever be its limitations and imperfections, the monograph on ivory carving in the Punjab, which Mr. T P Ellis has just published, is an effort on which the anthor and the service to which he belongs may be congratnlated. Generally speaking, tbe art of ivory carving in the Punjab is much as it was described by Mr. Lockwood Kipling some twenty years ago: it is not an art that flourishes. "At Amritsar great quantities of combs are made, an industry which probably originated with the Sikhs, who are Nazarenes in the treatment of their hair and beard. The ivory combs, paper-cutters and card-cases of Amritsar are ornamented with geometrical open-work patterns of some delicacy of execution, but no great interest in design. Figure-work is but seldom wrought in the Province owing to the predominance of Mussalman notions, and the only figure-carver at Delhi, Fakir Chand, does not appear to meet with much encouragement." Since then, however, says Mr. Ellis, ivory carving in Delhi has improved, and inlaying in Hoshiarpur, but in both Patiala and Amritsar the industry has fallen upon evil days. The ivory used in India is drawn from three sources: Africa Burma and India itself, and the indigenous article is everywhere at a discount owing to its inferiority of quality, due, according to experts, to the food of the animals, but also to inferiority of breed, climate and surronndings. Except in a few instances, the ivory iudustry is confined to the large towns; purchasers being mostly Europeans, work is necessarily conducted near some centre frequented by them. Ivory carving proper may be said to be confined to Delhi, Amritsar and the Patiala State capital. In the former city, Lala Fakir Chand of the Dariba (already referred to) practically monopolises the trade, and, in fact, no one in the Province can compete with him. Bangle-turning, though general throughont the Province, has its chief centres at Amritsar, Dera Ghazi Khan, Gujranwala, Mooltan and Lahore Districts. The great centre of the iulaid work industry is Hoshiarpur, the work of Basi Ghulam Hussan being famous not only in India but throughout Europe and America.

IVORY CARVING IN DELHI

is almost exclusively a hereditary occupation, the system of training being long and arduous, tending to limit the acquisition of the art to families. Thus the family of Fakir Chand has carried on this work for four generations. The training of the would-be artist begins nsually when the boy is about ten or twelve. A good deal depends upon individual aptitude, but even with the advantages of hereditary instinct, application, and natnral gifts, a period of from twenty to twenty-five years of careful training is required before a workman can be trusted and is considered proficient in all the branches of the art. The master-craftsman employs his carvers at fixed wages, varying according to the capabilities of the man, supplies him with material, sets his task, he himself taking the risk of sale, destruction of material, and the long period of waiting before a return is made for the outlay. Everything is done under the supervision of the head worker, and no one is allowed to take work home with him, as is common enough in the case of other handicrafts. Iu Lala Fakir Chand's factory the workers congregate in a small room along with wood carvers and miniature painters; some sitting on balconies or on the stairs, and others at the open doors and lattices to obtain sufficient light to work by, and, snrrounded by their various implements; the whole scene forms

A TYPICAL PICTURE OF THE INDIAN ARTIST AT WORK.

The whole trade of Delhi may be said to be in the hands of Fakir Chand, who practically supplies all the jewellers in Chandni Chowk. Neither there nor in Amritsar is any special caste identified exclusively with the art, like the *sunar* of the gold and silver industry. Profits vary, of course, but all round it cannot at best be termed a remunerative business. The necessary tools, although rude, are numerous (some 38); altogether considerable outlay is incurred, and returns are long in coming. Good prices are sometimes obtained; in the winter of 1899, for instance, a certain *chef d'œuvre* realised £500; another beautiful carving of some Hindu gods was valued at R2,500; but the latter was executed fifty years before it found a purchaser. The prevailing inadequacy of prices, indeed, is considered to affect greatly the quality of the work in general. It is to be noted, however, that when goods are specially ordered, the greatest skill is devoted to their production, and amongst these the best specimens of work are to be found.

IN AMRITSAR,

the work being of a much less ambitious character than in Delhi, the apprenticeship to be served is shorter and less arduous. Lads at from ten to twelve are bound for six months or a year to a master-craftsman, who sets them to work in soft woods, then on to harder and harder, until hand and eye can be trusted to be employed on the costly ivory, the pay gradually mounting with the degree of skill attained. Here the most that even trained workmen expect to earn is from R8 to R18 a month —a very poor wage compared to that of superior workers in Delhi, but then the best of Amritsar carved work can only be compared with the cheap goods turned out by Lala Chand. The work in Amritsar consists of (1) bangle-making, and (2) toy, figures, and such ordinary useful articles as combs, paper cutters, *zurmadani* (little boxes to contain the black antimony wherewith the Eastern belle intensifies the blackness of her eyelashes), card cases, as also the geometrical and floral designs for inlaying work in wood or metal. Hoshiarpur is described as the main centre of the inlaying industry and manufacture of decorative furniture, although bangle-turning is also carried on to a certain extent. One learns with regret that the future of the ivory carving trade in Delhi is generally regarded as by no means assured, although Mr. Ellis takes a less gloomy view. Naturally the arts are no longer patronised as they once were by Native Courts, while the classes to whom most wealth has come under British rule have unfortunately small pretensions to artistic taste. On the other hand, the market has widened in another direction; year by year the swarms of tourists increase in volume, and artistic products are eagerly sought and purchased, though not always, or perhaps often, with much discrimination.—*Pioneer*, March 2nd.

CHEAP ESTATES IN THE WEST INDIES.

Reviewing a paper in *Blackwood* for February 9th, the *Spectator* says :—

The author of "My House in the West Indies" not only gives a charming picture of the delights of winter residence on the shores of the Caribbean Soa, but throws a good deal of light on the economic situation in a typical West Indian island, in which sugar has been superseded by arrowroot and cacao, and the constitutionally indolent natives are confronted with increasing difficulty in finding the rent to pay for their provision-grounds. The only hope of financial salvation, in the writer's view, is the influx of new blood and new capital; "not winter residents like myself, but young men with enough money, after paying for their estates (which may now be had cheaply enough), to work a small sugar-plantation up to the first crop without borrowed money."

THE UVAKELLIE TEA COMPANY OF CEYLON, LTD.

THE REPORT

was submitted as follows :—

REPORT OF THE DIRECTORS.

The Directors have now to submit their Report and Accounts for the year ending 31st December, 1900.

The crop amounted to 162,110 lb. Tea costing 26·95 cts. per lb. against 152,660 lb., costing 26·82 cts. in 1899. The amount of profit earned is R24,422·54 which is equal to 10 per cent on the Capital of the Company.

After estimating the unsold tea at a safe figure, the crop has realized 43·39 cts. per lb against 41·67 cts. in 1899 which the Directors consider highly satisfactory.

After adding R925·19 surplus proceeds of tea estimated last year and R187·30 balance brought forward, the amount available for distribution is R25,535·03. After paying an interim Dividend of 3 per cent and writing off 7½ per cent for Depreciation on Buildings and Machinery, the profit amounts to R16,297·15, and the Directors recommend that this amount be disposed of as follows :—

By the payment of a final Dividend of 5½ per cent] (making 8½ per cent for the year) absorbing...	R13,200·00
By carrying a sum to Reserve, of...	2,000·00
By the payment of Bonus to Superintendent of	500·00
By carrying forward the balance of	597·15
	R16,297·15

The Estimate for the current year is 162,000 lb, Tea to cost R45,739·50.

In terms of the Articles of Association Mr. W Kingsbury retires from the Board, but being eligible offers himself for re-election. It will also be necessary to appoint an Auditor for 1901. By order of the Board of Directors, J. M. Robertson & Co., Agents and Secretaries.

Colombo, March 1st, 1901.

The Chairman, in submitting the report, said that as it had been in their hands for some time it might be taken as read. There was not much to say on it. Their tea showed a profit of 16·44 cents per lb and even in their plucking there was a profit of R57·86 this year for each acre. The price realised for the tea this year was 43·39 cents as against 41·67 last year. This profit, he thought, was largely due to the good work done by their Superintendent. He then moved the adoption of the report.

KNAVESMIRE ESTATES COMPANY.

THE REPORT

was submitted as follows :—

The Directors have the pleasure to submit the balance sheet and profit and loss account for the year ended 31st December, 1900, duly audited.

The profit for the year is R24,488·38, to which must be added R4,081·71 balance from 1899.

An interim dividend of 2½ per cent absorbing R10,375 was paid last September, and the Directors propose that a further dividend of 1½ per cent be paid absorbing R6,225, and that the balance R5,294·68 after providing for Directors' fees be carried forward.

The profit earned represents a return of R5·90 per cent on the capital of the Company. and is equal to R50·40 per acre on the area in bearing.

The total tea crop secured was 323,118 lb., or 23,118 lb. more than estimated for. The plucking area was 486 acres giving 664 lb. por acre. Total amount of tea for disposal was 337,232 lb. including 14,114 lb. made from purchased leaf. Tea sold to end 31st Dec. was 285,135 lb. netting R28·49 cents per lb. leaving

52,097 lb., to be disposed of estimated to net R22·43 cents per lb.

Cost of production including all charges and including cost of bought leaf was R20·355 cents per lb. of made tea.

The Company's property consisted on 31st December, 1900, of:—

Tea in bearing	486	acres.
Tea not ,,	15	,,
Jungle	88	,,
Buildings and Waste	5	,,
Total	594	acres.

Estimated crop for 1901 is 300,000 lb. to cost R20·31 cents per lb.

PLUMBAGO.—The mining rights were leased in March to a Syndicate on terms of 1-5th royalty and work was immediately started. The nine months' work since that date has been mostly of a prospecting character, for the land near the first prospecting shaft, which was so favourably reported on by Capt. Tregay, turned out quite barren of plumbago. Two distinct tunnels have been made, and from both cross cuts have been cut. Roughly, 10 tons have been won to end of December, 1900, at which time prospects may be said to have been better than at any time since the work was started.

THE ROEBERY TEA COMPANY OF CEYLON.

THE REPORT.

of the Directors was submitted as follows:—

ACREAGE.

Tea in bearing	497	acres.
,, 3 years old	109	,,
,, 2 ,,	36	,,
	642	acres.
Cardamoms	4	,,
	646	acres in cultivation.

The Directors have now to submit their fifth annual report and accounts, being those for the year ending 31st December, 1900. The yield of tea during the period has been 237,228 lb. costing R26·89 cents per lb., as against R30·32 cents last year; and realising R41·60 cents as against R40·46 cents for the same period.

After providing for commission due to Superintendent and making a liberal allowance for depreciation of buildings and machinery, the amount at credit of Profit and loss is R22,529·61 cents. To this must be added the sum R541·15 cents brought forward from last year, making a total of R23,070·76 cents now available for distribution.

The Directors recommend the payment of a dividend at the rate of 5 per cent on the paid up capital of the Company, which will absorb R15,000·00; that a sum of R7,500·00 be placed to extension account, and the balance R570·76 cents be carried forward to current season's account.

The Directors are pleased to state that £1,000 of the mortgage has been paid off during the year, and their future policy will be to finally liquidate the indebtedness as soon as possible.

The estimate for this year is 250,000 lb. tea on an expenditure of R65,825·00, which includes a sum of R900·00 for clearing and planting up 10 acres of jungle.

The retiring Director is the Hon'ble W H Figg, who is eligble for re-election.

The appointment of an Auditor for the current year rests with the meeting.

THE REPORT

ACREAGE OF THE ESTATE.

	Queensland. acres.	Palmerston. acres.	Total. acres.
Tea in Bearing	254	205	459
Young Tea	4	0	4
Total Tea	258	205	463
Jungle	19	0	19
Timber	0	7	7
Grass, &c.	4	0	4
Total Acreages	281	212	493

The Directors have now to snbmit their Fifth Annual Report and Acconnts, being those for the year ending 31st December last. The yield of tea during the period has been 235,579 lb., costing cts. 26·74 as against cts. 28·08 last year, and realising 44·17 as against 45·63.

As will be seen from the accounts, the net profits for the year amount to R28,277·21 after writing off the sum of R5,261·88 for depreciation on Factory and Machinery. An interim dividend of 5 per cent. was paid on 7th August absorbing R20,500, and the Directors recommend that a final dividend of 1½ per cent. be declared, making a total of 6½ per cent. for the year, and leaving a sum of R1,627·21 to be carried forward.

In terms of the Articles of Association, Mr. Stanley Bois now retires from the Board, but is eligible for re-election.

The appointment of an Auditor for the current year rests with the Meeting.

PRODUCE AND PLANTING.

COLD COMFORT.—The circular issued by members of the sub-committee of the Indian Tea Association, which we printed last week, does not meet with the commendation of the "Grocer." That part of the circular in which "all interested in the production of tea" are invited to communicate with their M. P.'s irrespective of party, asking them to support Sir H. Seymour King in an endeavour to get the tea tax reduced to its former rate of 4d per lb, is the subject of special criticism as "not altogether wise." Says the journal mentioned: "The next thing will be, we suppose, to denounce the Government as exacting 'tribute' from India; and possibly that may be followed by an outcry in India itself which may have the gravest effects far beyond the effects of any duty on tea. Then we hear of 'the mischief' and the great damage done by the imposition last year,' and so on. Is it fair to blame the Government either in such a tone or on such a ground? If 'great damage' was done last year, was it not mainly the fault of those in the trade who intercepted part of an impost which would have fallen wholly on the consumer? No one can say with fairness that tea at the price the consumer now obtains it is excessively dear; on the contrary, it is excessively cheap compared with what it was only a generation ago. With as little reason can the fair taxation of tea be condemned. All alcoholic beverages are already heavily taxed (and rightly so), and there is no good economic reason why teetotallers should wholly escape taxation. Providing we do not thereby restrict or render unduly dear the supplies of the people, especially the poor, there is no reason why an article like tea which is almost universally consumed, should not bear a fair import tax for the purposes of revenue. The real question seems to be whether the tax falls or has fallen on the right shoulders. That is to say, in any change of duty, is it of such an amount as to be readily passed on to the consumer, who should rightly bear it? That is a question on which experts in the wholesale trade may and should offer valuable advice to a Chancellor of the Exchequer, but that can surely be done without raising dangerous political questions

and creating imaginary grievances. Granting that the incidence of the duty is not necessarily upon the producer, the latter's hardship should be but of a very temporary nature unless the tax be so high as to destroy trade—which nobody can in this instance pretend it is"

"Imaginary Grievances."—Without attempting to fathom the meaning of the references to "tribute from India" and "those in the trade who intercepted part of an impost which should have fallen wholly on the consumer," we suppose the moral of this is that Indian and Ceylon tea-planters should look on placidly while the industry they have built up is crushed out by the Juggernaut of circumstances over which no one in particular has any control. So long as the tax does not quite destroy their trade planters, instead of worrying the Government and other people with their "imaginary grievances," should bear their troubles with equanimity, and turn their thoughts to political economy and taxation problems. When a man is in danger of drowning, arguments about the depth of the water and how he got into it have no interest for him. The *Grocer* goes on to say:—"The producers in India and Ceylon appear to be suffering mainly from miscalculations—either made by themselves or by those who advised them. Secondly, they are suffering from the miserable failure to arrive at an understanding throughout the trade whereby it might have been possible to pass on the duty to the consumer, on whom that impost was meant to fall. Thirdly, they are suffering from the shortsightedness, not to say foolish avarice, which caused some of them to dump down upon this country so-called 'tea' which was merely rubbish, and should have been treated as rubbish in India and Ceylon. With every desire to show practical sympathy for the Indian and Ceylon planters, we cannot help feeling that they a little over-reached themselves last year; and that their best course now is to pull themselves together without bothering about Government action on this side; and if, rather than stretch again on the rack people such as the income-tax payers under Schedule D who already pay too much, Parliament should think well again to interfere with tea or sugar or what not, it is to be hoped that the producers and importers concerned may be found to have profited by the lesson of last year on the disadvantage of non-combination." To this the producer can say, "Thank you for nothing." Sympathy of the kind here tendered does not amount to much.

THE CALIFORNIA ORANGE CROP.

Estimates of the California orange yield grow larger as the season advances. The estimate of all citrus fruits for 1901, in the San Francisco *Chronicle* annual, was 22,000 carloads, of which 1,145 were set down for central California. The railroad authorities are said to now estimate the southern crop of oranges alone at between 19,000 and 20,000 carloads, of which up to January 19, 4,400 carloads had been shipped, which breaks all records to that date, while 850 carloads have gone forward from the central part of the state. Our contemporary's estimate of the shipments from the district of which Oroville is the centre was 500 carloads, and the Southern Pacific Company now estimates the total crop from that district at between 900 and 1,000, which goes to show that new groves are coming into bearing of which no one knew anything. It is probable, as is usual in good years, that the citrus crop will exceed all estimates and that this will be the most prosperous year California citrus growers have ever known. The abundant rains which have fallen in the southern counties will improve the quality of the fruit and strengthen the vitality of the trees to produce next year's crop.—*Home paper.*

THE TEA DUTY.

[To the Editor of the *Home & Colonial Mail.*]

Sir,—We would solicit your powerful aid towards arousing public attention to the subject of the taxation of tea. It will be fresh in your recollection that last year's Budget laid on this article an additional duty of 2d a lb, being an increase of no less than 50 per cent. We contend that the fiscal burden is wholly excessive, and is alike unjust to consumer and producer.

It is unjust to the consumer. Tea, with a duty of 6d per lb, now contributes about six millions sterling to the Exchequer, or 5 per cent. of the national revenues. The duty exceeds the wholesale price of the great bulk of the tea consumed in this country, seventy five per cent. of the quantity imported being now sold in bond at 6d per lb and under. Thus the duty falls most severely on the poorer classes, and infringes a fundamental law of political economy. If there is one thing which should be encouraged in this country above another it is the supply of a harmless beverage in universal demand. The evils arising from the extensive use of intoxicating drinks are too patent to need enlarging upon; and all interested in promoting the cause of temperance should join in condemning the excessive taxation of tea.

It is unjust to the producer. Under ordinary circumstances the greater portion of the enhanced duty should have been borne by the consumer. But markets are so abnormal as to render this impossible. Prices have fallen in a direct ratio with the enhanced duty. In other words, the latter is being largely paid by the producer. The following table, showing three years' fluctuations in the price of type-tea, places this fact in a clear light:—

Description of Tea.	1899.	1900.	1901.
Indian Pekoes ..	7·73	7·20	5·97
Ceylon Pekoes ..	7·81	7·25	5·21

But this process has its limits. In view of the cost of growing and manufacturing tea, and transporting it 6,000 miles and upwards, it is clear that this burden cannot continue to be borne by the producer. The enhancement in the retail price caused by the increased duty must re-act on the demand to his detriment. The deep injury inflicted on the industry is shown in a serious shrinkage in the value of tea companies' shares, and in a general depression which has no parallel.

The effect of the existing duty on the countries of production is equally prejudicial. Their congested areas are relieved of surplus population by a steady flow of emigrants to the tea districts, and if famine is to be fought it must be by precisely similar means to those employed by the planter. His ruin would be severely felt by the peasantry of India and Ceylon, and the consequent check to the influx of British capital would lower the standard of existence and be prejudical to the interests of both countries.

The industry thus heavily handicapped is one which should be fostered by every legitimate means. Tea differs radically from sugar, which stands in the same category as a constituent of our diet, but pays not a farthing to the Exhequer. Tea employs £30,000,000 of British capital, and is essentially a creation of British enterprise. Half a century back the whole consumption of these islands was supplied by China. In spite of many failures through losses which would have daunted most men, and at a vast sacrifice of life and money, we have succeeded in distancing

our rivals; and the great bulk of our tea is now produced within the limits of the Empire. The following figures are pregnant with suggestion for the Chancellor of the Exchequer. They represent our imports in cwts. of tea and sugar in 1899:—

Importations of	From British Empire Cwt.	From foreign countries. Cwt.
Tea	2,188,000 ..	391,102
Sugar	1,582,337 ..	29,348,553

In other words, while 84 per cent. of our tea is produced by fellow subjects beyond the seas, 94 per cent. of our sugar is sent us by commercial rivals aided by State bounties.

With apologies for trespassing on your space, We are, Sir, your obedient servants,

D CRUICKSHANK, A BRYANS, Vice-Chairmen, the Indian Tea Association, London. Ernest Tye, Secretary.

Indian Tea Association,
14, St. Mary Axe, London, February 21.

RESTRICTION OF OUTPUT.

(To the Editor of the *Home and Colonial Mail.*)

Dear Sir,—The telegrams, of which copies are enclosed, may be of interest to your readers. The planters' resolution referred to, passed at the annual meeting of the Planters' Association on the 16th inst., was in favour of restricting the output of black tea by reducing the plucking area by 10 per cent., and by the manufacture of green tea,—Yours faithfully,

WM. MARTIN LEAKE,
Secretary, Ceylon Association in London.

The following telegrams have been received from Ceylon by the Ceylon Association in London:—"Kandy, February 18th. Ceylon taking steps to reduce 10 per cent. acreage." "Colombo, February 20th, Rosling (Chairman Planters' Association) is very anxious to have the planters' resolution carried out. Colombo agents are waiting instructions from principals. Steps must be taken immediately. Ascertain at once and telegraph."—*H and C Mail*, Feb. 22.

THE DEADLY MOSQUITO.

CHILDREN DIE WHOLESALE IN LAGOS.

Lagos, Jan. 28.—The arrival in Lagos of the Governor, Sir William MacGregor, who was originally a doctor in Fiji, has been followed by a noticeable impetus in medical affairs, just as the rule of Governor McCallum, an engineer, did much for the public works. The present Governor is credited with the determination to wage ceaseless war on the dreaded mosquito, convicted of being a malaria propagandist. An excellent hospital has been maintained here, and it has been said with grim humour that a man in Lagos dies luxuriously in comparison with some ports less advanced. The advice to a newcomer of the old coaster at one port: "Keep friendly with the Wesleyans, they have a hearse," is quite unnecessary here; and certainly the death-rate during the last year or two shows signs of marked improvement—as regards the white community. The children, however, are not so fortunate. Nearly half the negro children born here die before reaching twelve months. According to the latest returns available—those for 1899—out of 1,929 births registered 864 children died within their first year, a death-rate of 447·9 per thousand, or nearly one half.

It is supposed that this dreadful mortality is caused by malaria. Every child born has to pass through the ordeal of acclimatisation—at least, the blood of those examined has revealed the presence in large numbers of the malarial parasites. To thoroughly sift a question so vital to the population of the Colony, a Commission has been formed, consisting of one European doctor, one native doctor, and a lay member, to inquire into the probable causes and cure of this mortality. If the inquiry shows this to be due to malaria, then it is probable that the compulsory administration of quinine among the native children, in conjunction with other measures in view for the destruction of the breeding places of the anopheles mosquito, may do much to save many infant lives.—*Daily Express*, Feb. 19.

VALUE OF BEES.—A scientist estimates that bees in an ordinary colony will visit 2,000,000 flowers in a day or 200,000,000 in a season. If they fertilize one-tenth this number, and the fertilization of 20,000 workers is worth 1c., then a single colony is worth $10 a year for this purpose alone.—*American Agriculturist.*

COCONUT OIL.—We are much obliged to the mercantile correspondent who throws so much light on the trade in, and distribution of, one of our most important staples, in the letter we give elsewhere. The fact that America has been buying coconut oil in the London market last year, shows how difficult it is to arrive at exact conclusions as to distribution.

COCOA.—The consumption of cocoa is steadily going ahead. Germany heads the list of consumers, taking 39¾ million lb. in only eleven months, whilst the United States come next with an estimated consumption in twelve months of 39 million lb., and the United Kingdom is third with 38 million lb.; then comes France (34½ millions), Holland (24 millions), Belgium, Spain, and Austria. Russia, who, with its 94 millions of population in Europe alone, her cold climate, and large army, might be looked on as a likely customer for cocoa and chocolate, evidently is not so, for her name does not appear in a recently published list at all. The total quantity consumed by the countries mentioned amounted to 194 million lb. last year, against 107 millions in 1894.—*Home & Colonial Mail*, Feb. 22nd.

COFFEE.—There is no doubt the cost of production [of coffee] is constantly changing in all countries. What the real cost of production is, and what will check increase of production of coffee, nobody has so far been able to determine in a satisfactory way, and as production is still increasing, not decreasing, all talk from coffee-growing countries everywhere in reference to the hardships of present prices may be dismissed from the minds of coffee people. It is apparent that the coffee world at large continues very nervous, and at the slighest improvement, due to any cause, no matter how slight, speculators are for ever claiming or clamouring for higher values under the misconception that minor causes can materially alter conditions.—*W. H. Crossman & Bros'. Circular.*

LORD CURZON AND TEA PLANTERS.

We direct special attention to the following important extracts from the recent speech of the Viceroy, dealing with the "Exchange" and "Tea Overproduction" questions. These give the official view of the Exchange problem in opposition to Mr. R. H. Elliot, and afford most sensible advice in regard to promoting a taste for tea throughout India. It would pay if the planters set aside 10 per cent—that is of inferior grades up to that proportion—to be devoted to exploiting both the opposite Continent and this island, in the way Lord Curzon points out:—

THE EXCHANGE QUESTION.

In his concluding speech on the Assam Labour Bill at the last meeting of the Supreme Legislative Council, the Viceroy remarked:—

There is another claim that was specially put forward by the Hon. Sir Allan Arthur which I must equally decline to accept. It is the claim that we owe some special reparation to the planters for the currency policy, which, by raising the rate of exchange, is alleged to have raised against them the cost of production. Now this case was argued before the Currency Commission in London in 1898 by prominent representatives of the planting interest, and I do not hesitate to say that it completely broke down. It was conclusively proved before that Commission that the depression in the industry was due not to the closing of the Mints by the Government of India, not to the fiscal policy of the Chancellor of the Exchequer in raising the tea duty, but over-speculation, over-competition, and over-production. I have gone very carefully into the figures, and they show most conclusively that whereas in the nine years preceding the closing of the Mints, *i e.* from 1885 to 1893 inclusive, the area under tea cultivation in India increased by 39 per cent and the quantity produced by 85 per cent in the six years following upon the closure of the mints, namely 1894 to 1899, the area increased by a further 43 per cent, and the produce by a further 76 per cent., while in 1899 the increase in production was double what it had been in any previous year. So much for all India. I will next take the case of Assam alone. In the nine years from 1885 to 1893, the increase in area was 39 per cent., in production 75 per cent. in the six years from 1894 to 1899 it was 18 per cent. in area and 67 per cent. in production. Further, if we eliminate the years 1893 to 1897 while the rupee was steadily rising from 13d to 16d, and if we take the years posterior to 1897 only, during which the rupee reached and maintained stability, we shall find that in the two years 1897-99 there was an increase of 20,000 acres in Assam alone brought under cultivation, and of 21 million pounds of tea produced. Moreover, the fall in the price of tea, about which we have heard so much, continued long after exchange had become stable. It is clear, therefore, to me that the argument derived from the closure of the Mints is of very little value: and that the tea industry has been disastrously affected not by the currency policy of the Government of India, but by the ill-considered rush of speculation, and by the production of more tea than there were markets to purchase or mouths to swallow.

A TEA MARKET IN INDIA.

The Viceroy continued later:—

"I am a believer in the policy of helping those who know how to help themselves. I see the tea merchants of India and Ceylon scrambling for the markets of England, the Continent, and the United States of America. Why do the Assam planters not recognise that there lies the most splendid market in the world at their doors? Millions of Indians now burn kerosene oil, consume ice, carry umbrellas, and smoke cigarettes. Twenty-five years ago these habits would have been scouted as impossible. Now they are common and in some cases universal. Why do you not tempt these people also to drink tea? What is the good of scouring the world for the thousands? You have the millions at your gate. If I were a planter in Assam I would never rest till the pluckings of my garden became the staple drink, of the Indian artisan in place of the spirituous poison which he is now tempted, for want of anything better, to pour down his throat. I give you this suggestion for what it is worth; and, whether it be taken or not, I hope that Honourable Members will at least admit that throughout the controversial discussion of today the Government has shown itself a critical but not unfriendly champion of the composite interests of the most interesting Province of Assam.

DUM-DUM BULLETS FOR USE IN SPORT.

NOTES ON THE ·300.

(*To the Editor of the Asian,*)

Sir,—In a former letter, written from Ceylon, I mentioned that the mark IV hollow-nosed bullet could not be relied upon to expand properly, even in so tough a creature as a crocodile. Sometimes these bullets expand perfectly; at others, under apparently the same circumstances, they make a wound but little larger than that caused by the ordinary Mark II bullet. I have lately been trying the dum-dum bullet on blackbuck, chinkara, crocodiles and smaller animals. I have come to the conclusion that it also is very unreliable for shooting game. A crocodile hit about the right place through the shoulders got back to the water without any signs of distress. Another one raked fore and aft, left his sunny sand-bank with great nimbleness. In neither case was there any after disturbance of the calm water to show that the reptiles were suffering pains below. On another occasion I fired at a black buck, the range being about 180 yards. The buck fell to the shot, but almost immediately recovered himself and made off. I followed after him and fired two more shots which, as they produced no visible effects, I took to be misses. The buck moved away slowly and by keeping out of sight behind some scrub, I was enabled to get a fourth shot which killed him. I then found that all four of my shots had hit the antelope, and moreover that any one of them, had it expanded, would have killed or disabled the animal at once. Another case was that of a chinkara. He was hit far back in the haunch with a Dum-Dum bullet, and made away slowly. I eventually cut him off, and killed him at short range with a 192-grain hollow-fronted sporting bullet. The difference in the two wounds was most noticeable, the Dum-Dum had not expanded at all, while the sporting bullet had made an enormous hole. A jackal hit about amidships with a Dum-Dum ran fifty yards

before falling. A Sarus crane, shot through the points of both wings, ran seventy or eighty yards and then fell dead. I have heard it asserted that the soft-nosed sporting ·303 bullet is badly balanced, and that it does not shoot accurately. My own experience has been that it is most satisfactory in every way. I have also no fault to find with the 192-grain hollow-point; this last bullet from its lighter weight has no doubt a higher muzzle velocity than the 215-grain bullets, and this extra speed makes it break up all the more thoroughly. The Geffery split-jacketed bullets I have not tried myself. There is no doubt, however, that they are noisy in flight, less accurate than the other types, and that when the nose is cut off as well as the jacket slit, they occasionally break up in the barrel. They are, however, very effective on game. The hollow-fronted 192-grain bullet is somewhat safer than the Dum-Dum, as it is more likely to break up on striking the ground. The Dum-Dum is a most alarming missile in a thickly-populated country, as after passing through a buck and striking the ground beyond, it goes humming away with energy enough to kill a man hundreds of yards further on. Altogether I think the ·303 is a most unsafe weapon for black buck shooting, as these antelope are so often found right among the cultivation with natives on all sides of them.

A further objection to the ·303 is the amount of trouble that is necessary in order to keep it properly clean. Of course pull-throughs alone are not sufficient; a clearing rod is necessary and the bolt should be removed, and the rifle thoroughly cleaned out from the breech, an old brush with worn-down bristles is an excellent thing to put a rag round, and much less trouble than the ordinary jag. I found this out with a ·250 rifle; for the rod and brush of a Morris tube proved first rate for wiping it out, when the diameter of the brush had been slightly increased by placing a bit of thin rag aronnd it. Curiously enough I see that Mr. Tippins in his book, "modern rifle shooting in peace, war, and sport" mentions that he too has found an old brush, with the bristles shortened, the best form of jag for rifle cleaning, as the bristles hold the rag firmly, and the cleaning flannel thus used never gets stuck fast in the barrel, as it does sometimes with a pull through. A ·303 wants very conscientions cleaning to keep it in good condition. One may wipe out a rifle most thoroughly and oil it carefully, and the very next day a rag passed through will come out black. My own method is to wipe the rifle as clean as possible, directly after shooting, and oil it well with the usual ·303 oil, which contains mustic soda. The following day I wipe thoroughly clean again, and oil afresh; then about the third or fourth day, I wipe out all the oil and coat the bore with vaseline. The rifle can then be left to take care of itself till it is next wanted. If some such precautions are not taken, a ·303 will soon go off its shooting. I think there is a tendency now-a-days to make rifles too light. It is much easier to shoot with a weapon of moderate weight, say about 8 lb., than with these feather-weights of under seven. Any ordinary man can carry an eight-pound rifle without fatigue, and would probably find that he shot better with it, on the whole, than with a lighter weapon. As an example, the extra light weight, 1886 Model Winchester, which weighs from 6¼ lb. to 7¼ lb., according to whether it is a "Take down" or not, requires to be differently sighted, if it is to be used with smokeless powder. The ordinary sporting Model 1886 rifle of 8¾ lb. shoots alike with the same sighting whether black or smokeless cartridges are used. The cartridge used in the extra light-weight 1886 Model is the ·45—70, which as well as the ·45—90 one can now obtain loaded with smokeless powder.

The sole reason which makes the modern small bore rifle so dangerous for use in thickly popnlated districts, is the length and weight of the bullets employed. A short light bullet, which would expand readily, would get rid of most of the danger, and be quite sufficiently deadly for chinkara and black-buck. I believe a soft-nosed bullet of 150 grains would be just about right. A considerable amount of muzzle velocity would moreover be gained with a light projectile, and the trajectory flattened over sporting ranges.—"Fleur-de-Lys."

THE INTRODUCTION OF TROUT INTO KASHMIR.

PROCESS OF THE EXPERIMENT IN PISCICULTURE.

(To the Editor of the Pioneer.)

Sir,—I have read the article in your paper dated 8th February 1901 regarding the experiment now being made to introduce trout *(salemo fario)* into the streams and lakes of Kashmir and as I have been entrusted with the care of the ova I am in a position to give you an account of the progress made so far and of the facts which have been established. Under the care of my friend Mr. J S MacDonell who went from Kashmir to Bombay for the purpose, the box containing the ova reached Srinagar on 19th December 1900, and on opening it, we discovered to our joy that the contents were in as good condition as could be expected after the long journey. A few improvements in the method of packing the ova suggest themselves, but without going into considerable detail it is not possible to describe them here, nor would they be of general interest to your readers. The main fact is that out of 10,000 ova shipped 7,000 were, on arrival at Srinagar, considered fit to be transferred into the hatching boxes, but of these a certain number were as was to be expected, doubtful. Had the ova which was shipped in 1899 arrived safely, I would have been in a better position to make the experiment, as His Highness the Maharajah had then permitted the use of the Dilwar Khan Bagh for the purpose. In it the hatching boxes and rearing tanks would have been close together and there would have been no risk in transferring the fry from the one to the other. Owing to a mistaken idea that the experiment had proved a failure and had been abandoned finally, the Dilwar Khan Bagh had been assigned for other purposes and was not available when a cable advising despatch of the ova arrived. I had therefore to

CONDUCT THE EXPERIMENT IN MY OWN VERANDAH

and as it turned out it was just as well that I did so. I am however indebted to His Highness the Maharajah for the use of the town-pipe water for the first part of the experiment, viz. the hatching and care of the "alevins"—also for the use of a suitable stream for the second part of the experiment, viz. the rearing of the fry after they have emerged from the "alevin" stage until they are fit to take care of themselves in the great struggle for existence which lies before them. I may here explain that an "alevin" is an

embryo trout just emerged from the ova with the umbilical sac which provides it with its first nourishment: a very quaint-looking object indeed and delicate in the extreme. For the first two days after the ova had been placed in the hatching boxes, a considerable number of bad eggs had to be removed, an operation requiring the most careful manipulation: a certain number of "alevins" were also hatched out. But for the next eight days the number of white, and burst eggs dropped to an average of between 20 and 30 daily and the hatching out ceased almost entirely.

On 29th December, 1900, the pipe water was suddenly cut off without warning for a period of four hours and I had to put my servants on to carry water from a well in the compound in order to maintain a steady flow through the hatching boxes. On the re-opening of the pipe supply a rush of very dirty water followed, overflowing the filter-boxes and it took another four hours' work before we could get the deposit removed from the ova and hatching boxes and then only with the loss of many broken eggs. The burst eggs seem in many cases to be due to the "alevins" trying to hatch out head first, the result, no doubt, of the shaking the ova has been subjected to. Sometimes we are able to assist nature, but in most cases the eggs are lost when this takes place. The rise in temperature when using well water hurried on the hatching which went on much more quickly until the night of 7th January 1901 when the water was again cut off from 10 p.m. till 9 a.m. on the 8th, during which time a

CONSTANT STREAM OF WELL WATER WAS MAINTAINED

by buckets. The change of temperature had again a marked effect and the hatching out was completed with the exception of some 20 or 30 ova, most of which ultimately proved to be bad. The change also had a bad effect on the "alevins" and nearly 100 dead ones had to be removed when the grills were lifted after the hatching out was completed. For the next few days the casualties did not exceed four or five daily till the 11th January when the pipe water was for the third time cut off and well water had again to be used, causing some 30 deaths. At this stage of the proceedings, although the bulk of the "alevins" seemed fairly healthy, they remained bunched up in a torpid state at the lower end of the hatching boxes; some however seemed to suffer from dropsy or blue swelling, but as they appeared to do best when left alone, I did not attempt to treat these to the pin-prick remedy suggested by some rearers.

On the morning of 19th January, heavy snow having fallen during the night, I took out 65 dead "alevins," the cause of death being apparently dropsy; and the climatic change had evidently hastened the end of the delicate ones. On the following day 35 dead ones were found and from this time forward till the 7th February 357 in all were removed.

On the 7th February, the fish having to a great extent absorbed their umbilical sacs, I commenced feeding with excellent results, and from that date I have only lost 24 fish in all, although there are still some deformities which can hardly be expected to survive. I estimate, however, that there are now

NOT FAR SHORT OF 5,000 HEALTHY FRY IN THE HATCHING BOXES,

and the fact is therefore established beyond all possibility of dispute that trout ova can be successfully imported into Kashmir. I should mention that on 16th January and again on 29th January I found a large shrimp in the hatching boxes. These had no doubt been introduced with the well water; but whether they had penetrated the filter screens as tiny microbes, or had climbed over the screens in a more advanced stage it is difficult to say. I have little doubt that they were fattening on the helpless "alevins" when discovered.

On the 3rd, 4th, 5th, and 7th February I took out smaller shrimps dead. In these cases I think the tables had been turned and the shrimps had been killed by the stronger "alevins." These fresh-water shrimps which are found in nearly all Kashmir waters will prove excellent food for the trout hereafter, and I think there need be no anxiety as to the food supply if once the fish are able to take care of themselves. The experiments made by the 5th Gurkhas under Captain Kitchen's direction in 1896 have proved that

TROUT THRIVE AND INCREASE IN SIZE RAPIDLY WHEN PUT INTO A SUITABLE STREAM,

and if that is the case at Abbotabad the same or even better result, may be hoped for in Kashmir. The first stage of the experiment may now be regarded as a success, but there are great difficulties still to be surmounted before your readers will have a chance of luring my speckled beauties with an artful fly. Indeed the second stage of the experiment, now about to be undertaken, gives me almost as much anxiety as the initial one. The rearing tanks are situated at a distance of 12 miles from the hatching boxes, and I fear I shall lose a lot of fry in transporting them to their new home. Every care will be taken, but only those who have tried it know how difficult it is to guard against loss. I can only hope for the best. In the meantime Captain Godfrey writes that our good friend the Duke of Bedford is sending out

ANOTHER SUPPLY OF OVA, WHICH IS DUE IN BOMBAY ON 22ND MARCH.

If we are able to afford the funds, the same care will be taken to get this consignment up safely as was bestowed on the last one. When on this subject I may mention that the Punjab Banking Company, Srinagar, are the Treasurers for the "Kashmir Fishing Club;" and that subscriptions are urgently wanted from Messes, Clubs and private purses: *bis dat quicito dat.* There are many people to whom I would like to exprces the thanks of the Fishing Club: to the Steam Navigation Company who brought out the ova, and especially the chief officer of the vessel in which it came; to the Customs and Railway authorities in Bombay, and to Mr Dhanjhibhoy, the proprietor of the Imperial Carrying Company; but perhaps I had better leave this pleasing duty to the Honorary Secretary, Coaptain Godfrey, who is expected to reach Karachi on his return from furlough about the 15th March —*Srinagar.* F. L. MITCHELL,

Pioneer, March 4th.

COCA-LEAVES are decidedly scarce. There is a good inquiry for Bolivian leaves, but there are no good green to be had. The nominal value is from 1s 1d to 1s 2d per lb. Sales of Truxillo have been made this week at 1s 3d per lb, leaving a stock of less than 5 cwt in hand.—*Chemist and Druggist*, Feb, 23.

FRUIT SEASON AT NUWARA ELIYA.

A VISIT TO MR. JOHN COTTON'S ORCHARD.—Our Nuwara Eliya correspondent writes :—

Visitors to Mr. John Cotton's orchard at Lake View will be agreeably surprised at the loads of English and Australian fruit that may be seen on the trees. Most noticeable for colour and appearauce are the plums, five varieties of which have been successfully grown, viz. :—(1) The Red Heart Plum, (2) the Burbank, (3 and 4) Japanese Plums of two sorts, (5) the ordinary variety. Of the above varieties the Red Heart is the best in the orchard. The trees (which are three years old and now carry their first crop) were grown from cuttings from grafts produced in the orchard. Many of the fruits borne by them have attained the size of the smaller apples of the Ceylon market, while the smallest are larger and plumper than the largest plums that have ever been grown in Ceylon. The colour of the frnit when ripe is blood-red. The flavour is delicious, albeit a poiut of appreciable acidity prevails, as is the case with all plums. Two of these plum trees yielded 6 lb of fruit at one gathering. The Burbank Plum is much the same as the Red Heart in appearance, except that the colour is not so dark, being of a yellowish red. The flavour too is not so delicious owing to what is called a "woody" taste, peculiar to the latter. The parent tree, on which these and other plum grafts were produced, was brought out as a cutting by Mr. H W Kellow at Mr. Cotton's request, and may be still seen in the orchard. The Japanese trees are not in fruit, being too young to bear; but they look very promising. A fruiting bush that has been very successfully grown is the Currant (the black and the red). These are perhaps the best specimens of growth that may be seen anywhere in the island.

The pears and peaches are not what may be correctly called prolific; but the fruit on the trees is second to none in Nuwara Eliya in point of size. Lemons too have borne well.

A plot of strawberries (about 30 by 40 ft) yielded as much as 300 lb of fruit, at a gathering towards the end of the last year aud the beginning of this, and Mr Cotton says that he can safely count on another hundred pounds before the season goes out.

Three English (grafted) Apple trees in the orchard look very promising, and are at present covered with foliage.

Fruits, all about the place, are doing exceptionally well and Mr Cotton is to be congratulated upon his intrroduction and successful cultivation of the beautiful pums. Vegetables are not so flourishing up here and it is seldom one sees such good cabbages, celery and leeks here as those that come from Kandapola, Uda Pussellawa and Hakgalla way.—Local "Times."

MYSORE PLANTING NOTES.

SOUTH MYSORE, March 11th.—The coffee blossom which resulted from the recent rains has, on most estates, been a particularly disappointiug one. Young coffee has, however, done well, and on this class of coffee the quantity of blossom was all that could have been desired. Old coffee which requires longer to bud up will have another nice blossom later on if we are only favoured with a month of fine weather. Crops, however, on the whole will this year be surprisingly bad, as the recent heavy bearing and severe attack of leaf-disease late last season have left their usual legacy in the way of dry trees. Some splendid results have of late years been obtained from the application of tank silt and lime in this District. In a bad season, like the present one, it is particulary noticeable how well coffee looks under the jak tree. In going round coffee estates looking at the recent blossom, one could not fail to notice how vigorous the coffee was looking under this formerly much-abused shade tree. The show of blossom, too, was good, being far better than the show under many other descriptions of shade in the vicinity. The fact that the jak tree, apart from its mulching and manuring deposits, is an *evergreen* tree and does not expose the coffee beneath it to the sudden trausition from dense shade to the open at the termination of the South-West Monsoon—as is the case with many other shade trees, the Geraweggay and Howligay especially—is undoubtedly one of the chief factors in bringing about this result. The ravages of the borer and the bad after-effects of leaf disease are minimised under this excellent shad-tree.—*Madras Mail*, March 14.

PORTMORE TEA CO. OF CEYLON.

REPORT OF THE DIRECTORS.

The Directors have the pleasure to submit the General Balance Sheet and Profit and Loss Account for the year ending 31st December, 1900. duly audited.

	£ s. d.	£ s. d
The net amount at credit of Profit and Loss after providing for General Expenses, Income Tax, &c.		5,407 1 4
To which should be added Balances brought forward from last year		477 13 7
		5,884 14 11
An interim Dividend of 5 of per cent was paid July 30, amounting to	2,000 0 0	
It is proposed to pay a final Dividend of 8 per cent (making 13 per cent in all, free of Income Tax) which will absorb	3,200 0 0	
And to carry forward to next year	684 14 11	
		5,884 14 11

In presenting their Fourth Annual Report, the Directors have pleasure in recommending a dividend of 13 per cent.

The Tea Crop from the Estates for year ending 31st December, 1900, has been 265,710 lb, being at the rate of 553 lb per acre against 510 lb per acre last year, the highest previous yield, and this increase has been attained by tne ordinary system of cultivation and not by the application of manure.

The cost of production has been £4,653 15s 11d, being at the rate of 4·20d per pound, and the crop has netted £10,544 0s 9d, being 9·52d per pound equal to a profit on the capital of the Company of 14·72 per cent.

The average rate of exchange has been 1s 4 9-64d against 1s 4 13-64d during 1899.

Mr. R C Bowie retires from the Board by rotation, but beiug eligible offers himself for re-election.

The latest reports from the Manager in Ceylon show that Estates, Buildings and Machinery are in a satisfactory condition, and the estimate of crop and expeuditure give promise of continued good results, but in accordance with the scheme put forward by the Indian and Ceylon Associations the Board has issued instructious to the Mannger in Ceylon to reduce the plucking area during the current year.

The Directors feel that great credit is due to Mr R G Grant, the Manager, and Mr. H A Grigg, the Superiutendent, in Ceylon for the way in which they have cultivated the Estates and maintained the high quality of the Tea during the past year.

By Order of the Board,
SHAND, HALDANE & Co., Secretaries.

TEA IN THE ANDAMANS AND NICOBAR ISLANDS.—We direct attention to the interesting summary of progress with the tea experiment in the Andamans, on page 692. So much in earnest are the promoters that the nearest markets, the Nicobars, are being worked for all they are worth; and alcoholic drinks only too popular there, are being rapidly displaced by gifts of tea-pots with the tea introduced.

THE MAZAWATTE TEA COMPANY:

HOW TEA PAYS THE BIG DISTRIBUTORS.

By the mail we have received a circular inviting applications for 26,000 five-per-cent. cumulative preference shares in this Company, of £5 each (all the unissued preference shares), at a premium of 5/- per share. Applicants may, on allotment, pay up the whole balance in advance, and will be allowed interest at the rate of £4 per cent. per annum on the amount so paid in advance. Dividends will be payable in the months of July and January for the half-years ending 31st June and 31st December. The first payment will be calculated from the dates fixed for payment of the respective instalments up to 21st June, 1901. The minimum subscription on which the directors may proceed to allotment is £100,000. It is added:—During the past year the process of consolidating the Company's business premises has been proceeding; the building of the new factory at New Cross has been pressed on; the tea department is now established there; the necessary new buildings to enable the Company to commence business in cocoa and its allied trades have also been proceeded with and are in course of rapid completion. The registered office and sale rooms have been removed from Eastcheap to the Tower Hill Warehouses, which have been converted and altered for the purpose, and when finished will form a complete business establishment in a fine position. Owing to the very much greater volume of trade, the rise in the tea duties, and the extension of the basis of the Company's operations, a larger amount of working capital is required. The Company's capital has been increased accordingly by 20,000 five per cent. cumulative preference shares of £5 each, and 50,000 ordinary shares of £1 each, making the total capital of the Company £400,000 in preference and £400,000 in ordinary shares. All the un-issued preference shares (26,000 in number) are now offered at the price of £5 5s per share. The 50,000 further ordinary shares are kept in reserve to provide for future capital requirements, and may be issued as and when the directors think fit, but at a premium of not less than 10s per share. The directors do not contemplate issuing any debentures, and the articles of Association provide that no issue of debentures or debenture stock shall be made without the authority of an extraordinary resolution duly passed by the Company in general meeting. The last annual report and accounts show £75,000 has been placed to reserve in the five years of the Company's trading:

The dividends paid by the Company on its ordinary shares have been as follows:—

1896..	8 per cent
1897..	8 per cent
1898..	8 per cent
1899...8 per cent with a bonus of 1 per cent =	9 per cent
1900...8 per cent with a bonus of 1 per cent =	9 per cent

The preference shares at the price of issue will return to the investor £4 15s 3d per cent. It will be seen from the profits of the past eight years that the dividend is very amply secured. The amount required to pay the dividend on the whole 80,000 preference shares is only £20,000.

"MANURES" REQUIRED TO IMPROVE THE QUALITY OF TEA:

MR. MANN INSTANCES THE PARALLEL CASE OF VIRGINIAN TOBACCO

One of the most interesting speeches made at the Calcutta meeting of the Indian Tea Association was by the Scientific Expert, Mr. Mann. We quote the remarks in full as of special interest to Ceylon producers at this time:—

Mr. Mann said: The Chairman has asked me to say something about the tour recently made by me in the tea districts and in the course of which I visited almost every section in Assam. There was nothing which struck me more during the whole of that tour than the fact that during the past few years there has been a continual expansion of tea, and really without any effort or very little being made to keep up the production of the area already under tea; in fact one or two gardens which I saw gave figures that seem to show that with the area doubled the product of tea was precisely the same as it had been before. I cannot help the conviction that the whole of that decreased reduction per acre under tea cannot be explained by any method of finer plucking. What we need is a concentration of attention to the area already under tea. To say the least, it is a bad thing to go on extending the tea area without giving time, attention or money to keeping up the production of the area already under tea. At the present moment it does not seem the idea of the Committee or of the tea industry to increase production at all. The idea is more that we should devote our attention to improving the quality, or rather keeping up the quality we have already attained to. There seems to be no doubt that during the past ten years the quality of the tea from a very large number of the Assam gardens has deteriorated; that is more especially the case on those districts which have up to the present been famed for a high quality of tea. I am at present devoting more attention to this point than to any other. My investigations at present are directed to finding what constituents in the soil render it capable of producing high quality tea and what constituents are present in those gardens which are or have been famed for the quality of the tea they have produced. This improvement of retentive quality may be dealt with in different ways; one is fine plucking. Here I should like to make a distinction which is not always made between fine and close plucking. Fine plucking I don't think will improve the quality of the tea to any great extent; on the other hand, close plucking will undoubtedly do so, but at the expense of the tea bush. Therefore one will have to balance the gain by an increased product with the injury to the tea bush caused by close plucking. Another way of dealing with the subject is to ascertain what measures are likely to improve the quality. This has been the line which has been followed in America in relation to other industries with great success. I might instance tobacco in Maryland and Massachusetts where the quality has been improved to a very appreciable extent, and on similar lines I think we may im-

prove the quality of our tea. At any rate I am at present working on these lines, not so much to increase the quantity per acre as to improve the quality from the same garden. The questions such as pests, blights, the manufacture of tea etc., I hope to deal with later, But at the present time the question of the improvement of tea in quality by methods of plucking, pruning, and manuring seems to be the most important, and to that I am devoting my chief attention. (Applause.)

TEA IN THE ANDAMAN AND NICOBAR ISLANDS.

The Government Tea Plantation in the Andaman Islands has been doing well. The latest report issued states that 80,000 lb. of tea were made during the year and sold at a net profit of R13,000. The labour employed on the gardens is all convict labour, and as sufficient of it cannot be spared to work them efficiently their out-turn has suffered. The manager states that he could have made more tea, had he had the labour. Owing to the extensive building operations on the Islands, that were in progress at the time, it was not found possible to detail more than a small portion of the labour force for the work of the tea gardens. Now, however, that the tea gardens have passed the experimental stage, and have proved themselves a paying speculation, it is probable the Administration will arrange to amply supply the manager's requirements. There is a good demand for the tea produced, so much so that the supply is not equal to it.

An attempt has been made to create a taste for tea amongst the natives of the Nicobar Islands, who are very partial to the fermented beverage known under the name of *Tari*, or in truth of any description of ardent spirits they can get hold of. Under the influence of arrack, and other vile concoctions surreptitiously introduced, the otherwise peaceable aborigines have been giving the officials responsible for their welfare a considerable amount of trouble. To supplant the place of the various alcholic drinks, the Andaman Island officials have introduced into the Nicobar Islands packets of Port Blair tea together with teapots. The tea and the pots have been distributed amongst the influential inhabitants of the islands, and they have been instructed in the art of brewing tea. It is hoped that by these means the islanders will mend their ways and ultimately give preference to the cup which cheers but does not inebriate. The experiment is certainly a step in the right direction, and is an example the Indian Government might well follow. In connection with this subject we would suggest that prisoners in Indian jails should be supplied with tea and be moreover taught the proper way to brew it. As prisoners do not get liquor in jail, were tea supplied a taste would be created for the beverage, and on their release the prisoners would purchase tea, having once got accustomed to it. Every little helps a little, so we put forward the suggestion for what it is worth —*I. P. G.*, March 9th.

GAME AND FISH PRESERVATION ON THE NILGIRIS.

A perusal of the last annual report of the Nilgiri Game and Fish Preservation Association, while satisfactory in respect to the efforts of that body to preserve the indigenous game of the district, is disappointing in so far as it shows that nothing was done by way of importing exotic birds and beasts, which at one time formed no inconsiderable part of the Association's operations and rendered the district an attraction to the sportsman. That was ten or eleven years ago, when chikore were imported, pheasants reared in captivity and subsequently let loose in the sholas that abound on the Nilgiris, and rabbits, partridges and peafowl introduced. In 1892, for instance, 39 chikore were turned out, and in that year two were seen in a state of liberty and in the next a covey of 15, but nothing afterwards. The obvious inference is that the birds either failed to breed or were shot down, and no subsequent attempt to introduce them appears to have been made. Several members of the Game Association tried to introduce pheasants to the hills, but their efforts proved unsuccessful. Mr. Hodgson on one occasion brought 12 birds with him from home the previous year. They were under the personal care of the importer for some time, and are said to have laid eggs ; but at that stage the progress of the experiment terminated, so far as anybody knows. Mr. G Oakes spent over a thousand rupees in importing pheasants from England at his own expense, but he seems to have arrived at the same conclusion as Mr. Hodgson did, namely, that there was something inimical in the climate. The last batch of his pheasants, however, did not prove this, for they fell a prey to a marauding jackal which gained entrance into the pen where the birds were kept during the night. Rabbits appear to have been thought of in consequence of a reported scarcity of hares : but doubt was expressed whether the hares were really being killed off, and so no very great interest was taken in watching this part of the Association's efforts. The

EXPERIENCE OF CEYLON AND OF AUSTRALIA,

too, in regard to rabbits, rather alarmed the members, and the first or second importation was not repeated. Patridges and peafowl were tried, birds were procured and distributed, but these efforts were afterwards relaxed, except by Mr. Hodgson who successfully reared them at Kartairy. Guinea-fowl also were tried, but abandoned before much success attended the experiment. It is a curious fact that, in the first years of the existence of the Game Association of the Nilgiris, many sportsmen spent considerable sums in introducing game birds, such as guinea-fowl, partridges, pea-fowl, Himalayan pheasants, and the like, at a time when the law gave no protection to these exotic birds, but now that the Game Act has been so amended as to do so effectually, nobody has enterprise enough to carry on the experiment. The Association, in order to develop this part of its work, is anxious to raise the annual gun license from 30 to 50 rupees, but there is little hope of success for this proposal, as a large number of licensees are protesting against the enhancement, and it is very probable their remonstrances may influence the Madras Government, especially as the principal argument relied upon is the necessity for the destruction of wild pig and porcupine, which cause much damage to growing crops.—*Pioneer*, March 11th.

RUBBER IN SOUTHERN NIGERIA.

HOW THE INDUSTRY IS FOSTERED—GOVERNMENT REGULATIONS.

Major H L Gallwey, Acting High Commissioner for Southern Nigeria, reporting on the administration of the Protectorate during the year ended 31st March last, says that the general condition of the colony, both as regards finances and the prospects of future development, may be considered very satisfactory. "In a climate like this," he adds, "where for more than half the year any real efforts towards opening up country are defeated by the heavy rains, progress must necessarily be slow, although it is probably very sure. The very low type of native which inhabits the greater part of the Protectorate is also a factor which has to be considered when taking account of the actual progress made. The natives of the Protectorate, without exception, are conservative to a degree, especially among the older chiefs, and it is with the greatest difficulty that improvements of any kind can be introduced amongst them, and the only way by which this has been achieved has been by the use of the greatest patience, energy, and tact. It is needleess to say that from time to time punitive action has had to be taken in order to put down wholesale massacres, cannibalism, and closing of trade routes, but such punitive means are never resorted to unless all efforts of a pacific nature have utterly failed. The factor, the conservatism of the people, must also be considered when the work which has been performed in this Protectorate during the nine years of its existence is looked into. The work of opening up inland from the coast has been slow, and must always be so, for if done in a hurry and with no thought for the welfare and improvement of the people, it would take a very short time for the country to fall back again into its former state." The total trade during the period under review came to £1,614,753 as against £1,507,288 in the previous year. Imports fell off nearly £7,000, but exports moved up over £14,000, so that the net result was a fair increase. The principal commodities sent out are palm kernels and palm oil, but rubber is beginning to take an important place in the list: Last year 1,450,567 lb of the value of £105,117 was exported, as against 874,298 lb of the value of £60,608 in 1898-9, an advance of more than 65 per cent. Very great care is exercised in developing the rubber industry. It is practically under the control of the Forestry Department, which has issued regulations designed to preserve the trees and foster trade. The Forestry Inspector, referring to the way these regulations work, says :—" I endeavoured to make them preventively operative by personally inspecting and assessing the value of rubber forests belonging to nearly 100 Bini towns and villages; by creating, in accordance with the extent of forest staffs, *ex-officio* rubber inspectors in each of them; by instructing the inhabitants of all of them in the only safe regulated way of tapping suited to local circumstances; by explaining in detail the rubber regulations prohibiting tapping during the dry season; and by constituting every Bini an ex-officio policeman to bring to justice any rubber gatherer infringing the regulations. ... ... Fortunately the Binis, whose eyes I have opened on every possible occasion to the value of their rubber forests, responded with alacrity, and today exercise such restraining influence on prohibited rubber-tapping and adulterated rubber-producing that not a single rubber-gatherer is free from close 'shadowing,' and not a single ball of rubber and prohibited root rubber could work its undetected way to Lagos or our own trading factories. Even though gathered out of this Protectorate, it could not work its way down unchallenged, provided t had to pass any portion of the Benin City territories. This is so in every part of the territories—even in the newly-acquired districts stretching eastwards." It is only in the Benin territories that such regulations are in force, as the other rubber forests in the Protectorate lie in those parts where native councils do not exist, and it has not been found possible to enact native laws by which the regulations can there be rendered effective. Major Gallwey thinks it will probably be advisable to issue a proclamation dealing with rubber forests throughout the whole of the colony. Nurseries have been established in some centres, the object being to form plantations close to villages for seed-producing purposes. This will eventually allow every village to collect its own seed in order to sow in the bush at the commencement of the rainy season. It is also interesting to note that, out of an approximate length of roadway in the Benin territories of 450 miles, the Forestry Inspector has planted 250 miles with rubber seed, four deep on each side of the road. Before very long it is not improbable that the Government will establish rubber reservations in different parts of the Protectorate.—*Financial Times.*

A BIG "BASKET."

(To the Editor of the *Pioneer.*)

Sir,—The following record of fish recently killed in the Jumna by Mr. Herbert Vansittart of Goodrich Castle, Dehra. Dun, may prove of interest to your angling readers.

February 19th, morning—1 gonch, lb 40.
,, ,, afternoon—1 gonch, lb 125. (weighed in camp not counting loss of blood.) This enormous fish was hooked about 4 p.m. and landed between 6 and 7, after being first drawn into shallow water, where its backbone was severed with axes. It took four men to carry it to camp. Length, 6 feet, girth round shoulders 40 inches. With this fish, Mr. Vansittart has beaten his previous record for the Dun by 5 lb.

Feb. 20th, Mahseer, 31 lb, 30 lb. 22 lb. 11 lb, 14½ lb, 15½ lb, 23 lb, 18¼ lb, 15 lb and 21st Feb. Mahseer, 38 lb, Gonch, 96 lb.

Feb. 22nd, blank day. Water coloured, unfishable.
,, 23rd Mahseer lb 44
,, 24th ,, ,, 30½

making a total of lb 553¾ in six days' fishing. The tackle used was ordinary American salmon line, wire trace and treble hook on a fifteen foot bamboo rod. The fish were all taken with dead bait.

H. G. Mainwaring, Colonel.

Meerut, March 7. —*Pioneer*, March 13.

PENSIONS WITH TEA.

COMBINATION OF SHOPPING AND INSURANCE.

Widows, tea merchants, and insurance offices will be interested in a case that is to be heard in the High Court about May.

This is the appeal of Messrs. Thomas Nelson and Co., tea merchants, who were prosecuted for doing assurance business without depositing £20,000 with the Board of Trade, as is required by the Insurance Act. To every widow who has purchased half a pound of their tea every week for a year before

her husband's death Messrs. Nelson promise a pension of 10s a week until death or re-marriage. Widows who have purchased a quarter of a pound of tea instead of half a pound receive 5s a week.

Whatever its legal aspect, the scheme is novel and ingenious. According to Messrs. Nelson and Co., although they only started in January 1898 their yearly turnover has reached £250,000, and their pension-roll £35,000 per annum. The widows' cheques are posted every Friday from the head offices at Louth, in Lincolnshire. Last Friday, when an *Express* representative was invited to see them despatched, in proof that there was no deception, the total was 1,832, and a dozen male and female clerks toiled against time to catch the post.

"How do we make our profit?" said the manager. "By simple arithmetic. Of every hundred women who become regular customers only an average of 1¼ become widows. The remaining 98¾ pay for the pensions of their less fortunate sisters and at the same time provide for themselves and their families, should they in turn lose the bread-winner.

"It pays us better to push our tea in this way than to spend mammoth sums in advertising.

"No, we don't sell cheap tea. We sell the best Indian."

"We claim that this is not only a good business scheme, but a step as well towards the solution of the Old Age Pension Question."—*Daily Express*, Feb. 26.

THE WORLD'S TIMBER SUPPLY.

At the Society of Arts on Wednesday Dr W Schlich read a paper on the "Outlook for the World's Timber Supply." Sir W T Thiselton-Dyer was in the chair.

The first part of the paper was occupied with statistical details on the export and import of timber in the various countries of the world. As regards Europe Dr Schlich reached the conclusion that the present deficiency of 2,620,000 tons was sure to increase because the European sources of supply were not likely to meet the additonal 600,000 required annually; personally he would not be surprised, if ten years hence the deficiency amounted to three or four times the present quantity. Of the importing non-European countries taken altogether there was no doubt the net imports would increase as time went on. Of the exporting countries, the regions round the Caribbean Sea exported mahogany and other furuiture woods, but they also imported so much lumber that their net exports were only 13,000 tons a year. The West Coast of Africa exported various hardwoods but they were so expensive that they hardly affected the question. British India could not do more than send some teak and furniture woods. In Asiatic Russia, even supposing there was a surplus of production for export, the cost of transport would be practically prohibitive. The Timbers of Central Africa were not of the sort required in Europe in large quantities, apart from cost of transport, and in South America matters were in a similar position. It would not be possible, he felt sure, for the United States to meet for any length of time the increased demand which they had supplied for the last few years. Their present annual production, estimated at 75 million tons, was exceeded by the present annual consumption by 33 per cent, and this meant that they consumed annually not only the legitimate growth or increment but also a portion of their capital unless decided steps were taken at once to start thorough protection and systematic management on selected areas, or, as they might be called, reserved State forests. There should be no difficulty in permanently reserving 100 million acres, and if half the annual revenue—£700,000—derived from Canadian forests were devoted to that purpose, substantial progress could at once be made to secure not only the present, but an increased, output for any length of time, leading ultimately to a revenue tenfold, or more, the present amount and securing a permaneut supply of coniferous and other timber for the world. In the second part of his paper Dr Schlich drew attention to a few lessons that might be learned as regards the British Empire as a whole and these islands in particular. With all the forest wealth of the colonies, we imported into the Empire timber valued at nearly 18 millions sterling every year, and the sum lately had risen at the rate of £771,000 annually. Surely the time had come for a more vigorous forest policy on sensible lines throughout the Empire. Systematic forest management should be introduced, more particularly into Canada and Australia, and, above all, let the self-governing colonies consider a little more seriously than hitherto the magnificent example set by India. But we should begin by putting our own house in order. The imports of timber into the United Kingdom in 1899 were valued at 25 millions sterling, and of late years they had increased at the rate of 332,000 tons, £919,000, annually. Eighty-seven per cent of the total consisted of pine and fir, the sources of which were specially exposed to exhanstion, and where were we to obtain the nine or ten million tons of coniferous timber we required when the countries round the Baltic, and perhaps also Canada, had begun to fail us? Yet we had sufficient, and more, surplus land at home to produce all this timber without putting a single acre out of cultivation. There were 12 million acres of waste land and 13 million acres of mountain and heath land from which to choose the necessary six or seven millions, and surely £25,000,000 going out of the country every year was money enough to take some trouble about.

SIR W T THISELTON-DYER, in opening the short discussion which followed, pointed out that of coal and timber—the two sources for the sustentation of human comfort and industry supplied by solar activity—the former was limited in amonnt and there was no hope that it could be reproduced, but in the case of the latter nature had a regenerative power, so that, except when the perversity of mankind interfered, one tree when felled was succeeded by another. But there was no question more hard to drive into the head of the administrator or politician than that of afforestation; he was always anxious to reserve it for his successor. Still, a forest service had been established in India, which was an example to civilisation, and more recently others of our depeudencies had been induced to do something for their forests. There was, however, no good in being unreasonable in the matter. We were told that we paid 25 millions sterling a year for imported timber, but he personally was not so deeply impressed by this fact as the lecturer seemed to be. We were a business nation, and as such bought in the cheapest markets and he did not think we could be made to grow our own timber merely as a matter of sentiment. He doubted if people in this country would engage in forestry unless they could be convinced of a return of 4 per cent. on their money, and he could not see the way to that at present.—London *Times*, March 1st.

POTATOES IN CHINA.—The Chinese are just taking to the cultivation of the Potato. Though this most indispensable vegetable has been cultivated in England for the last two and a half centuries, it is believed that the Spanish introduced it from Peru in the beginning of the sixteenth century, but it was not till two hundred years later that it came into general use in Germany and France, and even then popular prejudice was so much against it in Prussia, where it was credited with causing leprosy and fevers, that Frederick the Great had to resort to legislation to promote its use.—*The Gardener.* (March.)

Correspondence.

To the Editor.

A RAILWAY FOR NYASSALAND, B. C. AFRICA.

Jan. 12.

DEAR SIR,—I cover latest prospectus for the B.C.A. Railway sent to me by Mr. T H Lloyd. It is supposed by those who know that some London capitalists will be got to take the matter up, and that we will get our Railway soon. The transport difficulties are really serious; goods lie sometimes a year or more at the river terminus for want of carriers to bring them upcountry. —Yours truly, H. B.

	£
CAPITAL ..	250,000
Permanent way constuction ..	230,000
Rolling stock ..	20,000
REVENUE—Freights.	
1. Import, 4,650 tons at £4 ..	18,600
2. Export, 1,250 tons at £2 ..	2,500
PASSENGERS—	
1. Europeans, 400 at £5 ..	2,000
2. Natives, 1,000 at 5s. ..	250
Mails, subsidy ..	200
Passengers' luggage ..	100
	£23,650
WORKING EXPENDITURE—	
Depreciation, 10 per cent on £20,000	2,000
Insurance fee, 10 per cent on capital	2,500
WAGES—	
Superintendent of line, Traffic Manager, 2 accountants, 3 clerks, 4 drivers ..	3,000
Native wages ..	1,000
FUEL—	
20,000 yards at 1s. 3d. ..	1,000
Paints; oils, grease, iron, etc., for repairs to engines, trucks and permanent way ..	1,000
	£10,800

Nett profits—£13,150 on £250,000 = 5·42 per cent.

N.B.—It is to be noted that the statistics of tonnage deals with *dead weight* only, the method in which the road and river dues are collected. The Transport Companies have the option of charging by measurement. This makes a difference in their favour of more than *one-third* in the returns. The Railway Company would have a similar option. Allowing for this we have roughly £23,650 plus £7,000, *i.e.*, £30,650 total receipts, less expenses £10,500. In other words, a profit of £20,150 instead of £13,150 or 8 per cent.

CEYLON COCOA IN LONDON.

Feb. 15.

DEAR SIR,—Cacao growers in Ceylon must be struck with the extremely high prices which are being paid for Ceylon cocoa. For several weeks past now, values, particularly for the finest, have been gradually in the upward direction until 108s. 6d per cwt has been realised. In the last sale, we would mention that for our friends we secured the record price of the sale notwithstanding the fact that there was better quality sold at 3s or 4s per cwt. below our price.

Looking into the near future we cannot hold out a very glowing prospect for cocoa; as we cannot but feel that, notwithstanding the fact that, taking Cocoa as a whole, prices are lower than has been the case for some time, yet the position is not altogether the same. There is no getting away from the fact that cocoa production is making rapid strides and at the same time those who are constantly in communication with the leading cocoa manufacturers of the country know that the manufacture of the prepared article also is being greatly pushed and that consumption is going ahead. Supplies are now coming in freely and we fear that for medium and common cocoa, especially common, we shall see lower prices; we should not be at all surprised to see native Ceylon, which is now in the neighbourhood of 72s, down to 64s or 65s per cwt.

Fine cocoa, as we have said above, will take care of itself; there is a keen demand for the fine pale break Ceylon cocoa. At the sales on the 12th inst., 2,704 bags Ceylon were catalogued. 1,041 bags found buyers, small at 54s 6d to 69s 6d, common to fair dull 66s 6d to 75s, middling to good 78s to 90s 6d, fine 96s to 102s 6d per cwt.—Yours faithfully,

p. p. JOHN HADDON & CO., G. F. A.

DISTRIBUTION OF COCONUT OIL IN 1900:—OSCILLATIONS EXPLAINED.

DEAR SIR,—Referring to your article in Saturday evening's *Observer*, the oscillations to which you refer are more easily explained than you appear to think. During the past year the Presidential Elections in America caused the usual disorganisation in trade and were the cause of that country taking less Coconut Oil than usual; but it is not to be supposed that the figures given in the Chamber of Commerce Returns expressed the total quantity of Ceylon Coconut Oil taken by America in 1900. As a matter of fact very large purchases of Ceylon Coconut Oil were made *in London* last year by American buyers who found it cheaper to buy in London than in Colombo!

As regards shipments to the Far East, Singapore has now a large Copra mill of its own, which supplies the demand which Ceylon used to meet. A little Coconut Oil is still shipped to Penang from this port, but not much.

The Indian demand for Coconut Oil is a very steady one, and when the Ceylon exports to India are small it is well-known that Cochin has made up the deficiency. Last year comparatively very little Cochin Oil went to Europe or America, the bulk going to Indian ports, principally Calcutta.

Hoping these explanations may be of some use to you,—Yours truly,

COCONUT OIL.

TEA-PLUCKING AND THE MAKING OF GOOD TEA.

Colombo, March 15.

DEAR SIR,—I beg to quote the following extract from Mr. Jas. Sinclair's letter, which appeared in your issue of the 12th inst.:—

"Exorcising from their minds some of the senseless cuckoo cries always rampant in Ceylon, such as 'tea is made in the fields,' which is only the case in the same sense as that porridge is made in the oat-fields.'"

When I was an assistant on a tea estate in Dikoya; my "P.D." always impressed upon me the importance of carefully plucking the tea bushes in order that a good tea might

be made. As this does not seem to agree with Mr. Sinclair's statement, might I ask the favour of your advice on the matter, as I am anxious to know the right course to pursue? Thanking you in anticipation of your reply,—I am, dear sir, yours faithfully,

JOHN F. WILMAN.

[We have no hesitation in saying that, in his justifiable desire to show the importance of greater attention to factory work than has, perhaps, hitherto, been generally shown in Ceylon,—Mr. James Sinclair went too far in minimising the importance of careful work in the field, and more especially in the careful plucking of leaf. For, we suppose, it will be generally admitted that good and fine teas cannot be made by the most careful attention in the factory, if coarse unsuitable leaf only is supplied? Careful plucking, careful withering (for which plenty of room is indispensable) and careful manufacture generally, all undoubtedly go to the turning out of the best tea any particular plantation is capable of; but we see Mr. Mann, the scientific expert for the North Indian planters, declaring that "quality" is most likely to be improved by suitable manures.—Ed. *T.A.*]

PEPPER GROWING ON THE ANAIMALAIS.

Pollachi, March 17.

Dear Sir,—I see in your March number of "*T.A.*" that a correspondent of the *Madras Mail*, writing about these hills—the Anaimalais—says he believes the elevation is too great for pepper to do well at. Can you or any of your experienced readers give me an opinion on this, confirming or refuting the suggestion, as I am now arranging to put down several thousand cuttings?

In my experience in Mysore at this elevation, 3,000—3,500, with the same class of forest, but with twice the rainfall (300 inches), the plant *grew* well and sturdily, fruiting well for a few years and then becoming subject to a blight which materially reduced crops,—too much wet perhaps.—Yours faithfully, "ANAIMALAIS."

[We have never heard of pepper-growing above 2,500 feet in Ceylon, while the most successful culture in the time of the Dutch was quite in the lowcountry, indeed, at Madampe and Kalutara near the seashore and in the Kegalla and Matara districts a few hundred feet above the sea level. Still, Dr. Thwaites and his successors have cultivated pepper successfully at the Peradeniya Gardens near Kandy, say 1,600 feet elevation; but we should doubt very much the pepper vine fruiting successfully at 3,000 feet or over in Ceylon, and the chance should be less farther north on the Anaimalais or in Mysore?—Ed. *T. A.*]

A BIG PYTHON,

Kalutara South, March 24.

Dear Sir,—I send you measurements below of a Rock Snake (in Sinhalese, "Pimbura") caught yesterday and afterwards killed:

Length while in its natural state	9½ feet
Circumference	15¾ inches
Stretched out and in motion ...	17½ feet
Circumference	12 inches

Has this ever been beaten? W. A. L.

[Tennent in his "Natural History" says of the Python:—One that was brought to me tied in this way measured seventeen feet with a proportionate thickness: but one more fully grown, which crossed my path on a coffee estate on the Peacock Mountain at Pussellawa, considerably exceeded these dimensions. Another which I watched in the garden at Elie House, near Colombo, surprised me by the ease with which it erected itself almost perpendicularly in order to scale a wall upwards of ten feet high."—Ed. *T.A.*]

BIG PYTHONS.

Galle Face Hotel, Colombo, March 25.

Dear Sir,—A correspondent in today's issue of the *Observer*, while giving the dimensions of a python killed in Kalutara South, asks:—"Has this ever been beaten?" Some years ago, when a party of planters in the Kalutara district were hunting for red deer, they missed one of their beagles, and, on searching for him, found him enveloped in the folds of a python. The animal was shot; and on being measured found to be 22 feet long and 22 inches in circumference. I had these figures from two of the gentlemen who were present. Natives have got an exaggerated idea of the size to which pythons grow, as the following story shows:—A party of honey-hunters rested to cook their afternoon meal and finding a log convenient sat down upon it, placing two stones to form a fire-place, the log forming the third support. When the meal was nearly cooked, a queer motion was observed in the log, and on examining it closely lo! it was a python. Needless to say the party did not stay to partake of that meal.

W. J.

[Are both stories equally reliable?!—Ed. *T. A.*]

Enormous Coffee Cargo.—The arrival in the port of New York of the Lamport & Holt's Line steamer "Rossetti" with a cargo of 126,000 bags coffee from the port of Santos is quite significant as marking a new era in the coffee-carrying trade. The Lamport & Holt's Line is the oldest established line of steamers in the coffee-carrying business from Brazil to the United States, and this line owns an enormous quantity of tonnage. Going back some twenty, years it was considered quite an event to get a cargo of coffee from Santos in excess of a total of 10,000 bags or from Rio of about 30,000 bags, and in the old days of the Baltimore clippers it was quite a circumstance to have a whole cargo of 12,000 or 15,000 bags of coffee come in here belonging to one firm. The enormous jump during the interval can be understood when we look at the cargo by the "Rossetti" of which nearly 75,000 bags belong to one house in New York, representing a total value of about $750,000.—*Rio News*, Feb. 5.

THE TONACOMBE ESTATES COMPANY OF CEYLON, LIMITED.

THE REPORT.

The following is the report :—

ACREAGE.

The acreage of the Company's Estates is as follows :—

		acres.	acres.
Tea in bearing	..	578	
Tea not in bearing	..	12	
Tea seed bearers	..	3	
			593
Cardamoms in bearing	..	..	101
Reserved Forest	..	..	24
Fnel trees	..	..	20
Chena and Patana	..	..	1,142
		Total ...	1,880

The total quantity of Tea secured dnring the year was 225,178 lb. which has been sold at an average of 38·01 cents per lb. nett as against 42·74 cents per lb. realised last year.

The total Cardamom crop was 10,469 lb. which realised R1·70 per lb. nett as against R1·76 per lb. last year.

The total expenditnre on Working Account amonnted to R65,001·29.

During the year the permanent improvements on Capital Account inclnde the erection of a set of 12 roomy lines.

The balance available, after providing for depreciation amounts to Rs 28,459·05, and the Directors propose to pay a dividend for the year at the rate of 5 per cent, absorbing Rs 14,000; to write off the balance standing to debit of New Clearings Account Rs 5,841·95 and Cart Road Rs 1,061·73= Rs 20,902·68, and to carry forward Rs 7,555·37 to next account.

The Directors have pleasure in reporting that the Debenture debt has been further reduced by £1,000 during the year.

In terms of the bond no further repaymeuts can be insisted on by either party before 30th June, 1902, but the Directors are negotiating with a view to repayment of £1,300 or more on 30th September next on terms which they consider favourable to all interested.

The Coast advances have been still further reduced from Rs 5,125·98 on 31st December, 1899, to Rs 2,955·16 on 31st December, 1900.

The Crops for 1902 are estimated at

230,000 lb Tea
10,000 lb Cardamoms

against an expenditnre of Rs 68,951·93.

During the year Mr R S Templer and Mr G H Alston resigned their seats on the Board, and Mr H Cumberbatch and the Hon'ble Mr W H Figg were appointed in their places.

Of the Directors Mr H Cumberbatch retires by rotation, bnt is eligible for re-election.

The appointment of an Auditor for the current year will rest with the meeting.

THE UDABAGE COMPANY, LTD.

REPORT :—ACREAGE.

215 acres in full bearing
84 „ 4 years old
36 „ 3½ „ „
164 „ 2½ „ „

499 acres cultivated
641 „ available reserve

1,140 acres more or less

The Directors beg to submit to the Shareholders the accounts for the year ending 31st December, 1900.

The Crops secured amounted to 157,295 lbs. made Tea against an estimate of 165,000 lbs., and realized R39,769·04, or an average of 25·29 cents per lb. against an expenditure (exclusive of cost of works on capital account) of R40,375·16, or an average cost of 25·67 cents per lb.

The disastrons condition of the Tea Market in the latter part of the year for all low-country production, coupled with the financial embarrssments of the Company, caused by the exhaustion of all available working Capital; has resulted in a serions loss in the season under review, and the Shareholders will be called upon to consider proposals (1) for liquidating the debts of the Company, or (2) a sale of the property, subject to the existing first mortgage debentures amounting to R100,000.

The Directors issue with this Report a scheme advanced by tbe Agents and Secretaries, for reconstruction of the Company, which will be considered at an Extraordinary General Meeting held immediately after the Annual General Meeting called as above, and all Shareholders are earnestly requested to be present to consider the proposal and dccide on tbe course to be adopted.

The Estimate for the current season is, including 7,500 lbs. of Tea from brought leaf, 232,500 lbs. made Tea.

To complete the extensions deemed necessary in the Factory and supply the required equipment in Machinery for the manufacture of Green Tea, a further expenditure in Capital Account this season will be necessary, but the Directors consider that ample provision will then have bcen made for the manufacture of 300,000-350,000 lbs. Tea which may be regarded as a maximum Crop from the present cultivated area.

Green Teas.—The necessary machinery has been supplied to the Estate for tbe manufacture oi Green Teas, and if the state of the market warrants their manufacture in preference to Black Teas, they can be produced at a small additional cost. The facilities provided for the manipulation of Green Tea will, the Superintendent estimates, be snfficient to deal with 150,000 lbs. made Tea ont of an anticipated Crop of 232,500 lbs. Samples already reported on and valued by Messrs. Forbes & Walker are eminently satisfactory.

Mr. J P Anderson, the Company's Visiting Agent, reported as follows as to the condition of the property, namely :—"I visited the Estate on the 22nd and 23rd January and found the Estate in excellent order, clean, and all works up to date," from which it will be seen that given the necessary Working Capital it only requires an improvement in the Tea Market to ensure tbe future success of the Company.

Coast Advances.—Of the amount R26,239·09 shown as ontstanding in the Balance Sheet, the Superintendent reports R10,669·25 as recoverable, R13,969·84 as doubtful, and R1,600 are irrecoverable.

In terms oftbe Memorandum and Articles of Association of the Company Mr. W Shakspeare retires from the Directorate and does not offer himself for re-election.

The appointment of an Auditor for the current year rests with the Meeting.

THE CEYLON TEA AND COCONUT ESTATES CO., LIMITED.

REPORT OF THE DIRECTORS.

ACREAGE.—*Tea.*—In bearing, 402·1·32 acres; in partial bearing, 8·0·30 acres=410·2·22 acres; coconuts, 559·3·3 acres; cinnamon, 21·2·30 acres; rubber, 35·0·0 acres; grass, forest and chena, 380·2·38 acres; total 1,407·3·13 acres.

The Directors have now to snbmit to the shareholders the accounts for the past year.

Tea Division.—The crop secnred amounted to 132,186 lb. being abont 12,814 lb. nnder the estimate which is accounted for by the extremely bad season, and because at the beginning of the year the tea still suffered to a certain extent from the effects of the attack of Grey Blight referred to in last year's

report, but the Directors are glad to say that the bushes have fully recovered, and are now in a more healtby condition than ever.

The nett average price realized was 30·68 cents, against 36 43 cents in 1899.

Coconut Divison.—Tbis crop was 20,884 nuts short of the estimate entirely owing to the unfavourable season. The total crop gathered during 1900 was 579.116 nuts of which 2,118 nuts were sold on tbe estate at R30 per thousands nuts. The remainder were made into copra—Candies 444·4·0 18 and sold at a nett average of R44·93 per candy, as compared with candies 421·0·2·8 in 1899 which realised an average of R44·20 per candy.

The estimates for tbis year are: *Tea.* 180,000 lb. against an expenditure on working account of R39,285·75. *Coconuts,*—700,000 nuts on an expenditure of R14,440.

After making the usual provision for depreciation of buildings and machinery, the result of the year's working shows a loss of R9,715·92 as compared with R5,993·30 in 1899.

Mr G H Alston having resigned his seat on the board, the Hon W H Figg was appointed to fill the vacancy. The vacancy cansed by the resignation of Mr F Capper was filled by the appointment of Mr H H Capper, and on his subsequent resignation, the Directors appointed Mr F Crosbie Roles to the vacant seat.

In terms of the articles of Association, Mr H Tarrant retires from the board of Directors, but is eligible for re-election,

The appointment of an Anditor for the current year ill rest witb the meeting

THE NAHVILLA ESTATE CO., LTD.

REPORT.

The Directors herewith present their Report for the season ended 31st December, 1900, together with a duly audited Statement of Accounts for the same period.

Conditions generally throughout the year were favourable for yield, and the Tea crop amounted to 539,974 lb., against an estimate of 390,000 lb. It is also very largely in excess of the ontput of last season.

The Coffee crop, nearly all of which came from Nahavilla estate, amounted to 1,176 bushels of parchment, and is about 400 bushels more than had been expected at tbe beginning of the year.

Tea prices show a falling-off from season 1899, the net average per lb. being 35·42 cts. and 40 cts. respectively, but the cost of producing tbe crop and placing it on the market has been reduced from 30·32 cts. to 29·42 cts. per lb., including one cent per lb. for manure.

The working is still rather expensive owing to the large acreage of Tea in partial bearing, but further reduction will be possible as these fields reach matnrity.

The total profit on the working of the several estates for the year under review is R50,212·61, which, after allowing for interest on mortgages, &c., is equal to about 9 per cent. on the paid-up capital of the Company, a highly satisfactory resnlt, having regard to the fact that Ceylon Teas have receded so mucb in value of late, and that there is still a large acreage of young Tea (nearly a third) from whioh little or no leaf has yet been gatbered.

Tbe Directors regret, nevertheless, that the financial position of the Company does not in their opinion justify the payment of a dividend, and they recommend therefore that the balance as per Profit and Loss Acconnt, namely R32,914·51, should be carried forward to Extension Account.

Since the Company was formed, a snm of about R250,000 has been spent on improving and developing the estates, with the result that we have now close on 1,500 acres of Tea in place of 837 at starting, and new Factories have been erected on Ury and Nahavilla, which, although fairly complete in themselves, will require some further extensions in the near future as the returns of leaf inorease.

This expenditure has been partly met by money raised from time to time on mortgages of the Estates, at reasonable rates of interest, but there is still a considerable sum outstanding, and at the beginning of the year the Shareholders were invited to come forward and assist the Directors in placing the Company on a sound financial basis by snbscribing to an issue of Preference Shares, the object being to pay off these mortgages and provide funds for any additonal expenditure that migbt be required for the completion of the Buildings, and for bringing the young fields of Tea into bearing.

The response to this Circular was not such as to admit of the scheme beiug put through, and other suggestions for providing tbe necessary funds having for various reasons also fallen through, the Directors feel that there is now no alternative but to adopt the course tbey have suggested in respect to the disposal of last year's surplus.

With regard to the future there is more land that could be planted with tea on some of the estates, but all that is at present contemplated is to bring into bearing the fields which have already been opened and improve the Factories on Ury and Nahavilla in such a way as to place the respective Superintendents in a position to do full justice to the requirements of an increasing output of tea.

The expenditure necessary for the above purposes is roughly computed at R30,000, but this does not inclnde the erection of a Factory on Galella which may perhaps be undertaken if funds are available at some future time though not just at preseut.

As already intimated there is a large acreage of young tea on the Company's estates to come into bearing yet; and tbe capital cost of the property per acre when fully developed will probably be about R400 on the cultivated area, which is fairly moderate for a good going ooncern with a large reserve of land and a steadily increasing yield.

We are, however, in need of money, and although the present may not be an opportune time for attempting to provide what is required in this connection and enable the Shareholders to participate in the annual profits, it is hoped that the commercial aspect of Tea may improve in the near future and afford opportunities for putting the affairs of the Company on a good financial footing.

From an agricultural point of view tbe outlook on the Company's Estates continues satisfactory, the estimates for the new season being 565,000 lb of Tea and 520 bnshels Coffee against an expenditure of R162,388, including manure which, however, is to be sparingly used.

Mr. E S Grigson retires from the Board of Directors by rotation, and is eligible for re-election.

Tbe appointment of an Auditor rests with the Meeting—By order of the Directors,

GEORGE STEUART & Co.,
Agents and Secretaries.

Colombo, 1st March, 1901.

CLAREMONT ESTATE COMPANY.

REPORT OF THE DIRECTORS.

The Directors submit herewith the accounts for the year ended 31st December, 1900.

The crop secured was 86,374 lb. as against 81,281 lb. in 1899, and the cost of putting it on the market was 24·58 cents, realizing 26·40 cents nett, as against 24·54 and 34·97 cents respectively in 1899.

The estimate of crop for the current year is put down at 95,000 lb. to cost in Colombo 24·08 cents.

Interest on mortgage (£3,000) has been paid to the end of September, 1900, and the next payment will be due on the 31st March, 1901. Interest on the mortgage debentures remains as yet unpaid.

A change of Superintendent was deemed necessary during the year, and the present arrangements are giving satisfaction.

In consequence of the poor results of the year's working, the Directors have written back their fees.

The mortgage of £3,500 was called up during the year. The Directors, however, were able to effect a fresh mortgage of £3,000, and secondary mortgage debentures to the extent of R23,500 were raised to cover the balance of the old mortgage and the amount due to Syndicate appearing in last year's balance sheet.

During the year Mr. J G Russell resigned his seat on the board, and Mr. W P Barber was elected a Director. In terms of the articles of Association Messrs. A. Orchard and R. Huyshe Eliot retire from the office of Directors, but are eligible for re-election.

The appointment of an Auditor for the current year also rests with the meeting.

TEMPLESTOWE ESTATE COMPANY.

THE REPORT

of the Directors was submitted as follows :—

The Directors have the pleasure to submit their report and accounts for the year ending 31st December, 1900.

The crop amounted to 202,405 lb. tea costing about 26¾ cents per pound, and the price realised was about 37 cents per pound, shewing a profit of fully 10 cents per pound, which, in view of the low prices ruling, especially during the latter half of the year, may be considered satisfactory.

An interim dividend of three per cent on the preference shares and two per cent on the ordinary shares was paid in September last, and after allowing for this the amount now available is R11,939·46, which your Directors recommend should be disposed of as follows, viz. :—

	R c.
By the payment of a final Dividend of three per cent on the Preference shares (making six per cent for the year)	3,258 00
By the payment of a final Dividend of two per cent on the Ordinary shares (making four per cent for the year)	3,284 00
By transfer to Depreciation account	3,375 00
By carrying forward the balance of..	2,022 46
	R11,939 46

In terms of the articles of Association, Mr Giles F Walker retires from the Board, but being eligible offers himself for re-election.

It will also be necessary to appoint an Auditor for 1901.

A MALARIAL EXPERIMENT.

The *Indian Medical Gazette* reports that Captain C J Fearnside, I.M.S., of Rajamundry, succeeded in inoculating himself experimentally with malarial fever by means of mosquitoes. On the 17th Decembery, 1900, several anopheles (of a light fawn colour) were fed on the blood of a person known to be affected with spring tertian fever. On the 12th day, 29th December, two of these infected mosquitoes were made to bite Captain Fearnside's arm. The presence of zygotoblasts in thes veneno-salivary glands was verified by microscopic examination. Other infected mosquitoes also bit him on 1st January and 8th January, 1901; on January 12th, 14 days after the first bites by infected mosquitoes, he felt "seedy." His indisposition became more marked and on the 18th he felt distinctly ill. On examination of his blood there were found much pigment in the leucocytes, young spring tertian hæmamœbae and pigmented spheres. The fever lasted all night and he was too ill to work on the 19th. There can be no doubt of the genuineness of this experiment, or that it was produced by the infected mosquitoes. We are glad to state that Captain Fearnside has taken plenty of quinine and is now none the worse for his scientific experiment.

CARDAMON CULTIVATION.

For the three districts—Medamahanuwara, Nitre Cave and Rangalla—we showed 1891 acres in our last Directory as under Cardamoms. A planter, thinking of native gardens, considered we were much below the mark in reference to the first-named district, but referred to a well-known resident as the best authority. This gentleman, on being appealed to, dissented, as we expected, from the larger estimate, and shows that Mr. de Silva's Kandewatte and some of the bigger gardens might aggregate 200 acres apart from very small gardens of other natives. We do not think, therefore, that there can be now more than 3,000 acres under cardamoms in all the three districts, including native gardens. Even at 100 lb. an acre, such an area would yield more than half the total export from Ceylon for last year which was 538,000 lb. Of course, the greater the area already planted, the greater the discouragement to extend cultivation; but Ceylon has nearly got to the end of its suitable land, and it is in India that there is a risk of overdoing cardamoms, as well as tea, unless planters there take warning in time.

COCONUTS IN THE KELANI VALLEY.

We have few regular returns from estates; but we hear generally that a great many tea estates in "the Valley" have fields planted up with coconut palms at 30 to 40 feet apart. This is carried out up to 1,000, 1,300 and even to 1,600 feet above sea-level, and so far the palms flourish. The oldest planting in the district is from 6 to 7 years, so that the time has not come for bearing. Most of the seed nuts have come from Mr. Beven's well-known Franklands property in the Veyangoda district. We do not find fault with—in fact we highly approve of—this plan of having a second product in the Kelani plantations; but at the same time we are quite sure that proprietors should lay to account the getting of smaller returns from the tea when the palms—voracious feeders with wide-spreading roots—come into bearing. At the same time we should expect the crop of nuts to more than compensate for any deficiency in the tea,

INTERESTING NEW TROPICAL PLANTS.

The new orchid, Lœlio-Cattleya, called after the Empress of Russia, is a hybrid between the Cattleya Mendeli and Lœlia Digbyana. A single plant sold in England for £200. It is the result of skilled experiments by Maron, and attracted much attention at the Paris Exhibition.

Another new plant is the red banana with purple foliage, discovered at the Catholic Mission of Brazzaville, and found elsewhere in the French Congo. The fruit is long, without seed, and good for making fritters. The plant is highly ornamental, and is likely to figure in European gardens or conservatories.

Of new flowering shrubs the Rhododendron Halopeanum, a hybrid with rosy white blossoms, is notable, but requires a mild climate like that of South or Central France. The Dahlia "President Viger," produced at the Lyons Botanical Garden, is likely to found a new race.—*Globe*, March 1.

THE ÆRIAL STEEL ROPE TRAMWAY.

ON THE KANAN DEVAN HILLS.

(*Communicated.*)

So many enquiries have been made about the Ropeway recently erected from the Plains to the Kanan Devan Hills Produce Company's property in North Travancore that the following notes are penned in the hope they will interest your readers and answer the enquiries that have been made from time to time.

The first Ropeway line surveyed was about six miles long and the country was very difficult, added to which one span was about 2,700 feet which, as any one acquainted with Ropeways knows, greatly lessens a rope's efficiency because the weight of the rope itself between the standards, 2,700 feet apart, would have been nearly 1½ ton, whereas with the present longest span between of 1,400 feet, the weight of the rope between the standards is about ¾ of a ton and the difference (¾ of a ton) can be carried in line load (*i.e.*, goods) instead of the strength of the installation being expended carrying its own weight. Another disadvantage of this line was that part of it was very flat and part very steep so that there would have been a continual variation of the load on the driving motors when heavy loads left the flatter portions and got on to the steeper ones. The apparent difficulties of this line decided me to try a new trace and it was laid in following pretty closely an old cooly track with the result that we got a line 2·6 miles long at a comparatively even gradient touching a point at the foot of the ghaut to which a railway could conveniently be brought and a point near the top of the ghaut to which a cart road or tramway could be brought and we had then got the skeleton of a complete scheme which has gradually been filled in.

From the end of the old cart road on the plains, a railway trace was laid—10 miles long, 4½ of which ran over the plains and 5½ ran into a narrow valley with grades from one in 80 to one in 25 for the last three miles and curves of 100 feet radius. The bridges are all steel structures running up to 60 feet long and safely capable of carrying narrow-gauge engines and the concession granted by the Indian Government to a Madras Firm (Messrs. Wilson & Co.), for the construction of a narrow gauge railway from Amanayakannur to Utamapalium includes a branch to the foot of the Ropeway. From the top terminus of the Ropeway some 40 miles of cart road and tramways have been cut stretching to Munnar and in various directions therefrom, tapping the Company's estates and factories.

These tramways and roads, the former especially, a Ewing's one-rail tram, may form the subject of a separate monograph; but for the present we will 'return to our muttons' and deal with

THE ROPEWAY ALONE.

The distance between the upper and lower Termini is 2·6 miles, the difference in elevation 4,000 feet; the steep country is naturally very rough and the lower half a very deadly climate.

The first thing we did was to cut a 5-feet bridle path approximately along the Rope line to transport the material for the Ropeway construction along. Estimates were called for from the most eminent English and local Ropeway Engineers, but not one would undertake *its erection in this deadly ghaut* (which showed their wisdom, as events proved) and an offer was made to the Directors to design, construct and erect the Ropeway locally if they would not hold the worker responsible for any failure, and if they would not protect themselves by engaging a competent Consulting Engineer, and to this they agreed, and the work was placed in the hands of Mr. W Kemlo, whose great ability and training under Lord Kelvin marked him out for the task. One of first difficulties was how to drive the horse-power to be provided (and in this connection the difference in horse-power considered necessary by two great Ropeway Firms was very striking). Another point to be decided was the form of Ropeway, whether of the fixed Rope type, or a moving rope carrying its own loads. After great consideration it was decided that the latter form would be the more suitable, *provided grips could be designed* which would be effective on such a steep Ropeway. Believing that *we* could design what was wanted the plans were prepared.

In order to keep the driving station in as healthy a point as practicable we put it half way up the rope, and divided the Ropeway into two halves at this point, the reasons for the latter being: (1) that if a breakdown occured at any time on one half of the rope, the other one half could still go on working and, (secondly) had the whole 2·6 miles of Ropeway running down 4,000 feet vertical been in one piece, the wear on the rope at the upper end and on the gear there, due to the weight of the rope itself, would have been very excessive.

The next point we decided on was the driving arrangements and as at a convenient point we were able to get in Beeton wheels, having a vertical fall of water operating them of over 700 feet and developing 100 H.P., we fixed this as the Power Station and transmitted the power through a 28 E.H.P. Dynamo one mile over a thin cable to the Centre Station where the motor in its turn operates the Ropeway. By actual results the whole Ropeway requires only about 20 H P. to drive it, full of loads, at two miles an hour, but of course the power required is greatly regulated by the amount of *up or down loads* at any given time. The dynamo is capable of driving it fully loaded on the *up going side only* at two miles an hour. To save risks of accident we put in duplicated peltons, dynamos and motors.

The erection of the 1,500 feet of pipe and the 1,500 feet of spouting in the watercourse as well as the Peltons was slow and expensive and was done by Mr Kemlo's brother. The country is very rugged, and deadly unhealthy, and the spouting as well as much of the pipe had to be carried on iron supports and there were two bridges made for the spouting, one 80 feet long. The Ropewire is ⅝ inch diameter best plow steel and was brought out in eight pieces, each 3,000 to 4,000 feet long, wound on a drum. These were all bored for the same axle and the rolls of wire hauled along the track by block and tackle till they came into the Ropeway line where the wheels were fixed and the rope hauled out, the drum revolving on the axle. This was a very neat locally designed arrangement, made at home, and worked perfectly.

Everything comes to him who waits and; after much sickness and great trouble, we got the rope up and splices all completed and

PREPARED TO MAKE A START

when the starting resistance sent specially by the providers of the dynamo fused and we had a grand example of pantomime magnesium lights. Part of the current went through Mr Kemlo's thumb and the place smelt of beefsteaks, while the natives went over that ghaut like another flash.

Mr. Kemlo designed and made with native carpenters a salt and water resistance Box which is working very well and cost a few rupees and that difficulty was got over and the rope started.

You can imagine our disgust and annoyance when we found the rope grips supplied from home so badly made that they would not work, and we had to have new jaws made locally in brass which although not sufficiently strong have worked well and now new jaws of annealed steel are being put in and are working very perfectly.

These jaws, which are the secret of the Rope's success, I will describe later when a patent has been granted. Suffice it to say that they automatically grip the rope at any point desired, go up to the top, and automatically leave the rope and run on to the rail. The pulleys on the standard heads have such deep grooves that the rope cannot get off by any chance and the result of this combination of essential points is that the life of the Rope itself is greatly prolonged and probably more than doubled, while accidents have been reduced till, I believe, 8,000 loads passed over the rope before the last accident, due to a defective pulley and not in any way connected with the grips, and it really did not do any damage to speak of.

The Ropeway *running at half speed two miles an hour* is fully loaded with 66 grips which with loss of time loading and unloading do three rounds a day. Each load should be two cwts. and this equals 40 tons of out and in traffic a day and assuming that it worked only 250 days in the year this equals 10,000 tons of traffic which is far more than sufficient for present purposes. When it is worked up to 10,000 tons it will certainly show a profit of £10,000 as compared with what it would have cost to move this weight up and down the ghaut by cattle and ponies and donkeys of which we had about 3,000 at work, when the writer came out three years ago. So I think the most captious critic will admit that it is a magnificent success. The greatest credit is due to Mr W Kemlo who has designed and had constructed every detail of it from beginning to finish and to his Assistant.

The automatic working of the Ropeway is very attractive and everyone who has seen it says he or she would not have missed the sight for a good deal. L. DAVIDSON.

ABYSSINIAN COFFEE.

A British consular report from Harrar, printed in the London *Grocer*, says: "The Harrar coffee is of a very good quality, known in the London market as 'Moka long berry;' where it is preferred to the real Moka. Occasionally its price in London is higher than that of Moka. Plantations of coffee are increasing slowly, because the natives prefer to cultivate the Kiatt (*Celastrus edulis*) as more lucrative, one pound of leaves of which are sold for $1 and sometimes $2; the natives, as in Arabia, eating these leaves. Nevertheless, more than 150,000 coffee trees have recently been planted, especially in the districts of Chercher and Itto. The Abyssinian coffee is wild and grows in Kaffa (whence the name), Limmu, Gimma, Gumma, Ghera, Ennarea, and Hillu. It has a very good aroma, and if cultivated it would be a very keen competitor of the real Moka. Monseigneur Massaya (afterwards Cardinal), when Bishop of the Gallas some forty-five years ago, cultivated in Ennarea 3,000 trees and obtained a quality much superior to the real Moka, both in flavour and aroma. This coffee used to be imported here from the above countries *via* Addis Abiba, and exported to Europe after being cleaned in Aden. In the European market it is known as Abyssinian coffee, but, on account of the present low prices of American coffee, the export of this coffee is decreasing. Most of the import is stocked in Harrar, and now the imports from the interior are next to nothing, the price, $4 per farasla, not covering the expenses of transport from the above-named countries. Should the American crop fail, the increase of export of Abyssinian coffee would recommence. On representations made by the merchants of Harrar, the Emperor Menelik has abolished the export duty of 8 per cent on Abyssinian coffee this year.—*Rio News*, Feb. 5.

PLANTING NOTES.

COFFEE IN VENEZUELA.—Coffee planters in Venezuela are lamenting the condition of the coffee trade. In a memorial from the Caracas Chamber of Commerce to the President of Venezuela, the text of which has been brought by the mail, it is urged that the condition of the coffee trade has been for some time lamentable, owing to the steady fall in price, through well-known causes, and that the measures which the present Government have just taken have aggravated this position, by putting on the highest tariff, which will cause the trade to lose the French market, where hitherto the greater part of the Venezuelan crop has been sold. The abolition of the Venezuelan export duty on coffee is recommended. The duty amounts to 3 bolivars 22 centimes per quintal.—*Home and Colonial Mail*, March 8.

NILGIRIS GAME AND FISH PRESERVATION SOCIETY.—Further interesting particulars of the work of this active society, in which Ceylon Fishing Club and Game Protection members will doubtless be interested, appear elsewhere. But the reference to Ceylon, as being troubled with rabbits, shows curious ignorance. There is an agitation, we see, for an increased gun license. Elsewhere we have also quoted Mr. F L Mitchell's most recent letter (from Singapore) regarding the introduction of trout into Kashmir.

ROYAL BOTANIC GARDENS.

EXTRACTS FROM THE REPORT OF THE DIRECTOR FOR 1900.

1.—Changes and Movements in the Staff.

The Director was absent in India on privilege leave from December 6 to the end of the year, during which period Mr. J. B. Carruthers acted as Director. The staff has been enlarged during the year by the appointment of Mr. Carruthers as Assistant Director and Mycologist, and by the retention of Mr. M. Kelway Bamber as Chemist, paid by fees for work done for the Department up to a guaranteed amount of at least Rs. 3,000 per year. Mr. Carruthers entered upon his duties on March 30, but was absent on leave from April 16 to May 24, owing to the results of a serious accident. Mr. Bamber's duties were begun on July 1. Under the vote for Skilled Assistance the services of Mr. H. Wright have been obtained from June 28. In the early part of the year this vote was partly expended in the salary of Arunar Chinnappu, who was employed as tobacco curer in the experiments in progress.

On April 11 the late Head Clerk, Mr. J. Ferdinandus, died in Colombo; he had served efficiently from 1894, and his loss was much felt. He was succeeded on June 1 by Mr. R. H. Pereira, of the Colonial Secretary's Office, formerly employed in this Department.

2.—General.

The past year has been marked by a considerable increase in the sphere of activity of the Department, which enters upon the new century with an increased scientific staff and equipment. The permanent staff now includes the Director, who also acts as the Botanist; the Mycologist, who attends to all questions of diseases of plants other than those due to insects; the Entomologist, who attends to all questions of economic entomology; and the Chemist, who attends to questions of analysis of soils, economic products, &c. There is also the temporary Assistant, who devotes himself to the detailed study of some one particular question.

The new Laboratory was completed and handed over by the Public Works Department in February, but there was a considerable delay in the completion of the furniture, and it was not till the end of the year that it was really ready for work. The equipment of the Laboratory with apparatus will be gradual, but it already contains a good supply of all the ordinary utensils, chemicals, &c., required for scientific work. Since its completion the building has been largely used, and has proved very convenient and well arranged in most respects. A number of botanists from abroad are now working here, and a noteworthy and gratifying feature is the large number of visitors who have been sent officially by various Governments during the year to study the organization and working of the Department.

The Mycologist and Entomologist have carried out a great deal of work during the year, and their departments are becoming gradually organized on the lines which experience shows to be most useful. The bulk of their time is of course taken up with researches into the nature and life history of the numerous insects and fungi which are or may become of importance with regard to agriculture, but they have also travelled through many districts of the Island to investigate diseases and to give advice and assistance in dealing with their attacks. One method employed with some success has been for one of them to attend a meeting of the local Planters' Association in a given district, and there to discuss particular diseases and the modes of dealing with them, subsequently visiting selected estates to give practical instructions and to study the diseases more in detail. Such work is at present considerably handicapped by the extreme reluctance of cultivators to say or do anything that may seem to confess the presence of disease among their crops, but as time goes on the advantages of taking early advice and action will become more evident, and this source of difficulty and friction be lessened. Detailed reports of both officers are given as appendices.

The organization of a department to deal with prevention of disease is a new and a very important, though perhaps a less showy, line of work than that of the introduction of new industries. The losses caused by disease are enormous, and to save even 5 per cent. of them is a great gain.

The establishment of other industries has, however, not been lost sight of. The Botanist and the recently appointed Chemist have devoted much attention during the year to camphor, which seems, owing to the action of the Government of Japan, likely to prove worth cultivation in Ceylon. They have also commenced a detailed investigation into the chemistry and botany of the citronella and tobacco industries, with a view to discovering what improvements are possible that may avert the threatened danger of collapse from overproduction and foreign competition. Further details are given below.

The office and clerical work of the Department has increased very much during the year. The correspondence with planters and others on diseases, modes of cultivation, &c., is rapidly increasing, and takes up a very large part of the time of the scientific staff. It is hoped to relieve this pressure during the next year by the publication of more frequent circulars, &c., which may be distributed instead of letters in answer to many of the most frequently recurring questions. A lithographic press has been recently obtained, and it is intended in future to illustrate the circulars, a proceeding which should add to their usefulness. Their circulation continues to increase, and they seem to meet with approval from the agricultural public.

The Library has been much improved during the year. The catalogue has been completed and sent to press, and will appear early in 1901. The offices of the clerks have been moved from their former inconvenient position near the Curator's office to two small rooms at the back of the Museum, and thus close to the Director's office. Office space is needed for the Entomologist and Mycologist, and can be provided at a very small cost by the alteration of two of the rooms under the Library, at present only available as godowns on account of their want of windows.

In the Botanic Gardens themselves there is little to chronicle of special importance. Their general condition has been steadily improved. Many new plants have been introduced, and the buildings, conservatories, &c., have been put into better repair. In the two chief gardens and at Badulla the general condition of the plants is good, the buildings, &c., in good repair, and the work of the staff is efficiently carried on. The other gardens are not at present in a satisfactory state, and will be overhauled during 1901.

The experimental plots of economic and useful plants have been extended as much as possible during the year, but the space at our command is too small to allow of really satisfactory experimental cultivation.

A reorganization of the gardening and subordinate staff was proposed and sanctioned during the year (see Sessional Paper XVI. of 1900), and will be gradually put into operation as vacancies occur. An incremental scheme has been adopted, and the prospects of the officers concerned improved. Two posts, those of Assistant Plant Collector and Kankani, will be abolished, and three new ones, those of Herbarium Assistant, Clerk to the Curator, and Sixth Gardener, created. The total cost under the new scheme will remain as before. The total cost of the Department, including special votes, has been Rs. 71,740, against Rs. 58,822 last year. The increase is due to the salaries of the Mycologist and Entomologist, and the retaining fee to the Chemist, with the slight increases in the other votes rendered necessary by the increase of the staff. The receipts from sales have been Rs. 4,658·52, against Rs. 6,114·41; the decrease is due to the lower price of rubber seed.

3.—Notes on Economic and other Plants.

Tea.—The past year has been one of depression for the industry. The export has risen in an unprecedented and unexpected manner to 148,431,639 lb. against 129,894,156 lb. in 1899. Fortunately the export to Russia, now one of the largest consumers of Ceylon tea, has risen to 8,917,185 lb., an increase of 5 millions over 1899, and the exports to Australia and America show increases of 2 million lb. and 1 million respectively, while there has also been an increased export to France and other European countries. Nevertheless, so great has been the increase in production that 10 million lb. more than in 1899 have been sent to the markets of Great Britain, an increase of 10 per cent., which has been accompanied by a decrease of 10 per cent. in the average price (7·20*d.* as against 7·96*d.* in the preceding year). The rise in the duty from 4*d.* to 6*d.* per lb. has also helped to depress prices, especially of the lower grade teas. As the extension of cultivation, though practically over in Ceylon, is still going on in South India, Java, and elsewhere, it is probable that the full effect of overproduction has yet to be felt, and that the tea industry has now to pass through a trying period, which may lead to considerable alterations and reorganizations in methods of working, &c. Greater specialization, larger factories under specially trained managers, manuring and plucking for quality rather than for quantity, selection of the best and most suitable jâts as regards quality of tea and power of resisting disease, replacement of inferior bushes and fields by better and by other products, careful precautions against disease, and improvements in methods of cultivation and manufacture, are some of the directions in which relief may be looked for.

Tea has been comparatively free from serious outbreaks of blights during the year (see supplements).

A commencement, which may lead to important developments, has been made in the manufacture of green teas suited to the American markets. If this extend, it will temporarily relieve the overproduction difficulty.

An important paper on Ceylon Tea Soils and their influence on the quantity of tea has been published by Mr. Bamber during the year.

Coffee.—The rise in the exports during 1899 was a mere temporary one, and in 1900 the total export was only 10,777 cwt. as against 18,542. This is the lowest figure that has been reached since the beginning of the decline in the industry.

Cacao.—The Assistant Director, who now takes charge of all matters connected with this product, reports as follows :—

> The exports for 1900 show a considerable decrease, from 42,745 cwt. to 33,476. This, however, may be explained in a variety of ways. The year from January 1 to December 31 is not the best period for a record of cacao yield, and it is probable that the pickings of the last few weeks of the year and of the first weeks of 1901 will to some extent make up the deficiency, the crop in 1900 having been later than usual. That the canker of stem and pod and the attacks of Helopeltis, &c., are a factor in lessening the yield, is no doubt true, but a large diminution in fruit crop has occurred in trees which have no disease. In fact an unusual number of dull and rainy days in some cacao districts has told against the production of fruit and in favour of the blackening of pods and the growth of canker.
>
> The prices which have been obtained for Ceylon cacaos show that the quality of our cacaos is still up to a high level, and encourage cultivators to devote attention to further improvements of their methods of curing.
>
> The canker and blackening of pods still causes a serious diminution of crop on many estates where little or no care is taken to combat these evils, but where preventive and curative treatment is thoroughly carried out a marked decrease has resulted, and in some cases estates which two or three years ago were seriously handicapped have been almost entirely freed from the disease. Local attacks of Helopeltis on the pods have been more virulent than usual. The cacao industry will, however, be benefited by these evils to some extent, as they have undoubtedly led to more sanitary methods of cultivation, and such advances, as well as efforts to improve our varieties by selection and other means, tend to an increase of profit from this fruit tree, which grows vigorously in different climates in Ceylon.

Cardamoms.—The export rose from 499,959 to 537,455 lb., a slightly larger figure than in 1897, hitherto the largest recorded. Extension of cultivation continues both here and in South India, and the price shows signs of a considerable fall in the not very distant future.

Cinnamon.—The export of both bales and chips has risen, the former from 2,515,031 lb. to 2,678,111, the latter from 1,829,127 lb. to 1,863,406. The export of the "wild cinnamon" mentioned in last year's report has enormously decreased, to 43,339 lb. bales and 105,914 lb. chips. The price of this material has fallen very low. The export of oil has also fallen largely, from 118,778 to 72,904 oz.

Cocoanuts.—Extension of cultivation continues, and there has been a great rise in the export figures for all the various products of this palm, which has now become a very large staple. The export of oil has risen from 400,979 cwt. to 443,959, of copra from 325,401 cwt. to 362,467, of desiccated cocoanut from 13,571,084 lb. to 13,604,913, of poonac from 174,786 cwt. to 185,992, of nuts from 11,723,392 to 14,995,909, of coir rope from 12,090 to 12,572 cwt., of coir yarn from 75,525 to 87,415 cwt., and of coir fibre from 91,588 to 115,090 cwt. The industry seems in a prosperous condition, and the trees are on the whole remarkably free from any serious disease, considering how long they have been cultivated in the Island.

Other Palms.—The export of palmirah and kitul fibres has risen, though not to the figures of 1898. The sago palm continues to do well at Peradeniya, and should be tried in swampy places in the low-country, where it might prove a valuable source of food for local consumption, if not for export.

Indiarubber.—Extension of cultivation of both Hevea and Castilloa continues in favourable localities, and very good valuations have been received of rubber sent home from certain estates. The demand for seed has been less than last year, and the supply much larger. A very large quantity of seed has been exported from Ceylon to Burmah and the Straits, where Hevea cultivation is now becoming an important industry. Very favourable reports have been received from Europe on samples prepared in the Botanic Gardens by Mr. Parkin's methods, and it is hoped during 1901 to test these on a commercial scale with certain modifications that have been found beneficial.

Guttapercha.—There has been no demand for this during the year, and it is doubtful if it will ever be taken up by private planters.

Fibre.—There has been a small demand for sisal hemp and other fibre plants, but there seems no prospect at present of any one seriously engaging in the cultivation of any new fibres in Ceylon. The palm fibres have been mentioned above.

Cinchona.—The Assistant Director reports as follows:—

> The export shows a further decrease, being 510,462 lb., against 618,921 lb. last year. There has been an increased demand for information relating to the various hybrids and the conditions of successful cultivation, and an unusually large amount of seed has been purchased (chiefly abroad) and planted during the year. Specimens of various kinds of barks from different localities in Ceylon were obtained, and these will be worked out in Europe by M. Reimers, who is devoting himself to the study of chemical and botanical questions in cinchona.

Camphor.—This product has come much into prominence during the year as a possible paying adjunct to tea in many districts. The bulk of the world's supply at present comes from Formosa, and a monopoly has now been established by the Government of Japan, resulting in a rise and a steadying of the price of crude camphor, which is now from 185 to 200 shillings per cwt. At this price there seems a fair prospect of a paying return, now that it is certain that camphor can be distilled from the leaves and twigs of quite young trees. It must, however, be remembered that what can be done here can also be done in Japan, and probably at least as cheaply. The plant succeeds well in many districts of Ceylon, from sea-level to 6,000 feet; its cultivation is easy, and there is no great difficulty or expense involved in cropping and distillation. A series of distillation experiments have been carried on by the Chemist in the latter part of the year, with varying but fairly promising results. When completed, a circular will be published giving all details as to planting, harvesting, distillation, &c.

Tobacco.—Much attention has been given to this product also in the past year, but the problems in hand will require many years for solution. While at present this industry is fairly prosperous and profitable, there is great risk of overproduction when the new railway and irrigation works come into operation and the Vanni country, which contains much land suited to tobacco, is opened up. The market for Ceylon tobacco is confined to Ceylon and parts of South India, and may easily be flooded. With the aid of the Chemist and of native cultivators and others experiments have been begun to test the qualities of our tobaccos and the soils on which they grow, and to see whether Ceylon (like South India) cannot grow something marketable in Europe, thus enlarging the demand and enabling more land to be profitably opened. That Ceylon should grow first-rate cigar or wrapper tobaccos is unlikely, but there seems no reason why it should not produce a good filler, which may be wrapped in Sumatra or Borneo leaf. The seeds of Cuban and other tobaccos distributed last year to native growers in the Northern Province and elsewhere mostly cropped fairly well, though in the Peradeniya Gardens and in the Central Province they were almost completely destroyed by a grub described in the Entomologist's report. The crop, however, was not appreciated for the local market, as it was lighter and less pungent than the coarse native kinds. Probably for the formation of an export trade in tobacco some form between the two will prove best suited for cultivation.

Oils.—Cinnamon and cocoanut oils have been mentioned above. There has been a decrease in the export of citronella oil from 1,478,756 lb. in 1899 (the largest recorded) to 1,409,058 lb. The price of this product, in consequence of overproduction, adulteration, and foreign competition, continues to fall, and is now barely remunerative, and the industry, one of the most important minor ones in the Island, is in a depressed state. The plumbago "boom" took away many of the workers for some time, but this is now over. The Java planters have lately embarked in this industry, and by careful selection and distillation have begun to place upon the market an oil which is far superior to the Ceylon oil, and which fetches a much higher price. This will lead to a further fall in the price of the Ceylon oil unless new markets can be opened, which seems unlikely, or the quality of the oil improved. With this in view the Director and Chemist have made during the year a thorough investigation upon the spot into the industry, and a full report will be published during 1901. The general condition of the industry affords a striking parallel to that of tea, but is distinctly worse.

Fruit.—The supply of fruit plants has been kept up as well as possible to meet the increasing demand for them. This demand, however, is merely for planting round bungalows, and there has been little or no planting on any large scale. Interesting notes on certain fruits will be found in the reports of the two principal gardens.

Fodders.—*Trifolium Johnsonii*, mentioned in last year's report, has now proved a complete failure at Hakgala.

Trees.—Notes on a few on trial at Hakgala will be found in the report of the Superintendent. A detailed study of the Ceylon species of Diospyros and their timbers (ebony, calamander, &c.) has been undertaken by Mr. Wright, whose report is given below.

Ornamental Plants.—Cannas have continued in great request, and are now a conspicuous feature in most Ceylon gardens. Other ornamental plants are also in demand, and the interest in horticulture in the Island seems increasing.

JOHN C. WILLIS,
Director.

Peradeniya, January 25, 1901.

SUPPLEMENTS.

1.—REPORT OF GOVERNMENT MYCOLOGIST AND ASSISTANT DIRECTOR.

DURING the six or seven months that I have been engaged with the work of my appointment nearly 200 inquiries have been dealt with, chiefly dealing with diseases of economic plants. The unusual number of dull days with a humid atmosphere has been most favourable to the growth and spread of parasitic fungi during last year.

Both in the field and laboratory the fungus causing grey blight, *Pestalozzia Guepini*, Desm., has received a great deal of my attention. In order that the life-history of a fungus may be known it is necessary to make cultivations from the spores and continuously watch the growth of the organism with the microscope. These cultures are, as a rule, grown on a gelatinous medium, or some substance favourable to rapid growth; unfortunately the behaviour of the fungus in this artificial cultivation is often quite different from when it is grown in nature in living tissue.

The spores and living mycelium of Pestalozzia and several other parasitic fungi have been cultivated and examined in this manner in the laboratory, and, with the object of making observations and experiments on the fungus as it grows on the tea leaf, ten healthy bushes from two to five years old were transplanted to an experimental bed outside the laboratory. These were carefully removed without much injury to their root system, and have all continued to grow vigorously. With the help of these experimental bushes and material in the laboratory, it is hoped to work out the complete life-history of Pestalozzia and other parasitic fungi on tea.

A series of experiments has been planned and will shortly be established with a view to obtaining a more exact knowledge of the distribution of spores of grey blight and other leaf disease fungi.

Six stations have been selected at elevations of 50, 1,600, 2,500, 3,000, 4,000, and 5,000 feet respectively. At these places a jute hessian screen or tabernacle open at the top, 9 feet high, 45 feet long, and 8 feet wide, enclosing two rows of 15 tea bushes—*i.e.*, 100th part of an acre—and placed at right angles to the prevalent winds, will be erected.

The bushes inside this enclosure will be pruned (at the same time as the rest of the field) and all leaves taken off the bushes and swept out of the enclosure. Much interesting information should be gained by observation of the conditions as regards "grey blight" and other parasitic fungi of the enclosed bushes and those outside on either side of the tabernacle.

In order to test the practicability of taking off all diseased leaves from tea bushes an experiment was carried out at an estate of 4,000 feet elevation. The bushes first selected had gone 12 months from pruning; they were big healthy bushes with little, if any, disease apparent. All leaves with any spot due to fungus or insect were taken off, as it is impossible to instruct coolies as to any special blight. A quick "podian" plucked the leaves, and was closely watched to see that no leaves with any spot were left. The time taken was nearly 6 minutes per bush, or 10 bushes per hour, and about 60 leaves were taken from each bush. Ten weeks later these bushes were examined and only three leaves were found on 15 bushes with "grey blight," and a few with insect injuries. The surrounding tea was, however, not attacked to any extent. A second series of bushes in a field which had gone 22 months from pruning were treated in the same way; the bushes were healthy, but the leaves were spotted, and a large quantity of dead leaves were on the ground. In this case the time taken was 41 minutes to a bush, and nearly 3,000 leaves were plucked from each bush; in some cases 90 per cent. of the leaves were taken off.

It appears from this trial that such measures to prevent the spread of leaf blights when adopted should be taken as soon as possible after pruning, when the number of spotted leaves is few; and no doubt the most economic and most effectual method will be found to carry out this treatment periodically with the plucking by making the pluckers take off all diseased leaves.

If this were generally done, an immense decrease in the amount of "grey blight" in the Island would no doubt result. It is, however, the lack of co-operation in these sanitary matters that vitiates the good work done by the few.

Though the climatic conditions have not been at all unfavourable to the growth of fungi, ye the amount of grey blight on growing tea has not increased, and in many localities has lessened to considerable extent. This may be to some extent explained by the measures taken by not a few in burning or burying with lime diseased leaves and so destroying vast quantities of spores, and also t the close pruning of some large areas of badly affected tea.

A less encouraging circumstance with regard to "grey blight" is that I have found it on the leaf stalk as well as on the leaf. Specimens of such diseased stalks have been collected and sent t me from various localities, and on them the fungus and its characteristic spores were abundant.

This calls for careful observation on the part of planters, as it is most important that any such attack should be at once stopped by pruning back the bushes below the browned and diseased parts and carefully burning the prunings. The chief reason why "grey blight" has not done more harm to tea is that, as a rule, it only attacks the leaf, and when the diseased leaves fall the bush is free from disease; were it to spread to the permanent portions of the plant it would become a more serious enemy. It will be of advantage if any planter finding the leaf stalks discoloured, and suspecting this to be due to grey blight, will at once forward specimens for determination.

Another leaf fungus, *Cladosporium herbarum*, Pers., was found on the leaves of tea bushes among which Liberian coffee was growing. I observed on the coffee leaves (which were also attacked by *Hemileia vastatrix*, Berk.), a disease which produced the concentrically marked grey patches associated with grey blight. On examination this proved to be due to another fungus, the Cladosporium mentioned above, and on investigating similar patches on the leaves of neighbouring tea bushes this same fungus was found. *Cladosporium herbarium* is a common fungus on dead plant tissues, but also occurs as a parasite on the living leaves of many plants; it is recorded on such varying hosts as wheat, peas, apple, raspberry, cycads, agave, and pine seedlings. It has a greenish grey septate mycelium and oval conidiospores.

A report was sent on a leaf disease on tea which is common both here and in Indian tea districts. It is caused by a lichen, *Cephaleurous mycoidea*, Karsten, which produces characteristic reddish and white or grey spots on the leaf; it is partially parasitic, but it does very little harm and can spread only very slowly, and is consequently not a matter for such serious attention as a fungus parasite.

A root disease of tea has been investigated in regard to its habits and the best method of combating it. It is caused by a fungus, *Rosellinia radiciperda*, Massee, and most frequently found in clearings where the stumps of jungle trees are left, more especially those with soft wood, but any decaying wood under ground either of stem or root, if the soil is in a moist condition, may be the harbourer of this fungus. It has been found in Ceylon on stumps of various jungle trees, buried logs, stakes put in beside young plants, and buried prunings; from these it frequently spreads to and invades the roots of living tea bushes, and when it has once attacked a tea bush it gradually decreases the vigour of the plant, and in the end, as a rule, kills it. It can be recognized by its white felty mycelium, which forms strands as thick as or thicker than a piece of cotton, and runs underground from one host to another.

The fruit—which is not so commonly found underground, but can be seen on pieces of wood which have been on the surface after it has been permeated by the fungus for some time—is black and consists of numerous globose bodies.

The best preventive means against the spreading of this root enemy—as indeed against many other root parasites—are to take out the dead or dying bush, burn the roots, thoroughly lime the hole, also to cut a trench not less than two feet deep round the bushes affected, not only round the dead one, but those neighbouring which may be attacked in a less degree, in order to isolate the patch from the rest of the tea bushes. Lime forked in the infected patch will often kill the mycelium and save some of the other bushes. The trenches also have the effect, if properly cut, of draining the place and so removing the conditions which favour the progress of the fungus.

This disease is fairly common in various districts, in some cases three or four supplies in succession having been killed where the new plant has been put in without taking out the old roots. It, however, is generally very local in its effects and rarely occurs where the soil is thoroughly drained. In fields where it is found it is inadvisable to bury any prunings until the disease is entirely eradicated.

An experiment with regard to the treatment of isolation and liming the infected area was carried out on an up-country estate with encouraging results. A trench two feet deep and one foot wide was cut round a patch on which one bush had been killed by the attacks of Rosellinia and some

others were "shuck"; the space inside was heavily limed, slanting holes being made with an alavanga and lime put in. By this means lime can be introduced more intimately round the roots than by surface liming or forking. No bushes have died or appear to be affected without the trench, and some of the bushes inside are recovering.

The question of the effect of Lichens on the stems of tea bushes was inquired about and attention given to it. In the first place, *Physcia speciosa*, Fr., a lichen with a leaden blue coloured flattish thallus bearing on the under surface black hairs, was observed. This lichen is found on exposed branches and stems not protected from the sun and rain, and thus is commonest on the less vigorous bushes. It is not parasitic on the living tissues of the tea plant, and can be cultivated on glass or stone, if suitable conditions are obtained. It gets its nourishment independently of the plant on the surface of which it lives, it does not prevent leafbuds from being formed, and it is probable that its habit of growing on exposed older portions of stem and branches has originated the belief that to its effects are due the lack of vigour of the bush on which it is seen. Some of the less conspicuous lichens which lie closer to the bark will be investigated and the results mentioned in a future report. That lichens and other epiphytes are a sign that the best conditions for the tea are not present is in most cases true, but their removal at more or less cost does not take away the reason for any lack of vigour in the bushes on which they grow.

Several inquiries relating to cacao canker, *Nectria* sp., both on stem and pods, have been received and advised on. In more than one case it has been sent as an entirely new disease which has not been noticed or heard of by the cultivator before. The life-history of the canker having been worked out and the methods of counteracting its evil effects having been laid down, and during the last two years carried out with a large amount of success, it is most important that all growers of cacao, either European or native, should be on the constant lookout to detect the first appearance of this fungus and take steps to get rid of it before any serious loss has accrued and its removal becomes a more difficult and costly matter. Their neglect is also a serious injury to other cacao planters. Other work in regard to cacao is mentioned later.

In connection with the investigation of Pestalozzia, the leaves of some thirty or forty different jungle and garden plants attacked by fungi have been examined, but in no case have the spores of Pestalozzia been found, though in all cases badly "grey-blighted" tea was near or around the plants searched. The injuries which in most cases by their similarity in appearance—to the naked eye—with grey blight being due to other causes, it is important, from an economic point of view, that any invasion of another plant other than tea by the Pestalozzia should be noted and measures taken to prevent increasing the amount of the disease. Seedlings have been submitted suffering from "damping," a disease caused by a fungus, *Pythium De Baryanum*, Hesse, which spreads with great rapidity through a bed, generally so damaging the young plants at the "collar" that they fall down. It, as a rule, implies that the seed bed is too damp, and where it is noticed all dying and dead seedlings should be taken out of the bed immediately. Before the bed is again used it should be sterilised by thoroughly baking all the soil, either by burning bushwood above it or by heating it piecemeal over a fire on a shovel, in order to kill the spores of this and other fungi which grow with great vigour and rapidity in the soft tissues of seedlings.

In sending diseased plants or parts of diseased plants for diagnosis it is important that the specimens sent should show as far as possible the different stages of the disease and not only the last stage when the plant is killed; also that the conditions and environment of the plants diseased should be given and any special circumstances which may have affected them.

All diseases of plants are the effect of a conjunction of many factors, and the most essential and prominent factor is called the cause, as in the case of parasitic fungi. It is often not sufficient to know only one of the factors causing the lack of health; we must know what other conditions are concerned in the effect produced.

The work of a pathologist and therapeutist is to learn all about the life-history and habits of a fungus or other organism which has an injurious effect on a plant, and by studying the relationship between it and its host and the conditions and environment which encourage it, to discover at what time and by what means the prosperity of the parasite can be most easily interfered with.

A good many matters relative to the cultivation of cacao and its improvement have been investigated and are still being worked out. Two of the most striking things in the cultivated varieties of cacao are the amount of blossom produced in relation to the fruit ripened and the number of small fruits, from half an inch to four inches long, which die off without being attacked by any specific disease.

In some cases the weight per tree of these withered fruits has been found equal to ten to twelve ripe pods. This waste energy is clearly a disadvantage to the attainment of greatest profitable yield in a cacao tree.

The fertilization and subsequent ripening of the fruit in cacao is therefore a most important question. The method of pollination is not thoroughly known, and with this in view the flower is being studied ; when the method of pollination is discovered some experiments will be initiated to endeavour to produce an increased fertilization.

A cacao tree has been under observation at Keenakelle, Badulla, elevation 3,800 ft., of the Caracas variety, but not very typical—probably a hybrid—which has for the last five years borne on average of 434 harvested ripe pods per annum. The tree is about 17 years old, 22½ feet high, with a spread of 30 feet, and an abnormally abundant leaf production.

The propagation of cuttings from this tree has been tried, but so far without success, and a series of experiments as to the best method of striking cacao cuttings is in progress. However, any experiments in this direction by planters or others which add to our knowledge will be welcomed, as the ability to perpetuate the characters of any specially fruitful tree would be of great economic importance.

198 seeds from eight pods on this tree were sown in an experimental plot. Each seed was weighed, and those above the average weight (3·4 grammes) were placed in one-half of the plot, and those below the weight in the other half. The plots were further divided into beds according to the pods from which the seeds came, the shape, size, weight, and thickness of wall of the pods being recorded. By this means data will be gained which will show the best directions in which to work in selecting cacao fruits for seed.

For the same reasons a large number of cacao pods have been examined, measured, and weighed to find out what relation, if any, there exists between the size and shape of the pod and the number and weight of the seeds it contains. So far as the investigation has gone no such relationship has been found to be constant, the size of the pod in many cases being simply due to a thickening of the fruit wall, and in many cases the largest pods contain fewer seeds than are found in smaller fruits, but a definite conclusion cannot be formed until a much larger number of different pods have been so examined.

Experiments as to the fermentation of cacao seeds before drying have been made with a view to finding whether the process can be accelerated with good results, and these will be carried on as far as possible.

I have visited various planting districts to make observations and collect information and material for laboratory research, and have attended several meetings of District Planters' Associations, where matters of scientific and economic interest have been discussed and explanations given of certain technical points.

J. B. CARRUTHERS,
Government Mycologist and Assistant Director.

2.—REPORT OF THE ENTOMOLOGIST.

THE following circulars have been issued from the Entomological Department during the year:—

No. 17.—Tea Mites and some suggested Experimental Work against them.
No. 18 (Supplement).—Insect Pests attacking Timber and Shade Trees in Ceylon.
No. 19.—Some Caterpillar Pests of the Tea Plant.

CORRESPONDENCE.—485 letters on entomological subjects were received and filed, and close upon 600 letters on similar subjects were despatched from the Department.

OFFICIAL TOURS AND ENTOMOLOGICAL VISITS.

A tour through the Badulla and Passara districts and across country to Batticaloa was undertaken in April, occupying sixteen days. The main object of the tour was to study a caterpillar pest that was seriously affecting the cocoanut palms in the neighbourhood of Batticaloa. On badly attacked estates the fronds of the palms were being completely skeletonized. A few trees are killed outright ; but this is exceptional. I was informed that they usually recover from the attack, but that their bearing capacity is seriously diminished for several years. It was found, as expected, that the properties that were suffering most severely were those on which no efforts had been made to check the pest, or on which unsuitable methods had been employed. On estates where prompt and intelligent action had been taken from the commencement of the attack, comparatively little damage was incurred. The only course to adopt is to watch for the earliest signs of the pest, which are quite easily detected, and immediately to cut off and burn the affected fronds. It is useless to wait until the leaves have been killed before removing them. By that time the caterpillars will have deserted such fronds and migrated to fresh ones. The insect responsible for all this damage is the caterpillar of a small moth belonging to the family *Gelechiidæ*. The species appears

to be undescribed, but specimens have been sent to England for determination. The caterpillar may be recognized by the black head and second segment, the hinder parts being of a pale yellowish tint. It conceals itself beneath galleries composed of silk and sawdust-like pellets of excrementitious matter. The resulting moth is of a pale gray colour with minute black specks on the front wings. It measures about one inch in expanse.

A short visit was paid to Kurunegala in September. This was partly to visit a cacao estate suffering from an attack of *Thrips*, an account of which insect is given below; and partly to examine the feverish parts of the locality in connection with the Mosquito-malaria Theory. Though, from the shortness of the time at my disposal, the larvæ of Anopheles (the particular genus of mosquito associated with this disease) were actually captured in only one pool, I satisfied myself that the available breeding places of the insect were practically unlimited, and that it would be quite hopeless to attempt to exterminate the mosquito by either obliterating or chemically treating the Anopheles pools. The large extents of paddy fields alone would be sufficient to keep up the supply of mosquitoes. I am of opinion that preventive measures—*i.e.*, protection against the actual bite of the mosquito, coupled with the removal of the principal source of infection by the enforced medical treatment of every case of malarial fever, is the only rational course of action. The Mosquito-malaria question is discussed more fully elsewhere in my report.

A third tour, occupying one week early in November, was made in the Kelani Valley district. Many tea estates were visited, a meeting of the local branch of the Planters' Association was attended, and advice was given to the planters with reference to *Helopeltis* and other insect pests.

The past year has not been marked by any very startling outbreak of insect pests, though many cases of more or less serious injury, due to insect agency, have been observed and recorded.

The following are some of the principal species that have attracted attention :—

Heterusia cingala, Moore.—The caterpillars of this moth, locally known as "Red Slug," were prevalent in the Lunugala district in April, where a considerable acreage of tea was completely defoliated. Fortunately the damage was of a temporary nature. The caterpillars were collected and destroyed in large numbers, and in some cases the fields were heavily pruned and the prunings burned. Similar damage was reported from Rangalla in June. During my tour in the Kelani Valley district the caterpillars were observed very commonly on the tea, though no serious injury had been noticed there. It is, however, a dangerous insect to neglect, and whenever the caterpillar is seen search should be made for the rest of the brood.

The "Croton Caterpillar" (*Amyna selenampha*, Guen.)—Croton oil plants in both the Matale and Peradeniya districts suffered rather severely from this caterpillar, repeated broods following each other in rapid succession, devouring the fresh foliage as fast as it was produced. In Matale the principal attacks were in the months of January and June, while a fresh outbreak was reported in December. The pest was observed in Peradeniya in July, only after it had reached its crisis. Experiments were conducted with insecticides, some of the trees being sprayed with Macdougall's insecticide wash, and others with a preparation of arsenate of copper sold under the name of "green arsenoid." It was noticed that the former, applied in the proportion of 1 pound to 4 gallons of water, caused the almost immediate death of the caterpillars; but experiments with the arsenoid, which acts through the alimentary system, were negative, being vitiated by the fact that the caterpillars were already dying off from a bacterial disease. The pest did not reappear on this plot of croton trees.

"*Nettle Grubs.*"—Several species of these stinging caterpillars have been noticeable during the year. The species responsible for most damage appears to have been *Natada nararia*, Moore, which was very destructive to tea in the Passara district early in the year. Over 100 acres of tea on one estate were completely defoliated, and hundreds of coolies were employed in collecting and destroying the insects.

The larvæ of *Thosea cana*, Walker, were received from Elpitiya; *Thosea recta*, Hampson, from Morowak korale and Yatiyantota; and *Spatulifimbria castaneiceps*, Hampson, from several parts of the Kelani Valley. The first three species have been fully described in my circular on "Some Caterpillar Pests of the Tea Plant." The fourth has only recently attracted attention as a tea pest. It is a small and inconspicuous grub, of a chocolate brown colour, with a reddish saddle-shaped mark on the middle of the back and a few yellow spots. Though belonging to the family of "nettle grubs," this particular species is unprovided with the usual urticating spines. The cocoon is very small, broadly oval, smooth and compact. The male moth is uniform dark purplish brown, with indistinct darker transverse bars across the fore wings, the expanded wings measuring just half an inch. The female moth is rather larger, measuring three quarters of an inch across the wings, and is of a much paler shade of brown.

If left to their own devices, any of these caterpillars may suddenly appear in such numbers as to prove a serious pest. The only safe way to treat them is to take them in time, which is when

they first appear. If the earlier broods are systematically collected and destroyed, no further trouble will be experienced.

When visiting in the Kelani Valley recently, I was informed that crows were very active agents in destroying "nettle grubs." During a bad attack of the pest the crows were said to have gorged themselves with the caterpillars until they could scarcely rise from the ground. They should be encouraged in every way.

Dichocrosis punctiferalis, Guen.—The "Cocoa-pod Borer," which is the caterpillar of the Pyralid moth, *D. punctiferalis*, was troublesome in the Kandy district in March. The local treatment, which appears to be very successful, is to employ a force of small boys to examine the growing fruit. Whenever signs of the borer are observed, a few drops of kerosine oil are run into the tunnel of the insect, when the little grub immediately wriggles out and is captured. When the hole does not penetrate into the seed cavity, the application does not injure the pod.

"*Tobacco Pest*."—What may prove to be a rather serious pest has destroyed all the young tobacco plants in the experimental plots in the Peradeniya Gardens. The disease is characterized by a swollen condition of the stem, producing very much the appearance of a half-grown knol-kohl plant. On cutting open this swollen part the tunnels of a small caterpillar are found. Eventually decomposition is set up, and the plant rots away. Specimens of the caterpillars, kept in captivity, turned into minute brown Tineid moths, examples of which have been forwarded to England for determination. The pest was noticed this year only in Peradeniya, but a Tamil cultivator from Jaffna reports that the same disease is known in the north of the Island. The only possible treatment is the immediate removal and destruction of the affected plants. On inquiry from the Botanic Gardens, Buitenzorg, Java, I am informed that an identical or closely related disease occurs on the tobacco plant there. This disease is there locally known by the name of "dikbuikziekte," which may be literally translated as the "paunch-belly sickness," a highly descriptive name.

The "Tea Tortrix," *Capua coffearia*, Nietner, still gives occasional trouble upcountry. This pest has been fully dealt with in the Royal Botanic Garden Circular No. 19.

Boarmia bhurmitra, Walker.—A case of rather extensive injury caused by caterpillars of this moth affords an interesting instance of how a hitherto obscure insect may suddenly assert itself as a dangerous pest. The caterpillar belongs to the family *Geometridæ*, many of which assume, when at rest, the appearance of a piece of dead stick. The species is by no means uncommon, but, until this last year, has not gained any notoriety as an enemy to cultivated plants. It has, however, quite recently appeared in immense numbers on a few estates in the Kandy District, and, after defoliating the Grevillea trees, has attacked the tea. When full grown, the caterpillar buries itself in the ground and turns into a smooth reddish chrysalis. The moth is of a dull brown colour, very finely mottled with darker specks, and is difficult to distinguish when resting on a rock or tree trunk, though, when found, it is easily captured, as it seldom attempts to fly away. The coolies soon become adept at seeing and catching them. On one estate it was estimated that over 50,000 had been killed in this manner. At the time of my visit the caterpillars were dying off from some fungal disease. It was noticeable that there were few birds on these particular estates. Where there are abundant small birds they would be most valuable asistants in checking the increase of the pest.

"*Cardamom Borer*" (*Dichocrosis evaxalis*, Walker).—The larvae of a Pyralid moth, *D. evaxalis*, have been troublesome in parts of the Matale and Rangala districts. The caterpillar tunnels into the mature stems of cardamom plants, making its entrance at one side and boring either upwards or downwards, eating the pith and causing the death of those particular stems. After the caterpillar has vacated them the tunnels often become tenanted by ants, the presence of which first attracts the attention of the superintendent, who, not unnaturally, attributes the damage to the ants themselves. The presence of the borer may be detected by the accumulation of pellets of excrement at the base of the injured stems. The affected stems should be at once cut and destroyed.

Nepita conferta, Walker.—In August immense numbers of the small hairy caterpillars of this moth were invading the bungalows, swarming upon every rock and piece of brickwork, and wandering over the roads and garden paths. This insect is not mentioned here on account of any damage attributable to it, for, with the exception of inconvenience caused by its occasionally coming in accidental contact with one's person and leaving its irritating hairs in one's skin, it is quite harmless. The caterpillar feeds only upon minute lichens and algæ growing on rocks and stones, and will not touch any of the higher plants. But the appearance of such thousands of caterpillars often causes unnecessary alarm to those who do not know the habits of the insect.

Agrotis C-nigrum, Linn.—The sudden appearance of the caterpillar of this moth on a young tea clearing in Bogawantalawa is another instance of the unexpected increase of an insect hitherto considered somewhat of a rarity in Ceylon. The attack seems to have been only temporary, the pest disappearing almost as suddenly as it arrived.

The "Mango Pyral" (*Orthaza euadrusalis*, Walker).—It is a by no means uncommon thing to find the foliage on one side of a mango tree completely destroyed, the leaves withered and riddled with holes and matted together with web. I have recently ascertained that the insect responsible for this damage is the caterpillar of a pyralid moth, *Orthaza euadrusalis*.

Helopeltis Antonii, Signoret.—This well-known insect, sometimes called "Mosquito Blight" from a fancied resemblance to the common mosquito, has been a source of considerable annoyance to both tea and cacao planters. On tea estates in the Kelani Valley and Kalutara Districts the pest annually causes an enormous loss of flush. This may possibly be considered a not unmixed evil by those who are now advocating a reduction of our outturn of made tea; but as the loss falls very unevenly, it can scarcely be considered a beneficial insect. Although the knowledge of the breeding habits of the insect enables us to attack it at its most vulnerable stage, much yet remains to be discovered of its life-history. The most pressing problem is, What becomes of the insect during the months when it deserts the tea plant? It is only careful observation at a number of different stations that can give us any clue to the solution of this mystery. A circular is now being prepared, setting forth what is known about *Helopeltis* and what remains to be discovered.

The *Helopeltis* insect attacks the cacao plant in a different manner. Though there is occasional injury from the puncturing of the young cacao leaves, the principal damage is confined to the pods, which are often so badly punctured when quite young that they are unable to develop properly, or may even be killed outright. I have suggested the spraying of the young pods, at the time when the eggs of the insect are being deposited, with Macdougall's solution or some similar insecticide. This treatment is now being carried out on a few estates with apparently good effects.

Thrips.—A serious attack of Thrips was reported from Kurunegala District in September. The species appear to be the same as has been recorded from the tea plant, but in this case it was injuring cacao trees. I made a personal visit to the estate in question, and found the damage had been really severe. The insect is a most minute one, only just visible to the naked eye. But the work of myriads of individuals results in an excessive loss of leaf and endangers the safety of the crop. The symptoms of attack are a yellowish blotchy appearance of the upper surface and a brownish discolouration on the under surface, which is also covered with small black spots due to the deposition of the excreta of the insect. No eggs could be found; but on crushing the body of the female insect and examining it with the microscope a powerful serrate ovipositor is noticeable, which suggests a probability of the eggs being embedded in the tissues of the plant. It is probable that they are deposited in the younger leaves after these have attained their full size, but before they have become hard. On such leaves the adult insects are found, but few, if any, of the immature individuals. The actual injury to the leaf occurs after it has reached maturity. It was most noticeable that plants growing under dense shade were less affected by the pest than those in more exposed situations. It was also apparent that hardy hybrids, when once they have reached the fruiting stage, are able to withstand the attack very much better than do the old red varieties. The young hybrid plants do not share this immunity, and often succumb to a bad attack. On this account, although it would be quite impracticable to treat a large area with many trees over 20 feet high, attention may be given to the supplies with great benefit, to enable them to reach the immune stage. Such supplies might be sprayed with any of the soapy insecticides in the market. It may be necessary to repeat the treatment at intervals during the critical period.

A case of death from the sting of the common hornet, *Vespa cincta*, Fabr., has been brought to my notice. It appears that a cooly boy, aged about twenty, disturbed a hornet's nest while pruning a tea bush. He was badly stung at 3 P.M., and died before midnight.

A case of bite from the so-called "Tarantula spider," *Poecilotheria subfusca*, occurred in the gardens. The man had been struck in the foot and appeared to be suffering considerable pain. I could find no definite wound. Six days later he was still laid up and was complaining of pain in both arms and legs. His eyes were affected, the surrounding parts swollen. On the day after the bite he was unable to see clearly, but this symptom was slowly passing off. There was no local suppuration or inflammation.

Mosquitoes and Malaria.—So much attention has recently been drawn to the connection between malaria and mosquitoes, and the question is of such importance, that a few remarks on the subject may not be out of place here. Whatever the opinion may be as to whether it is the sole cause, I believe that no one who has investigated the evidence fails to acknowledge that the mosquito (or rather one particular genus of mosquitoes) is a material cause of infection. If we believe that the mosquito plays its part in the dissemination of the disease, we must also recognize the importance of offensive and defensive action against the insect that carries the germs that induce malarial fever. Offensive action is practicable only under favourable conditions. In some towns and situations, where the nature of the land allows of free drainage, or where there is little surface water, it may be

quite possible to exterminate the malarial mosquito by depriving it of its only breeding grounds. But such conditions are seldom found in Ceylon.

Defensive action, on the other hand, is always possible. The malarial mosquito (*Anopheles* species) flies only after sundown. It seldom flies high above the ground. Mosquito netting and upstair bungalows will be the logical policy to meet these two cases. There is of course a period, between sundown and bedtime, when—unless we have made our houses mosquito proof—we are unprotected by mosquito netting. During the evening the feet and ankles are particularly liable to attack. To guard against this it may be suggested that boots might be worn in the evening instead of shoes. The after-dinner nap is another dangerous time, when the mosquito can take his fill without interference. It would be easy to fit up a small mosquito-proof retreat in the verandah of most bungalows, large enough to contain a small table and a couple of chairs, where it would be possible to read (or sleep) in safety and comfort. Those who (like myself) have satisfied themselves of the accuracy of the facts recorded by recent distinguished investigators, that the Anopheles is the sole carrier of infection, and that the malaria parasite cannot exist outside the body of either the man or the mosquito, recognize the importance of isolating and medically treating every single case of malarial fever, and of so preventing the mosquito from acquiring fresh infection, for, unless the Anopheles has previously drawn a supply of the malarial parasite from some fever-stricken patient, its bite is quite harmless. Natives who have to sleep in malarious localities may protect themselves by covering the exposed parts of the body with oil.

In connection with the Mosquito-malaria Theory, the British Museum authorities have called for specimens of all the different species of mosquitoes to be found in various parts of the world. I have sent to England, for determination, some fifteen distinct species, and I understand that other collections have been made and forwarded by members of the Medical Service.

Besides the danger of malarial infection from the bites of Anopheles, the discomfort and irritation caused by the bites of the ordinary species of Culex are not to be disregarded. These species can find convenient breeding places in any chance accumulations of water about a bungalow. Tubs of water should not be allowed to stand undisturbed, or will soon become filled with the small wriggling larvæ of the mosquitoes. Water standing in the saucers of flower pots, in any discarded cans or tins or broken bottles, will also serve to increase the number of insects. All such receptacles should be repeatedly emptied. Another prolific source of mosquitoes is to be found in the hollows of the bamboo stumps after the stems have been cut down. I have recently made a careful examination of the giant bamboo clumps in the Botanic Gardens, and have estimated the number of mosquito larvæ existing in the stumps at any one time. The result of my calculations worked out at the enormous figure of 57,000 larvæ within the area of the Peradeniya Gardens. The larval and pupal stages of the insect occupy from ten to fifteen days according to temperature. Allowing for two generations only per month, for the eight months during which water is likely to remain in the bamboo stumps, we must multiply the above figure by sixteen, producing the total of 912,000 (close on one million) mosquitoes raised from these bamboo clumps in one year. To the above must be added the number breeding in the stumps of the common yellow bamboo, which remains to be estimated. This vast swarm of mosquitoes may (and in future will) be prevented by the simple expedient of trimming off the bamboo stumps to the next knot and leaving no receptacle for the accumulation of water.

Beneficial Insects.—I regret to have to report the final loss of the small colony of imported ladybirds that has been cultivated for the last three years. These beetles were received from the Cape, where the species (*Exochomus nigromaculatus*) is said to be most useful in checking some of the local scale insects. But it is apparently unsuited to our work in Ceylon. It does not breed sufficiently rapidly, and in fact ceased to breed at all after the first eighteen or twenty months. The adult beetles remained alive for a surprising length of time, but died off one by one until the colony became extinct. The several lots of beetles liberated from time to time have shown no signs of having established themselves, and have presumably acted in the same way as those kept in captivity. This failure does not necessarily mean that the introduction of beneficial insects to fight existing insect enemies is useless. It only means that we have not yet introduced the right kind of insect for our purpose.

I have been experimenting on the introduction of the cochineal insect (*Coccus cacti*) and the lac insect (*Tachardia lacca*). Through the kindness of Mr. Lounsbury, Government Entomologist at Cape Town, I have received living colonies of the cochineal insect, and have found no difficulty in establishing them on plants of both *Opuntia Coccinellifera* and *O. Dillenii*. Similar attempts to procure living colonies of the lac insect from India have so far failed. Through the courtesy of Dr. George Watt, I have received repeated consignments of the insects from various districts, but in each case the young larvæ have died in transit.

There has been some correspondence between the Ceylon Government and a company desirous of starting Sericulture in Ceylon. It is unfortunate that the negotiations broke down. If once properly started, this industry would be of great benefit to the native population. The rearing of silkworms is a work which the Sinhalese would soon learn, and which could be carried on in addition to their usual occupations, the cocoons being sold to central factories.

Experiments in the destruction of termites (white ants) by the use of bisulphide of carbon have been conducted with considerable success. But the very limited supply of the chemical obtainable in Ceylon has prevented the continuation of the trials. Three main shafts of a large ant-hill were plugged with the bisulphide, about half a pound in all being used, and all the openings closed with clay. Twelve hours later the nest was opened. A few living insects were observed close to the surface, but lower down the slaughter had been immense. All the comb-like material was blocked with corpses. Unfortunately the queen cell could not be found, so it is uncertain whether that most important individual was killed or not. Even if the poisonous gas failed to reach her, she would probably soon perish for want of attendance, and the mass of putrifying bodies would further poison the air in the lower chambers. The few individuals observed at the top of the nest were doubtless some that had been foraging at the time of treatment and had since returned. I feel satisfied that, if the bisulphide could be obtained cheaply in the Island, it would prove a most valuable agent in checking the ravages of white ants.

Insecticides.—The difficulty of obtaining stock insecticides at prices that will allow of their being freely used has greatly interfered with the treatment of many insect pests. I have now made arrangements with a firm in Colombo to import and stock such articles as may be recommended for the purpose.

E. ERNEST GREEN,
Government Entomologist.

3.—REPORT OF THE SCIENTIFIC ASSISTANT.

I ARRIVED on the 28th June, 1900, and since that time have been engaged in an investigation of the floral and vegetative characters of the genus Diospyros. If time permits, the inquiry will be extended to the members of the other genus—Maba—of the Ceylon Ebenaceæ.

The rarity of flowers and the occurrence of coloured woods (ebony, calamander, &c.) in the genus Diospyros had led to some confusion, and it is hoped that the present investigation will lead to a better understanding of the specific characters of the members included under this head. Hitherto my work has been confined to collecting the vegetative organs and to an analysis of the anatomical features of the seedlings and timbers yielded by the various species of this genus. Evidence has been obtained to show that in the details of the anatomy and disposition of the conducting tissues of the seedlings, specific characters are presented, and these will be used for purposes of classification as is now done in other natural orders by modern systematists.

In studying the development of seedlings of calamander (*Diospyros quæsita*, Thw.), observations have been made which indicate one of the causes threatening the extinction of this valuable timber tree, and these, together with remedial suggestions, will be subsequently published. In analysing the black and variously mottled timbers obtained from these plants, the cause of discolouration has been determined, and experiments have been initiated with the object of inducing a blackening of the timber in the peripheral sapwood.

In consequence of the slow rate of growth and evergreen nature of these trees, it is difficult to obtain an intelligible interpretation of their age, and experiments have been organized at Hakgala, Badulla, Anuradhapura, and Peradeniya, which will assist us in our efforts to obtain a correct elucidation of the seasonal anatomical peculiarities of these and other tropical timbers. In these experiments upwards of 300 observations are being taken every month, and by this means we shall be able to determine what tissues have been formed during any particular period. These facts will then be correlated with the general behaviour of the plants and the climatic conditions under which they are growing. When the flowering period arrives a thorough re-investigation into the morphology of the reproductive organs will be undertaken and correlated with the timber yield of each species. As there is so much doubt in this direction an organized system of collecting will probably be instituted.

The Forest Department of Ceylon has generously forwarded new and rare specimens, and the officials of the Botanic Gardens at Sibpur, Madras, Saharanpur, Singapore, and Mauritius have likewise given every assistance.

H. WRIGHT.

4.—LABORATORY, MUSEUM, HERBARIUM.

The new Laboratory was completed on February 24, but owing to difficulty in obtaining teak the furniture was not ready till nearly the end of the year, and work was carried on with many inconvenient makeshifts. In addition to the regular workers (Director, Mycologist, Entomologist, Assistant), the following visitors have used the Laboratory during the year:—Dr. Preyer of Berlin, January 1 to 19; Mr. R. H. Yapp of Cambridge, February 1 to 15; Dr. Giesenhagen, Lecturer in the University of Munich, March 8 to 30; Dr. W. H. Lang, Lecturer in the University of Glasgow, August 6 to November 24; Mr. A. G. Tansley, Assistant Professor in University College, London, October 1 to November 24; Dr. C. Holtermann, Lecturer in the University of Berlin, November 29 to December 31. The Director was engaged in various economic studies, and in completing the monograph of the Podostemaceæ (a short tour in Western India was made in the latter part of the year to obtain material for this work and to visit the gardens, &c., of Bombay, Poona, Madras, Ootacamund, privilege leave being granted for the purpose). The work done by the other members of the staff is described in their reports. Dr. Preyer was engaged in the study of certain problems in economic botany, especially cacao and indiarubber; the other workers were occupied with investigations into the anatomy, morphology, and physiology of plants.

The fifth and last volume of the Flora of Ceylon appeared early in the year, written by the veteran botanist, Sir J. D. Hooker. The Colony now possesses perhaps the best existing Colonial Flora. At the same time, this flora is anything but complete; there are yet many new species to be discovered, and many occur in other localities than those mentioned. For the filling up of the gaps we must rely largely on the help of local botanists, and an attempt will shortly be made to interest more of the public than have hitherto cared for such things in the study of this most fascinating of the sciences. Suggestions to this end will be cordially welcomed.

Conifers or Fir Trees.—It is interesting to note that several species of these, chiefly Australian, find here congenial conditions for growth, some of them (the *Araucarias* and *Agathis*) attaining to a great height. The site set specially apart for this order on the highest elevation in the gardens has been laid out to better effect, the number of species being also added to.

Cultivation and Experiments.—It has been found necessary to propagate and maintain an unusually large stock of young plants of fruit, shade, and windbelt trees in order to meet the increased demand for such caused by the recent publication of Circulars on these subjects.

Efforts which at present promise some success have been made to graft the mangosteen (*Garcinia Mangostana*) on the Cochin goraka (*Garcinia Xanthochymus*), a species of quicker growth and easy cultivation.

Partly successful attempts have been made to raise nutmeg plants by layering. This will be of importance if found generally practicable, as the nutmeg tree being unisexual the risk of too many male trees occurring in a plantation made from seedling plants may thus be avoided.

A new kitchen garden, for the purpose of testing the suitability of native and exotic vegetables to local conditions, has been made behind the Palmirah avenue, where it does not mar the view.

A beginning has been made in getting together a collection of all the principal varieties of plantains (bananas) growing in Ceylon, with a view of making the best kinds better known and discarding the worthless ones. Upwards of 23 varieties have so far been obtained.

The mango trees received as grafted plants from Poona in 1884 have not as yet fruited, though some have flowered irregularly since the last seven years. One cause of this is probably that they were too thickly planted (15 by 15 feet). Early in the year some of the trees were cut down with a view of inducing the remainder (10) to come into bearing. Of the latter, some were trenched round then at a distance of 7 feet from the trunk, others supplied with about 12 lb. of salt forked in with the soil round the tree, while the rest were "thrashed" by means of a long bamboo, which acted as a severe form of pruning. These are treatments which are said to be effectual in other countries, but as yet unsuccessful here, though it may yet be too early to expect good results.

In regard to experiments in vegetable or fruit cultivation it may be mentioned that possibly the greatest drawback here is the daring pilfering habits of the natives. For example, sets of selected yams were stolen from the ground after being planted out with particular care for experimental purposes.

The introduction of special varieties of tobacco, referred to in last year's report, has not proved a success. Plots were prepared in different parts of the garden, and the seedlings planted out as soon as strong enough and the weather suitable, viz., in the beginning of April. Shortly after, however, these began to show a swelling of the stem at the ground surface, this being the result of a grub which embedded itself in the young stem and gradually ate away the heart of the plant. Only a few of the plants survived, and these were preserved for seed purposes, a few plots being again planted out with their offspring, which so far have not been similarly attacked.

I would point out, however, that circumstances do not favour such large experiments being carried on within the gardens, and that their undertaking can only be incomplete and at the expense of other important matters.

The Brazil-nut tree (*Bertholletia excelsa*) of Brazil, introduced in 1880; *Pangium edule*, a Java tree with large edible fruits, introduced in 1891; and *Dimorphandra Wora*, a tree of British Guiana with enormously large and edible seed, introduced in 1881, have each produced fruit here during the year for the first time; whilst at Henaratgoda station a tree of the Sugar palm (*Arenga saccharifera*) of the Malay Archipelago has borne (for the first time in Ceylon as far as I can learn) a large quantity of fertile seeds, from which a stock has been raised. Among others which have flowered and fruited for the first time here are *Joannesia princeps*, *Sideroxylon dulcificum*, *Diplothemum maritimum*, *Pritchardia grandis*, *Euryale ferox*, and *Enterolobium cyclocarpum*. The following have flowered only for the first time:—*Acalypha Sanderiana*, *Allamand Wardleana*, *Caryocar nuciferum* (at Henaratgoda), *Glomeria jasminiflora*, *Renanthera alba*, *Sterculia acerifolia*, *Strobilanthes Dyerianus*, *Randia mussænda*, *Lagerstræmia tomentosa* (?), *Bignonia magnifica*, *Agave glaucescens*, and several orchids.

It may be recorded as a rare occurrence that a tree of "Calamander" (*Diospyros quæsita*), which is becoming very rare in Ceylon, was found in the Province of Sabaragamuwa, in July last, bearing a crop of fruit. Seeds from these have been sent us by the Assistant Conservator of Forests, Western Province, and the plants raised from them are being carefully attended to.

Visitors.—Foreign visitors have been slightly on the increase, judging by the number of signatures (2,780) in the book kept at the entrance lodge. Among these the following botanists may be mentioned, apart from those who have worked at the Laboratory: Mons. Prudhomme, Director of Agriculture, Madagascar; Mr. Maiden, Director of Botanic Gardens, Sydney; Mr. D. G. Fairchild, Agricultural Explorer to the United States Department of Agriculture; Mons. L. Pynaert, Director of Botanic Gardens, Upper Congo, Africa; and Mr. Stanley Arden, Superintendent of Government Experimental Plantations, Federated Malay States. It is interesting to mention that a departmental album (purchased by the staff) has been placed in the Library. This is intended for photographs of scientific visitors as well as European and native officers who have held prominent offices in the Department, with a brief note as to service, &c., accompanying each photograph.

Fences.—Several of the old fences have been repaired, the one round the Lucerne plot was renewed, and a new fence, 128 lineal yards long, made of posts, rails, and wattles, was erected round a plot of land below the young gardeners' rooms. This enclosure is required for an additional nursery and for growing small patches of fodder.

Cinchona.—A small piece of jungle to the north of the camphor plantation has been cut down, cleared, and planted with plants of a special variety of cinchona. The plants were presented by the Manager of the Ceylon Tea Plantations Company. They made a very good start and grew into strong sturdy plants, but unfortunately the sambur deer found them out in the early part of December, and destroyed nearly every one.

Casuarina plantations.—The Casuarina plants, planted in patana land last year, have done very well. The rows which received a handful of lime to each plant show much better growth than those without. Some of these plants have grown to a height of 8 feet. They have, however, suffered much from the attacks of sambur deer, which have on several occasions broken through the fence and eaten off many plants. New plants have been set out to supply those destroyed, and this plantation promises to be a success.

Camphor.—There has been a great demand for camphor plants, and although we have not been able to supply the actual numbers applied for, every applicant has been supplied with some. No seeds have been received during the year, and as cuttings do not strike readily our stock is very nearly exhausted.

Experiments as to the quantity of camphor contained in the trees here have been undertaken by Mr. Kelway Bamber, and the results have been encouraging.

The plants here have continued to grow rapidly, and a few have flowered, though no fruit has set. This plantation is now five years old, and the largest tree is 22 feet high with a spread of branches of 15 feet, the stem being 27 inches in circumference at the base. One tree was partly coppiced on the 8th August, and gave 112 lb. of leaves, branches, and stems: three old stems were left uncut. The shoots from the cut stems number 39, the largest being 4 feet high and 1½ inch in circumference. This is remarkably good growth, and shows how well this plant will stand coppicing. Several plants have been clipped with hedge sheers, and others cut down like tea bushes. All have stood this treatment well and have broken into new growth in a very satisfactory manner. Judging from the way it behaves here, it is a very desirable plant to grow, and is likely to prove profitble.

Oaks.—The plantation of *Quercus ceris*, "Turkey Oak," has now become established, and promises to be successful. Both this species and the common English Oak, *Quercus robur*, broke

out into new growth in October. Several of the last named flowered and a few acorns have set, which proves that the plants are now established.

Holly.—It may be interesting to note that a plant of the common English holly, which was raised from seeds sown in 1895, has borne a few berries this year. I believe this is the first time that holly berries have been produced in this country.

Fruit Trees.—The dry weather appears to have been very beneficial to the foreign fruit trees, as they made very good growth after the light rains in May, especially the apples and plums.

Anona Cherimolia.—It has been generally supposed that the "Cherimoyer," though it grows remarkably well and flowers freely, would not fruit at this elevation—5,600 feet. However, I am glad to be able to report that one of the first plants introduced to Ceylon, and perhaps to the Eastern World, has borne 30 fruits here this year. The fruits, which ripened in November and December, were well shaped, of good size, weighing up to two pounds, with a circumference of 15 inches, and the flavour was delicious. Plants of this desirable fruit grown at elevations from 3,000 to 4,500 feet generally bear fruit in from four to five years from seeds.

The plant mentioned above is 15 or 16 years old, so that the higher the elevation the longer it takes to come into bearing. But the fruiting this year is probably due to the fact that the first 5½ months were very dry and favourable for the ripening of the buds and setting of the flowers.

Porcupines, Hare, and Mouse Deer.—Porcupines were again very destructive to arum and other lilies and bulbous plants at the beginning of the year.

Hares and mouse deer, especially the latter, have been very troublesome all through the year, more particularly among the violets and poppies, which plants they appear to be very fond of, the foliage of the plants being regularly eaten down.

Visitors.—The number of visitors recorded during the year was 1,818, against 1,805 last year. The largest number in any one month was 301 in April against 421 of the same month of the year before. The smallest number in any month was 34 in June against 19 in October last year.

8.—HENARATGODA GARDEN.

This has been kept in fair order during the year ; the conservatory has been repaired, and also the bungalow. It is proposed to attach it in 1901 to Peradeniya in a more intimate way than has been the case hitherto, and a plan of working is being drawn up. The garden was visited by 310 visitors.

The average fall for the ten years 1891-1900 is 99·94 in. 162 days.

9.—ANURADHAPURA GARDEN.

This garden has as usual suffered much from drought. It has been kept in fair order, and various interesting experiments have been tried on a small scale. Until the opening of the new railway and irrigation works, there is but little to be done in this district. A small sale of plants goes on, and through the assistance of the Government Agent free distributions of useful plants and seeds are made in the outlying villages, a useful work which is beginning to bear fruit.

10.—BADULLA GARDEN.

This has continued to improve, and is now in very good order. The trees have been considerably thinned out, and the remainder have now room to expand. New and permanent cooly lines are much needed as well as a good plant house. The stock of plants for sale has been kept up, but there has been less inquiry for them than last year. Experiments on a comparatively large scale have been tried with tobacco and other products, but the space available is too small to do much more than keep up one or two plants of each of the kinds likely to be asked for. The main road through the garden was gravelled by aid of a vote of Rs. 100 kindly granted by the Local Board.

PRODUCTION OF COTTON AND COFFEE IN BRAZIL.

The Austro-Hungarian Consul at Rio de Janeiro reports that there are cotton trees throughout the Brazilian territories, which supply the whole of the material for the very numerous cotton factories there, the activity of which is yearly increasing. In the states of Rio de Janeiro and Minas Geraes, there are about thirty factories, having an aggregate of about 16,000 looms; the machinery, which is supplied by England, Germany, and North America, is set in motion by a great many waterfalls by means of hydraulic wheels. The manufacturers of yarn mix the Brazilian cottou with North American and Egyptiau cottou, which ensures greater firmuess. The most superior sorts, amongst them the genuine Sea Island, are produced in the neighbourhood of Alcantara, in the state of Maranham. The arrivals in 1899 amouuted to 159,029 bales of about 80 kilos each. According to statistical returns the world's stock of coffee on January 1st, 1899, was 387,000 tons, or about 6,450,000 bags, a quantity which has never before been attained at that season of the year, and the 1899-1900 crop promised very abundant yield. The over-production in the Brazils had created a situation which filled even optimists with dismay. Although the cousumptiou, in consequence ot the low prices, had considerably augmented, it was feared that the heavy stocks and the large anticipated arrivals would prevent buyers coming forward. In order to counteract such a contingency a union was formed, styled "Centro da Lavouro do Café do Brazil," to carry on an active propaganda in order to augment consumption.—*Chamber of Commerce Journal*, for Feb.

"LES CULTURES COLONIALES."*

We have received a copy of this work (in French) by Henri Jumelle, Science Professor and Lecturer in Marseilles. In two volumes, one on "*Plantes Alimentaires*" and one on the "*Plantes Industrielles et Medicinales.*" The object of the author in these two volumes has been to collect, for the benefit of planters and the pupils in the Colonial Schools, information on the various methods of culture in use in different regions of the sub-tropical zone. There is great variety in these methods, probably owing to special conditions of climate and soil. M. Jumelle has tried, by comparing the climates and soils of countries in which the same product is cultivated, to deduce general laws as to the conditions most favourable to its growth.

This work is in two volumes. The first is devoted to Food Plants. M. Jumelle includes among these not only farinaccous plants, vegetables, cereals, sugar-yielding plants and fruits; but also spices, aromatic plants, and coffee and tea.

In the second volume, M. Jumelle takes up textile growths, oleaginous plants, rubber and gutta plants, perfume and varnish-yielding plants, dyes and tannin, medicinal plants, and those used for chewing and as narcotics, and those for fodder. This volume of 358 pages has 101 illustrations amongst the letterpress, while the former has 104 illustrations and 430 pages. (4 fr. per vol.) Seventeen pages only are devoted to Tea. We have first, broadly given, Habitat, Varieties of Tea and botanic description, their climate, soil and moisture, requisite manure, seeds and nurseries (how arranged,) transplanting, pruning, which is carefully described; harvesting or plucking and the making of tea; machinery, Jackson's roller being specially indicated; also Jackson's and Davidson's Drier. A sorting machine by M.G. Collom, and packing machine of Davidson & Co., are advised. "Green Tea is prepared almost exclusively in China," say they, "and is a little poorer in theine, but richer in tannin and essential oils, and therefore more exciting than ordinary tea." The process of manufacture is carefully described. One page is given to the Diseases of Tea, *i.e.*, to the Tea Bug, and cures, suggested by Dr. Trimen and Mr. Green, are described.

Every cultivated tropical product seems equally carefully disposed of. The work ought to be very valuable to residents in the tropics who can read French and meditate trying some new cultivation. There is a complete index of names of plants, etc., technical, botanical, and popular. The work is likely to be translated into other languages shortly.

* J. B. Baillière et Fils, Rue Hauteville 19, près du Boulevard St. Germain. Paris. 4 fr. per vol.

THE RETAIL SALE OF TEA TO NATIVES.

SHAKE OFF THE SENSE "OF INFRA DIG."

It is to be devontly hoped that the Tea Association will lose no time in taking to heart the lecture upon self-help contained in the concluding paragraphs of the Viceroy's winding-up speech in the debate upon the Assam Labour Bill. There are two difficulties, however, that present themselves at the outset of driving a country trade in our teas; first, we have to encounter and overcome that unacknowledged but undeniably existing over-strained sense of gentility that pervades all classes of our countrymen when transported to India; anything like shop-keeping as pursued at home being considered *infra dig*, and yet, if we are to create a business in tea among all classes, the patrician toga must be discarded; in the second place, we venture to say there is not a tradesman connected with the Association, and one as an organiser is a *sine qua non*. We have urged repeatedly the opening of stalls at such places in town where the hordes of natives that are constantly on the move could obtain a cup of decent tea for a pice, and last year suggested the setting up of somvas at the large railway halting stations, but no attempt has been made to follow such up although the success as indicated in His Excellency's speech is assured. We are not in Messrs. Cresswell's confidence and, beyond knowing that they are credited with some plan or other for widely distributing tea among the masses, are quite in the dark as to the nature of what proceedings they purpose adopting. As far as Calcutta is concerned we have overwhelming evidence that, were some systematic method devised of furnishing the present peripatetic vendors of made tea with the means of filling their cans with a properly-concocted brew, the already pronounced taste would expand enormously and rapidly. We do not look for more than covering expenses at first, for the scheme must be regarded as a simple advertisement. Hitherto all idea of introducing our teas to the working classes has been centred upon selling small packets, but little ad-

vantage is likely to arise from that, as the consumers we wish to reach have no means of investing in teapots, *chulahs*, pannikins, etc, any more than their compeers at home have, yet the consumption of made tea among the latter is enormous. Our own opinion is that, if tea depots properly supervised were established at the several points where natives congest during the day, European supervision would not be needed for more than a couple of months, as the profits would be ample enough to induce respectable natives to take up the business; and in a very short time depots for the sale of ready-brewed tea would be as numerous as are those now for the sale of ice and the various syrups, while the demand from these places for leaf would go on increasing annually. Putting the matter into figures the returns from one pound work out as follows:—6 annas 1 lb. tea, 2 annas fuel, etc. 128 cups at 1 pice=Rs. 2. We allow one-eighth of an ounce to a cup. Profit enough in all conscience to justify the venture.—*Indian Planters' Gazette*, March 16.

THE ENGLISH AND FRENCH IN ABYSSINIA.

SOME ACCOUNT OF KING MENELIK'S NEW RAILWAYS,

(BY HERBERT VIVIAN.)

The French traders at Addis Ababa are really too fine for their place. They did very well so long as they possessed more or less of a monopoly. One of them, M Chefneux, is partner with M Ilg, Menelik's Swiss Minister for Foreign Affairs, as concessionaire of the Jibuti Railway, and they all consider themselves very great personages indeed. When Menelik grants them an audience, they go away again if he keeps them waiting five minutes. But their day is done. They cannot compete with Indian traders, who bring frugality, industry, and even honesty to bear, and therefore are not easy for a Frenchman to compete with. An Indian is content to travel down to the coast attended by one native servant and just the necessary amount of men to look after his baggage mules or camels. A Frenchman, on the other hand, thinks it necessary to travel like a prince, with a great retinue of armed men, and the expense of this swallows up the greater part of his profits. Moreover, he labours under the delusion that anything is good enough to sell to a native, whereas his system of sharp practice, though it may pay for a moment, cannot do so permanently. Before my departure from Addis Ababa, I had occasion to visit the store of one of

THE LEADING FRENCH TRADERS,

as some of my supplies were running out. He showed me several shelves of bottles, and I noticed in the two lower ones some very elaborate labels—"Grande Marque Extra Fine," and all the rest of it. Moreover, many bottles were done up elaborately in wire, like the very choicest and oldest brands in Europe. My curiosity was pricked as to the market which the man could hope to find for such luxuries in the heart of Abyssinia, but he said with a smile, "I don't recommend those. They are intended for the natives, and contain the filthiest stuff you ever imagined." This struck me as a very eloquent as well as a very frank epigram upon the attitude of French colonial trade.

The advantage which the French obtained by being first in the field is now rapidly fading away before the superiority of our methods and the superiority of our commercial honesty. The French themselves readily admitted Colonel Harrington, our representative at Addis Ababa, is an extremely able diplomatist, and he has certainly secured the confidence of the Emperor in a way that no European diplomatist ever did before. He is feared as well as respected, and Menelik knows that he will stand no nonsense.

"Our influence in Abyssinia," wrote a Frenchman, who has spent many years in the country, "is *nulle archinulle*, and has never existed there, save in the imagination of the promoters of the railway company. . . . The only nation which possesses a real and serious influence, imposed by fear, is the English, who use M Lagarde as their catspaw. The English have at Addis Ababa a master in the art of diplomacy, a man who knows his own mind, who does not humiliate himself with humble entreaties, and who has obtained everything he desires, and will continue to do so, for he exacts it." This is an exaggeration in so far as concerns the statement that French influence never has existed in Abyssinia. Indeed, at one time it was almost paramount, and I believe that an able diplomatist could revive it again. At present, Menelik feels that he cannot trust the French; while, as he told me when he received me in audience, he knows that

WHAT AN ENGLISHMAN SAYS IS A FACT,

and that what he undertakes to do is as good as done.

Just as French laudatory articles on Abyssinia were spread out over many years, to pave the way for the flotation of a French railway into the country, so the whole of my remarks have been intended to lead up to a survey of the past, present, and future of that enterprise. On March 9th, 1894, Menelik conceded to MM. Ilg and Chefneux the right to make a railway from Jibuti to Harrar, on to Addis Ababa, and thence to Kaffa and the White Nile. This railway was started as a commercial enterprise, and money was obtained from ordinary investors, who were actuated by the ordinary expectation of dividends. The promoters knew very well that the railway never could be a commercial success, and that it was impossible that there ever should be any dividends. But they were content with what the articles of association have called "the gratuitous transfer" to the company of their rights in the concession. This, being interpreted, means that they should receive (1) 8,000 shares; (2) £40,000 on the commencement of the second section from Harrar to Addis Ababa: (3) £40,000 more on the commencement of the third section towards Kaffa; (4) 100 founders' shares.

THE KEYNOTE OF FRENCH POLICY IN ABYSSINIA

for a very long time was to raise up an adversary against England in the Valley of the Nile. Menelik lent himself to this idea for what he could get, and negotiations proceeded very far for the advance of a Franco-Abyssinian army against us at the time of Fashoda. Whether or not his professions of friendship for France ever meant anything, he has now certainly come to his senses, and understands that if he weakened himself by a fruitless struggle with Egypt, the only result would be that he would find himself threatened with a French occupation. He gave a concession to the French railway, with the idea that he would obtain arms and ammunition more easily and more cheaply. But he has since realised that, while the railway would make the

transport of his guns easier, it would also enable the French to bring a formidable army into the heart of his empire at a moment's notice. So he hastened to modify his concession, and refused to allow the railway to have a terminus at Harrar. By a quibble, he fixed a place called El-Bah as the terminus, and gave it the name of Addis Harrar or New Harrar. It is sufficiently remote to eliminate danger, and at the same time sufficiently near to make the importation of arms very easy. For the commercial purposes of the railway, however, it will be of very little use, as the railway will not be able to divert the whole trade of Harrar, much of which will continue to follow the old caravan route. But even if the railway did secure the whole existing trade of Harrar, this would not suffice even to repay the expenditure. And this trade is rapidly falling away. During last year not a single Abyssinian merchant, coming from the interior, entered the place, though previously large numbers were wont to do so. The reason is that all the big merchants have already taken the Gallabat route. Gallabat is on the frontier of Abyssinia and Egypt, and the railway from Khartoum will be brought up the Blue Nile very near to it. This is the natural channel for trade, which in two or three years will all go that way; and, railway or no railway, there will only remain to Jibuti and Zaila the trade of the provinces of Harrar and Shoa. The Soudan and Khartoum railway will take all the trade that has hitherto been brought to Harrar from the interior. The Kassala-Suakim Railway, when finished, will also deflect much of the trade which has hitherto been brought to Harrar. From Lake Rudolph to Gallabat, the trade will follow the Nile Railway and Suakim Railway routes. At present one *corja* (*i.e.* twenty pieces of American piece goods), imported *via* Aden, Zaila, and Harrar to the Kaffa and other districts, costs in transport expenses alone about forty-five Maria Theresa dollars, while the cost of importing *via* Alexandria and the Nile Railway to the same district will only be twenty-five dollars. This will kill all Harrar trade with the interior, leaving only the Harrar and Shoa province trade. In two or three years the Harrar trade will be simply a local one in connection with the Harrar river and the Arusi country,—chiefly coffee. Thus the Jibuti Railway, if it reaches Harrar in two years, which is very doubtful, will get, say a quarter or a fifth of the total present trade. As the total

PRESENT TRADE COULD NEVER REPAY THE SHAREHOLDERS

it is bound to be a ruinous concern.

Knowing this, the officials of the railway have been content to allow the enterprise to proceed as slowly as possible, receiving their emoluments and delaying the day of reckoning as long as they can. In this matter they have been assisted considerably by circumstances. When, in Dec. 1897, the Issa tribe of Somalis realised that the first surveys of the railway were being made, and that a railway would take away their only means of livelihood, they gave out that they would make forcible opposition to every step of the undertaking. Accordingly the interim Governor of Jibuti made a provisional arrangement with the Okals (chiefs and elders of the Issas), undertaking not to survey or lay down lines for more than twenty kilometres from Jibuti without further notice. This extraordinary arrangement was intended to secure protection for French caravans going to and from Jibuti, at any rate until it should be necessary to proceed beyond the 20th kilometre. The French, however, have never regarded treaties with natives as binding upon themselves; and so soon as the dry season came and the Issa tribes went off with their flocks in search of fresh pastures, the railway people quietly went on with their surveys further inland. The natural result followed: caravans were attacked, and reprisals only aggravated matters. The authorities of the railway company tried to hush up every outrage and summoned a palaver of the chiefs of the Issas, with whom they concluded a fresh truce. The work of the railway was to be allowed to continue slowly, the Issas undertaking not to interfere, in consideration of the payment of 12,000 rupees. Four thousand rupees were paid in the course of the year 1898, but demands for the balance were resolutely ignored, and the tribesmen again felt that they had been tricked.

And the measures for defending the outposts of the company seem to have been exceedingly insufficient. The outpost at the 62nd kilometre, for instance, found itself on a given day with only forty cartridges. After endless demands and protestations, it succeeded in obtaining a hundred cartridges more from Jibuti. When on February 22nd, 1899, this outpost was attacked by a large band of Issas, the authorities need not have been surprised. Six Italians, one young Swiss, and two native guards were killed, and five Europeans were wounded, including an Italian woman and her child. It is to be hoped that the relatives of some of the victims will take proceedings against the company, whose non-payment of the 8,000 rupees due to the Issas was the direct cause of the attack. So far the only reply obtainable from the company has been that such attacks are to be expected in a state of war. The existence of a state of war upon French territory does not seem to strike the directors of the company or the French authorities as anything extraordinary. Moreover, when the servants of the company were engaged, they were not warned of the likelihood of any danger, lest they should demand heavier wages in consequence. The only consolation offered was that energetic measures would be taken to ensure the security of the works. These energetic measures, however, consisted merely in despatching sixty marines to Jibuti. They landed on March 13th, 1899, but only remained there until June 13th. The withdrawal of the garrison was due to a demand made by Menelik, who threatened to cancel the concession for the railway if so many troops remained in French Somaliland. Meanwhile no protest is directed againt the establishment of an Indian garrison in British territory at Zaila.

NOW COMES OUR OPPORTUNITY.

The Jibuti Railway has failed as a commercial enterprise. We must prevent the French Government from taking it up and utilising it as a stragetic instrument. If they do so, our prestige in Somaliland will perish, even Aden will suffer, and Jibuti may be utilised against us in the Soudan as a second Delagoa Bay. Already the fear of this has induced many merchants to migrate from Zaila to Jibuti.

There are many ways in which England might interfere. The moment is highly auspicious for buying up the shares in the railway, as those in the Suez Canal were bought up by Disraeli. Then we might negotiate with the French Government for the acquisition of French Somaliland by purchase or exchange. I hear that they would not be at all unwilling. Failing that, we ought to lose no time in constructing a railway from Berbera

into the interior. Menelik's consent is not necessary for a line up to our frontier at Ujawaji, a little south-west of Hargeisa, in the direction of Jigjiga. This has already been surveyed, and presents no difficulties, there being a steady rise all the way. The distance on to Jigjiga is only forty miles over a plain, and Menelik should have no objection to a railway terminus at Jigjiga. But even if we only penetrated to our frontier at Ujawaji, all the Harrar and Shoa trade would be attracted, and we should tap all the trade of Ogaden and South-East Abyssinia. Moreover, the tribesmen of the district would be benefited, instead of being ruined, as they will be in the Issa country by the Jibuti line.

I am convinced that the whole future of

BRITISH INFLUENCE IN NORTH-EAST AFRICA IS AT STAKE,

and that, unless prompt measures are taken, our Government will be responsible for a disgraceful and irretrievable surrender.

[The news has just been made public that the French concessionnaires of the Jibuti-Harrar-Addis Ababa Railway, which connects the capital of Abyssinia with the Red Sea, have concluded an agreement with three English companies whereby the latter find the money needed for the construction of the line, and thus practically control the undertaking.—ED. P.M.M.]

—*Pall Mall Magazine* March.

GRASS FARMS IN INDIA.

Of the nine grass farms in the Bengal command all excepting one showed a saving on the work of the year 1899-1900, the largest amount being R63,696 in the case of the Allahabad farm, and the smallest, R1, 634 on the Dinapur farm. The solitary loss was that of 1,146 rupees in the case of the farm at Bareilly The net saving for the year over all the farms amounted to R208,320, and it is the largest which has accrued to the State since the inauguration of grass farms, The increased savings were conspicuous at Allahabad, Cawnpore Lucknow Sitapur; Meerut, and Muttra. The year was not very favourable for grass operations, as the rains were somewhat irregular. The establishment of grass farms has tended to reduce market rates very considerably. This was the experience as far back as 1886 when only one or two grass farms existed. Now the grass produce at the various farms is found sufficient to feed all Government animals on an average for ten months in the year. The abundance of the grass supply from these farms must result in the market being over-stocked with *bhoosa* (trodden straw), with the inevitable consequence of reduced rates. The nine farms range in area between 2,70[illegible] acres at Allahabad and seventy acres at Dinapur, and the aggregate area is 9,654 acres, the production of green grass upon which in 1899-1900 was 98,152,102 lb. The scarcity of fodder throughout the country during the year was unparalleled, andthere was a very large demand from native States, even so distant as Baroda. It is in such times that the actual benefits derived by Government from the establishment of grass farms can be adequately realised. If the farms had not existed and Government grass-cutters had been permitted, as in former years, to encroach on the lands of the ryots for grass, the hardships of the latter would have been intensified, while the Government requirements could not have been met without extreme difficulty and heavy expenditure. All Government horses and cattle were fed throughout the year at Cawnpore, Bareilly, and Fyzabad; and at Allahabad also except for about three months, when the transport cattle were fed on *bhoosa*. The balance of produce that remained on hand at the close of the year comprised 4,425,404 lb of silage, and 6,719,410 lb of hay dry bedding. The expenditure during the next few years on manuring operations is expected to be heavier than in past years as it is intended to trench lands more extensively with town rubbish for the cultivation of dub grass. This will not only yield a better quality of grass and a larger output but will obviate objections on sanitary grounds. Experiments on the fattening of cattle were made during the year at Allahabad, and the Government of India have since directed their continuance. The question of extending these investigations to other stations is under consideration. The improvement in the meat is very marked and Capt. D J Meagher, the special forage officer is of opinion that the benefits which will be derived from the fattening of slaughter cattle will more than compensate for the extra cost incurred in the feed. A training class in agriculture and dairying for British soldiers was started in Allahabad early in the year, under the orders of the Government of India. Fifteen students were selected, but they were not all of the stamp of men required for grass farming—probably owing to Government not being able at the time to hold out any definite prospects to applicants. Reverting to the the Government butchery, worked in connection with the grass farm at Allahabad, Brigadier-General Sir Charles Leslie reports that the experiments made in fattening slaughter cattle seem to indicate advantage to Government in not only getting a much superior quality of meat for the soldiers' rations, but in actually procuring these rations at a cheaper rate. He had some of the beef issued to himself and found it to be the best he ever tasted in India.—*Indian Agriculturist*, March 1.

WHERE CAMPHOR COMES FROM.

AND THE VARIED USES IT IS PUT TO NOW-A-DAYS.

A page of the March *St. Nicholas* is filled with a paper by Ralph Benton entitled "Talking of Camphor."

"Where does this come from?" asked Sandy McLaurin, picking a block of camphor out of a jar that stood on the counter.

The druggist at the corner near Sandy's home was a good friend to all the boys, and they liked to ask him questions.

"Camphor? That 's a long story." The speaker and questioner sat down behind the prescription counter. "Have you ever noticed that row of lindens down on Fourth Street, near the grammar school? Well, the tree that produces camphor looks very much like any one of those. It grows in China, Japan, and other parts of eastern Asia. Occasionally a camphor-tree becomes so old and so large that it is a veritable land-mark. In 1691, for instance, a traveller in Japan described a tree which he found that was thirty-six feet about the trunk. Almost a century and a half later the same tree was said by another traveller to be fifty feet around.

"Did your grandmother ever make you take a few drops of spirits of camphor? You know what a fiery taste it has, then? You wouldn't think that camphor and the cinnamon sticks that you like so well are first-cousins; but they belong to the same botanical family.

"If you take one of the shiny green leaves from a camphor-tree and rub it gently between two stones, you smell the same odour as comes to you when you take the lid off a camphor-jar. Every part of the tree contains its part of the gum, but the bulk of it comes from the root, trunk, and branches. The first step is to reduce a tree to chips, and these are put into iron vessels having a

cone-shaped cover lined with rice straw. Then the vessels are heated, and the camphor is driven out of the chips. Do you know what I mean when I use the word 'volatile'? No? Well, a thing is volatile that seems to fly off in the air. Now, camphor is volatile; it is capable of being changed into vapor. When heat is applied to the iron vessels the camphor is volatilised, but it condenses almost at once; that is, it is changed to a multitude of tiny little lumps of solid camphor, which fasten themselves on the straw that lines the cover. It is then scraped from the straw, refined and pressed into blocks."

"Is camphor used for anything but medicine and to keep off moths?" asked Sandy.

"I was just coming to that. Strange as it may seem, we can get a substance from it that looks almost like ivory—hard and beautifully white. Go out to the first show-case on the left, and bring me a white comb and one of those hand-mirrors with a white back."

Sandy looked puzzled as he obeyed.

"This material," tapping the back of the mirror, "is called celluloid, and it is made from camphor and cotton. It is used for hair-brushes, soap-boxes, knife-handles, and many other articles. In another field we find that it plays its part in changing the map of the world or shaping the destiny of a nation. Camphor is used in making smokeless gunpowder. Our country certainly learned the value of it in the summer of '98."

"Why," Sandy ventured, "I should think, with all the big armies everywhere, that most of the camphor would be used for powder."

"A great deal of it is. That is why camphor has been so dear for a number of years past."

"Couldn't tar camphor be used?"

"Oh, no! Tar camphor is really not camphor at all, though somebody discovered, about twelve years ago, that it would take the place of camphor in preventing the ravages of moths. For many years it was thrown away; it was a puzzle to get rid of it. It comes, in a roundabout way, from bituminous coal. When this kind of coal is heated in a certain way it is split up into gas (used for lighting), a heavy, black liquid (coal-tar), and coke; and it is from the coal-tar that tar camphor is made. I couldn't begin to tell you all about coal-tar in one night, Sandy. Some other time we'll talk about it again."

INDIAN TEA ASSOCIATION LONON.

The following is part of the proceedings of a meeting of the Committee held on March 5th, 1901, when the following members were present:—Mr D Cruickshank (in the chair), and Messrs A Bryans, J S Hulbert, Robert Lyell. C C McLeod, F A Roberts, A G Stanton, J N Stuart, and C W Wallace.

Green Tea.—The correspondence on this question was read, and after discussion it was agreed that the decision come to on June 21st, 1900, should hold good in respect of the current season, viz., "that 1½ annas per lb, up to a maximum of 200,000 lb to be manufactured this season, be allowed out of the funds of the levy on the shipments of green tea for the American market, sent there direct from India, such funds to be distributed as a bounty at the discretion of the Calcutta Committee," the definition of the term "green tea" for the receipt of the bounty being taken to be tea made from the ordinary leaf plucked on the gardens, such as would be ordinarily made into black tea, but which in its altered manufactured state will not compete with the sale of black tea in America or elsewhere. The bounty to be paid on the same quantity as before sanctioned, viz, 200,000lb, until it is seen what success is attained in the manufacture of green tea, the Association in Calcutta to be requested to notify the committee promptly if a larger quantity than 200,000lb is likely to be specially prepared for shipment to America.

Fish Culture at the Crystal Palace.—An interesting experiment in fish culture is being made at the Crystal Palace. For some time past trout have been hatched and reared in the aquarium from eggs received from various parts of the country, and the process of treatment from the time when the eggs are placed in the hatching apparatus up to the full growth of the fish may be seen by visitors. The tanks contain a number of fine two and three-year-old trout. The experiment of rearing them has been undertaken by the Crystal Palace Company for the purpose of ascertaining whether the trout will live in the stagnant water of the great lake in the palace grounds. About 150 two-year-old rainbow trout (*Salmo Iridens*) have just been taken from the rearing tanks and placed in the lake. The number will be added to from time to time, and it is hoped that the trout will thrive, as there are no jack in the lake. In course of time, if the experiment succeeds, fly-fishing will be introduced at Sydenham. Anglers in the district are taking great interest in the matter, and a joint committee of various angling clubs is in course of formation with the view of protecting the waters and of arranging conditions under which the trout will be fished for. It has been already agreed that for the first year all fish hooked shall be returned to the water.—London *Times*, March 14.

THE

AGRICULTURAL MAGAZINE,

COLOMBO.

Added as a Supplement Monthly to the "TROPICAL AGRICULTURIST."

The following pages include the Contents of the *Agricultural Magazine* for April :—

Vol. XII.] APRIL, 1901. [No. 10.

THE SCHOOL OF AGRICULTURE.

ON the recommendation of the last Commission appointed by Government to deal with this institution, the School was closed on Friday, the 29th March, the end of the first term of the year. Thus terminates an educational venture which, if it was not a complete success, was certainly not a complete failure. We do not for a moment intend to contend that the school fulfilled the object with which it was launched by Mr. H. W. Green, late Director of Public Instruction, but what we do say is that it surely and certainly exercised an influence for good,—by its very existence, if in no other way—on local agricultural ideas and agricultural practice in general. The institution was a centre of various forces, some sharply directed towards it as adverse and very often unjust criticism; some rising out of it as benefits (however insignificant) it conferred on the agriculturists of the Island, while between these opposite forces were others inclined at various degrees representing various other phases of public opinion. The very circumstance of the school, its work, and its object having been a subject of so much criticism and discussion was itself a factor in directing public thought to the latest developments of agricultural teaching, and so of the science and practice of agriculture, and we make bold to say that but for the existence of the school with its much criticised methods of instruction, the advancement of agricultural knowledge, and especially the expansion that has undoubtedly taken place in local ideas regarding agricultural practice, would have taken twice or perhaps three times as long to reach its present stage. In this way we say the school has served its purpose, and it is with some regret that we think of its passing into the region of the "Has Been." We also fancy that there will be some who will miss the old place, for it had its correspondents and enquirers, those who came to look up the library of authorities, or read up the latest information in the excellent agricultural reading-room attached to the school. With the institution will also no doubt go the useful little monthly publication which the school had reason to be proud of, as having appeared regularly since July, 1889. The Magazine will probably cease to be issued after June, when it closes its XIIth Volume.

We are, however, glad of one thing, and that is, that the cause of agricultural education is not to be altogether abandoned, as a new scheme of agricultural instruction (already referred to by us in the March number) has received the sanction of Government. We have reason to believe that this scheme has much to commend it, and we wish it a full measure of practical success.

OCCASIONAL NOTES.

We are greatly in favour of a Veterinary Hospital being established in Colombo, and with the expansion of the Veterinary Department this should be an easy matter and entail very little expense if worked in connection with the Society for the Prevention of Cruelty to Aniamls, as in Bombay. In the last report issued by the Madras Department of Land Records and Agriculture we read:—"The Veterinary Hospital continues to increase in popularity and the number of cases treated has risen from 280 in 1895-6 to 724 in 1890-99 and 804 in 1899-1900."

Mr. J. W. Mollison, late of the Poona Farm and Deputy Director of Agriculture, Bombay Presidency, has been appointed Director-General of Agriculture for India. We do not think a better appointment could have been made. Mr. Mollison, with his mature experience of Indian Agriculture, should make an ideal Director.

An American fruit-grower is said to have discovered a plan by which ants can be kept from getting on to trees, so desirable especially when budding or grafting has been done. This plan is most simple, viz., saturating woollen strings with castor-oil and tying these tightly round the trunks of the trees. It is said that ants will not cross over the wool. Experiments with cotton string and other oils are reported to have been unsuccessful, but some of our Ceylon oils should surely do as well as Castor.

"Preserved eggs" is the name given to eggs that have been kept in a solution of salt and lime. It is said that there is no appreciable difference between them and fresh eggs after nearly six months, and that the plan of preserving eggs in this way enables poultry keepers to wait for good prices when eggs are cheap.

PRACTICAL HINTS TO HORSE-OWNERS.

CHAPTER III.—SHOEING.

Shoeing may be described as "a necessary evil," and like many other "evils" of civilization requires the greatest attention, in order that the conformity of the foot may as far as possible be preserved. The artificial protection of the foot that is necessary in the case of animals impressed into the service of man, has been secured by various means since the usefulness of the horse was recognized. It was to the interest of horsemen to see that their animals suffered no discomfort arising from bad shoeing. Faulty shoeing not only directly affects the foot, but is indirectly responsible for many forms of lameness. It is on this account that so much importance is put on the shoeing question by all Veterinary Colleges, where both a scientific knowledge as well as a practical acquaintance with the structure of the horses' foot and the means of protecting it by shoes is insisted on.

As this paper is intended for laymen, I do not propose to enter fully into the anatomical and physiological structure of the horses' foot, but will only refer to its constituent parts so as to indicate the true functions which the foot is intended to perform.

Anatomically the foot is divided into three parts, viz., (1) the bone structure; (2), the sensitive structure; (3), the non-sensitive outer covering of the foot or the hoof. The outer hand and horny layer is intended by nature to protect the internal soft and vascular tissue, but this provision fails when the horse is taken from its natural habitat or surroundings, and is put to work on hard and often metalled roads. The object of putting on shoes is to prevent the wasting of the protective structure, which is an out-growth from the coronary band. The outer hoof is generally spoken of as the wall, and is protected by a hard glistening surface called the perioptic layer, which if filed of as is usually done by ignorant smiths gives rise to "brittle hoof" and other troubles.

THE "UNCULTIVATED' OILS OF CEYLON.

(Continued.)

7. DORANA OIL.—This is the product of *Dipterocarpus glandulosus* (Dipterocarpaceae), a large tree endemic to Ceylon and found in no great abundance in the moist low-country of the Island. The oil is blackish and resinous, and is said to be a good substitule for the well-known gurgun (the product of *D. turbinatus* and other species) used in the treatment of leprosy. Being got from the wood it is described as a wood oil. With Hal resin (exuded by *Vateria acuminata*) it forms an excellent varnish, and with vermillion in addition, produces a red lacquer.

8. ME OIL.—This is the product of *Bassia longifolia* (Sapotaceae), a very large branched tree common to the dry region. The oil is got from the seeds, and is used in native cookery as well as medicinally in the external treatment of cutaneous diseases. The residual cake after the expression of the oil is called "arappo," and exported to the Indian Coast. This substance is used as a deterrent and also largely employed for washing the hair. The oil when kept settles down into a solid fat.

9. KEKUNA OIL.—This is the product of *Aleurites triloba* (Euphorbiaceae), and is sometimes spoken of as candle-nut oil. The seeds yield about 50 per cent of oil which is very suitable for soap-making and cloth-dressing, and for these purposes there is some demand for the oil from abroad. The refuse cake is a valuable fertilizer. Kekuna oil in many ways resembles linseed oil, and may be used as a substitute for the latter in mixing paints. The roasted nut is pleasant to eat but is laxative in its effect.

10. DOMBA OIL.—This is the product of *Calophyllum inophyllum* (Guttiferae), a moderate-sized tree found in the low-country, principally on the sea-coast. The nuts from which the oil is obtained are to some extent exported to India. The tree is sometimes called the Alexandrian laural. The seeds contain abundant oil, according to some reports even up to 60 per cent of their weight. This oil is used for burning as we

as for caulking vessels, but is chiefly valued as a medicine, being employed externally for rheumatism and also in the treatment of indolent sores. Watt mentions the curious fact that though it cannot compete with castor oil for industrial purposes, it fetches in Burma four-times the Calcutta price of castor oil. Samples of the three last-mentioned oils were submitted to Mr. L. Field, a well-known expert in oils, and in a report submitted by him he speaks very highly of them, and expresses the opinion that a very large demand for them would arise if they could be supplied at a cheap rate.

11. Margosa or Kohomba Oil.—This is the product of *Azadriachta indica* (Meliaceae), a handsome, tall tree common in the dry country. It is extensively employed as an external application for rheumatism, also as an anthilmentic and antiseptic. It is invaluable as a cattle medicine in the treatment of wounds, and even foot and mouth disease, owing to its antiseptic properties, and in keeping off flies. The powerful and disgusting odour of the oil is its most objectionable property.

12. Kon Oil.—This is the product of *Schleichera trijuga* (Sapindaceaceae), a handsome tree called the Ceylon oak. The oil which is clear and liquid is used for culinary and illuminating purposes. It is reported, says Watt, to be the original Macassar oil, and has recently reappeared in German commerce under that name.

QUARTER-ILL.

We omitted to acknowledge the authorship of the short account of this disease which appeared in the last number of the Magazine, and which was written by Veterinary-Surgeon Chinniah. We make no apology for returning to this subject in view of the report that cases of Quarter-ill occurred in the Government Dairy not long ago, and as an unfamiliar form of disease among local stock, we would quote from an exhaustive article by Veterinary-Surgeon Hutcheon (appearing in the *Cape Agricultural Journal* of January 17th) the reference to "Preventives" in dealing with Quarter-ill:—

The only preventives of Quarter-ill are a complete change of pasture and inocculation. Even if it is impracticable to remove the susceptible cattle to another farm, a change to a different part of the same farm, accompanied by a change of kraal as well, will often arrest the further spread of the disease.

Care should, however, be exercised not to remove any affected animal along with the herd, as that would tend to spread the infection. If it is impossible to arrange for a complete change of pasture, no time should be lost in getting all the young stock inocculated.

Previous to the discovery of inoculation by Arloing, Cornevin and Thomas, a considerable number of preventive remedies for this disease were practised by stock-farmers, and even by the Native tribes. Reasoning from the fact that the young stock which are rapidly improving in condition are the most susceptible to an attack of the disease, a large number of these preventive remedies took the form of measures for lowering the condition of the animal and reducing the richness of its blood, such as bleeding, purging, driving the animals violently for considerable distances, or swimming them through a river or large dam daily, turning them on to poor pasture, or in other ways reducing their allowance of food. "Want of exercise causes an accumulation of lactic acid in the muscles, this favours the germination of the spores." (Salmon.) Inserting a peg or seton in the dewlap is a preventive upon which great reliance is placed. In what manner this seton exercises its beneficial effects has never been properly explained. Many are of opinion that it is the means of introducing septic organisms which have an antagonistic action to the organisms of Quarter-evil. Be that as it may, a firm belief in the efficacy of setoning as a preventive of Quarter-evil was world-wide, and many still believe in its efficacy, notwithstanding that it has completely failed to justify that opinion when submitted to an experimental test. Others again placed great reliance on the introduction of certain medicinal or antidotal agents into the system of the animals to ward off the disease. The following amongst a host of others were largely used: the sulphite and hypo-sulphite of soda, and carbolic acid and its compounds. One writer pins his faith to madder, while another has equal confidence in saltpetre. There are many who believe in the efficacy of a lick made up of common salt, sulphur, copperas, lime and saltpetre, while others again pin their faith to the administration of Stockholm tar. Garlic is another remedy which is largely used in this Colony, not only as a preventive of sponsziekte, but of the majority of the specific diseases of stock, such as Rinderpest, Horse-sickness, &c. There are various methods of using the garlic. Some make a small pocket under the skin in the dewlap, and insert one or two of the bulblets in there, while others insert them into similar pockets under the skin in various parts of the body. Oil of garlic, like oil of mustard, is a germicide; it is also very volatile, permeating the whole system in addition to setting up severe local irritation. It is just possible, therefore, that garlic and some of the other popular remedies may exercise some preventive effect against Quarter-evil for a limited time. It is probable, however, that many of these popular remedies have established their reputation as preventives of the disease from the fact that, during certain years when the remedy has been resorted to, the disease did not occur, the local or general conditions not being favourable; and on other occasions it has ceased to spread owing to the presence of natural causes, concurrent with the application of a certain remedy, but few—if any—of these popular preventive remedies have stood the test of continued experience.

Quarter-evil exhibits certain peculiarities in respect to the manner in which it may appear and disappear amongst cattle on a farm. The disease sometimes appears with great virulence on a farm during one year, and it may then skip one to two years before it reappears. Further, cattle may have been grazing for six, nine, or twelve months on certain pastures without a single case of the disease

occurring, when it will appear suddenly, attacking the young stock in rapid succession. The cattle are then removed to another locality and the disease suddenly ceases. After an absence of one, two, or three months these cattle are brought back to the infected veld, and in the great majority of cases, with perfect impunity, no more cases occurring perhaps for many months. These facts indicate that there are certain local conditions which favour, or otherwise, the development of this disease, in addition to the presence of the spores in the soil. It is also very probable that the beneficial effect of the change upon the cattle themselves renders them less susceptible to the action of the spores of the disease when they return to the tainted pasture. MM. E. Leclainche and H. Vallée give a very clear explanation respecting the manner in which these influences favour or hinder the development of Quarter-evil. The conclusions arrived at by these savants are supported by a series of carefully-conducted experiments; for a description of these see *The Journal of Comparative Pathology and Therapeutics*, vol. xiii., parts 2 and 3. They say Quarter-evil is a disease in which the infection comes from the soil, causing disease only in certain conditions of susceptibility, and due to a sporulating organism. It is probable that the spore derived from the soil does not reach the body charged with toxin, and spores without toxin do not kill. The phagocytes—or living cells which are present in all healthy tissues, and whose main function is to absorb and destroy disease organisms—triumph rapidly over spores that have been deprived of their toxin. But if the spores are protected against the phagocytes by the properties of the toxin, the spores germinate at the place where they have been introduced, and infection takes place. The addition to the spore of lactic acid, potassium lactate, and the application of some simple traumatic injury will produce the same effect as the toxin, in preventing the action of the phagocytes on the spores. Spores that may safely be given in millions will kill with a dose ten times smaller, if one drop of lactic acid is added. The harmlessness of the spore by itself is not due to any attenuation of its virulence produced by heating or other means which deprives it of its toxin; this is shown by the fact that the addition of a certain quantity of toxin or lactic acid restores its virulence, and the pure spore then kills as rapidly as the fresh culture from which it was taken. This is clearly shown by the fact that if the spores are protected by purely mechanical means such as coagulated albumen from the destroying action of the phagocytes, they have time to germinate, and the evolution of the disease is only slightly retarded.

The occurrence of diverse forms of bacteria in the tumours of the disease also exerts an action that is sometimes favouring and sometimes hindering to the development of the disease. Every influence, therefore, which is capable of diminishing the vitality of the tissues and hindering the action of the phagocytes will facilitate the development of the spores, and permit them to manifest their virulence; and per contra, every influence which tends to increase the vitality of the tissues nd thereby favours activity of the phagocytes, will have a tendency to prevent the development of the disease.

If, however, we admit the influence of all these local conditions which under certain circumstances favour or hinder the development of Quarter-evil, are we justified in totally ignoring the temporary effects of many of the popular preventive remedies, which are artificially applied, because we cannot explain how they act?

POULTRY NOTES.

Shade is very necessary for poultry in hot weather. Heat affects them, and they often die by this cause alone. Shelter of some sort must be provided. A supply of fresh and clean water, which should be well shaded from the sun and kept as cool as possible, should always be available. There is no need for very large quantities, and 6 inch or 8 inch flower pots with a cork in the bottom serves the purpose of a water trough excellently; the water is kept cool and the evaporation is less than from a dish or pan.

Green food is a necessary ingredient as a diet for poultry, and it is specially so in hot weather as it is cooling to the blood. A patch of land should be specially devoted to the growth of such food for poultry. When no green stuff is available, give once a week a small quantity of Epsom salts which could be mixed in the water used to make up the soft food for the birds.

Young growing fowls should have a liberal diet containing plenty of bone-forming material which can be provided in the form of grouud bone. Bone cutters can be purchased for from 30s. upwards, and well repay their cost. A good one is called "The Mann." This "cut green bone" is just what is required for pullets that have begun to lay early; it provides much egg-forming food and lessens the drain on the immature system.

As most people shrink from operations, the following method of curing cup-bound fowls (says a correspondent in the *Queensland Agricultural Journal*) will be read with interest:—Get a piece of window-glass or any ordinary glass and put it on the fire till it bends; then take it out and plunge it into cold water, when it will crumble up quite easily with the tap of the hammer. It makes good sharp girt, but it will not injure the cup in the least. Give the sick bird 1½ tea spoons of this and follow up with a tea spoon of salad oil. Now start working the cup gently with the hand and continue doing so till it is quite pliable in every part. Shut the bird up with nothing to eat, and if its cup is not empty in twelve hours, repeat the dose and keep without food until it is. The second dose will not fail.

BACTERIA AND THE DAIRY.

(*By H. Potts, Dairy Expert, Department of Agriculture, Victoria.*)

Bacteriology, whilst one of the youngest sciences, already occupies a prominent place in all the laboratories of the world. Pathologists, botan-

ists, chemists, brewers, dairymen, agriculturists, tobacco manufacturers, tanners, and others are engaged in unravelling the mysteries of this subject in combating disease and prosecuting important manufactures. Some of the organisms which gave it its name were seen as long ago as 1675—when Anton Leeuwenhoeck, a Dutch philosopher, not only made his microscope—a simple one—but applied it to such good purpose, that he discovered and described organisms which are now known as bacteria, bacilli, spirilla, and micrococci. He called them animalculæ, but he failed to discover their object in nature. Subsequently original research was conducted by Muller, Needham, Spallanzani, Schwann, and Davaine. The real initiation of the science dates its birth to Louis Pasteur's classic researches upon fermentation. The question of spontaneous generation and its obscure origin had occupied the attention of great minds, including Liebig. His masterly essay on fermentation with his chemical theory received a rude shock when Pasteur gave forth his startling proclamation in 1860. "No fermentation without germ life." Robert Koch gave the science a lasting stimulus in 1882 by the discovery of the tubercle bacillus. Baron Lister, the brilliant surgeon, expressly thanked Pasteur for having given him the only principle which could have conducted the antiseptic system of surgery to a successful issue, and through which he is justly accredited with having saved more lives than were lost in the Franco-German war. Owing to the prominence given to bacteriology in medicine and surgery, a belief has been engendered that germs are only associated with these sciences; but the army of earnest workers now engaged in the elucidation of their life history proves that the ubiquitous microbe is omnipresent. We know now without it the world becomes uninhabitable. In air, water, and soil we find it busily engaged in varied forms on nature's phenomena.

To classify them into four great groups. First, the useful organisms.—The application of these to the arts and manufactures are daily becoming better defined, and are exerting a wonderful influence. In commercial life, we find the correct fermentation of wines and beers, and all the "diseases" to which these beverages are liable are due to microbes. The successful development of flavor in butter and the ripening of cheese, the flavoring of tobacco, the curing of opium, the manufacture of Indigo, the tanning of leather, the production of yeast for bread-making, "retting" in the jute and linen trades, and other processes depend upon the use of the most desirable forms of these useful minute organisms; the agriculturalist in the nitrification of his soil, the reduction of nitrogenous manures to a condition in which they can be utilised by crops, the sprouting of his seeds, and the success of his hay-stack and silo, is dependent upon the behavior of friendly bacteria. Second, the putrefaction of hostile bacterias.—In this section we find the putrefactive organisms associated with filth and decomposition. They habitually flourish in darkness, organic matter whether it be a dead body or vegetable material is reduced by them to original constituents or elements. By this invasion, they interfere with the progress of useful processes, check suitable fermentations and changes, impart false flavors and aromas, and interfere with the functions of the desirable organisms. Third, the pathogenic or disease-producing micro-organisms.—With this large and influential section we find eminent scientists and medical men have prosecuted the most profound researches through the instrumentality of which we find pathogenic germs are responsible for such diseases as tuberculosis (consumption), small-pox, diphtheria, typhoid fever, measles, cholera, hydrophobia (lock-jaw), anthrax, and bubonic plague. Fourth, the unknown families of bacteria.—We are cognisant that there are numberless species of organisms distributed throughout the world of life whose identity and functions are not yet discovered. So far, only about 700 species have been isolated, named, and their life histories and characteristics recorded. To attempt to give an adequate conception of the vast and ramifying influences exerted by bacteria would occupy too much space, I must therefore confine myself to the subject, as it effects the dairying industry.—*The Station, Farm and Dairy.*

(*To be concluded.*)

INTRODUCTION TO ENTOMOLOGY.

(Miss Eleanor A. Ormerod.)

Pupa (*Chrysalis*).—It is much to be regretted that we have no generally-adopted word, excepting "chrysalis" (which is commonly used in the case of Butterflies or Moths), to describe the second stage of insect life in which it is changing from the state of larva to that of the complete insect.

Whilst in this condition it is for the most part without power of feeding and perfectly inactive, lying (as in the case of Beetles,—the common Cockchafer for instance,—Bees and Wasps, and some others) with limbs in sheaths folded beneath the breast and body, or (as with Butterflies and Moths) protected by a hardened coating secreted by the pores of the creature within, when it casts its last larval skin. The method of this change may be easily observed in the case of the caterpillar of the Peacock Butterfly, which fastens itself by the tail, and then (after its black and silver-spotted skin has cracked) by infinite wriggling and struggling passes this cast-off skin backward, till it is pressed together at the tip of the tail, and the creature from within appears in its new form as a bright green chrysalis or pupa. It is covered with a moist gummy exudation, which quickly hardens and forms a protecting coat, and in due time (if left unharmed) the butterfly inside would crack through this and appear from within the case; but if it is wished to observe that the beginning of the change to the Butterfly form has taken place already, one of these chrysalids may be dropped into a little warm turpentine, or turpentine and Canada balsam, directly the caterpillar skin has been cast; this will soften the gummy coating just mentioned, and the limbs of the future Butterfly will be seen. In some cases the change takes place (as with

various but not all kinds of Flies) in the hardened skin of the maggot, which may be called a "Fly-case"; and in some (as with Plant Bugs, Aphides or Green Fly, Grasshoppers, and some others) this state of pupa is an active one, in which they move and feed and resemble the perfect insect, excepting in having more or less rudimentary wings or wing-cases. When the time for development has come, the pupa (if it is one of the active forms, as of a Grasshopper, for instance) may be seen looking heavy and stupid; presently the skin of the back splits lengthwise, and through the opening the perfect insect slowly makes its way out of the pupal skin, carefully drawing one limb after another from its precisely-fitting case, the longhind legs the last, till (in the instance observed, in twenty minutes) the perfect Grasshopper stands by the side of the film of its former self. Flies press out one end of the fly-case, or crack it open, or leave the sheaths of the limbs and body behind, and Beetles and Wasps cast the film from their limbs; Butterflies and Moths crack open the chrysalis-case, and after a short time (during which the wings that had lain undeveloped are expanding) they appear of their full size. The insect is now fully formed; it will grow no more; its internal, as well as external, structure is complete; and it is what is known scientifically as the imago.

Imago (Beetle, Butterfly, Wasp, Fly, &c.) This is defined as an animal formed of a series of thirteen rings or segments, breathing by means of tubes (tracheae) which convey the air from pores in the sides throughout the system, and divided into three chief portions. Of these the first is the head, furnished with horns (antennæ), a mouth (differing very much in form in different kinds of insects), large compound eyes (which consist of many small ones formed into a convex mass on each side of the head), and frequently two or three simple eyes on the top.

The second portion (called the thorax, or sometimes the "trunk") is formed of three rings bearing a pair of legs attached to each, and having usually a pair of wings on the second and third of the rings; but sometimes the wings are wanting, sometimes there is only one pair.

The third portion (called the abdomen) is formed of the remaining nine rings, and contains the organs of reproduction and most of those of digestion. Insects in this perfect state are of two sexes, male and female; in some instances (as with Wasps and some others) there are imperfectly-developed females known as "penters."

After the insect—whether Beetle, Butterfly, Fly, or other kind—has come from its chrysalis or fly-case (that is, from the pupa), and its limbs have expanded, it is complete, and its remaining work is to support life until it has propagated its species. Usually pairing soon takes place, and the male dies; but the female has great tenacity of life until she has laid her eggs.

The length of life, however, is various; in some instances a few days, or even hours, is the extent; in others the insects "hybernate," that is, find some shelter in which they pass the winter, and from which they reappear with the return of warmth and sunshine.

INOCULATION AGAINST RINDERPEST.

From Dr. Alfred Lingard, M.B., M.S., D P.H., Imperial Bacteriologist—To the Secretary to the Director-General. India Medical Service—(No. 8, dated Mukhtesar, Naini Tal District, the 5th January 1901.)

As desired by his Honour the Lieutenant-Governor of these Provinces during his visit to Mukhtesar in October-November last to put forward a concise statement of success obtained with serum inoculations and modes of its operation, with a view to give it publicity and persuade the leading zemindars and talukdars to give prompt information concerning outbreaks of rinderpest, so that they may have their cattle inoculated before its ravages be felt, I have the honour to summarize in the following paragraphs the results obtained up to date, and request you to be good enough to submit this letter to the Chief Secretary to the Government of the North-West Provinces and Oudh:—

Serum Simultaneous Method.—This method, which has been very widely adopted in South Africa with most encouraging results, consists in injecting a small dose of protective serum on one side of the animal's body, and at the same time a small dose of virulent rinderpest blood on the opposite side. A mild form of the disease is produced in 90 per cent of the animals, with a loss only of one-half per cent and with the production of a permanent immunity, while the other 10 per cent are also protected for some months, even though they fail to re-act to the inoculation. In this connection I would point out that when a totally unprotected animal is subcutaneously inoculated with the most virulent blood, it shows no symptoms of disease previous to the 3rd, 4th or 5th day following inoculation, and then only does the temperature begin to rise. It is not until at least three days later, *viz.*, the 6th, 7th to 8th day that any symptoms of rinderpest become manifest. Therefore, in practical field inoculations it has to be first ascertained whether the disease is already incubating in the animals about to be inoculated, as in such cases the simultaneous method of inoculation should not be employed, but serum alone injected in large quantities should diarrhœa not yet have supervened. If this latter symptom should have already made its appearance nothing can save the affected animal.

Experiments in the Laboratory.—The experiments carried out with the above mentioned method in this Laboratory prove that the animals which show temperature reactions with fairly marked symptoms are immuned for upwards of one year, and there is no reason to doubt that it will last for a much longer time, if not for the life of the animals. On the other hand, the animals showing no temperature reaction or symptoms of the disease, partly due to the large doses of serum used, may wear off their immunity earlier than those which reached to the simultaneous method, and this difficulty can be got over by reinoculating those animals, which have not reached within a week or ten days of the simultaneous injection with a second dose of from 1 to 10 c.c. of virulent blood.

Results in Field Inoculations.—The inoculation carried out by the serum manufactured at this Laboratory in Bareilly, Alighar, Bulandshahr, and Dehra districts gave eminently successful results, and Mr. Holmes, in his report from Madras, states: "Out of 339 bullocks inoculated, nine died, but these deaths were attributed to old age and debilitated conditions and to the fact that the animals were suffering from rinderpest previous to inoculation. I do not consider that any of the deaths occurred as a direct result of inoculation. I think it is safe to say that, as a result of these inoculations, rinderpest was at once checked and a heavy loss averted among the cattle."

By referring to Table C. of the Assistant to the Inspector-General, Civil Veterinary Department's annual report for the year 1899-1900, we find that out of 1,730 animals inoculated by the above method, only three died after inoculation.

Hill Cattle.—There is a great difference in the dose of serum required for the inoculation of hill cattle as compared with that which is safe in plains animals. Notwithstanding that the serum simultaneous method by itself has not been found to be reliable in this particular breed, yet on reinoculating these animals with from 1 to 10 c. c. of virulent blood during the seven or eight days following the injection by the simultaneous method, protection has been brought about and an active immunity conferred.

Serum Alone.—The use of serum alone causes no reactionary fever, and it affords immediate full immunity and is very useful in the case of dairy animals and pregnant cows, where it is desirable that the milk supply should not be interfered with, and no cases of abortion take place. The temporary immunity given by injecting with serum alone is sufficient to protect the animals throughout an outbreak. The experiments carried out at Mukhtesar proved that the animals injected with 10, 20, 50, 100, and 150 c.c. per 600 lbs. body weight, were found immune on the 43rd, 76th, 103rd, and 164th days respectively, after serum injections, and in each case when tested by the introduction of virulent blood subcutaneously only a slight temperature reaction followed, clearly showing that the animals submitted to the above test were perfectly protected and would remain so for a much longer period than those stated above.

Manufacture of Serum.—During the year 1900, 464,765 c.c. of protective rinderpest serum were produced at Mukhtesar and 119,880 c.c. have been issued to the Veterinary Superintendents of differents Provinces in India. At the present time we have 33,673 ones tested and ready for despatch on receipt of a telegram, but in addition some 50,003 are already in stock and only need testing, a matter of two weeks' duration. The manufacture of rinderpest protective serum will be continued at the Imperial Bacteriological Laboratory, and a depôt might be opened in the North-Western Provinces, as has been arranged for by Government for the supply of Bombay, Bengal, and other provinces, so that the serum may be readily obtained when required.

THE HONEY-BEE—ITS LIFE HISTORY.

Some little attention has begun to be given to the domestication of the honey-bee in Ceylon and an account of its life-history—so full of romance—should prove of interest to our readers. We take the liberty of making use of a short but full account from the pen of Mr. Helms in the Journal of the Agricultural Department of Western Australia for February, as more suitable to the pages of a little monthly than a longer account would be. Indeed, as the writer of the article remarks by way of preface, to become expert in the art of bee culture, it is necessary to become thoroughly acquainted with the life-history of the insect, as also with the special functions assigned to the organs of the structurally varying members of a bee-family. Without a clear conception of the phases of life and the interaction of the differently-constructed individuals upon the whole community, a bee-keeper will for ever remain a mere dabbler, and will always be liable to bungling.

1. *The different members constituting a Colony.*—A community of bees is variously termed a colony, swarm, and frequently also stock or hive. The two latter terms apply more correctly to the artificial dwellings of the bee, but by conventional habit of speech it is understood to mean a large assemblage of the insects as well. A colony is in reality a large family including many thousand members, most of which are sisters, and the offspring of the same mother. But periodically there are also male bees met with among them. This, however, generally only occurs in the early part of the summer, when through increased vitality and impulse arises in the family for a portion of it to migrate, which is commonly known as swarming fever. Such migratory instinct is much stimulated by a rapid increase, when, in order to avoid over-population, it becomes necessary for a number to leave the hive and seek a new home. At such time males are produced for the fertilisation of the future mothers, which are still unhatched when the old one leaves with the swarm.

With the honey-bee three distinct physiologically differentiated creatures are necessary to propagate the race. Still, as with other animals, only two sexes occur. The vast number of bees seen constantly emerging from and entering the hive are neuters—an application objected to by many writers as not being strictly correct. Those so-called neuters are the working masses of the community, and are in reality females with aborted sexual organs. Through some extraordinary influence acting upon the immature young, their sexual organs remain only partially developed, and in their place they become possessed of certain physical features not found in the true sexes. Although this abortion of the sexual organs has made it impossible for these bees to be themselves reproductive, their maternal instinct is no wise diminished, and is, in fact, developed to an extraordinary degree. Were it not for their devoted attention to the young, the community could not prosper. The three different bees are known as the queen, drone, and worker. The

queen is a perfect female as regards her sexual organs. The drone is in the same manner a male. The worker or so-called neuter is sexually imperfectly developed female.

The Queen, owing to her great laying power, is generally regarded as the most important member. It is true a fertile queen may soon increase the number of workers, and transform a weak into a prosperous colony, but she could not have done this without having been first fertilised by the drone. Nor could the brood be reared without the help of the foster mothers, the workers. When it is considered how the different elements which constitute a colony depend upon each other, and how their functions interest with one another, it becomes obvious that none deserve to be called the "most important." Without the one the other could not exist for long, only the male members may be dispensed with periodically, because their influence, when once manifested, is of extraordinary duration.

THE QUEEN.

The interesting member of a bee colony, now generally known as queen, was formerly also called king or leader (Weisel or Weiser, German). This was before her sex had been recognised, and no doubt arose from the fact that she appears singly among a great number of other bees and receives considerable attention from them. She is, in reality, during the early part of her life, the sister of the workers and drones, and later the mother of all who surround her. Her true position is that of mother-bee, and her importance begins after she has been fertilised. The term king originated in antique times, when she was thought to be a male, and the supposition that she possessed monarchial powers and influence gave rise to this name. In no sense, however, does she exert monarchial power, nor can she be called a leader, for she does not lead, but, on the contrary, is led by her children. They well knowing that upon her depends the reproduction of their numbers, and consequently the future welfare of their family, tend to all her wants and display the greatest filial attachment towards her. A number of workers constantly surround her, and according to the desire of greater or lesser increase, which is regulated by the flows of nectar and the season, she is suppulied more or less abundantly with food. Consternation seizes the offspring should the mother be lost through death or accident. Soon after emerging from the cell the young queen leaves the hive a few times on fine days and circles about over it for the purpose of getting acquainted with the surroundings, and then, under the sexual instinct, flies off one warm afternoon to meet a drone. The mating flight generally takes place on the fourth day after the queen has emerged from the cell, but sometimes earlier, and frequently later, if prevented by inclemency of the weather. If delayed for more than 20 days fertilisation rarely takes place, and in that case the queen becoms a "drone-mother." She is generally successful in accomplishing her desire, and when she returns, after her nuptial excursions, she does not voluntarily leave the hive again. After coition her ovaries develop rapidly, and in a few days she begins to lay. The power of oviposition grows considerably for some time, and when it is at its height she may lay as many as 3,000 eggs daily. Considering that the average life of a queen is about three years, and sometimes extends to over five, it is not impossible that she may lay over a million of eggs during her lifetime. She is one of the most prolific insects known. The laying of eggs is the important function of the queen.

(To be continued.)

The TROPICAL AGRICULTURIST

MONTHLY.

XX. COLOMBO, MAY 1ST, 1901. No. 11.

COFFEE IN B. C. A.

PAST, PRESENT, AND FUTURE OF COFFEE GROWING IN B. C. A.; CONDITION OF COFFEE GROWING IN OTHER COUNTRIES COMPARED WITH B. C. A.; PROSPECTS OF COFFEE GROWING IN B. C. A.

THE first Coffee Arabica plant introduced into B. C. A. came from the Edinburgh Botanical Gardens in the charge of Mr. J. Duncan, the Church of Scotland Mission Gardener, and was planted in the Mission garden about 20 years ago.

This plant succeeded well, bore heavily, and became the parent, I believe, of all the present existing coffee of that species or variety in this country.

Blue mountain, Orange, Liberian, Sierra Leone, "Standsphyilca," and Maragogipe Coffee have all been subsequently introduced and are to be seen growing on some Estates throughout the country—but although those varieties have been tried on some Estates, they do not seem to suit the climate so well as Coffee Arabica.

The first Coffee garden planted in B. C. A., and it was from the seed of that parent tree (I was informed) consisted of 15,000 plants, which were planted 6 × 6 feet apart giving about 1,200 trees to the acre; so that there would be about 13 acres. I was told that 10 tons of parchment Coffee was secured from this garden, which would be equivalent to about 15 cwt per acre in its third or fourth year.

I have myself seen blossoms on B. C. A. Coffee which should have resulted in crops equal to the above amount.

In those early days the mechanical part of the work was as well done as it is at present, but pruning, handling, manuring, and even weeding were much neglected with the result that, as coffee got older, crops decreased because the health and vigor of the tree were not maintained.

There is no plant or tree suffers so much from bad treatment, or responds so readily to good cultivation, as coffee; and once neglected, especially when young, it seldom recovers.

Until within the past few years enemies of the coffee tree were little thought about, and I venture to say no steps were taken by pioneer planters to fight those pests. But it was considered necessary to cut down the coffee tree after it had borne a few crops. Shade was not thought of either, I believe, until 5 or 6 years ago.

Up to about 10 years ago there was little coffee planting done in the country, and that was done only by the late Buchanan Bros and the African Lakes Co. on a small scale; about 40 acres at Zomba and 100 at Blantyre.

At present the coffee enterprise of B. C. A. is suffering from a good deal of depression owing to four causes:—1st, short crops, owing to bad seasons; 2nd, scarcity of labour; 3rd, low prices.

The first of these we cannot prevent and adverse seasons are to be met with in every country where coffee is grown, resulting in short crops, and sometimes hardly any at all. It is seldom however that two seasons follow each other which are absolutely abnormal, although wet and dry cycles are not uncommon in B. C. A. as in other tropical countries.

An insufficient labour supply is also partly to blame for short crops, because neglected or half-abandoned coffee is more or less choked and cannot nourish and bring to naturity its fruit, as would be the case with well-cared for trees on a clean estate.

The low price of coffee is the result of overproduction which never lasts more than a few years, because large coffee-producing countries cannot cultivate more than will repay

The price of labour soon rises, short deliveries and advanco in prices being the result, owing to want of confidence; hut a re-action soon sets in as a rule; with a good crop, an efficient lahour supply, and good prices, the turn of the tide may be looked for. Such experiences as set forth in the foregoing pages are not uncommon in other coffee-growing countries, but things are usually much more serious, owing to the greater amount of capital invested; so it is to he hoped that our wave of depression will soon pass over aud have no disastrous result. From the latest statistics, issued by the London, American, and Continental markets, it is evident that stocks are low and that prices will now improve and he maintained for some years to come.

The future of coffee planting in B. C. A. should not by judged be the results of the past. It may be considered for various reasons (which I shall endeavour as briefly as possihle to point out) that we have arrived at a more enlightened stage of this country's coffee culture, and that there is a bright future in prospect for the coffee enterprise here.

The fact has heen recognised that a permanent and efficient labour supply must be maintained to warrant success with coffee planting and to ensure remunerative results; and it is believed that the Labour Bureau just formed will in time solve this difficulty; that agents residing on the spot will be able to gain the confideuce of the people and supply all the needs of the planting industry, provided they are allowed a free hand by Government.

Amongst enemies of the coffee tree, spotted hug and borer are the two worst; aud fortunately they can both be kept in check, if proper measures are adopted by planters and lahour is availahle for the purpose.

It was only *supposed* that spotted bug did harm to coffee, till Mr. K. I. Cameron discovered that they are a serious enemy of no minor importance. I am convinced after eareful experiments carried out by myself that those hugs are the cause of much unsound coffee. I also believe that those bugs sucking at the terminal shoots, which form the secondary, lateral and tertiary hrauches of the coffee tree, disease the sap of those branches, causing black patches in the wood and bark; and that in the course of time the disease spreads with the flow of sap to the fruit, so that all suhsequently produced wood yields a light and empty berry as well as harren or bastard wood.

I have proved by experiment that the spotted bugs when imprisoned upon healthy yonng shoots do disease the bark and suck the wood, and if the experiments I am at present making go to prove that bugs do the same harm when at liberty,—it will certainly revolutionize the coffee industry in the future.

It is not to he woundered therefore that planters, when they discovered that no sound coffee could be got from old trees, cut them down as the only remedy for barren bushes.

I am quite certain that uo souud coffee can be got from a coffee tree that has had one or two bugs on it during the blossoming months, and for one or two months after tho herries have formed. Then, although the fruit does come forward, it is unsound and worthless.

The spotted bug is to he found throughout the year, although not so numerous during the winter months, May to August. During the bush fire months, Septem ber to December they fly before the bush fires and find a home and breeding ground in a Coffee Garden.

The Borer longicorn heetle also flies before the bush fires, October to December, and also finds a home on a Coffee Estate where they feed npon the bark of the Coffee trees and lay their eggs.

To ensure success with Coffee in B. C. A. my experience proves that the searching for both bug and horer must be considered by planters oue of the most important works on a plantation and ifnot fought against constantly it is useless expecting mature Coffee trees to yield crops.

If those enemies are carefully and successfully overcome, I am of opinion that there is no need for cutting down or uprooting coffee trees in B. C. A., any more than in other countries, and that a good yield of crop can be maintained without the aid of fertilizers for several years at least.

After the coffee trees on an eastate have formed a network of roots in 6 to 8 years, over the avail ble feeding area, manuring and pruning must be done to keep up a good yield.

In this country the cheapest manure available is bush grass, either made into compost with ammonia or applied *green* by digging it in or burying in trenches.

Leguminous crops might also be grown during the rainy season and dug in when matured, saving much wash as well as being useful as a fertiliser.

This country has better facilities for manuring, than any I know of, owing to the extensive area of hush grass surrounding most coffee estates. It has been proved by analysis that green manure is richer than cattle manure.

Both manuring and pruning have heen proved to give better results hy practical experience; so that any system laid down on paper would not be of much service, for opinions differ, and hardly two men can be got to apply manure or the knife alike.

The climate of B. C. A. is not unlike that of Mysore, Coorg, and Travancore, in India—and the drier parts of Uva, Ceylon. The seasons may be divided as follows;—

15th Decr. to 15th April 5 mouths' rain, 15th April to 15th July a few showery days each month, 15th July to 1st October occasional showers, 15th October to 15th Dec rainless except for one or two thunderstorms.

May to August are cool and temperate months and sometimes there is frost in June and July.

Blossoms come on coffee August to Nov, and crop April to July.

With regard to the Indian districts mentioned above, most of the Estates were opened by Ceylon men originally, and every stick of timber felled, with the result that after a number of years' cultivation it was found that estates did not pay and total abaudonment was the result in most cases. Shade was then thought of and tried and proved a success; many estates that had been abandoned were re-opened, and during the past 15 or 20 years shade has heen considered as absolutely necessary for the successful cultivation of coffee, and I believe no coffee is grown now in those districts without a canopy of shade. The climate of B. C. A. during the blossoming months cannot be relied on for rain and they have often 3 or 4 months without any at all. When they do get the rain however they get crops, which was not the case with coffee in the open, as then blossoms and herries too were destroyed hy hot winds and sun.

In Travancore I saw myself estates of 200 and 300 acres with hardly a leaf on the trees and laden with blossom to the tune of 7 or 8 cwts per acre, but it was all destroyed for want of rain. Had there heen shade on those properties, I was told the blossoms would have been saved.

The climate of B. C. A. in some years is all that could he desired. On the other hand, my experience proves that 6 out of 10 years were bad and unfavourable for the health, vigor, and successful fruiting of coffee without shade, or protection from hot winds.

If shade is too dense, coffee will not yield well at from 2,000 to 3,000 ft. above sea level, although it might do better at a lower elevation. I do not think dense shade is required for the Shire Highlands, and I am of opinion that the silver oak, Grevillea Robusta and the Eucalyptus Rohusta, and other red gums would suffice to temper the hot winds and cool the atmosphere on a coffee plantation; provided those trees are planted north and south in lines, and pretty close together.

Grevilleas and red gums do no harm to tea or coffee and have heen planted for many years as wind breaks and for timher on most estates in Ceylon and India. Blue gum again cannot be grown with tea or coffee, without starving those products.

Grevilleas and Red Gums do exceedingly well in B. C. A. I have trees of the latter 8 years old, 70 to 80 ft. high and 3 feet in circumference near the ground. The wood is durable and makes excellent furniture &c.

Shade has many advantages over open ground. Weeding is cheaper. There is a litter of leaves always on the ground which can be dug in and buried in holes as manure. There is no wash. Rainfall and the moisture are preserved as well as the fertility of the soil.

It has been shown by analysis that soil on a coffee estate under proper shade is as rich as that of the adjoining forest land. A coffee estate under shade has been known to be abandoned in bad times, and the owner has returned and cultivated his coffee again and found it as good as when he left it, and perhaps the better for the rest.

All the districts that have been opened for coffee in India and Ceylon have not proved a success; some were too wet, some too dry, some too hot, and, some too cold; and were ultimately abandoned, after much capital had been spent in the hopeless endeavour to get paying crops.

On the other hand large fortunes were made where the soil and climate were suitable for coffee, for there is no agricultural product which pays better under favourable circumstances.

Space will not permit of my entering minutely into details regarding the success or failure of coffee in those districts, which is more the subject for a treatise on coffee cultivation than an essay, I mention the fact, however, as B. C. A. may have a similar experience.

I may mention a few of the districts in Ceylon where coffee was not a success: Kurunegala, Kegalle, Lower Matale, Dumbura, were all too dry and the blossoms invariably failed. Blossoms would hang in spike for weeks, the same as they do here, and ultimately fail for want of rain at the proper time. Irrigation was tried, and thousands of pounds spent on large schemes but to no purpose.

I have seen blossom come out here repeatedly for 7 to 8 cwts. per acre, and apparently set well, and even come forward to be the size of peas, and the clusters fall off, owing to drought, till reduced to one or two berries and only 1 cwt. per acre got.

The coffee referred to was 3 and 4 years old and planted on Virgin *Forest* land so that the sap could not be said to be weak or lacking in fruitifying power. I never saw finer young coffee anywhere and there was no bug, to speak of; so the climate was at fault, I think.

The opinion is now held by experienced planters in Ceylon that, had the above-mentioned Districts been all opened in shade, coffee would still be in existence.

Too much care cannot be exercised in the selection of land for coffee, and it should not be that which has recently borne a crop of cereals or is otherwise poor in fertilizing ingredients. There are jungle lands to be found in B. C. A. with soil almost inexhaustible. This fact is borne out by the natives growing crops of grain on them for 50 years or more.

As to the age or lasting powers of the coffee tree, I remember coffee in Matale, Ceylon, in 1889, looking well, with stems as thick as my thigh, whose age could not be less than 80 to 100 years, for they were 15 to 20ft. high and growing native fashion under shade. The yield was not much, owing to leaf disease.

There is coffee, I believe, still in existence in Ceylon, which was planted during the last century; but it must be borne in mind that the coffee referred to is growing under specially favourable circumstances, getting the benefit of leaf mould from village fruit trees enjoying good soil, and not being forced to over-bearing by the hand of the cultivator.

By fighting the enemies of the coffee tree in B. C. A., by liberal manuring and tillage of the soil, by helping one another with information *re* our staple industry, given free and unselfishly, by the adoption of shade to mitigate the evils of our climate, I can see no reason why the coffee industry of B. C. A. should not be as lasting as it is in other countries and as remunerative too.

With better means of transport, and the labour which is used for that work at present set free, and all the pests that the coffee tree is subject to avercome, let us hope there is a bright and prosperous future in store for the coffee enterprise of British Central Africa.

Before closing this brief essay I would urge upon planters the need for importing new seed, and the most careful selection of sound B. C. A. seed for nurseries, as I have no compunction in saying that all barren coffee trees are not caused by bug. So far back as 94, I showed disease in a new clearing and in my nurseries to Mr. J. H. Carson (of the Nyassaland Coffee Co., who has had great experience in Coffee, and he said it was new seed that was wanted and imported Brazilean seed for Leechimya Estate.

HENRY BROWN.

COFFEE IN QUEENSLAND.

From the report of the Instructor in Coffee Culture to the Government of Queensland:—

I have made tours into the surrounding coffee districts, giving advice and demonstration to those who applied for it....In detail, the places visited, and where coffee is grown, include Cooktown, Daintree, Port Douglas, Cairns, Atherton, Myola, Oaklands, Mantaka, Kuranda, Mulgrave, Lower Russel, Clump Point, Mackay, Mount Jukes, Hampden, Rockhampton, Byfield, Yeppoon, Maryborough, Pialba, Bundaberg, Blackall, Coolum, and Buderim. Space would not admit of even short notes regarding each individual district and place where coffee is being more or less cultivated. In general, however, I found from Cooktown southward to near Townsville a zone of country having a somewhat heavy rainfall—eminently suitable for the cultivation of coffee, but possessing a climate that will necessitate artificial methods of drying by means of kilns or drying machinery. At Cooktown and Townsville, and as far south as Rockhampton, the climate is such that there is every probability of growers being able to dispense with kilns and to dry in the open air, which, when possible, is always the more satisfactory method. South of this, again, the absorptive power of the sun is less strong, but, the atmospheric moisture not being great, it is probable that open-air curing may be possible. There is at present scarcely sufficient fully-grown coffee in these parts to thoroughly test this. The majority of gardens are small, though I found several of fair size, the largest being Messrs. Cutten Bros.' estate at Clump Point, of 80 acres; Messrs. De Moleyns Bros., of the Lower Russell, running them very closely with 75 acres. There is very little coffee in cultivation of more than five or six years of age, the majority being either new, in its second year or bearing its maiden crop this season. Some few acres in each of the three districts of Cairns, Mackay, and Buderim may be called old coffee, but their exact age is in nearly every case doubtful. The first coffee-tree ever imported has been pointed out to me, and it is healthy and flourishing; but, as this has occurred in several different localities, its exact age is somewhat vague.

The varieties of coffee to be found are *Coffea Arabica* and *Coffea Liberica*. The former is the principal species, and is the usual coffee of commerce, and the most valuable, growing and cropping readily. It is comparatively easily cured, and, though delicate as a seedling, is hardy enough once it has reached maturity. The latter is the larger and hardier shrub, but is more difficult to pulp and cure, and is only worth about one-third the price of *Coffea Arabica*.

Of *Coffea Arabica* several varieties are noticed:—*C. Arab.* var. *Mocha*, a small stunted-looking and small-leaved tree, slow-growing bearing freely, but having a very small bean; *C. Arab.* var. *Maragogipe*

almost the opposite of the former, being a loosely-knit tree, with large leaves and berries, but somewhat delicate, and a sparse bearer; *C. Arab.* var. *Nalknad*, which would seem to be identical with the varieties known as "Ceylon" and "Java"—a strong, heavily-bearing tree; *C. Arab.* var. *Coorg*, a variety having a very few points of differeuce from the previous variety, and being also a hardy tree and good bearer; *C. Arab.* var. *Chick*, I have come across iu one place ouly, and this is essentially the worst variety of *Coffea Arabica*, recognisable readily by its primary branches pointing invariably upwards.

Of these, several hybrids are to be seen, especially between the *Nalknad* and *Coorg* or *Ceylon*. These prove somewhat delicate but good-bearing trees. *Chick-Nalknad* or *Chick-Ceylon* hybrids are extant, and in every case seem to have been raised from seed obtained from the estate on which some healthy specimens of "Chick" are still to be found. Several young plants are to be seen that look uncommonly like *Maragogipe-Ceylon* hybrids, but which are not yet old enough to identify as such. Such hybrids would probably prove valuable trees, if the bearing capabilities of the *Ceylon* can be combined with the size and quality of the *Maragogipe*. *Arabica-Liberica* hybrids I have not seen in this colony as yet, though experiments are being conducted at the State Nursery, Kamerunga, with a view to obtaining this valuable hybrid.

On the whole, the condition of the estates as I found them was not encouraging—in some cases the weeds were over the coffee. Where the coffee had been kept clean, the growth and bearing were remarkable. For amount of crop the Buderim mountain is noticeable, the quality being also specially good here. On the Daintree River one or two estates that had been kept assiduously free from extraneous growth showed remarkable development, trees of thirteen and fifteen months being topped at 4 feet, having a good spread of secondary growth, and spiking heavily, showing promise of a 5 to 6 cwt. crop that would ripen when the trees were not more than two-and-a-half years old. For all-round good qualities some of the properties in the vicinity of Cairns, specially on the range about Kuranda, are pre-eminent.

To summarise, the area specially adapted to coffee culture may be said to extend from Rockhampton northward to Cooktown, and the principal centres to be at, or in the vicinity of, Mackay, Geraldton, Cairns, and Port Douglas. The places that I have yet been unable to visit are Bowen, Cardwell, Geraldton, Johnstone River, the Bloomfield, St. Lawrence, and Percy Island....Figures regarding the extent of the industry, ... are still necessarily approximate rather than exact; statistics later on.

There would appear to be some 200 growers; aggregating 700 acres or more. I have not included in this the areas that have been allowed to lapse during the past year, and which amount to over 100 acres alone. The industry is now on a much firmer and better footing than last year. I found in some instances that areas had been opened by growers (perhaps in an excess of enthusiasm) without experience, knowledge of coffee culture, or consideration of the natural conditions governing the growth of the coffee-tree, which they were in consequence subsequently utterly unable to cultivate or properly attend to. In such cases I have advised the concentration of attention upon some lesser part of the estate, and the selected portion. The result of such work on the part of the grower has been to reduce the extent of the industry, but to put their estates on an infinitely better footing, financially and otherwise. The increase of area under cultivation is steady, though not rapid, for the same reason. Under my advice, those intending to open up are clearing perhaps 4 or 5 acres to begin with, in the place of 20 or 30, but with the obvious result that what is opened is well cultivated, satisfactory, and in a condition to pay the cost of subsequent openings in due course, instead of large and unsatisfactory estates, which, being difficult to keep clean from the commencement, are ever after a source of extra expense in weeding alone.

The number of applications for seed and advice *re* opening up is increasing, and the areas reduced will, it is to be expected, be more than made up during the coming year by these new clearings. The value of the industry cannot be gauged by the mere acreage, coffee being considerably more valuable than most farm staples. The area under coffee in the colony at present is capable of giving easily—with ordinary cultivation and no manuring—an average of 10 cwt. to the acre, a crop worth some £20,000, and possibly giving a crop worth at the same cultivation £25,000, to £30,000 annually.

The improved methods of work started last year are showing good results, the samples of coffee at the various shows improving vastly, both in size, shape, and colour, and showing better and more satisfactory returns both to the grower and buyer. At present, practically all the Queensland-grown coffee is bought up and manufactured in the colony, the prices remaining fairly steady at from £56 in the parchment to £112 per ton clean according to sample. Last season some buyers complained of the quality of coffees received, owing to the loss they sustained in both weight and bulk on manufacture. This I found to be due, to a great extent, to the insufficient drying of the crop before hulling. In hulling insufficiently-dried coffee the quality of the manufactured article is seriously impaired, and loss in weight of from 30 to 35 per cent. sustained. It is not always easy for growers to dry thoroughly in bulk, but it was possible to very greatly improve, in this matter alone, on last year's work, and this has been very generally done. Growers see the advantage of drying thoroughly, and having buyers ask again for consignments, and buyers appreciate the absence of heavy losses in weight and possible loss by mould, etc., in storing, an advantage that is satisfactory to both parties, and one that has resulted in an apparently newly-discovered improvement in the quality of colonial coffee generally. The improvement is very noticeable in the manufactured articles now being put on the local retail market.

Coffee is being put on the local market in tins well got up, and of very good quality, at from 1s 6d to 1s 9d per lb. and the local sales of such would tend to show an increase and increasing consumption of the commodity. Local manufacturers are finding, as was to be expected, that they have to purchase from smaller growers to supply the demand—a healthy state of affairs that will, it is to be hoped, continue, enabling small estate owners to dispose at once and for cash of the raw article. Seeing the apparently large price obtained for coffee per lb. manufactured, compared with the price in the raw, there seems to be an inclination among some of the growers to attempt the manufacture individually, which is to be deprecated. The putting on the market of an unlimited number of brands would result, in course of time, in a lowering of prices, adulteration, and reduction of quality. The grower will find it pay better to sell in the parchment than to spend the time in manufacturing small quantities; and *vice versâ* the manufacturer will find that the work entailed and time occupied in manufacturing will not admit of the proper working of an estate for cultivation of the coffee also.

The prospects of the industry are decidedly good. That the sample, when properly treated, is of high-grade quality has been amply demonstrated this season, and, in spite of labour competition in other countries, it has also been demonstrated that the colony's natural advantages can compete with them, by the fact of a high-grade coffee being put on the retail market at the same or a lower figure, with a fair margin of profit to both grower and manufacturer. The removal of intercolonial tariffs will also open up the Australasian markets to this staple of Queenslaud, and in the home markets the prices are slowly but surely rising.

From the grower's point of view it is one of the most paying of products, giving a return of 10 cwt. and, possibly, a 15 to 20 cwt. crop, which, at even 6d. per lb. in the parchment, or £56 per ton, would

mean £28 gross, or a net return of from £15 to £20, at least, per acre. In the present state of the industry it seems to be inadvisable to open up large areas for various reasons, and smaller gardens are more readily managed. Most of the growers have, at present, also small areas, and, in consequence, coffee is looked upon, to some extent, as a by-product. It will, undoubtedly, prove a very valuable by-product for any farmer, though with due attention to cultivation it will be found, as it is already in several instances, a profitable crop to grow as a sole staple, the returns giving a good living. And as the colony becomes more populated, large areas will be possible where, at present, labour difficulties practically prohibit the opening up of, say, a 100-acre estate.

Want of experience and carelessness in opening up coffee gardens can account for considerable loss and disappointment in the colony, ignorance and inexperience of coffee culture, in many instances, only showing in the second and third year. The necessity for ordinary attention at the area planted up in order to ensure satisfactory results cannot be too strongly dwelt on.

The initial three years or so of waiting before any return can be obtained has, unfortunately, been the cause of the neglect of even the fundamental laws of agriculture, occasionally, with the result that the field has either taken four or five years to come into bearing, or that the trees have been so retarded and hampered in their growth that when the strain of the maiden crop was felt they were found to have no stamina to carry it.

Coffee is perhaps one of the most responsive of any fruit-trees to cultivate and it is certainly one of the most profitable, but at the same time, not being indigenous, is very susceptible to neglect, and easily damaged and stunted by weed growth, etc.—*Planting Opinion.*

COFFEE IN THE SURMA VALLEY.

(*From our own correspondent.*)

Given suitable soil and shade there does not appear to be any reason why coffee should not grow and pay as well in the Valley of the Surma as elsewhere. But suitable soil and shade must be the very first consideration. As we mentioned in our issue of the 16th, the yield per acre in South Sylhet has not as yet been made public. Now we learn that this cannot be done, for the simple reason that the most of the land planted has been put down with the Liberian species 10′ by 10′ apart and the spaces between filled up with Arabian as a catch crop. Under the circumstances it would be difficult, if not impossible, to give a definite estimate of what may be reckoned on per acre. We have advocated, when putting down fresh plants to introduce the best Jamaica procurable, as the finest of this is now quoted on the London market at $125 per cwt. Of course it is possible, we may say very probable, that the species which brings a top price when grown in Jamaica might turn out an entirely different berry if grown in South Sylhet. Given the soil and climate, elevation is now looked upon as only a secondary consideration. Formerly it was found that coffee was better flavoured when grown at considerable elevations above sea-level. But the fact was generally lost sight of that at the highest elevations the most suitable flavouring soils, as a rule, were to be found. Coffee of any species when grown upon strong alluvium naturally will not, as a matter of fact does not, produce such a well-flavoured berry as when it is grown upon soil which, to a certain extent, is composed of humus. The Liberian berry has been recently described as a heavy enough bean, but wanting in flavour; but we have been assured that when this species is grown upon a light laterite, which has been under forest, it has even a superior flavour to a great many of our Arabian growths, which are famed for their flavour. The flavour of the Liberian bean, even when grown upon alluvial land, is said to be improved so much when kept in the parchment and thoroughly seasoned, that it compares very favourably with good Arabian. Be this as it may, there is no doubt about all the species improving much in flavour by keeping the beans in the unroasted state. Botanists, it would appear, have enumerated about sixty species of the genus coffee, and these are spread over various countries in both the Eastern and Western hemispheres. According to a well-known authority, most of these must be mere varieties resulting from accidents of soil, climate or cultivation, produced subsequently to the naturalising of the plant, for we know that all the coffee trees now grown in America and the West Indies are the progeny of one plant introduced in the year 1714, and yet botanists have individualised no less than sixteen species in Brazil alone and nine in Peru, whilst in the East Indies we have seven, and Africa is credited with five. Among the Indian species at least one, *C. Bengalensis*, Roxb., is a native of Sylhet, and in former time used to be cultivated in Bengal. But all the species most valuable for economic or commercial purposes are confined to Africa, or are of African origin. So intending growers of the flavoury berry in South Sylhet have a large enough number of species to choose from to suit their soil and climate. The choice of a suitable species is by no means the least important thing to be taken into very careful consideration. Although the present season's long drought is by no means normal, and cannot be taken as the average of the South Sylhet climate, still it must be always borne in mind that such a spell will be experienced from time to time. There are species, if not varieties, of our finest coffees which stand drought and certain conditions of soil and sunshine better than others. A writer recently accounted for the Arabian species standing the drought better in South Sylhet than the Liberian, because the latter was essentially an evergreen tree, and that the Arabian was either deciduous or otherwise according to climate, soil and general environment. Although this may be to a certian extent quite correct, we would point out that there are certain kinds of coffee which stand sunshine much better than others, and are more productive when exposed than they are when shaded. On the other hand, again, there are kinds which will not thrive at all unless they are grown under shade. We are inclined to think that a moderate shade, that can be thinned when necessary, will be found to be a *sine qua non* to successful coffee culture in South Sylhet. We wish the pioneers of this and other industries in that district every success. Coffee is by no means the only product which is being tried. Some of them already give promise of becoming very important staple products, which will not be limited to the Surma Valley, and we hope to be enabled to congratulate the district of South Sylhet upon being in the very forefront of success, as it certainly deserves to be for its tropical agricultural enterprise.—*Indian Planters' Gazette.*

INTENSIVE CULTIVATION.

In most progressive countries, more attention is being paid to improved methods of cultivation, by greater care in the preparation of the soil, selection of the choicest seed, and more intelligent care of the growing plants. The history of the sugar beet perhaps affords the best illustration of this. But it pervades every branch of agriculture, including fruits, flowers, etc,—in all which new and unlooked-for developments are every year recorded, increasing the value of such products, whether for food or in the arts and sciences. In no other branch of agricultural industry has there been greater progress than in the culture of beets and the manufacture of sugar from them. The result is that every year shows gain, the latest being seen in the reports of the French exposition on beet culture and manufacture. But while these evidences are more conspicuous on account of the magnitude of the beet sugar industry, yet the remark applies equally to cane, and almost

every branch of agricultural industry. The man who is most successful is he who supplies the necessary food and stimulants demanded by each product, and by returning to the soil what each plant has absorbed from it.

In remarks made at one of the planters' gatherings in Louisiana, Prof. Stubbs expressed surprise that Hawaiian planterrs did not cultivate pea vines and other plants for soil manuring. Had he visited Hawaii he would have seen lupins growing and used successfully for this purpose, which has been done for several years, and with as good results as in other countries. The practice is extending each year to all the islands. Prepared manures, made expressly to suit the needs of each estate, have generally been preferred on account of the good results attending their use. The needs of the soil of different localities here are so varied that it is only by actual test that the best can be determined. In Louisiana the soil of large sections may be of one class—alluvial perhaps, while here the soil of no two islands, or even districts, is the same. The chemist is employed on each plantation, and his investigation generally determines what manures are best adapted to it. The result is that each estate which is so equipped and conducted secures large returns in its annual crops.

THE FLORIDA ORANGE.—A piece of news in a small way that will be deeply appreciated is the announcement that Florida will have an orange crop of 1,000,000 boxes this year, the largest yield since the great freeze. One million boxes is not much in comparison with the 1894 crop of 5,000,000, or the last big yield, but it is about four times as large as the production of 1899. The 1901 yield, it is estimated, will reach 1,500,000 boxes. From this it may be seen that the Florida groves are being rapidly restored. In a few years the output will be larger than it ever was before, and the delicious fruit will once more abound in the market. The Florida orange is the queen of fruits. All the grapes and figs and dewberries that were ever grown are not equal to one perfect orange with its golden rind packed full of the sweetness and exquisite flavor of the tropics. What makes the orange so welcome is that it comes to the North in the holiday season, reaching here about Thanksgiving Day and being most perfect just at Christmas time. The oranges of California, though very good, are inferior to the Florida product.—*Louisville Journal*

RAFIA FIBRE IN MADAGASCAR.

Rofia, or as it is generally spelt "rafia," is the Malagasy name of a palm which furnishes a staple article of commerce, called rafia fibre. It is indigenous to Madagascar, and is to be met with everywhere on the coasts, needing neither cultivation nor attention of any kind. It is not a stately palm, but sends its enormous branches from near the ground; in a fine specimen one branch is almost a tree in itself. The rib in each branch is as much as 20 feet long, of a pearly grey colour, smooth and shiny, flat on the inner surface, but otherwise round, without any knobs, and so exceedingly hard. At the base it is as large as an ordinary champagne bottle, and tapers to a point at the top. The inside consists of a light pith, which can be spilt into layers of any thickness. Possibly, says the the United States Consul at Tamatave, it is this, or an analogous production, which is used in making pith helmets in the East. Naturally these ribs combine great strength with wonderful lightness, and are used for shafts for "filanjanas" or palanquins, ladders, or other purposes, but otherwise have no particular commercial value. It is the pinnifoliate leaf of these branches which produce the rafia fibre of commerce. One palm branch, or frond, will produce eighty or hundred long green leaves from two to five feet in length, like the leaves of the sugar cane, but of a dark, lustrous green, and both thicker and stiffer. These, again, contain a round and pliant rib which the natives utilise for making baskets and dredges for catching small fish and shrimps in the rivers after they have stripped off the green part which furnishes the fibre. The under part of this green leaf (which is not exposed to the light, as it remains folded) is of a pale greenish-yellow colour and from that side the inner skin can be peeled off in the same manner as the skin on the outside of a pea pod, except that it peels off straight to the tip without breaking. It is then of the palest green, and after being dried in the sun assumes a light straw colour. This is the rafia fibre of commerce. It was originally sought for by the natives for use in articles of clothing. The men bring in the fronds, and women and girls weave it on handlooms, of any coarseness or fineness. Woven just as it is peeled off from the fronds, it forms a kind of sacking used for wrapping goods, while the perfection of the art, as known by the Hovas only, is to weave a tissue of which the warp is rafia fibre split very fine, and the weft of white silk. This gives an article called silk lamba, which fetches fancy prices in Europe and America. The coast tribes use it for clothing, but of moderate fineness, with dyed stripes of indigo, saffron, black, and a dirty green. It is a cold, comfortless looking material, and refuses to adapt itself to any folds that a sculptur would care to copy. Rafia fibre is used in Madagascar by nurserymen, gardeners, &c., for tying up vines and flowers, and possibly for grafting. It possesses the advantage of being as soft as silk, and is not affected by moisture or change of temperature so as to risk cutting or wounding the most delicate tendrils, and it does not break or ravel when folded or knotted. These qualities bring it into use all over Europe and consequently maintain its price. It is virtually inexhaustible in Madagascar, the supply being limited only by the scarcity of labour. For export, the fibre is merely collected in large skeins twisted up or plaited, and then baled like raw cotton. Madagascar exports about 20,000 bales annually.—*Journal of the Society of Arts.*

BANANAS AND FIGS.

Attention has been called to the drying of tropical fruits, including those named above. Both cooking and eating varieties of bananas grow readily here, and could be made a profitable business for export, by drying them as is done in other countries. No healthier fruits can be found than the two mentioned, nor any better adapted for exportation, as both, when properly cured and packed, will keep in good condition for one or two years. Some forty or more years ago there was a family living in Kona, Hawaii, which dried bananas in the sun and packed them for export or local consumption. The fruit there put up was much relished, and found ready sale in Honolulu. Owing to the duty then imposed on dried fruits in the U. S., the business was finally given up. The Smyrna fig ought to be cultivated here now, as it can be had from California, where it grows and bears as well as it does in Smyrna, where it originated. A very interesting article on the introduction of this variety into California will be found in this issue of the "Planter," and we advise all who are interested in fig culture to read it, and learn the peculiarities of this —the finest kind of fig grown. Mr. Koebele brought from California specimens of the fruit now grown there. Nature, in this instance, provides in a most wonderful and intricate method for the perpetuation of the choicest fruit of this description known. Prof. Koebele was wise in not importing woodpecker birds, which Dame Rumour stated he intended doing but of which he had no thought, as he knew them too well. They are handsome birds and, like most others of their kind, live on insects, some of which they dig out from under the bark of trees—hence their name. In this connection it may be asked what

has become of the mynah birds, which formerly were so numerous here? Can it be true that the rats and mongooses attack them while asleep on the trees, where they are accustomed to roost? The mynahs are harmless, living mostly on ground worms and other insects which infest flower bushes and vegetation. Birds have their uses, but throughout the islands they are becoming more and more rare, excepting doves and pigeons and migratory birds, which seem to hold their own.—*The Hawaiian Planters' Monthly.*

THE TREATMENT OF GRASS LAND.

Experiments have been carried out in Berar by the Forest Department to determine the relative yield of dry fodder per acre from (1) areas annually burnt over, (2) areas burnt over and subsequently grazed over, and (3) areas neither grazed nor burnt. The results obtained are reported on as follows, by the Conservator of Forests, Hyderabad Assigned Districts:—

"The experiments regarding the treatment of fodder grass areas in Amraoti were continued with the following results;—

Plot (B State-forest).	Out-turn of dry fodder, in pounds, per acre.						Average last five years.
	1893.	1894.	1895.	1896.	1897.	1898.	
I—In the area burnt ..	2,736	2,501	1,091	739	2,558	2,850	1,948
II—In the area grazed ...	2,668	2,338	1,223	988	1,919	2,702	1,834
III—In the area cut over and neither grazed nor burnt.	2,386	2,417	1,228	755	1,825	2,268	1,703
Average ..	2,597	2,419	1,181	834	2,101	2,607	1,828

"The experiments have been carried on over five years of varying rainfall and growth, and will now be discontinued. They tend to prove that burning gives the highest yield, but that grazing down the stubbles (without, of course, injuring the roots by excessive trampling) gives a fair average yield. In Berar sufficient grazing is accordingly being tried in "ramnas" that lend themselves to this treatment."

These experiments merely relate to quantities of fodder produced. No account is taken of the quality of the grass, and it is a pity this question was not dealt with in carrying out the above experiments. There is a widespread notion in India that burning of grass lands is necessary, in order to improve the grazing. This, however, it does not do, as has been conclusively proved in Madras. In reality, by firing the grass, most of the delicate annuals, such as *Panicum Oplismenus*, *Isachne*, *Poa*, *Eragrostis*, etc., which are especially good for cattle, are destroyed, while the coarser kinds, such as *Andropogon, nardus* and *Schœnanthus*, *Apluda aristata*, *Chrysopagon sp., sp.*, *Imperata arundinacea* and *Anthistiria ciliata*, which are not so good for fodder, and of which only the young shoots are eaten, are encouraged. We should be glad to see some experiments carried out on these lines in Berar.—*Indian Forester.*

THE DETERIORATION OF PASSION VINES AND FRUIT.

W. J. ALLEN

Last season growers of passion-fruit in the Dural, Galston, Arcadia, Glenorie, Kenthurst, and other districts suffered much loss from a trouble which affected their vines and brought about the production of malformed, unsaleable fruit.

The disease is characterised by a thickening and hardening of the rind to such an extent that it more resembles a smooth bark than anything else, and in fact has been named by some of the growers as "ironbark" fruit. Only a small proportion of the fruit develops properly, most of it being undersized, ill-shapen, contorted, and with little or no pulp. The disease makes its appearance soon after the fruit has set, and can be easily distinguished then, the vines also showing its effects by an improperly developed appearance, the leaves being small. In many of the vineyards, an occassional vine is found dying from the effects of a disease resembling very much the disease known as Mal di Goma (collar rot), which attacks the citrus trees just above the surface of the ground.

I regret to say that harvesting of the spring crop had just been completed when I visited the districts named, so that I did not see to what extent the crop had been damaged; nor have I been able to trace this "ironbark" disease to any one cause, but am of opinion that a multiplicity of causes are accountable for the falling-off of some of the vineyards, chief among which are the following:—

I.—Planting in exposed positions, where the vines are subject to high winds.

II.—Frosts and cold weather during winter and at time of blooming.

III.—Heavy, cold, and poor soils and subsoils.

IV.—Improper fertilizers or neglect to supply sufficient, if any.

V.—Insufficient moisture owing to hot, dry summers.

VI.—Not selecting soils and positions most suitable for the passion-vine.

VII.—Age of vines.

VIII.—A fungus disease.

Treating of these causes separately, I find as regards—

No. I *Exposed positions.*—In a few instances I saw vineyards situated in very exposed positions, and where they were subjected to very heavy winds, which are detrimental to vineyards, and particularly to those planted on indifferent soils, where the growth is less vigorous and less able to withstand the strong winds. The consequence is that vines planted in such positions, and in such soils have, after the first year or two, borne more or less valueless fruit.

No. II. *Frosts.*—In some districts during the fall and winter frosts are of frequent occurrence and these are very severe on the vines, often causing the vine to lose nearly if not the entire crop, and also causing the vine itself to split open and crack in different places, and the death of all undergrowth and small lateral branches.

When cold winds and cool nights prevail at the time of setting—particularly at the time of setting of the crops which have just been harvested—it is noticed that the fruit produced has a

large percentage of worthless fruit, especially so on old vines which have become impoverished through age or lack of proper fertilizers. The succeeding crop, viz., that which is just now setting, is comparatively free from these worthless fruits.

No. III.—*Heavy, cold, and poor Soil and Subsoil.*—On such soils the vines have, after the first couple of years, steadily gone back, producing small crops of fruit which in many instances are almost wholly worthless, especially as regards the Easter and Spring crops.

No. IV. *Improper Fertilizers, or neglect to supply any.*—Vineyards planted in any soil show signs of distress sooner or later unless they receive a liberal dressing of manure periodically, and it is claimed by some that rows which have been well dressed with kainit and other manures rich in potash have produced heavy crops of good fruit, while adjoining rows which were unmanured had a large percentage of poor fruit. In fact, the growers are at one in their opinion on manuring, and assert that to grow good crops they must manure, and that where this important work is neglected the vineyards soon weaken and cease to produce either good crops or good fruit, such as are generally taken from all vineyards the first year or two.

No. V. *Insufficient Moisture, &c.*—Many of the growers attribute the failure to the excessively dry summers which have prevailed lately in many districts, and say that the vines did much better with them in those years when occassional soaking showers fell during the summer.

No. VI. *Soil and position best adapted for the Passion Vine.*—The soil which has been found best adapted for the growth of the passion vine is a rich, loamy soil, or sandy loam with a good natural drainage. In these soils they will live and continue to bear good crops from six to ten years, and on such soils there is the least diseased fruit found. They may also be found doing very well on poor light soil, but when they have exhausted the soil, which they do in a year or two, they must be constantly manured to keep them in a healthy and profitable condition, and as this vine produces three main crops of fruit each year, unless the land is very rich it soon exhausts itself if not well fed.

No. VII. *The life of the Passion Vine.*—The age to which this vine produces the best fruit, and when least woody fruit is noticed is during the first four years of its lifetime. In some vineyards, on rather poor soil, a shorter period (from two to three years) exhausts its productiveness, and on good soils, or those which are well manured, there are vineyards which have produced good crops up to twelve years old, but, generally speaking, the older the vineyard the more susceptible it has shown itself to woody or diseased fruit. It is therefore best to renew the vines before they become too old.

No. VIII. *Fungus Disease.*—An examination of the stalks and leaves of the passion vine revealed a fungus disease, which may or may not be the cause of the ill-shaped fruit. This is for the Pathologist to determine.

I do not consider this partial failure of the passion vine in a few of the vineyards to be a very serious matter. Many of the vineyards have been planted among trees, and as these attain to any size, there has not been sufficient moisture to keep both going properly, and the vines have become weakened, and suffered accordingly. In such instances a large proportion of the fruit has become diseased, and of no commercial value. The growers, however, are alive to the fact that they cannot continue to grow trees and vines together for more than three or four years without seriously damaging them, and consequently many of them are now taking out vines from between bearing trees.

As this vine does particularly well under ordinary conditions, bearing three large crops of fruit each year, that is to say in an almost perpetual state of fruit-bearing, it is not to be expected that it can keep up this strain without the application of proper fertilizers; therefore, at least every year, suitable manures should be applied, and as potash manures have given good results, I would recommend their use.

Pruning should not be neglected, as an unpruned vineyard with a lot of dead and useless laterals furnishes a harbour for disease, and the unpruned vines do not continue bearing or growing so well as do those which are well pruned back once a year.

For the fungus disease I would recommend a spraying with Bordeaux mixture (summer strength) just before each of the main crops blossom, and another as soon as the crop is fairly well set. This would not be found very expensive, and should be the means of keeping the vines fairly clean of fungus diseases.—*Agricultural Gazette of N. S. Wales.*

THE POSITION IN CASSAVA.

A recent analysis made by Professor Carmody, Government Analyst, confirms the previous work of Francis as to the presence of Prussic acid in sweet cassava, the proportion found varying from 0·005 to 0·019 per cent. The skin was found to yield from 0·014 to 0·042 per cent., while the inner part gave only 0·003 to 0·015 per cent. The interior part of bitter cassava yielded 0·013 to 0·037 per cent., while the skin and outer layer yielded from 0·012 to 0·035 per cent. Peeling sweet cassava before cooking is therefore a wise precaution. Professor Carmody also suggests that the acid may in part be formed by fermentative change.—*Trinidad Bulletin.*

THE METRIC SYSTEM, whatever may be said against it, is so infinitely more convenient than our present idiotic weights and measures, that it is very wonderful that even British conservativeness should have been able so long to obstruct so practical a reform. Other countries have adopted the metric system with little difficulty, and not one has evinced the slightest wish to return to chaos.—*Gardiners' Chronicle.*

GUTTA CULTIVATION IN JAVA.—The subject of gutta-percha cultivation in Java has been brought before the States General. The Minister for the Colonies explained that the Government intend to start gutta-percha plantations in Java only. There the soil and climate favour the undertaking, and labour is cheaper than in Sumatra and Borneo. A beginning will be made with planting on a large scale the *palaquium* variety, which has been found to thrive very well. Within the next five or ten years, it is intended to plant large areas with three kinds of this variety. The Director of the Government Botanical Gardens at Buitenzorg will be charged with the supervision work at the outset.—*Planting Opinion.*

Wilson, Smithett & Co.'s Ceylon Tea Memoranda for 1900.

Summary of CEYLON TEA sold at public auction in London between January 1st and December 31st, 1900, estimated quantity in lbs. and average prices realised :—

Average Price for the Year was 7·25d per lb., against 8d in 1899 and 7·78d in 1898.

The initial letters following the estate names refer to the mean elevation, as follows :—

L (low) sea level up to 1,000 feet HM (high medium) 2,500 to 3,500 feet HH (highest) above 5,000 feet
M (medium) 1,000 to 2,500 feet H (high) 3,500 to 5,000 feet

Prussic Acid in Sweet Cassava.

By Professor Carmody, F.I.C., F.C.S.

(Revised Reprint from *The Lancet* of Sept. 1900.)

Francis, one of my predecessors in the Trinidad Government Laboratory, was the first* to point out that prussic acid was present in sweet cassava to a considerable extent. Francis's results have not received the attention which they deserved, probably because they were a direct but unconfirmed denial of statements repeatedly made by recognised authorities. There are very few recent editions of toxicological handbooks that make any reference to the results published by Francis. Even in standard reference works like that of Dr. Thorpe's "Dictionary of Applied Chemistry" it is stated that "the milky juice in the sweet variety is innocuous, whilst that in the bitter is highly poisonous."

The question is of importance from a toxicological point of view in those places in the tropics where cassava is used extensively as a food. For poisonous symptoms are not infrequently reported after a meal of sweet cassava; and as the two kinds of cassava—the sweet and the bitter—are so much alike as to be almost indistinguishable, the conclusion usually arrived at is that the bitter variety has been cooked in error.

My results fully confirm those of Francis as to the presence of hydrocyanic acid, although his average figures are somewhat higher than mine. This year has been an unusually dry one for Trinidad and a diminished supply of rain does affect the character of plant juices.

The method of analysis adopted by me differs somewhat from that of Francis. He grated 500

* Analyst, April 1877.

grammes of cassava into 500 cubic centimetres of water which was left for two hours in a well-closed vessel. It was next strained through a linen cloth into a flask which was then corked and allowed to stand until the starch subsided. 200 cubic centimetres of the clear liquid were decanted and distilled and the results obtained were multiplied by four for the total in 500 grammes. This calculation was based on the assumption that the original 500 grammes contributed 300 cubic centimetres of water —an assumption which is not far from the truth if the cassava is quite fresh. Francis also remarks that a slight loss occurred during the process of grating, and in a tropical laboratory this loss might be appreciable. I endeavoured to avoid this loss on the one hand, and the possibility of error through assuming that all cassavas contained 60 per cent. of water on the other, by taking the whole root, slicing it quickly, and allowing it to stand in water all night in a well-corked flask. The liquid was decanted in the morning and the whole distilled. The extraction with water was repeated a second and a third time. The slices effectually prevented the great disadvantage arising from the starch finding its way into the distilling flask, which Francis prevented by subsidence but which necessitated his distilling an aliquot part, this aliquot part being a *definite* volume of 200 cubic centimetres taken from an *approximate* total volume of 800 cubic centimetres.

Francis does not appear to have made more than one extraction with water. I have made three in all cases and in some as many as five. I have found that with slices the second extraction yields as much, and sometimes more, than the first. I have repeated Francis's method of grating and find that a second extraction yields about half as much prussic acid as the first. It would appear from this, therefore, that Francis's results are not as high as they would have been had he made a second extraction. The figures obtained by Francis and myself are:—

	HCN per cent.	
	Francis.	Carmody.
Mean	0·0168 ...	0·010
Highest	0·0238 ...	0·019
Lowest	0·0113 ...	0·005

It will be seen from this that while my "lowest" percentage is much below that of Francis my "highest" is nearly the same as his. This establishes the truth of the statement made by Francis, "that the so-called *sweet* or harmless cassava not only yielded prussic acid, but the quantity obtained from it so nearly equalled that from the *bitter* that no line of distinction could be drawn between them," so far as it relates to the amount of prussic acid in the cassava; but I have discovered an analytical difference between the two kinds by means of which they can be satisfactorily distinguished.

This discovery arose in trying to avoid the difficulties caused by the presence of starch in the distilling flask At first I placed the slices in the distilling flask, added water in one set of experiments, and passed steam through in another and collected the distillates. This failed in each case through the gelatinising action of the boiling water or steam on the starch. This starch being chiefly confined to the inner protions, in my next experiments I soaked the inner slices in water at ordinary temperature, decanted and distilled. The quantity of starch thus admitted into the flask was so small as not to interfere with the distillation. The skin and outer cortical layer, which together constitute about one-fifth of the total weight of the sweet cassava, could be placed direct in the distilling flask, and the distillation carried on satisfactorily. It was this separation of the parts for convenience in distillation that led to the discovery that in sweet cassava the prussic acid is located chiefly in the skin and outer cortical layer.

The following are some of the results obtained from fairly representative samples of sweet cassava.

Inner part. HCN per cent	Skin and outer cortical layer. HCN per cent.	Inner part. HCN per cent.	Skin and outer cortical layer. HCN per cent.
0·006	0·033	0·004	0·024
0·003	0·014	0·010	0·030
0·015	0·033	0·004	0·042

0·014	0·013	0·032	0·035

*Exceptional.

The general conclusions to be drawn from these results are: (1) that in sweet cassava the prussic acid is not uniformly distributed throughout the tuber and that in bitter cassava it is uniformly distributed, or nearly so; and (2) that this affords an analytical means of distinguishing between *sweet* and *bitter* cassava.

Cassava is cooked either by roasting the entire tuber (this removes all the HCN) or by boiling. An important observation in connection with local methods of eating cassava is that the skin of the sweet kind is removed before boiling, the inner portion alone being cooked and eaten. This custom is no doubt the result of experience and accords with what science would now teach as a wise precaution. But, notwithstanding this removal of the skin, ill-effects are said to follow from the use of the inner portion if water is drunk some time after a meal. This may now be accounted for in this way. It is shown in my experimeuts that whilst a first boiling removes a certain amount of hydrocyanic acid—all, in fact, that exists ready formed in the tuber—that a second addition of water and subsequent boiling removes a further portion. It would appear from this that cassava in a person's stomach would also develop an amount of prussic acid equivalent to that obtained in a second distillation, and that the drinking of water would dissolve this and cause it to act more readily on the system. The total quantity would, however, be far below the minimum fatal dose and would only be expected to produce those unpleasant results occasionally reported. The question next arises—Is this second portion of hydrocyanic acid produced by fermentative changes, as is known to happen in the case of bitter almonds; or is it part of that originally existing in the tuber and in some way protected from the solvent action of the first treatment with water? It is possible that, with slices, the water would penetrate slowly to their interior, and thus produce a second yield of prussic

acid; and that if the cassava had been grated, as was done by Francis, the water would, within Francis's limit, dissolve the whole of the acid. I have not found this to be the case, as the following experiment shows:—

Sweet Cassava.

Duration.	Half (408 grammes) sliced n/10 $AgNO_3$.	Half (427 grammes) grated n/10 $AgNO_3$.
First extract 2 hours	3·0 c.c.	2·2 c.c.
Second „ 2 „	1.3 „	1·4 „
Third „ 20 „	3·5 „	1·4 „
Fourth „ 2 „	1·0 „	0·7 „
Fifth „ 2 „	1·0 „	0·9 „
Sixth „ 17 „	1·1 „	0·5 „
Seventh „ 2 „	0·4 „	0·7 „
Eighth „ 2 „	0·5 „	0·9 „
Ninth „ 2 „	0·2 „	1·3 „
Total ...	12·0 c.c.	10 0 c.c.

It would appear from this and similar experiments that the whole of the hydrocyanic acid cannot be removed from grated cassava by a two hours' extraction with water, and that there is apparently a loss of acid even when the grating is done under water. And, notwithstanding that my yield from slices is the higher of the two, Francis's results from a two hours' extraction are appreciably above mine. As already stated, this may be due to the exceptionally dry season. Next year I shall continue the experiments in order to clear up this difficulty. At present I am inclined to believe that part of the acid may be formed by fermentative change. If this be so, cassava starch on keeping would be likely to be more poisonous than when freshly prepared. Fermentation beyond a certain limit entirely decomposes the hydrocyanic acid.

There appear to be no grounds for the common belief that sweet cassava contains more HCN the older it is. In all the samples examined during a period of nine months from the time cassava was first brought to market the proportion of HCN showed no increase that could be traced to age. Nor is there any ground for the belief that the locally grown sweet cassava is but a degenerate growth resulting from many years' association with the bitter variety. A selected sample imported from Jamaica and grown at the local Government gardens contained the same amount, and the same relative proportions in skin and inner part, of HCN as the ordinary product of Trinidad.

The subject is not yet exhausted, and I hope to be in a position to publish further results next year.

SISAL HEMP IN CUBA.

(Specially translated for "Indian Gardening and Planting.")

We are indebted to M. J. Vilbouchevitch of Paris for a copy of a most interesting report by M Léon Hautefeuille upon his mission to Cuba on behalf the Cayo-Cruz and Cayo-Romano Company to inspect their lands under Sisal Hemp in those parts. From the report we gather that the Company has leased its lands to the Paris firm of Bridat-Mont'Ros et Cie. for a period of two years, renewable by mutual consent for the same period. The necessary capital has been supplied by the Maison Bridat-Mont 'Ros, the net profit to be shared between the firm and the Company. The local management is confided to M. Mahiquez. The enterprise has only just (1900) reached the productive stage. It is now in full bearing, but was at the commencement of last year handicapped by insufficient supply of bullocks for traction and to work the decorticator. Twenty-eight pairs of bullocks have now been sent from Havana, and this want is therefore well supplied. The following is a translation of M. Hautefeuille's report of the actual state of the plantation :—

"An inspection of the *henequen* plants produced upon me a most happy impression. They were superb in size, vigour and health. Nothing is more satisfactory to one who has an agricultural taste, than the sight of a cultivation well suited to the soil and in conditions in which it finds itself well placed. The lands occupied by the *henequen* are incontestibly of a poor nature. No one would seriously think of planting there any rich cultures, and yet here is the fact that a plant, formerly wild, brought here, flourishes, develops marvellously and furnishes in abundance an industrial product in good demand, of which the sale is indefinitely assured at a good price.

"*Henequen* fibre is in fact very much in demand for the manufacture of strodg fabrics, and above all for ropes employed on shipboard, by reason of its lightness, strength and resistance to rot.

"*Henequen* is an Agave (*Agave Mexicana Agave sisalana*), which was long considered a plant without value, very common in the Bahamas in Yucatan and other parts of Mexico, where one variety is utilised for the manufacture of a fermented drink called *pulque*. The fibre having been found utilisable, experiments were made in Mexico, after which importance plantations were made as soon as a machine allowing of the fibre being economically obtained was devised. Yucatan in particular undertook the production of *henequen* ; subsequently the lands, till then uncultivated, in the Bahamas furnished a superior variety. Cultivation modifies the characters of the plant a little, of which it develops the size ; but it is the nature of the soil which has the greatest influence on the value of the fibre obtained.

"The old administrators of Cayo-Romano (the Spaniards) attempted to turn to account this novel cultivation. They made experiments in all the soils of the Cayos. The plant grew irregularly ; very badly in the gravels of Cayo Cruz, which were besides too humid ; better at Cayo-Romano, in the low dry soils; less well on the heights not on account of the soil, but because of the altitude ; in an inadequate manner in the lands, although of better quality, of the northern slope.

"*Henequen* requires a poor dry, rocky soil ; it loves the pockets of soil formed between rocks to which it seems to cling. It needs plenty of heat and the rocks store up and emit heat. Hence there arise very appreciable differences of quality. The finest specimens producing the best fibre are

found in dry and stony soil. As in France the best vineyards are sometimes found in soils of poor appearance."

There is a complete demonstration of the preferences of *henequen* at Cayo-Romano. A walk of a few hours suffices to take account of these preferences. One can henceforward plant almost to a certainty.

"The actual plantation (Cayo-Romano) occupies about 600 hectares (1,482 acres, 1 hectare=2·47 acres) I could not say how far it may be extended. It would have taken me five or six days to indicate and limit the size of possible extensions. I do not doubt, however, that 3,000 hectares (7,400 acres) of land suitable for *henequen* could be found by clearing certain wooded parts, and I do not say that it would not be possible to push the cultivation up to five or six thousand hectares or more, by utilising, in course of time, the distant lands of Versalles.

"It would be premature to attempt an account of the receipts and expenses of *henequen*. The price is not definitely fixed, and we believe it is destined to rise on account of the quality of our fibre, recognised in commerce as superior to that of Yucatan. The fibre of Cayo-Romano is whiter, finer, of greater resistance and longer. These qualities have a very appreciable influence on the price.

"The machine installed at Port-Versalles decorticates on an average 50,000 leaves per day; furnishing about 2,000 kilogrammes (4,400lb) of fibre, or 13 balls of 150 to 160 kilos each. The fibre is sold at the rate of nearly 1 franc the kilo. But the machine does not work at present at its full power. If it were regularly fed so as to work without intermission 10 hours per day it could turn out 4,000 kilos of fibre which represent 100,000 leaves, or the yield of 1 hectare 78 ares 5 centiares (4 2-5th acres).

"A hectare contains 2,000 plants placed at two metres distance in all directions with a path line between at least every five rows. Each plant should give on an average 28 leaves, or at the rate of 40 grammes per leaf, 1,120 grammes of fibre per plant, or 2,240 kilos (4 928lb) of fibre per hectare and by the year 56,000 leaves.

"Mr. Galan, the Sub-Director of the Plantation, estimates that 1,000 leaves of *henequen* may give 40 to 45 kilos of fibre; but he generally calculates on 40 kilos. M. Mahiquez indicates figures nearly the same. He goes as far as 45 kilos per 1,000 leaves."

M Léon Hautefeuille further on in his report remarks that as he was not representing the proprietary society, but only the house which had rented the plantation, he was not in a position to ask for accounts. Therefore his remarks on working expenses must necessarily be imperfect. Still, certain of the expenses are known and he proceeds to give them as follows :—

"100 men are employed daily in the actual cultivation for the service of the machine and these cost altogether 150 piastres (750 francs) for 2,000 kilos of fibre,

"It would need 200 men costing 250 piastres (1,250 frans) to furnish 4,000 kilos, of fibre. Cutting 1,000 leaves of *henequen*, putting up in bundles and placing in carts come to 6 francs 25 c. and then transport to the factory to 2 francs 50 c.

"So that 2,000 kilos of fibre require a daily expenditure of 1,187 francs 50 c and 4,000 kilos an expenditure of 2125 francs, but the produce goes backwards and forwards. The grain falls through, not of course absolutely clean, there must still be small particles of *bhusa* and chaff, but it is clean enough to store conveniently and the small particles are quickly got rid of when we have a wind. If a winnower in the place of a thermantidote can be built, it of course expedites matters greatly. I find it a good plan to erect a long grass hut at one end of the threshing floor to store the partially cleaned grain in as a protection against rain and also thieving.

ARTHUR L. HARMAN.

PLANTING NOTES.

POMEGRANATES.—The pomegranate fruits freely in Queensland, but no use is made of the fruit. The *Florida Agriculturist* points out that a good market for this fruit exists in New York. It is a highly popular fruit among certain classes, and is worth from 5 to 6 dollars (£1 to £1 5s.) per crate. The demand is yearly increasing—the more it is known, the more popular it becomes. Enough cannot be procured to supply the market. The *Agriculturist* does not state how many fruits are contained in a crate. Still, here may be another opportunity for Queensland orchardists.—*Queensland Agricultural Journal.*

BANANAS.—Humus, Drainage, Tillage, these three are the banana plants requirements, and without the first it is hopeless to expect bananas to grow and produce fruit; with the first, but without the second, they might grow, but would not do very well except in seasons of light rains; with the two first and not the third, bananas have been grown for many years in succession on rich alluvia and loams, and fine bunches produced, and are being grown still, but with Tillage better results would have been obtained in the end, for many of such lands have now been thrown up as worn out, which with cultivation all along, would have been bearing well as ever; and they can be restored with Tillage only, to almost their pristine strength. But the greatest of these is Humus.—*Journal of the Jamaica Agricultural Society.*

PURE KEROSENE FOR SAN JOSE SCALE.—Further reports are to hand as to the effectiveness of pure kerosene, applied carefully with a brush, in destroying San Jose scale on deciduous fruit trees. In a letter to the fruit expert, Mr. F. Mason, of Beecroft, says: "I wish to tell you that I painted, on August 23 last eighteen Carrington Apple trees with pure Kerosene, and also four Nelson apple trees, on September 17, that were all badly affected with this terrible San Jose scale. The trees are now looking well, and there is not a scale to be seen on any of them. I have a number of Carrington apple trees that have not been so treated for the pest, and they are very badly affected. Some of the trees are suffering badly, and the fruit is literally dotted all over with the young scales. I shall be pleased if you can kindly tell me what to do with these." When the scales attack fruit it is difficult to devise any economical method of destroying them. With a pest like San Jose scale the only really effectual means of destruction is to attack the scales in winter while the trees are bare of leaves, and after pruning. All prunings should be carefully collected and burnt, and the tree either treated with pure kerosene or fumigated with hydrocyanic acid gas. The kerosene method is, however, so simple and efficacious that unless one has extended use for a fumigating outfit for the destruction of scale in citrus trees, it is scarcely worth while going to further expense in procuring one.—*Agricultural Gazette of New South Wales.*

TEA IN PEERMAD, TRAVANCORE: GREEN TEA MANUFACTURE AND RESULTS.

Mr. Drummond Deane has always some practical suggestion to make, as well as useful information to give, when he puts his pen to paper. Under date of 24th March, he writes of his Peermaad district (elevation 3,600 feet):—

Places here in bearing average well over 450 lb per acre and some up to 600 lb per acre and I take it the average cost *f.o.b.* does not exceed 20 cents in this district and they are good highgrown teas. If you turn up Peermaad teas sold in Colombo some ten years ago you will find very fair averages, comparing with Ceylon, for Kuduwa Karuam, Bon Ami, Pendhurst, Mount Glenmary.

"I wonder when we shall begin to hear result of sales of green teas in America; why do not we see the prices quoted for teas like Brunswick, Moray, Darrawella, etc? If they are fairly good it would stimulate the manufacture and they cannot be very bad or those estates would not continue making. I think the '30 Committee' should when paying the bounty on green tea insist on having *copies of all sales* sent them."

We commend the closing hint to the consideration of the "Thirty Committee."

JAVA CINCHONA BARK.

Cinchona planters in Java have thrown off the yoke of a German ring of dealers, who had combined to keep the price of bark down for the enrichment of quinine manufacturers. They have started a quinine factory of their own at Bandong in Java, and arranged to sell their quinine at Batavia by auction. The German monopolists have threatened to start a rival quinine factory in Java. A German quinine manufacturing firm intends to carry the war into the enemy's country in a different way. It proposes to sell quinine pills in Java,—that is, quinine prepared for direct consumption,—at a price corresponding with that of Bandong quinine at the Batavia auctions. The firm will certainly suffer loss by this, but the Bandong factory will have also to stop the making of quinine pills, and will thus lose a main source of profit.—*Straits Times*, March 19.

WESTRALIAN ROYALTY ON GUANO.

The Minister for Lands recently received an application from Messrs. Broadhurst, M'Neil, and Co., who are associated with the guano trade, asking that the Government should remove the royalty on guano exported to the eastern States to the extent of 10s per ton on live and 8s. 6d. per ton on dead. They maintain that, now that the States are federated, the embargo should be abolished The Government was asked to consider the application, and the decision that was arrived at was that, as the amounts levied were not regarded in the light of an export tax, but simply a royalty for the removal of certain matter from Crown lands, it was not possible to accede to their request. —*P. M. Herald*, March 15.

THE CHAIRMAN OF THE INDIAN TEA ASSOCIATION ON THE PROPOSED TEA CESS.

(*To the Editor of "Planting Opinion."*)

DEAR SIR,—I notice that in your issue of 9th March you perpetuated an error made in reporting by a Calcutta Daily paper; and in doing so you not only put into Mr. Topping's mouth what I said, but you make me out an opponent in conjunction with Sir Patrick Playfair of the proposed tea cess. Instead of "Mr. H S Ashton and Sir Patrick Playfair have spoken," you should read "Mr. H S Ashton said Sir Patrick Playfair has spoken" and so on.

Inasmuch as I have, just been elected Chairman of the I T A, it is perhaps advisable that it should be clearly understood that I strongly approve of the proposed cess. The proposal has been made as an alternative to the present method of obtaining voluntary subscriptions for advertising purposes, which for seven years has resulted in an annual collection of about a lakh. In 1893 this sum might be considered respectable, but I think I am justified in saying that the failure to increase subscriptions as the output of tea has increased damns the voluntary system as inefficient, and justifies a resort to other methods if new markets are to be thoroughly exploited by Indian tea. Of course there are proprietors who deny the value of advertisement by other than private enterprise, and their influence may be sufficient to block the way, but it is also quite certain that there are a number who are willing to share the cost of exploiting new markets, and who do not now subscribe, if provision is made to protect them against subscribing more than their shares. The cess will meet their views, whilst I think it must be pretty obvious that those who have for years been doing more than their share will get tired of the present system, because, if for no other reason, "it is so difficult to tax and please" and there is just as little pleasure in the process whether you impose the tax yourself or not.

There appears to be another body of people interested who approve of all the exploiting that can be done, and who suggest far more expensive schemes than any yet attempted. At the same time they deprecate the intervention of Government, who, they seem to fear, would keep the tax on when the object for which it was imposed ceased to exist or, in other words, would divert, at some time or other, to their own uses, funds specially here marked. In view of the proved efficacy of the Ceylon system and in view of the practical failure of the Indian voluntary system, I would ask such people whether it is worth while opposing the tax because they hold the theory that the Government of India is shameless, for that is what their argument amounts to. Sir Patrick Playfair's suggestion is to distribute over 5 million lb. of tea (3 per cent of the crop) this year in India, and he thinks the cost of administration may be covered by sales, but not any part of the value of the tea. I thoroughly approve of something of the kind being done, but after seven years' experience on the I.T.A. Committee, during which the difficulty of obtaining money has been in constant evidence, and the crippling effects upon all operations of the uncertainty as to funds voluntarily

subscribed, I would rather see the Committee, which will shortly be formed to exploit India, commence operations with a solid fund behind it such as the proposed cess would bring in. The industry has never risen beyond a lakh a year by voluntary effort. If you value the 5 million lb of tea above referred to (the cost of which it is thought will not be recovered) at -/1/- a lb, it will cost the industry over 3 lakhs, at -/2/- over 6 lakhs and it is at least fair to infer that it will be difficult to get such a subscription responded to after past experience. The Committee having to find ways and means will undoubtedly be greatly handicapped and any scheme they may decide to adopt will consequently be delayed to the detriment of practical work.

To those who believe in advertisement and yet hesitate to support the cess, I suggest the above points. H. S. ASHTON.

PLANTING AND LIFE IN DOMINICA.

[We feel indebted to the gentleman who sends us the following correspondence for publication. Transferred to our *Tropical Agriculturist*, it will aways be available and useful for reference. —ED. *T.A.*]

Government House, Dominica, 31st Dec., 1900.

DEAR SIR,—I must apologise for my delay in answering your letter of 16th October last.

I have much pleasure in forwarding you herewith a series of answers to a number of questions that have been addressed to me by various correspondents on the subject of planting in Dominica. I hope these notes will give you some of the information that you require.

I may add that, as the distances are not long in Dominica, Crown land can be purchased for 10s an acre, payable by instalment. There are one or two partly developed estates for sale, but a large price is being asked. Several Englishmen have come out during the last few weeks, and are taking up Crown land. The first comers will naturally get the pick of the land that is being opened up by the new roads.

Dominica has never suffered very severely from a hurricane, and the effects of a West Indian storm are frequently exaggerated for various reasons.

Mr. Gordon Fowler, an ex-Ceylon planter, who started a coffee estate here about three years ago, is so satisfied with his results that he has increased his holding, during the last year, from 300 to 1,100 acres. His coffee is magnificent, and there is a complete absence of blight,—I remain, dear sir, yours faithfully,

H HESKETH BELL, Administrator.

W. Hardy, Esq., Gillardstown, Wattegama, Ceylon.

NOTES ON DOMINICA FOR INTENDING PLANTERS.

1. BEST ROUTE FROM ENGLAND.—By Royal Mail from Southampton. Leaves every fortnight. Fare £25 single, £40 return. Voyage lasts 13 days. Can also go by Scrutton's line cheaper, but a good deal longer, also via New York.

2. HOTELS AND THEIR CHARGES.—There is one Hotel in the town of Roseau, suitable for bachelors. Terms 8s a day.

3. PENSIONS OR BOARDING HOUSES AND THEIR CHARGES.—Several kept by ladies, very comfortable and moderate terms, Miss Pemberton's and Miss Shew's specially recommended.

4. HOUSE RENT.—Vacant houses are at present scarce. Rents vary from £30 to £60 a year.

5. COST OF LIVING.—A bachelor living on his own plantation, of careful habits, need not spend more than 30s to 40s a week on housekeeping. A great many spend much less, as they raise their own poultry, sheep pigs, vegetables and fruit. Fish is very cheap and plentiful.

6. SERVANTS' WAGES.—Female Servants get from 3s 6d to 5s a week. Men from 4s to 6s a week, and are usually not boarded.

7. PRICES OF HORSES AND MULES.—Ponies cost from £10 to £20. Mules average £20. Donkeys 30s.

8. HORSE HIRE.—Six to eight shillings a day.

9. HORSE KEEP PER MONTH.—From 30s to 40s.

10. CAN HARNESS AND SADDLERY BE OBTAINED IN THE COUNTRY?—They can be obtained locally, but it is better to get them from England.

11. IS THERE ANY SHOOTING? IF SO, WHERE AND OF WHAT DOES IT CONSIST?—Pigeons (Ramier) Doves, Parrots, Opossum, Agouti and Wild Pig, are fairly plentiful, but shooting in Dominica is not sufficiently good to make it a special object of a visit. A week can however be very pleasantly spent in the forests with a gun.

12. WHAT IS THE BEST RIFLE OR GUN FOR THE COUNTRY?—An ordinary fowling piece.

13. CAN AMMUNITION AND SPORTING REQUISITES BE OBTAINED IN THE COUNTRY, AND WHERE?—They cannot be obtained locally of good quality, but everything can be got from Barbadoes in a few days.

14. WHAT IS THE IMPORT DUTY ON GUNS AND CARTRIDGES, AND WHAT OTHER RESTRICTIONS ARE THERE IN THE IMPORT OF GUNS AND DOGS?—10s a piece. No restrictions on dogs. Long-haired ones are not very suitable. Fox terriers thrive best.

15. IS THERE ANY ANGLING? IF SO; WHAT KIND AND WHERE, AND WHAT BAITS ARE USED?—The rivers are well stocked with fish, principally mullet. Local Grasshoppers make the best bait.

16. AMUSEMENTS, CLUBS ETC.—The Golf Links 9 Holes, are very sporting, and are managed by a Club. There is also a Tennis & Croquet Club. A Social Club House is about to be built. Cricket is also played.

17. ARE THERE GOOD ROADS, AND ARE ANY FIT FOR CYCLING?—Very large works are being undertaken on the Roads, and bridle paths are being turned into Cart Roads. There is a good road round the Island with branch tracks leading up the Valleys. The sum of £15,000 is now being expended in making a central trunk Road, which is intended to open up the very fertile lands that lie behind the seaboard. The island is rather too mountainous for easy cycling but, owing to the improvement in the roads now being carried on, several bicycles have recently been imported.

18. IS THE CLIMATE HEALTHY, AND WHAT IS THE BEST TIME TO VISIT THE COUNTRY?—The climate is very healthy, especially in the mountains. Temperature rarely excessive. Rainfall varies from 60 inches to 200 inches per annum, according to locality and altitude. No special outfit is needed, ordinary English summer clothing does very well. A Terai hat is useful, also strong leather boots. All ordinary articles can be purchased locally at moderate prices. The best season to visit the Island is from November to May; but anyone intending to take up and plant Crown lands, that are covered with forest growth, should commence operations early in the year, so as to get a good "burn" during dry weather.

19. AMOUNT OF CAPITAL NECESSARY.—An intending planter should not be supplied with *less* than £1000. With this Capital he might purchase a block of 300 or 400 acres of Crown lands. He might clear and plant 20 or 25 acres the first year, and ten additional each succeeding year. A cottage suitable

for a bachelor could be built locally, by using native timber and shingles, for something under £75. Sufficient furniture could be purchased for £25. After the first year, the planter ought to begin to make some money out of "catch-crops," such as early vegetables, bananas, tobacco etc. Pineapples yield a crop after 20 months, and their cultivation gives large profits. Vanilla and coffee bear in three years. Limes and oranges give good crops at four years. An acre in cocoa, five years old, ought to yield from six to nine cwt. of beans per annum, and the price, during the last 20 years, has averaged over 60s a cwt. Trinidad cocoa fetches over 90s a cwt., and there is no reason why the Dominica product, if properly cured, should not be equally valuable. Nutmegs are of slow growth, but the value of their yield is very high. The cultivation of ramie-grass has lately been commenced in Dominica, and promises much success. There are vast areas particularly suited to rubber, and the "Castilloa" is found to thrive admirably. In fact, the most eminent authorities on tropical agriculture have given the opinion that owing to its diversity of soil, rainfall and altitude Dominica offers remarkable advantages for the profitable culture of almost every sub-tropical product. There are good shipping facilities to the markets of America and the United Kingdom, and an increasing demand for all its products.

20. SUPPLY OF LABOUR.—The local supply is provided by the coloured inhabitants of the Island, and is fairly abundant. The field hands require to be dealt with tactfully. There is a considerable influx of labourers from the Sugar Islands further north, and in 1899 these immigrants numbered over 1,700. In the event of very large demands arising for an increase of labourers, it is probable that coolies would be imported from India.

21. DANGER FROM HURRICANES?—Dominica has been remarkably free from hurricanes for very many years. The last severe storm occurred in 1883, but did comparatively little damage. The very accidented configuration of the island would probably prevent any wholesale destruction of growing crops, and there is really very little danger to be apprehended from hurricanes in Dominica.

22. INSECT PESTS?—The island is very free from noxious insects. Lime trees in some localities are troubled by a borer, but the damage done is, so far, not serious. Great care is taken, to guard against the importation of plant diseases from abroad. There are no venomous snakes and mosquito curtains are rarely used in the country districts.

23. CROWN LANDS *v.* OLD SUGAR ESTATES?—The whole of the coast lands, right round he island, are occupied by old estates which, for the most part, once produced sugar but are now planted with cacao, limes and fruit. Very few of them are for sale, and it is a significant fact that it is almost impossible to buy, for a reasonable figure, a plantation that is already yielding a large crop of either cacao, limes or fruit. The returns from these products are too valuable to be parted with save under force of circumstances. The Crown lands comprise about 120,000 acres, and occupy the whole of the centre of the island. They are undulating, well-watered, and covered with a magnificent forest growth. The soil, in most places, is remarkably fertile, and no fertilisers would be necessary for many years. In these virgin lands there are practically no weeds, and the continual tillage required on old plantations would be largely avoided.

The felling, clearing and burning of the forests is usually done by native contractors, and it has been estimated that the clearing, draining and planting of an acre of virgin land costs in the first year, between £4 and £5.

The "Imperial Road" which is now being constructed through a large section of Crown lands, opens up two large "spheres" of soil, and will soon render available some 30,000 acres. In one locality, the land varies in altitude from 3,500 feet to 1,000, and this tract is principally suited to the cultivation of high-grade coffee, nutmegs, oranges, rubber and early English vegetables; cacao, limes, vanilla and pine-apples are believed to be better adapted to lands varying from 500 to 1,000 feet, and the best conditions are to be found in the Layou Valley.

24. INSTRUCTION IN AGRICULTURE?—The Curator of the Botanic Station and the Agricultural Instructor are always ready to afford all assistance in their power, but it should be clearly understood that the Government will assume no responsibility for the success or otherwise of any settler. An intending planter should carefully follow the work that is being carried on in the sample cultivations at the Botanic Garden, and he would gain much valuable information. The planters in Dominica are very friendly and hospitable, and any new-comer with proper recommendations would be welcomed and assisted by them. It would be advisable for any inexperienced person not to decide upon the purchase of land until he shall have stayed some weeks in the Island. He will then be in a position to judge for himself of the merits and prospects of various cultivations, and be able to decide upon the nature and locality of the soil which would best suit his purpose. The return fare to Dominica is only £40, and a month's expenses in the Island could easily be restricted to £20. For an outlay of £60, a single man could most pleasantly spend a couple of months in making a voyage to Dominica and back, and there is every reason to believe that, having once seen that very beautiful and promising Island, he will develop a strong desire to identify himself with its progressive fortunes.

For further information concerning Dominica, see "Report on the Agricultural capabilities of Dominica," by C O Naftel late Inspector of Estates in Ceylon. This pamphlet is published by Messrs. Eyre and Spottiswoode, East Harding Street, Fleet Street, and costs 9½d. It contains a good map of the Island and a large amount of valuable information concerning the cultivation of various products that are suited to Dominica.

NEW AND OLD PRODUCTS.

So far as the Directory estate results have been worked out, the most striking fact to our mind, is the great extension of the planting of coconut palms in the old coffee and young tea districts below a certain elevation. The Dumbara, Matale and Gampola Valleys have long been known to grow excellent coconuts; and still greater success should be anticipated lower down, where soil and climate are suitable. So, it is no wonder that the Kelani Valley planters and their brethren in adjacent districts, North and South, have selected the coco-palm as a second string to their bow, after tea. But we are disappointed to find that so little has been done with the pepper vine, in the districts *par excellence*, best adapted for its growth. We cannot at all see why we should not develope an annual export of first-class pepper, equal to the quantity the Dutch shipped from Ceylon some 150 years ago and which was then nearly all produced by the Sinhalese of the Kegalla, Avisawela, Hanwela and Matara districts. A bounty, a medal and "order of merit" should go to the first Sinhalese landowner bringing five cwt. of good pepper for export from Colombo.

CLOSING OF THE AGRICULTUEAL SCHOOL:

MR. C. DRIEBERG.

The fate of the Agricultural School, like that of the "Alfred Model Farm," shews the folly of trying to achieve agricultural improvements among the natives of Ceylon save through the medium of the revenue officers and their headmen, the latter being specially influenced to spend themselves and be spent by the prospect of "honours." That is the talisman that always works wonders among the most apathetic of Orientals and we cannot see why it should not be more fully utilised. Why should the Governor not introduce a native "Order of Merit" to be bestowed, without reference to caste, creed or position, on all natives who lead the way with "new products," or other improvements,—who make two blades of grass to grow where only one grew before? Let the recommendation still come through the revenue (and judicial) officers of the Service, but let the badge and medal be given with due ceremony at an annual Durbar; and we feel sure there will soon be stirred up a spirit of emulation such as we have not seen among the rural Sinhalese for a long time past.

But if the Agricultural School is to be pronounced a failure, and to be relegated into forgetfulness, we feel quite sure this is in no way due to any want of adequacy on the part of the highly-trained, accomplished and zealous Principal. Mr. C. Drieberg has always proved himself a most useful Public Officer. He is "a handy man" only second to Mr. Ellis. What would the Society of Arts, or this or that Exhibition do without Mr. Drieberg? while, as Agricultural Principal, he was never properly backed nor got fair play. We earnestly trust he will have more liberty in his new vocation as Agricultural-Inspector, and that his very useful "Agricultural Magazine" may continue to the benefit of Agricultural teachers, intelligent natives, and even Europeans all over the island.

THE PROPOSED ZOO FOR COLOMBO.

SOME USEFUL INFORMATION FROM THE MYSORE GARDENS.

(Communicated.)

We have noted with pleasure the proposed scheme for a Zoological Gardens for Colombo. It is a wonder that a city and port of such importance, the very playground of all sightseers to the East, and one so easily accessible by steamer to all parts from the globe, should so long have been without one.

A few days ago a letter reached us from the enthusiastic practical collector of wild animals, who has been for some time in charge of the Zoological Gardens

IN THE NATIVE STATE OF MYSORE

Some of his remarks are exceedingly interesting, those especially referring to the hatching of ostriches, in which he has succeeded very well, being the first person in South India who has so succeeded. The young birds we have ourselves seen, and they are very fine, healthy specimens, although born in captivity. Mr. Hughes, the Manager, at first attempted to rear them by means of an incubator, and the young ones were so hatched, but proved weakly and died when a few weeks old. The incubator used was one by Messrs. Hearson & Co., Regent-st., London. It was a No. 35 machine and would hatch from one hundred to one hundred and fifty poultry or pheasants' eggs, and was large enough to hatch ten ostrich eggs.

THE INCUBATOR

was however not made for a tropical climate, and, although for one season, when quite new, it acted well, it afterwards warped and cracked owing to the heat. Had it been made of teakwood, instead of pine or dealwood, it would probably have better stood the test, and satisfactory results would have been obtained.

The working of the machine is very simple. With each machine illustrations are supplied and also two thermometers, one of which is a long one for use in the tank, while the other is a small clinical thermometer to test the temperature of the drawer in which the eggs are placed.

To save time, warm water may be poured into the tank, and the temperature brought up to 76 degrees. The best oil should be used for the lamp, as the cheap and heavy oils smoke too much and clog the tube through which the hot air passes.

When the temperature reaches 96 the capsule inside the drawer expands and allows the hot air to pass directly upwards instead of passing through the tube: as soon as the temperature in the drawer falls below 96 degrees, the damper lowers and the air passes through the tube thereby keeping the machine working automatically. There is a screw on the top which can be screwed up or down according to the temperature required, so regulating it exactly.

The same temperature will do for all kinds of eggs except the ostrich, and the number of days varies according to the subjoined table.

	Days.	At a temperature of degrees.
Ostrich eggs	42	102 to 104
Fowl eggs	21	100
Duck eggs	28	100
Turkey eggs	28	100
Pheasant eggs	23	100

Messrs. Hearson & Company supply books at 1/0, which give full information. Nevertheless,

BIRDS NATURALLY HATCHED ARE MUCH MORE HEALTHY.

About February, ostriches may begin to lay, and the birds should then be carefully watched. If the mother-bird be seen to dig a hole, she will probably lay an egg there in a day or two. If so, the space should be enclosed with mats, so that she may be quiet and screened from the view of visitors or passers by. No bird likes to be watched or disturbed at the laying season. If the mother-bird has selected an unsuitable spot, and if a better

one is at hand, the egg should be carefully removed from the spot where it was laid, and put into the enclosed space which has been provided. In this case the old nest should be destroyed by placing thorny bushes or any other obstacle in any unsuitable spot, as often as she choses such. If the bird appear shy of taking to the enclosed place to which the eggs have been removed, it is a good plan to place her food inside the enclosure for a few days, and she will wonderfully quickly take to the eggs and settle down. If not now disturbed she will hatch successfully, as has been the case in Mysore. The ostrich lays eggs at intervals of four days; and the three young ones naturally hatched in Mysore were born on the 11th, 13th and 16th of August 1899.

One of the three died by being trodden on by the parent-bird when it was only the size of a young turkey. This was owing to a stampede of the larger birds which had been frightened. The other two young ones are now 19 months old, and are, although hatched in captivity, far finer and healthier birds than the parents. The original pair were got from Magersfontein, Cape Colony, South Africa, when full grown, and their price, including shipping, was R1,400 the pair.

THIS SUCCESS IN BREEDING

appears to be unique and has not been accomplished in the Zoo at Calcutta nor in any other Indian gardens. The enterprising Superintendent at Mysore hopes to form a company and thinks there is not the least doubt that Mysore will be the future farm, as it is the best climate for these birds. Why not also Ceylon? The breeding of these birds would probably become a source of revenue to any state. What about the climate of Haputale? And, Mr. Editor, why not utilise the Boers as ostrich farmers? Mr. Hughes writes: "In starting a farm as a paying concern there should be one male bird to four females which should then produce sixty birds a year." His information is valuable because it is not theoretical but practical, and has all been put to the proof. [Photographs of the young ostriches taken at the age of eight months can be seen at *Observer* office till the end of April; also photographs of other animals reared in the gardens at Mysore.]

Referring to the Calcutta Zoo, Mr. Hughes writes: "The buildings at the Calcutta Zoo were created at great cost but some of them are not built in a proper situation; therefore the animals do not thrive or live long. In gardens where records are kept of the longevity of the animals in captivity, great care must be exercised in the choice of building sites, which should be selected by *practical collectors who know the habits* of the animals. I have collected thousands of animals for Mr. Carl Hagenbeck, and know the Islands all over the globe where the rarest animals can be obtained."

THE MYSORE ZOO GARDEN

though small is of considerable interest, and it has just been taken over by the state. Up till recently it was a private concern.

In one part of the grounds one comes to a double railed enclosure forty feet in length by twenty feet in height. Inside the inner compartment is a large stone cage, two stones high; not dark and solid, but with an archway on each of the four sides and covered with creepers bush. At first sight all is silent and empty apparently, but as one approaches there is a strange blowing and breathing like that of angry cats; and looking up one sees a magnificent huddled mass of barred fur, and out of this glare eight fierce eyes. These are a family of four splendid tigers which were caught in the jungles within a few miles of Mysore, in October 1899, by Commissioner H Mathia of Mysore. They were caught by order of the Maharani Regent in Nepal and were then driven into trap cages. The family consisted of father, mother and two nearly full grown cubs. It was at first intended to separate them at once, but the tender heart of Her Highness was so touched by the affection they showed for one another that for a full year she kept the four at Mysore; and only a short time before the death of Her late Majesty Queen Victoria, a pair of them, male and female, and exquisitely marked, were presented to her by the Maharani Regent. The male of this pair (now in the London Zoo) measures 9 ft. 3 inches to the top of crown: but from the nose to the tail it measures 10 ft. 2 inches.

Her Highness took great interest in this

FAMILY OF TIGERS

and allowed them daily as much raw meat as they could eat. The amount allowed to each tiger daily was 16 seers which equals 32 lb. English weight. The cubs generally lay piled upon their fathers and mothers, embracing them with their paws, just as human children twine round and fondle their parents.

Referring to the size of the tiger-cage, as herein specified, Mr. Hughes remarks that that size does not give adequate accommodation, and quaintly adds, "All the Mysore cages are built according to the purse, not according to the comfort of the animals, and I feel for them very much."

The various kinds of leopards are always interesting to watch. There is the restless black panther, almost the fiercest of all the wild animals, which will tackle an animal four times its size. It is never still a moment, but always sidling round its cage, lashing with its long tail, regarding all who approach with fierce furtive eyes, and ready to spring with a snarl and a furious bite at any unwary hand stretched too near. The Maharajah's hunting leopards, with broad leathern collars round their necks, come next. They are useful in hunting large game, and have this peculiarity that they will only strike once at their quarry. However, that "once" seldom fails to be effectual.

We trust that the Colombo Zoo will before long be an accomplished fact and that the scheme will receive generous support from the Government.

S. H. E. AMYAS.

CLARK'S BOOK ON "SPORT IN CEYLON."

(*By "Old Colonist."*)

What a very excellent little book Clark's "Sport in Ceylon" is! Nothing I have ever before read on sport has so fascinated me —and I have often read all that Baker, Forbes and Tennent have said on the subject. Clark has got hold of an admirable literary style, which would adorn any subject, and which he wields with much discretion. No sporting slang there: no bombastic boasting, and *no butchery*. His work, indeed, shows him to be more of a naturalist than a so-called sportsman. I wish, however, I had got hold of such a work 40 years ago; it would have added much to the enjoyment of my life in Ceylon and I rather envy the lot of the young novice who now takes up such a safe and pleasant guide.

My only doubt is as to whether "Sport" gives a sufficient indication of the value of the book. The title has so degenerated that one is apt to fight shy of the drivel under such a heading in the Daily Press.

In my youthful days, my own notions of Sport were such as might have been inspired by Goldy's "tuneless pipe" and even now

"The gay grandsire, skilled in gestic lore,
Can frisk beneath the burden of three-score."

I too have had my elephant hunt in my day, though I never cared to tell the tale! Standing one day in the end of my verandah at Everton, I saw, right opposite, a huge elephant on the top of the Cabaragala cliff, which rises perpendicularly to a height of 500 to 600 feet.

The monster stood coolly wagging his trunk to and fro as he surveyed with evident interest the busy valley below. 'Twas a grand sight, enough to arouse the most dormant of sporting spirits.

I had an English rifle which I shouldered with an air of "who says I m afraid?"

It took me some hours to climb up through the forest, and when I did reach the rock—no elephant was there, but the fresh droppings showed where he had stood. On the whole rather relieved that my pluck was not put to the test, I took a leisurely look at old Rakwana, and then prepared to descend. Scarcely, however, had I moved from the spot, when I heard a muffled tread and crashing of branches, and sure as I m a living sinner a herd of elephants passed within easy touch of me! I stood quietly at the back of a tree within a few yards of the edge of the precipice, my heart dunting audibly till I saw the last of the herd move off towards Kukulu Korle!

I escaped unscathed, but had I read such a book as "Sport in the Lowcountry of Ceylon" I would have known better how to go about the business. I should certainly recommend every young man going out to Ceylon, whether as visitor or planter, sportsman or naturalist, to read this handy and eminently useful little book.

Mr. C., I think, rather underestimates the extent of forest in the Central Province and, as to being lost in the jungle, I wonder he does not recommend following the first trickle of water—which has been my invariable rule when everything else failed and by doing so one cannot go very far amiss, in an Island like Ceylon.

THE SCIENTIFIC EXPEDITION FROM PERADENIYA TO OUR RUBBER-GROWING DISTRICTS.

Mr. Herbert Wright, Scientific Assistant at Peradeniya, whom we stated in our issue of 16th ult. to have started on an important tour in the Western and Sabaragamuwa Provinces, has now returned. Though reluctant to give details of his mission until he deals with it officially, we have elicited from Mr. Wright that he has obtained important results in connection with the yield of milk in the indigenous Palaquium trees known by the Sinhalese names of "Kirihembeliya" and "Mol-pedda." The Malayan species of Palaquium have hitherto been the source of the different sorts of guttapercha; but these are now becoming extinct, owing to the wasteful method of cutting down the trees for the purpose of collecting the latex. The affinity of the Ceylon flora to that of the Malayan has suggested that our species of Palaquium might also yield gutta of a marketable value, a supposition which now seems justified. From the copious material for detailed and microscopic investigation, which we gather that Mr. Wright has brought back with him, it appears, that there are at least two species of this tree in Ceylon which are deserving of attention from an economic point of view. These have been found to yield, in point of quantity, even a greater amount of milk than most Para rubber trees in Ceylon. Most important of all, however, is the fact that Mr. Wright has found, by a certain method of tapping, that these yield the latex freely without being felled, which not only saves labour, but also the trees, an obvious advantage over the Malayan method.

Asked as to the nature of the soil in which the trees are found in their natural state, "practically nothing but wet sand," is the reply. Their slow rate of growth, we are informed, however, is against their becoming an adjunct to planting products. Many other species of the family Sapotacæ are characterised by the presence of milk, though but few are as yet of commercial importance. A species of Mimusops in the West Indies furnishes what is known as "Gum balata."

TEA PLANTING IN CAROLINA, U. STATES.

The American *Review of Reviews* for March has an illustrated article by "Leonora Beck Ellis" on American Tea-Gardens, Actual and Possible. Most of the illustrations are familiar having done service in some of Dr. Shephard's pamphlets before now. Of course, the paper has to do with Pinehurst; but we learn that, so far back as 1804, a French botanist, Michaux, planted the first tea bushes

in Carolina, of course as ornamental oriental garden plants. The Agricultural Department first tried tea culture in 1881; but the experiment was abandoned in 1883. We ourselves saw a very fine tea bush in the Garden of the Agricultural Department, at Washington, in 1884.—Then we learn from the *Review* how Dr. Shephard took up the cultivation; but no mention is made of the part played by an old Ceylon planter—Mr. Henry Cottam—who, in the course of his multitudinous wanderings, found his way to Pinehurst, and we believe helped Dr. Shephard in some of his early operations and led him to order the *Tropical Agriculturist*. To show that there is an idea of Dr. Shephard's 60 to 70 acres proving the beginning of a great industry, we quote as follows:—

"If America were now raising her own tea, from 13 to 15 million dollars per annum would be kept in this country that under present conditions goes from us into foreign coffers. The sum is modest when compared with those represented by the great staples of America—wheat, meat, and cotton. But it is quite large enough for us eagerly to desire to keep it at home, especially when we reflect that if kept here it would go to support the tillers of the soil in the agricultural South. Over half of these snug millions of good American money we now send to John Chinaman, who raises 49,678,577 pounds of tea out of our average yearly consumption of 92,782,175 pounds. Would not this money make better count for civilisation in building up the homes of our poor white and black toilers? In regard to our supplying other markets than the American, we shall at present venture nothing further than the statement that it is by no means out of the range of possibilities for us ultimately to reach and claim our share also in them. At this a laugh may go around; for it cannot be denied that one successful tea-garden in all this great country seems a fragile base to build great expectations upon. But hark back to the handful of Smyrna cotton seed sown in a Virginia garden in the first quarter of the seventeenth century and carried thence, after many unsuccessful generations of the weed, to the Carolina and Georgia plantations, which seemed to have no need of the insignificant new plant, as their tillers were finding ready wealth in tobacco, rice, indigo and the silk mulberry. At the end of one hundred and fifty years from that first planting of cotton, its harvests were still only slight gleanings from odd corner patches, a purely domestic crop, and by no means a general one. Yet today, a century and a quarter later, undertake to eliminate this weed from the agricultural resources of the South-Atlantic and sister States, and what a transformation must be wrought in the farming life of the section which produces three-fourths of the world's annual cotton crop—what an upheaval, indeed, in the commerce of the world?"

But practical men must be satisfied there is not much in the Pinehurst experiment so far as wide extension goes, when they read the conclusion of the article before us:—

"The question of labor has been dealt with quite as skilfully as the natural problems of heat and moisture; and while it still costs something like eight times as much to have a pound of tea picked in South Carolina as the same service would demand in Asia, yet much of this comparative loss has already been balanced—and much more it is hoped will soon be balanced—by greater productiveness in the field, by the substitution of machinery for hand labor in the factory, and by the manufacture of varieties of teas which, from inherent chemical causes, cannot be brought from the Orient.

"We may not dwell now upon other points, interesting as they are. The practical results of these ten trial years are before us, and tea culture on a business basis is an actuality in the United States. Already rivals of the Pinehurst gardens are being inaugurated in a quiet way—one in Louisiana—another in South Carolina, a third at the Georgia experiment station. Dr. Shephard writes, under recent date, that he has this year increased his tea acreage, outside of the hedges in his park, from 60 acres to 75 and that the crop of 1900 is decidedly larger than in any previous year. Nor did he raise the price of his teas when the Eastern varieties recently went up, a fluctuation due rather more to the short crop in Japan than to the Chinese entanglement.

"Desiring to popularize the American product, Dr. Shephard is holding his prices just where a careful calculation of expenses shows he can afford to fix them. His actual cost of production and preparation for market is now 27½ cents per pound. He hopes to reduce this shortly to 14 cents. At present, the retail price of the 'Standard Pinehurst Black Tea' is $1 per pound. The margin between these figures of cost and selling price must, of course, be shared with the various middlemen who form the chain from producer to consumer, but even after the division a fair portion is left to the tea gardener. The wholesale selling-price, at a conservative estimate, will average up to 50 cents a pound, allowing the producers a profit of 22½ cents per pound, even at the present high cost of production.

"Dr. Shephard's 'Rose Garden' of Assam-Hybrids may be taken as a fair illustration of the possibilities in this new industry of our section. The Rose Garden is a little less than an acre in extent, and was set out in 1890 with nearly 1,000 plants. In 1892 it yielded 56 pounds of green leaves. Nearly doubling its yield every year since 1893, except in 1897, a year of prolonged autumnal drouth, it closely approximated 1,200 pounds in 1898, an amount of green leaf which affords about 300 pounds of the Standard Black. Here, then, was a profit in 1898 of nearly $70 to less than an acre. The present year the productivity is much increased, while the price remains the same. It should be noted in this connection that the most profitable crops in Japan are gathered from plants two hundred years old.

"Again, if the plants in the 'Rose Garden' were placed at shorter distances apart, as is the rule in the Orient and now at Pinehurst, the yield would be proportionately greater each year. But make the most conservative estimate and say 400 pounds cured to the acre, at a profit of only ten cents per pound. Yet, is $40 an acre clear profit regarded as bad farming in this section? We merely hint at the possibilities of expansion when we add that on many estates in Ceylon and India more than 1,000 pounds to the acre is the annual harvest, and that the highest product per bush in those countries has already been reached at Pinehurst. The tea has been a ready seller at $1 per pound, and the demand for it, stimulated by a growing acquaintance with its purity and its delicate and pleasing flavor, is increasing, so dealers testify, more rapidly than the Pinehurst gardens can expand. The lesson

is left with the progressive horticulturists and farmers of the South."

So long as South Carolinians are ready to pay a dollar (4s 6d) a pound for a novelty, good and well; but they must soon know that quite as good Ceylon or Indian tea can be supplied on the spot, duty paid, for 2s a lb. or at most 2s 6d, leaving a fair profit to dealers. And that being the case it is impossible to treat Dr. Shephard's as other than an interesting amateur experiment, worthy of support for the employment it gives to coloured children, but by no means able to compete, in a commercial point of view, with tea-growing in the Orient.

THE DECAY OF COPSE CULTURE.

Not the least hard-hit branch of the farmer's industry is the cultivation of the copse-wood that forms a conspicuous feature in the landscape of many of the Southern counties. Consisting of hazel, ash, alder, and other saplings clustering thickly from a close-cropped stump, the wood of these copses furnished till late years a considerable revenue. The trimming was done on the spot during the cutting of the copses, which were then left to themselves for a term of years till they had grown again; and the trimmed sticks were largely used to supply the wooden bands which formed the binding of the small rough casks in which sugar and other foreign produce was distributed about the country. Now, however, merchants have largely ceased to import their sugar in quantities too bulky for retail distribution; and with this improvement the need for repacking into smaller receptacles has disappeared, and with it one of the chief markets for the copse-wood. Add to this the increasing rarity of labourers skilled in trimming it, and the fact that, though this operation only comes once in several years, it is a lengthy and expensive business, and we have the reasons why at the present day the copses are being left more and more to run wild, and their produce used when eventually cut down chiefly as pea-sticks and firewood, which is all it is often fit for if not cut at the right period.—*Globe*, March 16.

LARGEST TROUT IN CAPE WATERS.

Some few years ago Messrs Halse Bros. obtained, through the late Mr J D Ellis, a number of trout fry taken from the Hatcheries, Pirie Forest. These were carefully placed in a magnificent dam—one of several on the estate—and for some time nothing was heard of the result of the experiment. Suddenly the hearts of Messrs Halse Bros. and three enthusiastic gentlemen in King were gladdened by the capture of three-year-old trout, weighing respectively 7½lb, 8½lb, and 8lb. 2oz. Now, again, "Carnarvon" has topped the record. On the 20th instant a magnificent trout (four-year-old) was caught in the dam, weighing 14lb. before cleaning, and a trifle over 12lb. after, the length being 31in. Of this Messrs Jakins Bros. have turned out a splendid photograph.—*Natal Mercury*, March 16.

TEA BROKERS' CIRCULARS AND OTHERS.

I notice your contemporary is exercised over the diversity of opinion shown in the various tea circulars. This is surely rather a *naive* way of looking at things. Those who write the circulars are men of flesh and blood like the rest of us and their views are tinged not only by their dispositions, which may be either optimistic or pessimistic, but also by their interests. It may not be generally known in Ceylon that many of the selling brokers have "buying-over" departments. Far be it from me to suggest that this operates against the interests of the owner of the tea. In some instances the reverse may be the case, for the manager of the buying-over department may be able to give an order above the market price. Still if the writer of the circular knows that his firm has a large stock of, say, low-priced Ceylons, he is not very likely to crab common Ceylon tea. As regards China tea, many of the people in Mincing Lane worked in this for years and some of them made fortunes out of it. It is not surprising, therefore, if some of them have a hankering for the good old times when a cargo of tea could sometimes be sold at an all-round profit of a shilling a pound. I think, however, I am expressing the opinion of the vast majority when I say that unless Ceylon and Indian teas become considerably worse even than they have been for the last six months—and there have been some pretty bad ones about—there is no chance of China teas again getting a hold in England. Then there are the dealers' circulars, and very well written some of them are. But it is well to bear in mind that they are written for the benefit of the dealers' customers. If you read in one of them an eulogium of (for instance) Java teas, you need not run away with the idea that the writer has any particular admiration of our brother planters in Java, or even that he is a man of pro-Boer proclivities. Not at all. You simply make a mental note that Messrs. So-and-So have a stock of Java teas and would not be averse to selling them at a reasonable profit.

As the time of the Budget draws near, it is the custom with many dealers to write to all their customers, pointing out that there is a chance of the duty being raised and that it would be a wise precaution to lay in a stock of tea, of which at the moment they have an exceptionally fine selection, etc., etc., etc. Last year the grocers, and others who took the advice so suavely offered them, did well for themselves; this year we hope things will be different; but, in any case, the dealer makes his profit.

No, as things are done in London, I am afraid we shall have to wait for the millennium before the views and ideas expressed about tea are in entire agreement. There is an old saying: "Tell me the company a man keeps, and I will tell you the character of the man." One might paraphrase it and say: "Tell me the business a man does, and I will tell you the character of his tea-circular."—Local "Times" London Cor.

[One of our principal points is overlooked in the above, namely, how is it that with good Ceylon tea so cheap, the export of "China" tea from London keeps up and even showed an increase at the time we wrote? Were we not all assured that when 'Ceylons' fell below a certain price, which they did long ago, they would sweep China black tea out of America and the European continent.—ED. *T.A.*]

BANANA FLOUR.—Attempts are being made to introduce banana flour into Northern markets, which is manufactured on a large scale in Colombia and Venezuela, as well as in Central America. The process of making it consists in stripping the fruits of their skins, cutting the bananas into slices, and drying the slices either in the sun or by artificial heat, after which they are ground and sifted. Thus treated, a bunch weighing fifteen pounds will yield three pounds of flour.—*Grocers' Journal*, March 23.

THE CONDITION AND PROSPECTS OF TEA:

NEED OF GOOD MANAGEMENT AND OF ABANDONING UNPROFITABLE FIELDS.

(*By a Specialist.*)

During the first quarter of the year, the tendency throughout the country has been towards more *careful plucking*. On many estates *fine* plucking has been resorted to; but it cannot be said that this is in *general* favour, the feeling being that, if care is exercised in the selection of the leaf gathered, and no hard or coarse leaf is allowed to enter the Factory, things would soon right themselves. My own conviction is that *careful* plucking, as distinguished from *fine* plucking, is all that is necessary, and if it is continued, it will very soon have an appreciable effect on the output. It may add to the cost of plucking a little, but a better class of tea will be produced; and if India does not look out, we shall be running her very close as regards quality. I do not, of course, mean to say that we shall be able to compete with the better run of places in Darjiling and Assam; but the bulk of Indian teas consists of invoices such as we should have little difficulty in equalling, while cost of production would be in our favour. It is more than ever important, however, that the very best possible attention should be directed towards making the most of all the advantages that Ceylon possesses for the successful working of estates, and we may be sure that

"MANAGEMENT"

will be a very important factor in the near future, more so than it has been in the past. It is quite possible to concede this without saying anything disparaging about planters as a body. It is simply this, that circumstances have arisen which call for *special* efforts on the part of our managers, and unless I am much mistaken, it will be found before long that individuals will be achieving reputations for themselves, and passing over the heads of those who are inactive and do not move with the times. There has probably never been a better opportunity for men with the capacity for dealing with difficulties to come to the front and show us what they can do.

Carefully conducted experiments both in plucking and manufacture may bring to light much that is now hidden and obscure, and there is ample prospective reward for those who are able to distinguish themselves on these and other lines.

Referring to the general question of

"OUTPUT,"

I have all along (as you know) regarded it as a mistake to "rest" tea in the manner indicated by Messrs. Rosling and Rutherford, nor am I in favour of curtailing the yield from estates on the lines laid down by the London Association. Neither of these schemes, even if generally adopted, would be likely to ensure anything more than temporary relief. A better plan would be for estates to *abandon outright* their unremunerative fields and not allow them to be a burden on areas which can be profitably cultivated, as they frequently are. No doubt there are many estates where all the land that is kept up gives good paying returns; but there are, on the other hand, a number of places where the plucking area might well be restricted without lowering profits or adding in any way to the cost of production.

The relief to the market, if some such plan as this were adopted, would be very appreciable and it would rest on a thoroughly sound basis. "Abandoning" is obviously better than "resting." The latter would constitute a permanent menace to the enterprise, making it difficult to sell estates, or shares in Companies; for who would invest in tea property if it were known that a large acreage of land was resting, waiting in fact in readiness for an improved range of prices to place its produce on the market?

The London people were evidently misled to some extent by the telegram sent home by the Planters' Association after the meeting of the 17th of February. No doubt they regarded the message as indicating that the "resting" scheme had been generally approved, whereas, as a matter of fact, it had merely received the benediction of a very unimportant majority of planters representing not much more than a fraction of the capital of the country. Telegrams such as these should not be lightly sent, but fortunately in this instance no great harm has been done and absent proprietors will have learned long before now from other sources that the "resting" scheme has never received any wide support in this country. Nevertheless, the agitation will have done good and a distinct check has been given to extensions as well as to the liberal use of manure. With the lesson of last November before them, men will think twice before they again flood the market with poor liquoring teas. Prospects for April and May do not, so far as I can judge, point to anything very exceptional in the way of yield; but there will be a good lot of stuff going forward all the same.

(*By another Specialist.*)

The exports in the first quarter give little clue; for in January, at any rate, the bulk of tea exported was made from leaf plucked in November and December, 1900, before the edict had gone forth to make better tea. Where very close plucking was the order of the day up to January 1901, I believe the altered style reduced the tea made 20 per cent; where men had not gone to such violent extremes as 700lb per acre, I fancy the reduction brought about came to 10 per cent, falling down even by very careful managers to 5 per cent, had weather, style of overtaking pruning, etc. been the same.

In many districts weather has, in the first quarter of 1901, been decidedly showery, which has made the tea flush better than it would have done had the weather been very dry in February and March; but the knowing ones are of opinion that there will be no large rushes of leaf in April and May, as would have been the case if we had a drought in February and March. I believe, therefore, even allowing for a natural in-

crease in young and manured tea, the exports for Ceylon at the end of June will be less than in *1900* by, say, 5 per cent. If we are not tempted to go in for coarse plucking in the last *six* months of the year, there will certainly be 7 per cent less tea exported in 1901 than in *1900*.

Green teas.—Mr. Mackenzie, I see, wires 'a better feeling in the market.' About time! I only hope the wish is not father to the thought. The feeling is now pretty general that our Commissioner ought to reside in America and must be able to advise his constituents, the Thirty Committee, to better purpose than he has done during the last *twelve* months."

NATAL BOTANIC GARDENS.

The Report for the year 1900, by J Medley Wood, A.L.S., has reached us. There is a good deal of interesting reading, especially to Natal Colonists. Here is a reference to the way a very dry year affected fruit crops :—

We have been in the habit of sending out from year to year from 4 to 7 tons of Mangoes, plucked green for making chutney, &c, but last year none were gathered and but very few are left on the trees. The crop of Lichis also was a complete failure, and all other fruit trees suffered in a similar way.

We take two further paragraphs showing how certain tropical products will not grow in the "Garden Colony" of South Africa :—

Cola acuminata.—This is the tree which produces the Cola nut of commerce, and I regret to have to report that all the plants are dead; the soil and climate do not appear to be suitable to the growth of the tree

Theobroma cacao.—I regret to have to report that all the plants placed in the open ground have since died; two were reserved for the conservatory and these are alive and healthy. I have never thought that this plant would succeed in the colony as our climate is not sufficiently tropical for it; in the summer it is warm enough but the cold winter months are not suited for plants of this kind. I have several times had sent to me fruits which were said to be Cocoa grown in the colony, but they have always turned out to be those of Carolinea, or Pachira alba, a plant in no way related to the Theobroma.

TEA PROSPECTS.

(Extract from Geo. White & Co.'s Annual Tea Report, for 1901.)

PROSPECTS.—Although the present Season closes without any near prospect of relief, so far at least as the value of common and inferior grades of all kinds are concerned, the position can hardly be considered as devoid of brightness in the future, as in the nature of things it will work out a cure for itself, though in doing so individual interests may suffer. Production has overtaken immediate requirements, but the Trade is a sound one and if given a respite from the burden it has lately had to bear in the way of excessive supplies it should right itself ere long, partly through the expansion of business fostered by low prices. It is to be hoped also that the action to restrict output taken by the Committee appointed by the Indian and Ceylon Tea Associations may bring home to Directors of Companies, Owners, and Managers of Estates generally, the absolute need of serious attention to this matter, and, although it may be difficult to formulate any scheme which can be universally adopted, that all will strive towards the desired end. In many cases it may be feasible to gather the leaf more quickly, i.e., without letting it run so long. In others finer plucking may be resorted to, or portions of properties which do not give an adequate or satisfactory yield may be allowed to lie fallow. Planters in India specially may elect to finish their Season rather earlier and thus curtail the crop, while on some gardens in Ceylon more rest may be given to bushes where stimulating manure has been used. In different ways therefore the same object may be kept in view, the result being that the Industry will assume a healthier condition and that the cloud which now hangs over it will gradually disperse, leaving behind a lesson which should not however be forgtten for many years to come.

While there is much to be done by Producers, Distributors are not backward in taking their part and progress is being made in this respect, though slowly in some quarters. The Continent of Europe, and especially Russia, is consuming more British-grown tea every year, consequent on the persistent efforts of exporters both in this country and at the ports of origin. In Canada and the United States of America many are engaged in pushing the trade, and so in spite of a number of drawbacks the produce of India and Ceylon is gradually being more used in other countries than our own. If the manufacture of green teas suitable for the requirements of our Trans-Atlantic cousins should prove a success, as is confidently hoped by those who have taken it up so earnestly, a further important step will have been gained and one which will afford great relief to all concerned.

Another matter which should engage notice is that of encouraging retail sales locally, and it does not seem beyond the bounds of possibility that herein may be found an outlet for coarse leaf which might be sold at such a figure as to induce the natives to be large consumers and yet be remunerative to growers. In this connection it may be noticed that a considerable business is at present transacted by South Indian Estates, chiefly from the Nilgiris, whence the people all along the West coast up to Bombay are principally supplied. A certain amount from Ceylon too also finds its way there. This is done entirely through native shopkeepers and there is no doubt that the existing demand in the bazaars might be much increased by the offer of cheap tea in small packets. It is estimated that already 4¼ million lb are disposed of in India alone.

MANUFACTURE.—With reference to the treatment of the leaf, what we wrote last year seems still applicable, viz. :—"Taking into consideration the larger area coming into bearing in some districts, it would seem policy to avoid very coarse plucking and the manufacture of undesirable sorts which foster a low quotation here and tend to glut the market. Where briskness, pungency, or full-bodied liquor are attainable, every effort should be put forth to secure these characteristics. Plain featureless teas are more or less neglected, especially in the very busy months, and good appearance without sterling cup no longer satisfies even the Continental buyers who used to take that style of China Congou."

There have been occasional instances this season of breaks tainted apparently by eucalyptus leaves (where these trees are cultivated) having been

allowed to find their way into the picker's basket, and becoming mixed up with the tea during manufacture, which frequently leads to less competition among buyers, and should be guarded against.

The number of "cheesy" lots has again considerably decreased, due possibly to more thorough final firing, and also to the extended use of patent packages (especially of those lined with thick lead) of which such a large portion now arrive. Partly due to weak wood, but more often to carelessness in loading on board the steamers, damaged packages have given much trouble recently, involving loss in weight and necessitating an allowance to buyers. Some economy has been effected by slight reductions in warehouse charges, and also by the adoption of an improved system of weighing by the Customs.

THE OLDEST RUBBER PLANTATION.*

In the *Indian Forester* (vol. xxiv., p. 160), I presented some facts in relation to the oldest India-rubber plantation in the world, which is located on the Pamanukan-Tjiassem estate, in the Residence Krawang, in Java. At that time I wrote that the plantation came into existence in the year 1872, basing my information on personal conversation with the owner of the estate, but the opinion of the present chief overseer, Herr van Henkelom, seems to be that the plantation dates from the year 1864.

The young plants of *Ficus elastica* were obtained from the adjacent forests, by cuttings of branches, or by marcotting the uncultivated trees, an operation to which the inhabitants of Java frequently resort. The before-mentioned rubber trees are especially adapted to the process of marcotting. All that is necessary is the removal of a strip of bark ⅔ centimetre wide, and to bandage the wound with earth. After about fifty days roots will appear through all sides of this ball, which can then be cut off. It is advisable before planting these young plants, which are about ½ metre in height, to place them, or rather nurse them, in rich, well-shaded soil for a period of about fifty days, in order to heal the cut thoroughly.

It is my opinion that the original cost of this plantation on the Tjiassem estate was not very much, because the *Ficus elastica* was planted about 8½ yards apart each way, or 72 to the acre, within coffee plantations which were no longer productive, and required not much cultivation. I estimate the cost of the plantation at about $7 per acre. Altogether 72½ acres, embracing 5,200 trees, were planted.

The first tapping was done in 1886, and the following figures will give the details :—

Years.	Pounds.	Average ounces per tree.	Value.
1886 ..	5,512	17	$2,880
1887 ..	4,954	15	2,592
1888 ...	1,514	4	792
1890 ..	3,307	10	1,728
1891 ..	6,113	18	1,858
1892 ..	5,992	18	1,229
1895 ..	3,197	10	1,973
1896 ..	3,113	10	1,561
1897 ..	6,731	21	3,648
1898 ..	6,731	21	4,213
Total..	47,164		$22,474

* This letter is reproduced from *The India Rubber World.*

Tappings could not be made in every year. In thirteen years (in three of which the trees were not tapped) a total of 47,164 pounds was harvested, an average of 3,628 pounds per year, or 10 ounces per tree per year. During the four years 1895-98, the average was 4,943 pounds, or 15 ounces per tree. The yield per acre, therefore, from 1886 to 1898, averages 50 pounds, and from 1895 to 1898, 68 pounds.

The figures given above, by the way, in the column headed "Value," must be understood as referring to the income to the planter after deducting all expenses, not only of harvesting the crop, but also the initial expenses and the yearly expense for care of the plantation. From the information supplied to me in regard to the prices obtained for the rubber, I should infer that the yearly expense for the last four years covered by the table had amounted to an average of $12 per acre per year.

An analysis of the figures above given will show an average yearly nett profit of $39·30 per acre, the figures for 1898 showing a profit per acre of $58.

With respect to the possible yield from *Ficus elastica*, it may be mentioned that Herr Mulder, in Sudimara (West Java), obtained in 1897 from three trees 48 kilograms, and 20 months later from the same trees 45 kilograms. This is respectively per tree 35½ pounds and 33 pounds.

A. H. BERKHOUT,
Late Conservator of Java Forests.
Wageringen, Holland.
—*Indian Forester* for April.

TEA REFORM.

(To the Editor of the *Home and Colonial Mail.*)

Sir,—What I would suggest is that the Tea Associations of India and Ceylon be organised on more comprehensive lines—that all tea proprietors, whether public companies or private concerns, and their agents, become members of one or other of those associations ; that suitable persons from among them be elected and appointed to act as a general committee, to whom questions relating to the tea industry should be referred, and upon their report on any important question being submitted, a joint meeting of members of both associations be convened for the purpose of approving or of modifying, if necessary, such recommendation, and when finally approved and accepted that decision to be loyally observed by all members.

At present these associations appear to represent only a portion of the tea proprietors of India and Ceylon. To make them really effective every producer should be a member. At present their views and recommendations, however sound and excellent, are merely an expression of opinion, which has not the weight and force of authority as of an association representing the whole body of tea producers. This is not as it should be.

Reform is also much needed in other directions. A great deal of complaint is heard of the general low class of teas manufactured during the past few years. It is a strange coincidence that with the introduction of machinery quality generally has fallen in the same ratio. In this connection I do not lay the blame on the adoption of machinery, but on the practice of working up a coarser class of leaf by machinery than could be done by hand, in order to increase output.

The Use of Fertilisers.—In Indian plantations very little is done in the way of applying fertilisers to tea plants. The consequence is that in

the older portions of a garden the quality of leaf deteriorates, and a low class of tea is produced. Can this be surprising when for decades gardens are plucked season after season without an ounce of manure of any description being applied to the soil to compensate for what has been so persistently taken from it?

What is surprising, however, is that in Ceylon, where manuring is a great feature in cultivation, the average value of the tea produced is lower than that manufactured in India, where practically no manuring is done. This fact would argue that the effect of fertilizers is turned to account in Ceylon by increasing quantity rather than by improving quality by a system of plucking coarse overgrown leaf. This would go a long way towards accounting for the large proportion of coarse teas which have done so much to overstock the market.

There is yet another practice which accounts for a large quantity of coarse tea—i.e., the undue prolongation of the plucking season. I know, as a planter, how anxious every manager is to avail himself of every obtainable leaf towards the close of a season to enable him to get nearer the quantity estimated to be produced, but it is at the best only a low class of tea with an autumnal flavour, the product of a plant whose life energy is sapped by the plucking of leaf at a time long after the tea bush should have been at rest—recuperating itself—it left unplucked.—Yours truly,

JAMES HODGES.

4, Birmingham, Mareh 19, 1901.

THE IMPERIAL TEA DUTY.

TO THE RIGHT HONORABLE THE SECRETARY OF STATE FOR INDIA IN COUNCIL.

MY LORD,—I am directed by the Indian Tea Association, London, to address you on the subject of the late enhancement of the Import Duty upon tea, with a view to your urging the Chancellor of the Exchequer to reduce the duty to its former level of 4d per lb.

The Industry which this Association represents, though supported by many millions of British Capital, is carried on in India, and is thus, perhaps, outside the sympathetio consideration of the Chanoellor of the Exchequer. Indian interests are, however, especially within your Lordship's cognizance and protection, and the Association ventures to hope for your sympathy and assistance in the present highly critical state of the Industry.

That Industry has brought wide and unhealthy wastes under cultivation, it supports several hundreds of thousands of native labourers, and it makes a material contribution to the Land Revenue of the Empire of India. It holds an important position in Northern Bengal and Southern India, and is the very backbone of the well-being of the Province of Assam. Moreover, after some vicissitudes it has proved financially a success. The Industry for a considerable period prior to 1897 showed a steady prosperity. It was found to return to English investors regular, and in some cases liberal, dividends. This prosperity naturally attracted further capital, which was employed in making additions to the area under Tea.

These extensions were perhaps in some cases unduly large, but they would have had no serious effect upon the well-being of the Indian Tea Industry, but for the occurrence of two grave events.

The first of these events was the action taken by the Government of India by which the exchange value of the rupee was fixed at about 1s 4d. Without entering into the question of the effect of this action on the country generally, I am desired to point out that the policy adopted has undoubtedly resulted in heavy loss to the Indian Tea Industry. The artificial enhancement of the rupee has, in regard to Tea, greatly increased the cost of production, and has thereby reduced the margin of profit to an extent which can hardly be conceived. But for the very serious increase in the cost of production caused in this way, producers would now be able to accept with small risk of loss, the low prices of Tea at present ruling.

The second event was the addition last year of 2d per lb to the duty, which is proving most injurious to the producers of Indian tea. The increase in the duty cannot fail in one of two things: it must either, by an increased price exacted from the consumer, check consumption, or, if not paid by the consumer, it must come out of the pocket of the producers. The result so far appears to be that the increase has materially checked the regular expansion of consumption, and at the same time thrown upon producers the payment of a large share of the additional duty.

These two events have so seriously affected the Indian Tea Industry—the first by raising the cost of production, and the second by reducing to the producer his net profit—that, coming as they do on the top of the increased production, they have brought the Industry into such straits that at the present moment but few tea properties can be carried on without loss.

It is hardly necessary to point out to a statesman how much the failure of a large proportion of the Indian Tea Industry is to be deprecated. The public revenues both of Assam and Bengal are much interested in the prosperity of Tea, and if, as seems probable, many estates must be closed up, the distress to the labourers employed on them will be very great. Moreover, I am to urge upon your Lordship's consideration that, both for the United Kingdom, where capital is ever seeking for new channels of employment, and for India, where capital is greatly needed, it would be a mistaken policy to allow the one Indian Industry, into which private capital has flowed freely from this country, to be crushed in its hour of weakness and difficulty by the addition of heavy State burdens.

The Association desires to draw attention to the very heavy percentage which the Duty on Tea now bears to the wholesale price of the article. In 1881 the average price of Indian Tea in London was 1s 5d per lb., the Duty being then 6d per lb. (about 35 per cent). In 1891 the average price was 10½d, the Duty being 4d, or about 38 per cent. During the current season the average price has been 7⅛d, and at the present moment it is about 6d, while the Duty is also 6d, or 100 per cent. on the average price. Large quantities of Tea are now being sold at less than 4d per lb., the Duty here being 150 per cent. Accompanying is a statement showing the average price of Tea from the Tea Districts of India, giving the above figures in the form of a comparative statement.

There is one further point to which the Association respectfully venture to draw your attention. While agreeing with the Chancellor of the Exchequer in thinking that "a very large class of the population who do not pay income tax, who do not consume alchol, and do not smoke," should contribute towards the expenses of the South African war, they do not consider it to be equitable that Tea alone, of the commodities used by that class of the people of England, should be singled out for an increase of Duty. It seems to the Associat on that there are other commodities more capable than Tea of bearing increased taxation—Cocoa, Coffee, and Sugar for instance. The Duty on Cocoa, the consumption of which has largely increased of late years, varies between 1d and 2½d per lb. for different qualities, that on raw cocoa being 1d. The quantity of raw cocoa entered for home consumption in 1879 was

10,111,526 lb. as against 37,750,000 lb. in 1900, showing an increase of 270 per cent, while during the same period the consumption of tea rose from 160,500,000 to 249,750,000 lb., being an increase of 55 per cent only.

The duty on coffee, which has an average value of 8d per lb., is 1½d per lb., or only 25 per cent of the duty on tea, with which article it competes as a beverage.

Sugar at present contributes nothing to the Exchequer, but a duty of even ½d per lb., which could hardly be felt by consumers, would realise, it is calculated, about £6,750,000.

My Association have endeavoured to show in this letter that the increased duty has struck their Industry heavily at the very moment when, from other causes, it was least able to bear up against such a blow. They now venture to pray your Lordship to press upon the Government the serious nature of the crisis in which the Indian Tea Industry is involved, and the disastrous effect upon it of the continuance of the present high rate of duty.—I have the honour to be, My Lord, your obedient servant, ERNEST TYE, Secretary.

THE BAHREN PEARL FISHERIES.

In the centre of the broad V-shaped bay, that separates El Katr from Turkish El Katif, lies the object of much solicitude, viz. the Island of Bahrein, famous throughout the world for its pearl fisheries which rank with those of Ceylon. The island is thirty miles long and from six to nine miles broad. The pearl fishing at Bahrein lasts according to an Indian report from June to October, and it is pursued not only at Bahrein but along the entire Arabian coast. The Bahrein banks, stretching for a length of four to five leagues are, however, the richest and most certain. At the season of the fisheries some 4,500 boats of every size and rig may be seen, all busily employed. They carry from five to fourteen men each, and the total number of hands engaged is said to be 30,000. The scene is one of the greatest picturesqueness and animation. Like most of the gulf ports and trading settlements, it was taken early in the 16th century by the Portuguese who established a station there and at El Katif, to ensure a monopoly of the pearl trade. When the pearls have been picked out of the shells they are handed to the master of the boat who proceeds to sort them by the manipulation of a triple set of brass sieves pierced with holes of different diameter. The pearls that are unable to pass through the largest sieve are called "Ras," the residue of the second sieve are "Batin," while the resulting contents of the third sieve are known as "Dzel." Made up into separate batches, according to their classification, the assorted pearls are then sold to the pearl merchant upon an intricate scale of values, depending upon the shape, colour, specific gravity, and size. The merchant re-arranges them in small packets and despatches them to the Indian market whence a great many go back again to Arabia and Persia. Generally speaking, the Bahrein pearls are not so white as Ceylon pearls but are larger and more regular in shape; while they are said to retain their lustre for a longer period. The Ceylon banks require to be carefully watched and fishing is only permitted by Government at various periods. On the other hand, the Gulf banks give no indication of a failing supply.—*Journal of the Society of Arts*, March 15.

THE AXE AND THE TREES:

A REVIEW OF THE WORLD'S TIMBER SUPPLY.

Timber for ordinary building is dear at present, a fact which renders the public rather more attentive to the voice of the professional forester than it generally is. The figures and areas dealt with by experts in this art are generally so large that they are looked on as rather outside the range of practical business. But the shrinkage of the world is bringing all its "timber properties" into reach. Their sites, boundaries, and contents are all well known, with one notable exception, that of the great tropical forest which belts the globe; and all nations and languages—the civilised ones, that is to say, for the savage, like the peasant, is always the enemy of trees—are beginning to take stock both of the waste and extravagance of the past and of

THE PRINCIPAL LEFT INTACT FOR THE FUTURE.

Among the latest lights on this subject are a paper read by Dr. Schlich before the Society of Arts on the outlook for the world's timber supply, the Reports of the Forest Commissioners of the United States, the handbooks of the New South Wales Government, and a paper by Mr. Alder Anderson in *Pearson's Magazine* for February on "Russian Imperial Forestry." Most of the demand for European timber has been met hitherto from Sweden and Norway. But this supply is not sufficient, and the Russians are getting their forests into order to meet the coming demand. Their autocratic Government has passed Forest laws almost as strict as those of the Norman and Anglo-Kings, with this difference, that, while the latter laid an embargo on private lands, and forbade the owners to cut down their trees that the cover for game might remain, the Russians forbid private owners to cut down their timber except under Government inspection, and recognise no absolute ownership in trees except by the State, in

order to protect the forests themselves. They affect to regard the woods as part of the balance of Nature, which must not be disturbed to the possible detriment of the community. Parts of the steppes are being planted, and all woods cut down are at once replenished with a suitable stock. The general aim of the Government is to bring the line of the woods further South, where they will be useful to protect the corn-growing plains, as well as nearer to the navigable parts of the great rivers pouring into the Euxine and Caspian.

DR. SCHLICH'S OUTLOOK

over the world's forests is not only comprehensive but detailed. He knows, so to speak, where the shoe pinches, and shows the present uselessness of great areas of wild timber for the wants of the hour. All Northern Siberia is covered with wood,—but it is too far off for transport. The United States' lumbermen have been so wasteful that the Government have had to take over the woods and limit the output. It is impossible, he thinks, for the United States to go on for any time spending the capital of their trees. For some years thay have been using 33 per cent more timber annually than their woods can replace by natural growth. He is probably rather too pessimistic on the subject of Canada. That is, except the prairie region and the barren lands, one immense forest or wood. It is the perfection of a timber ground, for all through these forests there are lakes, rivers, and streams without end, almost naturally connected, to transport the trees by the only means which pays in the timber business, viz., by water. The Dominion now draws £700,000 a year from these forests, which cover with spruce, pine, maple, poplar, and oak a region nearly as large as the whole of the Indian Peninsula. The corn-growing region seems already marked out by the natural absence of forests. The prairies of Manitoba are already clear, so that the ground on which a natural crop stands ready need not be ravaged to make room for the first necessity,—bread. Mining and manufacture are increasing in the Dominion, and with a concurrent demand for timber, which will be a source of revenue, there is every reason to think that the

CANADIAN FORESTS WILL BE AN IMMENSE ASSET

of the best kind. Among the paradoxes of the timber trade, pointed out by Dr Schlich, two are very striking. The first is a detail, but a suggestive one. In the great mahogany-exporting regions on the Caribbean Sea, the export is almost balanced by the import of building wood, though the mass of the Central American forest lies behind them and at their doors. Into the whole British Empire, including our Colonies, with their vast area of trees, we import £18,000,000 worth of wood every year, and the amounts rise by about £700,000 per annum. It is from Canada, from our own great Colony only separated by a week's sea voyage, and not from Russia, that we should hope and desire to draw the pine and fir for our ordinary domestic use. The hard woods of the Dominion will probably be needed for home use and for the States south of the great lakes. But it is a pleasant and probable forecast to picture the millions of acres of the great Canadian woodlands preserved and prosperous, the forest populous with deer and moose, the lakes and innumerable rivers full of trout and salmon, at once the source of riches to Canada and the great reserve for sport and recreation for Englishmen at home and over the seas.

If there is a real rise in the price of timber before the supply overtakes the demand, it may

ENCOURAGE THE PLANTING OF WOODS

in this country. We wish it were possible now to advocate this as a commercial enterprise. But common knowledge holds the contrary opinion, and Sir W Thiselton-Dyer himself, under whose control Kew has become more than ever a practical oracle on the natural products of earth, holds that, as things are, it can never pay 4 per cent. It has been said by good authorities that land letting for less than 7s per acre will, as a rule, pay when planted. There is also a great sentimental inducement to do so. The present rating of plantations is almost Turkish in its strangling effect. The ground is rated as soon as it is planted. Not a penny comes in for at least ten years, yet the rates may be anything from 2s per acre upwards. The rate might be dropped and *deferred*, and then re-imposed in the form of a duty when the trees are felled. This would make the heir to the trees pay the taxes, and not the planter of them, and would be no more a hardship than the payment of succession-duty. Partly from its moist climate, partly from the abundance of hedgerows and hedgerow timber, we in this country have not felt the real damage caused by the absence of woods which accrues in mountainous Italy, or sandy Germany or Russia. Otherwise we should probably give bounties for tree-planting, instead of imposing taxes. Outside,

IN GREATER BRITAIN, OUR NATURAL FORESTS ARE ENORMOUS,

and, on the whole, singularly little damaged. India, as Sir Dietrich Brandis has more than once shown, needs much of her woods for other purposes than timber. They are the great reserve of cattle food in famine, the collectors of moisture, the feeders of rivers, the maintenance of mountain waters. Still, that national wood reserve, with teak at one end and deodar at the other, yields a splendid and increasing revenue. But, by what seems almost a stroke of luck, our other great Colonial forests have largely escaped the waste suffered by the other nations of the world. We have no part of our territory where the wood has been utterly or mainly ruined, as in Italy, in Spain, in Greece, in parts of Turkey in Europe, and vast areas in the United States. The slow peopling of Canada saved her woods during the "stupid" period of colonisation, and now they will be preserved. Our greatest hard-wood province or continent is perhaps Australia. Only one of the native trees seems to have been destroyed, the red cedar, and that is a furniture wood. There are five million acres of State forests of sorts in New South Wales alone. The number of species of hard-wood trees is unusual, and they are exceptionally lofty. This is one of the great desiderata of the builder, and one which English timber never fulfils. In replacing two of the cross-beams in the roof of Winchester Cathedral, English oak of the proper length could not be got at a reasonable price. The first ten forest trees on the New South Wales list average from one hundred feet to one hundred and fifty feet at full growth. Behind these Colonial supplies lies the enormous and

UNTAPPED RESERVE OF THE TROPICAL FORESTS

of Guiana, of West Africa, and, if we buy from our neighbours, of the Amazon, the Orinoco, and of the Philippines, where the trees average two hundred feet in height, and water-

ways are abundant, and penetrate the forests. These woods will stand till they are wanted, for the sound of the axe is not heard in them. In many the natives do not know even how to handle the implement. When making the Uganda Railway for instance, the natives were so awkward at its use that they begged to be supplied with *swords* instead to cut down the bush.—*Spectator*, March 9.

THE LINNÆAN SOCIETY.

At the last ordinary meeting, held at Burlington House, Piccadilly, Professor Sidney Vines, F.R.S., the President, occupied the chair. Mr H E Smedley exhibited and described a series of botanical models. Among the most striking were a flower of *Rafflesia Arnoldii*, about a yard across, a native of Sumatra, parasitic on the stem and roots of a species of vine, the cups of pitcher plants, sections of garden flowers, and, on a greatly enlarged scale, the reproductive organs of the pine, showing the process of pollination, the development of the pollen, the structure of the ovule, and the process of fertilisation. With these were shown some models, also greatly enlarged, of amœba ingesting food, the slipper animalcule, the bell-animalcule and the green hydra in section, with bud and ovary, to emphasise its two modes of reproduction. A paper by Miss Gulielma Lister on the occurence of *Tristicha hypnoides* in Egypt was communicated by Mr Arthur Lister, F.R.S. This species belongs to a group of aquatic moss-like flowering plants growing on rocks more or less covered by flowing water. It was met with among the islands below the First Cataract and the interest of the find lies in the fact that till now it was believed that the species did not flourish north of Abyssinia.—*B. and C. Druggist* March 15.

MINES AND MACHINERY ORDINANCE.

The following regulation made by His Excellency the Governor, with the advice of the Executive Council, under the provisions of section 4 of "The Mines and Machinery Protection Ordinance, 1896," is published for general information:—Every entrance to or exit from any mine, and all machinery at or about such entrance or exit, shall, if situated within 20 yards of a public road, be screened by a screen at least 8 feet high of boards or other sufficient material so as to be effectually excluded from the view of persons and beasts of burden using such road.—*Gazette.*

A CRYPTOGAMIC BOTANIST FOR INDIA.

The second appointment in the British Empire of a scientific man to devote his time to the organisms causing disease and death to plants was recently made in London and the recipient, Dr. Butler, with Mrs. Butler, has been staying a few days at Peradeniya; but will leave by the ss. "Borneo" for Calcutta. His official designation is not Mycologist, but the perhaps more correct title of "Cryptogamic Botanist." Dr. Butler, who has already done excellent original work, has studied in Ireland under Prof. Marcus Hartog of Cork University (whom we remember well when under Dr. Thwaites in Ceylon), and later when in receipt of a research scholarship, in Paris. Dr. Butler is an enthusiastic "plant doctor" and no doubt will be of great service to Indian agriculture, although his field of work between Cape Comorin and the Himalayas is wide enough, we would think, for half-a-dozen or more of Cryptogamic Botanists.

CEYLON TEA IN RUSSIA.

ANOTHER RUSSIAN TEA FIRM TO BE REPRESENTED IN COLOMBO.

One of the best evidences of the progress of Ceylon tea in Russia is to be found in the increase in the number of Russian tea buyers in Colombo. The latest arrival is Mr. W P Ampenoffe, who represents one of the largest firms in Russia, known as "The Trading Company, successors to Alexis Goobkin, A Koosnetzoff & Co." Mr. Ampenoffe will be heartily welcomed by the whole of the mercantile community. The firm which Mr. Ampenoffe represents has been dealing largely in Ceylon teas, and he has been sent out to Ceylon owing to the increasing business of the firm. Hitherto, there were three Russian and one English house buying tea for them locally. Speaking of the progress of Ceylon tea in Russia, Mr. Ampenoffe testified to the growing taste for it. A good deal of it was sold pure, he said, but the people still preferred a mixture with China tea. The medium class of Ceylon tea was liked best. Mr. Ampenoffe, from some figures in his possession, pointed out that the Ceylon exports to Russia could hardly be compared to the 55 000,000 lb. of congou tea alone that was now imported, but he believed that the amount of Ceylon tea going annually to Russia was bound to increase. What chances Ceylon green tea would have in Russia he was unable to say. A good deal of China green tea was now sent. —Local "Times."

RICE IN COCHIN CHINA.

RICE-MILLS INCREASING.

Saigon, March 3.—A new rice mill has been started this year—the "Yee Cheong" mill. This brings the number of our mills to nine, of which seven are Chinese and two European, all of which are big ones. This seems also to be an indication of the prosperity of the country, if we consider that in Tonkin not a single steam rice-mill exists yet. Cochin China exports yearly almost 12 millions of piculs of rice or paddy of different sorts and everything is on the increase.—*Hongkong Weekly Press*, March 16.

ADIANTUM FARLEYENSE.—This magnificent East Indian species may well be termed the Queen of Maidenhairs. The large lobes of the fronds are finely crimped, so that the effect is splendid. As an exhibition plant there is no mistaking its value, either as a single specimen or in a collection of Ferns, judges too rarely seeing it in perfection. I have found the most common error is to put too much peat in the compost. In commencing the cultivation use clean pots and ample drainage. The compost I have used with conspicuous success consisted of two parts of loam, one of fibrous peat, leaf mould and coarse silver sand. Cover the drainage with the rougher portions and pot somewhat firmly, lightly watering the following day. Place in a temperature of 55° or 60°, being particular not to overwater or expose to bright sunshine, or the plants do not assume the rich, deep colour found in shaded plants. When the roots fill the pots it will take a good share of water, but too much or not enough will completely ruin its prospects. As Adiantum Farleyense produces heavy fronds a little staking is quite necessary; this, if carefully done, will show no unsightliness. —R. P. R.

PLANTING NOTES.

Eucalyptus Distilling.—According to the report of the Chief Inspector of Distilleries in South Australia, there are fourteen eucalyptus-oil distilling licences in force in that colony. Thirteen licences are on Kangaroo Island, the other at Punyelroo The value of oil exported increased from £1,131 in 1892 to £2,224 in 1899.—*Planting Opinion*, April 6.

Raw Rubber Notes.—It is stated that the rubber trade in the Lagos district has almost reached a position of complete standstill. This anxiety is well founded and there are some substantial reasons for believing that causes other than the failure of the rubber trees are operating to obstruct and kill the trade.—*India Rubber Journal*, March 18.

The Analysis of Gutta Percha—by H Borntrager.—Crude commercial gutta-percha has the following composition according to the investigations of different chemists:—Water, 1 to 1·5; dirt (wood and soil), 3 to 5; pure gutta, 30·5 to 83·5; albane, 7·0 to 44·5; and fluavile 3·0 to 21·0 per cent. An analysis of a sample of crude gutta-percha by another method gave the follwing results:—Water, 1·5; dirt, 2·5; pure gutta, 77·5; fluavile, 6; albane a1. 3·8; albane a2, 3·7; and albane a3, five per cent.—*India Rubber Journal*, March 18.

Inferior Tea.—It is all very fine (says the *Indian Planters' Gazette*) for our local papers to gird at the Ceylon and South Indian planters for sending out refuse tea for local sale, and even export; but what about our own damaged and repacked? Hardly a sale passes during the monsoon without several chests being put up under the above denomination. What becomes of them? and have brokers a right to publicly auction damaged food goods? Is the Calcutta Health Officer a dummy? Any muck brought forward ought to be forthwith confiscated, and the Tea Association are bound to see to this for the sake of the good name of our teas.

Dosing an Elephant.—A difficult operation was performed the other day at the Zoological Gardens at Hanover. An elephant was suffering great pain from a growth on the lower part of one of its hind feet, and it was deemed necessary to cut this malformation away. In order to render the animal insensible a dose of 600 grains of of morphia in six bottles of rum was administered. This dose took about an hour before any visible effect was produced. The elephant then fell over in a kind of sleep, and the operation was successfully carried out without any further ado. The operation lasted in all three days.—*Globe*, March 22.

The Season at Darejeeling.—March 4.—Darjeeling has burst into spring early this year, and nothing could surpass in India the beauty of the last three weeks, soft cloudless skies, bright cheerful sun, the long line of snows clear but not hard, taking delicious colouring in the early morning and late afternoon. Rhododendrons are already bursting into their glorious blooms of white, pink and scarlet, and trees are putting on their young light green, and very soon the hill-sides will be white with magnolia. True indeed it is that only the cold weather residents of the place ever see Darjeeling at its best, for, barring six weeks of rather dreary cold and mist, the climate this winter has been perfect.—*Pioneer.*

Sugar and Jaggery from New Sources.—An attempt has been recently made by the Madras Government to ascertain the amount of sugar and jaggery manufactured in the Presidency from material other than sugar-cane. Jaggery (raw sugar) is produced from palmyra, sago, date, and coconut palms; but there is a consensus of opinion that it is not feasible to prepare any estimates of out-turn, whilst to arrive at any approximate idea of the area occupied by these sources of jaggery from year to year is not possible, owing to the fact that the trees are scattered and promiscuously planted.—*Madras Mail*, March 14.

Graphite from Ceylon.—More concessions for digging for graphite on Crown lands were granted last year than in any previous year, notwithstanding the drop in prices. The district of Kurunegala, to the north-west of Kandy, has 154 graphite mines. In the southern part of the island 117 acres of land on which graphite had been discovered were leased for ten years for 333,450 rupees. In the central districts of Ceylon 112 mining concessions have been accorded. Since European firms have taken up the development of graphite deposits more scientific methods are employed in the working of the mines, and the ratio of production has been increased accordingly. —*Newsagent*, Feb. 23.

Manuring Bananas.—Mr. R H Elworthy, of Priestman's River, took five acres of his coast lands in Portland, red soil which, he states does not grow bananas; he manured one acre with sheep manure, and on this acre the bananas made luxuriant growth and came in earliest, but bore small bunches of seven and eight hands. On one acre, rotten coconut husks were dug in and here the fruit came slow, with less stem and head growth than the acre with sheep manure, but the bunches were larger and fairly good on the whole On the remaining three acres no manure was applied and the bananas grew very poorly, producing when they produced fruit at all, small bunches and poor fruit.—*Journal of the Jamaica Agricultural Society*, Feb. 1901.

Indian Tea Companies.—During the week a number of tea companies have published their reports—says the Calcutta Correspondent of *The Pioneer*, writing on March 29th. Reading the reports as a whole one carries away the impression that the results are not so bad as might have been expected, considering all the outcry that there has been and that the cry of "stinking fish" that has been raised over the industry is perhaps a trifle premature. Even although no profit may have been earned, and although most of the companies are unable to declare a dividend, yet the losses are small; and bad as prices have been, there is a ray of light in the fact that those companies, I take Dehing as an example, that have devoted their energies to making the better class of teas, have obtained a better average price than during last year, and even where low grade teas are manufactured, as in the case of the South Cachar Co., it is possible by capable management and a sufficiently large outturn to obtain remunerative results. Taking this last company, which declares a dividend at the rate of 10 per cent per annum, its successful results are doubtless due to good management, combined with the fact that it is able to turn out about 14 maunds of tea per acre as compared with an average outturn of about 5½ to 6 maunds in other Cachar gardens.

THE LINDOOLA TEA COMPANY, LIMITED.

REPORT.—To be presented at the Fourth Annual General meeting of the Lindoola Tea Company, Limited, to be held at the Offices of the Company, 12, Fenchurch Street, London, E.C., on Monday, 1st April, 1901, at 2 o'clock p.m.

The Directors have the pleasure to submit the Balance Sheet and Accounts of the Company for the year ending 31st December, 1900, duly audited.

It is with the deepest regret that the Directors record the great loss that the Company has sustained through the death of Mr. Walter Sandys Thomas, the Ceylon Manager, which occurred soon after his arrival in England on well-earned furlough.

The result of the year's working may be considered satisfactory, and is very similar to that obtained in 1899. The crop amounted to 185,634 lb. Tea, being at the rate of 580 lb. per acre, against 189,020 lb. last year. The cost free on board at Colombo was 25·11 cents per lb against 24·78 cents, and the gross average price of the 174,820 lb sold in London was 8½d, the same as in the previous season.

Drafts were negotiated at 1/4 9-32d against 1/4 19-64d last year. The current season's crop is estimated at 185,000 lb Tea.

The Net Profit for the year amounts to	£2,190	19	7
And the Balance from last year to	153	19	11
Making a total of			£2,344 19 6
The Directors have already paid out of this dividends on the 6 per cent Prefereuce Shares for the year ending 31st December, 1900	£780	0	0
Interim Dividend on the Ordinary Shares of 2 per cent free of Income Tax	520	0	0
Income Tax	47	18	8
And it is proposed:—To pay a Dividend of 3 per cent free of Income Tax on the Ordinary Shares, making 5 per cent for the year	780	0	0
And to carry forward the Balance of	217	0	10
			£2.344 19 6

The sum of about £150 expended on new machinery having been charged against Revenue, the Directors do not consider it necessary to write off a specific sum for depreciation.

The Director retiring on this occasion is Mr. Walter Cross-Buchanan, and, being eligible, he offers himself for re-election.

The Auditor, Mr. J Hamilton Alston, also offers himself for re-election. By Order of the Board,

ROBERTSON, BOIS & Co., Agents and Secretaries.

London, 19th March, 1901.

THE BATTALGALLA ESTATE CO., LTD.

Eleventh annnal report to the shareholders.

The Directors, in presenting their annual report on the working of the Company's business for the past year, are pleased to be able to give again a generally satisfactory acconnt.

The increased production has necessitated a considerable outlay for new machinery, but the factory is now thoroughly equipped to cope with the larger output, and no further expenditure is likely to be incurred under this head for some years to come.

The quantity manufactured shows a considerable increase on the past year, totalling 274,556lb, against 224,803lb in 1899. The average selling price in London has been 8·38d per lb, against 8·43d in 1899, and in Colombo 36 cents, against 37·04 cents in 1899. The total crop averaged a selling price of 7·85d, against 8·22d last year.

London sales were 169,285lb, netting £5,128 12s 1d, and Colombo sales 104,925lb, realising R37,737·95. This compares with 191,350lb, netting £5,835 7s, and 32,600lb, realising R12,075·20 in 1899 in London and Colombo respectively.

Exchange for drafts has averaged 1s 4 7-16d, against 1s 4 13-32d in the preceding year.

An interim dividend of 5 per cent on the shares, free of income tax, was paid in September last, and there is now a balance at credit of profit and loss account of £766 14s 1d, from which the Directors propose to pay a further dividend of 5 per cent, free of income tax, absorbiug £750, and to carry forward £16 4s 1d.

In accordauce with the Articles of Association, Mr. C A Reiss retires by rotation, and, being eligible, offers himself for re-election.

The Directors are very sensible of the services rendered to the Company by their estate Superintendent, Mr. G C R Norman, who has handled a very large crop with unceasing attention and efficiency. In tendering him and his assistants their very best thanks, the Directors desire also to express their appreciation of the valuable services rendered to the Company by their Colombo Agents, Messrs. E Benham & Co.

50 and 51, Lime Street, London, E.C., 18th Mar. 1901.

THE PANAWAL TEA COMPANY, LIMITED.

The report of the directors for the year ending December 31, 1900, states that the net amount at credit of profit and loss account, including balance brought forward at December 31, 1899, after providing for general expenses, directors and auditors' fees was £1,577 12s, dividends on the 7 per cent cumulative preference shares were paid for 1900 in full amounting to £371, an interim dividend of 2 per cent on the ordinary shares was paid on November 10, 1900, amounting to £340. It is proposed to pay a final dividend of 2 per cent on the ordinary shares for the year ending December 31, 1900, making a distribution for the year 4 per cent, free of income-tax, which will absorb £340, to increase the reserve funds to a total of £1,720, by the addition of a sum of £505 19s 6d, leaving a balance to be carried forward to next season of £20 12s 6d. The directors recommend the distribution of a final dividend at the rate of 2 per cent on the ordinary shares of the company for the year ending December 31, 1900, making with the interim dividend paid to June 30, a distribution at the rate of 4 per cent for the year. The directors having in view the very unsatisfactory state of the tea-growing industry, consider it advisable to recommend the shareholders to strengthen the reserve funds. No alteration has taken place during the last twelve monhts in the acreage of the company's properties, which stand at: On December 31 last, tea in full bearing 590 acres; jungle, 341½ acres; total, 931½ acres. The directors consider that the shareholders have every reason to be satisfied with the result of the year's working. The crop realised for 1900 was 339,550 lb as against an estimate of 316,000lb. The yield in 1899 was 334,922lb. The visiting agent (Mr Melville White) before his departure from Ceylon, reported the properties as being in every way in excellent order at the date of his last inspection.—*Home and Colonial Mail*, March 29.

THE TALAWAKELLE ESTATES CO.; LTD.

REPORT.—To be presented at the third ordinary annual general meeting of the Company, to be held at the Office of the Company, on Wednesday, the 3rd April, 1901, at three o'clock p.m.

The Directors have the pleasure to submit the balance sheet and accounts of the Company for the year ending 31st December, 1900, duly audited.

The mortgage has been reduced to £17,000, by the payment of the third instalment of £1,500 on the 31st December last, which has been charged against the profit of the year.

From the statement at foot giving particulars of the past year's working, as compared with the previous two seasons, it will be seen that, while the yield and cost of production remain practically the same, the gross average price of the Tea sold in London on account of last season was the highest recorded, viz., 11·21d., there having been a good market for Teas combining strength and quality.

The Expenditure on new clearings, about £330, is charged against Revenue.

Statement shewing results of working for the three years ending 31st March, 1900:—

Season.	Acreage Plucked. Acres.	Total Tea Crop. lb.	Yield per lb. Acre.	Sold in London lb.	Gross Average per lb. Tea sold in London. d.	Cost of Crop per lb. f.o.b. Colombo. cents.	Average Rate of Exchange per Rupee. s. d.
1898	802	421,284	525	418,565	10·57	27½	1/4 3-16th
1899	802	419,544	523	419,110	10·23	27	1/4 5-16th
1900	802	419,632	523	417,978	11·21	27½	1/4 9-32th

The net profit for the year amounted to	£8,310 3 4	
To which has to be added interest	76 16 8	
And the balance from last year of	563 16 1	
		£8,950 16 1
Interest on the mortgage for the year has been paid, amounting to	£905 14 7	
The third instalment of the mortgage of £21,500 has been paid, viz.	1,500 0 0	
Dividend on the 6 per cent. Preference shares for the year *less* income tax, has been paid	314 17 6	
An interim dividend of 5 per cent., free of income tax, on the ordinary shares was paid on the 30th September	1,853 10 0	
Income tax .	256 7 4	
It is proposed—To pay a final dividend of 10 per cent. on the ordinary shares, free of income tax. making 15 per cent. for the year, which will require	3,707 0 0	
And to carry forward the balance of	413 6 8	
		£8,950 16 1

The Directors desire to place on record their appreciation of the efficient management of the estates by their Superintendent and his staff.

The Director retiring on this occasion is Mr. Charles Murray Robertson, and he being eligible offers himself for re-election.—By order of the Board

Robertson, Bois & Co.,
Agents and Secretaries.

Schedule of the Company's Estates.

Estates.	Tea in bearing.	Tea not in bearing.	Forest and Timber.	Grass Land, Buildings, &c.	Approximate Total. Acres.

(*a*) 3 acres leased from the Proprietors of the Boutiques.
(*b*) 25 acres felled.
(*c*) 2 acres leased to Messrs. Davidson & Browne.

HIGHLAND TEA COMPANY OF CEYLON, LIMITED.

Report of the Board of Directors, to be presented to the Shareholders at their fifth annual ordinary meeting to be held at the office of the Company, 16, Philpot Lane, London, E.C., on Tuesday, 16th April, 1901 at 3 o'lock p.m. The report of the directors for the year ended December 31st last states that the net profits have amounted to £2,438 19s 10d to which has to be added a balance of £86 10s 5d brought forward from previous accounts, giving a total to be dealt with of £2,525 10s 3d. An interim dividend of 3 per cent, (free of Income Tax) paid in September, 1900, absorbed £960, and it is now proposed to pay a final dividend of 3 per cent., free of income-tax, making 6 per cent. for the year, amounting to £960, and to write off estates account £500, leaving a balance to carry forward of £105 10s 3d. The profits shown by above figures fall somewhat short of those earned for the previous year, but, in view of the period of severe depression through which the tea industry has been passing, the directors think the shareholders are to be congratulated on the results attained. The total crop of tea produced by the Company's estates was 262,510 lb, against 259,233 lb in 1899, showing an increase of 3,277 lb; the average yield per acre all over was 448 lb, against 443 lb. and the average price realised in London was 8d per pound, against 8½d per pound. With regard to exchange, the directors issued instructions early in the year that the drafts against estate expenditure were to be drawn at a shorter usance than formerly, and the result of this course is a reduction in the rate of exchange from 1s 4 25-64d to to 1s 4 19-64d per rupee, by which some saving has been effected. The reports from the company's properties continue to be of a satisfactory character.

A POSSIBLE PARADISE: CYPRUS.

Reporting upon the condition of Cyprus for the past year, Sir W F Haynes Smith, High Commissioner, says:—

"The climate is exceedingly good, and the southern or Troodos range of mountains affords an excellent summer sanatorium. During five months of the year the top of the Troodos range is covered with snow, and a sanatorium might be established in its bright and clear air, which, even in winter, would afford a better climate than can be found anywhere else on the shores of the Mediterranean. A cool temperature would be obtained in summer, and a bright and warm sun enjoyed in winter on the crisp snow as in Switzerland.

"The irrigation works which are being constructed from the loan of £60,000 granted by the Imperial Parliament have been continued and have made good progress. Every one who has seen the magic effect of water on the cultivation in Cyprus must watch this experiment in irrigation with keen interest and with hope for its complete success.

"The Cypriot peasant lives for a very small sum on bread, olives, oil, raisins, vegetables, and wine, the products of the country, using little meat and buying tobacco at a low price. His clothing is, to a large extent, home made from the cotton grown in the country and from the produce of his flocks. The cost of living to Europeans is moderate, but the tendency is to increase.

"There are favourable openings for the investment of capital in the establishment of central wine factories and in further developing the silk industry. Silk of a high quality can be produced. There, is, I believe, also a profitable opening for capital in developing the sponge fisheries, and the Govern ment is now in a position to afford advantageous terms to any undertaking having adequate capital to work the sponge beds of Cyprus under proper regulations.

'A land bank or an agricultural bank working under a carefully-considered system could employ capital to yield a remunerative return, and such an institution is much wanted, as the usurious rates of interest now exacted for advances to the producers are a heavy weight on the industry of the island."—*Daily Telegraph*, March 21.

GEOLOGY AND MINERALOGY OF CEYLON.

We take the following extract from an interesting review in *Nature* of work done under "The Tamnau Mineralogical Endowment," by Dr. F. Grünling, the well-known Assistant of Professor Groth of Strasburg:—

The thirty-third volume of Groth's *Zeitschrift fur Krystallographie und Mineralogie* is almost entirely occupied by the scientific work done upon the material which was brought back from Ceylon, and those who wish to see the excellent results of a wise scientific endowment wisely administered cannot do better than glance over this publication. Dr. Grünling brought back rich collections, especially of the dolomite and the minerals which it contains, of the graphite and of the gemstones; among the latter the most remarkable are the tourmalines, which constitute a unique series of beautiful crystals.

All these minerals have now been examined by various workers in Prof. Groth's laboratory. The graphite has been the subject of exhaustive study by Dr. Weinschenk, the lecturer on petrology in the University of Munich, who has already published papers on the subject in the *Zeitschrift fur Praktische Geologie* and in the *Abhandlungen* of the Bavarian Academy of Sciences. The dolomite has been analysed by Dr. Schiffer, whose results have been given as an inaugural dissertation. And now has appeared this triple Heft of Groth's *Zeitschrift*, containing a general description of Ceylon and its minerals by Dr. Grünling, a research upon the chrysoberyl, the sillimanite and the blue spinel by Dr. Melczer, and a voluminous report upon the tourmaline crystals by Dr. Worobieff, whose memoir occupies nearly 200 pages, and is in reality a crystallographic monograph of the mineral.

The fact that so much has been achieved will suggest to the reader that the collection and scientific study of Ceylon minerals has been sadly neglected by our own countrymen. A perusal of Dr. Grünling's paper serves but to strengthen this conviction. With the exception of an interesting paper on the graphite and rocks of Ceylon, contributed last June to the Geological Society of London by Mr Coomara-Swamy, but published too late to be alluded to by Dr Grunling, little has been done. Mr Coomara-Swamy himself remarks, "No geological survey is in progress in Ceylon; it is much to be hoped that the Government will soon realise the importance of instituting one."

To give a very brief survey of the scientific results:—

Dr Grünling makes it clear that the graphite always occurs in typical symmetrical veins, though these have been much crushed and altered by earth movements which have spent their energy upon the soft graphite, and have consequently spared the country rock (granulite). Dr Weinsschenk comes to the conclusion that the graphite is of volcanic, and certainly not of organic, origin, and is probably due to the action of vapours containing carbon; he suggests that carbon dioxide and cyanogen compounds have played the chief part in its production. Among the associated minerals it is remarkable that, as at Passau, nontronite is one of the invariable decomposition products accompanying the graphite.

Dr Grünling is of opinion that the gemstones of the sands and gravels were derived from the dolomitic limestone which abounds in some parts of the island, for the spinel, which is certainly found in the limestone, contains sapphire, phlogopite, &c., while the corundum contains phlogopite, rutile and spinel. A granular marble from Wattegama, on the Kandy railroad, proves to be a theoretically pure *dolomite*; it contains, among other minerals, a remarkable blue apatite, which has been analysed by Dr Schiffer and is found to be a fluor-apatite containing 15 per cent of chlora-apatite. It is curious that Dr Grünling was unable to obtain any information concerning the original locality of the tourmalines; they are probably all derived from the cabook or laterite, and from some one place.

Worobieff's crystallographic measurements relate to 110 crystals remarkably rich in faces, and have resulted in the establishment of no less than 131 new forms? one crystal alone presented faces of fifty-nine forms; the table of calculated angles fills forty-three pages. He finds that the symmetry of tourmaline is undoubtedly ditrigonal, and not tetartohedral as has been supposed by some authors. The paper also contains numerous observations upon the pyro-electric properties of tourmaline, and distinguishes between the faces of the analogous and of the antologous poles.

Dr. Melczer's paper establishes beyond doubt that the chrysoberyls of Ceylon, of Brazil and of the Urals (Alexandrite) possess the same axes, and that the twinning takes place parallel to (031), not to (011). His optical study of the spinel leads him to the conclusion that the refractive index of this mineral varies with the colour; it is least in the most highly coloured parts.

The whole series of investigations reflects much credit upon the administration of the Tamnau fund, upon those who have collected and studied the minerals, and upon Prof. Groth, in whose laboratory the investigations have been successfully carried out.

The next award of this useful fund will be expected with interest. H. A. MIERS.

RUBBER FROM CEARA TREES.—Mr. F. E. Tringham brings us a very clean, superior sample of rubber, the result of tapping a single Ceara tree—four to five years old—on Pen-y-lan, Dolosbage. Trees giving so much for four hours' tapping are worth looking after and planting should be extended.

Correspondence.

To the Editor.

"REH" AND IRRIGATED LAND.

Paris, March 1.

SIR,—A letter of "A. D." (p. 542) in your *Tropical Agriculturist* for February, 1901, informs me that you have ("du saland") *reh* in Ceylon. In that case you would do well to ask M. C W Hilgard, Director of the Agricultural Experimental Station, at Berkeley, California, to send you his last memoir on this question, and you might give a translation of it in the *Tropical Agriculturist*. The ideas of "A D" seem to me right. Will you also have some specimens sent to M. Hilgard? He will be happy to analyse them. Cordially yours,

J VELBOUCHEVITCH.

[We suppose M. Hilgard's memoir, if for use in California, must be in English? Perhaps our correspondent "A D" (in the Tangalla district) will send us a few specimens of what he called "reh" to have transmitted to M. Hilgard.—ED. *T.A.*]

RUBBER EXTRACTION FROM BARK.

Paris, 2nd March, 1901.

DEAR SIR,—The process of extraction of the rubber from the bark is making very quick progress. Ten years ago nobody was thinking about it. Today we have a few reports on the opportuneness of such a process. You know that many plants are exploited by the cutting of the stem, what you call I believe peeling the tree; such are many roots, and slow growers such as *Mascarenhasia* and others from Madagascar, *Landolphia Hendelotii* from Soudan, and a lot of roots primitively neglected because it was quite out of practice to tap them by the common process.

Some were cut in pieces and put to bleed into recipients, as is done with *Urceolo*; but all the sap remaining in the bark after the operation was lost for ever. Now you can obtain from that neglected bark more rubber than the quantity obtained from the latex; and I know people asking for our process, intending to use it for the neglected barks left by the natives on the spot.

If it is true in the countries where the natives are accustomed to tap the vines, how much more in the regions where the collector must make the education of the collector of rubber, what can be the colour of his skin? If *par-dessus le marché*,* I cannot translate this French locution, the Governor of the colony has promulgated laws for the regulation of collecting the rubber, avoiding the cutting of the vines, stating that they must be tapped in official mode; when these vines are so long, so old, so large, the collector thinks that the weather is too bad for working and he sleeps till better times. But if you can say to the collector: go and cut the vines, but bring me the rubber you have obtained and if it is too meticulous [timid !] for you, bring me the bark, the white, yellow, black or undetermined,—the coloured man will think that to cut the vines is a very pleasant work for him and the crop of the bark a very pleasant one for his wife and he will go to work at once.

If it is true for the collecting of the bark, how much more it is for the *enrichissement* *—another word I cannot manage—of this bark.

The *Landolphia Hendelotii* per oz. contains from 7 per cent to 1 per cent of pure rubber. When the bark is dried quickly,—and I say quickly because when the operation is done slowly the fermentation is a cause of loss of the gum,—this bark is easily broken in a mortar, a common one for the decortication of paddy; so after a few minutes the operator can separate a few per cent of the impurities, and as generally native women are expert in the manipulation of the pestle, their lords and masters have no hesitation in entrusting them to perfect this work.

I have received bark or better rubber prepared by the female beauties of Senegal, containing no more than 20 per cent of impurities. Such rubber is a very commercial one and will be accepted on any market.

It is naturally much more difficult to bring this rubber to purity, but we must not be too exacting and such rubber will lead the way in the manufacture of pure rubber. With patience it is possible to obtain nearly pure rubber by these primitive processes; but the buyer is judge of the question; he can pay the rubber on the percentage and the analysis is quite mechanical. If the buyer take one ounce of the product and use an iron mortar and pestle and take the formation of nature; after a few minutes, if he has had the precaution of wetting the bark, he will extract a certain proportion of impurities and obtain a parcel of rubber nearly pure and a sufficient sample for judging the quality and the quantity of good rubber in the sample. After a very short time he will be able to avoid any mistake.

The extraction of rubber from the bark gives better product than the bleeding:—I send you a little sample of Borneo rubber obtained two years ago, and you will see that it is much better than the rubber generally offered on the market from this country. It has been prepared by a collector using this process for the first time. It is enough for today.—Believe me, yours truly,

A. GODEFROY-LEBEUF.

COFFEE AND ITS ENEMIES IN B.C. AFRICA.

[BY AN OLD CEYLON PLANTER.]

DEAR SIR,—I send you a paper which I penned about 18 months ago, relating to the difficulties we have to contend with in B C A. in regard to the many enemies of our staple industry, coffee planting.

To these enemies we have now to add the spotted bug. This little pest is very like a lady-bird and, unlike all the Ceylon coffee bugs, flies about from tree to tree sucking at the juice of the flower, fruit and tender shoots or buds as they appear on the coffee trees. The damage done to the flower is terrible, completely destroying the fructifying power even in the most favourable weather. In regard to the fruit the insect sucks the juice, and seems to inject poison into the berry when young which turns it black or spotted or streaky, so that the fruit withers up and drops off the trees, even when it reaches the size of peas, just the same as the leaf disease

* *i.e.* If the labour is too expensive.—ED. *T.A.*

* Improvement of the bark.—ED. *T.A.*

affected the Ceylon crops leaving only small clusters or single berries to come forward to maturity and those berries that do reach that stage are mostly damaged.

The buds or terminal branches when sucked at, turn a dark green colour and are stunted or bastard, having a shrivelled-up appearance with a black pith and black spots shewing between the bark and the wood.

The damage alluded to is worst during the dry season when there is very little sap in our coffee trees, and does not shew much during the growing or rainy season. I lost a fine crop about 6 cwts per acre this year with this bug. They came before the bush fires in swarms and found a safe harbour amongst my coffee. In addition to the new arrivals, those that had come in, and bred amongst the coffee for some two years unheeded (I was not aware they did any damage) added to the damage done. To show you what a number of bugs I have gathered, I have had an average of 20 children at work collecting daily for the past 6 months and they have each brought in from 30 to 60 per diem. Thank goodness, they can only get a few, 3 to 5 each, now. So that I may get a bumper crop next year. It was always next year in Ceylon, I remember, during the leaf disease days. It is now quite certain in B C A that we cannot rear bug. and get coffee to yield crop. It is very fortunate however that we have a remedy, although a tedious one, in catching the spotted bug I was always loath to believe that our spotted bug did damage to coffee before I proved it by experiments.

I have further proof this year by the fact that my crop is saved on the pieces of coffee where there is a colony of soldier-ants established; this tiger-ant eternally racing about on the coffee keeps the bug lively, not allowing them to rest and do damage, even if they don't succeed in catching them, which they sometimes do, and of course the ants pull the little wretch to pieces and devour it at once. I am going to set a boy on with a piece of meat on the end of a stick to trap a party of ants and distribute them about the plantation to help to fight the bug and other insect pests. I remember, I think, doing the same with red ants in Ceylon, to try and get rid of helopeltis or some other pests on my cacao in Matale.

Our red ant seems to be identical with the Ceylon one, that used to torment the coolies so when handling, where they established themselves and made nests amongst the coffee leaves. Only they don't seem to bite so hard, or it may be the African negro has a thicker hide.

I am growing tobacco for which I can get 1s 3d per lb. for clean in South Africa. Tea I may turn to good account by-and-bye also in South Africa. Chillies pay very well here, I have been getting up to 55s 6d lately for them. You in Ceylon seem to be having a hard struggle for it with tea; low prices and exchange must alter, otherwise it will prove serious for proprietary planters, although companies may not feel it so much. You can never stop rubbishy tea getting into your markets. People who want cheap tea or rubbish will and must have it, the same as rubbishy coffee, tobacco, &c. H. B.

[Our correspondent's longer essay will be given in the *Tropical Agriculturist*. Let him send specimens of his new "poochie" for Mr. E. E. Green's report.—ED. *T.A.*]

HOW TO DEAL WITH INFERIOR TEAS.

AN IMPORTANT SUGGESTION.

March 20.

SIR,—It would perhaps save a good deal of very inferior tea coming on to the market if the Tea Brokers in Colombo put an upset price on all tea of say eighteen cents, for the sake of a figure, and refused to sell any privately or publicly under that price. This would ensure at any rate in Colombo the destruction of most red leaf, mixed, and general rubbish, and it would not pay any one to send such stuff to England or Australia probably. If the Brokers did not care on their own initiative to take the step, they would do so if a resolution of the Planters' Association and the Chamber of Commerce were passed, asking them to institute this rule. Any Broker, after such a resolution, contravening the agreement would be boycotted, so there would be no fear of any lapses from the path of virtue.

The Broker would perhaps lose some commissions, but after all they are very small on the prices realized by such common rubbish. And the improved prices we trust to get would much more than recoup them afterwards. If, what is sincerely to be trusted, with all the finer plucking etc., we do get the prices of tea up, the danger will be the severe warning we have had will be forgotten, and a return made to the old system of coarse plucking, with consequent collapse again. The "Thirty Committee" might add to their duties that of advising the Planters if more or less leaf should be produced. If tea were being forced too high, it would be good policy to pluck coarser to prevent competition from outside, and large extensions. The Thirty Committee should have their fingers on the pulse of the market and advise accordingly.

It is an exceeding pity the question of the reduction or total abolition of the tea duty was not brought forward by a stronger debater, and properly threshed out once for all. If Mr. Christie, for instance, believed in the advisability of the step and brought forward a motion, no fear of the weight of his adversary's mettle would deter him from doing the utmost justice to his side of the question.

Very possibly there are insuperable objections, but they have not been brought forward publicly so far, *pace* Mr. Harcourt Skrine.

In its favour we have for certain the increase of buyers, of business generally, and Ceylon teas compete with the advantage of being *in situ* and, therefore, *per se* worth to a buyer their value plus certainly $\frac{7}{8}$ of cost of transit of foreign teas. That is say it costs, say, 5 cents to deliver a 6d China tea into the blending house; it would be worth a buyer's while to pay 6d plus 4 cents for an identical Ceylon tea. The grower of the latter would gain 4 cents extra and the buyer save one. Under such circumstances can there be any doubt Ceylon tea both high and low grown would be used for preference wherever possible to our profit.

To a lowcountry proprietor especially, the total abolition of the duty seems most desirable. If some small duty is considered necessary, Ceylon tea would also, being free of it, get the extra value of that also.

Surely anyhow the question is worthy of a proper debate. LOWCOUNTRY.

CACAO:

Cultivation v. Longevity.

DEAR SIR,—There is no question, I take it, that the cultivation of cacao, if carried on at all, should be done more or less in co-operation with the tree itself.

I may be pardoned this platitude on account of the number of planters who appear to forget in their treatment of it that cacao is one of the most delicate of fruit trees; and this is manifest in numerous ways, but in two ways very specially, namely (a) the condition of Suckering, and (b) the condition of Manuring. I think I see in these two conditions of treatment, as applied to cacao in Ceylon, something of the conditions under which coffee was grown to the comparative disadvantage of the former. In this connection also, I may venture to indicate a parallel between the leaf fungus of coffee, and the bark-fungus of cacao: that, as some have thought the coffee-fungus may be traced, however indirectly, to drastic manuring, so the cacao-fungus may perhaps be traced to the accumulation of damp litter; the point of the analogy being that both improper manuring and excess of litter induce *dirt*, and hence ill-health in the tree. Analysis of the soil, and sometimes of the tree itself are resorted to for purposes of discovering if possible what natural constituents of life are respectively lacking and present: chemical analysis therefore tells us what to manure with; but practical analysis, *i.e.* knowledge of the tree and its nature, is also required before any manure should be applied. The just combination and intelligent application of these two methods constitute the scientific lines on which a product should be cultivated.

But, although the object of manuring coffee and cacao is identical, namely, the production of fruit, it by no means follows that the system of manuring as applied to coffee is applied with equal benefit to cacao, irrespective of whether cacao will stand the treatment. On the other hand cacao is a delicate plant, more delicate certainly than coffee, and should consequently be treated more leniently—within certain prescribed limits; and these limits have direct reference not so much to the method of treatment as to the actual life of the tree.

If the natural quantity of fruit borne by a tree is insufficient to render its cultivation remunerative, the tree must be forced. This is undoubtedly the case with cacao; for a cacao tree allowed to grow at its own sweet will does not bear soon enough for impatient mortals. Quick returns first—then large profits: it can be done, but it is done at a cost; and that cost, I hazard the opinion, is *canker*—not the only cost, but the greatest, I believe.

This question of manure, too, is all the more important owing to the extremely unnatural conditions under which the cacao tree is alone speedily remunerative. I shall never believe that the tree's original nature is to throw up '*suckers*.' What the tree does throw up in the first instance is not a 'sucker'—not a 'gormandiser'; *it is the tree itself.* To cut this off is *to top the tree*; and the proof of this is that, if the so-called 'sucker' is allowed to grow, it in turn spreads out in another platform, and a little later another so-called 'sucker' grows up and forms a third platform, and so until five, six, seven platforms may successively be reached. It is true that, whatever that first 'shoot' is called, it has to come off if crop is the objective; but I have done something more than say the same thing in other words. I have made it clear (if indeed it was necessary) that the conditions under which a cacao tree is cultivated in Ceylon are at least as unnatural as those under which coffee was grown; and, if it is admitted that cacao is more delicate than coffee, it will be seen that this only increases the disability under which cacao necessarily labours.

Weakness in a cacao tree is dependent upon many things; but three especially, namely,—soil, climate, treatment. The tree may fail, early or late, but it is bound to go in the long-run. It has neither the longevity nor the vitality of tea; but trees in a natural uncultivated state have been known to live—I write under correction—fifty and sixty years, and perhaps longer; and such trees are in the Island. Now, the oldest trees in the Island are Caraccas, but what Superintendent can point to a thirty-year-old Caraccas field and believe it good for another twenty-years at 3 cwt. per acre? It is said that "Cacao Walks" of the West Indies have been handed down from father to son for generations; but it has never been urged, I believe, that the original trees are still living. The soil of the West Indies is infinitely finer on the whole than our average Ceylon soil, but soil is no guarantee of longevity any more than is the air we breathe. Bad air poisons us, but good air is not, conversely, *elixir vitæ*, but a natural food; and similarly good soil to the cacao tree is a sustainer of life in proportion to the quantity of it consumed and the method of consumption. The first indication of this weakness therefore may appear early or late, according to the absence or presence of certain necessary conditions. A time comes when the tree, worried by suckering and fatigued by bearing, fails; then is the time to manure. Coffee was manured by cutting half-moon trenches about the tree. Shall the same be done for cacao and in the same way? If we scrape away an inch or two of soil around the base of the tree we come upon a very network of fine silky roots. Not everyone knows that these are the *fruit-roots*. Shall we cut them through with our half-moon trenches, first on one side the first year and then on the other side the following year? It was so done to coffee. But cacao is more delicate than coffee; surely, therefore, such drastic treatment should not be entered upon without sufficient reason. Where is the reason then? Is it to be found in root-pruning? The ruthless cutting through of the roots, upon which we depend for one crop, can scarcely be called that. This root-amputating, fibre-smashing, crop-obliterating treatment is not root-pruning. What other reason, then, for this extraordinary manner of application? Is it hallowed by habit, or cursed by custom? At any rate, the fruit-roots being all on the surface, it is folly to dig for them! Uncover, sprinkle the manure over, cover them up again, and the thing is done cheaper, because quicker; better, because all indiscriminating amputation is avoided. And we need to manure because the trees would otherwise grow weak—nay, they grow weak in any case—slowly, gradually weaker; the object of manuring being to delay this natural process, the common miracle of decease, and to let the tree—and the proprietor—down lightly.

Ever since the tree was topped, it has done all it knew to follow its own bent. For every 'shoot' pulled off, it has put up two, four, six, until new

'shoots' have been forced out of the hard trunk-bark anywhere and everywhere. But of these it has been deprived, and every shoot or 'sucker' so pulled off has had its certain effect on the nature of the tree; and the energy of the tree, expended in frustrated efforts to grow to its normal height, has been transformed, according to certain natural laws, with development of its laterals. But these laterals have developed slower than the energy was stored, and this stored energy therefore has been transformed into the extra crop we needed. In other words the tree has gradually been degenerated into a perennial condition of reproduction—considered a condition of high culture in many plants, and some animals. But prevention is better than cure, and, long before the tree reaches this prematurely senile period, such steps should, to my mind, be taken to prevent it ever arriving at it.

A tree once afflicted is, if nothing else, a source of infection: and it is a question whether more harm is not done trying to pick out all the 'borers' (the small 'borers' are ineradicable) and cutting out the canker than by felling the tree 'root and branch,' then and there. Perhaps it may be preferable to lose the tree, especially if we have already a plant close by, just beginning to bear. Then the loss is nil—a gain in fact, for we have a new tree for an old tree, youth for age. What, I ask, is to prevent us deliberately re-planting the whole estate, say, every fifteen to twenty years and cutting out the old cacao, either *en masse* or tree by tree if we prefer it? The expense is not great, and if canker can be avoided by the simple contrivance of not permitting the cacao to reach that age when, in the opinion of many practical planters, it becomes more liable to it, the better procedure is obvious. For nothing can be worse than canker.

We should then have a clean bill of health, a brand new estate (bearing proportionately to our own foresight) and essentially a new lease of life.

POD.

PLANTING NOTES.

AGRICULTURE.—The whole of the splendid Dunga estate, with the exception of land selected for Vanilla, and experimental products, is now being planted with coconut and clove seedlings. The careful cultivation of cloves, with the aid of the plough for the last year or two, is now beginning to prove how much superior the plough is to the native hoe. The trees are much larger than they used to be, and are bearing heavily. Nurseries for clove and coconut seedlings are being rapidly prepared at different stations on the Island for a supply of seedlings to planters. —*Zanzibar Gazette*, March 20.

SOMALI AND TEA PRODUCTION.—While Indian and Ceylon planters are thinking out the best means to restrict the output of tea, Mr. Joseph Foulkes, an African explorer, tells us that the region traversed by the Juba river is an ideal tea-growing country, as the wild-growing tea plant is found there. There is reason to suppose that Jubaland may become in the not distant future a considerable rubber-producing territory also. Mr. Foulkes, who is now on his way *via* Mombasa to the Juba district in command of an expedition, will make an especial study of these two plants with the object of furthering, if possible, their cultivation in Jubaland. It is understood that he has considerable financial support, and should his surmises with regard to the possibilities of the country turn out to be correct, he will be in a position to at once commence arrangements for the transforming of the cultivable areas into rubber and tea plantations.

THE ORANGE TRADE OF COORG.—A Coorg correspondent writes to the *Madras Mail*:—"A good thing is being made out of oranges by traders from Mysore, who purchase a cartload of fruit at R10 or R15 and realise R30 to R35 for the same. Allowing the liberal sum of R8 for cart hire to Mysore, it will readily be perceived that a handsome margin of profit remains over. In view of the Railway being made through Coorg, oranges might be largely planted. The trees would probably come into bearing just when the iron horse reaches the country, ready to take away their burdens of golden fruit. Other fruit trees might also be planted, but it would have to be done on a sufficient scale to allow of measures being adopted for safeguarding the crops. In one case, I believe the cultivation of fruit as an auxiliary to coffee will be undertaken here next season."

RUBBER AND ITS EXTRACTION.—We are indebted to Mr. Godefroy-Lebeuf for another letter on this subject, and we trust he will continue to report to us the progress and improvements made in the extraction of rubber from the bark, branches and twigs of rubber-yielding trees. It is marvellous to us how well our correspondent expresses himself in English, and we hope he will continue to write in that language; but it might help us where difficult points come up, if he gave his sentence also in French, which might lead all the more quickly to the clearing up of any difficulty in the understanding of a particular phrase or scientific process. We sent some time ago a small bag of bark samples from a Ceylon rubber plantation to be tested; but the result was disappointing —indeed *nil*—showing that the trees were too young to yield rubber from their bark or branches. Our correspondent sends us now a sample of Borneo rubber prepared by the new process. It seems very satisfactory.

FRUIT FROM THE WEST INDIES.—The steamer "Port Morant" arrived at Avonmouth recently, fully laden with fruit, besides carrying thirty-five passengers and mails, being the first of the Imperial direct West India Mail line to make the return voyage from Jamaica to Bristol. The vessel had a stormy homeward trip. Interest centred in the condition of the Bananas which formed the main part of the cargo, 18,000 bunches being stored in bins, the temperature of which was regulated by air-currents. Mr. Robert Thomson, formerly head of the Jamaican Botanical Department, has been appointed adviser to Messrs. Elder, Dempster, & Co., owners of the line, with regard to the growing and packing of fruit, the appointment giving great satisfaction in Jamaica, where his scientific attainments are greatly appreciated. Bananas in various degrees of fulness were packed, so as to thoroughly test the appliances of the vessel, and all the fruit arrived in splendid condition. The London and Liverpool buyers, who had an opportunity of inspecting the bins, expressed gratification at the excellence and soundness of the fruit. The whole cargo was sold, mainly for London, Liverpool, Manchester, and Bristol markets. The vessel also brought a large consignment of Mangoes, Pineapples, and Oranges, all of which stood the voyage remarkably well, fully answering the expectations formed as to the capabilities of the line in developing new trade with the West Indies.—*Gardeners' Chronicle*, March 30.

POTATOES.—It takes from 12 cwt. to one ton of seed potatoes to plant out an acre, the quantity depending on whether small sets, large sets, or whole potatoes are used—*Journal of the Jamaica Agricultural Society.*

MANY OF THE COFFEE PLANTERS in Southern India are going in for rice cultivation, and consider it a useful, if not highly remunerative, supplementary crop. This is especially the case in the Malnad district of the Mysore province.—*Indian Agriculturist*, March 1.

A CORRECTION.—In case anyone may take the trouble to notice the mistake, I may note by the way that, in the report, quoted in *T.A.*, of my "Curiosities," &c., I am made to say *Gutta Percha* is found in the Amazon Valley. I never said so. It is merely one of the vagaries of the reporter. *Borneo*, &c., in the *East*, I said, was the home of the *Gutta Percha* and I think, I noted this on the margin of the paper sent.—*Old Colonist.*

AN INCH OF RAIN.—What does an inch of rain mean? Few persons have a definite idea. An acre if calculated out, will prove to be 6,272,640 square inches. An inch deep of water on this acre will be as many cubic inches of water, which, at 231 to the gallon, is equal to 27,154 gallons. This immense quantity of water will weigh 228,190 lb. or 114 tons. One hundredth of an inch (·01) alone is equal to over one ton of water to the acre. In forty-eight hours, during the month of January, 15½ inches of rain fell at Geraldton. This was equal to 420,837 gallons per acre or 1,767 tons, or about one-seventh of the total quantity required to irrigate a crop of sugar cane during the growing season.—*Queensland Agricultural Journal.*

BOTANIC GARDENS, NATAL.—The rainfall for the past year has been 13·20 inches below the average of the last twenty-eight years, the total for the year being 27·24 in. as against 88·03 in. the average rainfall at Colombo for 31 years. Many plants have died in the Gardens owing to the droughts. The climate has been found unsuitable (as shewn above) to the growth of cacao (*Theobroma cacao*) though it appears that the fruit of another tree called *Pachira alba* is sometimes mistaken in Natal for that of cacao. The climate seems well suited to the cultivation of pineapples, and a long extract is given on the question of manures for these. The gardens are supported by subscriptions and a Government grant.—*Cor.*

RUBBER AT MANAOS.—The Government of Amazonas has decreed a law that is now being carried into effect, and must, like all artificial restraints on trade, prove highly prejudicial to the real interests of the State itself. Designed to injure Para by depriving that city of the great transit trade in rubber, it is likely to react on the rubber industry itself, and give rise to a still further fall in prices. The advantage of concentrating the export trade at one centre, at Para, is evident, as competition was always certain to secure the best possible prices for producers. With two markets, the second at an enormous distance from the coast, and with uncertain telegraphic communication with foreign markets, competition by buyers is certain to suffer. The decree we refer to obliges all rubber from the State of Amazonas to be landed at Manaos, packed in cases, and reshipped at a special wharf under Government inspection.—*India-rubber Trades' Journal*, March 4th.

GREEN TEA MANUFACTURE.—Mr. Deane reports the following as using his machine in Ceylon :—

LIST OF CEYLON ESTATES USING DEANE'S PROCESS.

Brunswick Estate. (2)
C P Hayley, Esq.
E Rosling, Esq., (Chairman, Planters' Association).
Ceylon Tea Plantations Co.
Eastern Produce and Estates Co. (2)
Messrs. Geo. Steuart & Co. (2)
Lipton's Limited
Carolina Estates.
Darrawella Estate.
Messrs. Finlay, Mauir & Co. (2)
Hardenhuish Estte.
Elkadua Estate.
The Hon. J N Campbell, M.L.C.
St. Leonard's Estate
Ratnatenne Estate.
Messrs. Whittall & Co.

CONIFERS AS RAIN GAUGES.—According to a recent number of the *Revue Horticole*, M. Felix Sabut has lately communicated to the Congrès des Sociétés Savantes observations respecting certain plants that act as registering rain gauges :—"Mention has already been made of the influence of certain more or less severe droughts in the French Mediterranean upon *Pinus Laricio* of Corsica. and Cephalonian Fir. The lengthening of the branches of these two species is always proportionate to the quantity of rain falling during those months of the year when it is most profitable to them. Co-efficients have been established indicating what the degree is for each month of the year. These co-efficients enable the relationship that exists between the amount of rain fallen and the greater or less intensity of the vegetation which it has encouraged to be determined. It is shown that, under these conditions, it is possible to judge approximately the quantity of rain which has fallen by measuring exactly the length of the leader, or of the branch produced yearly on these species of pine, and, if the estimate is not absolutely proportionate to the quantity of rain registered by the rain-gauge, it closely approaches to it; and a still closer estimation may be made by taking into account the relative value of the results produced by rain in the several months of the year. It is, therefore, possible, to a certain extent, to use plants specially selected for this purpose as actual registering rain-gauges."

THE CHEMISTRY OF SOIL.—"Undoubtedly one of the most wonderful discoveries of modern chemistry has to do with the soil," says the *Saturday Evening Post.* "It has been ascertained that the most barren land can be made rich simply by adding to it certain mineral elements which cost but little. On this basis it is estimated that the United States will be able eventually to maintain 500,000,000 people—more than one-third of the present population of the world. It is merely a question of supplying the requisite quantities of nitrogen, phosphoric acid and potash. The last two are readily obtainable at small expense, whereas the first may be supplied either by furnishing to the soil condensed nitrogen in the shape of slaughter waste, of nitrate of soda; or by planting clover, beans or peas, which have an affinity for nitrogen and absorb it from the atmosphere. It is now known that nitrogen is the most important plant food, and, inasmuch as this element composes four-fifths of the atmosphere, the question is merely to absorb it into the soil. It has also come to be understood that only 2 per cent. of the material of plants is derived from the soil, the remaining 98 per cent. being drawn from the air and from water. —*Bradstreet's*, Feb. 9.

FOREST ENGINEERING.

We have to acknowledge receipt from the author of a copy of "A Manualof Forest Engineering for India" by Charles Gilbert Rogers, Fellow of Cooper's Hill, Deputy Conservator of Forests, Imperial Forest Service of India—Volume I—Price Four Rupees, English Price Six Shillings. It is a very useful compilation of some 300 pages with over 140 illustrations, after the style of the well known Roorkee Treatises. From the preface we learn :—

This Manual has been written by order of the Government of India for the use of Forest Officers in India in the first instance, but will, it is hoped, prove of some practical value to the general public, and especially to that section of the community who are engaged directly in the management of tea and coffee gardens, indigo concerns, and in agricultural pursuits generally.

The Manual has been divided into the following parts :

Part I.—Building Materials.
Part II.—Building Construction.
Part III.—Road Making.
Part IV.—Bridges.
Part V.—Transport of Timber.
Part VI.—Wells.
Part VII.—Construction of Embankments and Water Channels. River Training Works.
Part VIII.—Demarcation of Forests.

Parts I and II will form the first, Parts III and IV the second, and Parts V to VIII the third and last, volume. The first two volumes contain information which will be useful to anyone who is interested in simple engineering problems, while the third volume contains those parts of the subject which are of more special interest to a Forest Officer.

Mr. Rogers has had the help of experts, in different departments, and the Manual as a whole cannot fail to be a very valuable one.

A SUCCESSFUL MATABELE HUNTER.

Mr. Phillip Stellwagen, the hunter, returned to Beira from Cheringoma and the Zambesia districts by the *Matabele*. During his absence from town he has shot big game which have yielded him about 7 tons of heads and horns, including many fine specimens and probably some records. One pair of buffalo horns, the pick of 42 shot, measures 52 inches from tip to tip, which must be almost a record for a cow. Mr Stellwagen has been very successful in his trips lately, and evidently works very hard on the veldt, and has a knowledge of a very pretty bit of hunting country which always yields good sport. He is also well spoken of by shooting parties to which he has been attached, as the guarantee of a good bag.—*Central African Times*, March 9.

SCIENTIFIC EXPERTS FOR INDIA.

TWO IMPORTANT APPOINTMENTS.

Planters, agriculturists, and gardeners in this country have reason to congratulate themselves on the attention now being given by the Government of India to the appointment of scientific experts. We have quite recently had a competent entomologist added to the staff of the Indian Museum. We have now to record the arrival at Calcutta of two other experts, viz., Mr. Isaac Henry Burkill, M.A., F.L.S., from the Royal Gardens, Kew, as Assistant Reporter on Economic Products to the Government of India, who has taken up his duties, and Dr. Butler as Cryptogamic Botanist for India. This gentleman arrived here last Friday from Ceylon, where he spent a short time on his way to Calcutta. He has now taken up his duties at the Royal Botanic Gardens, Calcutta, under Dr. Prain, the Superintendent. Dr Butler has worked under Professor Van Teighem at Paris on fungi, and under Mons Poivault at Antibes. Before he studied in France he was a pupil of Professor Hartog, at the University of Cork. The officers of our "Indian Agriculturist Bureau" scheme, sketched out in our issue of 8th December, 1898, are gradually being appointed, and we hope to see before long the formation of the Bureau *un fait accompli.—Indian Gardening and Planting*, April 11th.

CEYLON IN 1889 AND 1901.

(Return to Ceylon after an absence of twelve years of an old planting correspondent.)

ARRIVAL AT GALLE.

After a passage of 18 days in the "Clan Ross" from Natal, we sighted land on Good Friday and as the mist rolled away Adam's Peak was the leading feature. Being too late for entrance into Galle harbour we anchored within a cable's length of the Bell-Buoy and waited till daylight to come in.

There were a number of waterspouts around the ship, some of them very near us the day before we came in sight of lands.

The weather was good from the day we left South Africa and there were numerous flying-fish to be seen every day skimming the waves.

The late rains had brightened up all vegetation and Galle looked very beautiful as we entered the harbour. Clearing our baggage at the Customs, we (four passengers) made straight for the Railway Station, crossing the esplanade where a Cricket Match was in progress and a number of lookers-on in the grandstand. The Easter holidays seems to have commenced, to judge by the number of people travelling by train. We had never before journeyed by the sea-side railway and this was an agreeable change from the old Coach, keeping the sea in view through openings in the deep fringe of Coconut-palms. The railway trip to Kalutara South Station was very enjoyable. Kalutara is a lovely place with a very large and comfortable Resthouse. The servants there are very attentive, and a good breakfast prepared at short notice. We were not in want of much rest after a fortnight on board the steamer and took advantage of a break in the weather to drive out and see the tea estates of Kalutara. Driving is cheap here, especially the neat little bullock hackeries with hoods complete, the roads fairly good, and the tropical mass of vegetation lining the roadways most picturesque and romantic ; almost every conceivable fruit tree and palm making lovely avenues and rendering grateful shade from the setting sun.

The climate of Kalutara islsomewhat trying to men of advanced age ; and the bungalows being perched on the elevated ridges, there are some stiff climbs to make before shelter is found.

We have already visited half-a-dozen thriving tea plantations in

KALUTARA DISTRICT;

and on Monday last had the good fortune to meet nearly all the planters of the district at a cricket match played between the K.C.C. and the M.C.C. There was some hitch about the first day and the match commenced and was finished on Tuesday the 9th instant and was a very interesting match, displaying good fielding and bowling.

In fact the contest between the gentlemen of Kalutara and Moratuwa was so keen and fierce that it was continued to the finish in a storm of heavy rain and only won by two wickets by the M.C.C.

The drive home was cool and pleasant and then another good climb in the dark to Glanrhos Bungalow, a warm bath and Pyjama Suit—good dinner and early to bed.

PRODUCTS.

The district of Kalutara is a huge tropical garden; everything flourishes: the jâk or artocarpus integrifolia, the breadfruit or artocarpus incista, with a broad-leafed artocarpus of the forest left as a shade tree intermingled with kittool and arecanut palms, coconut palms, cotton trees, acacias, lunumidella, and other useful and ornamental trees.

Rubber is largely cultivated and giving some returns; cloves, nutmegs and Liberian coffee are all doing well in Kalutara.

There is a new Papau introduced from the West Indies, a fruit which when stewed resembles the Californian pear.

Flowers are in great profusion: beautiful crotons equal to those seen in Colombo gardens; the Draciena or Chinese palm, many handsome marantus and Bougainvilleas; the numerous shade trees, including the Grevillea, give the Kalutara estates the appearance of Botanical Gardens.

TEA.

The first tea estate visited was Clyde, a most compact and valuable property with large factory. Glanrhos managed by Mr. J P Dove is another valuable tea estate with a large miscellaneous cultivation suited to the climate. The jât of Assam hybrid in Kalutara is much better than I expected to find and some of the places we visited though rocky give very fair returns of tea leaf per acre.

Putupaula (including Crurie) managed by Mr. H A Tipple is a beautifully situated estate commanding a grand view of the Kaluganga River and Mountain Scenery including some of the highest mountains of the Central Province.

The carriage drive through the Neboda Group (including Digalla and Narthupane) was very narrow; we left the trap and horse at the factory and walked to Putupaula in a very hot sun and felt rather pumped by climbing the short cut to Mr. Tipple's bungalow, who kindly invited the writer to accompany Mr. Dove to visit him; we were rewarded by having several games of chess when the rain was falling heavily outside.

The picturesque scenery from this bungalow was well worth the hardship of the trudge to and from the carriage drive to the cart road and we felt all the better for the walk and drive back.

We passed a very comfortable bungalow or rather two-storeyed house with a windmill to pump water up the hill; this nicely situated residence belonged to Mr and Mrs Morrison away from Ceylon. We met Mr Heath at the factory returning to Glanrhos.

The Sinhalese holiday has commenced and a man got killed last night for stealing toddy. Plenty of Chinese crackers are going off in the villages below us this evening.

The weather still continues stormy, great heat during the day and heavy rains in the afternoon preventing me from exploring the district, especially as I have no horse and know so few people. I had thought of travelling across the low country to Avisawella and then through the Kelani Valley, but, after making enquiries about the tea estates and the planters of that district, I find that a new generation has sprung up, that knows not Joseph.

I had the pleasure of seeing the Duke and Duchess of York at the grand reception given to Lord Roberts in London and hope their visit to Ceylon has been a success H. COTTAM.

A CEYLON PLANTER ON TEA-GROWING IN RUSSIA:

MR. E P WILLISFORD TAKES CHARGE OF MR. POPOFF'S ESTATES NEAR BATOUM.

GREAT EXTENSIONS PLANNED—NOT PLEASANT READING.

We extract from a letter sent to our evening contemporary, dated 18th March last:—

Mr. Popoff owns three estates in the Caucasus, near Batoum: the principal one, Prevolnoyer, is where I live. It is about two miles' drive from Batoum—the hills, which are very similar to those in Ceylon, run down close to the sea—the house is situated on the top of the highest, overlooking a fort, and with the whole of Batoum and a long line of sea-coast to the north of it below. My interpreter lives with me, and there are two rooms in the house reserved for Mr. Popoff's use when he visits. The factory is on this estate. About two miles further inland is another estate called Zawatnoyer, and the third estate, Otradnoyer, is reached by rail (station on the estate) eight miles from Batoum. Out of 15,950 tea bushes brought by Mr. Popoff from China, Japan, Ceylon, Himalayas, Assam and Java, only some 2,760 are now alive; but there are on the three estates a total of plants, put out to the end of 1896, equal to 17 acres, and in 1897, 24 acres—taken at 2,700 to the acre—there are now in all about the equivalent of 185½ acres planted. After I had thoroughly gone over these three estates I proceeded to Moscow—a day and night by steamer and 52 hours by train—to interview Mr. Popoff. I found the cold *too terrible*, in spite of the fur coat Mr. P was good enough to lend me! My stay in Moscow was protracted longer than would have been the case, as the Dowager Duchess of Sutherland was on a visit to Mr. and Mrs. Popoff, and his time was not always at my disposal. All estate matters, as conducted in Ceylon, were most thoroughly gone into with a view to the introduction of such changes in working as might be suitable here. It was decided that no new clearings should be opened this year, but that the existing area should be worked up to a better state than at present. We were delayed by a gale on our return journey to Batoum. The hillsides are terraced, and the banks of the terraces turfed—from a distance this has a very untidy

ppearance—the levels of the terraces are dug two feet deep and planted; the flat land is also dug in a similar way and every root and stone removed. There are two large glass houses for germinating seed. At the present moment we are expecting from China *665* maunds of tea seed! which, planted 4" by 4" would, if all germinated, require nurseries to the extent of 81½ acres including drains, &c.!! and there are now *three* million seedlings in nurseries. They tell me they have found pruning a mistake, and before last winter only cut off the *ends* of each branch with scissors: The flush is now coming on, but has been delayed this year by the cold weather; in about a fortnight I hope we shall begin plucking and it will be my duty to give the order for this work to be carried out. My especial duty is the manufacture of tea. There is a good factory—*all* iron, withering loft above with jute hessian tats—it was built by Messrs. "Sirocco" Davidson, who also supplied all the machinery, viz:—12 H.P. steam engine, roller, dry tea sifter and equaliser, ditto cutter and equaliser, oxidiser, down-draft sirocco, packer, machine for compressing pillules and hydraulic press for tablets, and electric machine. Also, Chinese hand sieves, pans, chulas and winnowers. It is lighted by electricity; there is a telephone from the factory to the office and thence to my house.

Each of the estates is worked by a head-gardener with an assistant, the labour being Turks and Grozines—all *men*. The office and financial part is managed by a gentleman with an assistant, the latter being also a dispenser. A weekly meeting of the three gardeners, the book-keeper and myself takes place, when the work being, and to be, carried out is discussed, it being necessary for each of us to visit the three estates weekly. At these meetings we air our opinions and pass them on to M. Popoff, who decides what is to be done. Should the others differ from me on what I consider a vital point I am to write or wire to Mr. P. direct.

The crop will be only some *12,000 lb.* of tea this season, as I have advised husbanding a great part of the estate.

The pillules and tablets made here would be of inestimable value for soldiers' use during warfare as the space and bulk is so much reduced, and I commend this *seriously* to the attention of the military authorities.

I called on the British Consul here, Mr Patrick Stevens (Badminton Club), who was very civil. He showed me samples of Indian *green* teas which he says are largely consumed in the Asiatic provinces. (By the way, I am still in Asia!) On the 1st instant I entered in my diary that I thought it would be long, if ever, before Indian or Ceylon teas (black) ousted Chinas in Russia, for the reason that they do not lend themselves to the customs of the people, as does the China tea; and Mr Stevens used to me almost identically the same words. The Russians like *very* weak tea, *very* hot, and *plenty* of it at a sitting, many times a day. The China article is put into a teapot with only a little boiling water and kept on the top of the Samovar (or urn) where it is continually "drawing." A little only of this is poured into a *tumbler*, which is filled up with boiling water from the samovar, two or more lumps of sugar are added and generally a slice of lemon—it is *rare* to see milk used—the teapot is replenished with a little boiling water on the old leaves continually. This method cannot be carried out with Indian and Ceylon teas as, after the five minutes' "drawing," it begins to cool and it would be difficult to make it in sufficient quantities for their constant use. Indians and Ceylons are nicer with milk than with lemon. The poor classes drink an immense quantity daily, *very* weak, and they could not get milk.

MR. J. C. ROBERTS' NEW TEA BOX.

Mr. Roberts writes:—"It is encouraging at least to hear that merchants, and others amongst the unofficial residents, have accorded my sample some favorable notice and attention. Numerous specimens of compressed wood (made of Ceylon timber with my cement) forwarded to the Colonial Secretary, have attracted no interest in Government circles as I have not received any acknowledgment of them. I really hoped that they would be of public interest, (also possibly the Tea chest going forward shortly) as they are made of common kinds of wood at present practically of no value, and which in fact never can be as plain timber. It means in fact that, if the processes are a practical success, as I think these samples sent forward shew, the Island possesses in its forest reserves an unsuspected value, if encouragement is given to develop it."

COFFEE PLANTING IN BRAZIL.

THE DUMONT ESTATE.

35 MILES OF RAILWAY: THE LARGEST COFFEE PLANTATION IN THE WORLD.

12th April, 1901.

Four and a half years ago the group of Coffee Estates known as the Dumont Company changed hands and the French proprietor sold out to the London Company who paid the enormous sum of *one million eight hundred thousand pounds* for the property. It was the general

OPINION IN BRAZIL

that Dumont sold out for a good price and that it would take the new Company all their time to work the estates to pay, as they were taken over in bad order and during the past four years required a liberal expenditure to keep down the heavy weeds and grasses *(for Brazil grows weeds)* and labour is very expensive. Chiefly Italian and Spanish families engage themselves as "Colonials," working by contract if married and possessing a family. The single men work as daily labourers called in Brazil "Comarádos"; their pay is from 2·50 to 3 milreis, (a mil means one thousand, therefore the milreis would be 1,000 nickel coins.) Paper money is used in Brazil and

EXCHANGE

is always rising and falling; three years ago the milreis were down to 5d. English money and last August went up to a shilling. One of our contractors who planted and cultivated eighty thousand trees was recently paid off and doubled his money by the rise in Exchange. On the other hand the officers of the company, who are paid in gold, stand to lose money in Brazil as the purchasing power in stores of the milreis never changes; and one Officer or Superintendent of a section had his pay raised fifty pounds, yet he had to draw on private money to meet expenses. This was brought to the notice

of the company in England and they refused to increase the salaries of the Administrators or Superintendents. The consequence is they are all very much dissatisfied. The necessaries of life are much

DEARER IN BRAZIL THAN IN CEYLON,

and not of such good quality; beans, rice, and corn arethe chief articles of food used bythe labour.

It is an old-time custom in Brazil to allow the Italian and Spanish Colonials to grow their own crops of rice, beans, corn, manioc, tobacco, arrowroot, and sweet potatoes between the rows of coffee; the result of this is impoverished soil, short crops of coffee, and a large percentage of dead trees.

However, there is no remedy against this evil; for the European labourers and their wives and children must live; and, in addition to growing food stuffs in the coffee, they keep an immense number of goats, pigs, cows, and horses.

Hard-working families make money and save sufficient to return to Italy and Spain. Others, who fall sick and get into debt, have an exceedingly rough time of it on the coffee estates of Brazil.

ON THE GREAT DUMONT ESTATE

there were about 5,000 (five thousand) people, including women and children; of the above 5,000 perhaps 1,000 men would be obtained as contractors and daily labourers. There are 13,000 (thirteen thousand) acres of coffee under "cultivation," that would be about 13 acres to one man to keep in order and harvest the coffee crop. This

BARBAROUS SYSTEM OF STRIPPING THE TREES

with the crop in all stages of ripeness, wasting the green coffee, because scarcity of labour prohibits more than one round of picking, is the ruin of Brazil; and much of the crop is trodden into the ground by men and horses. Another "eye-sore" in Brazil is the old crop hanging on when the new crop sets its blossoms.

The trees suffer fearfully from overbearing. The crop ripens in April, May, June and July. The gathering is hardly begun and the estates must be cleared of grass and weeds. The weeds are ploughed into the ground with a considerable quantity of coffee dropping off the trees with every shower of rain.

Thousands of pounds worth of coffee are lost every year in Brazil through estates not being ready to secure their coffee crops before the heavy rains set in. Theplanting of food crops throws everything into arrears and the fields must be cleaned up before the stripping commences; no wonder the prices of Brazilian Coffee are always so low in the London market when the green coffee is mixed with the matured.

THE PRUNING, TOO, IS BARBAROUS,

five or six trees in a hole, some of them ruthlessly chopped down with an Axe, trusting to the judgment of an Italian farm labourer as to which should be taken and the others left. I have seen fine trees killed and four or five long fishing rods left for next year's crop. One of the most ghastly sights to be seen is a "*pruned*" field of coffee in Brazil.

There is little or no chance of any improvement being made in the "*cultivation*" of coffee in Brazil for practical experience is at a considerable discount. "*Nigger driving*" from daylight till dark, the old slave-bells only ringing for meals in the field, and work from sunrise to sun-set and such a long trudge back to the Colonial barracks. *Slavery is supposed to be abolished!* But in Brazil there are *white slaves.* I have known them work 18 hours out of 24 and in some cases hoe the coffee by moonlight to keep clear of debt and get out of Brazil and return to Italy. And what is it all for? To enrich a few individuals, non-resident.

BRAZIL WILL ALWAYS BE A HARD COUNTRY TO LIVE IN.

There is no enjoyment of life there for an Englishman and only men who have led a hard life could endure life in Brazil.

The Dumont Company has not got a practical coffee planter in their employ; some of them had never seen a coffee bush until they went to Dumont.

A slight knowledge of Portuguese seemed all that was necessary to drive and get as much work out of the Italians as possible (the Italian Estate labourers speak and understand Portuguese.) Most Fazendas (estates) keep an "Amazame" or general store and supply rum—pork—rice—flour cloth and ready-made clothing. New arrivals generally get into debt the first year in Brazil.

The Dumont Company get their goods from the Army and Navy co-operative stores and their "Amazame" does a good business with the employees. Another great advantage on Dumont is the

THIRTY-FIVE MILES OF RAILWAY

promptly despatching stores to the different sections of the estate and to the Colonials.

The making of the railway has much improved the value of the property since it was purchased from Dumont. Accidents have occurred through the sparks from the engines falling on rubbish-heaps and coffee has been burnt as well as buildings. A great fire took place shortly after the completion of the new factory. All the newly-put-up machinery for pulping and curing coffee, with a considerable quantity of coffee undergoing the process of curing, was burnt with the buildings in one night—a very bad thing for the shareholders of the company in the second or third year from the starting of the company. The coffee crops have steadily increased during the past three years. Thirty-two thousand cwt from 13,000 acres only works out *3 cwt per acre*—a mere maiden crop in the palmy days of coffee-planting in Ceylon. The twenty or thirty per cent of vacancies were supplied, and now the young trees, three and four years old, are cropping heavily, particularly on "Aqua Vermilia" (red water) and "Moreira" the section on which the writer was employed.

If the weather and other circumstances are favourable

THE CROP THIS YEAR

will be a very large one, but the young trees, unless relieved of their heavy crop of berries, will die out or take a rest from bearing for two or three years. Prices are likely to go down, owing the Brazilian crop expected being unusually large this year, fifteen thousand hundredweights being spoken of as under the estimate. Labour will be very short indeed, through the rise in the value of the milreis. The Italians drew their money (Brazilian) and turned it into gold and, as they are obliged to give notice to leave the estates before being paid off, many will remain in Italy. The Government of Brazil had lately discontinued giving passages to intending immigrants; consequently the Dumont Company were obliged to send an officer from Dumont to recruit Italian labour.

There are

TWENTY THOUSAND ACRES OF FOREST LAND AVAILABLE FOR COFFEE

planting belonging to the Dumont company, but the *five millions* of coffee trees now under "cultivation" will take them all their time to manage with labour daily getting scarcer and dearer There are some "*smart*" Directors in the company, particularly the one who visited Brazil and reports occasionally on Dumont. He ought to go there again and try and give the anxious shareholders a dividend; they have waited very patiently for the past five years and ought to get a fat one this year. I should take a small gang of practical coffee planters from Ceylon with good digestions and not afraid of ghiggars, ticks and Berne flies—to say nothing af the dear little mosquito (the writer had extracted during four years in Brazil *no less than 200* ghiggars from underneath every toe-nail of both feet.) The Portuguese. Brazilians, Italians and Spaniards called it a recreation on Sunday to dig them out of each other's feet. Of all the vile insects on earth, the Berne-fly is the worst. She

LAYS HER EGGS INSIDE YOUR FLESH

and hatches three very ugly insects an inch long with three rings of bristles round the body and sharp nippers. They take abont six weeks to develop under your skin, then eommence to turn somersaults just when you want to go to sleep after a hard day's work in the sun.

The natives of Brazil adopt a novel way of extracting the brute when full grown; they tie on a piece of raw pork and the Bèrne comes out of your skin and takes a header into the piece of pig skin.

Eighteen took up their lodgings in the plumpest parts and it was very interesting to stick a little nicotine from an old pipe into their nest, then out they would jump; but some were so fat they had to be screwed out and great was the relief.

Ticks were very plentiful in the grazing grounds and we often got covered with them when out at night, fighting with the bush fires on our boundaries and trying to save our fences and gates from destruction.

I had a

VARIED EXPERIENCE WITH SPECIMENS OF BRAZILIAN ENTOMOLOGY

and I have brought back as a trophy the nine rattles of a large rattlesnake I killed in my coffee. His chum came to look for him next day and was duly killed—snakes are very numerous and the ones most frequently found in the coffee were the rattlesnake and the black and red-coral snake.

"There are snakes in the grass" in human form of every nationality and an Englishman little knows what is in store of him in that nigger country. The more polite the people are, the greater the injury they are likely to inflict. There is much to write about Brazil after four years in the coffee districts of Sao Paulo. My first Estate was called "Vista Alegre" (cheerful view.) Mr W the proprietor took me round to see some of the large Coffee Fazendas. This district between San Carlos de Pinhal and Colonia was much cooler than the district of Reberu en Prato (Black River) where the Dumont Estate is located.

After this I will send you a few more notes on Brazilian life and customs and tell your readers something about the cities and the Government Railways.—Yours faithfully, HENRY COTTAM.

THE PROPOSED NYASSALAND RAILWAY.

(*From a correspondent.*)

A petition has been recently presented to His Majesty's Consul-General by residents and Civil Servants at Blantyre for transmission to the Home Government, asking for a guarantee for the proposed railway between Chiromo and Blantyre. It appears that the present system of land transport by porterage of natives has become inadequate to the needs of the country, and is tending to the rapid depletion of the labour market—an evil which, apart from its injurious effects on coffee-growing, the staple industry of the country, has so seriously impaired the import trade that at times many thousand loads may be seen lying for months on the wharves between Katungas and Chinde blocked *in transitu* through lack of labour.

To the more far-sighted traders these delays present a graver aspect than that of individual loss or inconvenience, for they leave the little Protectorate exposed as a trade route to the rivalry of Portuguese and German enterprise. On the borderland the Portuguese administration is in full activity, and the natives from the Protectorate are crossing over, despite the hut tax, to support in alien territory those industries which are the mainstay of the Protectorate. The stream of labour is thus diverted, and the production of coffee, tea, tobacco, and fibre in British Central Africa is threatened with extinction.

It is calculated that the construction of the railway would place at the disposal of this industrial community more than 40,000 labourers annually, and would set the planting industries on an assured economic basis.

The estimated cost of the proposed line which is to connect the Upper and Lower Shirwa—thus opening a thoroughfare for 1,200 miles into the heart of the Lake districts—is £300,000, and the petitioners seek a guarantee from the British Government of 2½ per cent on this amount.

Founding their calculations on the imports and exports for 1899-1900, they count upon a return of 7 per cent. on the capital invested, and maintain that, unless exceptionally bad seasons are met with, no call is likely to be made upon their guarantors.

The civil servants in the Protectorate have left nothing undone to make straight the way for the construction of the line. To prevent the transport and industrial systems of the Protectorate from being disorganised by the removal of a large quantity of labour from the already insufficient market, the Chief Judicial Officer has made a provisional contract with the Companhia da Zambesia which will provide from outside the Protectorate a supply of labour at a moderate price for building the railway, and negotiations have been entered into for the purchase of the material of the old Beira Railway.

The project possesses no inconsiderable political importance, as it would, if successfully carried out, effectively secure the British hold upon the Lake country of Africa.—London *Times*, Feb. 28.

CITRUS TREES.

We like to gather the experiences of fruit-growers of other lands, especially those that are now competitors with us. A successful orange-grower in Florida writes of his experience there as follows:—"In planting a tree I would cut the taproot off,

and three or four others will come out in its stead. The grape-fruit is a raining tree. It draws water from the ground by means of its dense foliage, and exhales it into the air; the rough lemon is the same. Both will often cause rain to fall from their leaves on a dry day. The rough (Florida) lemon has the largest plexus of feeder roots of any of the citrus family, and will thrive on poorer soil. The sour orange, the healthiest of the family, hardly grows fast enough for the grape-fruit but if you will often split the bark from the bud to the ground, you will hasten its growth in size and strength. In a plot of ground 210 feet square I would plant 81 grape-fruit trees about twenty-three and half feet apart, leaving a strip ten feet wide between them and the fence, and in square between four grape-fruit trees I would plant six by four tangarines and king oranges, making 145 trees to the acre." Our own experience points to the Seville sweet orange stock as being even healthier than the Seville orange, but as being a slower grower. The rough lemon stock makes a marvellously quick-growing growth but doubts are thrown upon it here as to whether it lasts long.

Another writer says:—The Dancy tangarine does best on rough lemon, grows faster, yields more fruit larger fruit and it matures earlier. Grape-fruit does well on lemon or on sweet stocks; on rough lemon you get large fruit on sweet or sour stocks, medium. He has planted from October to January, and even in June; but the best time is from November 20th to January 1st, according to his experience. Cut off half the top before planting or defoliate it; defoliate it entirely is still better. It takes nerve to do this, but it is true wisdom. You hate to spoil the pretty top, cutting it all to pieces, but you get some with all their tops left on and some without, and in a year or two you will surely wish you had cut them. See that no nut-grass roots are in the tree roots before you plant; it is a great nuisance. Plant about twenty by twenty-two feet. You may plant 125 trees on one acre, and 75 on another, and for the first ten years you will gather more fruit from the 125 trees; but how about your son and your grandson? One orange tree is for a century, and one should not plant for his selfish gain alone, to the robbery of after generations. You can, for a few years, plant four or five rows of pineapples between the orange rows and do them no harm; but beware of letting them stay too long. Examine the trees carefully as to when they are ready to occupy the middles themselves. Apply two or three pounds of good fertilizing at planting.—*Journal of the Jamaica Agricultural Society* for February

AERATION IN TEA.

Aeration is a word writ large in every planter's note-book being an operation employed in almost every process connected with tea cultivation and manufacture. The object of hoeing is to open up and expose the soil to the free action of the air, aeration of the soil being essential to the growth of the plant. In pruning also the bushes are thinned out to allow full play of air. In plucking, however, instead of allowing the air free access to the leaf nipped off the bushes, it is jammed tight into baskets, the result being that, owing to the absence of aeration, at certain seasons of the year heat is engendered, fermentation is set up, and the leaf turns red and emits an offensive odour. The fermenation is solely due to heat produced by the want of aeration. Needless to say that such leaf can never possibly make good tea. This matter deserves every attention, and if only teas of good quality are to be manufactured this season it behoves planters to make some arrangement whereby aeration shall be insured. One leaf gets heated in the baskets it is deteriorated and no after manipulation will ever recover it. Withering or wilting is aeration pure and simple, the air circulated over and through the leaf being cool or warm according to the season. The next process, in which aeration should always have place, although it does not do so, is rolling. Rolling always generates heat, and the latest machines are so constructed as to admit of as much air as possible getting to the leaf, so as to counteract the heat set up and caused by the friction of the leaves one against the other in the process of rolling. The leaf should in no way become discoloured in rolling, it should be discharged from the machine a healthy green colour. Rolling and oxidation are two distinct processes, and must on no account be united into one operation. In former days some planters used to roll out their colour, but no one dreams of doing such a thing now. Oxidation or colouring is nothing more or less than aeration, cool damp or moist air being played over and through the rolled leaf. For oxidation, pure and simple, heat is not required; if anything it is inimical rather than favourable to the process,—it should in fact be wholly eliminated. Finally, aeration is everything in the firing of the green leaf, and in the final firing of the dried and sifted tea. Here, however, heated air is the substance employed, being driven over and through the leaf or dried tea in the driers. Air then, either cool, warm or hot, dry or moist, plays an important part in every operation or process connected with the cultivation or manufacture of tea, save the very last stage, when the finally fired tea is packed in a lead casing which is soldered down to exclude the air. Aeration is thus a subject which requires close study, and more attention than has hitherto been paid to it, if good quality tea in the future is to be the rule rather than the exception. —*Indian Planters' Gazette*, Mar. 30.

FAILURE OF COFFEE IN BURMA.

We (the Rangoon *Gazette*) hear that Mr. de Souza's coffee plantation at Thandaung has completely failed this season, all the trees having been attacked by blight. Our crop in the Toungoo district have also been seriously affected, but none to the extent of Mr de Souza's. Mr de Souza's former plantation is to be leased for building purposes by the Government.—*Times of Burma*, April 10th.

PLANTING IN MEXICO.—We omitted yesterday to draw attention to the interesting letter respecting "rubber" sent us by Mr. E. O. Darley, formerly a well-known Knuckles Planter. Mr. Darley should tell us a little more about his everyday planting life and the crops he is gathering in.

TEAK PRESERVATION IN SIAM.—Teak merchants in Siam are manifesting considerable interest in the new precautions for forest preservation, which are being taken by the Siamese Government with the advice and assistance of Forest Officers from Burma. The Government is now bringing the teak forests of Siam under systematic control. It proposes in effect to considerably limit the area of forests now being worked, and to charge rentals in addition to the present royalties. It now issues the forest leases itself instead of allowing the local "Chaos" or chiefs to grant them as formerly. It is increasing, too, the limit of girth of trees which may be felled, so as to bring the practice more in line with that obtaining in Burma. The effect of all these measures will, no doubt, be to somewhat limit the teak output while preserving the lives of the forests. No diminution from this cause is likely to be felt for some years yet, however.—*Pioneer*, April 13.

THE SO-CALLED "LOST ART" IN TEA MANUFACTURE.

I.

Ere proceeding to deal with the chief theme of this paper, we must premise that the enormous accumulations of low grade tea in importers' and traders' hands at home will need a very large proportion of Pekoes to salt them for consumers' use, so that the argument for instance on fine plucking may be considered closed, and we do not see any necessity for departing from the usual method of manufacture, in so far as the three or four leaves and bud are concerned, as such leaf will be needed for the necessary blending, but as in the usual course of plucking a good quantity of larger leaf is unavoidably brought in, and autumn requirements denoting depletion of home stocks may demand more being taken off the bushes, the planter has to decide whether he will still treat this leaf in the fashion hitherto in vogue or, by departing somewhat from that, fit it for accommodation to the pronounced taste of the working classes in Europe and that which the American and Colonial consumer looks for. What we have to say upon the subject, it must be understood, is not written to provoke controversy, but to put before the manufacturer a summary of the methods pursued both in the plains and hills that resulted in furnishing the consumer, who had been used to the slightly sweetish teas of China Congous, an imitation that was approved of, leaving our readers to flout or adopt the suggestions according to their own inclinations or prejudices. On most, if not all, factories, everyone employs the common cane or wire sieve to separate as much as possible the coarse leaf from the fine after the first roll; the more effectually this is done the less manipulation is required subsequently. Now we leave the finer teas alone for the present and recommend that the coarse leaf be placed in the roller, going slow as possible, in order to retain the juice in the same way as in the old hand-rolling days, 1869-72, when the leaf was passed from hand to hand along the line of men, the balls being broken up and disintegrated by each, with the result that, on reaching the end of the line, the leaf had acquired that light mahogany colour and sticky consistency indicating oxidisation has sufficiently been attained for firing. In very wet weather the desired condition will not be reached as quickly as when the reverse obtains, in which case resort must be had to forcing under blankets as is now done in some factories, and here again constant testing of the mass to detect fermentation will be necessary; the leaf must be turned over and over and the hand thrust in: a bath thermometer will prove of service in denoting any tendency to heating. Then if spread thinly out on mats, chelnies, or tables, provided a temperature of at least under 50° can be secured, an evaporation of tannin takes place and at this stage the greatest care is necessary, for, if actual fermentation is allowed to set in, it is almost needless to say sourness results; if the leaf is constantly examined by being held against the light, diminutive hairs show upon it, and as soon as these appear the leaf must go to the sirocco at once, but thinly spread in the trays to be *set*, in the first instance; if the heat in the machine can be properly controlled, five minutes will be quite enough for the contents of a dozen bottom trays to be collected together and transferred to the upper ones, but overpacking (as we showed on the 31st March last year) must be avoided; the main object to be kept in view is to avoid haste and dumping too much damp leaf together; for however careful the battyer may be, dumping and too rapid firing dries the exposed layers, only half drying the centre, destroying all chance of uniform roasting and, despite the most thorough bulking, an ununiform tea results. We do not pretend to a knowledge of what chemical action is set up in oxidising by exposure at low temperature to evolve the saccharine principle that distinguishes tea so treated; that it acquires such is undoubted, as anyone can satisfy himself of by tasting samples of genuine China or Japan Congous; and it was by treating leaf in the manner roughly sketched out that the teas made in the Nilgiris in 1871 acquired their well-deserved popularity, but that the method was not unknown in Sylhet can be proved, if papers are extant so far back as 1861, when samples sent home through Messrs. Grindlay and Co., on account of the Sylhet Tea Company, received high encomiums from Messrs. W J and H Thompson, as also from a well-known tea dealers' firm of that day, Antrobus and Co. With the inadequate space and *kutcha* buildings then available, coupled with want of appliances to cool down the leaf in those days it was found quite impossible in the plains to carry out this forcing later than the middle of March, so the method gradually fell into disuse and was forgotten, being replaced by the present hurried system by which, as has been repeatedly pointed out, undue evaporation is stimulated from the outset; the rolling machines squeezing out the constituents by turning the leaf into a sodden stodge. Panning slightly rolled leaf does away with the tedious process of slow rolling out the colour to a great extent, and if care is taken in regulating the heat the grayish tinge will be developed, while, if all leaf is put through the process indicated, the slower the rolling, the more gradual the firing, coupled with close attention to the appearance of the hairy fluff, the finer will be the tips, the more delicate the flavour, and more pronounced the sweetish taste the bulk of consumers demand.—*Indian Planters' Gazette*, March 30.

II.

It would be impossible to lay down one general rule for all factories, as sites, temperature, and requisite accommodation differ so widely, but we have endeavoured to give an outline of the conditions leaf should assume at the several stages of manufacture. Actual green tea such as is imported from China can be approached, in so far as flavour goes, by elaborating the tedious panning and exposure, very slow firing, and the admixture of small quantities of powdered gypsum, as also the sprinkling of the leaf, in the final panning, with the same preparation—weak tincture of copper—that is sometimes used in giving the brilliancy to pickles; but the use of either of these minerals is to be discouraged, and in fact, if Mr Mansell's contemplated Bill passes the House of Commons, would render teas so doctored liable to confiscation at the Home, as they are now at the American Custom houses. Less objectionable colouring matter could be obtained from the solution of the plant used by Manipuris in dying their *keishes*, but it would need to be administered when the leaf was almost finished. We, however, may leave the

facing of tea alone, as one or two of the ingredients, used by such Chinese farmers as combine tea and sericulture cannot be more particularly alluded to for fear of creating a prejudice against all and any green teas our planters may send forward. No pans were used at any stage in the manufacture of the Belmont teas or other estates in the Nilgiris on which the same system of manufacture, introduced in 1871, was adopted; nor were any fabulous prices realised; the London auction figure was 2s. 9d., the retail price at Ooty and Madras Rs 1-8 per pound. The use of bags was taken up under a misconception, the leaf being placed in these and rolled, in an old-fashioned mangle, to wither, after the invention of Mr James Nelson on the Labac garden in Cachar in the same year; the fallacy of the operation as to mechanical rolling soon became apparent, and it was at once abandoned by the owner of Tudor Hall, who alone tried it. No secret was ever made as to the method of manufacture pursued; but as curious visitors intruded at unseasonable hours, requesting rather liberal samples, a notice had to be placed on the gateway that the premises were private and not public.

The experiments carried out by Mr McGuire in Ceylon tend to show that with suitable buildings the temperature needed to secure that necessary for developing the syrupy flavour can be had in hill and plain alike, irrespective of climatic influences. Should this be correct, all difficulties of fitting our teas to suit any taste may be considered at an end; and although the spreading out or keeping leaf in a state of suspended animation, as it were, may involve the erection of a cooling house, such need not be more expensive than the sheet-iron rooms on board our large fruit and meat carrying vessels; while in Assam and Bengal, at any rate, we have no dearth of a non-heat-conducting material in the common sola of the paddy fields; refrigerating appliances also are becoming cheaper and more simple in construction almost daily. Adverting to the "steamers," of Messrs Dean and Rae, that Messrs P R Buchanan and Co. suggest should be sent up to some gardens for green tea manufacture, from all we can learn these are a revival or adaptation of the jacketed steam pans invented by Mr. Thomas Barry of the firm of Barry Smith in 1861-62. Though only used for panning half-rolled tea, and consequently abandoned when all panning was discontinued, they would have been useful in withering; but, as Mr Davidson with his above-mentioned cool wither has anticipated them, unless they will serve some other purpose, no further allusion need be accorded them. We are not in a position to say whether the process of manufacture now pursued at Belmont is the same as introduced in 1871, but a glance at the Directory shows that, besides Messrs MacDowell of Madras, there are seventeen residents round about Ooty and Conoor who can vouch for the superiority in flavour and suitability of taste those teas were distinguished for at the time we refer to. We do not see that any difficulties present themselves in making tea in the manner suggested. Slow rolling, constant separation of the leaf, retention of the juice, with ordinary care in carrying colouring to the verge of, but not up to, actual fermentation, are not much to demand from the manufacturer; and, if meteorological vagaries can be rendered of no account, night working would be unnecessary. The present machinery is all that is required, while, if pans should be deemed necessary, those of suitable size are procurable in almost any bazaar throughout the country. In conclusion, we may mention that the late Dr. Barry contended, and his opinion was confirmed by other chemists, that flavour in tea was better attained by direct heat from charcoal than by any hot air or other means of curing. Unfortunately the wholesale destruction of wood that has gone on in the tea districts renders a universal return to charcoal out of the question; and we ourselves do not think the above contention can be sustained, as the slump in tea has arisen from over-production and throwing coarse mediums on the market; while we believe the American, Colonial, and home demand for sweetish Congous can be as well met by sirocco dried tea as by the old methods or modifications thereof. It would be advisable, however, that this matter should be set at rest; and we invite one or two of our readers to prepare samples in the above described manner for submission to the London trade; for, high as the price of charcoal has risen, some means of cheapening it or substituting an inodorous fuel in its place may be devised. However, this is a matter for subsequent consideration.—*Ibid*, April 6.

PLANTING NOTES.

Cardamoms.—In the Ash of Cardamom Messrs Cowley and Catford have discovered cobalt, nickel, manganese, and iron, and they attribute the black ash to the formation of phosphite.—*Chemist and Druggist*, March 23.

Competition in Quinine Pills.—The *Sourabaya Courant* states that the united German quinine-factories propose shortly to commence the sale of quinine pills in all the principal towns in Java, at prices based upon those paid for Bandong quinine at the Batavia auctions. This would doubtless result in a loss to the German works; but it is thought that it will have the effect of forcing the Bandong factory to discontinue the manufacture and sale of quinine pills, from which they derive a considerable income. The Java paper mentions this as a danger threatening not only the Bandong factory but also indirectly the cinchona-planters, and it exhorts the latter to persevere in the co-operation which has led to the present favourable state of the local quinine industry.—*Chemist and Druggist*, March 30.

Java Government Cinchona.—The report on the Government cinchona plantations in Java for the quarter ending December 31, 1900, states that the young plants are in excellent condition, and are developing strongly. This is due not only to the favourable weather during the period under review, but also to the fact that only healthy and large plants have been used for planting out. The plantations are free from disease and insect-pests, with the exception of those in the western part of Tirtasari, which are somewhat seriously affected. Contrary to recent experience, there has been a great lack of labourers, a fact which is also felt in private tea and cinchona plantations. By the end of December practically the whole output had been shipped, partly to Tandjong Priok (for export and partly to Bandong quinine factory. The whole yield of bark in 1900 came to about 560 tons; of this quantity 378 tons were exported to Holland, and 182 tons worked up at Bandong. At the auction of cinchona-seed some specimens fetched as much as 46*l.* per packet of 25 grammes: shoots for grafting were sold at 16*s.* 8*d.* each.—*Chemist and Druggist*, March 30.

Correspondence.

To the Editor.

COFFEE IN B. C. AFRICA.

I.

Dear Sir,—The cause of diseased beans is in my opinion not far to seek and may be attributed to three particular enemies of the coffee tree viz.—Drought, Borer and Grub.

DROUGHT.

The first of these three is very much to be dreaded at low elevations from 1,500 to 2,700 feet altitude; above the latter elevation coffee does not suffer *visibly* so much, but it does in the course of years become very visible indeed, and experience has shown careful observers that the trees become so damaged by the scorchings of a few dry seasons, drying up the very life sap of the trees and murdering the whole of the bark, pith, and even the wood of the coffee bushes, leaving alone the (*lungs leaves*) brittle dry, cankered and almost sapless —which is quite unnatural to a healthy coffee bush in its proper element. When the coffee tree gets into the condition alluded to above, there is no cure for the resulting light chipped, and black beans, caused I think by the weakened state of the tree, but to cut it down, and let a sucker grow up from the bottom. By selecting the healthy sucker, which is usually the biggest and strongest, a sound crop is secured again after 18 months or so. Now to prove that the scorching has a lot to do with damaged beans, I am quite sure no one will deny the fact that young coffee that has not been scorched always gives a sound crop, but the older the estate is, the more damaged the coffee becomes if the seasons have been exceptionally dry till almost worthless, unless cut down as I have stated above.

Cutting down does not always prove a remedy for light and damaged beans, especially at the lower elevation, for I have observed in a very dry year that the trees have been burnt right into the ground in fine or very light friable soil that has undergone much tillage so that cankered, sickly suckers came up, and the only cure for this condition of the tree is pull it out, and replant; and as this usually happens in the richest of soils composed almost entirely of vegetable humus—the plants take root and grow as vigorously as in virgin land.

At this lower level, about 2,000 feet, in dry seasons, our coffee suffers much more than it does at and around Blantyre, where the elevation of most of the estates runs from 3,000 feet upwards; not only does the sap get drained out of the bushes by excessive heat but they lose their leaves and the wood dies back. In such a year as 1897, coffee 1 year old was so damaged that it had to be cut down as it was nearly all black-hearted and cankered, and the trees that were left (supposed to be healthy) were so much damaged that the maiden crop on those trees had any amount of diseased leaves so that it would have been better to have cut all down. This is my own experience, and I am quite convinced that no amount of moisture put into the soil by means of irrigation would save our coffee in such a year. What is wanted is moisture in the air, which this country, being so far from the sea, is singularly void of during October and November, even in favourable years.

To prove this fact I only need to mention that a number of coffee trees under my bath-room where the soil was daily moistured, and by the sides of streams in damp and satuated soils, lost their crops, (when blossoming to the tune of 10 cwts per acre) and wood also. Whereas coffee under a canopy of shade held its crop without losing leaves or wood, and further the coffee under proper shade has never in my experience produced black or spotted beans; this I am prepared to prove any day, that is provided the coffee has always been healthy and grown under proper shade, and not damaged before putting it under shade. What I mean is, healthy plants, *not black-hearted*, planted under a canopy of shade, lofty, does not produce diseased beans in B. C. A.— Unfortunately however the older our coffee grows (when it ought to be in its very prime, yielding fine crops) it gets so rotten that it is hardly worth cultivating in some localities; this fact we need no longer deny.

Low topping in green wood just before the dry months, usually resorted to to force blossom, is a dangerous proceeding in B. C. A. It causes much canker on the upper part of the coffee bushes, and forces out too much flowers, more than a 3-year-old tree can stand, resulting in much injury to the whole bush, impairing its health and vigor for the rest of its existence I may say; whereas if left to nature, say, till a height of 8 feet or more is attained before topping, the tree would not be taxed with over-blossoming and over-bearing before it is able to stand it. Further the bushes are not so easily scorched by the sun and hot winds when well grown high off the ground, and any canker or damage done to the top of the tree, when young, is likely to grow out of it or be topped off when the tree is ultimately topped in matured wood; at whatever height wind and fertility of soil direct. I don't think in any part that I am acquainted with in B. C. A., that coffee should be topped low on account of wind, but I have seen estates where the soil would not support a big tree, in fact coffee should not have been planted at all.

I am not so sanguine now as I was some years ago that coffee is the permanent and remunerative investment that it should be in B. C. A.: doubtless good crops of 6 to 8 cwt. per acre have been secured by some lucky individual planters, mostly maiden crops; and until shade be universally adopted in this country, I am sure those good crops will be the exception instead of the rule.

As for my own part I regret ever having cleared the land to plant an acre of coffee here, and would not do so again after the experience I now possess for I am convinced that

SHADE IS ABSOLUTELY NECESSARY

for the successful cultivation of our staple product, coffee, which let us hope in spite of black beans will always remain king.

If good land could be get at an elevation of from 3,500 to 4,500 ft. coffee would not get scorched, and it would not suffer from borer and grub to the same extent as it does below that elevation, and although we are some 16 degrees south of the line frost need not, I think, be feared unless the situation be such as to prevent a current of air passing over the coffee during the months of June and July (such as in a very low sheltered hollow), by the way, our windy months in B. C. A.

When a coffee tree is weakened by over-bearing, leaf-disease, borer, or grub attacking the skin or roots, or any other cause, the yield will consist of a greater or less amount of defective beans, as a natural consequence, which the application of manure helps to remedy, but no amount of manuring or careful husbandry will prevent the alarming amount of defective beans found in our coffee. This is proved by coffee trees growing amongst manure at my cattle-shed door, which were severely scorched and yield a heavy crop of worthless coffee.

Nothing but lofty well-regulated and thin shade will ever, in my humble opinion, mitigate or remedy the above defects. It is no use advocating the Loquat, Pride of India, or other bushy small trees, as I have seen some writers stupidly doing. One has only got to stand under a Loquat and afterwards under a large-spreading lofty tree on a hot day in November to see the absurdity of some people's ideas of shade, for a shade-loving shrub like coffee, which is a surface-feeder if its roots can only but exist on the surface, which unfortunately they cannot do during the dry months in exposed land

The fine feeding white rootlets' vitality is I am certain destroyed ; in fact, strange to say, very few feeding roots are to be found near the surface on our fields of coffee on this account, but with shade or in a wet climate a singular network of coffee fibrons feeding roots is to be found on or near the surface.

The great heat caused by the sun shining on bare land increased with hot winds during our hot and almost rainless September, October, and November, months does a great amount of damage to our soil, as well as coffee, by exhausting the fertilizing ingredients, which would or should go to benefit the growing crops on the land. This fact is well borne out by the difficulty we have in getting supplies to grow the second or third year; also in this simple fact, viz—when a native hoes a garden in September for a crop of cereals, he does not burn it off till just before he sees the rain is coming, but on the other hand should a bush fire by accident run into his garden, he assuredly abandons that garden and hoes another, for he well knows the nitrogen soon vanishes from exposure to one or two months' sunshine before the rains with which only he is able to plant. Very friable soils retain the heat of a day's sunshine all night and in fact is seldom cool in October and November and no Analysing Chemist is required to prove the damage done, under such conditions, to our best soils through exposure.

It can be easily seen how rich our sonls are in fertilising ingredients from the flora they support and the rich harvests of Indian corn and millet they produce, crops which a poor soil will not even grow ; but those almost inexhaustible soils, (which nature never intended to be exposed to the full force of our tropical sun) in the course of a few years must be allowed to run to bush and be covered, to once more renew its fertility—not lost so much by the feeding of a few crops of cereals as by exposure and wash which does not happen from covered land.

It may be said that a good field of coffee covers the land, and it should do so ; but unfortunately coffee, as far as I have seen, never covers the soil in this country.

It needs no scientist to tell us that the soils on our coffee estates are wanting in nitrogen and other organic ingredients after some years' exposure; on the other hand we also need no scientist to show or prove to us that most of our soils are the very richest to be found in Africa or elsewhere. But what we do want to know is, how we can best take care of our rich soils, preserve their fertilizing properties, and renew them for the benefit of the growing product on the land and of man.

It need hardly be doubted that shade trees do all this for us to a great extent.—Then why bare our lands entirely for coffee cultivation ? H. B.

II.

BORER AND GRUB.

DEAR SIR,—BORER is one of the worst enemies of our coffee and it escaped my observation till 1893 ; and well do I remember the first beetles I saw and seized on a Momba, bark cloth tree, in the month of November of that year. This longicorn or stag beetle was no stranger to me in Ceylon, although the specimen in that island is darker in colour, glossy, and altogether a handsomer insect than ours is here. The damage done in Ceylon was only very limited and confined principally to the drier districts, and in those districts, only round the edges of the forest and grass lands.

IN TRAVANCORE

at low dry elevations I saw much damage done to coffee, in fact every other tree suffering from the ravages of what was said to be the same borer as ours. A coffee expert introduced to me by the manager of one of our local companies assured me the Indian borer is the larva of a *fly* ! Query, is this so ! ?

Well, to proceed with our borer, the beetle is a dirty slate colour, not numerous by any means in its natural element, for it is rarely met with. This is no doubt accounted for by the bush fires destroying the beetles, when they are fully formed or nearly so and ready to fly in October and November but still confined in the cavity of woody fibre, in which they remain for about three months, being changed from the grub to the beetle ; besides, natural enemies in the forests and grass lands evidently keep the number limited.

As there are no bush fires on a coffee estate and few if any natural enemies the stag beetle finds a luxurious and very

COMFORTABLE HOME FOR PROPAGATING,

feeding on the bark ; the grub, boring in the wood and making its nest in the stem of the coffee and emerges thence a full-fledged beetle in the course of 12 months, and in the course of a few years they become so numerous (for each female lays from six to seven eggs) that a regular nursery is made of a coffee plantation till you can gather a hatful of the beetles in the course of an hour, and the ravages of the borer become so great, that an estate may be abandoned in the course of 8 or 10 years, unless steps are taken to save it. The earlier this work is attended to on a plantation the better for the owner. I therefore consider it worthy of my time to tell my fellow planters, who may know nothing of the ravages of the borer in B. C. A., how to prevent the great amount of damage done, which only becomes visible after years of labour in bringing a coffee tree to its prime, and supplying a breeding garden for longicorn beetles and their larvæ.

DURING THE FIRST YEAR'S WORK

on a coffee estate the planter need not trouble about borer, beginning work say in June and planting up in February, the beetles only being in existence from say 20th November to 20th February (for they only live three months) they are never seen on a new clearing.

The second year when the plants are about 20 inches to three feet high the trouble begins, and not later than 15th November a few boys, according to acreage should be told off to search for beetles, and go over the garden, marching up and down line after line of coffee daily, to the end of the beetle season in February-March ; the boys usually bring in one or two each daily, all through the season, and a young planter will crow and say " Now I have saved so many coffee trees and not a borer exists on my estate"; but he is mistaken. The borer beetle

NEVER FLIES DURING THE DAY-TIME

unless tormented till it is obliged to take to its wings, but sits quietly feeding off the coffee bark, usually on the sunny side of the plant, till dusk. It then flies off to another and another tree, visiting several, perhaps, during the one night and the habit seems to be to lay an egg in the soil, by making a small cavity near the stem at the bottom of the tree. I however am open to correction as I have never found an egg either on the ground or on the tree, although I have found many a beetle on the coffee trees and searched for eggs. Boys however assert that the eggs are laid in the ground and as it is the natural habit of the beetle family to lay eggs in the ground, I believe them. Only *one* egg seems to be laid at or near each coffee tree by one beetle, although others may lay in the same place ; for when the beetles become numerous on old plantations three or four grubs may be found on one stem of a coffee tree. I have not however found more than one borer in each tree during the first year, and usually two or three affected trees appear where a beetle has been caught.

On old properties where coffee is riddled with borer I have seen boys gather a hat-ful of beetles in a

day, and I myself have picked off as many as half-a-dozen from a coffee tree (so this proves how numerous they are) just after the first heavy rains in November and it is alarming to think of the amount of damage done if no steps are taken to check this pest.

AFTER THE BEETLES HAVE DISAPPEARED,

signs of their presence begin to show by a change of colour in the foliage of a few plants where each beetle (if a female) has been caught, the leaves of the plants turning from a deep green to a light yellow. The searchers must continue their good work, but now armed with a foot length of fine wire, and a knife, going regularly over the estate as before (the boys must be visited daily, watched, and carefully instructed at their work or they will do as much damage as the borer by cutting the trees &c.) It will be found on examination of the trees attacked that the grub, at least for one or two months, does not enter the wood of the plant, but works at the bark, sheltering itself from any natural enemies by a covering of refuse fibre made from the bark and ringing the tree, working first one way, and then another, feeding on the inner bark till a complete circle is made; it is then the signs of an attacked tree become visible; the flow of sap being completely cut off. At this stage many grub can be caught, and when the trees are furred up, they often recover. I make it a rule however to put in a supply beside all doubtful plants. Many grub

ESCAPE DETECTION

at this time, but by keeping the searchers at work going over the estate, and again later on, when the borer manages to enter the wood, the sawdust appears and a wire must be pushed into its hole to kill it. It can be seen that it is squashed by rubbing the point of the wire across the back of the hand, when mucilage matter will be found on the wire, if it is killed. The grub is sometimes difficult to get at as it sometimes makes a crooked tunnel, in which case the tree has to be cut to get at it It is frequently found that a borer goes down the stem, after entering the wood, into the ground; in this case it is difficult to get at, and the tree is usually destroyed by the roots blackening and dying right away, whereas when attacked above the ground there is every chance of recovery, if taken in time.

Borer enters the chrysalis stage about the end of July or early in August, but an odd one is to be found later than this. So that you are practically at work about seven months at borer beetles and grub, from December to June, both months inclusive. Any extra care and attention by planters to this most important of all works on coffee estates in B.C.A. will repay them. In addition to

REGULAR SEARCHERS FOR BORER

it is not a bad plan to give a little salt or other trifling reward to the ordinary workers, weeders for instance, during the season for any beetles they may secure in their line of work; but care must be taken that they don't leave their work to go off in search of them.

The borer beetle is well known on a coffee estate by the name "Nyanza," or horned beetle, and the larva as budzi.

I was informed, when in India, that when coffee trees get old and hard-wooded they are impervious to the attack of borer grub. This may be the case there; but I am quite certain that eight-years-old coffee if neglected is attacked with the insect here; but I think the older the coffee trees become the less likely they are to succumb to an attack of borer, and I am quite sure on a badly attacked estate that three or four years old coffee suffers most, especially in a very dry year. This may be partly dne to heavy cropping at this age.

Of course, diseased leaves are partly caused by borer; as the lateral roots die off, the primary roots turn black and diseased, and as the root surface diminishes the foliage and branches lack in nourishment; and as a natural consequence, through loss of health and vigour, the tree with its fruit becomes diseased, if it does not all together perish.—Yours truly,

H. B.

RUBBER IN MEXICO:

INDIAN MODE OF PREPARING RUBBER FROM "CASTILLOA ELASTICA."

Mexico, 12th March 1901.

DEAR SIR,—The following method of preparing rubber by the Mexican Indians, which was quite new to me, may be of interest to you and your readers:—"On taking over charge of this (Hacienda) last August, I found scattered through the coffee fields some 25 or 30 rubber trees (*castilloa elastica*) of different ages and sizes and all much the worse for barbarous tapping in years past. Some Indians asked me if they might tap the trees on shares, and considering them of no value I allowed them to do so. They proceeded leisurely to work and in a few days brought me to the house three old kerosine oil cans of rubber milk and an armful of a jungle creeper called by them 'Amole bejuco' but which I have since had identified at Kew as *Ypomœa* (*colonyclion*) *Bonanox L.* They asked for an old soap-box and proceeded to pound the creeper with a stone, putting about double handfuls of the crushed creepers into five gallons water, they then poured some five gallons rubber milk into the box and two gallons or so of the water, stirred it for a moment or two and in less than 10 minutes took from the box a slab of white rubber 34 by 16 by 6 inches, poured away the water left and proceeded as before until they had four large slabs of rubber. These they split in two and hung in the sun, and in a day or two it turned black. The nett result of rubber was 53 lb, which sold in Vera Cruz for 95 cents (say two shillings) per lb, or $50·35. Had I employed my own peons to do the work at 62½ cents per day, the cost of producing the rubber would have been about $6·25 silver. In a regular rubber plantation of course it would have cost a little less, as these trees were scattered about.—Yours truly,

E. O. DARLEY.

TEA FOR THE MILLIONS IN INDIA AND CEYLON: A PACKET COMPANY WANTED.

DEAR SIR,—I was glad to hear that the I. T. A. had, at last, begun to take action in trying to secure a local market for their teas, but are they going the right way about it? They seem to be still under the impression that the natives will only buy the cheap low-grade teas. This is a great mistake. When trying to sell tea to the natives some years ago, I found that rich natives and even fairly well-to-do traders always preferred to buy the very best tea though at the time Orange Pekoe was R2 per lb., while the Muhammadans wanted green tea. The natives are all fond of tea and the poorest of them spend more in arrack, bhang or other stimulants than they need ever spend in tea; but to win this market it is necessary to pack the teas in very small packets, a 4 oz. packet is the biggest that would sell well, one and two ounce packets would have a far better chance.

Planters could not be expected to make up these tiny packets at the factory. They have enough trouble with larger packages; what is wanted is to start a Company who would buy their teas in the open market and put it up in small packets and distribute them by means of Commission Agents in every native bazaar. The Company would need liberal support from the I. T. A. for the first year or two, after which

they would probably be able to stand alone. There should be no difficulty in raising such a Company, as I should imagine every planter in India would be glad to take a share. The packets should consist of at least 20 per cent of the finest tea and a fair proportion of commons. Then there is the green tea trade with Persia and Afghanistan established years ago and which paid well even in those days when tea was selling at more than double its present value; this needs only a little pushing to develop enormously. I see they have just made up their minds to despatch a large caravan of tea to Persia; it is to be hoped that this will be Green and not Black Tea, as I know that neither Persians nor Afghans will drink black tea; and if the Indian planters send Black Tea there, they are bound to fail.

With regard to making a small packet, it is absurd to contend that this would be too costly and troublesome to pay. See how neatly even matches are packed and labelled, a properly arranged factory could turn out hundreds of thousands of these small packets daily; and the labels, which should be in the native languages, would cost a mere trifle to print owing to the number required. In many of the large cities, China Tea in neat little paper packets can be bought for a few pice and these constitute the chief supply, not only for the natives but Eurasian and poorer class Europeans who all prefer to get their daily requirement in this way rather than buy even a lb. of tea at a time. This is the sole reason why China Teas still continue to hold their own in India.

The I. T. A. would do well to devote their whole time and attention to developing the local market rather than waste their money in trying to capture foreign markets; it would cost less money than is required for America alone, and the possible results are practically unlimited. It would not be a matter for great surprise if, in a few years, India ceased to export tea; their total crop does not amount to 1 lb. per head of population, a rate of consumption already about in Ceylon.

I make no charge for the above, but if the I. P. A., after testing its value, should desire to express their gratitude by sending me a handsome bonus, I promise not to refuse it.

AN OLD EX I. P.

CACAO PODS AND SEED.

DEAR SIR,—Will you kindly allow me space to comment on Mr. Carruthers' article on "Cacao Pods and Their Seed," appearing in your issue of the *Tropical Agriculturist* for April, of this year.

Mr. Carruthers' examination of a certain number of cocoa pods leads him to the conclusion that "the character and size and weight of the fruit do not afford any criterion of the weight of contained seed."

There is, however, one way in which recognition of a variety may well be made, namely, by *its name*, which, in connection with the diagrams of pods and their contents which you publish, has unhappily been omitted. This cannot but rob the table of half its interest, and all its utility. Will Mr. Carruthers be good enough to name his diagrams? Nos. 2 and 7 are presumably Forastero; but for all we know perhaps Nos. 1 and 20 are too, and in view of the great importance of sorting out and making known the more remunerative varieties of Forastero, I am surprised such an obvious sign-post as a plant's name should have been omitted—doubtless by oversight.—Yours &c.,

POD.

P.S.—In reference to your Editorial note on my cocoa letter, I was not aware "that *hemileia vastatrix* first appeared on young coffee which had never been manured, but was growing near jungle where the fungus had its habitat." In this case the 'dirt' was generated in the jungle, and not therefore through drastic manuring. But drastic manuring—the suggestion is not original—may have had a hand in nursing the fungus elsewhere, may it not? Further, from the extract you quote from Berthelink, is it implied in the sentence "have not only not lost a jot of their original value, but have rather increased in productiveness" that the original cacao trees are still living? If this is so, local conditions must have changed everything; and that certain varieties of cocoa greatly vary in behaviour even in this island's localities seems to point to a very sensitive appreciation of surroundings in the cacao tree.—P.

[Any treatment that left coffee weak or played-out undoubtedly made it an easy prey to the fungus when once it had found its way all over our coffee country.—The rich deep cacao-growing soil of Dutch Guiana is, we suspect, without parallel in any part of Ceylon.—ED. *T.A.*]

TEA CULTIVATION AND MANUFACTURE IN SOUTH CAROLINA.

17TH APRIL, 1901.

(*By a Ceylon Planter*).

DEAR SIR,—Ten years have elapsed since I assisted Dr Shephard, the proprietor of Pinehurst, Summerville, sixteen miles from Charleston, S C.

The acreage then under tea was only twelve acres in patches, all doing remarkably well and looking very promising. There was also a small Government tea garden located near a lagoon and Dr S advised me to leave it alone as it was considered unhealthy.

However, I was very keen on restoring to cultivation the Government patch of tea and should have applied to Washington, had I not been employed by Dr Shephard who through correspondence with Mr Reed, tea merchant of 13th street, Philadelphia, engaged me as a tea expert to make an improvement in the manufacture of Pinehurst teas. Through Mr Reed I was engaged for one hundred and fifty dollars or £30 for one week's work and gave Dr Shephard material assistance. I went round from New York by steamer and met Dr Shephard at Charleston.

The first question I put to him was—Have you got any sieves for grading your teas; his reply was "*not one sieve*"; so we went immediately to the Ironmongers in Charleston and purchased wire work of Nos. 16, 14, 12, 10 and 4 mesh. We then took train to Summerville, carrying the rolls of wire with us, and the estate carpenter made the sieves according to my instructions. Dr. Shephard made me very comfortable in his beautiful house surrounded by one of the most valuable botanical gardens in the world. For I must tell you Dr. S. is a botanist of no mean order. Roses from all parts of the world, flowers, shrubs, ornamental trees, both indigenous and exotic, tastefully arranged, a list of which I possess and will send you some day when settled down. The largest rose bush in the world was growing over Dr. S.'s house in Meeting Street, Charleston, the stem as thick as a man's body and climbing over the roof of the house, festoons of

beautiful large white roses hanging round the walls and over the arches and gate-way. I have a photograph of this gigantic rose, which you shall also see at some future time. But to return to tea, there was a good golden finish ready for plucking.

Our pluckers were little boys and girls from Dr. S's mixed school on Pinehurst and, when called upon to pluck tea leaf, the young lady governess promptly attended with red silk umbrella to supervise the field work; the writer had occasion to call them to order sometimes and to pluck finer. The result was, the plucking was a success, and the leaf brought in withered the same evening. Every available room and the staircase was used for withering. I told Dr. S. to have it well withered; next day we got some sturdy negroes to hand roll and ferment, and we fired it with an American evaporator.

Our temperature was 180° and, after sifting the roll, I reduced the temperature to save the golden tips; and Dr. S. lent me 16 silk handkerchiefs to save them from burning and disappearing. This was a great point gained, and our first chest of tea was a fine sample. The No. 1 Flowery Pekoe and Orange Pekoe were sent to Washington. Dr. Shepherd's sister being a Senator's wife and interested in the Pinehurst Tea enterprise, helped to bring the tea into notice and Mr Reed's reports at Philadelphia made it a name in the American markets.

I am glad to mention it was very favourably reported upon in both New York and in London.

Dr. Shephard was very pleased with my work and we remained in the tea house until 1 o'clock in the morning to finish our work. It was a pleasure to me to work for a man like Dr. Shephard, a perfect gentleman in all respects and a very clever man, not only on botanical subjects and tropical agriculture, but upon mining subjects and the analysis of soils and minerals.

When writing up my instructions for cultivation and manufacture I found it necessary to gain some information regarding climate, temperature, and *average rainfall.*

Accordingly I took a letter of introduction to the Government officials and made extracts from their Government statistics for twenty years in South Carolina. The result of my extracts proved that the rainfall average for twenty years was only sixty-two inches, little more than half the quantity of rain required to make the tea enterprise a success commercially in South Carolina, and in this respect Dr. Shephard quite agreed with me that tea would not pay well on a large scale, whereas irrigation could be applied to a small area; then again, there are the cold months with cold winds checking the growth.

Several other people were growing tea on their farms in Carolina; some of them placed themselves in correspondence with me.

It was very encouraging to Dr. Shephard to obtain tea seed from all parts of the world through the Washington Government and make his selections from the best Assam-Hybrid jats. We spent a considerable number of hours in selecting seed bearers and tied pieces of silk ribbon round the stems of those to be reserved, so that the pluckers should pass them over. Some of the leaves on three-year-old bushes were as large as a man's hand and very strongly embossed.

I gave Dr. Shephard the addresses of both Colombo and Calcutta firms who supplied reliable tea-seed and told him it would be well packed. Some of the shipments from China and Japan arrived in bad order. Dr. Shephard had a nursery of thriving tea plants raised from imported seed, but I told him to select only Hybrid-Assam to get uniform fields of tea and large crops of leaf of good quality.

The Government tea plantation was a low China jat, though the bushes were large and required a good pruning. I believe I pruned a few of those bushes in June, 1891.

The people of the United States are fond of green teas and buy nearly the whole of the Japanese crop of 50,000,000 lb. (fifty millions). They like young Hyson mixed with black.

The best black teas are called *English Breakfast* and, when working with Mr McCombie Murray (late of Ceylon) in Philadelphia, I did a packet trade with customers at German Town, about 15 miles from Philadelphia city. When the very hot weather set in, my "English Breakfast" customers went to the sea-side, my tea business suddenly collapsed, and I had to write up about "Elephants" in the Philadelphia Press to keep from starving; then Dr. Shephard sent for me, and all was well that ended well.

Great interests are often involved in trifles and this was a remarkable instance. When tasting some teas for Mr Reed in 13th Street, Philadelphia, my eye rested on a small picture on the wall. I said to Mr Reed, "that looks like a plantation." "Yes," he said. "That is Pinehurst Tea plantation at Summerville, South Carolina, the property of Dr. Shephard." "What!" I said, "tea growing in the Southern States: *you don't say.*" "Yes," said Mr Reed, "*That's so* and I value his teas." "What would it cost to go down South?" said I, "it interests me." Mr Reed said he would write to Dr. Shephard and arrange for my visit, which he did, to our mutual satisfaction and benefit. I am glad cultivation has been extended and one dollar per pound paid for Pinehurst Tea.—Yours faithfully,

HENRY COTTAM.

Eucalyptus Resinifera.—Some two years ago, in the course of some most interesting and luminous letters from Rome, the Rev. H Ewbank told us that the Italian authorities recommended this species as the hardiest and most reliable of the species. Mr Ewbank obtained seed, distributed some and grew others. Five young seedlings were planted out last year near Ryde, Isle of Wight, and all five have so far got through the winter safely without any protection, whilst E ficifolia, on which great hopes had been based, has been severely injured by frost.—*Gardeners' Chronicle*, April 6.

Imitation Cinnamon.—The *British Food Journal* calls attention to the "manufacture" of imitation cinnamon. The adulterant used for cinnamon is gnava, or jungle bark, which costs about sixpence per pound in Colombo. This bark is carefully peeled, prepared and dried like cinnamon, and closely resembles it in appearance. The sweet odour, and the still sweeter taste, peculiar to cinnamon, are obtained by immersion for a few hours in large tubs of waste from the distillation of cinnamon oil, and afterwards, when dry, by touching the end of each bundle of the false guava pipes with a cloth saturated with cheap cinnamon oil.

THE KANDYAN HILLS COMPANY, LTD.

The report is as follows :—

ACREAGE STATEMENT :

Tea in full bearing	352 acres
Partial ,,	58 ,,
Planted in 1900	25 ,,
	435 acres
Cocoa	90 ,,
Reserve Land	785 ,,
Total	1,310 acres

The Directors beg to present their report for season ended 31st December, 1900, together with a duly audited statement of accounts for the same period.

The tea crop, including bought leaf, amounted to 227,611 lb ; and we secured 130 cwt of cocoa.

The tea gathered from the Estate itself was 182,013 lb, an advance of 22,013 lb over estimate, while the bought leaf represented 45,598, a total of 227,611 lb ; the two together costing 24·73 cts per lb to produce.

Taking Pansalatenne alone, the cost of placing the tea on the market was 22·27 cts per lb including 2·31 cts a lb for manure.

Prices were fairly good until the close of the year, when, with a large quantity of tea to sell, the market became greatly depressed, the results being a serious falling off in receipts, which has affected the profits on the season's working.

The surplus, after meeting all estate expenditure, represents a sum of R12,300·55, and after paying interest and other charges and providing a sum of R3,809·66 for depreciation, there remains a balance of R1,414·38, which the Directors recommend being carried forward to the new year.

During the season under review a sum of R15,970·87 has been spent on a Pelton Wheel Installation and other improvements to the factory, and R4,427·07 on the planting and upkeep of young tea. No further extensions are at present contemplated, and it is thought that the factory is now sufficiently equipped for the crops of the near future.

The new season's estimate of expenditure is based on a crop of 200,000 lb of tea at a cost of R43,481, including R1,800 for manure and 130 cwts. cocoa costing R3,760.

Mr. Edward S Grigson retires from the Board of Directors by rotation, but is eligible for re-election.

The appointment of an Auditor rests with the meeting.

THE TYSPANE TEA COMPANY, LIMITED.

THE REPORT.

To be presented at the fifth ordinary annual general meeting of the Tyspane Tea Company, Limited, to be held at the offices of the Company, 12, Fenchurch Street, London, E.C., on Wednesday, 10th April, 1901, at 2-30 p.m.

The Directors have the pleasure to submit the Balance Sheet and Accounts of the Company for the year ending 31st December 1900, duly audited.

With the deepest regret the Directors record the great loss that the Company has sustained through the death of Mr Walter Sandys Thomas, late Managing Director in Ceylon.

Compared with last year, the Profit and Loss Account shews increased expenditure and reduced receipts, but the former includes the sum of about £720 spent on Factory extension and up-keep of new clearings, which might legitimately have been charged to Capital instead of Revenue, had the Directors not deemed it inadvisable to do so in existing circumstances. The reduction in nett proceeds is due to the fall in the market value of medium teas.

The total crop amounted to 252,373 lb. Tea, which averaged 5·72d per lb. nett, against 258,370 lb. last year, netting 6·24d per lb.

Exchange averaged 1/4 5-16th per Rupee against 1/4 23-64th last year.

The Net Profit for the year, after payment of the Interest on Debentures, is	£501	11	11	
To which has to be added the balance brought forward from last year of	214	15	4	
				£716 7 3
The Directors propose to pay a Dividend of three per cent, requiring ..	540	0	0	
And to carry forward ..	176	7	3	
				£716 7 3

Mr John Philip Herringham, the retiring Director offers himself for re-election. The Auditor, Mr J Hamilton Alston, also offers himself for re-election. —By order of the Board, ROBERTSON BOIS & Co., Agents and Secretaries.

LONDON, 1st April, 1901.

The acreage of the Estates is as follows :—

Tea in bearing ...	..687 acres
Tea in partial bearing ..	... 6 do
Tea planted in 1896 ..	... 47 do
do do 1897 ..	... 10 do
do do 1898 ..	... 28 do

KELANI VALLEY TEA ASSOCIATION, LIMITED.

Report of the Board of Directors. To be presented to the Shareholders at the Fifteenth Ordinary General Meeting, to be held at the Office of the Company, on Monday, 15th April, 1901, at 12 noon.

The Directors beg to submit to the Shareholders the Report and Accounts of the Company, duly audited, for the year ending 31st December, 1900.

The total crops from the Company's four Estates amounted to 662,248 lb. against 575 255 lb. in 1899 ; the average price realised was 5·794d per lb., against 7d., and the average rate of exchange was 1s 4 27-64d as compared with 1s 4 25-64d for the previous year.

Owing to the very depressed condition of the Tea Market during the last six months of the past season, the profit earned for the year under review compares most unfavourably with that secured in previous years, but, with an improving Market, a natural short-fall in crops, and the steps now being generally taken to further reduce output and improve quality, your Directors have good reason to expect that very different results will be shewn for the current, and, it is to be hoped, succeeding seasons.

Including £419 2s 5 brought forward from 1899, the net profit for the past year amounts to £1,019 14s., from which has to deducted the Interim Dividend of 3 per cent., £562 19s paid in September last, leaving £456 15s., available, and this sum is proposed to carry forward to next season's account.

Debentures to the amount of £2,100 which matured on the 1st January, 1901, have been renewed for a further period of five years at 5 per cent per annum.

Two vacancies have occurred on the Board, one caused by the resignation of the Hon. D A C Scott, on account of ill-health, the other by the regretted death of Mr. Donald Andrew.

It is not proposed at present to fill the first-named vacancy, but, to occupy the seat of their deceased colleague, Mr. Donald Andrew, your Directors have appointed Mr. George Gray Anderson, who, in accord-

ance with the Articles of Association, retires from the Board at this time, and being eligible, offers himself for re-election. Mr. J B Laurie, C.A., also offers himself for re-election as Auditor.

G W PAINE, Chairman.

16, Philpot Lane, London, E.C., 3rd April, 1901.

THE BALMORAL (CEYLON) ESTATES COMPANY, LTD.

REPORT.—To be presented at the Third Annual General Meeting of the Balmoral (Ceylon) Estates Company, Limited, to be held at the Offices of the Company, 12, Fenchurch Street, E.C., on Thursday, 11th April, at 2·30 p.m.

The Directors have the pleasure to submit the Balance Sheet and Accounts of the Company for the year ending 31st December, 1900, duly audited.

The total yield of Tea was 563.556 lb. against 528,804 lb. last year, being at the rate of 606 lb. per acre all round; the cost of production, exclusive of Capital Expenditure, was 26 cents per lb free on board at Colombo, and the gross average price obtained was 8·86d per lb. against 9·47d per lb. last year—Sandringham Teas averaging 8·90d and Clydesdale 8·81d per lb. Exchange has averaged throughout the year 1s 4⅛d against 1s 4 19-64d last year.

The Net Profit for the year amounts to ...	£7,767 3 7		
And the Balance from last year to ..	1,152 14 5		
Making a total of ..	..		£8,919 18 0
The Directors have already paid out of this Dividends on the 6 per cent. Preference Shares for the year ending 31st Dec., 1900 ...	£1,800 0 0		
Interim Dividend on the Ordinary Shares of 5 per cent. free of Income Tax..	2,601 15 0		
Income Tax ...	152 16 8		
AND IT IS PROPOSED:—			
To pay a Dividend of 7 per cent. free of Income Tax on the Ordinary Shares, making 12 per cent. for the year ..	3,642 9 0		
And to carry forward the Balance of ...	722 17 4		
			£8,919 18 0

The Auditor, Mr. J. HAMILTON ALSTON, offers himself for re-election. By Order of the Board, C. G. BOIS, London, 2nd April, 1901. Joint Secretary.

RUBBER IN N. E. RHODESIA.—The rubber district round the southern end of Lake Bangweolo has been largely devastated through the vandalism of the natives, carelessness in the method of gathering, and the wholesale destruction of the plant in search of the root-rubber. On the Loangwe, near Molilo, Mr Highfield, a former resident of Salisbury, is farming and planting Brazilian rubber.—*Chemist and Druggist*, March 30.

PLANTING NOTES.

EXTRACTION OF CRUDE INDIA-RUBBER.—Patent No. 9906, 1900. Date of Application, 29th May, 1900. Accepted, 23rd February, 1901. A L Arnaud, 35 Rue de l'Arbalete; A V L Verneuil, 25 Rue Humboldt; A M G Wehry, 16 Rue Raffet; and A G Lebeuf, 4 Impasse Girodon—all in Paris.—*Home paper.*

MALAYS BUSY WITH GUTTA IN SARAWAK.—At Sadong, in Sarawak, Malays are unusually busy in collecting "Jelutong" gutta. Instead of the usual wasteful method of felling the trees, these Malays tap the bark about four feet from the ground. Two of their employers are the sole possessors, at least in that district, of a secret for refining this "jelutong" gutta and producing a gutta of high quality, for which they hope to obtain large prices in Singapore.—*Straits Times*, April 17.

CAMPHOR CULTIVATION.—Having ourselves been moving for some time past to secure a fair trial of camphor cultivation in the island, we are interested to find in an Indian paper that in view of the increasing price of camphor a German firm has suggested India and Ceylon as suitable countries for cultivating the camphor tree. The world's requirements of camphor are estimated at 10,400,000 lb. per annum; of this, under the new administration, about 5,200,000 lb, will be supplied by Formosa, while about one-third of the whole will be exported from Japan, leaving a diminution in the exports, compared with 1898, of about 3,640,000 lb.

TEA-GROWING IN CAROLINA, UNITED STATES.—We call attention to the interesting account, given on page 787, of Dr. Shephard's attempt at tea culture near Charleston, by Mr. Henry Cottam, who did much to show him the proper mode of manufacture as well as of cultivation. It is a curious fact that, while Ceylon proprietors are lavishing their money to try and win the American and Russian markets for its teas, a Ceylon planter should have started tea growing in Carolina on its right course, while another is at this moment trying to show the tea managers for Messrs. Popoff at Batoum the way "how to do it."

BOUVARDIAS: OF THE CINCHONA FAMILY.—It may interest gardeners in this country to learn that Mr A C Rolt, of Kissengunj, has succeeded in growing these beautiful plants in his garden in Eastern Bengal. The genus is a native of Mexico, but several fine hybrids have been raised at home. The plants belong to the natural order *Rubiaceæ* of the Cinchona family), and the flowers resemble those of the Ixora in character and form of inflorescence. In fact, a bunch of Bouvardia flowers may be easily mistaken for a bunch of Ixora blooms. They are extremely difficult to grow on the plains of India; and that Mr Rolt has succeeded in growing them says much for his skill as a gardener. He writes to us on 4th instant:—"My Bouvardias, which never flowered before, are just coming into bloom. They grow very strong with me, but have not hitherto flowered. This year, however, they are full of buds. Bouvardias on the plains of India are, I suppose, something quite new." On the hills, and notably on the Nilgiris, these plants should grow and flower most luxuriantly.—*Indian Gardening and Planting*, April 11.

OUR STAPLE EXPORTS:

TEA *vs.* COCONUTS.

It is curious to note the widely different positions our two principal staples of Export have occupied during the first quarter of the current year. Tea had dropped in price to a point which had never before been touched, and which we sincerely hope will never again be experienced; while the remedy for the depression, caused by overproduction, was yet in the future. True, the past few weeks have seen an appreciable advance in price; but the reduced output, by whatever means to be accomplished, has yet to be arranged for, although it is well-known that an unusual quantity of last year's tea entered into our January's shipments. Still, whether an actual reduction will be realized is a question, now that prices have risen and are keeping up, and that so many Companies have refused to give their support to any scheme for reduced exports. But that is not the question we wish to discuss now. What we desire to point out is that, while Tea Exports have risen, and while prices were disappointing during the first quarter of the year, the out-turn of Coconut products, on the other hand, show a falling-off in quantity to the accompaniment of high prices maintained for an exceptionally long period.

We had thought, on the authority of published reports and the forecasts of our own correspondents, that the effects of the drought of 1899 on the Cocount palm would cease to be apparent after the end of 1900, and that the current year would show an advance in Exports. That expectation has not yet been realised; but, not to travel out of the first quarter, the following are the figures which the Chamber of Commerce returns up to 1st April show (for the first quarter):—Of Coconut Oil, there were sent away 62,286 cwts., against over 102,000 cwt. the previous year and over 82,000 cwt. the two years preceding; of Copra 57,034 cwt. against 111,585 in 1900, and 68,900 and 69,275 cwt. in 1899 and 1898 respectively. In desiccated nuts too, there is a falling-off from over 2,800,000 lbs, 2,700,000 and 2,300,000 lbs in the three previous years to 2½ millions this year. Poonac, with 17,952 cwt, shows the largest proportional decrease, being less than half the quantity sent away in each of the two years immediately preceding, and less than one-fourth of the exports for 1898. Only in Coconuts in the shell is there an increase, with over 3½ millions in nuts against less than 2½ millions in each of the three years preceding; but this increase of a million nuts represents but a fraction of the deficit we have noted under the several important heads given above. The interpretation of these figures is that the expectation that this year's crops will compensate for the deficiency of last year has not yet been fulfilled. We do not say it will not be fulfilled, for we hear from many sides of the promise of very heavy pluckings during the next two crops; but even March and April crops have been disappointing in many places. The fact is that the Coconut palm in a congenial climate can scarcely get too much rain; while it is specially affected by drought, and the longer the latter lasts, the more prolonged the effect on the crops of nuts. Meanwhile the demand for Copra is keen, the prices keeping up to close on R 52 per Candy for "best"; and the Desiccating Mills may have to work short time until the coming big crops lower prices and render a large supply of nuts available.

"SPORT IN THE LOW-COUNTRY OF CEYLON":

BY ALFRED CLARK.*

The reading of this little book has afforded me much pleasure, and, as those portions of it that I consider myself qualified to criticise appear to me to be absolutely correct, I can only suppose that the remainder of the work is equally trustworthy. Being fond of sport, and having frequently visited the low-country of Ceylon, I had begun to fancy that I knew a good deal about the manners and customs of the fauna of its jungle; but, after reading Mr. Clark's book, I am ready to admit that my knowledge thereof, as compared with his, is woefully incomplete. I can therefore conscientiously recommend any one, really a sportsman at heart, who intends making a trip to the lowcountry of Ceylon after game, to provide himself with a copy of Mr. Clark's book, as it will be found not only to contain useful hints] on Sport, and on the characteristics of the wild animals, but also a brief account of the game laws. The chapters on elephants are specially interesting, although shrouded by what I fear is the not too pessimistic view that 2,000 is probably the sum-total of wild elephants now in the island. The greatest number I ever saw on the hills, in a herd, was eight, and these lived for many months on the top of the range above Rangalla. Near the ruins of Pollonnaruwa, however, I saw about 40 together, and these figures seem to corroborate Mr. Clark's experience. I was glad to read that the author's opinion is that "in spite of the thousands killed every year, there is no reason to think that snipe are less numerous now than they were formerly." When I recall the tremendous bags the planters of Rangalla and Medamahanuwara were wont to make, in the paddy-fields of Bintenne, I would not have been surprised to learn that they had become as scarce as that less palatable bird the dodo! If sportsmen in Ceylon are as keen as they were twenty years ago, I prophesy that Mr. Clark's book will in future as certainly be a part of the furnishing of their bungalows, as "The Directory" has always been.

COSMOPOLITE.

SIR JOHN MURRAY'S EXPEDITION TO CHRISTMAS ISLAND.

Sir John Murray, who has just returned from a six months' expedition to Christmas Island, during which he crossed the island from end to end—the first occasion on which it has been traversed—has made a statement with reference to his travels to a represent-

*Published at "*Ceylon Observer*" Office, 1901.

ative of Reuter's Agency.—Christmas Island, which is situated in the Indian Ocean, is 220 miles from the nearest land, and is some 12 miles long by seven broad. It is covered with dense forest, having an area of nearly 50 miles, and the sea depth around its shores is between three and four miles. There is no good anchorage, but only an open roadstead When Sir John Murray was on the island there were 13 whites, including a doctor, a chemist, and an engineer, living there with their families, together with 720 Indian coolies engaged in working the rich phosphate deposits. The animals and plants on the island are of extreme interest. The whole place is overrun with curious red crabs as much as 18 inches across. They are excellent tree climbers, and once a year there is a regular migration of these crustaceans, who travel in bodies like ants, taking 15 days on the journey, and returning inland after hatching their eggs. There are only five mammals on the island, including two species of rat not known elsewhere. They are of two colours, those on the plateau being brown, while those nearer the coast are black, and in order to keep them down a number of terriers have been imported. On the island are also to be found a toothless snake and a blind snake much like a worm. In exploring the island Sir John Murray had to cut a track through the dense forest until he reached the central plateau at an altitude of 1,000 feet, where travelling was not so difficult. One night he got lost in the forest, and had to subsist on the tops of sago palms, which he cut down. The island is under the Straits Settlements Government, and a resident magistrate has just been despatched thither from Singapore, together with an official of the Public Works Department, a scientific commission, and a force of police, 35 in all. They will select sites for the administrative buildings to be erected on the island. The climate is perfect, like a hot English summer, and prior to the British annexation no human being is supposed to have lived on the island.—London *Times*, April 1.

RUBBER FROM THE HULE PLANT IN MEXICO.

A process for extracting rubber from the Hule plant was discovered about a year ago by a Mexican doctor residing in Sierra Mojado. This plant, which contains about forty per cent of rubber, grows in the mountainous district of Mexico, as well as in certain localities of Texas, Wyoming and Nebraska. It is a species of sage bush, with small leaves and grows to a height of about three 3 feet. A patent on the process has been taken out in the United States of Mexico, and a manufacturing plant has been located at San Luis, Potosi. All the machinery for use in extracting the rubber has been invented and patented in both countries by the Monterey Foundry and Manufacturing Company, Monterey. The principal steps in the process of manufacture are as follows:—There are special machines which feed the plant automatically into the cutters; after it comes out of the machines, it is carried by a bucket elevator and dumped into steam-jacketed mixing tanks containing certain chemicals; the product then runs by gravity into hydraulic filter presses after which it is subjected to hydrostatic pressure of seventy-five pounds to the square inch; it is then conveyed into settling tanks where the gum being heavier settles at the bottom, while the chemicals and residue are drawn off. The cost of production is slight. The principal difficulty to be overcome is the high freight rate, a box-car being quickly filled on account of the lightness and bulkiness of the plant.—*India Rubber Trades' Journal.*

A GOOD BUNCH OF BANANAS.

A correspondent writes:—The enclosed is a Banana grown in my garden. Will you kindly give me your opinon about it? I cannot find any so large in the fruiterers' shops about here. The bunch weighs 57 lb. I cannot count the number of fruits nearer than 160. The enclosed is not one of the largest fruits.—J. J.

[The fruit sent by our subscriber tasted remarkably well, having a rich mellow flavour; and his bunch certainly shows good culture. Many larger bunches of fruit, however, are known, and we would refer "J. J." to the "Impney" bunch, which, so far as we know, is a record one, whose weight was one hundred and fourteen pounds (exactly double the weight of "J. J.'s") and contained 283 "fingers." See *Journal of Horticulture* for May 26th, 1898, where an illustration of the "Impney" bunch is given.—Ed.]—*Journal of Horticulture*, March 21.

CAPE TO CAIRO.

COFFEE-PLANTING IN NYASSALAND.

(From *The Daily Telegraph* Commissioner, Mr Lionel Decle.)

This territory of the British Chartered Company owes its importance as a Colony to coffee-planting, which is yearly assuming more importance, and Nyassaland coffee is of so superior a quality that it commands the highest price on the London market, where it has fetched treble the sum paid for Brazil coffee. There are in Nyassaland about 10,000 acres of land

UNDER COFFEE,

all of which is not, however, in bearing; and the last crop is estimated at 1,100 tons, an enormous amount if one considers that the plantations date only from ten years back. The industry traces its origin to Mr Buchanan, a Scotch gardener attached to the Blantyre Mission, who brought out from Scotland a coffee plant, and it is almost exclusively from this single plant that all the millions of coffee trees planted in the country have come. Land can only be procured now either from private holders or else from the Government. Uncultivated land can be purchased from the former at prices ranging from half-a-crown to 10s per acre, and from the Government at 5s to 7s per acre. Land under coffee ranges from £7 to £20 per acre for estates of 200 acres or more. An estate was recently sold for £6,000. It consisted of 300 acres of land under coffee, with 1,700 acres of forest land, with houses, buildings and machinery. All the planters with whom I have discussed the subject seem to agree upon the point that a small plantation of 150 acres will pay better if thoroughly cultivated than a plantation of 300 acres or more, on account of the labour conditions and of the difficulty of securing sufficient skilled assistance. Under this heading are included plauters, sowers and pruners, as well as carpenters and bricklayers. Most of the skilled labour is supplied by the Ya, and in a smaller proportion by the Atonga, tribes. Un-

skilled labourers consist chiefly of Angoni from districts west of Lake Nyassa, and also of a few Angoni from Portuguese territory near Lake Shirwa and of Atonga, a tribe inhabiting the western shore of Lake Nyassa. This

LABOR QUESTION.

is a difficult one to solve, as the time when workers are chiefly required by planters, from November to March, is the very time when natives are reluctant to leave their homes, where they are wanted to cultivate their own fields. Unskilled labourers are paid at the rate of 3s to 4s a month, and skilled men get from 5s to £1 : but while the former come from long distances, the latter usually live in the villages forming part of the estates. Planters calculate that they require an average of two labourers per acre of cultivated land, so that 20,000 men are wanted to do justice to the land now under cultivation. Lack of assistance is the planter's incessant cry, and all of them greatly fear that the high wages paid in Southern Rhodesia may divert there the labourers, and cause a rise in the pay, which would kill the coffee industry. Planters, I think, exaggerated the danger, and I doubt whether the proposed railway from the south will cause a serious exodus of natives towards Southern Rhodesia, provided, however, that the planters treat their people better than they have done so far. Until now, it has been customary to allow the labourers, in addition to their pay, one yard of calico, equivalent to 3d, per week, for their food, but the natives within a radius of 200 miles from Blantyre will not sell food for calico. To obtain food the plantation labourers have to work on Saturday afternoons and on Sundays in the gardens belonging to the natives of the villages surrounding the plantations on which they are engaged, and in exchange for such work they receive a few cobs of corn, on which they have to subsist for the remainder of the week. In their own country such people are accustomed to eat meat, and cobs of corn are not sufficiently nourishing for them, so that the natives who go to work on the plantations usually return to their country in a state of semi-starvation. Sufficient rations would mean to the planters only an extra monthly expenditure of 1*s.* per head, and so long as labour does not cost more than five shillings per month, all told, plantations must pay handsomely. Most of the

PLANTATION LABOURERS HAVE TO WALK FROM FOUR TO SIX HUNDRED MILES

to come from their homes to the coffee-growing districts, and as much to return to their country. On the way they usually suffer from scarcity of food, and most of them are more or less exhausted by the journey, so that they cannot perform the amount of work which they might otherwise do. If the planters combined together they could easily get their men brought by steamer at a cost of two shillings and sixpence per head, which for four to five months' work usually supplied by these men would increase their cost by sixpence per month. If this were done the present scarcity of labour would soon cease to exist, and the danger of its being diverted south would not arise. At present the people who come to work for five months in Blantyre are away nine months from their homes, so that none of them return to work two years in succession. The high wages paid in Rhodesia do not constitute the attraction one would think to the Nyassaland natives. Most of those who have been to Salisbury, where they earned from one pound to thirty shillings a month, have returned without a penny, and they complained that everything was so expensive that they had been unable to save anything of their wages. It must also be noted that these people do not care to go so far away from their country among other natives, whose language they do not speak and whose habits are quite different from their own. Many planters, led by an irresponsible rag published in Blantyre, make a great fuss over the Administration allowing natives to leave the Protectorate. They forget that the Administration has no power to prevent individuals from leaving the country. Everything legally possible is done to discourage them. For instance, when a man applies for a pass to go outside the Protectorate, he must first show that he has paid his hut-tax, and must satisfy the collector that he has made provision for the support of his wife and family during his absence. But more cannot be done. Stringent regulations have been issued prohibiting the engagement by labour agents of natives to work outside the Protectorate, and in order to help the planters the Administrator has gone so far as to allow the natives to go and work in Blantyre, the first month's wages being collected by Government to cover the payment of the year's hut-tax. From Central Angoniland alone 9,000 natives went down to Blantyre last year on those terms. To close the subject, I can only say that, as I have shown, the planters hold the remedy in their own hands, to avoid the present scarcity of labour and to prevent the exodus they fear, and if they do not adopt it they will only have themselves to blame for the consequences.

FOUR YEARS IS THE TIME REQUIRED

for coffee to bring returns. Trees begin to bear at the end of three years, but a full crop is only gathered in the fourth year. I have tried to obtain estimates of the cost of a plantation, but no planters seem to agree as to figures. Some calculate that, until coffee has been brought into bearing, £12 will have been spent on each acre of land under cultivation, about £3 per year, the cost of land, buildings, and machinery, not being included in this calculation. After coffee has begun to bear, the cost per acre is estimated at 20s to £2 per acre, to which must be added the cost of porterage and transport to London and the salary of European assistants, one man being sufficient to look after 300 acres ; but above that amount an extra assistant is required for every further 150 acres. The returns vary considerably, according to the quality of the soil, manuring, and other causes. Some gardens only give 1 cwt per acre, while others have produced as much as 7 cwt. The average return may be calculated at 2½ cwt per acre, which, even at the present low price of coffee, ought to pay well. At the price of £60 per ton coffee should yield a profit of £40. The cost of porterage from the plantations to the navigable portion of the Shiré River varies from 30s to £2 per ton, according to the distance ; and 50s per ton is charged by the transport companies for the carriage by steamer to Chinde, at the mouth of the Zambesi, whence the freight to London comes to £3 per ton, or a total of about £7 10s. As I have already said, Nyassa coffee fetches the highest price on the London market, where it

has been sold for as much as £114 per ton. One of the difficulties planters have to contend with in this part of the world is the impossibility of borrowing money locally. Want of capital and lack of credit would prove fatal to most of them, if they met with two successive unproductive years. Fortunately for them, no leaf disease has yet made its appearance among Nyassa coffee, but there is an insect—a kind of bug, of the ladybird species—which causes spotted berries. If, however, they are collected in time, no great damage is done to the coffee. Early rains are the best for the plants, which require altogether about fifty inches of rain. Another difficulty planters have to meet is that of finding suitable

EUROPEAN ASSISTANTS.

Many of the young men who are sent out here are unsuited to their work. To be really useful an assistant should possess a good deal of practical knowledge; he should be able to show natives how to make and burn bricks, understand something of carpentering, and have had some experience in the management of animals. Young men having had some practical training on a farm are usually the most useful. It is true that they generally lack the knowledge of bookkeeping, which is one of the duties they have to perform. Assistants on plantations receive from £150 to £200 a year, with a house. Fifty pounds are sufficient to cover all their expenses. But their life is not a pleasant one. They are most of the time alone, and even supposing that they should have a neighbour within ten to twelve miles, their only means of conveyance is by machilla, a hammock carried by natives, a slow and disagreeable mode of locomotion. Horses are most expensive and difficult to get, £40 being the average price paid for a horse. Natives do not understand them, and there is the risk of their dying of the dreaded horse sickness, besides the impossibility of taking them to any district where tsetse fly is found.

In addition to coffee some planters grow

TOBACCO,

but no serious attempt has been made in this direction. The tobacco grown here is of inferior quality and badly cured. I am sure that, if good plants were imported from Cuba, Manila, Syria and other tobacco-producing centres, excellent results would be obtained. Experts would have, it is true, to be brought out to train the natives in the various operations of this industry. When I visited Nyassaland seven years ago Messrs. Buchanan Bros. had begun experimenting on these lines and I bought from them splendid yellow tobacco which made cigarettes equal to many of those sold in Egypt. They also turned out cigars as good as any Indian cheroots, but after Mr. Buchanan's death all the machinery was sold and the culture abandoned. At present the tobacco produced is somewhat like the Boer variety of South Africa, and of so inferior a quality that it would hardly find a purchaser at the London Docks.

CHILLIES

are grown in small quantities with splendid results, but no attention is given to their cultivation, as it is feared that large production would bring the prices down. Tea grows well in some parts of the Protectorate, but the process of curing is unknown here. Cinchona has also given satisfactory results, and ramie fibre ought to prove remunerative, since suitable machinery for its treatment has been invented by Mr. Foa, of Limoges.

There is one thing planters urgently claim, and which I have long advocated as well for Rhodesia as for Nyassaland. This is the creation of a

PUBLIC LABORATORY,

to which would be attached a public analyst and an experimental farm. On such a farm experiments would be carried out in all the different cultures under an able specialist, planters being able to send manures and soils to be analysed, and coffee to be tested and valued. They should be able to send their assistants or to go themselves to be taught the cultivation and curing of coffee, tobacco, tea, and other products likely to suit the country. From this institution planters should be able to get an expert to examine their estate, to advise them as to the most suitable methods of improving them, and, from time to time, the superintendent of this institution could publish in the Government Gazette any information likely to prove of use to the planters. To open such an establishment would mean an original outlay not exceeding five to six hundred pounds, and to keep it going would cost less than £1,000 per annum. The greater portion of this expenditure would be covered by the fees paid by the planters, and I am sure that none of them would object to paying six pence per ton on the coffee exported from their estates, if the money were used to cover the cost of maintenance. In addition to the plantations, the most important trade of British Central Africa is india-rubber, a trade which has taken an extraordinary extension within the last few years. While in 1897 the exports of india-rubber amounted to £1,000 only, they had reached £10,000 in 1898. Most of it comes from the west coast of Lake Nyassa, but unfortunately, the natives gather it in so careless a fashion that unless proper supervision is exercised by the authorities all the plants will soon be destroyed. I am told that steps have already been taken to avoid such a result. I will now try to sum up in a few words

THE PROGRESS WHICH HAS BEEN ACCOMPLISHED since I came here in 1893. Magnificent roads have been built, the most absolute security has been assured throughout the Protectorate, a regular administration has been established in the remotest districts, where justice is rendered exclusively by Europeans, slavery has been completely wiped out, the facilities of communication have increased in a remarkable way, and their cost has considerably decreased. Coffee-planting has passed from the experimental to the practical stage, and the cost has been greatly reduced. Last, but not least, the whole Protectorate has been put in direct telegraphic communication with the Cape and Europe, a result entirely due to Mr Rhodes, without the cost of a single penny to the British Central Africa Administration. I have absolute faith in the future of the country, and I do not share the views expressed by many people as to the precarious state of the coffee industry. The railway from Lake Nyassa to the coast, a thing of the near future, will give a fresh impulse to coffee-planting, and reduce the cost of transport; and if it causes a small exodus of local labour this will be fully compensated by the increase of facilities it will give the natives to come and work on the plantations. It will also relieve the strain now existing on the local resources of labour, so much of which is absorbed by the transport of goods to

and from the Shiré River. The Tanganyika Railway will give a fresh impulse to the opening up of Northern Rhodesia, and when the federation of South Africa is an accomplished fact, Northern Rhodesia and the British Central Africa Protectorate will naturally be included in that great movement. The Protectorate will soon be as ripe for self-government as Southern Rhodesia, so long as it does not stand isolated as it now does, but as part of a system, and its only hope for such a result lies in the prospect of becoming a portion of the Great Federation of the South. This ought to give fresh and increased vitality to the country, and fittingly crown the great work so brilliantly inaugurated by Sir Harry Johnston and continued by Mr Sharpe, who has successfully performed the most difficult of tasks in showing himself able to carry the weight of the heavy legacy left to him by his distinguished predecessor.

THE FOOCHOW TEA TRADE.

DIMINISHED SUPPLIES EXPECTED NEXT SEASON.

The statistics for the season now closed show the Total Export to be 40,342,288 lb against 44,148,650 lb in 1899-1900, 38,718,940 lb in 1898-99, 35,887,522 lb in 1897-98.

As compared with ten years ago, the past season's export shows a falling-off of 33 per cent. The following comparative figures are given to show the changes that have taken place in the destination of the shipments :—

	1900-1901.	1890-91.
	lb.	lb.
Europe	11,299,703	25,661,017
Australia and New Zealand	6,514,722	15,250,738
United States and Canada	11,855,217	3,404,957
South Africa	1,378,864	1,543,652
Coast Southward	4,260,213	4,713,889
,, Northward	5,033,569	8,884,486
..	40,342,288	59,458,739

The comparative figures of the deliveries of China tea in London and Australia are correspondingly disappointing, notwithstanding that the lowness to which prices have made the tea attractive to buyers, if solely on account of its unprecedented cheapness. It has been apparent for some time past that Foochow tea, with insignificant exceptions, is only bought in London to mix with that from Indian and Ceylon, and not then until the importer, tired of holding, parts with it at a price below the cost of production.

Under these circumstances the prospects for the trade are exceedingly gloomy. The Chinese were losers last year and will act with great caution this year. They know, as well as we do, the low scale of prices current in the consuming markets and will run as little risk as possible. Everything points to diminished supplies next season. The money usually advanced about this time of the year is not forthcoming, the native banks giving as a reason for withholding facilities the unsettled state of affairs in the north. Thus the teamen will have to fall back on their own limited resources which the well-informed say may be taken to mean that a considerable portion of the first crop will not be picked at all : and if present current prices in the consuming markets are to be any guide to the Chinese in their later operations in the season the export figures at this date next year will compare very unfavourably with those just published.—*Foochow Echo.*

THE SALE OF NOXIOUS TEAS.

(To the Editor of the London *Times.*)

Sir,—Permit me to refer to and protest against the recent refusal of the Government to use the powers they possess to protect the British tea drinkers from the injurious use of spoilt and damaged teas. For some time past most unpleasant rumours from some of our tea-producing countries have warned us that damaged, and, therefore, injurious, teas were being craftily blended and manipulated and sold as genuine or sound commercial articles. For such purposes "the fine art of blending" was being unworthily used, and should be promptly stopped by the Government authorities. In the Ceylon newspapers, for instance, quite recently, there is a report of a meeting of Planters, called to consider a resolution requesting the Government to supervise or impose checks upon the exportation of unwholesome tea. The mover of this resolution stated, and (what is most significant) he was not contradicted, "that it was well known" that "teas known to be unfit for human consumption" had been exported as tea for sale and consumption. In the examination of a number of recent samples of tea obtained in this country I have been struck by the discovery of dried but perfectly rotten leaf tissues, upon which colonies of microbial forms, both adult and in ova, were found, indicative of damaged and objectionable materials for dietetic use.

I will admit that the adult microbial forms may be destroyed in the process of tea infusion, but the ingestion of the ova and the products of rotten vegetable matter are neither useful nor invigorating to healthy or invalid. If tea was a production of the British Isles, no doubt the Sale of Food and Drugs Act would meet the want and stop the mischief; but, unfortunately, tea is an imported article, and in its dry rolled condition the consumer sees no suspicious signs, and the chances of detection and conviction are in consequence rendered doubtful and remote ; and, again, should detection result, the guilt might rest upon the ignorant middleman and the real culprit escape.

Instead of throwing the responsibility upon the British local authorities, as the Government seem disposed to do, it would be perfectly easy and simple for the Government to supervise the imported teas at the London, &c., bonded warehouses. These officials would be in touch with the Government experts of the chemical and biological laboratories of Somerset House and South Kensington. In point of fact, such stoppage of "rubbishy tea" would be advantageous to the trade and prove beneficial to the consumer. In this case the truth of the old saw may be again seen—prevention is better than cure.

The Adulteration of Food and Drugs Act is a useful instrument for local authorities in local matters, but as regards teas and other imports we possess the immense advantage of port supervision. Let damaged tea, like diseased matter, be stopped there and the mischief is stopped from circulating, for it is probably the cause of the modern dyspeptic or "I can't drink tea" condition to a far greater extent than many are aware or have any idea of.

I am, Sir, yours faithfully, Geo. Brownen, F.C.S.

38, Gloucester-place, Boscombe, Hants, April 9th.

FLOWERS WITH PERFUMES.—A German botanist is said to have discovered that out of 4,300 species of flowers cultivated in Europe only 420 possess an agreeable perfume. Flowers with white or cream-coloured petals are more frequently odoriferous than others. Next in order come the yellow flowers, then the red, after them the blue and finally the violet, of which only thirteen varieties out of 308 give off a pleasing perfume. In the whole list 3,880 varieties are offensive in odour, and 2,300 have no perceptible smell, either good or bad.—*Journal of Horticulture*, April 11.

EUCALYPTUS IN LONDON.—Mr Colenso Blogg, of Blogg Brothers, Melbourne, who has returned from his European trip, reports that in spite of the competition of Algerian and other encalyptus oils the demand for Australian oil is increasing, and the price is rising, but it was evident to him that only oil of a high eucalyptol content could be sold. The result probably will be that inferior oils will be kept in Australia, and the best oils will be sent away, so that as in many other places the country of produce will be worse served than the distant market.—*Chemist and Druggist*, April 13.

MARKET RATES FOR OLD AND NEW PRODUCTS

(From Lewis & Peat's Fortnightly Price Current, London, April 17th, 1901.)

	QUALITY.	QUOTATIONS.
ALOES, Soccotrine cwt.	Fair to fine dry ..	44s a 85s
Zanzibar & Hepatic ,,	Common to good ..	20s a 60s
ARROWROOT (Natal) lb.	Fair to fine ..	5½d a 6¼d
BEES' WAX, cwt.		
Zanzibar & White ,,	Good to fine	£6 a £7 10s
Bombay Yellow ,,	Fair ,,	£6 5s a £6 17s 6d
Madagascar ,,	Dark to good palish	£6 10s a £7 5s
CAMPHOR, China ,,	Fair average quality	175s
Japan ,,	... .	185s
CARDAMOMS, Malabar lb.	Clipped, bold, bright, fine	2s 3d a 2s 4d
	Middling, stalky & lean	1s 5d a 1s 7d
Ceylon.—Mysore ,,	Fair to fine plump ..	1s 6d a 3s 9d
	Seeds ..	1s 11d a 2s 6d
,, Tellicherry ,,	Good to fine ..	2s 11d a 3s
	Brownish ..	2s 6d
,, Long ,,	Shelly to good ..	1s a 2s 9d
,, Mangalore ,,	Med brown to good bold	2s a 3s 6d
CASTOR OIL, Calcutta ,,	1sts and 2nds ..	4½d a 4¾d
CHILLIES, Zanzibar cwt.	Dull to fine bright ...	35s a 45s
CINCHONA BARK.—lb.	Ledgeriana Orig. Stem	3d a 5½d
Ceylon	Crown, Renewed	5d a 7d
	Org. Stem	3⅜d a 5½d
	Red Org. Stem	2⅜d a 4½d
	Renewed	3d a 5¾d
	Root	3⅜d a 4d
CINNAMON, Ceylon 1sts per lb.	Ordinary to fine quill	10d a 1s 6d
2nds	,, ,,	9d a 1s 5d
3rds	,, ,,	8½d a 1s 4d
4ths	,, ,,	8d a 11d
Chips	,, ,,	2⅜d a 10d
CLOVES, Penang lb.	Dull to fine bright bold	4½d a 9½d
Amboyna ..	Dull to fine	4⅜d a 5½d
Zanzibar and Pemba	Good and fine bright	4½d a 4¾d
	Common dull to fair	4½d a 4⅜d
Stems ..	Fair	1⅜d
COFFEE		
Ceylon Plantation ,,	Bold to fine bold colory	92s 6d a 110s
	Middling to fine mid ..	80s a 90s
	Low mid. and low grown	
	Smalls	50s a 60s
Native	Good ordinary	30s a 70s
Liberian ,,	Small to fine bold	35s a 40s
COCOA, Ceylon ,,	Bold to fine bold	80s a 100s
	Medium and fair	67s 6d a 75s
	Native	55s a 68s
COLOMBO ROOT ,,	Middling to good	12s a 22s 6d
COIR ROPE, Ceylon ton		nominal
Cochin ,,	Ordinary to fair	£13 10s a £18
FIBRE, Brush ,,	Ord. to fine long straight	£16 a £19
Cochin ,,	Ordinary to good clean	£20 a £24
Stuffing ,,	Common to fine	£7 a £9
COIR YARN, Ceylon ,,	Common to superior	£15 a £30
Cochin ,,	,, ,, very fine	£12 a £32
do. ,,	Roping, fair to good	£10 a £14 10s
CROTON SEEDS, sift. cwt.	Dull to fair	25s a 35s
CUTCH ,,	Fair to fine dry	23s a 35s
GINGER, Bengal, rough ,,	Fair	34s
Calicut, Cut A ,,	Good to fine bold	80s a 100s
B & C ,,	Small and medium	40s a 77s 6d
Cochin Rough ,,	Common to fine bold	33s a 38s
	Small and D's	30s a 31s
Japan ,,	Unsplit	29s a 31s
GUM AMMONIACUM ,,	Sm. blocky to fine clean	20s a 45s
ANIMI, Zanzibar ,,	Picked fine pale in sorts	£10 7s 6d a £20
	Part yellow and mixed	£8 2/6 a £10 10s
	Bean and Pea size ditto	70s a £9 2/6
	Amber and dk. red bold	£5 10s a £7 10s
	Med. & bold glassy sorts	80s a 100s
Madagascar ,,	Fair to good palish ...	£4 8s a £8
	,, ,, red ...	£4 5s a £9
ARABIC E. I. & Aden ,,	Ordinary to good pale	35s a 55s
Turkey sorts ,,		50s a 75s
Ghatti ,,	Pickings to fine pale ...	12s 6d a 35s
Kurrachee ,,	Good and fine pale ...	52s 6d a 55s
	Reddish to pale selected	30s a 40s
Madras ,,	Dark to fine pale	23s a 35s
ASSAFŒTIDA ,,	Clean fr. to gd. almonds	40s a 90s
	Ord. stony and blocky	6s a 25s
KINO ,,	Fine bright	1s 6d a 1s 9d
MYRRH, picked ,,	Fair to fine palo	90s a 107s 6d
Aden sorts ,,	Middling to good	50s a 80s
OLIBANUM, drop ,,	Good to fine white	35s 6d a 50s
	Middling to fair	25s a 35s
pickings ,,	Low to good pale	18s a 23s
siftings ,,	Slightly foul to fine	16s 6d a 18s
INDIARUBBER, Assam lb.	Good to fine	2s 2d a 2s 6d
	Common to foul & mxd.	1s a 2s
Rangoon	Fair to good clean ...	2s a 3s
Borneo	Common to fine	1s a 2s 3d

THE
AGRICULTURAL MAGAZINE,
COLOMBO.

Added as a Supplement Monthly to the "TROPICAL AGRICULTURIST."

The following pages include the Contents of the *Agricultural Magazine* for May :—

Vol. XII.] MAY, 1901. [No. 11.

A NEW INDUSTRY FOR CEYLON.

THE output of Cacao in Ceylon is not very considerable; in 1900 the quantity exportedw as between 1,600 and 1,700 tons. But as regards quality of produce and market value Ceylon cacao, as the Americans would say, is always 'on top.' That only a very small proportion of Ceylon cacao duce is used in the manufacture of the prepared article can be easily proved by figures and it is therefore clear that a great deal of inferior cacao must enter into the composition of the preparations placed upon the market. But it is an open secret that a good many other ingredients assist in the production of the different brands of cacao powder and chocolate in their various forms, so that the concrete results of manufacture, as carried on on the Continent, are as a rule highly complex mixtures wherein the art lies in the mixing, and the perfection of that art in the concealment of the fact that anything but pure cacao (sweetened it may be with sugar) is used.

When the taste has been vitiated it is no easy matter to educate it to an appreciation of excellence or purity. Coffee, another of our tropical products, has been the object of approved adulteration, and a mixture of coffee with chicory was for a long time more highly appreciated than the pure article. But economical householders may be trusted to recognise before long what is a very clear fact, viz., that it will be cheaper for them to do their own adulteration, and that if there are virtues in the addition of starch to cacao powder (which is problematical) they can make the additions more economically themselves; while the chemist and the family physician may be trusted to complete the victory for the manufacturer of the pure article by reconciling the consumer to the slight natural bitterness of the cacao bean and the true "chocolate colour" which the mixer by his arts has converted into a "burnt sienna."

To Messrs. C. C. Barber & Co., of Grove Estate, Ukuwella, from whose plantations the best of Ceylon cacao reaches the London market, belongs the credit of having started the first factory in the island for the manufacture of cacao powder and chocolate. Their preparations have only just been placed on the Ceylon market, but long enough to secure the high appreciation of all those who have been looking for, and have now found, a pure article; and we have no doubt that the Company's produce has a big future before it outside the island. Prepared on the plantation itself, the raw material used is fresh, uncontaminated by the odours of the ship's hold and of warehouses on this and that side of the ocean, and free from must or rancidity—ready enough to attach any oily seed or preparation. With the saving of freight to and from the West, and crop at hand, the Company have peculiar facilities for turning out a cheap, pure and wholesome article which is bound to have a ready market and a large sale, results which the enterprise of the promoters only deserves.

OCCASIONAL NOTES.

An enterprising Sinhalese gentleman has made a trial shipment of Ceylon fruit (oranges, pine-apples, plantains, cajunuts, &c.) to Perth, Western Australia, with a view to ascertaining the possibilities of carrying on a regular fruit trade between the two countries. With many details to be mastered the first trial naturally resulted in a deficit, but not to such an extent as to damp the enterprisng young man's ardour. With experience gained he means to make a second shipment before long, and hopes that in the absence of unavoidable errors and difficulties associated with the first trial, the second will give more promising results. We want more such enterprising men who, with some capital in hand, are anxious to turn it to good account by means of honest trade for the good of their countrymen as well as their own advantage, instead of frittering it away indangerous and reprehensible speculation.

A direct trade in pineapples has now been established between Jamaica and London. We read of a consignment of 500 packages having been received in fine condition and fetching from 1*s.* 6*d.* to 2*s.* 6*d.* per pine. The favourite pine in the London market is the smooth Cayenne, and it is said that the chief reason for this fact is not so much its superior quality but its good looks, size, fine colour and handsome top, the weight ranging from 3 to 8 lbs., the average 4 to 6 lbs. Larger fruit, it is said, are not required in England. Another important fact about this particular variety is that it reaches the market in better condition than any other. Of course a sweet pine is essential for a good market.

The Royal Botanic Gardens Circular, No., 15 has the following note regarding the pine referred to:—"Kew pine" (smooth Cayenne). The best variety for generel cultivation, being a robust grower, usually bearing in the low-country in 6 months from time of planting suckers. Fruit grow to a large size, sometimes weighing over 20 lbs. (exceeding the record for other countries); is very juicy and of a delicious flavour. Leaves not spiny. Suckers of this pine are obtainable from the Peradeniya Gardens at R1·50 per doz.

The proposed Indian Dairy and Agricultural Supply Co. of India is what the Americans would call "a big thing." Among the numerous objects—for the enumeration of which our space is far too limited—are the establishment of dairy farms throughout India and Burma, both for the military and the public, and of breeding depôts, the supplying of milch and ploughing cattle, to teach Dairy Farming and Agriculture, the carrying on of experiments in feeding, &c., cultivation of fodder, the introduction of sterilizing and pasteurizing, the supplying of fodder to Government and the public, the introduction of the co-operative system in dairying, the organising of annual Agricultural and Cattle Shows, the supplying of stud bulls, &c., &c. The Company's operations will be managed by a Board of seven Directors, and the working staff will consist of a Managing Director, two Assistant Directors, one Agricultural and Dairy expert, one Vet, one Medical Officer, one Engineer, one Treasurer and Agent, one Secretary, and such clerical and other staff as may be necessary. Among other details is the arranging with the railway companies for suitable refrigerating vans for conveying milk. The Capital required is estimated at R300,000.

We hear that a local Dairy Company is about to include the manufacture of ice and ærated waters among its operations, which would seem to indicate that their constituents are as solicitous in the matter of "pure milk" as of "iced sodas."

The *Exchange* has the following interesting figures referring to sugar: The English are the largest consumers of sugar in the world. They import 1,500.000 tons every year, equal to 30 % of the world's output of beet sugar. Their consumption of sugar is equal to 86·151 lbs. per head of the population per annum. The next largest consumers are the United States. On the consumption there is only 65·49 lbs. per head. In Denmark the demand falls to 43·65; Switzerland was 42·95 lbs.; France 28·24 lbs.; and Germany only 27·141 lbs., although she is the chief producer of beet sugar. Sugar is thus used more freely in England than elsewhere. The English are the Jam-makers of the world, but the manufacturers import all their sugar and also some of their fruit; and are simply mixers and boilers of the commodity they export to all corners of the earth.

The acme of perfection in the orange world, is as the *Planters' Monthly* of Hawaii remarks, the "Navel." Its superiority over any other variety is admitted all the world over. We have in a previous issue related to the story of the origin of this wonderful fruit.

Dr. Woodbridge, a well-known Agriculturist in California, has succeeded in producing a "Navel" lemon absolutely seedless, and possessing the characteristics and advantages of the orange after which it is named, for he has named the new lemon the California Naval lemon. Besides the entire absence of seed, the texture and thinness of the rind strongly remind one of the model orange which it resembles even to the navel-mark. Here, however, the resemblance stops, for the acidity runs very high.

A king-coconut seedling planted in the grounds of the School of Agriculture on "Diamond Jubilee Day" has already produced its first flower. Taking the age of the seeding when planted at 6 months, it has taken a little under 4½ years to flower.

Mr. D. O'Connor, writing on mangoes in the *Queensland Agricultural Journal*, says:—"If mangoes are not the most extensively grown and abundant fruit in Queensland, they soon will be . . . Almost every one having a garden goes in for mangoes . . . . As an evidence of the in-

creasing appreciation of choice fruit by growers, a seedsman has during the last three years realized 2*s.* 6*d.* each for some fine specimens." Happy seedsman! How the Ceylon fruit seller envies you.

THE ROYAL BOTANIC GARDENS.

The work of the Botanical Department in Ceylon now comprises a good deal of what bears directly on the Agriculture of the country, and in the absence of a distinct Agricultural Department, this circumstance must be welcomed. The staff of the department has been considerably augmented within the last year or two, and now includes a botanist, an entomologist, a mycologist, and a chemist, besides a temporary assistant who devotes himself to the detailed study of some one particular subject.

Among the more interesting experiments and researches referred to in the annual report of the Director and his staff for last year are (1) the analysis of the black and variously mottled timbers of the Diospyros family, whereby the cause of the discoloration is said to have been determined, while experiments have been initiated with the object of inducing the blackening of the timber in the peripheral sapwood; (2) the efforts (which are reported to promise success) to graft the mangosteen (*Garcinia mangostana*) on the Cochin goraka (*Garcinia xanthochymus*) a more hardy species; (3) the partly successful attempts to propagate the nutmeg by layering and so secure a certain means of raising female trees; (4) the bringing together of over 23 distinct varieties of plantains; (5) the study of the pollination of the cacao tree with a view to produce an increased fertilisation; (6) the attempt to raise cacao plants from cuttings, which, if successful, will be the means of perpetuating the characters of special trees. All such work as is referred to above must help to give us an amount of definite information, which the individual grower is not in a position to ascertain for himself, but which should considerably help him in the practical work of cultivation.

The reports of the Entomologist and Mycologist shew that a great deal of work has been done, and the fact that the advice of these experts is always available must be very consoling to the cultivators of crops.

We have no doubt that the Botanical Department will continue to extend its sphere of usefulness each year under its present Director and his able staff of assistants.

SOME FACTS AND FIGURES ABOUT COW'S MILK.

In a report of investigations made at the New Jersey Agricultural Station, an average analysis of cow's milk is recorded which may be accepted as a guide and useful information on Dairying subjects; but, as the *Cape Agricultural Journal* (to which we are indebted for a summary of the report) remarks, the average, it is to be presumed, is that of the milk of profitable cows :—

Milk is not a product of fixed composition. But the total amount and the proportions of the constituents contained in it are influenced by a variety of conditions, the chief of which is, perhaps, the individuality of the cow. Breed, food, age, health, period of lactation, and time and season of milking are also determining factors. Of the constituents of the dry matter of milk, viz., butter-fat, proteids (chiefly casein and albumen), sugar and mineral salts, fat seems to vary more than the others, though each may vary considerably. Normal milk may be said to contain on the average the following amounts and proportions of the different constituents, also weights in a gallon of 10 lb. 2 oz. :—

	Per cent.	oz.
Water ...	87·50	141¾
Total solids ...	12·50	2 3¼
Butter fat ...	3·50	5¾
Casein and albumen	3·75	6
Milk sugar ...	4·50	7¼
Ash (mineral salts)	·75	1

This average composition has served as the basis in both State and City Governments for the enactment of laws or ordinances, the purpose of which is to prevent watering, skimming, and other forms of adulteration. The standards adopted seldom require more than 12·5 per cent total solids and 3 per cent. of fat. Thus, what may be regarded as the average quality of milk usually exceeds the limit fixed by the various laws, particularly in fat contents.

Normal, or whole milk, will, however, show wide variations in both directions from this standard; that is, it may be very much richer or very much poorer.

The influence of breed is also very marked, so much so that dairy breeds are classified into milk and butter breeds; that is, those which give a larger quantity of poorer quality, and those which give a smaller quantity of a higher quality. The milk from animals which naturally produce large quantities shows average quality, and that from

animals which produce a smaller quantity shows a quality considerably above the average. That the contents of fat in milk varies more than the other constituents, is also distinctly shown in the investigations of milk from different cities.

The food is an important factor affecting the quality of milk, not always appreciated. A specific breed possesses certain capabilities, the values of which are dependent in large measure upon the food that is supplied. Owing to the inherent tendency of the animal to produce milk of a definite composition, food may not exercise a positive and immediate influence in improving the quality of the milk; still, a cow cannot reach her normal capacity in this respect unless she is supplied with sufficient food.

The age and health of the animal also affect the composition of milk. Young animals produce richer milk than older ones, though much depends upon health, vitality and vigour. The period of lactation, that is, the length of time which has elapsed since the birth of the calf, also exercises an influence upon the composition of the milk. The milk flow is usually greatest, and the milk poorest, soon after calving; as the period increases the flow gradually falls off, and as a rule the quality improves. However, the influence of all these factors is not so marked in mixed milk as in the milk of individual animals.

The following notes give an idea of the variation in the composition of milk:—

In one series of analyses the variation in total solids ranged from 11·82 to 14·03 per cent, a difference of 2·21 per cent; the variation in fat from 2·99 to 4·57 per cent, a difference of 1·58 per cent. In the case of another series of samples, the total solids ranged from 10·81 to 14·86 per cent, a difference of 4·05 per cent; the variation in fat ranged from 2·56 to 6·92 per cent, a difference of 4·36 per cent.

In the third case the percentage of solids ranged from 10·64 to 13·96 per cent, a difference of 3·32 per cent; the fat from 2·97 to 4·80 per cent, a difference of 1·83 per cent.

In the last series the range in total solids was from 12·06 to 16·55 per cent, a difference of 4·49 per cent; the fat from 3·28 to 7·76 per cent, a difference of 4·48 per cent.

Among these samples was one in which the content of total solids and fat was abnormally low, another contained an undue proportion of fat.

On the whole the samples are reported as extremely good, the average composition of all being total solids 12·97; fat 4·13; casein and albumen 3·37; sugar 4·75; ash ·72 per cent.

A CHEAP WAY OF COOLING.

The *Rural World* describes the cheapest and best method of cooling, particularly suitable for milk, but also available for other purposes as well, by means of sal ammoniac and saltpetre (ammonium chloride and nitrate of potash respectively).

Three pounds each of these ingredients dissolved in a gallon of water will reduce the temperature of a gallon of milk by about 40 deg. F., if the full cooling effect is conveyed to the milk. Here are the directions for use:—The salts, which must be quite dry and ground to a fine powder, are weighed out, put into the measured quantity of water, and stirred slowly about until completely dissolved; the crystals, in going into the liquid form, absorb heat and produce an intensely cold solution. This can be used for cooling purposes, and afterwards, by evaporation, the crystals can be re-obtained for use again. Hence, with care there need only be a trifling loss, and the same portion of cooling salts can be used for an indefinite period. When cooling milk by means of freezing mixtures it will be found most economical to reduce the temperature first as much as possible with water only, and then to complete the cooling by means of the cool solution. Thus, to begin with, the milk in the bucket as it comes from the cow will be about 95 deg., and by immediately running it over a cooler through which cold water was flowing it might be cooled down to 75 deg. By then passing it a second time over the cooler through which the cold solution was flowing it could be cooled form 75 deg. down to 55 deg. Thus only half the cold solution would be needed that would have to be used if the whole of the cooling were done by its means. In this way 3 lb. of sal ammoniac, 3 lb. of saltpetre in one gallon of water would then cool two gallons to the desired temperature. At this rate, to cool 50 gallons 75 lb. of each salt would be needed; and as it would be advisable to have two lots, one to be evaporating and drying while the other was in use, 150 lb. of each would be required, or say 1½ cwt. The salts, which, as before stated, must be powdered and quite dry, are best dissolved in a cask or wooden tub, covered with a lid at the top, provided at the bottom with a tap, and wrapped around and underneath with 6 in. or 8 in. of straw or thatching to prevent loss of cold. The evaporation of the solution after it has been used should be done in a shallow pan or tray. A number of kerosene tins cut in half lengthwise and provided with handles will do if nothing else can be obtained. Then place over a slow fire, so that the water will evaporate gently without boiling, loss of salt by splashing or spurting being avoided. When the material is evaporated nearly to dryness, the hot, somewhat pasty mass should be dug out of the pan and spread out on clean wood or iron to finish drying in the sun or in some warm, dry place. When perfectly dry it should be powdered up ready for use.

DISEASES OF POULTRY—HOW TO TREAT THEM.

FOWL CHOLERA.—This is one of the greatest scourges of the poultry yard. Fortunately, it is not of frequent or general occurrence. Uncleanliness and overcrowding are great contributors to this disease, but we have seen scores of fowls die of cholera on our farm, where the birds had the whole farm to roam over and roost

at night in the open air with only a shelter of bark over their heads. There is practically no cure for the disease.

BRONCHITIS.—Young chickens often develop this disease in wet weather, which can generally be cured, if taken in time, by removal of the affected chicks to warm quarters and feeding them on soft food only, with mustard, ginger, or hot spice added to it. Give them also a tea-spoonful of glycerine twice a day.

ROUP.—Roup is one of the highly contagious diseases, and is mostly communicated to healthy birds by the medium of the drinking trough. One sick bird will by this means infect a whole flock. The disease is easily recognised, as the bird's head swells and a foul discharge proceeds from the eyes and nostrils. When the disease has made great headway, it is safest to kill the bird, because a disgusting fungus has grown in the throat, giving rise to the term "diphtheric roup." It is then very dangerous and is communicable to children. The remedies are given in most publications devoted to poultry. Isolate the affected birds; disinfect all their roosts, nests, and houses; destroy or at least thoroughly cleanse with disinfecting fluid all drinking and feeding utensils, and for some time afterwards add a little Stockholm tar to the drinking water. As for the affected fowls, bathe their heads frequently with hot water and Condy's fluid. Use a syringe to clean the nostrils and throat, injecting a solution of bluestone and warm water, sufficient bluestone to turn the water pale-blue. Be sure to prevent the bird swallowing any quantity of this as it is a poison. On first observing the symptoms of roup, give the bird a dose of Epsom salts. Afterwards the best treatment is a pill containing two grains of quinine, morning and night. The only certain way to prevent the reappearance of disease is to kill the affected birds and thoroughly cleanse and disinfect the house and runs.

SCALY LEGS.—The cause of scaly legs is a kind of mite which burrows into the skin and causes white scales to appear. Some recommend kerosene as a remedy, but this is too severe; birds often become lame from its application. The best way is to soak the legs in warm water for five minutes, and then rub them with a stiff brush to break the scabs. Then rub in a mild arsenical wash, or sulphur ointment made of ten parts lard, three parts sulphur, and one part crystallised carbolic acid. Usually one application will suffice, and a cure will be had in three or four days.

LICE.—Fowls are infested by four genera and about twenty species of bird-lice. The best treatment for the bird is the dust bath and thorough spraying with powdered sulphur and tobacco dust for the house. Here a hot kerosene emulsion is most effective. Thoroughly spray all the roosts and boxes. Remove the droppings at least once a week. Lice breed in the droppings. The dust bath should be made either in a hollow in the ground or in a roomy enclosure made of three sheets of galvanised iron. Put a quantity of dry road dust in this, mixed with wood ashes and a little tobacco dust. The object of the bath is to destroy the insect parasites. As these do not breathe through the head but through the pores in the body, the dust chokes the pores and the insects die.

GAPES.—The gape-worm (*Syngamus treachealis*) is the most destructive of all the parasites of poultry. It infests the windpipe and bronchi of most land birds, but never of water fowl. The symptoms are the well-known gaping cough or sneeze. The bird seems about to choke.

Treatment.—First remove all the healthy birds to some other place; then kill all the badly infested birds and burn them. If you bury them, earthworms will find and eat the eggs of the parasite and convey the disease to other fowls. Then thoroughly disinfect the pens and yards by sprinkling with a diluted solution of sulphuric acid (two or three pints to 25 gallons of water). If acid is not procurable, use kainit or air-slaked lime, and dust the yards liberally with it. Then give one teaspoonful of turpentine and one of assafœtida in a warm bran mash to each 25 birds A pill of camphor, the size of a wheat grain, pushed down the throat has often given good results. Another good remedy is to remove the fluff from a small feather, except the tip. Moisten this with turpentine or kerosene, and carefully push it down the windpipe, twisting it round. It will kill all the worms it touches, but cannot reach those in the lower bronchial passages. Turpentine and assafœtida in the food soon load the fowl's breath with ther fumes, and so kill all the worms in the lower as well as in the upper passages. For drink, give the birds a solution, of salicylic acid—one-third ounce to a quart of water.—*Queensland Agricultural Journal.*

[We have succeeded in stamping out fowl-cholera by the liberal external use of Jeye's disinfectant and giving the birds camphorated water, *i.e.*, drinking water in which a piece of camphor is kept soaking.—Ed. *A.M.*]

BACTERIA AND THE DAIRY.

(*By H. Potts, Dairy Expert, Department of Agriculture, Victoria.*)

(*Concluded.*)

Milk from a healthy cow, and taken under suitable conditions of cleanliness, is free from germ life. During the process of milking, as daily practised at our cow sheds, organisms of various kinds fall into the milk through the medium of the germ laden dust of the shed, the cow's body, the dirty clothes or hands of the milker, the swish of the cow's tail, or the invisible dirt left in the bucket. The most common variety in a cowshed is the bacillus *Deilus lacticus* or lactic acid producing bacteria. They are single cells rodlike in shape, and so small that it requires 20,000 to form a line an inch long, or about 400,000,000 to cover a penny postage stamp, and hence invisible to the naked eye. Milk is a most suitable media for their propagation. Of necessity they must be provided with three conditions to encourage their growth—suitable food, moisture, and temperature. In milk as it leaves

the cow's body they secure these requirements in the most favourable form. Bacteria are vegetable cells and absorb food in like manner to the cells of higher plant life. On reaching the milk they attack the milk-sugar, break it down so as to secure the oxygen associated with it. They disturb the chemical character of the sugar, and through their agency release lactic acid or sourness, carbonic acid gas, and a little alcohol.

After milk is allowed to stand it becomes increasingly sour. This is due to the lactic acid germs, each of which is contributing its quota to the sense of sourness evolved. A study of the germ shows that when immersed in milk the heat maintained at blood or body temperature, they increase by fission, and this is observable every half-hour. This one germ will split in half at the end of the first half-hour, in another it is four, again eight, 16, 32, and so on in progression, and at the end of ten hours this single organism has increased to over a million. To the proper control and development of this family of organisms we are indebted for the correct flavour and other desirable characteristics in butter and cheese. Most organisms, however, may be air dried, and putrefactive germs becoming associated with dried masses of decaying vegetation, stagnant water and drainage, or animal excrement. These are carried about on dust, and contaminate food products. In milk, the milk sugar, casein, and mineral salts provide them with food, and they propagate in similar ratio to the desirable forms, but emit taint, produce false flavors and objectionable odors. These we have to understand and control. It is known that most organisms cease to multiply or propagate at 50 degrees F. From this forward the multiplication increases, where food and moisture are ample, to 98 degrees Fah., when the maximum point of propagation is reached. A gradual decline then ensures until we reach what is known as the pasteurising point, viz., 157 degrees F., when the bacteria die. Organisms, such as the lactic acid series, increase by fission, and hence are readily controlled by heat. Other forms, and particularly the putrefactive series, increase by the formation and shedding of spores or seeds, which often resist high temperature, even boiling in water for several hours. Such abnormal fermentations as we get in milk, denominated false curdling, thinny, stringy, bitter, blue, red milk, as well as milk giving off gases, bitter in flavor, and tainted, may be credited to the invasion or presence of peculiar species of micro organisms, as a rule the result of dirty practices at the milking shed, filthy surroundings, impure storage, and other causes at the source of supply. To prove that milk is absolutely free of germ life, and that bacteria produces sourness and creates the fermentative changes in milk, Pasteur's brilliant successor, Duclaux, took a healthy heifer that he milked under strict methods of bacteriological cleanliness into a sterile flask. The precautions observed were such as to ensure the exclusion of germ life from any external source. The flask was hermetically sealed and kept for four years. The only change observable was the rising of the cream. The bottle or glass was then broken, and it was found the milk was as sweet, sound, and as pure as when it left the heifer's udder. Thus Duclaux conclusively demonstrated the contention of bacteriologists that milk is free from germs in the true udder, and to the introduction of germ life is due the fermentative changes. All bacteria possess in a more or less degree mobile power, chiefly through the use of flagelloe. In form they are found as rods, spherical bodies, or spiral.

We apply the knowledge of germs to everyday life in the dairy, where the aim is to suppress dirt and dust. Cleanliness and coolness are the watchwords to be ever remembered by individuals who are associated with every phase of the industry from the milking of the cow to the consumer's table. The cows should be keenly scrutinised at all times for symptoms of ill-health on the first symptoms of which appearing they should be isolated. This applies with equal force to the milker who may suffer from contagious skin or other forms of diseases. Cow and milker are equally dangerous to the consumer's health if diseased. The cows after being leisurely driven to the sheds and quietly bailed up ought to be groomed, *i.e.*, the belly brushed, udder and teats washed and all wiped with a damp cloth. The milker ought to wear clean clothes, have clean hands and finger nails, the latter well pared. A clean well scalded bucket is essential. The cow's teats are divided into two chambers, an inner and an outer, the former being controlled by the cow through a sphincter muscle. This completely shuts off the inner chamber from invasion by bacteria. The outer chamber is open to invasion through the teat opening. After each milking there remaind in this part of the teat a small quantity of milk. On returning to the paddock the cow, when lying down, creates a suction in the udder by breathing, which causes the milk to ooze from the teat. This communicates the putrefactive and other objectionable forms of organisms on soil, grass and cows' body. They float into the interior of the teat, where suitable conditions of moisture, temperature, and food prevail, with the result that at the following milking the chamber is swarming with hostile forms of bacteria, and these are milked straight into the bucket or over the milker's dirty hands first, there to propagate and impregnate the pure milk, which follows with taints and other milk disorder. To obviate this, the first tablespoonful from each teat should be kept separate, scalded, and sent to the pigs.

Steam and boiling water are acknowledged as most valuable cleansing and disinfecting agents, yet their application proves insufficient at times. In such cases contamination could be rendered nugatory by a process long followed by housewives, viz., the use of a boiling solution of common washing soda. Scientific experiments have been conducted with resistant forms of germ life, and the most obstinate we know are those which create that terrible disease, anthrax. The spore of this bacillus will resist boiling water and steam for hours, but it instantly dies on being immersed in a half per cent of boiling solution of soda. All spores are thus controlled and dealt with. When

the housewife adds 1 lb. of common washing soda to 20 gallons of boiling water, and applies it hot, she is using one of the most powerful germicides and disinfectants we possess. In all cleansing operations relating to dairying, this germicide, where possible, should be used, followed by rinsing the utensils or vessels with water that has been recently boiled.

Flies are a constant source of bacterial invasion to milk. They convey on their wings and feet innumerable organisms, and generally of a very undesirable class. Potable waters and methods of filtration fail to provide a germ-free water. The filters in ordinary use are shown to be faulty; dripstone, charcoal and other forms were proved to pass pathogenic germs, and hence were useless in preventing typhoid and other germs invading the body. The only filters proved to be reliable were those made of a special isinglazed porcelain with a certain density, and the filtering process only made available by means of high pressure. Filters, such as the Abbott, have been submitted to rigid bacteriolgical tests, and found to supply a germ-free water.—*Statics, Farm and Dairy.*

THE HONEY BEE—ITS LIFE HISTORY.

(*Concluded.*)

The Drone.

The function of the males is solely that of fertilising young queens. The excessive number of drones always present in a strong colony during the summer has been a puzzle to naturalists and still more to bee-keepers. By some they were considered defenders, others maintained that they assisted in keeping the young brood warm, and others again believed them to be water carriers, and that they also probably assisted in ventilating the hive. The fact, however, that they lack the defensive organs of the other bees—the sting—makes the drones quite harmless. And as regards keeping the brood warm, this supposition falls to the ground, because they appear mostly in summer when the brood does not require to be constantly covered. During early spring when warmth is most needed in the hive they are generally not present, or only in the larvæ stage, and require external warmth themselves; but towards autumn they are, as a rule, driven out and perish. Except when a colony should become queenless late in the season, the drones are spared and may at times even be allowed to live through the winter, That part of their function is to provide water or keep the hive ventilated is likewise a mere supposition. In fact, when in the hive the drones do nothing but eat, most of the time allowing the workers to feed them. For what purpose, then, are so many as sometimes over two thousand produced by a vigorous colony? It is all important that the young queen should be fertilised soon after she becomes mature, and as the act of coition must take place while on the wing, and at a considerable height in the air, it is necessary that there should be many drones available to ensure her meeting one when issuing on her wedding flight, But another more important fact must be considered. When a young queen ventures out for a martial embrace she will, as likely as not, meet one of her brothers, under natural conditions, probably as a rule. This might lead to deteriorations of the race were it not that in the competition for her possession the strongest and swiftest has the best change to achieve the desire. To secure a prompt fertilisation by *natural selection* combined with *sexual selection* the large number of drones are provided. This view corresponds with the general law of nature. The importance of the drones is enhanced by their numbers. Probably no more than one out of upwards of a thousand copulates, but then his virility may assert itself for upwards of five years.

The Worker.

The name "worker," given to the great mass of bees found in a colony, is perhaps the most correctly and justly applied. It is in no way misleading like that of queen, and not derived from a mere peculiarity as that of drone (because the male, owing to the much greater expanse of wings, hums much louder than the rest when flying). The worker has to do everything except reproduce the race.* This they are unable to do owing to their aborted sexual organs, which has suppressed their sexual desires without impairing their love for the young. The queen produces the young, but cannot rear them, and this the workers do with a zest that is without parallel. They divide, so to say, with the real mother the labour and pleasure of maternal care. The welfare of their immature sisters absorbs their whole being. They toil incessantly for the young, and sacrifice, in fact, their lives for them in every sense of the word. Their work begins a few hours after they leave the cradle, and only ends with death. During the first ten days or so they tend the larvæ, seeing that everyone is supplied with the proper nutrition. For this they are best adapted at the early age of maturity, owing to some physiological characteristics. Whilst engaged in this duty they do not fly, except for a short period during the warmest part of the day, round about the hive getting exercise (play), and at the same time making themselves acquainted with their environments. In due course the sealing of the cells over the full grown larvæ has to be attended to, and during the progress of these various operations they cluster more or less thickly on the comb for the purpose of keeping the brood warm. All insects being cold-blooded, sufficient warmth can only be created by them through continued agitation. The bees staying at home engaged in the before-mentioned work are more particularly called "nurses."

Meantime the older bees, also called "foragers," are busy bringing pollen and honey, which is transferred to the nurses for immediate use, or stored in cells handy to the brood nest. These provisions are in several ways elaborated into food for the larvæ. To further liquify the honey

* As the ovaries are not entirely absent but merely atrophied in the workers, some, under exceptional circumstances, are able to produce eggs. This abnormal phase will be discussed later on.

and to separate the agglutinated pollen grains considerable quantities of water are needed, which are brought to the hive as required. Feeding, moreover, is not merely needed for the development of the larvæ, but this task requires also to be extended to the queen and the drones, and particularly whilst the queen is laying she has to be provided with large quantities of a nitrogenous substance. During the period of her greatest fertility the weight of the eggs deposited per day amounts to more than three times that of the body of the queen. To enable her to balance this exhaustive process, she requires to be supplied with rapidly assimilable food. This the workers elaborate in their bodies and secrete in minute globules, through glands situated near the mouth. The constantly changing retinue which surrounds the queen when laying, escorts her for the purpose of supplying food to her. The addition and dimnution of food re-acts upon her laying power, and is entirely regulated by it. In order to stimulate their virility the drones also require to be fed with nitrogenous food. This the workers produce and supply in the same way as with the queen. and the early stage of the larvæ.

Another important duty is the building of the combs. Without these the young could not be reared nor food stored. When a swarm takes possession of a new home the first work is the construction of new combs, which sometimes proceeds with marvellous rapidity. After a few weeks, when young begin to crawl out, their cradles require to be cleaned and thoroughly smoothed inside, to receive another egg almost immediately. When thousaads mature daily many are kept busy with this work. Partly for protection against enemies as well as against draught, and to keep the light out, every chink and crack is plastered up. This is done with propolis, a resinous substance, gathered specially for the purpose. A number guard the entrance against intruders, and often combats occur to keep aggressors out of the hive. Everything of an obnoxious nature is carried out of the hive, or else imbedded under a wax and propolis covering. The sanitary, as well as the other duties, are under the control of the workers. Some are generally engaged fanning fresh air into the hive, which is done by vibrating the wings. In warm weather this is a very trying exertion, and at times nearly all the members of the colony require to be engaged in this work. The functions of the workers, as we have seen are, manifold. They have to build combs, caulk the hive, refit the cradles for the reception of new inmates, remove objectionable inmates, and sometimes fight them, ventilate the home, keep the brood warm, and feed the other inmates, whether larvæ, queen or drones. They hardly ever rest, for the feeding goes on at night as well as during the day. Moreover, their foresight or innate industry keeps them constantly engaged in storing provisions for future emergencies. All this labour takes their energy greatly, and during the busiest time of life, when plenty of honey and pollen is gathered, and consequently much brood is reared by them, they wear out rapidly. The life of the workers lasts on an average only forty days during the summer, but in times of inactivity continues up to four months and sometimes longer.

GENERAL ITEMS.

Reports reached us, writes the Editor of the *Cape Agricultural Journal*, of a new process for branding stock in New Zealand, which is said to be proving satisfactory in that Colony. It consists in the application on a wooden brand of a caustic which obliterates the hair without injuring the skin. It is stated that the cost of branding 100 cattle only amounts to 15*s*., which is fully compensated for by the sound skins put on the market. As cattle must be marked in some legible and indelible way, any method which may supercede the hot branding iron will prove of great advantage.

The uses of ground-nut oil are numerous, and it has been described as the most polymarphous of all oils, adapting itself to all purposes, including nutrition, lighting, lubrication, and blending. It is the most difficult of all oils to detect when adulterating olive oil, for its chemical reaction is white. The best qualities are used for the table, either pure or mixed with olive (or salad) and sesame (or gingelly) oil; as an illuminant it gives a soft, white light. When neutralised it is much esteemed for lubricating, and is always preferred to cotton seed oil. It is also largely used in the manufacture of soap, and is the characteristic component of the famous Marseilles white soap.

The fruit of the banana contains 72 per cent of water, 2·14 per cent of nitrogenous matter, and 22 per cent of saccharine substance, the latter giving it its great nutritive quality. The banana plant, says M. de Lovedo of Mexico, will feed 150 men from the produce of one hectare ($2\frac{2}{5}$ acres), while the same area of wheat will only supply six individuals; for the same time and under the same conditions of cultivation its produce is forty times that of potatoes and hundred times that of wheat.

Here is a recipe for a good liniment: Take two eggs and put the contents into a bottle, then add half-a-pint of spirits of turpentine and half-a-pint of best imported vinegar. Shake the bottle till the ingredients are well mixed, and in about two hours, with frequent shakings, a white liniment will he produced of about the consistency of cream, when it is ready for use and will improve by keeping.

The TROPICAL AGRICULTURIST

MONTHLY.

XX. COLOMBO, JUNE 1st, 1901. No. 12.

HELOPELTIS.

[*From the Royal Botanic Gardens, Ceylon, Circular*, April, 1901.]

"WHAT WE KNOW AND WHAT WE WANT TO KNOW ABOUT IT."

HELOPELTIS Antonii, the so-called "Mosquito Blight,"* was described by Dr. Signoret (a French Entomologist) from Ceylon more than forty years ago in 1858. The description published in the Annals of the Entomological Society of France † makes no mention of the plant upon which the insect subsisted in those days, before the introduction of cinchona or tea. Cacao—according to Trimen—had been established in Ceylon for some time previous to that date, and it is possible that there was a sufficient number of trees to afford food for the *Helopeltis*.

The recorded food plants of the insect in Ceylon are cacao (*Theobroma cacao*), the several species and hybrids of tea, cinchona, and annatto (*Bixa Orellana*). Besides these economic plants, I have observed *Helopeltis* feeding and breeding upon the "wax apple" (*Eugenia aquea*).

The earliest notice of the appearance of *Helopeltis* on cacao in Ceylon was in 1880 or 1881 in the Matale District. In 1884 Dr. Trimen exhibited specimens and read a short note upon their occurrence at a meeting of the Linnæan Society in London. It is remarkable that it was the damage done to the young leaves and twigs that then attracted the attention of cacao planters. At the present time it is the pods of the plant that suffer most from the attacks of the insect.

With respect to cinchona, I observed it myself puncturing the young leaves of *Cinchona ledgeriana* and *officinalis* in 1886 in the Pundaluoya district, at an elevation of over 3,000 feet. An allied insect (*H. bradyi*), was reported to be injuring cinchona in Java in 1882.

I have found it difficult to obtain accurate information about the appearance of the pest in the various tea districts. My first personal acquaintance with it was from specimens sent to me from the Morowak Korale district in 1889. But the earliest record is from the Kelani Valley, where it is said to have first appeared on an estate in Yatiyantota in 1892, though it did not become plentiful until 1893, when it was reported from several other estates. In 1893 the matter was brought up at a meeting of the Kelani Valley Planters' Association, when concerted action was suggested, so it is probable that the pest was then causing considerable injury to the tea. In 1890 my attention was drawn to serious damage by the insect to tea in the Kalutara district. The pest was first noticed in Udagama in 1898. I have this year (1901) observed a few cases of attack in the Balangoda district. I am told that it has been noticed there for a year or more, but has not as yet caused any appreciable injury; but it would be rash to suppose that the pest will not increase if no attempts are made to check it.

* The popular name of "Mosquito Blight" is an unfortunate one, and has led many planters—by a false analogy—to suppose that the *Helopeltis* may breed in swampy ravines and stagnant pools. The very slight resemblance to a mosquito is purely superficial. The two insects belong to widely separate Orders, and undergo a very different development in their early stages.

† VI., p. 502, t. 12, II. f. 2 (1858).

LIFE HISTORY.—Though we have a knowledge of the different stages of the insect, from the egg to the adult, the full life-history is not accurately known. The eggs are laid either singly or in groups of from two or five, in the rind of the pod (in the case of cacao), and in the young stalks (in the case of tea). In the latter they are almost invariably deposited at some point above the "initial" or "fish" leaf. They are embedded in the tissues of the plant, the only external indication being the presence of a pair of silvery hair-like horns projecting from the extremity of each egg. In ten days' time the egg hatches out into a small reddish insect, with longish legs and antennæ, looking not unlike one of the slender ants that frequent the tea blossoms. This insect grows rapidly in size, without greatly altering in form, until it is nearing the final change when small rudimentary wings may be observed sprouting from the sides of the body. In the course of its growth it changes its skin some three or more times (the exact number has not yet been determined), and, after the last change, appears in the red, black, and white grub of the adult *Helopeltis*. In all its stages the insect may be readily recognized by the so-called "drum-stick," or erect-knobbed horn projecting from the middle of the back (technically from the part called the scutellum). We do not yet know how many moults occur during the growth of the insect, the duration of these immature stages, or the length of life of the adult insect. The young insects do not thrive in captivity, and I have never been able to rear one up from the egg to the adult.

Nothing is known of the natural enemies of the *Helopeltis*, if it has any. Should any insect or other animal be noticed attacking the *Helopeltis*, I should be greatly obliged if the observer would send me particulars of the fact, and, if possible, specimens of the assailant.

HABITS.—The *Helopeltis* insect feeds—in all its stages—upon the sap of the young leaves and shoots (or, in the case of cacao, upon the fruit). The symptoms are almost too well known to require description. Each puncture of the insect is followed by a dark brown or black spot, the tissues of the leaf being actually killed at that spot, partly by the exhaustion of the contents of the cells, and partly (probably) by the injection of some irritating fluid, though this has not been actually demonstrated. When the punctures are close together the spots coalesce, and the whole leaf shrivels and dries up. When a young bud is punctured, that bud dies back. When the insects are very numerous, every single bud may be killed back in this way, resulting in a complete cessation of flush.

The insects feed at night and during the early hours of the morning. After 9 a.m. it is often difficult to find a specimen at work. It is still somewhat of a mystery where they conceal themselves. It was thought at one time that the adult insects flew away to the jungle during the heat of the day, or retired into neighbouring shade trees. But this has never been proved, and is extremely doubtful. It is certain that the immature insects cannot remove themselves in this manner, and it has been observed that when disturbed these young insects run down the stems into the heart of the bush. It is most remarkable how, even in fields where they must be swarming, the *Helopeltis* insects secrete themselve during the heat of the day. I have frequently tried to shake or beat them out of the tea bushes, but it is quite exceptional to secure a specimen in this way. A minute examination of the centre of the bush produces no better results, though it is almost certain that they are somewhere there. It was thought possible that the insects might go into hiding under stones and loose earth below the bush. To test this theory, a broad band of sticky substance (jak juice was used) was applied to the stems of a certain number of trees at midday. All punctured leaves were plucked from these marked trees, but fresh punctures—evidently made by immature insects—appeared during the following night, proving that they had been resting somewhere above the sticky zone. Bunches of dry grass were placed in the centre of some bushes to see if the insects would hide in them, but on pulling these to pieces later they were found to be untenanted.

The comparative immunity from attack of certain species or varieties of tea is most marked. Pure Assam indigenous is practically untouched. Of the hybrids, the more the plant partakes of the Indian strain, the greater is its immunity; the nearer the China strain, the more is it open to attack. This fact was most conspicuous on an estate visited by me in Kalutara. Two adjoining blocks, without any intervening boundary, were planted, the one with Assam indigenous plants, the other with a low jat hybrid. It was possible to walk up between the two adjoining rows and see the tea on one side quite healthy, while every bush on the other hand was badly blighted. In another field of "indigenous" plants supplies of an inferior hybrid had been put in. These supplies could be at once detected from a distance by their unhealthy blighted appearance.

It is difficult to obtain careful records of attack—noted month by month—extending over several years. But I have one such record from an estate in the Kelani Valley, which gives the numbers of *Helopeltis* insects collected month by month during the last seven years, together with the monthly rainfall throughout that period. From these figures it appears that the worst attack takes place in July and August. After September there is a rapid drop, reaching its lowest level in November, followed by a tendency to gradual (fluctuating) increase up till February or March, when there is another rapid fall. In April and May the pest practically disappears. The recrudescence commences towards the end of June and reaches its height in July or August. There thus appear to to be two periods of increase and decrease during the year, a major and a minor period. The major period is represented by the zero point in April and May, followed by the maximum in July and August. The minor period consists of the fall in September, October, and November, followed by the increase up to March. The March attack never approaches the gigantic proportions of the July-August attack, the figures being approximately as 4 to 9.

The results obtainable from a study of the rainfall are rather conflicting. December, January, February, and March, during which time the pest is on the increase, are comparatively dry months and register the lowest rainfall. April, May, and June are very wet, and there is then scarcely any attack. Studying this period alone, one would be led to the supposition that dry

weather favoured the pest, while rain deterred it. But if we examine the second period, we find that July, August, and September are distinctly wet months, and it is during these very months that the pest attains its maximum development. We find, therefore, that the two periods of increase viz., December to March and June to August, are marked by dry weather in the first case and wet weather in the second. Similarly, the first period of inactivity (in April and May) occurs during heavy rains, and the second period (October and and November) during comparatively dry weather. It is noticeable that both the maximum and minimum of attack occur during the wettest months.

It should be observed that these deductions are made from records from a single estate in one district. To be of real value they should result from the comparison of a number of records from many estates in different districts. I would appeal to all those interested in the subject for such particulars as will enable me to formulate more accurate deductions. There are doubtless many records of captures now available. I know that it is the custom to count the number of insects brought in each day, and the figures are entered in the estate books. Even a statement of the number of coolies employed in the work, day by day, will be of considerable value in estimating the rise and fall of the attack.

But the chief problem requiring solution is, "What becomes of the insect during the period or periods when it disappears from the tea?" Does it subsist upon some other plant? Does it lie dormant in some hole or crevice? Or does the insect, towards the end of its period of activity, deposit specialized eggs that remain unhatched for a much longer period than is ordinarily the case?

These questions are of the greatest importance, and can only be answered by very careful and long-continued observation on the spot. I hope to undertake this investigation very shortly by repeated visits to an affected estate at the critical periods.

Until these points have been satisfactorily elucidated I can suggest no other remedial measures than those which are now being carried out on most affected estates, viz., (1) the careful collection and destruction of the insects; (2) plucking to the initial leaf, in badly attacked fields, to ensure the destruction of the eggs.

E. ERNEST GREEN,
Government Entomologist.

Peradeniya, March, 1900.

CORUNDUM GEMS.

BY LEOPOLD CLAREMONT.*

The mineral known as corundum (from the Indian "Korund") consists of almost pure crystallised oxide of aluminium (Al_2O_3). It crystallises in the hexagonal or rhombohedral systems, and is generally found in six-sided pyramids, scalenohedrons, and prisms, although the coarse opaque variety also occurs massive and granular—that is, devoid of any natural crystalline formation.

In hardness, corundum is only inferior to the diamond, and it, therefore, occupies the position of No. 9 in the recognised scale of hardness. It occurs both opaque and translucent, and its specific gravity varies between 3·90 and 4·16. The opaque variety of corundum, which is generally dull grey, reddish brown, or greenish, and sometimes colourless, is found in large masses in most of the Asiatic countries; it also occurs plentifully in America and Australia. It is, on account of its extreme hardness, of value as an abrasive material, entering largely into the composition of emery. It is, however, the translucent variety of corundum with which we are chiefly concerned at present. Every imaginable shade of every colour presents itself in this variety of the mineral, and the difference in the colour is due in a very great measure to the addition of minute quantities of metallic oxides to the alumina of which the mineral is composed. To every colour in which translucent corundum occurs a different name has become attached—*e.g.*, red corundum is called "ruby," blue corundum is called "sapphire," the yellow "Oriental topaz," the green Oriental emerald, the purple "Oriental amethyst," &c., &c. Therefore, to the scientist, these gems are absolutely identically the same stone, only differing in an infinitesimally small degree in the nature of the colouring matter to which they owe their distinguishing quality. But to the prospector, the dealer in precious stones, and the wearer of jewels, this little distinction with regard to colour makes a great difference, for upon it depends the commercial value of the gems. It is, therefore, necessary for the present work that each precious stone, no matter what relationship it has to any other gem, should receive separate attention from my pen. I do not propose, however, to make a repetition of all the physical and optical properties of these stones, except in the case of the ruby and sapphire.

RUBY.

The ruby or red corundum is, undoubtedly, the most coveted of nature's treasures by the human race throughout the universe. In this most precious material it is possible to concentrate the greatest amount of wealth in the least possible bulk.

A ruby equal in value to a "king's ransom" can be carried in the corner of one's waistcoat pocket without inconvenience. A fine ruby weighing, say, four carats, is worth in the gem market to-day quite ten times as much as a fine white diamond of the same weight. As already explained, the ruby is one of the group of the precious stones, which consists of oxide of aluminium and, consequently, has many of its properties in common with all the other members of the same group. The specific gravity of ruby is 4. The hardness is generally recorded as 9, but, as a matter of fact, ruby is slightly softer than the other corundum gems, which occupy the position of being next in hardness to the diamond.

The ruby acquires electricity by friction and retains it for several hours. The lustre is vitreous, but the surfaces of the crystals are usually more or less dull. The fracture is conchoidal or uneven, and the cleavage basal, but imperfect. Some specimens of semi-opaque and cloudy rubies display a shimmering six-pointed star when cut with a convex surface. These are called star rubies, and will be more fully described under the heading of "Star Stones."

Ruby occurs in the hexagonal or rhombohedral system, assuming the form of the hexagonal prism or pyramid. Water-worn and rolled fragments are, however, of much more frequent occurrence, often showing, by the absence of any trace of crystalline formation, how severe are the many hardships endured during the unrecorded ages of their existence. The ruby is doubly refractive, but not to a very great extent, and is always dichroic, showing the two squares of the dichroiscope of distinctly different colours—namely, aurora red and carmine red—when viewed at right angles to the principal axis of the crystal. This is a most useful means of distinguishing ruby from garnet and spinel, which show both squares of the instrument of the same colour, no matter in what direction through the crystal they be viewed.

*This article appears in our columns by permission of Messrs. Claremont and Ward, lapidaries and experts in gems, 88, Condult-street, London, by whom the copyright is reserved.

The occurrence of corundum in the form of ruby is extremely rare in comparison with the immense areas in different parts of the world where the opaque coarse variety is plentifully distributed. There are three principal sources whence the rubies of commerce are derived, viz :—Burmah, Siam, and Ceylon ; but they are also found in unimportant quantities in Brazil, Thibet, Afghanistan, New South Wales, and the United States of America.

The centre of the ruby-mining industry of Burmah is the town of Mogok, and the operations of mining extend over an area of upwards of 400 square miles to the eastern bank of the Irriwaddy River. The rubies are found associated with garnet, graphite, and spinel in beds of course gravel, and embedded in more or less crystalline limestone which exists alternating with gneissic and schistose rocks. By the ever abrading effects of the elements these igneous rocks have become disintegrated, the debris forming the gravel beds lying in the valley below. It is in these gravels that the finest rubies are found, the explanation of which probably lies in the fact that flawed and imperfect stones are unable to withstand the hard wear and tear to which they are subjected by nature. They gradually get chipped and broken up by the constant process of grinding and pulverising which they are destined to undergo, leaving only the flawless and more perfect stones to survive.

In Siam, the most productive district of rubies is the province of Chantaboon, Bo Wen and Taphad Hin being the principal centres of mining operations. Another locality which produces large quantities of rubies is Krat, in which province the most important mines are situated at Bo Van and Navong. In the district surrounding Ratnapura, which town is often alluded to as the "City of Gems," and Rakwana, are found the finest rubies in Ceylon. They are found in the detrital deposits of valleys, river beds, and mountain torrents, generally as water-worn pebbles and broken fragments. They are always associated with the paler and many-coloured varieties of corundum, which will claim our attention in due course. The colour of the ruby varies very greatly, for, although it is characteristically red, there are innumerable different shades and degrees of depth of colour in which it occurs. The tone of colour which is the most rare, and which is, consequently, the most sought after by connoisseurs in precious stones, is termed "the pigeon blood" ruby from its resemblance to the scarlet blood of a recently-killed pigeon.

The rubies which come from Burmah more nearly approach to this desired colour than those from any other country and, consequently, they are proportionately of greater value, for it is only in rare and isolated cases that a gem of the true colour is brought to light. Siamese rubies are generally much darker than the Burmese stones, and have a tendency towards being purplish and puce in appearance. Although very occassionally a Siamese stone is found the colour of which may be compared with the rubies of Burmah, the majority of rubies from Siam are unsatisfactory from a marketable point of view.

Ceylon rubies are different altogether from the rubies of either Burmah or Siam. They are very limpid in brilliancy and pale in colour, possessing all the qualities of the most beautiful and attractive gems, yet they do not rank among rubies of fine quality. The actual cause of the flame-red colouring of the ruby has been the object of a great deal of most interesting investigation by some of the greatest scientists of the day. Although it is believed that the many varieties of corundum derive their colour from the presence of most minute quantities of different metallic salts, it has comparatively recently been discovered that the real cause of the colour of the ruby is still unknown. The absence of any salt of chromium, which was formerly suspected of causing the red hue in ruby, has been conclusively proved by the most careful chemical analysis, and endorsed by the still more delicate method of spectrum analysis. When oxide of aluminium is inserted into a partially exhausted glass bulb, and exposed to the action of a high tension electric current, it flashes with a lovely crimson glow, and it has been demonstrated, under similar conditions, that ruby itself will give precisely the same result. Moreover, if to the oxide of aluminium be added some oxide of chromium, the glow will not be produced.

If the light naturally transmitted (through absorption) by the ruby be examined by the spectroscope, it gives the same bands which are characteristic of the phosporescent glow which comes from the oxide of aluminium, in the vacuum tube. Another curious fact is that white oxide of aluminium, when exposed to electrical bombardment for a long time, gradually alters to a pinkish hue.

Altogether, it is quite obvious that some mysterious property exists in connection with oxide of aluminium which the science of the day has not satisfactorily explained. That the ruby has always taken the first place among precious stones is evinced by many references to this beautiful gem by writers of all ages, although, before the development of the science of mineralogy, great confusion seems to have existed with regard to rubies as with many other precious stones. It is apparent that almost any red stone was classed by the Greek and other ancient races under the general heading of "carbunculus," which doubtless included, besides the true ruby or red corundum, spinels and all the many different kinds of garnets.

Pliny, for instance, although he gives the first rank to the "Carbuncle Amethystizontes" (our modern almandine garnets) describes under this heading many of the chief characteristics of the true ruby of to-day. The "Pantarbes" of Philostratus was undoubtedly the modern ruby, and the gem alluded to by Theophratus, as "Anthrax," was also probably ruby, for he writes of its value being equal to forty gold staters, about forty guineas, for a small stone, whereas garnets were so common that their value could not have been very great at the highly civilised period of which he wrote. Both the words "Carbunculus" and "Anthrax" were used in allusion to the 'burning coal' effect of the stones described. The quotation, 'For wisdom is better than rubies," one of the many references in the Holy Scriptnre to this precious stone, proves that rubies were of considerable importance at the time of King Solomon, to whom the words are attributed.

From old writings we learn that by the ancients the ruby was always enveloped in mystery and accredited with all kinds of strange properties and powers one of the most striking of which was the belief that the stone possessed the power of shining of its own accord in the dark, emitting flashes of light dazzling to behold. It was also supposed to attract other gems in much the same way as a magnet attracts bits of steel. If a ruby were tied to the end of a string and lowered into a river, the bed of which contained precious stones, it would be found upon its withdrawal that the ruby would be encrusted with other gems which had been attracted to it—a most usefnl virtue indeed !

Ruby was used as a talisman against all kinds of ills but chiefly against fire, which virtue is illustrated in the legend of Charielea, who, when condemned by the jealous Arsace (Æthiop VIII. 2), escaped nnhurt from the pyre by means of an amulet in the form of the espousal ring of King Hydaspes, "which was set with the stone called Pantarbes, engraved with certain sacred letters embodying, as it has proved, some divine charms by means of which a virtne is imparted to the gem antagouistic to fire, and thus giving to the wearer immunity from hurt in the very midst of flames." A peculiar idea, not altogether restricted to by-gone civilisations, is that the different corundum gems alter or ripen in the earth, and that a ruby has changed gradually from yellow to blue, from blue to purple, and from purple to red, which

might be looked upon as the perfection state, which the blue, yellow, and purple varieties of corundum have not reached.

We know that the ruby was the most highly-prized of all gems at the period of the Renaissance, for Cellini, in his "Orificena," referring to the relative valnes of precious stones, gives the value of a carat ruby as eight times that of a diamond, and 80 times that of a sapphire of the same weight.

Many are the tales of immense and magnificent rubies seen by travellers of old to the Courts of Asia. As these writers generally describe not only what they saw, but what they had described to them, it is wise to take many of their statements with the proverbial grain of salt. We find, for instance, "allusions to a ruby of perfect quality as large as a hen's egg, which was worn as an ear-drop by the King of Ada." Even Tavernier, in his "Travels" although imparting much valuable information about the gem-producing countries visited by him, and the customs and habits of the inhabitants, often taxes our credulity with regard to the gems he describes. But I think we may place reliance npon his account of a fine ruby in the possession of the King of Vishapoor, which he describes as being almost triangular in shape, of a most vivid red colonr, and of about 50 carats in weight.

In a curious old book, pnblished in the 14th century, Sir John Mandeville describes a ruby and a carbnncle half a foot in length, which possessed the property of self-luminosity. These marvellons gems were seen by him at the conrt of the great Chan of Cathay. Some of the most notable gems in the Royal and Imperial regalias of Europe are rubies, and will be described in a chapter dealing with the historic interest connected with them. Besides these there are several magnificent rubies which have from time to time appeared npon the market either from the mines of Burmah or, which is more generally the case, from the treasury of an Eastern potentate. Often these gems, which, perhaps, have been worn for hnndreds of generations of their Royal owners, or formed part of the splendour of idol or Buddha, are parted with to relieve some financial crisis of the Court.

Two crndely-cut rubies of snperb quality came to light in this way in the year 1875. They weighed respectively 37¼ and 47 carats in the native-cut state, but after recutting in London the smaller stone weighed 32 5-16, and the larger one 38½ carats. The smaller ruby was a cushion-shaped stone of a fine rich colonr, and eventually fetched the enormous snm of £10,000. The other stone, althongh of a somewhat awkward drop shape, was of such exquisite quality that nearly double this amount was realised. The larger of these beautiful gems is now in the pcsession of a Russian count, while the smaller belongs to a well-known American millionaire.

Ruby is seldom selected as an object for carving or engraving npon, chiefly owing to the extreme hardness of the stone. The great intrinsic value of this gem also makes it an unsuitable material for the purpose, as the artistic conception of design and execution of workmanship should claim the first consideration with these works of art. Occassionally, however, to meet the reqnirements of some wealthy client, the gem engraver of all periods has used the ruby as a foundation upon whicn to work intagli and camei.

It must be said that among engraved gems of authentic antiquity precious stones of all kinds are extremely rare, as productions of the most famous glyptic artists of ancient Greece were executed upon material selected as most suitable for displaying to the g eatest advantage the inimitable genius of the period for oameo and intaglio, and as most suitable for giving a true impression when used as a seal.

A full face of a Bacchante, crowned with ivy, forms the subject of the most beautiful antique intaglio npon ruby known to connoisseurs. The exquisite treatment of the flesh and hair, as well as the half-devilish expression of the countenance, denote the work of an artist of the first rank, Emhn by name, at the period when Greek glyptic art was at its height.

Other examples of the use of ruby by ancient Greek artists are the head of Hercules upon a small stone of pale colour in a very bold, effective style, and a magnificent head of Thetis upon a pentagonal ruby of irregular shape. The latter subject is treated in a masterly way, depicting Thetis wearing the shell of a huge crab in place of a helmet. Both these intagli have the heads engraved *en profile*.

In regard to engraved rubies and other precious stones, it is generally the case that careful scrutiny will show the presence of some flaw or other imperfection within the gem, which it has been the object of the glyptic artist to partially hide.—*The Mining Journal, Railway and Commercial Gazette.*

THE FORMATION OF ALKALOIDS IN CINCHONA TREES.

The objective of the extensive system of cinchona cultivation now prevailing in India, Java, and other tropical countries, is the production of cinchona bark containing the largest possible amount of alkaloids since it is to the presence of the latter substances that the bark owes its useful properties. At various times methods of increasing the yield of alkaloid have been suggested, such as shading the stems of the trees from the direct action of the snn, but these have been, as a rule, based on preconceived motions of the *role* played by the alkaloid in the life history of the tree, and were not the result of any real investigation of the conditions under which these bodies are produced by the plant.

This defect has now been remedied by the results obtained by Dr. Lotsy, of the Java Cinchona Gardens, in the course of a series of investigations into the mode of formation and the occurrence of alkaloids in two species of cinchona, viz., *succirubra* and *ledgeriana*. Several papers giving an account and this work have appeared in Dutch periodicals, and recently a *resume* in English has been published in the *Bulletin de l' Institut Botanique de Buitenzorg* (No. 3, 1900), from which the following particulars have been taken.

In commencing his work the author subjected each part of the tree in turn to micro-chemical examination for the presence of the characteristic cinchona alkaloids, and, as a resnlt, was able to demonstrate the existence of these substances in certain cells of every portion of the plant. Thus, in the leaves no alkaloid occurs in the epidermal layer of cells, or in the veins, but the fleshy part of the leaf invariably contains in its constituent cells a certain amount of alkaloid. In a similar manner, the stem, even in its earliest stages, contains alkaloid, but only in the inner layers, never in the epidermis or in the large wood vessels found in adult trees. In the root a precisely similar condition of things is found, and so also in the petals and other parts of the flowers. In general it may be stated that the alkaloid occurs only in the tissne known to botanists as the *hypoderma*, *i.e.*, in the part of the plant where the building-np and breaking-down processes which constitute plant metabolism are most active. In the youngest parts of the plant, such as the tip of the stem and under the root cap, where no differentiation into tissues has begun, no alkaloid is found.

These observations afford an explanation of the phenomenon that the first bark obtained from a cinchona tree is always richer than that of succeeding crops. This is due to the fact that the bark first formed is produced by the drying up of hypodermal tissue, of which each cell contains alkaloids; while the secondary bark produced by continued activity of the cork cambium contains, in addition to hypodermal cells, bast fibres which contain no alkaloid.

A peculiar feature of the distribution of the alkaloids is that they never occur in the sieve-tubes, which are associated with the conveyance of the albuminous products of the plant.

The second part of the investigation deals with the method of formation of the alkaloid. Since the leaves of plants are mainly concerned in the production of starch and albumen, which serve for their nutrition, it was highly probable that here also alkaloids were produced, but the evidence already existing strongly negatived this view. Thus, Howard (*Quinology of the East Indian Plantations*, 1869, p. 14), found that leaves of *Cinchona succirubra* contained only ·11 per cent. of total alkaloid; while Broughton, in 1870, found percentages varying from ·0041 to ·019. In a specimen of leaves examined by De Vry in 1896, a larger amount was found, viz., ·162 per cent., but this was amorphous alkaloid only. As pointed out by Dr. Lotsy, however, a mere estimation of the amount of alkaloid continued in the leaves gives no reliable answer to this question, because it is quite possible that the alkaloid as soon as formed is transported towards the stem; consequently the author adopted a somewhat different procedure, of which the following short account may be given. A leaf of the tree under investigation was selected and cut into two, longitudinally, and on one side of the midrib, while still attached to the tree. The smaller half so removed was examined micro-chemically for its content of alkaloid, while the portion still on the tree was allowed to remain during a day or night, as might be necessary for the particular experiment then being carried out, when it also was removed and its content of alkaloid determined in the same manner.

A large number of observations carried out in this way showed that, under normal climatic conditions, a leaf accumulated alkaloid during the day and emptied itself during the night by allowing the alkaloid to be transported towards the stem. It was also observed, however, that this normal removal of the alkaloid from the leaves does not occur under adverse conditions, such as are found in extremely cold or foggy weather. These climatic influences also have considerable effect on the amount of alkaloid formed during the day. That the alkaloids are transported from the leaves to the stem of the plant was clearly proved by keeping cut leaves both in the light and in the dark, when it was found that the amount of alkaloid remained unchanged, even after a month. It was also found that empty cut leaves were capable of producing alkaloid when placed in stimulating liquids such as dilute solution of ammonia. The author concludes the report of the results of his long-continued investigations with some interesting remarks on the probable methods of synthesis employed by the plant in the formation of the cinchona alkaloids, but these are too technical for reproduction in the present abstract. Attention may, however, be drawn to the bearing which these results ought to have upon cinchona cultivation. In the first place it should be noted that, since the useful alkaloids are formed in the leaves of the plant, then in the selection of varieties for cultivation care should be taken to obtain those having a good foliage, both with regard to quantity and size of leaves formed. The author states that this plan has been generally adopted in recent years in the Java cinchona plantations, with excellent results. Further, it should follow that any method of cultivation which tends to increase the hypodermal tissue in the plant should yield bark containing an increased amount of alkaloids, and so one would expect better yields from *pollarding* than from ordinary growth.

FRUIT TREES FOR CEYLON.

A circular from A. J. Pearson, Colombo, dated March 29th, says that it is proposed to make an importation for S. W. monsoon planting, of first-class named varieties of fruit trees considered to be suitable for cultivation in Ceylon. The trees will be mostly three years old and are guaranteed to be true to name and description. Oranges and Lemons are put down at R2·50 each. Peaches, Nectarines, Apricots, Figs, Plums, and Olives are R2·00 each, while Grape vines are R1·00 each. The only ones suitable for Jaffna are Oranges, Lemons, and Grape vines. Years ago some figs were introduced into Jaffna, but, if we have been rightly informed, they did not thrive well. They might be given another trial, however, and they might prove more of a success. Of the grapes the "Muscat of Alexandria" is specially recommended for trial. A few years ago there was some talk about introducing several new varieties of grape, including the "Black Hamburg" and other dark kinds, but we have heard nothing about it since.

The Lemon advertised is "The Lisbon lemon." It is said that there are several trees of this in the island, three and four years of age, which are bearing heavily. Whether the Lemon would grow in the Jaffna soil and climate can only be known by giving it a trial.

A dozen varieties of Oranges are given, the Washington Navel being most highly recommended. We doubt whether it would thrive in Jaffna. The Mediterranean varieties are much more likely to be successful. Whether the Chinese and Japanese Mandarin oranges could be raised here or not is a question. We hope some of our rich farmers will try a few varieties. Orders should be sent in at once. Delivery is promised in June, and with care the trees ought to get a good start before the north-east monsoon sets in.—*The Morning Star*.

THE EUCALYPTUS.

In an interesting article in the *Scientific American*, Mr. Nicholas Pike makes some useful observations on the nature and uses of the eucalyptus, which appear worthy of notice. After remarking on the great progress made in medicine and surgery during the past half-century, Mr. Pike says that in most diseases fever acts a prominent part, and statistics go to prove that in more than half the cases malaria is found to be the actual existing cause; perhaps imbibed from sewers, foul odours and gases, marshes, etc., Surely, then, any remedy that could purify our surroundings should be heartily welcomed.

In the trees of the eucalyptus family a relief may be found for the malaria so prevalent in some parts of the world. Australia is the principal home of the eucalyptus, where it forms 90 per cent. of the forest trees. All have gummy secretions, and from the varied tints of the foliage go by the local names of blue, red, or white gum trees. From the peculiar bark of many they are also called "stringy bark trees."

Nearly all the encalypti grow very tall, some of them rivalling the giant *Sequoia Wellingtonia* in height. An English maturalist measured one 400 feet high, and four men on horseback could stand in a cavity of the trunk. One of the *E. Amygdalina* that had fallen in a mountain gorge was 420 feet long, with circumference in proportion, and some in the Yarra district are over 500 feet.

There are more than one hundred species of eucalyptus, but Mr. Pike only mentions a few of the most useful and important. Very many have long attracted notice from their valuable properties, and they ought to be better known Their flowers are apetaleous, but have masses of stamens like the myrtle. The bud has an operculate calyx, formed by several jointed leaves, united throughout, and separating at the articulation in the shape of a lid, which flies off when the flower expands.

The *E. oleosa* or *piperita* has the smell and qualities of the famous cajeputi (*Melaleuca miner*), so well-known in India for the cure of rheumatic affections. The wood is extensively used for fuel and the bark for

paper-making. It does not grow to the great height of some species, but covers large tracts of gronnd, the roots running horizonally over the surface.

From the *E. mannifera* exudes in the dry season a saccharine, mucous substance, resembling manna in character and appearance. *E gunnii* furnishes a copions supply of cool refreshing, slightly aperient liquid, which ferments and acquires the properties of beer. The giant eucalyptus is sought for its beautifully veined wood, and is called mahogany of Australia. The *E. resinifera* has pendant branches resembling a willow. The bark is very thick, and is taken off in sheets for the covering of the houses of the natives, and it yields also a kind of gum kino, sold in the medicine bazzars of India for its nse in diarrhœa. From the last two mentioned an abundant juice flows of a red colour, containing much gum and tannin, and a single tree will often yield 60 gallons. All the above are valuable, but none to such an extent as the *E. globulus*. It has strong roots and smooth bark, and the bluish leaves give it the name of blue gum tree. Every part of it exhales a powerful, balasmic odour, and the leaves and seeds when crushed smell like tobacoo. Bees are strongly attracted to this tree, and nests yielding abundant honey are often found in it. The wood is very hard and heavy, and greatly used for building and naval purposes. It is of a fine red oclour, and very durable, and insects do not attack it. It is especially sought for in the construction of railways.

Many species of eucalyptus have the properties of cinchona in their leaves and bark, but none equal to the *E. globulus*, which has them more abundantly than the Brazilian tree. Van Vauquelin obtained from it an essential oil containing eucalyptal camphor closely resembling the resin of cinchona. This extract yielded a substance capable of neutralising the strongest acids, and forming crystalline salts. The sulphate crystallises in star-shaped crystals, like sulphate of quinine or cinchona. The narrow leaves of the tree are principally used, dried and powdered, and strong tinctures are made from them. The bark also produces favourable results. So efficacious are preparations from this tree in marshand other feves that it is known as the "fever tree." The medicine has a warm, aromatic, bitter taste. and is invaluable in exciting the flow of saliva. It lowers arterial tension, and is useful in hysteria, cerebral anœmia etc. When the leaves are smoked, they relieve asthma, bronchitis and whooping cough, and have also been employed instead of lint for wounds. When properly administered, it will cure malarial fevers, where quinine utterly fails to do more than temporarily arrest them. The preparations from the eucalyptus have a great advantage over those of qninine. When excessive or constant dose of the latter are taken, they will often establish some local disease. In some malarial districts qninine pills are taken, with every meal for weeks together; the alimentary canal beoomes disordered in consequence, nausea and constipation ensue, and a febrile state is set up, with excitement of the whole vascular system. The cerebral and spinal organs become deranged, throbbing headaches and giddincss often occnr, sight and hearing are weakened, and the spleen sensibly affected. In fact, unless administered by a skilful physician, quinine is a dangerous drug, and Mr. Pike has known many fatal cases from its mis-use.

Now, the effects of encalyptus are almost the reverse of those of quinine; it produces none of the ringing of the ears and troubles caused by quinine, and prevents all stomach complications. If fresh powder could be procnred, it would be of incalculable benefit to the victims of malaria.

Up to 1870, one of the most fever-stricken countries of the world was the Maremma, the Roman Campagna, where the neglect of ages had allowed stagnant marshes to form in what was once a well-populated healthy district, till it conld only be inhabited during a small part of the year. At that time large plantations of the eucalyptus were made, and the Trappists have now a large establishme there where they live all the year round, fever being almost eradicated. They use the wood for their buildings, and say it is the best and strongest they can procure. In Nice, Mentone, Corsica, the South of France, Egypt, Sierra Leone, Natal. Tahiti etc., where they have been extensively planted, fevers are fast disappearing. Over a million trees have been planted in Algeria, and their sanitary influence has been most marked. Whcrever they have been planted in compact masses, there intermittent fevers are greatly diminished. They have been very largely cultivated in some districts of India, and the inspector of forests writes that, irrespective of their salubrity, the wood is very valuable, and at ten years old a tree is worth £20. In California the eucalyptus has been planted with the object of lessening droughts along the line of the Central Pacific railway.

All these places were more or less deadily from the miasma engendered by festering marshes and other causes. Now life is not only bearable, but enjoyable, from a very simple source—the taking advantage of one of nature's own cures. By planting these trees in numbers their roots have drained the soil, and the leaves give out the balsamic odours so healthful to breathe.

The peculiar region of these trees is the temperate part of Australia and Van Diemen's Land. They thrive in a mean temperature of 59°, to 72°, but will grow in 45° to 50°. Of conrse, this prevents them becoming hardy denizens of northern climates. They will, however, suit admirably in the Southern States, especially in sandy soils near the sea. They grow easily from seed, and are of very rapid growth, and if the various kinds are planted out unsparingly, they may become large factors in the new industries that would spring from their cultivation, and vast waste marsh lands would be ntilised as well as rendered salubrious for occupation.

Though our northern climate forbids this culture out of doors there are plenty of ways and means by which the eucalyptus can be made available. The pecular conditions of temperature, etc., of hot-and green-houses render all who work in them very liable to malaria. To florists it would be an easy matter to grow a plant in every house, which could be checked back to keep it within bounds, and the sanitary state of their premises would soon change. It would be well to grow the seeds of the *E. globulus* largely for distribution. Every railway depot, hotel, or any other building where many people congregate could use this plant advantageously. Especially is it advisable, as persons are constantly coming and going who are filled with malarial and other germs from varions infected localities. The powerful germ-destroying odonr of the plant would kill any floating in the atmosphere and help the sufferers too.—*Imperial Institute Journal.*

THE CAMPHOR INDUSTRY.

Considerable interest has been shown during the last few years in the production of camphor and camphor-oil, partly owing to the increased demand for these products in the arts, and partly as the result of the restricted output of the substances, which was the immediate consequence of the cession of Formosa, with its extensive camphor forests, to Japan.

Although camphor is still produced in China and Japan, and the cultivation of the camphor tree has been commenced in Florida, yet practically the world's supply of this commodity is derived from Formosa. In this island the distillation of camphor has been carried on from the earliest times by the natives, but in the 18th century the Chinese Government established a monopoly, any infringement of which was visited upon the offenders with savage penalties. In 1720, over 200 people were executed in the island for such offences, and so badly were the aborigines treated that they rebelled, and finally the right of production was declared free, the Goveru-

ment reserving the right of buying all camphor distilled in the island at a fixed price. This arrangement lasted until the opening of the treaty ports, when European traders refused to recognise the monopoly and began to trade directly with the native distillers. This procedure was resented by the Mandarins, and much trouble ensued between the Chinese and the Europeans. Finally the Monopoly was completely withdrawn in 1868.

Since that time the industry has flourished, and has gradually extinguished camphor production on the Chinese mainland and in Japan.

As a natural result of this unrestricted trade, the forests have been worked in such an improvident fashion that they would have been exhausted in a few more years. The restrictions on the output which have so far been the most remarkable feature of the Japanese administration are, therefore, to a certain extent justified by the condition of the forests. The island has now been divided up into six camphor districts, each being controlled from a central office, which issues licences, and fixes the price at which the Administrator will buy camphor in that district. The number of stills licensed has been reduced to 1,400, while formerly 4,000 were said to be continuously employed. The crude camphor bought by the Government is now sent to a central factory at Taipeh, where it is pressed free from oil, compressd into cakes and prepared for export. This preliminary refining ensures the camphor being put on the market in a better condition than formerly. It is not intended at present to make any change in the native method of distillation, although this admits of great improvement, as will be seen from the following short description. A rough oven of loam, clay and stones is first built to a height of about four feet from the ground; in this is placed a quantity of wood, and on the latter a large iron kettle, to which water is continuously supplied from a second vessel provided with a tap. The kettle is surmounted by a cylindrical barrel packed full of small pieces of camphor wood. From the the top of the barrel a bamboo tube leads to an air-tight box used as a receiver. The whole apparatus is carefully luted with clay, and when ready the wood is lighted, and, as a result, steam from the kettle passes up through the camphor wood carrying with it the volatile oil, which condenses in the long bamboo tube and runs into the receiver. Here the oil separates into a solid part, which is camphor and a liquid portion, which constitutes crude camphor, oil. The latter material still contains from 20 to 30 per cent. of camphor; formerly it was exported to Europe in this state, but now it is sent to Japan, where the valuable camphor is extracted, and the residual oil only sent to Europe. It should be noted, therefore, that the camphor oil now found in commerce is a much less valuable product than formerly. The distillation is chiefly carried on in the interior of the island, and is always liable to interruption from the semi-civilized natives, who also plunder the caravans on their way to the coast, the frequency of such depredations during last year accounting largely fo the high price of the substance, which is at present just 100 per cent. greater than before the establishment of the new regime (*Schummel's Report*, October, 1900). In addition to restricting the production, the Japanese Government also for a time prohibited the export of camphor, in the hope of forcing up the price with the object of obtaining a certain fixed revenue from the island. It is very doubtful whether this policy will succeed, since already celluloid, the manufacture of which formerly required a great deal of camphor, is now being made with naphthalene as a substitute. Camphor-oil also, which is chiefly used for perfuming common household soaps, will no doubt be replaced by other inexpensive oils, if the price increases largely.

It is of interest to note in connection with the rise in the price of camphor, that Messrs. Schummel and Co. have suggested India and Ceylon as suitable countries for cultivating the camphor tree (*Berichte Von Schummel*, April, 1896), and they point out that Mr. D. Hooper's investigations show that camphor may be successfully produced in India. This author found that the leaves of a camphor tree grown in the Indian Government plantation at Ootacamund yielded, on distillation in a current of steam, an oil containing 10 to 15 per cent. of camphor, while a second specimen of leaves collected at Nadavatam, on the slopes of the Nilgiris, gave a richer oil, containing about 75 per cent. of camphor. This possibility has also been favourably regarded by Dr. Watt (*Dict. Econ. Prod. India*, page 89). That the establishment of plantations of camphor trees would be very profiable is clearly shown by the following statistics, which are those upon which the selling price in Formosa has been fixed by the Japanese Government.

The world's requirement of camphor is estimated at 10,400 000 lb. per annum; of this, under the new administration, about 5,200,000 lb. will be supplied by Formosa, while about one-third of the whole will be exported from Japan, leaving a diminution on the export compared with 1898 of about 3,640,000 lb.

According to articles in the *Taiwain Nichi Nichi Shimpo*, published in Formosa, the actual cost of the production of camphor is 26·67 yen per picul (about £2. 14s. od. for 133 lb.), the expenses of administration amount to about 28 yen per picul, and the selling price in Hong Kong is 70 yen per picul. The profit accruing to the Government is therefore about 30 shillings per picul at present, but it is hoped to increase the price so that on the total production of the island a profit of £135,000 will be made per annum.—*Imperial Institute Journal.*

PLANTING NOTES.

HOW TO GET A GOOD MILKER.—If you want a good milker, make her, and begin to make her the day she is weaned. If you want to keep a good milking machine in good order when you have made it, take as much care of it, and look at it as often as you do at your watch, and keep it even more regularly wound up. You must keep time with your milch cow if you want her to keep time with you. Supply her with properly-balanced rations, if you want a good ration of really valuable milk. Dispense with any cow that does not prove a good milker after her third calf, but remember, the fault is usually altogether the owner's, not the cow.—*Journal of the Department of Agriculture.*

SAVING SWEET POTATOES FOR SEED.—Mr. E. J. Lance, of Colyton, *via* Mount Druitt, writes:—"Knowing the difficulty of getting sweet potatoes for seed, last March I got some from a greengrocer in Newtown, which were grown in the Gosford district. After picking out the soundest and best, I got some sand, dried it in the oven, and sifted it so as to have no gravel to injure the tubers. Then I got a box about 4 inches deep, and put a layer of sand and then a layer of sweet potatoes, then another layer of sand and a layer of potatoes till the box was full, the last layer being of sand. I kept the box in the house on a chair till September following, when they were all as sound as when put into the sand. On planting they all came up, and grew splendidly. I planted them in a warm position, close to the surface, and gave them plenty of water. I had frequently grown sweet potatoes on a small scale before, and my method is not to cut the shoots to grow, but to layer them when long enough, covering various joints here and there. I can always get a bigger crop of sweet potatoes in this way, off a given piece of ground than common potatoes. I might add that the seed-tubers had not sprouted when I put them into the ground, in September. The shoots did not show up until nearly a month later."—*Agricultural Gazette of N. S. Wales.*

THE PRODUCTION OF EXPORTABLE ORANGES.

In a lecture on "Orange Culture and Diseases," delivered at a meeting of the Malta Archeological and Scientific Society, Dr. J. Borg, M.A., M.D., made the following remarks concerning the production of oranges best adapted for export purposes :—

"Too sandy and too compact soils are alike unsuitable for the regular growth of the orange tree. This tree, when planted in a sandy soil, is very liable to suffer from dry weather. A sandy soil is, generally speaking, a poor soil, because the nutritive compounds on which the tree subsists are very readily carried away by rain water, beyond the reach of the roots of the orange tree, which, it must be remembered, is essentially a surface feeder. A too compact soil keeps the water stagnant and is one of the chief causes of chlorosis. Moreover the roots are compelled to remain very near the surface and therefore must be exposed to great heat in summer and to great cold in winter. Also, in a compact clayish soil the root system is particularly subject to dry rot. With regard to the chemical composition of the soil, we may say that the orange tree requires a soil containing a high percentage of carbonate of lime and oxide of iron, and only a moderate quantity of clay (alumina). When the percentage of clay is very high, or when the orange tree is situated on a subsoil of clay, it produces fruit having a very thin rind, and a very luscious flavour, but, unfortunately, easily subject to rot and cannot be much depended upon for exportation. This is the case of some orange groves at the Boschetto. When the subsoil consists of soft porous rock, the fruit is large, has a thick rind, the oil glands and the aromatic properties are well developed. This may be observed in the orange groves of Casal Lia, Casal Balzan, and Casal Attard, Malta. If the subsoil is very hard and compact, and therefore very dry, as the subsoil of the orange groves at Musta, the fruit is small-sized, the rind is thin, but the pulp is very juicy and delicious. Fruit grown on such a subsoil ripens early and is in every way suitable for exportation. Whatever the quality of the soil may be, still we may grow the orange tree to advantage, provided that the soil is so regulated that there will be a perfect drainage. A layer about two feet in thickness, and consisting of rubble and stones, and covered by two or three inches of thin rubbish will constitute by itself a perfect system of drainage to favour the flow of superfluous water in winter. The layer of earth which covers that of rubble should be two feet in depth and never less than one foot and a half. As the rootlets will hardly ever penetrate beyond the layer of rubbish, and as drought prevents the formation of roots within six inches from the surface, we may say that the soil in which the orange tree thrives is from twelve to eighteen inches in thickness."

Concerning manures, Dr. Brog said :—"The orange tree does not exhaust the soil very rapidly. The produce of the orange tree are the fruit and the pruned branches, so that, strictly speaking, the soil is depauperated of its nutritive substances for the same amount which these substances enter into the composition of the fruit and the pruned branches. If the nutritive elements of the pruned branches are again returned to the soil in the form of wood ashes, we will find that, even after the lapse of several years, the orange grove can hardly be said to be impoverished at all. In the raising of crops of cereals and other annual vegetables we meet with the reverse. In these crops we carry off both the fruit and the plant which produced it, or in other words the earth loses for ever all the nutritive substances absorbed by the action of the roots. Now, the vast percentage of the weight of an orange consists of water and hydrocarbons, and of a few nitrogen compounds which the tree receives directly or indirectly from the air. The small amount of phosphates and potash necessary for the formation of the fruit and the perfection of the orange pips is compensated by the stable manure which is supplied to the orange grove at regular intervals of six or eight years. The effect of a too liberal supply of stable manure on the orange grove is the production of exuberant foliage and large fruit with a thick peel. The fruit loses much of its aroma and becomes fibrous. On the contrary a soil very poor in nitrogen compounds produces tiny oranges delicious in flavour but unfit for commerce. The chemical manures which preferably should be supplied to the orange grove are the assimilable salts of phosphorous and potash. Already we see that the more experienced foreign cultivators are abandoning the use of nitrate of soda and have taken to use the superphosphates and "sulphate" of potassium in moderate quantities. To this chemical manure I prefer bone-dust and wood ashes, which are cheaper, less active, and have a more durable influence on the soil. Stable manure, particularly cow-manure, is an excellent compost for the orange grove, provided it is sufficiently rotten to prevent any undue fermentation when supplied to the soil. But as it contains a high percentage of nitrogen compounds, a liberal supply should be avoided to prevent the deterioration of the fruit."—*Agricultural Gazette of N. S. Wales.*

GASEOUS DIFFUSION.—Dr. Horace Brown, F.R.S., in the course of a lecture of the Royal Institution, said that:—

"The question how the minute quantities of carbonic acid in the air found their way into the leaves in sufficient quantity to nourish the plant had long been a matter of controversy; but it was now established that they entered wholly by way of the minute openings known as stomates. But this fact presented a further difficulty, since the aggregate area of these stomates, when expanded to their fullest, was less than 1 per cent. of the total leaf-surface, and the amount of carbonic acid taken in by the leaf was such that it must enter by these openings more than fifty times faster than it would if each of them were filled with a constantly renewed solution of strong caustic alkali. There appeared to be only one way out of the difficulty, and that was the assumption that the leaf knew more about the laws of free diffusion than we did. This was proved to be the case. If diffusion of gas were established down a cylinder of equal diameter from one end to the other, the rate, other things being the same, varied directly as the area of the cross-section of the cylinder. But if the cylinder were obstructed somewhere in the line of flow by a thin diaphragm pierced with a single circular hole, the acceleration of flow was inversely proportional to the diameters of the apertures—as the aperture was made smaller, the flow through a given unit of area was proportionately increased. Since the stomates corresponded to the latter case, it became easy to understand how, in spite of the small area of leaf they occupied, they could drink in the atmospheric carbonic acid with such rapidity; the leaf constituted a multiperforate septum, and the distance at which the stomates were arranged on the underside of most leaves was that which by experiment had been found the most economical arrangement of very small apertures in such a septum."—*Times.*—*Gardener's Chronicle.*

THE CUTIVATION AND USE OF SUN-FLOWER SEED.

The common sunflower, *Helianthus annuus*, is a native of Mexico and the northern portions of South America, and was probably first brought to Europe by the early Spanish expeditions to Peru and Santa Fe, since it was grown at Madrid in the sixteenth century. The plant has, therefore, long been known in most European countries as an ornamental shrub, but in Russia it has for many years been extensively cultivated as an economic product. In 1892, Mr.

Crawford, Consul-General for the United States at St. Petersburg, presented to his Government a report dealing in detail with the sunflower-seed agriculture of Russia, and this report aroused so much attention among farmers and others that the Agricultural Department of the United States has issued a bulletin on the subject for the guidance of farmers who propose to raise crops of this plant. The industry first began to assume importance in Russia about 1830, and since that time has steadily increased. The seed is the most useful portion of the plant, and this is commonly eaten raw or cooked, while the oil obtained from it is used as a substitute for almond and olive oils. The oil-cake left after the expression of the oil forms a valuable cattle food, being superior in this respect to maize or linseed cake, while it is also said to act as a natural "condition powder" for horses, owing to its easy digestibility and its great nutritive value. There is also a very prevalent opinion in America that the plant acts as a preventive of malaria in low-lying districts, which is probably founded on its capacity for absorbing water rapidly, and so improving swampy country. In America the seeds are at present mainly employed in feeding poultry, although they are also to some extent used as a cattle food. For the cultivation of the plant, it is stated that the best results are obtained by sowing the seed in April or May in a light soil, such as that which gives good results with Indian corn, liberal manuring being carried out, unless the land is very fertile. The number of seed heads to each plant should be limited, the superfluous ones being removed as they form. In harvesting the seeds, the heads are removed just before they are quite ripe, and the seeds obtained either by beating with a flail, or by holding ths heads againt a rotating disc studded with iron nails. The united States Agricultural Department bas collected a considerable amount of information regarding the composition of various parts of the plant, of which the following seleotions may be given, the composition of other better-known foods being added for comparison :—

Part of plant examined.	Where grown.	Water.	Ash.	Protein.	Fibre.	Carbohydrates.	Ether Extract (Oil).
Sunflower heads ...	Maine	84·0	1·16	2·18	4·21	5·96	2·49
Peas, whole plant ...	,,	86·1	1·12	2·59	4·51	5·29	·39
Sunflower heads ...	Canada	75·6	1·35	2·35	7·94	7·88	4·86
Sunflower stalks ...	,,	84·45	1·93	·96	5·67	6·12	·87
Sunflower seeds ...	Gardens of Agricultural Department	4·43	3·41	14·97	29·17	20·94	27·08
Black-eye peas	—	7·57	7·45	17·19	30·0	35·18	2·61

It will be seen that the plant possesses a high content of nutritious constituents, and since it is easily grown it should becomc an article of more general cultivation. It appears that no sunflower oil is made in America, several attempts to express the oil having given very poor yields in the hands of oil makers. It is now pointed out that the poor yield is due to the great absorptive power of the seed husks, which should be carefully removed before the expression of the oil is attemptod.—*Imperial Institute Journal.*

FERTILIZING ORANGE TREES

First of all, in growing oranges, we must remember we are not treating our orange trees in their natural condition, as forest trees. They are entirely artificial, and we are trying to improve upon nature as far as fruit and flower are concerned, though at present, in this Colony, the fruit is our only consideration. The orange fruit is made up roughly as follows:—

Potash	.. ..	36½ per cent.
Soda	... ..	11½ ,,
Lime	.. ..	24½ ,,
Phosphoric Acid	..	11 ,,

Magnesia peroxide of iron, sulphuric acid and silica comprising the remainder.

The tree is:—		
Potash	..	11 per cent
Lime	...	55 ,,
Phosphoric Acid		17 ,,

The rest in small quantities.

Frnit and tree together thus give :—

Potash	.. ..	47½
Lime	.. ..	79½
Phosphoric Acid	...	28
Soda	.. ...	11½

These chemical elements are extracted from the soil and what is contained in the frnit actually taken away. For instance, suppose the average orange weighs 4oz., a dozen weigh 3lbs. and 250 dozen or 3,000 oranges 6¼ cwt. A full bearing orange tree removes of absolute soil or soil elements, which must be in some way be restored, 2½ lbs., and taking 70 trees to the acre nearly two cwt. per acre. Now it appears that nearly the ha f of this in the case of the fruit is potash, the other half lime and phosphoric acid; and as potash is not supplied to the soil by water or the atmosphere, like some other essential elements, but exists in the soil in varying quantities, and is every year being used up, therefore, as you cannot have the pie after you have eaten it, you must in some form return the potash to the ground, and the moral is, when you throw away your wood ashes, throw them away around your fruit trees. But here comes the rnb. How are you to determine, short of analysis of your soil, whether any essential element is wanting or in insufficient quantity? One, and one hint only, have I come across by which you may be able to judge of an insufficiency of potash by the appearance and growth of the tree, and that is an excessive growth of weak, immature, angular wood, which does not harden up. The effect of nitrogenous farm manure is to cause tree growth at the expense of fruit. This is desirable while the trees are young, but, if continued, large fruit will result, bad in colour and very thick in rind and rag, and the evidence of a sufficiency of nitrogen in the soil is the beautiful dark green colour of the foliage; inclining to yellow is an indication of its supply failing.

Some rough and ready method is badly needed to enable farmers to supplement their observations as to quality and constituents of their soils. It is not enough to say the soil is deep and rich and only requires moisture. It may be lacking in one essential element, and one general lack in deep flat lands here is lime. Remember the ash of the orange trees shows 55 per cent. of lime, and one rough and ready method to find if your soil is deficient in lime is to pour a little muriatic acid upon it. If it bubbles, lime is present, and you can guess pretty near how much, if you mix lime in the testing soil, say half and half, and notice how much it bubbles, then try less and less till you come to the pure soil, which will bubble very little and yet may be sufficient for a fertile soil, but not enough to grow oranges successfully in.

I find the orange groves, counting their existence by centuries, such as in Spain are on dry situations well drained to carry off superfluous moisture. Strange also to say, shelter belts were not anciently

kuown in the Azores, the groves being allowed a free circulation of air, light and sun, very little cultivation was done and no manuring, but the drainage being neglected abont 1846, the trees began to show signs of foot rot which affected old trees and younger seedliugs alike. It was arrested by cutting down affected parts to sound wood and then treating them as previously mentioned. When they began to recover, manuring, alteration and planting large shelter trees was resorted to, with the result that they iucreased the quantity at the expense of the quality, and while they previously were able to send their oranges to Norway and Russia they wonld afterwards barely keep sound landed in England. This decided them to resort to old methods again. They cut down the high dense shelter trees and planted thin ones and not too high, pruned the trees to let in air and practised less manuring, with the result that the groves are improving.

The fact is, only broad principles can be given the individual to guide him, and these are somewhat approximate. The only true gnide is to learn from the tree itself by intelligent observation. Watch it as you would your child. The strongest and healthiest are those which are coddled least and astonish you with the amount of flesh and bone-forming food they can eat, but it must be wholesome. Our orange groves are not in qnite snch a natural condition, but they are equally under our control, only requiring of us an intelligent knowledge of their artificial condition.

For instance, we can stimulate and determine the character of our fruit by the kind of fertilizer we use, and as this is what we are mainly concerned in I offer you a few suggestions on the authority of Mr. H. J. Webber of the U.S.A. Agrioultural Bureau.

Realizing, then, that the character of fruit we aim at is size, with thinness of rind, and minimum of rag, he says, to promote this, use nitrogenous manure from inorganic sources, viz., chemical manure containing nitrogen in moderate qnantity with considerable potash and lime.

Sulphate of ammonia, a compound of nitrogen used in considerable abundance, and diminishing the potash will produce sweetness.

To render the fruit more acid use plenty of potash and juices mixed with farm manure rich in nitrogen.

A heavy dressing of nitrogen from organic sources will increase size and may be of service where the tangerine is coucerned, but remember the caution previously given as to "indigestion."

One word of caution as to chemical fertilizers. Personally, I would refnse to use any one unless a complete analysis was supplied and guaranteed with each consignment. It stands to reason that any particular fertilizer will not be equally good or desirable for every varying class of fruit or vegetable, much less may it be suitable for every variety of soil, and it may be that a particular soil would be benefited more by a particular manure at £5 per ton than one at £10 per ton.

Moisture conditions will probably differ in every case, and in face of protracted droughts it is well to know that chemical manures have the quality of preserving surface moisture and drawing moisture from below.

A finely pulverized yet compact condition of the soil when dry under and around the trees is a strong preservative of moisture, and on this condition solely depends the growth and productiveness of our orange trees and the ability of the roots to draw the necessary sustenance.

A concluding word as to irrigation of orange trees. It has been said that watering round the trunk of the tree is a fruitful source of the disease known as foot rot. My observation and study lead me to conclude it is more the result of improper manuring and cultivation and bad drainage. I know of groves in healthy full bearing where it would be a waste of time to try and teach the owners any new ideas or methods. The only mode of watering they understand is to make a miniature dam round the trunk, cutting all the surface rootlets in the operation, and then filling the dam with water. They have been practising this for years and yet the trees are healthy and profitable. I have often thought if I could apply my irrigation from overhead it would be more natural. What then should I witness! I have stood under one of my large trees during a heavy rain and observed how every twig and branch formed a channel to conduct the rain to the trunk, and while the root of the soil was watered by the drop from the leaves, a full stream was running down the trunk directly into the soil, and even in a light rain you will observe that all trees, however small or large, are wet round the trunks while all the rest is comparatively dry. I also observed that the millions of rootlets all over the surface covered by a large tree are near the surface quite healthy, and are ready to contribute their share to the maiutenance of the tree if only they get their share of moistnre and food, and I say again if I could devise a scheme for overhead irrigation I would prefer it in the absence of raiu. I do not recommend making a dam rouud the trnnk, but prefer runniug a furrow round the outside circumference, trusting the moisture will rise to the rootlets under the tree, and to ensure this I would discard organic manures altogether, and use chemical fertilizers: and though these latter days demand science with practice, yet one cannot help longing for the good old times when there was very little practice and much less science, and the groves were handed dowu from generation to generation. There is a great futnre in front of citrus growers not alone for the fruit, but for the production of flowers for perfume and essentials oils, and an abundant field before the intelligent energetic cultivator, and I see no reason why we should not prove powerful rivals to France and Italy in the perfume industry, and Spain, Portugal, Azores with our fruit. If we cannot do it, we can least begin on souud principles, and our orange groves, the noblest and most generous responder to our intelligence, will still remain for our children's children to carry on to our own credit and a blessing to our country.—"*Cape Agricultural Journal.*"

REPORT ON A VISIT TO THE AFRICAN LAKES CORPORATION'S GARDENS AT BLANTYRE,

AND SOME COFFEE ESTATES AT MLANJE WITH BRIEF REMARKS ON A COCOA TREE GROWING AT MR. MOIR'S LAUDERDALE ESTATE MLANJE.

At the request of Lieut-Colonel Manning, H.M. Aoting Commissioner & Consul-General, I visited Blantyre and Mlanje recently to ascertain whether oocoa or any other economic products, not represented in the Botanic Garden at Zomba, was growing at Mandala, and to observe the condition of the theobroma cacao tree growing at Mlanje, and also to repor on some of the coffee estates on the south and south western slopes of Mlanje mountain.

From the lists of plauts sent out from Kew to the African Lakes Corporation, in 1886, 1892, and 1894, it is seen that cocoa was sent out, as also to the Liviugstonia Mission.

Although there are a considerable number of introductions growing at Mandala, their identity, uuless specially kuown to the observer, is a matter of conjectnre, as all trace of their labels is gone. The majority of the fruit trees now in British Central Africa are represented in these gardens, such as apples,

oranges, lemons, limes, loquats, guavas, peaches, nectarines and figs, as also an avocada pear tree, although this latter is not in good health. Grevilleas, encalypti, coniferæ, ficus elastica and cotton trees *(eriodendron)* are all represented, and amongst these I noticed some rubber trees of about 15 to 20 feet high, which are probably *hevea spruceana* (Guiana rubber), six of which were sent out by the Kew authorities in 1886. A fair amount of milk might be extracted from these, and the yield of rubber is good. Few rare or unknown introductions were noticable, nor did I meet with either cocoa or coca *(erythroxylon.)*

The theobroma cacao at Mr. Moir's was next visited. Its general appearance is good : leaves large and a rich green, denoting active growth. It is in the form of a standard, branches commencing about 1½ feet from the ground. Side leader shoots have evidently been made a year ago and grown about 2½ feet, after which the point has been nipped as if by drought. Side leader shoots are now growing strongly. The tree was flowering when I saw it and had one fruit set; the other flowers were nearly out. The situation is somewhat exposed to strong south-east winds and a grass wind-break has been erected recently, close by, for its protection.

Eucalyptus trees are growing alongside it, and shield it from the morning sun, but it is otherwise exposed to the afternoon sun. Were it the reverse, I have no doubt but that it would be more to its advantage. As this tree is now over eighty years old, it may be considered to be a failure, as it has only grown some five or six feet in that time ; had it been in a more suitable and agreeable situation, I think it would have been a distinct success, and evidences may be adduced to show that cocoa cultivation may with confidence be taken up by the planting community. As the subject will form a special report, and be issued by this Department in connection with a recent treatise on cocoa, it is unnecessary for me to say anything more on it at present.

Regarding the importation of seed and the difficulty of transporting it from home in a satisfactory condition for growing, steps will be taken by this Department to have a quantity sent out, packed in a special manner. When these seeds arrive and are established here, arrangements will be made for their distribution as H.M. Commissioner may direct.

Some fine specimens of *cyphomandra betacea*, (tree tomato) were noticed, their clusters of fruit hanging in large numbers and evidently grown under the best conditions. Oranges, loquats, and lemons are abundant, and three mulberry trees seem to luxuriate in the rich black soil.

Tea seems to do well here also. The bushes show good growth, and a very palatable tea is made entirely, by natives, who were, I understand, instructed by Mrs. Moir. Tea has been largely planted throughout the upper part of the estate and, were more attention given to the preparation of the leaves, no doubt a tea of good class would be the result.

The coffee, with the exception of a small patch on a little hillock, is not in bearing ; much of it has been cut back, and much more requires this same operation. This operation, however, should be followed up by planting with young plants between the lines and removing the old roots after the crop is taken off. Since tea does so well, more attention should be given to this product at this plantation than coffee, for the soil being too much subjected to torrential rains gets washed away, leaving many of the coffee roots exposed, and, as a result, weakly coffee trees.

Leaving Lauderdale and proceeding round the south-eastern part of Mlanje, one passes over good roads where several streams are met with, bridged by wire-rope suspension bridges ; the country becomes densely wooded, and what might be considered ideal cacao land, temperature, rainfall and soil all being what is considered necessary for this product.

Situated in the midst of this dense forest and well watered country is the Nyasaland Co's Luchenya coffee estate of about 600 acres. A small crop is on some of the trees, but it is doubtful if there will be a satisfactory crop, as weeds have apparently got the upper hand (owing to the scarcity of labour) from which condition there can be no doubt the coffee will severly suffer.

Other estates in this neighbourhood are looking fairly satisfactory and, where the weeds have been kept in check, promise well.

Mr. Brown's interesting estate at Thornwood was next visited. On first looking at the coffee, it is difficult to believe that such good results could be arrived at from the dense shade under which the coffee is grown. Very few of the original forest trees have been removed, and as the forest is thick the shade is dense. It is remarkable to find, under these conditions in B. C. Africa, coffee trees of three years of age in such a promising condition.

The first blossom was, I am told, exceptionally fine and set well but, during the dry season of last year, following on the blossom, thrips infested the whole estate and almost destroyed what would have been a heavy crop. A curious instance of how ants have been of assistance in combating the thrips, and saving parts of the estate from damage, occurs here. On several patches throughout the plantation are colonies of reddish-yellow ants, probably "formica bispinosa," which live on the trees, making their nests by using some cotton-like material with which they fix together several coffee leaves in the form of a cocoon. On these trees the ants are numerous, and do not fail to attack any small insects which come in their way. It was evident they kept these trees clear of thrips and thereby saved part of the crop from the pest which infested the plantation and completely destroyed the crop on the trees where no ants existed. The soil at Thornwood is deep, of a rich reddish chocolate colour, apparently suited to the cultivation of tea which is also grown here. There is about six acres under cultivation and doing well : the older bushes are vigorous and very promising in appearance. Chillies are largely cultivated amongst the coffee and yield a good return, fetching frequently 40*s.* to 50*s.* and over, per cwt.

Tobacco is being grown in considerable quantities for local and South African markets, where B.C.A. tobacco is in great demand.

While going through the coffee gardens, I observed a few rusty spots on some of the leaves of a fungoid nature.

Examination shows that it is black rot, known in India as *pellicularia koterega*. It is a fungus affecting the leaves superficially and may be easily rubbed off with the thumb, but although it may not cause much damage, still it would be advisable that a few boys should be given this work to do before it spreads much more. The end of the wet season is approaching, and the time for fungus pests to disappear before the dry season, but attention should be given before it to be too late. It was only met with in a very few instances.

Mr. Bradshaw's Lujeri estate of about 400 acres, compared with Thornwood, presents an entirely different appearance. It is situated at an elevation of from 2,809 to 3,300 feet approximately, on the immediate slopes of south Mlanje. It is sheltered by ridges of hills to the west, by the high peaks of Mlanje to the north and east, and open to the south only. The soil is of a very deep nature, easily penetrated by a stick for about four feet on any part and composed of rich vegetable mould, and has undoubtedly accumulated for centuries past.

Huge timber is met with all over the estate, and where coffee has been planted nearly all trees have been cleared away; those that remain exhibit injurious effects on the coffee bushes underneath, and it would certainly be better if they were all removed. I felt that, at this elevation, the atmosphere was entirely different to that at Thornwood, and had in it the "nip" which is felt when one

ascends through different strata of tne atmosphere. Not only is it felt, but, from the robust healthy appearauce of the two-year-old coffee, one sees that the growth does not rush up so quickly as is usually the case at lower elevation. It presents a remarkably healthy appearence, and the few stray berries that were fonnd were seen to be of sound quality and no sign of light berry or any disease.

Of insect pests, very few need be feared at this elevation, and it is evident that neither borer nor bug visits this coffee.

A few red spots were observed on some of the leaves in which was found the coffee-leaf miner *cemiostamâ coffeellum*. It is remarkable that at about 3.300 ft altitude the best plants were observed, showing good sound healthy growth and giving great promise. As an experiment the owner had six two-year-old trees brought up from his lower plantation at Bloomfield and planted at about 3,000 ft. altitnde and now these trees show a heavy crop of clean berries, and all the six trees in good growth, whereas at the lower elevation plantation the coffee has not been a success. Aceording to a list of altitudes fixed by Mr. Lloyd, late Government Surveyor, tbe plantations of Bloomfisld and Thornwood are at about 2,200 to 2500 feet, so it would seem that, at the lower elevation of this part of Mlanje, where high temperatures are obtained and heavy rainfall predominates, dense shade is necessary but at the higher situations shade may be dispensed with altogether. The temperature is cooler and the rainfall, although quite as much as at 2,000 ft., does uot seem to be of such a torrential nature, as the soil does not exhibit much wash.

Tobacco and tea should do very well here, and for cocoa a more ideal situation could not be found. It is heavily forested country, well watered by numerous streams, and the soil is of that nature where cocoa would lxuriate, and with such conditions an even humidity would be maintained throngbout the year. The temperature for one year, I believe, did not go lower than 48° Faht. nor higher than 91° Faht. The rainfall at this part of Mlanje is large, and seems to culminate at Lauderdale, where the highest rainfalls are recorded.

The phenomenon apparently commences beyond the Ruo stream where the first peaks of Mlanje meet the south-east winds, and increases in volume till Lauderdale is reached, and from there round to the northern slopes at Lukulesi it diminishes rapidly, beginning at probably 60 inches at the Portuguese Fort and reaching 130 inches at the Luchenga and Lauderdale estates, diminishing from that to about 50 inches at Lukulesi, a fact which is indicated on comparing the heavily-forested country at the Ruo to the sparsely-covered country at the Lukulesi.

Although I did not visit Lukulesi and cannot say anything about its present condition, it is still significant tbat with such a small rainfall this estate has given heavy crops for some years, and shade is not extensively adopted.

Mr. Simpson's Ntundulima estate was visited, and I found that he had partially given up coffee and was directing his attention to the cultivation of chillics. He has also planted out a lot of ceara rubber trees. His fine orange and mango trees are objects of admiration, and from these he gets good crops.

On arriving at Blantyre I proceeded to Soche to observe a reported fungoid disease. On going over the estate with Mr. Inglis, I fouud that much of what had been affected had long since been cut away, and it was only a small patch of coffee which I observed showed any sign of injury.

A few of the shoots exhibited signs of the bark having been removed at the base or junction to the maiu stem. The wound appeared old and cankered, and the wood dry, while the shoot itself, although not dead, appeared unhealthy and somewhat swollen, from the fact that the sap therein could not return to the main stem because of the wound. It is probable that canker was the cause of the injury, but some of the shoots exhibited signs of having been eaten. The iujury, however, is comparatively slight and not likely to canse any considerable loss; to remedy it, ascertain if there is sufficient depth of soil where it, has occurred, and if not it will be advisable not to plant cffee on that part of the estate.

Lunzu and Chipande estates look clean, aud promise fair crops.

J. Mc. CLOUNIE,
Head of the Scientific Department.

SELANGOR PLANTERS' ASSOCIATION.

ANNUAL REPORT FOR 1900.

At the end of the year under review, the cultivated area accordiug to all the returns that could be obtained, and estimating the area of estates from which no returns could be obtained, is less by 473 acres than that of the previous year, and on the back of this report is a statement showing how these figures are arrived at.

PLANTING PRODUCTS.—(*a*) *Coffee.*—Prices ruling during the year have shown a distinct improvement ovsr those of last year and are as follows: January $20 per pikul, February $22, March $22.50, April $21, May $20.25, June $22, July $22.50, August $22, September $21.25, October $19, November $19, and December $19: an average of $20 89 per pikul, or $3·69 higher than the average for last year. Prices were firmer at the comencement of the year; but, towards the end, prices were dull aud the markst still remains so. The low prices, although better than those obtained last year, have necessitated the strictest ecouomy on all estates. Under these circumstances your Committee consider that it is a matter for congratulatiou that estates are looking so remarkably well, and that the planters are showing such determination to do everything in their power to tide over the present crisis.

The attempt to improve the quality of our coffee, commenced in 1899, has been continued during 1900, and it can safely be said that the sample generally is better than it ever before was. During the year five samples of sun-dried and machine-dried coffee were sent to a London Broker by the Committee of the Uuited Planters' Association for report and valuation, with the resnlt that such samples were favourably reported on, aud showed a considerable improvement in value on the Singapore prices for similar samples, aud your Committee have followed up the action of the Uuited Planters' Association iu obtaining promises of contributions from estates in Selangor to form regular monthly shipments to London: and we trust that this may lead to something substantial being done towards shipping our produce direct to European markets. To show that it is realised how important it is that the quality of our coffee be raised to the highest standard possible, the fact may be mentioned that three patent driers have been added to those already in use in the statc.

Your Committee cousider the above references to Brazil estates regarding mannre and casc of Ceylon sufficient to stimulate you in contiuuing to keep your youug and vigorous coffee in as good order as your finances will allow of, for we are in hopes that the days are comiug, and perhaps not far off, when large crops will mean large profits.

Para Rubber.—During the year the cultivation of this produot has increased considerably, 1,146,870 seeds having been imported or obtained from local sources, all of which have been planted out in the field or in nurseries. It is to be regretted that seed imported from Ceylon germinated exceedingly badly; but, as hitherto, we are indebted to Ceylon for a large percentage of the rubber now flourishing in Selangor, we hope this will not occur again. Local seed gave an outturn of at least 75 per cent.

Termites still continue to be the worst pest which cultivators of Para rubber have to deal with but these have been, more or less, kept in check by various remedies.

Bambong.—The planting of Ficus elastica has occupied the attention of planters much more this past year than hitherto, 52,147 trees having been planted out. A sample sent by the Superintendent of Forests, Perak, to London was valued at 3*s.* 6*d.* per pound, and sold at 3*s* 10*d.* per pound.

For further information your Committee refer you to the minutes of a general meeting, held on 5th January, which have been placed before you. The year shows that Gutta rambong is likely to occupy the attention of planters more in the future than it has done hitherto, for, although the largest operations are being carried on with Para, there seems to be a tendency to extend the cultivation of Ficus elastica.

Coconuts.—An area of about 500 acres has been planted during the past year, altogether 1,504 acres are planted with this product, all of which is reported to be doing well and promise, especially in the coast districts, to bear fruit at an early age; there are trees in the Klang districts which have started blossoming at the age of three years and three months from date of planting, or three and a half years from seed. The Government have been, and are still, doing their best to check the ravages of beetle and it is hoped in time, with the co-operation of planters, that this pest will be brought within such bounds that its presence will not be a serious drawback to the cultivation.

Ramie.—One estate is carrying on the cultivation of ramie in a praiseworthy way, and we wish this estate all success.

MINOR PRODUCTS.—The planting of catch crops has not been neglected in the past year, the largest operation in this line being chiefly in the coast districts. Your Committee are in hopes that the Superintendent of Experimental Gardens will be able to find out some paying catch-crops to plant with rubber.

LABOUR.—During the year under review, the number of coolies of all races employed by members of the Association shoows an increase of 181 over the year before, judging from all the returns that could be obtained, and estimating the amount of labour on estates from which no returns could be obtained (see statement on back of report.) Labour has been easily obtainable in sufficient quantities, and the full number of tickets agreed to be issued by the British India Steam Navigation Company at the cheap rate under agreement made with the Government of the Federated Malay States—viz., 6,000—were taken up, either by Government or other employers of labour.

Some considerable trouble has been experienced by planters by the action of the Agent for the Government at Negapatam towards kanganies and coolies, but on representation of facts to the Government a reply was received that the officer in question was being discharged and a new one appointed. Dr. Foston took up the duties of Agent for the Government of the Straits Settlements and the F.M.S. at a recent date. The British India Steam Navigation Company still continue the issue of cheap tickets, pending a new agreement being made with the Government of the F.M.S., the old one having expired. Some correspondence took place between the Association and the Government with reference to the arrangements for running a direct line of steamers between India and Kuala Klang; but up to the present nothing definite in that direction has been done. In connection with the question of labour imported from India and elsewhere, it may be mentioned that the Government has decided to erect a quarantine camp, and have chosen a suitable site for same. When this scheme has been carried out, coolies who arrive in the State, should there be a case of any infectious or contagious disease on board, will be landed at the camp. Formerly they were not allowed to land and this was a source of extra trouble and expense to employers.

EXPERIMENTAL GARDENS.—The Government of the F.M.S., have appointed a Superintendent of Experimental Gardens, and your Committee are in hope that he will as soon as possible make experiments in tapping rubber trees of different ages, and different kinds, and be able to give us some trustworthy information as to what yield we may expect from the different kinds of rubber; also that the Government will supply him with a Biffen separator which may prove of some use to him. We are also in hopes that Mr Stanley Arden will devote a good deal of his attention to hybrid coffee, and that he will be able to instruct us in the best methods of destroying and keeping pests in check.

As the planting of rubber has to some extent taken place in the attention of planters, a good deal of his time should be devoted to gathering and giving information on every branch of that cultivation, and his services in that direction will be most useful.—*Selangor Planters' Association.*

TEA-GROWING IN SOUTH RUSSIA.

The following report of H.M. Consul at Batoum on the tea industry in the Caucasus, published in the "Board of Trade Journal," will be read with interest and satisfaction by those concerned in the production of British-grown tea:—

"The progress made with the cultivation of tea along the south-east coast of the Black Sea is but slow. The opinion held by many is that this industry cannot possibly assume any very great proportions for a considerable number of years. With the exception of the Imperial Domains and the firm of Popoffs of Moscow, no other tea-planters of any importance have shown any inclination to come forward and follow the example of the pioneers mentioned above, by purchasing land near Batoum, or along the coast for this purpose, and in reality the results obtained up to the present are not of such a nature as to inspire would-be tea growers with the confidence which is necessary to induce people to place their capital in enterprises of this kind. The Imperial Domain authorities are, nevertheless, extending the area of land under the cultivation of tea, within the limits of their estates, and are also endeavouring to encourage their neighbouring small landholders to embark in the industry by giving them seed to sow and seedlings from their nurseries to plant out.

"The firm of Popoffs, which has three extensive plantations under tea in the vicinity of Batoum, after spending large sums of money on these estates and also in setting up a tea factory, has evidently become wearied of the results attained in the eight years during which it has been engaged in the industry, and it is rumoured that the negociations with the Administration of the Imperial Domain Lands are in course of progress for the sale of these estates.

"The quality of the limited quantity of tea which has been manufactured locally, about 12 to 15 tons at the utmost, is nevertheless fairly good, except that the samples of tea, which I have had an opportunity of tasting, differ from the ordinary teas imported into Russia from China, in so far that they have a somewhat astringent taste. Samples of the tea grown here have been analysed, and the results of the analysis have proclaimed the tea to be of satisfactory quality, but I am not in a position to give the detailed particulars of the analysis. Samples of the tea sent to London, however, were very favourably reported on.

"The great question does not, however, lie in the quality of the tea, which, I dare say, can be brought up to a high grade by scientific and careful handling, seeing that the climatic conditions of the district in which the plantations are situated are all in favour of the culture of tea, but in the fact that a permanent scarcity of labour exists: the rate of wages paid is comparatively high, and this circumstance makes it most difficult to render the industry remunerative.

"The rate for unskilled labour is from 1s 6d to 2s per diem I believe an unheard of price in any tea-growing district." This speaks for itself, since it is a well-known fact that cheap labour is one of the primary conditions under which the advantangeous cultivation of tea can take place.

"I understand that the scientific agriculturist attached to the staff of the Imperial Domains at Chakva is preparing a work on the cultnre of the tea plant, the publication of which may have the effect of extending the cultivation of this plant among the more intelligent class of landowners along the Black Sea littoral of the South-Western Caucasus."

"RINGING" FRUIT TREES.

I have read Mr. Pandya's letter (which the Editor has kindly sent to me, together with his reply) in regard to the European Olive tree not fruiting in Kathiawar. I am of the same opinion as the Editor, and believe that some result may be obtained by root-pruning. I would, however, suggest, as an experiment, that "ringing" may also be tried in the case of a few trees, For the benefit of your amateur readers, I may state that the process of "ringing" consists in removing a ring of bark sufficiently deep to prevent the reunion of the separated portions during that season of growth. The ring so removed should take away both the outer and inner bark, leaving the pith, or cylinder fully exposed. The best time to perform the operation is when the cambium layer (inner bark) is in its greatest activity of growth. The effect of the removal of this bark is a violent interruption of the normal processes of circulation of the sap of the plant. The upward passage of fluids is only slightly affected, and is practically maintained as in the ordinary shoot. It is in the downward passage of the sap that the interruption takes place. The upper end of the shoot or stem beyond the ring becomes gorged with the elaborated food brought down from the leaves, which results in its aging unnaturally and becoming mature. Shoots so treated will develop ripe fruit much earlier than the rest of the tree. Strangulation by a ligature of wire or cord has the same result, namely, the interruption of the downward sap.

I must point out, however, that in practice it has been found that the produce of "ringed" plants, though larger and more developed than that from normal plants, is not of the same good quality. My plan, however, in several cases, has been to "ring" the main stem, or trunk, of the plant, with very gratifying results in the matter of fruiting. Trees which had never flowered or borne fruit, did so when subjected to "ringing."

There is, however, the secondary and more permanent result of ringing to be considered yet. From what has been already stated it will be easily understood that the operation benefits the upper part of the shoot at the expense of the other. The effect of starving the body of the plant must be taken into consideration. No plastic material is received from above; the region of active growth (the cambium layer) is starved, and as a consequence of the defective nutrition the buds on this lower portion are not likely to form flowers and fruit. Whatever advantages are to be had by this operation may perhaps, be attained equally as well by judicious root-pruning, and if so, certainly without the almost positive danger of loss of limbs. The liability of the ringed branch to break off must be remembered; if constriction by a ring of wire is adopted, this danger is somewhat reduced, and moreover the wire itself will ultimately be enveloped by the new growth and the condition of the tree becomes normal again.

PRACTICAL GARDENER.

THE CAMPHOR MONOPOLY.

The export of camphor rapidly decreased after the Japanese occupation, and it ceased entirely from June 22, 1899, when the Formosan Government-General issued an ordinance establishing a camphor and oamphor oil monopoly. Up to that date 855 cwts., valued at £2,979, were exported. There were no deliveries during the year to foreign merchants, who thus for the first time had no share in a business originated and entirely developed in South Formosa by themselves. The reason of this is that foreigners had already invested large sums in camphor, for which no return had been made, and that it had become too risky to invest further capital owing to the persistent interference and obstruction of local officials.

All the camphor produced in the island during the remainder of the year, from June 22 to December 31, was purchased by the Government-General, but none was exported until after March 24, 1900, when the monopoly of the export of camphor from the island was disposed of.

The Government-General reserves to itself the right of disposing of up to 5,000 piculs of camphor at the same price, as that paid by the purchasers of the monopoly, to buyers in Japan, for use in the country, and has also sold the monopoly of the camphor oil production of Formosa to a Japanese in the main island.

Taking the mean production of Formosan camphor to be 40,000 piculs a year, there is still available for use in Japan or export abroad, independently of the monopoly, camphor to the extent of about 18,000 piculs a year. The area of the camphor forests is vaguely computed at between 2,000,000 and 3,000,000 acres, but this is merely guess-work. The monopoly was established with the object of protecting the forests which, it was said, were being wantonly destroyed by wasteful cutting; but its effect will, probably, be to accelerate their destruction.

For the information of those interested in the camphor business, a translation of the Camphor Monopoly Tender Regulations, together with some particulars of the contract between the Formosan Government-General and the purchasers of the monopoly is appended to the report by the Consul.—*Sell's Intelligence.*

COFFEE ON THE CLARENCE—Many persons who have grown coffee in the South of Queensland have affirmed that it will only prove remunerative in certain favoured localities, such as the Buderim Mountain and parts of the Blaokall Range. Others go so far as to say that coffee cannot be profitably grown anywhere south of Mackay. The Clarence River is very far south of Brisbane, yet we learn from the *Farmer and Grazier* that Mr. John Ball, of Chatsworth Island, has been most successful with his coffee crop this year. His last crop returned 1,694 lb., whioh sold at 1s. to 1s. 3d. per lb. This year the crop is expected to amount to something like 6,000 lb. Mr. Ball has mastered the manufaoture of coffee of the highest quality, and finds a good demand for it. His trouble is to secure sufficient quantities of beans. In reply to inquiries made of Mr. Holmes, a planter in Fiji, Mr. Ball has been informed that, owing to unsatisfactory prices offering in Sydney for the Fijian bean, the growers there were abandoning coffee-growing. Mr. Holmes forwarded Mr. Ball some seeds of the Liberia coffee, which is a sturdy-growing tree with deep tap root, and which bears a larger berry than the ordinary Arabian variety. In Fiji, even at the extremely low prices (3d. to 5d. per lb.) paid for the beans, this variety returned 4s. 7d. per tree. Mr. Ball finds that he can pay 10d. a lb. for good beans. His harvesting is done by lads, who are able to earn 15s. a week at the work.—*The Queensland Agricultural Journal.*

RUBBER CULTIVATION.

SUMMARY.

I have not seen any published accounts on Hevea (excepting Brazilian) where as good results are obtained as in Malaya, either in rate of growth, seed production, dimensions, yield and adaptability.

India Rubber (*Ficus elastica*). A sample of 5½ lbs. was sent to London, with the Para parcel, for sale and opinion. It was reported on as "good clean Java character" and valued at 3*s.* 6*d.* per lb., but sold for 3*s.* 10*d.*

The largest tree at Kuala Kangsar is about 90 feet high, measures 88 feet at 3 feet from the ground, measuring round all the aerial roots, the branches extend to 36 paces, and the largest leaves are 13" x 7", its age, 19 years. The growth of this tree has been remarkable during the last three years, from the time its aerial roots reached the ground.

Ficus elastica is an indigenous tree, found in Upper Perak. It is naturally an epiplyte, and its growth would be no doubt assisted if planted at the bases of felled trees. Its growth is slow at first but rapid when well established. Considering the enormous dimensions this tree attains, 10 to the acre would be close enough planting, and as perhaps 8 years would have to elapse before the tree could be profitably tapped, the intervening spaces could be utilized by some other crop, even Bevea, which would be beneficial to the growth of the *Ficus*.

TAPPING.

As the latex of *Ficus elastica* coagulates on the tree it is best to tap on dry days only. From single incisions, about 4 inches long, and rather more apart, the latex slowly exudes, and in 2 or 3 days afterwards can be collected. At times the latex runs more freely and then some drops to the ground, this can be collected on plantain leaves, but the quality is not so good as that which coagulates on the tree. At Kuala Kangsar seeds ripen about October, the fruiting season being between July and October, and I should not think these the months for tapping. I consider December, January, and the following months best.

YIELD.

I have not any information as to the age when *Ficus elastica* could be profitably tapped. At Kuala Kangsar there are two trees 12 years old, and two 19 years old, from the latter 25 lbs. of rubber has been obtained from each tree, and the tapping was far short of being exhaustive. The result of the other trees has not yet been ascertained, but I expect good results.

Getah Singret (*Willughlina firma.*) A small sample was sent to London with the Para parcel, and reported on as "good strong Borneo character," valued and sold at 2*s.* 6*d.* per lb. This is the best of the indigenous creepers, but I doubt very much if it ordinarily reaches the European market in a pure state, being usually used to adulterate getah percha.

Getah Taban Sutra (*Dichopsis gutta var*). There is one example of this tree in the Kuala Kangsar garden which is said to be 17 years old, and fruited for the first time in November, 1900. A few herbarium specimens were obtained, all the other fruits being carried off by squirrels before being ripe. The height of this tree is 25 feet, and girth 2 feet at 3 feet from the ground, a jungle tree growing under heavy canopy would of course be much higher, with less branching habit, and smaller girth.

Getah Percha (*Dichopsis Polyantha*). A variety of getah percha which grows from near the foot of Larut hill to 3,000 feet. A mountain form which may prove valuable for planting on high land. None, however, were observed in fruit, and it is probable that with this tree, as with many indigenous trees, a fruiting season only occurs every few years. Seedlings are abundant, but the smallest seem two years old.—R. DERRY.

PLANTING NOTES.

SUGAR IN HAWAII.—Regarding the possibilities of the cultivation of sugar cane in the Hawaiian Islands, Prof. Stubbs said the soil was the best in the world for the cultivation of cane, being superior to that of Cuba. The yield on the arid and irrigated lands of the islands is from eight to fifteen tons of sugar per acre, while in Louisiana the yield is about 1½ tons per acre. But about all the available lands having been taken up in the cultivation of cane already, the increase of production cannot far exceed the present output. The total value of the agricultural produce of the islands is $20,000,000 of which $17,500,000 is to be credited to sugar. Thus it will be seen that the islands have already reached, or nearly reached, the limit of yield. The drawbacks to the cultivation of cane in these particularly favored islands are the high price of coal—which reaches as high as $12 per ton—the cost of irrigation, and the great cost of sugar house plant. Nevertheless, the profits are so large as to practically preclude the cultivation of any crop but cane.—*Louisiana Sugar Planters' Journal.*

ZANZIBAR PRODUCE.—Mr R N Lyne, Director of Agriculture at Zanzibar, in his annual report for 1899, just issued, states that the cultivation of vanilla is increasing, and that three thousand vines are now planted out. No further expenditure has been incurred in experimenting with chillies, as they do not pay to cultivate in Zanzibar, except for the native, to whom time is no object. Their growth is uncertain, the crops light, and the collection of the crop expensive. The year was a very bad one for cloves, the general crop of the island being, if anything, slightly less. Rubber, tea and cocoa are also dealt with in the report, which, however, lacks interest owing to its stale information.—*Chemist and Druggist*, May 11.

INDIAN AND CEYLON TEA SHARES VALUES: RECOVERY BEGINNING AFTER A STEADY DECLINE.—In view of the smart drop which recently took place in many of these shares, the following figures, compiled by Mr. George Seton, of 120, Bishopsgate-street, E.C., should prove of interest. Recent figures, it will be seen, show that the values of the shares of 45 of the leading companies dropped to nearly the lowest point at the commencement of the month of April. There has been a slight recovery since, but the figures will not be again compiled until 1st prox.

Face value of 45 companies		£9,000,000
Market value	1st January, 1900 ...	9,500,000
Do	1st July, 1900 ...	8,900,000
Do	1st January, 1901 ...	8,550,000
Do	1st February, 1901...	7,950,000
Do	1st March, 1901 ...	7,450,000
Do	1st April, 1901 ...	7,500,000

The tendency, for the moment, is towards rather higher values, but in view of the unfavourable results for 1900 that are expected to be shown in many of the annual reports, some reaction may, not unlikely, again occur.

COFFEE UNDER SHADE.

In support of what our correspondent in Nyasaland says of the success of coffee under shade, it is cheering to have the following report from a well-known Passara planter: —"If only men had planted coffee under judicious shade, we should not have been bothered in Uva very much by Tea Over-production. I have coffee growing here as vigorously under shade as it was a quarter of a century ago." This is probably on or near to Mr. C. B Smith s estate of · Mousagalla, the first clearing on which we saw burned off by old Thomas Wood in 1865! The soil and lay of land were all that could be desired. Pity there are no suitable reserves on which to try coffee under judicious shade now.

REVIEW OF THE INDIAN TEA TRADE FOR 1900-1901.

FROM MORAN & CO.'S MARKET REPORT.

Calcutta, April 18.—The main feature of the crop, especially towards the end of the season, has been the undue proportion of poor tea made from rough coarsely plucked leaf; this style of plucking had the effect naturally of largely increasing the out-turn; and the very poor tea thus made not being in demand, has sold at very low rates. Much of this class was no better than common China tea in cup and vastly inferior in appearance. The extra weight forced on the trade tended to lower prices generally.

The average prices realised for the crop for the last season and the previous, including all tea sold in Calcutta and London from 1st June to end of March by public auction, are as follows :—

	TEA OF SEASON. 1900. Pkgs.	Av. As.	P.	1899. Pkgs.	Av. As.	P.
Assam ..	709,500	7	0	644,500	7	7
Cachar and Sylhet ..	564,000	4	7	585,000	5	6
Darjeeling ..	122,000	8	2	113,000	8	9
Dooars ..	304,000	4	9	273,000	5	11
Terai ..	56,000	4	5	52,000	5	5
Chittagong ..	15,000	5	0	14,000	5	10
Chota Nagpore ..	4 500	3	11	5,000	4	10
Kangra Valley &..	13,500	4	7	17,000	5	6
Packages	1,779,500	5	10	1,703,500	6	7

The estimate of the crop, based on the quantity made to 16th August, was published by the Indian Tea Association early in September, and it appeared from returns then available that the out-turn would be about one hundred and eighty-two millions pounds. The actual amount proved to be one hundred and eighty-seven and a half millions. Of this increase, Assam contributed about one and a half millions, the Dooars about two millions, and the Terai about one million, the other districts being much as estimated. The distribution has been as follows :—

	1900.	1899.
Great Britain	..160,440,589	149,374,164
Foreign Europe	.. 1,779,904	1,435,146
America	.. 4,529,604	5,923,404
Asia	.. 7,332,289	5,492,815
Australia	.. 10,102,292	8,250,436
	184,184,678	170,475,965

GREAT BRITAIN.—The heavy increase in the quantity shipped proved to be far in excess of requirements, and in consequence the market there gave way, and the lowest prices ever known have been recorded. This, however, has not been altogether caused by the increased imports, but to a great extent by the upsetting of the market, caused by the uncertainty about the duty, and the expectation that it would be raised 2d a pound in the coming budget. Latterly this difficulty appears to have been overcome, and it seems now probable that the tax will remain as before; in consequence, the Home market is higher for all good quality teas, in fact, for all but undesirable common kinds.

FOREIGN EUROPE.—The shipments from here have not increased to the extent that we hoped to see, but it is not that demand for our teas has declined, but buyers have been able of late to fill their orders more cheaply in London than in Calcutta, even after taking into account the heavy London Dock charges and the extra freight from London.

AMERICA.—Direct shipments have fallen off, probably for the same reason as above; in fact, it seems certain that it is so, as exports from London both to America and the Continent have very largely increased during the last few months.

ASIA.—The enlargement of the trade is very satisfactory, and there seems a certainty of a still larger demand this coming season. New orders are constantly coming into the market, and there are many enquiries from new places for samples and prices.

AUSTRALIA.—Also shows a large increase, and it is satisfactory to learn that many shipments are giving remunerative returns. The low prices at which Indian tea was selling have certainly been of some advantage here, and will evidently bear fruit in increasing the consumption.

RUSSIA.—We are glad to report that exports to this country are increasing, notwithstanding the great advantages enjoyed by Ceylon in the facilities afforded to those who ship by the Volunteer fleet.

From the above analysis of the Exports, it is, we venture to think, undeniable that London is oversupplied, and the other markets stinted. Our prices for kinds suitable for "outside" places have, owing to shortness of supplies, been run up to as much as 1½d per pound over London rates; in fact our market has paid as many annas as pence have been realised in London, with actual loss to gardens of the amount paid for freight and dock charges, besides interest. The heavy competition here for these classes, and their consequent high price, renders it difficult to fill orders: if there were sufficient supplies, and prices a little lower, the export to all these outlets would enormously increase.

LOCAL CONSUMPTION.—The difference between the crop and the shipments is about 3½ millions. This, we take it, must be held to represent the quantity consumed in this country, and it seems absolutely ridiculous that among such an enormous population so little should be used. There is no doubt in our opinion that there is a very large opening in this country for the disposal of a considerable proportion of the crop, and with the facilities now about to be afforded to the inhabitants of India to procure good sound tea, by the Indian Tea Association, there should be a far larger quantity consumed in the country next year;

GREEN TEA.—The Indian Tea Association in their endeavours to relieve the industry of the heavy surplus over consumption of our ordinary teas are offering a bonus for the manufacture of green tea. This description of tea can well be made in this country, and could be relied on as uncoloured and unadulterated, and, we think, there is a good remunerative outlet for it in America, where, we understand, such green tea would be taken freely. The quantity of green tea shipped to America from China is rather over 14 millions a year; surely some of this might well come from India. Some Indian greens made in Kangra Valley have met with a good reception in that market. Some 35 to 40 millions of tea goes also from Japan, and some of this, we do not know how much, is green.

For the coming season, we recommend most strongly the greatest attention to quality of cup, in all districts and gardens where strength or flavour can be expected; if leaf is good so much the better. For other places not so favoured as to soil and climate, we say, pay particular attention to leaf; if the liquor is good, too, so much the better; but the chief outlet and best market for these teas is the "outside" markets where well-made tippy leaf is wanted, and the liquor is of secondary importance. But avoid as much as possible sending down rough, coarsely-plucked, half-rolled leaf with no liquor to speak of; such tea is not in demand in any market, and only helps to lower prices all round.

TOTAL EXPORT OF SEASON.

Amounts passed through Calcutta from 1st April to 31st March:—

	1900-1901.	1899-1900.	1898-99.
Great Britain	160,440,589	149,374,164	135,381,722
Foreign Europe	1,779,904	1,435,146	1,171,146
America	4,529 604	5,923,404	3,273,096
Asia	7,332,289	5,492,815	6,972,251
Australia	10,102,292	8,250,436	6,398,002
	184,184,678	170,475,965	153,196,217

IDENTIFICATION OF VARIETIES OF CACAO.

In answer to our correspondent "Pod's" enquiry, Mr. Carruthers, at our request, has been good enough to supply the following explanation:—

The identification of the varieties of *Theobroma Cacao L.* is, like the identification of varieties of other cultivated plants, a matter which varies considerably with the expert who observes them, and in Ceylon so much crossing takes place that it is not possible to "classify" all fruits as "Forastero" or "Criollo."

Many pods contain seeds of the distinctly Criollo character, viz., white cotyledons when cut and roundish in shape as well as other seeds with the Forastero purple-coloured cotyledons and longer in shape. It is impossible to give a varietal name to such pods and they may be produced by a tree having the habit and characters associated with Forastero or those recognised as Criollo.

In a large number of examinations, weighings, and measurements of pods from trees of both varieties, I have not as yet found the mean weight of seed contained to be distinctly greater in either of the two varieties generally grown in Ceylon. The diagrams—of pods not typical of either variety—were published to show the unwisdom of trusting to external characters in valuing the fruit, the exact commercial value depending, as it does, on the quality of the individual seeds, and their preparation for the market. This was not considered; that is another and a most important question.

EWING'S ONE-RAILED TRAMWAY. MR. L. DAVIDSON AGAIN.

ON THE NORTH TRAVANCORE TRAM.

The writer has frequently been asked if the Ewing's tramway laid by us in North Travancore was a success, and the following notes will answer, so far as lies in his power, these enquiries. Unfortunately, we are still in the experimental, or rather experimenting, stage but the knowledge gained during the last two years, in rectifying mistakes and improving the installation, affords sufficient data to come to a reasonably reliable determination as to what conditions this class of tramway is suitable for, and under what conditions it would not be a commercial or, perhaps, engineering success.

I believe—and this is a point we would have determined accurately before this south-west monsoon, had the writer remained in Travancore—that the power necessary to move a given quantity of goods by Ewing's tramway on a fair road, with reasonable curves, is less than half what is required to move the same quantity of goods by country carts—in other words, the same number of cattle will do double the work by tram that they can do by carts, and having arrived at this factor, the other points to be determined are:

(1) What are reasonable curves?
(2) What is a fair road?
(3) What is the cost of laying in the installation?
(4) *a*, What is the extra cost, if any, of supervision and upkeep of rolling stock and permanent way as compared with (*b*) upkeep of a metalled cart-road.

Reasonable curves in the case of Ewing's tram are curves of about 60 feet radius or less.

What the writer considers *a fair road* is a metalled road with grades of about 1 in 28 or flatter.

The cost of laying in the installation on a *suitable existing cart-road* may be roughly put at R3,000 a mile, for a light tram to carry 1-ton loads.

The cost of upkeep of tramway will be far less than the cost of upkeep of road, which will be readily understood when one considers the wear and tear is mostly on the rail instead of on the road. At the same time I very much doubt whether it was a profitable investment to lay the tramway as we have done in South India, for the cost of constructing a road in a hilly country, with 60 feet radius curves, is at least 50 per cent. more than it would cost to cut a small road for a double-railed tram, which could negociate 30 to 40 feet radius curves quite well and do as much or more work than Ewing's tram.

THE SAVING AS COMPARED WITH CART HIRE.

I do not believe it will pay to lay the tram on ordinary low-country roads in South India, where transport charges are very low (about R8 per ton for 50 miles) and where the roads have a good many steep up-and-down grades on them, and many rivers are not bridged *but I do believe*, where cart hire is dear, as it is up-country in Ceylon, or Burmah, and especially where heavy loads (such as timber), of from a ton to 30 cwts. per pair of wheels have to be carried, it will pay well to lay this tramway along the edge of existing roads, where these are suitable. The writer had an offer from a contractor, shortly before he left Travancore, to transport goods over the tramway at R3 a ton for 21 miles and the same man asked R6 per ton for

cart hire, which shows a great saving in using the tram, more especially as the tram track cost much less for upkeep than the whole road.

I believe the 25 miles of rail laid in North Travancore is the only instance of Ewing's one-railed tram being tried on a practical scale.

Mr Ewing's Agents are Messrs. Parry & Co. of Madras, from whom all information regarding it can be obtained.

It need hardly be mentioned that the writer has no interest whatever in it, further than having been the purchaser of the above installation. Briefly, the system consists of

(1) A single rail attached to sleepers in the ordinary way ;

(1) Trucks, with two or more double-flanged wheels running underneath the centre of them, tandem-wise, so that, *theoretically*, if a truck were properly loaded on level ground, it should balance itself on the railwheels just referred to ; and

(3) An outrigger wheel of large diameter (four feet or more) made of very light materials and wide tyre (four inches or more) revolving on a hinged axle, fixed to the centre of the truck and projecting over one side, while attached to the axle at the edge of the truck are two spiral springs, one above and one below it, that allow the axle to move up and down freely and compensate for any inequalities of the road.

The object of the outrigger wheel is to prevent the truck from upsetting, and it is not *intended* to carry any load, the whole weight of the truck and the goods on it should be carried on the rail wheels.

SLEEPERS AND RAILS.

The rails we laid down were 14 lb to the yard, and they were dog-spiked on the sleepers 2 feet 3 inches and 4 feet 6 inches long by 8 inches wide and 4 inches thick, and we found it best to place alternately a 2-feet 3-inch sleeper across the rail, and then a 4-feet-6 inch sleeper, longitudinally, leaving a space of about 15 inches between them. Lighter sleepers would not, in the writer's opinion, do.

These rails cost R1,700 per mile, including fish-plates and spikes C.I.F. at Madras ; and sleepers cost R250 to R600 a mile, according to the cost of sawing and distance of transport, while bending and rail-laying and rolling-stock should cost another R700 a mile, bringing up the cost of the complete tramway to about R3,000 a mile.

Our trucks were 12 feet long by 6 feet wide, and had simple platforms running on two wheels for carrying rice and tea chests, costing about R400 each, and built to carry a load of 1 ton ; but, of course, rails of heavier section can be laid to carry heavier goods, and the trucks can be built of any ordinary form and have more than two wheels if necessary, in which case I think the *extra* wheels or wheel should have plain treads and no flanges as the friction on these double-flanged wheels is a serious drawback to the tramway.

EXACT POWER REQUIRED TO HAUL A TON.

I intended to test, with an electric motor-car we had built, the exact power required to haul a ton of goods on the tram, compared with the power required to move it in country carts ; and I hope this experiment will be carried out yet, as it would be valuable. It could either be done with the electric motor or with cattle and an ordinary hauling bar with a weight-tester attached, and I believe that the efficiency of the tram will be comparatively lessened *whenever curves of small radius have to be negociated*, because double flanges on the wheels involve much more friction than single flanges, as the wheels are fixed in a straight line, three or four feet apart, and any deviation of the rail from a straight line involves considerable friction on the rail at the four points where the flanges of the wheels bear on it. In ordinary railway-wheels this friction is overcome by the shape of the *tread* of the wheels, and, if any means can be discovered for getting over this difficulty in Ewing's tram-wheels, the power required for haulage will be greatly lessened, and the life of both rails and wheels greatly lengthened.

Mr. Kemlo designed two arrangements, one for swivelling one wheel to meet the curves, and the other for using four single-flanged wheels instead of two double-flanged wheels, but those have never got beyond the stage of drawings, so far, although they are well worth experimenting with.

CURVES.

We were led to believe that curves of 20 or 30 feet radius were suitable for our tram, but after seven miles had been laid it was evident that these sharp curves caused immense wear and tear to wheels, rails and cattle, so the writer reluctantly had seven miles of rails pulled up and relaid at curves of 60 feet radius as a minimum, and the grades of the road were at the same time corrected, the steepest part being one in 28, and I would not advise anyone to lay in a Ewing's tram at steeper grades than this, unless for a short portion of the total distance. In making a new track for a tram of this description, therefore, it should be borne in mind that curves should be 50 to 60 feet in radius, and where a tram road has to be cut in a steep and broken country, its cost is probably increased by 50 per cent. in extra embankments, retaining walls and extended culverts; and the whole question of the cost of laying the tramway, compared with cutting metalled road and using country carts or a double-railed tram, requires careful consideration.

The laying of the tram in our case was, therefore, under the misapprehension that it would work on curves of 30 feet radius or less and the cost of correcting this mistake was very considerable. I believe, however, that it will work all right when the outrigger wheel track is properly metalled, for reasons I will presently give, and this I believe is now being done.

A few of the mistakes made by us are noted below, and I think that the ompany did more than its share in making Mr. Ewing's invention a practical and useful means of transporting material.

(1) The curves of the road were too sharp.
(2) The trucks were not sufficiently strong.
(3) The brakes were defective.
(4) The outrigger wheels were too weak (to stand bad loading and bad road).
(5) There was great friction between the flanges and the rails.
(6) There were no proper points or crossings.
(7) There were no proper lubricating arrangements.
(8) The rail wheels were cast-iron and they should be of good cast-steel not chilled.

(*a*) With regard to the *sharp curves*, we put that right, but only at the expense of specially widening the road and relaying seven miles of rails.

(*b*) *Trucks* are now properly built and two new ones can be seen at Messrs Walker & Co.'s, Colombo, and will, I am sure, interest visitors.

(*c*) These trucks have the latest brake designed by Mr Michie and myself and it is very efficient.

Lever brakes, unless they have plenty of travel, soon wear the blocks of wood down while screw brakes blocked the wheels and caused "flats" to be ground on the tread due to friction between rail and wheel, and were therefore unsuitable.

d. The outrigger wheels supplied were too light for the inferior unmetalled road they had to travel over and the careless loading; but we have now a very good wheel, designed by Mr Kemlo, with tangent spokes, giving little trouble.

As I mentioned before, the weight of the loads is *theoretically borne* entirely by the rail wheels, but too often the native truck men load the trucks so that two or more cwts of the load is thrown on the out-rigger wheel, and besides this, when there is any hollow in the road and the out-rigger wheel is *below the proper level*, a lot of extra weight is thrown on it ; therefore it should be comparatively strong.

Mr Kemlo has designed a pair of springs, which I would have tried and which show exactly the weight

on the out-rigger wheel. If they work in practice they would be invaluable as they exactly indicate if any extra load is carried by the outrigger wheel

(*e*) The friction on flanges of rail, wheels, and rails is very serious; and this is one of the weak points of the tram.

I forgot to mention that Mr Kemlo and Mr Thorp both designed wheels with sloped flanges; and the former gentleman says, if they are properly made, they will work well. I hope so and would like to see them tried further.

(*f*) The difficulty in regard to points or ramps for crossings is considerable, due to the difficulty of dealing with double-flanged wheels, but this can be got over in a fairly simple way.

(*g*) Lubricating bearings have just been designed by Mr Michie and will be successful, I hope, as they would save a lot of wastage through oil running on to the track. Rail-wheels of cast-steel which can be returned are far the best. Our cast-iron wheels wore out very quickly, the chilled ones could not be returned, but the new wheels now being made should do well, and be easily returned with the lathe; while the chilled ones cannot be treated in this way and are lost as soon as they are worn somewhat, especially if they have a "flat" on the tread."

Although, theoretically, the out-rigger wheel carries no load, in practice it frequently carries a good deal and for this season the wheel track should be metalled to prevent its being cut up in wet weather; and the part the animals hauling the trucks travel on should be metalled too, as they cut up the track if of earth.

With those improvements in Ewing's tramway and a metalled truck to run it on, Ewing's tram can be made to do a lot of useful work.

It can be laid within 2 feet of the outer edge of any road and therefore impedes cart traffic very little, and although we were naturally disappointed at the mistakes made it did not get a very fair chance in the past; and if the road is properly metalled and trucks and track kept in proper repair, the writer will be surprised if it does not prove quite successful, and this is also the opinion of Mr Kemlo.—Local "Times."

L. DAVIDSON.

MOSQUITOES AND THE CASTOR OIL PLANT.

(*To the Editor of the Pioneer.*)

Sir,—Some short time back, there appeared, in the correspondence columns of your paper, I think, a recommendation to use the castor oil plant to keep a bungalow free from mosquitoes. I, being a sufferer, had six plants placed in pots in my rooms, I fancy we must breed a different variety of mosquito than your correspondent, for the castor oil plants are thickly covered with the insects by day, who, at night time, seem to be actually invigorated by the apparently stimulating effect of their new quarters.—*Pioneer*, April 22. D.

SCIENTIFIC AWARD TO THE CEYLON GOVERNMENT ENTOMOLOGIST.

The late Surgeon-Major Barclay, of the Indian Medical Service, contributed to science some most valuable work on various Fungi. His untimely death at the early age of 39 was a severe loss to science in the East and it was felt that some suitable memorial should be instituted so that the influence of his example and work should be kept alive. With this purpose the Bengal Branch of the Royal Asiatic Society founded the "Barclay Medal" to be presented annually to the investigator in Biology in India and Ceylon who has done the most valuable work. The first award has been made by the Council of the Society to Mr. E. E. Green, F.E.S., Government Entomologist, Ceylon, for his work on the Insects of India and Ceylon. That Mr. Green has been honoured in this way will be a gratification to those in Ceylon who know his work; for we feel sure that the first award of this medal could not have been made more judiciously, and we heartily congratulate the Government Entomologist who is so widely esteemed. The medal bears a clever bas-relief portrait of Dr. Barclay.

OLDEST TEA IN CEXLON.

DOING WELL IN ITS 33RD YEAR WITHOUT MANURE.

In answer to our enquiry, Mr. G F Deane, Manager of the Loolecondera Group, writes:—"About the old Tea fields on Loolecondera, I am glad to tell you that the oldest 20 acre-clearing (planted in 1868-9) is still doing well, the yield for last twelve months, ending with March, 1901, was 566 lb made per acre; this field has not been manured. The next oldest field 84 acres planted 1874-5-6 gave a yield of 390 lb. made tea per acre during a similar period, the smaller yield being partly due to some of it having been pruned during that time. No manure has been applied to these fields as far at I know."

THE TEA TRADE.

MARCH STATISTICS—RUBBISHY QUALITIES—RESTRICTED PRODUCTION.

(*From an expert correspondent.*)

INCREASE IN CEYLON AND INDIAN EXPORTS.

The only satisfactory feature in March statistics is the continued increase in the exports of Indian and Ceylon descriptions, and last month the former advanced 45 per cent and the latter 70 per cent as compared with the previous year. How the largeness of the bonded stock is to be accounted for in view of the recent heavy clearances I cannot make out, but doubtless the investigator's explanation will be forthcoming in time. During March the prices of all good teas improved generally a penny per lb—in many instances twopence—owing, it is said, to better quality. Common descriptions, especially those averaging from 5d to 6d per lb, have participated in the improvement in a minor degree, and even the lowest grades are ½d per lb better. From the tone of the market recently it looks as if the prices of the qualities averaging 9d per lb and upwards have for the present culminated, especially if the finer plucked common teas now on the way prove to be as satisfactory as they are reported to be. In the Colombo market the higher grades have been realising an advance of 2d per lb.

PROPORTION OF LOW GRADES.

It appears by the brokers' circulars that, whilst last year's Indian crop exceeded the previous season's by nearly 13,000,000lb, the sales were about the same; consequently, there is this surplus quantity to be got rid of during this and the next two months. This excess consists largely of the lowest grades of common tea, so there is not much hope of the average prices of Cachar, Sylhet and Dooars descriptions improving until it is disposed of, unless in the meantime the prospects of

largely restricted production affect the market generally. That the disastrous slump in prices of common during the last four or five months is owing to the excessive import of the lowest grades from India is clearly proved by analysis of the assortments offered for sale. Out of 36,790 packages sold last week 17,559, or 20 per cent, were Pekoe Souchong; 12,371, or 6½ per cent, were broken or Souchong, and 3,445, or 9½ per cent, fannings and dust, making together 35¾ per cent of those grades which dealers stigmatise as "rubbish."

EXTENSIONS AND COARSE PLUCKING.

Though Ceylon proprietors are by no means exempt from the charge of having contributed to over-production by extensions and coarse plucking, an analysis of the proportions of the grades of their tea show that they have not erred in the latter respect nearly as much as their neighbours. Of 25,479 packages also offered for sale last week, 2,991, or nearly 12 per cent, were Pekoe Souchong; 107, or ½ per cent, were broken and Souchong; and 1,167, or 4½ per cent, were fannings and dust; making together 17 per cent, as against India's 35¾. Moreover, whist 50 per cent of the Indian tea is selling on an average below 6d per pound, only 20 per cent of Ceylon tea is selling as low. From the Ceylon newspapers and private sources I gather that proprietors are very much in earnest both in intention and practice in reducing production. On every estate where finer plucking is practicable it is being adopted, and in all districts temporary abandonment of cultivation of unremunerative tracts is being carried out. The effect of this is already showing itself in the March shipments from Colombo, and it appears probable that the decrease in April, May and June will be on as large a scale.

PLANTERS' NEW POWER.

If Indian planters follow the example of their Ceylon brethren, as I believe they intend to do, the result may be to place the producers of common tea in a more permanent and prosperous position than they have ever been in by proving that they have the power of rapidly curtailing the output at a trifling increase of the cost, and of thus regulating to some extent the prices of their produce. The consensus of Ceylon opinion as to this year's crop points to an export to this country of about 101,000,000 pounds of better tea. To a small extent this depends on the export to other countries; so far there is no increase over last year, owing to Russia and America having taken less, probably because tea has been relatively cheaper here than in Colombo. This estimate would give a decrease of about 13,000,000 pounds, but there are some experienced planters who think the decrease will be larger. The question will, however, be settled by the close of June—the end of the heavy flushing months. In the meantime we know that restriction is being energetically carried out.

AN UNSUCCESSFUL EXPERIMENT.

Two or three months ago, when so much reliance was placed by intelligent planters and others on the capture of the American market by the manufacture of green tea in competition with Japan as a remedy for over-production, you may remember I expressed an opinion, based on personal knowledge and experience, that whilst Japan held 30 per cent advantage in exchange the enterprise could only be carried out as long as sufficient funds were available to pay manufacturers a countervailing subsidy. Industries are created and maintained indefinitely by state bounties, paid out of the general revenue of the subsidising country, but the bounties to be paid in Ceylon on green tea are not provided by the Government, but by the tea planters themselves from a fund raised by a small export duty or cess for the special purpose of sending emissaries to advertise and push the consumption of their tea in foreign lands. This fund will not admit of the committee who distribute it subsidising more than 2,000,000 lb. or 3,000,000 lb. annually. I never thought the game worth the candle. It is simply taking money out of one pocket to put it into another. I notice by the Ceylon newspapers that the experiment already shows symptoms of collapse. As usual with all novelties, last year the green teas offered for sale went off like hot rolls at remunerative prices; now they are unsaleable in Colombo, and a Press warning has gone forth to planters recommending them to hold their hands.—*Financial Times*, April 12.

PRODUCE, PLANTING, AND COMMERCIAL NOTES.

The *Grocers' Review*, a Manchester trade journal, comments as follows upon the tea crisis.

Twenty-five years ago it dawned upon coffee planters that tea would grow in Ceylon. They tried the experiment, and the result exceeded their most sanguine expectations. Its success was immediate, and, as they thought, assured. Ceylon tea became fashionable, dealers boomed it, and within a few years it was an indispensable adjunct to the British tea-table. From 10,000,000lb in 1879, the output increased by leaps and bounds. Suitable land went to a premium, existing estates expanded, huge companies were formed, and things went merrily on until last year, when it was found that the export reached nearly 120,000,000 lb, and that fancy prices had disappeared. But as to how the trouble came about, the planter himself is not to blame so far as the quality of the article is concerned. As much care is bestowed upon the cultivation and manufacture today as was the case twenty years ago. In spite of rumours to the contrary—and it must be remembered that it is advantageous to some people to disparage Ceylon tea—the quality is just as high as it ever was. It is the quantity that has done the mischief. Another very serious factor towards the downfall of tea has been the fluctuation of exchange. When the industry was in the most flourishing condition the rupee was worth little more than a shilling. The planter thus got over seventy cents for his tea at 9d a lb Today, when he is only getting 6d, his local inquivalent is thirty-seven cents. The cost of output, of course, never varies, hence a very big drop on the credit side of his ledger. But although 6d may be the average—and on 6d there is a microscopical margin of profit to be made—it must be remembered that scores of estates are now selling under that and a large number are actually realising in London less than the cost of production. These estates it will be that will go first. With their abandonment the others may look up, but even at that the result is dubious. The public has found that it can get its tea—and good tea too—at half the price it used to pay, and it is not likely on the score of sentiment to give more."

While new markets for British-grown tea are eagerly sought for, attention might well be directed to the needs of the Army in this respect. In an article on "British Fighting Food," by Mr Annesley Kenealy, in the "Morning Post," this is referred to. He says: "The soldier is blamed in season and out of season for his habit of drinking muddy and dangerous water on the line of march, and thus contracting enteric and malarial fevers. Now, one-sixth of an ounce of tea and one-third of an ounce of coffee was the daily drink ration issued to the South African troops. The resultant brews resembled the palest brand of pale sherry, and the entire day's issue was consumed at one meal, with the natural result that Tommy quenched his thirst at the first poisonous pool on his daily march. In the absence of any means of procuring the alcohol to which most soldiers are accustomed, tea

and coffee should be issued generously on field service with the double purpose of supplying the stimulating element which hardworking soldiers need and of obviating the possible dangers in unboiled water. A United States soldier on active service is allowed an extra 21 cents daily for 'tea and coffee.' British soldiers might feel a momentary temptation to belong to the American nation, were they to contemplate the liberal rations issued to those who fight under the Stars and Stripes."

TEA INSPECTION.

In Canada an effort is being made to push the sale of Japan tea, "every pound" of which is, according to an advertisement in a Canadian paper, "officially inspected before export; only that which is absolutely pure and of high quality is allowed to leave that country."—*H & C Mail*, April 12.

POOR OLD COFFEE:

COORG—THE STRAITS—QUEENSLAND—JAVA.

Looking over the latest Administration Report for the Province of Coorg, we are much struck with the evident symptoms of decay in poor old coffee even in this last stronghold of the Arabian plant in India; and the "Coorgites" (to coin a word) or rather the Anglo-Indian administrator has invented a term to indicate a discontinuance of cultivation. Where we in Ceylon speak of an estate being (in plain Saxon) "abandoned," or in the less disturbing term now adopted in the Directory of "uncultivated," in the Coorg Report before us, we are told of "resignations" among old estates! Thus during 1899-1900, we are informed that one of the best-known and longest-established of Coorg coffee plantations—Fischer's, with an area of 490 acres—"was resigned entirely." In the one year, over 2,000 acres were "resigned," leaving in cultivation:—

In the hands of Europeans	31,980	acres.
,, ,, Natives	70,234	,,
	102,214	,,

But then, this comparatively large area only gave a total crop of 55,200 cwt. or not much more than ½ cwt. on an average. We suspect that most of the native gardens are more than "semi-resigned," perhaps cropping at ¼ cwt. to the acre, leaving the European estates to average about 1¼ cwt—a miserable enough return only compensated for by rather better prices; but Mr. Meiklejohn estimates that the expenditure on coffee cultivation was, at least, three lakhs less than in the previous year owing to the short crop. This, of course, can only result in further "resignations."

Turning next to Selangor, we have a return published by the local Planters' Association for 1900 which indicate a total of 15,064 acres under cultivation and an estimated coffee crop for 1901 of 25,578 piculs—about 30,000 cwt—or an average of about 2 cwt. an acre, and this, mainly Liberian coffee which at an average of 20 to 21 silver-dollars per picul—say 42s to 50s a cwt. at the highest—cannot possibly leave much profit.

In Queensland, coffee-growers—of whom Mr. Newport reports some 200 altogether, cultivating from 1 to 75 or 80 acres (the biggest estates) or in all 700 acres—are so far more fortunate. They sell all their coffee for local consumption and get 56s per cwt. for it in parchment or 112s per cwt. clean, according to sample. With such a difference, it ought to pay to run a pulper and drying-ground in some of the districts. The oldest coffee is not more than six years old, and the Indian planter who is now Coffee Inspector for the Government is sanguine enough to peak of 10 cwt. an acre *without manure* and a total crop worth £20,000 to £30,000. This would mean £30 to £40 gross return per acre—rather a contrast to say £4 in Coorg and £4 to £5 in Selangor! And moreover Mr. Newport tells us that a good deal of the coffee is Liberian, though chiefly *C. Arabica*. However, we must remember that it is principally garden cultivation in Queensland, and the soil and climate must be splendidly adapted to coffee when we are told:—

On the whole, the condition of the estates as I found them was not encouraging—in some cases the weeds were over the coffee. Where the coffee had been kept clean, the growth and bearing were remarkable. For amount of crop the Buderim Mountain is noticeable, the quality being also specially good here. On the Daintree River one or two estates that had been kept assiduously free from extraneous growth showed remarkable development, trees of thirteen and fifteen months being topped at 4 feet, having a good spread of secondary growth, and spiking heavily, showing promise of a 5 to 6 cwt. crop that would ripen when the trees were not more than two and a-half years old. For a l-round good qualities, some of the properties in the vicinity of Cairns, especially on the range about Kuranda, are pre-eminent

Of course labour is the difficulty: a Ceylon planter with 50, nay 20, good coolies might quickly make his way to fortune; but would he be allowed to import even one cooly to work on the land is a question not likely to be answered in the affirmative from Queensland.

Finally, we are surprised to learn of the great progress made with Liberian coffee—(such a complete failure as it was in Ceylon)—in Java where, for 1901, Liberian is expected to contribute 131,000 piculs against 106,000 in 1900, and this out of a total coffee crop (Government, Private and Liberian) of only 383,000 piculs as against 542,000 piculs in 1900. So that in Java also, coffee is going back as a whole, though the Liberian kind is apparently keeping up. But then all that the Eastern and Austral world can produce, of coffee, is but as a very little in comparison with the great and ever-increasing coffee crops of Brazil, Central America, and Mexico.

RUBBER GATHERING IN BOLIVIA.

The Chicago Bolivian Rubber Co. (Chicago) is organised to collect rubber on a large scale on concessions in Bolivia, the rubber collected being shipped via Mollendo, on the Pacific coast, to Europe. We have a large force of Indians in the woods, and expect to get a large quantity of rubber during the current year. The rubber is of fine quality.

The Belgian company, L'Abuna, formed to develop a rubber property bought from Señor Ballivian, of Bolivia, report that this property is one of the finest on the upper Madeira. Some 2,000 *estradas* of trees are embraced, which will afford employment for 1,000 workers, with a possibility of gathering 7 kilograms (=17½ pounds) each per day. The season for employment is estimated at seven months in the year. Besides the rubber proper (*Hevea*), the lands contain a large number of Caucho (*Castilloa*) trees, which it is proposed to work. It is intended to send at least 150 collectors into the forest this season, besides such native labour as can be secured. During the past season twenty men, without supervision, gathered 21,560 pounds of rubber, or 1,078 pounds each.—*India Rubber World*, April 1.

CEYLON IN 1889 AND 1901: GAMPOLA AND ITS NEIGHBOURHOOD REVISITED.

April 29.

(*By an old planting correspondent*)

We reached Gampola in time for dinner and, after travelling from Neboda in the Kalutara district from five o'clock in the morning, felt tired. Next morning we found our way to good old

SINNAPITIYA,

the oldest estate in Ceylon (over three score years and ten and still "comes up smiling") everything looking as fresh as a daisy, the timber trees well grown and giving a grateful shade to the roads with fine old mango trees and jak and a most valuable collection of Grevilleas in all stages of growth.

There is no necessity to buy timber for firewood on Sinnapitiya, it is a dense forest of valuable timber; and as the trees are kept well-lopped, the tea flushes well and good average crops of leaf are obtained; only fancy, the oldest estate in Ceylon turning out such a valuable property. Over seventy years ago, the late Colonel H C Byrde ploughed Sinnapitiya with elephants for coffee planting and the coffee held its own until the seventies; the writer has known Sinnapitiya for over thirty years during the time the brother of the Rev. Mr. Mitchell was Superintendent, then Mr. Jones for a short time about 1879. The present Superintendent, Mr. Waring, has been many years in charge of Sinnapitiya estate and to him is due the great credit of bringing the tea and timber to its present state of perfection. The bungalow is shaded by two gigantic Flamboyant with their gorgeous scarlet flowers and by clusters of yellow bamboo and some grand old mango trees; the Grevilleas fifty or sixty feet in height protect the bungalow from wind and sun. The factory is a very fine one with plentiful supplies of timber cut and dried ready for use.

At the back of Sinnapitiya towers the Vellakande Hill and the zig-zag road leads to Mr Gaddam's properties,

BUKANDE AND AMBALAWA,

(formerly owned by the late A C White).

Mr. Wilkins owns a neat little estate beween Sinnapitiya and Gona Adika; he is trying cacao and cinchona in addition to tea. Mr. W. intends to put out 40 or 50 thousand cinchona plants of good quality, including Ledgeriana. This seems a wise thing to do, considering the low price of tea prevailing in Ceylon and India. Mr Wilkins is one of the old school of planters and had a varied experience in this island; it was a pleasure to have a conversation about Ceylon and the planting enterprise with Mr Wilkins and wish him every success.

Old

GONA ADIKA

like good old Sinnapitiya is still flourishing under the able management of Mr. W. Macgregor. There are some 360 acres of tea. The coolies call this place Massie Coombera and I found it a very stiff climb from Sinnapitiya during a storm of rain, taking shelter with Mr. and Mrs. Wilkins and reaching Gona Adika about six o'clock, very wet and tired. Shank's mare is not such a comfortable way of travelling in a steamy place like Kadugannawa, especially some of the lovely "short cuts" through wet mana-grass.

We remember the old bachelor days of this district. The scene is changed. When George Anderson was at Gona Adika—in the days of coffee—nearly all the planters were young bachelors except William Theobald of Mount Temple. Now we find married men in nearly every bungalow and of course their houses are more comfortable and lives more enjoyable. Talking of Theobald, he is still plodding on at Deltotte, another old and hardy planter, of over thirty years' experience in Ceylon. In Theobald's time

MOUNT TEMPLE

Estate was under coffee (planted by Dr Shipton and still called Doctor Dorai Totum); we remember tea being introduced there and poor James Robertson of the Mercantile Bank made this place his head-quarters; the last time we saw the old banker he was weighing his tea leaf at four o'clock. Arthur Calvert Hoare was stationed here and running the Nuwara Eliya coach. Mount Temple is now a *very important* place and *like the Phœnix risen out of its own ashes*! The estate has developed into a very pretty estate with a good

CART ROAD TO THE BUNGALOW.

Mr. Shelton Agar, the present proprietor, is planting avenues of coconut palms and these, added to the great quantity of ornamental and useful timber trees, will enhance the beauty of this property commanding one of the most comprehensive views of the lower planting districts with the grand old Mahaweliganga winding its way through the valley. Nestling under the shade of a palm and jak grove is the large and substantial factory of Mount Temple, five minutes' walk from the town of Gampola. Mr. Shelton Agar kindly showed me over his factory. There is a patent fan at the apex, oil-engine power driving three rolling machines: the Davidson, Brown and Jackson, all doing good work. Tea-sifting machines, tea cutter, sirocco and other machinery with good withering space upstairs, the jute hessian tats screwed to the stanchions with a coir rope binding to prevent the tearing of the jute hessian.

Mr. Shelton Agar is a man of inventive genius and he conceived the idea of binding the edges of the jute hessian with coir rope. This scheme is being generally adopted, I believe, by other factories. Mr Agar made some improvements in the Davidson roller but up to date received no remuneration, and the least the Messrs. Davidson could

do would be to present Mr Agar with a new rolling machine with the improvement added.

On Mount Temple the

COCA

(*Erythroxylon Coca*) plant is doing well, and there was a large quantity drying in the store, come from another estate. The leaves of coca are prepared for shipment. Most of the Kadugannawa estates are giving this enterprise a fair trial

The old fruit trees of Gampola shade the cart-roads, and cacao does very well under the mass of tropical vegetation skirting the high road to Kandy. My time was employed well in visiting a snug little estate belonging to Mr James Hawke, called

ORION,

managed by Mr Robert Northway. There is an imposing two-storey house built by Mr L D'Espagnac and now occupied by the Northways. The tea is a good jât and there were eight acres of indigenous Manipuri.

There is a nursery of good plants raised from that seed. I believe the price is reasonable and both plants and seed may be obtained by intending planters. Here is another oil-engine and water power, driving three rollers—the Davidson, Brown, and Jackson. Orion is about four miles from Gampola, a stiff pull up the hill, though an easy and pleasant walk back through Gampola wattie. Two of the Messrs. D'Espagnac were located on a small estate of their brother's, Mr. L. D'Espagnac. They were glad to meet the writer again and have a talk of old times. It was exactly thirty years ago since we met Mr. N D'Espagnac at Vella Kande in Gampola and at Kehelwattie when managed by Mr Fred. Hawke (late of Kirimettia, Kadugannawa.) We enjoyed a Kew pine-apple grown here, in fact it is one of the pleasures of returning to Ceylon to partake of the fruits of the country. At Kalutara we tasted the Mangosteen and enjoyed the cooling draught of the young "King-coconut"— at Gampola some mango and small sweet Bananas, papau &c.

Returning from the trip to Orion, we remained at the Gampola Hotel to dinner and to sleep. This is one of the great improvements of Gampola.—We have stayed at the hotel twice to dinner and slept there twice and breakfasted on Sunday morning at the hotel. The place is very clean and well-managed—the food very good and attendance everything one could wish. On Sunday evening I visited another small property of Mr James Hawke, about three miles outside the town of Gampola, on the Kandy road. There is a large quantity of cacao along this route, growing beneath dense shade of palms, breadfruit and jak. Some enterprizing Sinhalese have planted pine-apple plants between the tea. On Mr Hawke's place the cacao was doing remarkably well and here we found quite a forest of grevillcas. Mr H informed me that for building purposes or for firewood the grevillea was worth from one rupee to oneandahalf rupee per tree; in this case what a wealth of timber exists in Gampola at the present moment.

When Mr Kershaw lived near the Suspension Bridge over the Mahawelliganga, he little thought what a fine estate would spring up from his worn-out old properties purchased by Messrs Reid, Rutherford and Company after they had constructed the railway.

MARIAWATTE

is still doing well and looks as fresh as ever. Old

VELLA KANDE

has again changed hands and Mr. de Soysa has built a beautiful little villa on the site of the old bungalow and is making terraced flower and vegetable gardens down to the stable. The old breadfruit trees are still there, some of them with mango and jak planted by the writer thirty-two years ago.

In the old days of coffee we thatched the ground with mana grass shunted down to the field requiring it by means of a rope-shoot. We should recommend Mr de Soysa to thatch his tea in the same way with both grass and jungle stuff. This will absorb the moisture and prevent wash on the steep slopes of Vella Kande.

A small portion of

EOTAWA

has been put into tea. We passed by on our way to

COOROONDOOWATTE,

and found the estate in full swing though Mr John Stephens has departed and his son, Mr. Arthur John Stephens from the Fijis, returned to Ceylon and on his old totum. We hope Cooroondoowatte will be as valuable as a tea estate as it was in coffee, the lay of the land is so well adapted for manuring.

Cooroondoowattie is really in Dolosbage District and will form the subject of another letter exclusively on Dolosbage. There are a few places in Gampola we had not time to visit but from information gained regarding them they are much improved in appearance and value. Mr. James Hawke has just built a large factory and stocked it with Machinery, Sirocco's, Davidson, Brown and Barber rollers driven by oil-engine. I believe his store is in a position to buy tea leaf from the numerous small gardens around this part of Gampola on the old Kandy road. Vellakande, *my old diggings* thirty years ago, has got a new name, "Lantern Hill," named by Mr. de Soysa after a celebrated race-horse called "Jack-o-Lantern." The gentlemen I met at Vellakande or Lantern Hill were not aware that a race course exists on the top of the Vellakande Hill in front of the site of the top bungalow. We used to jump small hurdles there to get an appetite for dinner on Saturday nights and there was a small lake there.

HENRY COTTAM.

TEA *vs.* POTATOES.—When the former slump in tea occurred about the end of 1878, there was (says the *Indian Planters' Gazette*) a mild kind of rush for potato cultivation, but it died out as the former recovered. It may not be out of place to inform our planters that in some parts of the Nilgiris as much as R150 per acre is realised from raising the homely *spud*. Eight to ten tons is no abnormal yield, and this at R1 per maund is well worthy the attention of those who have low lying arable land at command, such as the edges of bheels and flats between teelahs, that, though submerged (or partially so) during the rains, are suitable enough for the six months of cold weather and spring cultivation.

AGRICULTURAL PROGRESS IN ZANZIBAR.

A DIRECTOR, MR. LYNE, ASSISTED BY A CEYLON PLANTER, MR. W J ROBERTSON, AND MR. H LESTER.

Zanzibar has so far come into line with the progressive States of the world as to have set up for itself an Agricultural Department, with a full blown Director of Agriculture. Mr. Lyne, who fills that useful post, has shown in a recent report to the first Minister that the Directorship is no sinecure, and that Zanzibar will not fall behind for want of energetic endeavours to develop its resources. In African native agriculture there is less danger than in India lest exotic attempts to improve things should prove to be so many essays in the art of teaching one's grandmother to suck eggs. Indigenous agriculture like indigenous labour is seldom of high quality in that part of the world, and an energetic Director of Agriculture, who has had tropical experience, may be able to introduce many practical improvements. In the Sultan's nurseries some excellent results seem to have been achieved by protecting clove seedings by planting rows of bracken ferns which shelter them from the sun and from the excessive dripping of water. Some successful experiments have been carried out in coffee planting, the growth of some Liberian plants being reported to be equal to anything seen in Ceylon, and as the soil constituents are said to be highly favourable for this culture we may hear more of Zanzibar coffee. Tea, too, has been introduced with satisfactory results. But Zanzibar is not destined to be a formidable competitor with Ceylon or India, notwithstanding that soil and climate seem to favour it, as there is not enough suitable land to allow tea to be grown on a large scale. The most that the Director looks for is the growth of as much as is required for local consumption, which cannot be much. Experiments in rubber planting both in Zanzibar and in Pemba have so far not yielded promising results. It is probable, however, that, until labour problems have solved themselves, the physicial conditions with which the Agricultural Department have to deal will be of secondary importance. Zanzibar and the country adjacent are passing through a transitional stage in the matter of labour supply. The Arab proprietor, instead of cultivating his land with slave labour, now deals with freed slaves, who settle on his land under agreement, giving him a certain amount of labour in return for cultivating rights on a portion of the estate. He has not yet brought himself into line with Western labour methods, and it will be long before he becomes reconciled to ordinary paid labour. His old hands are dying off, and he cannot replace them except by enticing people from his neighbours' land. Nor do the people themselves take kindly to the system of paid labour. So much is this the case that the Director of Agriculture says that, if these labourers were told that they would have to work regularly for payment, they would think they were hardly used. Labour difficulties in the Zanzibar and Pemba plantations have led to enquiries as to the suitability of the Indian cooly, but he is held to be too dear ; for, although the Indian is a much more efficient labourer than the Swahili, he is not four times as good, as he would need to be to make it worth while to employ him. Apparently when the Indian coolies have finished their work on the Uganda line they will not be tempted to settle in Zanzibar.—*Times of India*. April 27th.

AN EVENING ON DODABETTA.

(From a correspondent.)

It was a Sunday afternoon, and the bells of St Stephen's were ringing as I reached the Dodabetta saddle. From here to the top of the hill no driving road exists, and one must either ride or walk. The distance, however, is not more than 1½ miles. Once having attained the summit, one feels amply repaid for the trouble necessitated in getting there, and standing on the small crown which tops the

8,760 FEET, A SUPERB VIEW

is commanded. To the east lie Coonoor and Wellington ; beyond Coonoor, and, looking through a gorge formed by the picturesque Droog on the one hand and another hill on the other, the far distant plains can be seen, disagreeably arid and low-lying. Gazing around in a circle, and commencing from the Droog, one sees where the horizon rests, comparatively near Kotagiri, before stretching away and dipping deep into the far-off Mysore country, with its knolls of hills rising haphazard from the dead level of the surrounding country. Here and there gleams of water may be distinguished, indicating the existence of tanks, the habitat of wild duck and teal. Coming round the bend, the view is curtailed by Snowdon—barely a mile away as the crow flies—but lengthens again over Bilicul and in the direction of the Segur Ghaut, and thus runs into the Pykara and Neddivattum ranges of hills, and so on to the Kundahs, in which latter rises Makoorty Peak, to be seen of all men. Coming homewards and into the Straight the Kundahs are traversed, left behind, and one glances over the hills which presumably form the southern boundaries of Kartairy and Kulla Kumby and thus back again to the Droog. It was comparatively early when I reached the top, and Ootacamund to the West, peeping out here and there from beneath her mask of blue gums, with Coonoor and Wellington to the East, lay

BASKING IN THE SUBTLE CALM OF A SABBATH EVE.

Leaving Coonoor bathed in sunshine, one's glance travels towards Ootacamund, with her beautiful lake and fine Hobart Park, the latter conferring additional attraction and the former lending light and expression to her natural charms. Her various public and other buildings, too, may be seen, not arranged in the abhorrent regular maze of large cities, but existing in diversified disorder, in some places standing out clearly defined, in others indicated only by a glistening house top, or the tip of a spire, the rest being buried behind a leafy canopy of *Melanoxylon* and the ubiquitous blue-gum. Taken as a whole, and in conjunction with her climate, Ootacamund may surely rightly claim to represent the model of a "blessed Arcadie." The air at this elevation is delightful, pure and vivific, and one must have lived a twelve month in the plains to thoroughly appreciate a climate the antithesis to what one has been accustomed to. Lying stretched out under the shade of a hill-guava clump and lost in admiration of the scenery, I had well-nigh forgotten that it was growing late, and that night was fast approaching. Over the distant Kundahs

The evening sun, descending,
Sets the clouds on fire with redness,
Burned the broad sky, like a prairie,

It was not, however, the month for gorgeous sunsets, and this one, from a purely scenic point of view, was not extraordinary. Sinking and ever sinking, great Sol soon reached the boundary line where substance and shadow merge into one another. Here he stood for a moment, poised upon a hill top, and then sank peacefully into oblivion.

A QUIET TWILIGHT

now pervaded everything, but, on looking back upon Coonoor, alas! and alas! "what a falling off was there." Only a few minutes before she had worn a bright smiling face; with the departure of the sun, however, a sombre gloom had succeeded, in which the Droog stood out exceptionally forbidding in appearance and possessing a savage grandeur all its own. Yet a little while, and the scene was still further changed. Cloud upon cloud, masses of them, a whole army corps of them, floated down from the surrounding hills upon luckless Coonoor and ill-fated Wellington. One moment, and both the townships with their environments were in full view under a deep grey pall; the next, and the canopy had descended, blotting out and enveloping everything in a fleecy mist. A wind, starting from somewhere behind cloudland, had now arisen, and as one body

THE PHANTOM ARMY BEGAN TO MOVE UPON DODABETTA.

Soon, immeasurably soon, it had traversed the intervening valley and had arrived at the foot of the heights. As wave upon wave the fleecy clouds came rolling along, a rent in their substance occurred and for an instant revealed to view, below in the valley beneath, a Badaga homestead, or a cultivated field with a swathed figure travelling over it. The next moment, and, as if angry at its interior being revealed, a huge billow charged up, and again nothing existed but chaos. Phantom figures, too, with widespread sheeted arms, dashed themselves in frenzy against jagged rocks, were torn to shreds and partially dissolved, only to reappear the next moment, and, having donned forms a trifle more fantastic, to travel on, and ever on. But by this time

THE NIGHT RACK CAME ROLLING UP.

In another moment the heights had been gained and, standing up there, the phantasmagoria passed one in endless review order. Leaving detachments to hold the hollows and sweep the crests, it immediately rolled down towards Ootacamund. Looking thitherwards, a transformation in the scene was all apparent, the spirit of her beauty being essentially clouded. Twilight had almost departed and the town was wrapped in gloom, rendered almost impenetrable in corners wooded with blue-gum. The only physical feature which remained unchanged was the lake, which shone in all its purity, like a huge crucible full of molten silver. Then a breeze troubled its surface and it became ruffled. At this instant the rough portions caught a few departing rays of sunlight and lightened up with a deep crimson glory, which gradually toned away into shades of blue—into brown as darkness began to arrive—into grey as the mist next swooped down—and into indiscernible nothing as night (accompanied by squally gusts of wind) settled upon the landscape and assumed sway, clothing the world with chilly darkness.—*Madras Mail*, April 26.

THE AFRICAN ELEPHANT.

(*To the Editor of the London "Standard."*)

SIR,—It is discouraging to learn from books of travel like "The Cape to Cairo" that the reckless slaughter of this magnificent animal is still going on so relentlessly that in a very few years it must become extinct. The same book tells us that these elephants make their way through the dense bush in a marvellous way, and thus might prove most valuable as a means of transport into the interior, and so help to solve one great difficulty in the civilisation of Africa.

Why has no serious effort yet been made to domesticate the animal? Could not we, with our Indian experience, establish a colony of experienced Indian trainers and drivers in our East African possessions? We know that the ancient Carthaginians were very successful in taming and training the elephant, and it is said that the Jesuit missionaries in Angola have done it. Is it not a stigma upon us that nothing of this sort has yet been attempted?

I am, Sir, your obedient servant,

Shrewsbury, April 4. A GRADUATE.

The persecution of the African elephant by sportsmen and others is lamented by a correspondent whose letter we publish this morning. This magnificent animal is not, perhaps, so near extinction as some recent accounts would seem to suggest. Indeed, the convention recently made between the countries most interested should serve to check indiscriminate butchery. Unfortunately, however, the increase of man means the decrease of the beasts of the field. The great herbivorous creatures have large appetites, and prefer the fruits of cultivation to those of nature. A full-sized pachyderm in a maize field or kitchen-garden is about as bad as a bull in a china shop; we can hardly wonder, therefore, that the settlers wage war on big game. Efforts were made to preserve a small herd of hippopotami in one of the Natal rivers, but they became such marauders that they had to be killed off. This was unfortunate, for they, like the rhinoceros and elephant, are old-time creatures, and their lumbering forms seem constructed after ancient patterns. The elephant has alone lived on this earth longer than man; it made its way to these islands some time in advance of its future destroyer. But the genus once had a wider range than now. It has been found in all the great regions of the globe except Australia and South America, though in the Northern Continent of the New World a closely allied genus, called the mastodon, was more common. Even the Maltese Islands had a couple of species which, in harmony with their restricted range, were pigmy forms, about the size of donkeys. In our own islands primæval man, when he had no better weapons than roughly-clipped flints, must have some time hunted the ancestors both of the Indian and African elephants. The former, well known to us as the mammoth, was quite at home in a cold climate, for it had developed a woolly covering to keep itself warm. It ranged to the extreme North of Asia, and its carcase has been found frozen up in mud and ice on the Siberian Tundras. In fact, unlike the modern Indian elephant, which is undoubtedly its descendant, it seems to have disliked warmth, for in Europe it hradly reaches the extreme South, while the ancestors of the African elephant never wandered

so far North as the mammoth, and is found on both sides of the Mediterranean. Indeed, the present African species once existed in Spain. In each case the older forms are regarded as specially distinct from those now living, but yet as their undoubted progenitors. The African elephant may be readily distinguished from the Indian. Its ears are larger and of a different shape; so also is the forehead; the folds of enamel on its molar teeth make another pattern; its tusks often are slightly larger, and the animal is, on the whole, a little bigger. All that the Indian elephant can do the African should be capable of doing. It is said to be more powerful and active, more rapid in its movements, especially on broken ground. According to Sir Samuel Baker, it could beat an Indian elephant in a race, and keep up the pace for a longer time. It is also said to endure the sun better. This species was often brought to Rome in the days of the Empire, and the animals were tame enough to be led in processions and exhibited in the arena. Pliny has plenty to say about both kinds in his Natural History, including some stories which we fear would not now command respect. Elephants figured, as everyone knows, in the Punic Wars; indeed, Hanibal managed to bring nearly forty of them across the Alps, though it was hard work to get them down the slippery slope on the Italian side of the Pass. The late Mr. Oswell suggested that these were not native animals, but imported from India. This, however, is not very likely. Though the species is said to be rather less docile than the Indian, it could probably be made useful, if enough trouble were taken.—*Standard*, April 5.

COFFEE IN NORTHERN INDIA.

COFFEE IN SYLHET AND ASSAM.

I note, in your 4th of April issue, that your South Sylhet Correspondent attributes the want of a sufficient supply of moisture as the principal cause of his coffee bushes having been a month later than usual in coming into flower. No doubt the abnormal drought, which they have had to contend against down south, would have more than an ordinary tendency to delay the flowering period, but how would South Sylhet account for the bushes up here being a month later in coming into blossom than they were last season, or, as a matter of fact, any season since they have been planted? We had a copious and evenly distributed rainfall during January, February, and half through March. The latter month, too, was extraordinarily hot for March and brought on all other vegetation with a rush. It did not appear, however, to have the same effect on the coffee bush. About the beginning of March there were certainly a few flowers here and there stimulated to activity, but the principal show—and it certainly is a good one—is still in the unopened bud.

Perhaps the age of the bush has got something to do with determining the flowering period. I remember when my bushes came into flower for the first time that the display occurred about the 18th February.

INDIGENOUS COFFEE.

It is more than a month now since the indigenous variety (*Coffea Bengalensis*) was in full flower. By the bye, why "Bengalensis?" Would it not have been more appropriate to have named it *Coffea Assamensis*? I spent a good number of years in Bengal before coming to Assam, but I cannot remember having ever seen a single plant of it there; while here you cannot go any distance anywhere, where there is the slightest patch of jungle, until the large, pure, white, circular flower of Coffee Bengalensis catches your eye. It is one of the most plentiful and attractive shrubs which is to be found in the jungle up here. I even found one growing side by side with a tea bush the other day. I used to have a number of them round my compound, and during the flowering season they were the first to attract the eye, but my gardener cut them out last year when I was at home. There will, however, be little difficulty in replacing them.

It is not so very long ago since I met a planter, who had been "looking for land" on the north side of the Brahmaputra, who told me that he came across a piece of land amounting to some hundreds of acres simply clothed with the native variety of coffee. If such is the case—and judging from the number of bushes which are to be found almost everywhere, I see no reason whatever to misdoubt the statement—I should think that Upper Assam would be a much more suitable place for the other varieties than further South. It stands to reason that, if the native variety can propagate itself to such an extent and grow luxuriantly without any cultivation or attention whatever, that the other varieties of the species would do equally well with the ordinary treatment which they are supposed to require in all coffee-producing districts. Judging from my own robust and vigorous bushes, I should say that the Assam soil is capable of producing the very best of food for the coffee bush.

My bushes are luxuriating on a piece of ground which was formerly occupied by tea and has reared pineapples and fruit trees for years.

As a matter of fact their shed, if such it may be called, consists of a number of peach, banana and plum trees, and what little space remains unoccupied between them is filled up with pineapples. So much for soil. The Assam climate, I should say, is a long way ahead of South Sylhet for the production of coffee, as we are never troubled with the prolonged droughts which they are undoubtedly subject to. The elevation is something over 400 feet above sea-level and my bushes are growing rank and luxuriantly two feet above flooding level.—DIBRUGARH CORRESPONDENT in *Indian Gardening and Planting*, April 25.

"BONE MEAL AS A MANURE" is the title of an interesting and useful lecture delivered on the 23rd March in the hall of the Triplicane Literary Society by John Kenny of the Madras Bone Mills—a copy of which is before us. Mr. Kenny brings together a great deal of valuable information; but his pamphlet is chiefly noteworthy as a protest against the export of bones, and he winds up as follows:—

"That India has not hitherto used bone meal as a manure is not surprising. In Germany, the land of agricultural studies, its use was scarcely known, certainly not appreciated, even in the forties. Till then bones had been regularly shipped to England. Hunter had recommended the use of bone in agriculture in England in the year 1774. With the rise of the beet sugar industry in Germany exportation of bones soon came to an end. At present there is absolutely no export of bones from Germany but an immense import from all parts of the world. India will soon, like Germany, learn the worth of so valuable a manure and stop the dreadful drain from the land of one of its best fertilisers. Last year's exports must have reached somewhere near a lakh of tons, yet every bone that left these shores was sadly needed by the soil."

We shall quote several parts of the lecture in our *Tropical Agriculturist*.

TEA CULTIVATION:
MANURING TO LIVE—AND MANURING FOR QUALITY.

During the scare created by the excess of tea shipments to London, a great deal of nonsense was written about the injury done by "manuring", some writers—no doubt the owners of plantations on virgin soil—going so far as to recommend a prohibitive import duty on artificial manures. These gentlemen would probably have protested loudly, if they had been told:—"then, you want to ruin and snuff out your poorer neighbours with tea on old coffee land"; but such would have been the inevitable and immediate result of their policy. Liberal cultivation, including the application of a certain proportion of artificial manure, according to scientific principles, is an absolute necessity to make tea at all remunerative in certain old districts, and indeed we have lately had evidence put before us that it is equally required at an early stage in some of the younger districts if the crops are to be maintained and the bushes kept healthy and vigorous. What for instance do the opponents of manuring say to an authentic case of this kind:—

"Originally ——— was one of the finest estates in the Kelani Valley; but some two or three years ago, it was drifting into an exhausted, played-out condition, the flushes being poor, and the teas characterless, greatly wanting in body and strength. The fine free loamy soil and forcing climate produced heavy crops for 10 years with consequent exhaustion of essential fertilising constituents, while the excessive rainfall added to the exhaustion by loss of nitrates, through the soil, especially so when root decay set in, the first indication of declining fertility.

"Some 12 heavy crops were carried off on the older fields without manure; no prunings were buried. The crops and prunings represent a loss of 1,052 lb. nitrogen, 850 lb. potash, and 235 lb. phosphoric acid, apart from heavy mechanical surface wash and filtration loss by leakage of nitrates through the soil. It would cost to replace these essential ingredients by artificial mixtures R624 per acre. This represents the drain of capital in the shape of essential food constituents taken from the land, which is not returned in the case of tea by any ordinary natural process. The importance of burying prunings from the exhaustion point of view is clear, and can scarcely be gainsaid, as considerably more than half the loss would in this way be avoided.

We suppose it will be agreed that the proprietor of this plantation ought to have "manured to live"—to keep up his tea—from an early stage. No doubt the burying of prunings would have helped; but that is not enough as experienced managers in the Agras division of Dimbula, for example, know well.

Next as to "manure spoiling the quality of tea" instead of, when scientifically used, causing an improvement, we have a communication from a planter who ought to know a good deal experimentally on the subject. He writes as follows:—

"MANURE SPOILING THE QUALITY OF TEA."

A good deal has been written lately in regard to this. I have myself no evidence that manuring on the lines I have laid down lowers the quality, if elevation, soil and climatic conditions are similar, and the plucking and condition of the bushes from pruning, are identical. Until after September last year a large yield from more or less coarse plucking paid me best. On my return here in December last, however, I found the system completely played out,—for the present any way if not for good and all,—and that finer plucking must be adopted, if we are to realise a fair return on our capital. I gathered from my friends in London, including one of the largest blenders, that if Ceylon and India continued to glut the market with common teas, they might any day become unsaleable and with clear, and sweet pekoe-souchongs down to 3d to 3½d. per lb., we do not appear to be very far off this point; in view of this I altered my whole system. Two breaks have been shipped to London and the balance up to 10th April has been sold locally and includes all teas made during the time. The whole of the teas has realised 41 cents per lb. average. This compares favourably with any of my neighbours who are plucking fine and who don't manure or manure lightly. The prices realised are nearly double compared to what was realised for October, November and December teas plucked in the old way,—some 123,000 lbs of which sold for an average of 23·36 cents per lb. This only showed ¾ cent per lb profit over cost of production. So far as I have yet judged we shall get 500 lbs per acre average all round and produce it with liberal cultivation, at 28 cents including the keeping up of the full manuring programme, against 800 lbs produced at 22 cents and probably only realising 23½ cents, if that; in the one case showing a profit of Rs 12 per acre and in the other Rs. 65. I have on several occasions sent teas from the regularly manured fields on Pitakande, every two years since 1888-89, and have invariably had them reported on as better both in regard to strength and quality than teas from fields unmanured or manured only once—other conditions being as near as possible the same, the valuations were ¼ to ½ per lb. better in favour of teas from the manured fields. I consider the "lowering" of "quality" from "manuring" argument absurd, if all other conditions are equal. Of course, the manures must be balanced to requirements. There is still considerable scope for investigation in regard to this. I have no doubt further improvements will be effected and the joint action of the essential ingredients in regard to improvement in quality better understood. A good many of us are working at the problem and we may safely hope for good results when sufficient time has elapsed to test the various points raised."

There speaks common-sense as well as shrewd observation and actual experience. Manuring cannot be dispensed with in many cases; but it can be so used, with fine plucking, as to reduce the quantity of the crop—as in the above case—not 10, but 40 per cent; while the quality and probable prices are improved 47 to 50 per cent!

CACAO PODS AND SEEDS.—Following up the discussion started by Mr. Carruthers in the *Tropical Agriculturist* a "Cacao Planter sends us a register of measurements kept by him which may perhaps be of service, in pursuing the enquiry. It will be found an another page.

GOLD IN CEYLON.

We would offer a word of caution both to the Government and to the hero of the present exploitation of Ceylon for gold. Much has happened since we compiled, from every available source and authority we could find at the time, our little work on "Gold, Gems, and Pearls in Ceylon." Nevertheless, we would venture to commend the perusal of its pages, so far as "gold" is concerned, to Captain Reilly as showing him how often, by experienced miners as well as by scientific and amateur authorities, Ceylon has been pronounced an auriferous country with paying deposits in our river-beds, or better still with payable quartz reefs, if only they could be got at. First of all, it is well to bear in mind the adage of a leading Colombo merchant in his day, good old Robert Dawson, who was accustomed to say, as the result of his 40 years' observation in Southern India and Ceylon:—"Gold, gold—why, of course, there is gold—the very coolies when they have no work, go and wash in the nearest stream and sometimes make as much as two fanams (12½ cents) a day, and it is on record that a man once made four fanams"! Nevertheless, we, of course, know that Rangala, Ramboda, Ruanwella, &c., indicate where the King of Kandy got some of the gold in his treasury and jewellery, undoubtedly collected for him within his own territory; but at what expense of labour and even life, who can say? We know, however, that during the coffee depression, leading London Firms and their Colombo Agents, acting on the very best advice available, spent much money in blasting and mining into our quartz rocks and reefs in different locations; but with no result to speak of. Then came Sir Samuel Baker to trace the "home" (the matrix) high up in our rock and mountain system, of our sapphires and rubies as well as gold; and we know how he and Mr. LeMesurier worked and wandered; but with absolutely no result. Nevertheless, we should be very sorry to discourage Capt. Reilly unduly; but we think it a public duty to warn the Government since there is, perhaps, few members of the Executive or Provincial Agency, who have had personal experience, in any particular districts, of the "gold fever" of the sixties, seventies and eighties—the first outburst was in the early fifties. The first real step to progress in regard to the development of our mineral wealth is through a GEOLOGICAL SURVEY.

A NEW MANURE: BASIC SUPERPHOSPHATE.

We have received a pamphlet on a new fertiliser from Mr. John Hughes—the well-known Agricultural Chemist—accompanied by a small sample, which can be seen at our office, and the following letter:—

"London, E.C., April 18.

"I send you copy of a paper read on the 1st instant at Burlington House before the Society of Chemical Industry on my new manure, Basic Superphosphate. Favourable notices have already appeared in *The Times*, April 8th; the *Dublin Farmers' Gazette*, April 6th; the *Morning Post*, April 10th; the *Standard*, April 16th; the *Field* (page 522) April 13th. I enclose you also a small specimen that you may see the material which, though only invented last November, is now being made by six of the largest manure firms in the United Kingdom. Already the manure has been shipped to Calcutta, Mauritius, Demerara and Trinidad. You will see what a fine dry powder it is."

From the pamphlet we make one extract:—

ITS USE AS A MANURE.—Basic super is not intended to supersede ordinary superphosphate on good arable land containing plenty of lime, but is intended to be applied on soils that are either deficient in lime or contain an excessive quantity of vegetable acids such as sour pastures do. It is also recommended as specially suitable as a fertiliser for turnips grown on land subject to the disease known as "finger and toe." Manure manufacturers have suffered seriously from competition with basic slag because on sour grass land acid manures were unsuccessful, but now by the simple addition of slaked lime, ordinary superphosphate can be converted into a manure particularly adapted to all sour soils.

The manure is known as "Hughes' Patent": no doubt local Agents will be appointed and the article duly advertised.

NUWARA ELIYA FISHING CLUB.

A general meeting of the Ceylon Fishing Club was held on the 8th May, at the Hill Club, Nuwara Eliya, preceded by a meeting of the Managing Committee—the whole lasting nearly 3 hours.

MANAGING COMMITTEE MEETING.

At the meeting of the Managing Committee, there were present Messrs. E M de C Short, (Chairman), C H Bagot, Jeffries, Masefield, T Farr, C A Johnson, Major Hilman and J Fraser, (Secretary).

Mr. Fraser's letter of resignation, desiring that Mr. Masefield should take his place, was placed before the meeting. Mr. Masefield was unwilling to take up the post, in spite of its being urged that he was more conveniently situated for the post; and, Mr. Fraser agreeing, his resignation was withdrawn.

A letter from Mr. W F Dew, complaining that Ambawela had not had its fair share of fry and asking that the distribution be handed over from the Managing to the General Committee, was the subject of considerable discussion and was referred to the general meeting which then followed.

GENERAL MEETING.

Those present all remained for the General Meeting which followed, their number being added to by the appearance of Messrs. C De Winton and J Wickwar later on.

LETTER FROM MASKELIYA FISHING CLUB.

The CHAIRMAN read the following letter from the Maskeliya Fishing Club.

11th February 1901.

The Hony. Secy., Ceylon Fishing Club, Nuwara Eliya.

DEAR SIR,—I am requested by the Committee of the above Club to write and inform you that they understand that the original agreement between the Maskeliya Fishing Club and the Ceylon Fishing Club, as to membership and the grants of fry, no longer holds good, and that all future supplies of fry for the streams here, must be purchased by the Maskeliya Fishing Club. The members of the Maskeliya

Fishing Club will apply to the Government Agent of this Province for licenses to fish in the streams here.—Yours faithfully.

R. MACLURE, Hony. Secy., M. F. C.

Mr T FARR asked what the original agreement was.

Mr FRASER said it was that R100 should be paid to the Ceylon Fishing Club annually and that Maskeliya should get a certain proportion of the fry. Now they had their own Fishing Club, Maskeliya wants to fish in its own streams without paying any license whatever.

Mr MASEFIELD said they could not get on, unless they purchased fry.

Mr FRASER said the question was whether it was their own or Maskeliya water that they fished.

Mr FARR said it was the Ceylon Fishing Club water and that they had only a right to a certain proportion of the fry. They wanted now to fish for a license of R5 and pay nothing to the Club.

A long discussion ensued as to Government claims on streams running through private property, Mr. Farr stating that fishing from a balloon was permissible to licensees on a stream running through private property but not from the banks. The Government claim, it was mentioned, applied to all streams above 4,000 feet elevation, and all such streams, Mr. Farr stated, were leased to the Ceylon Fishing Club.

MR. MASEFIELD proposed, and Mr. T FARR seconded, a resolution that the Hon. Secretary, do write to the Maskeliya Fishing Club to explain how the matter stands and that their status is the same as that of other members of the Fishing Club.

MR. BAGOT.—That letter from Maskeliya was evidently written under a misapprehension.

LIMIT OF FISH KILLED PER SEASON.

MR. FRASER, at the Chairman's request, then brought forward his motion "That the limit of fish killed by any one member during the current season do not exceed 50 in number."

MR. FRASER said.—"You all know that some members have felt aggrieved more or less because of their being disadvantageously placed in comparison with other members of the Club and because they could not get a fair look-in in this Club. Members living in or near Nuwara Eliya kill a very large number of fish in a year. Of course we have tried to limit them before and get extra subscriptions out of them, but the thing fell through this year and we must keep up the supply. I propose, therefore, that some limit should be placed on the number of fish killed by each member and a fair limit would, I think, be 50.

MR T FARR.—How would your restrict them?

MR FRASER.—We must call for returns from each member. We must trust to the honour of members. There is no other way.

MR BAGOT.—Has any one taken fifty fish in one season?

MR FRASER.—Yes, Mr Farr got 78 last year. I am not aiming at him particularly, though.

MR BAGOT—Was pleased to hear it had been done.

MR MASEFIELD said he thought that fish caught in the lakes should be excluded. Trout was, of course, the only fish meant in the resolution. [Mr Fraser assented.] He thought that 50 would be a very good number for this season and that there should be a limit for every season fixed yearly.

MR T FARR opposed Mr Fraser's motion. He did not see how the members could be controlled. At the Horton Plains there was a register book and each man coming in could hardly fail to register his catch each day. There should, if the motion were carried, be a board of bailiffs appointed—two of them at least—and they should go up to each man and register his catch after a day's fishing, going to the houses of members if need be. They had a flagrant case of poaching to deal with that very day and, unless proper control of members were exercised in Nuwara Eliya as elsewhere, it was not fair to the whole Club. If one man could be dishonest, the whole rule fell to the ground.

MR MASEFIELD agreed that watchers should note who was fishing each day and make a point of getting their register for the days fished.

Mr FARR read a letter from Mr Cuff in which he suggested that a daily limit should be imposed. With this the meeting unanimously disagreed. Mr Cuff also wished the size of the fish caught to be increased to twelve inches.

Mr MASEFIELD said he had seen no watcher in Nuwara Eliya lately.

The CHAIRMAN said he had been engaged in the trout-house.—The opinion was expressed that at least one other watcher should be employed, when this was the case.

Places were suggested for sundry register-boxes to be kept, the idea being Mr Farr's. Mr Fraser mentioned scandal corner as the most suitable place for the Nuwara Eliya stream. Mr Masefield urged that the Managing Committee could arrange these details.

Mr FRASER'S motion was then carried, the Nuwara Eliya and Barrack-Plain lakes being expressly excluded from this new rule limiting the number of fish caught for the current season to 50.

A FLAGRANT CASE OF POACHING.

Mr MASEFIELD said that the watcher's duty would include the watching for fishing for trout with worms. Such a case had been seen of late and he asked Mr. Johnson to give the facts.

Mr. JOHNSON said that he had seen Mr. —— (a member, whose name was mentioned, but not to be published) fishing for trout about two or three weeks ago in the Barrack Plains, with worm bait, just where he was going to fish. He warned the offender it was against the rules, though he hadn't them with him; but agreed not to report him, as Mr. —— professed ignorance of them. The float ran away as they were speaking and a big trout was landed with the worm-bait. Last Sunday he had seen Mr. —— fishing just below the big white bridge on the Government Road. His own podian pointed out the "gentleman who fished with worms" and he accosted Mr. —— again, saying he would report him this time. Mr —— of course asked him not to, and asked what would come of it. He said that would be for the meeting to decide. That was all the story he had to tell.

Mr. FARR:—A very bad case.

Mr. MASEFIELD.—He must be asked for an explanation, and (if this is unsatisfactory) resignation of membership.

Mr. BAGOT.—Yes, without further explanation. He has a whole salmon roe he uses, too; and invites his friends down to join in his huge hauls. With salmon roe it is even worse than with worms.

Mr. FRASER.—His bag was 45 lb 14 oz. in March.

Mr. BAGOT.—Yes. I've seen that in writing.

Mr. de WINTON.—He fishes time after time in still water.

On the CHAIRMAN'S suggestion, it was resolved in the name of the Club) to ask Mr.——— for an explanation and, if it was not satisfactory, to cancel his membership.

LETTERS FROM MR. FARR.

The following letters were then read from Mr. Farr, by the Chairman. They were read piecemeal and discussed, but we give the letters as they stand:—

———

North Cove, Bogawantalawa, March 16.

The Hon. Secretary, Ceylon Fishing Club.

DEAR SIR.—(1) Has any rule been made about the taking of rainbow trout this year in Newara Eliya or elsewhere or is the old rule of last season "that they are to be returned to the water" to hold good?

I am of opinion that last season's rule should remain in force or, should this not meet with the approval of the majority, that the limit for these fish be raised to 12".

(II) I wish to propose the opening of the upper reaches of the Horton Plains stream. This water has been closed now about 2 years, with what object it is difficult to imagine, for it is, I should say, the very worst breeding ground on the Horton Plains.

(III) Is the close season on the Horton Plains to commence on the same day as at Nuwara Eliya or is it to be deferred until November 30th, 1901.—I am, Sir, Yours faithfully THOS. FARR.

———

North Cove, Bogawantatawa, April 20.

The Hon. Secretary, Ceylon Fishing Club.

DEAR SIR,—I find members are retaining all rainbow trout of 11 inches and upwards—would you kindly send a notice of the resolution of the managing Committee.—Yours faithfully, THOS. FARR.

[The resolution was that rainbow trout of above 12 inches only should be taken.—ED..

SIZE OF FISH.

Mr FARR urged his proposal that the size-limit of rainbow trout taken should be raised to 12 inches.

Mr BAGOT asked what the difference in weight was. Mr Farr said he had caught one 15 inches long weighing 1¼lb; and Mr Fraser 15 inches, weighing 1lb 7oz. Mr Farr added that 11-inch. fish were very good to return. Mr Fraser seconding, this was carried.

FENCED AREA IN THE HORTON PLAINS.

Mr FARR said, with regard to the stream in question, it was very muddy, had very steep banks and little sand. The fish caught there tasted muddy and were black underneath.

Mr BAGOT asked when these upper reaches were first reserved.

Mr FRASER said 2 years ago.

Mr FARR said no fry were put there for fear they should be eaten.

Mr FRASER proposed they should be kept closed indefinitely, the black appearance of the fishes indicating that they were ready to spawn and went to this quarter on that account. There was no better breeding ground in Ceylon. Mr Bagot saying that, if trout were going to breed, they would breed anywhere (except in deep water), Mr Fraser urged that, though this was true, if they *were* going to reserve any portion, these upper reaches were best suited for reserve water.

After discussion Mr. FRASER withdrew his amendment, and Mr. Farr moved that the upper reaches of the Horton Plains stream be thrown open, but that the tributaries throughout the Plains be closed water.

CLOSE SEASON FOR 1901-2.

Mr. FARR said he wished to see the Open Season prolonged, as it had been curtailed by a month at the beginning.

The meeting agreed to the fixing of the season for the Central Province from October 31st to the end of February; and for the Sabaragamuwa Province from November 30th to March 31st.

OVA.

The CHAIRMAN stated they had ordered three consignments of Ova from the Earl of Denbigh's, the Wyresdale, and New Zealand hatcheries, of 15,000, 10,000, and 5,000 ova each. The first were received, the second were not sent after all, and for the third the order had not yet actually been sent off. He read the following from the Wyresdale fishery Co:—

The Wyresdale Fishery Co., Ltd., Scorton, Garstang, Lancashire, April 2nd.

E M de C Short, Esq., Hon Secretary, Fishing Club, Eluja, Colombo, Ceylon.

DEAR SIR,—I was very sorry that the matter of the rainbow ova to be sent by our firm to your Club fell through at the last moment. We communicated with the P & O Co., as well as the Orient, and although we did our best to arrange matters they point blank refused to carry the ova to Colombo. I then made a special journey to Liverpool to consult with the Bibby Line, whose Manager I saw, and he very kindly undertook to do everything possible for us, but as your instructions were so emphatic about receiving the fish before the 15th of March no boat was available which would land the ova at Colombo before the latter end of March or early in April.

I suggested to Mr. Leeming, as an additional assurance that the ova would land in Colombo in fairly good condition, and so as to shorten the sea voyage, that he would allow us to send one of our staff to Marseilles to hand over the ova to the steamboat authorities there, as by this means we would reduce the voyage by five or six days.

Perhaps you will kindly communicate with me by and bye, and let me know whether your Club would care to place an order with us for execution next season. We would be quite willing to share in the expense of one of our staff going to Marseilles, or if you cared we might consider whether it were advisable to send you Alevins, that is, of course, the fish, directly they hatch out, before their umbilical sac is absorbed.

When you write me, please let me know what sort of temperature you would have in Ceylon, say about the beginning or middle of May.

I am very sorry that this year's order has fallen through, but we still hope to see our rainbow breed of trout introduced into Ceylon.—Yours trnly,

ANDREW HENRY, Secy.

The Chairman mentioned that Mr. Elhart had found the Denbigh ova excellently kept on board, but that nothing came of them. They now had 1,500 fry for distribution. They would certainly be glad to send another order to Wyresdale hatcheries but the question was what was to be done about the Denbigh order which had failed.

After discussion it was resolved (1.) to send another order to Wyresdale Co. and (2.) as it was against their positive instructions that the Denbigh consignment was packed, they (the Ceylon Fishing Club) desired to know what they proposed to do.

DUTY ON OVA.

The discussion on this evaporated in a few minutes, it being found that the duty was very

slight (R35 in each case) and not worth the request for a concession.

AMBEWELLA'S SHARE OF FRY.

The letter from Mr. W F Dew, complaining that Ambewella was not sufficiently served with fry last year, and asking that the General and not the Managing Committee, distribute the fry, was then considered. The letter was held to be out of order, not being addressed to the Managing Committee, nor given notice of as a motion. Another letter from Mr. Maudslay was answered but contained no points of importanee. The meeting lasted 2½ hours.

MEETING OF THE CEYLON KENNEL CLUB.

HELD AT NUWARA ELIYA ON THE 8TH MAY.

The Board room of the Hill Club was obligingly plaeed at the disposal of the members and though fixed for an early hour it was late before suffieient members attended to form the necessary quorum. A Committee meeting preceded the general meeting, at which Capt. Farquharson was in the chair, those present being Messrs. J A Henderson, W Saunders, H A Oliverson, J B Coles (Hon. Secretary) and J Wickwar.

The previous minutes &c., were read and confirmed.

THE GENERAL BUSINESS OF THE DAY.

Capt. FARQUHARSON resumed the chair and informed the meeting in a lucid but summary manner, mueh appreciated by his hearers, of the present state of the Club, whieh the speaker said was financially on a firm basis, though the figures given were disappointing as to the amount of co-operation reeeived outside the Assoeiation

There were 147 members, and Dogs Registered equal 163, and R156·20 to credit of Club. Subscriptions overdue, which were a good many, amounted to R14 and many members had been lost owing to the departure of the Ceylon Contin gent for South Africa.

THE LOSS AT THE KANDY SHOW

was R549·82, whieh was more favourable than the exhibition held later in

COLOMBO SHEWING FURTHER DEFICIT,

10 Entries costing R844·84.

MR. STURGESS CONSENTS TO CONTINUE

giving his valuable services to the Club as Veterinary Surgeon.

NEW PRIZES.

These eonsisted of a valuable one, kindly offered by H E the Governor; another by H E the Offieer Commanding the forces for the best dog exhibited by a soldier; and a 3rd prize given in a most sporting liberal manner by Mr Oliverson, value R160, for the best elass of harrier.

BALANCE AND ACCOUNTS

These were passed round, approved of, and duly passed.

PROGRAMME AND VENUE FOR NEXT SHOW.

Originally it was intended to hold this in Kandy but, owing to the postponement of the R A and C C, the place was altered to Colombo, but the date was not fixed; but it would be in August previous to the Horse show

DIFFERENCE IN CLASSES.

These had been eonsiderably altered and will no doubt be fully advertised. As a summary I give the prineipal ones to suit all breeders, being intended to "feteh" those outside the sporting circle.

1st—Toy Dogs—value off for weight.

"This should interest the ladies," said Capt. Farquharson whose genial and gallant presence is ever welcomed at all meets; 2nd. A prize for the best dog belonging to a soldier and the 3rd by Mr. Oliverson, as before mentioned, for best country-bred Harriers who have never won a 1st prize.

ENTRANCE FEES REDUCED

to R1 for members and R2 for non-members was a sum which would make no serious call on the public purse and should be popular.

ELECTION OF OFFICE-BEARERS

Mr. Wm. Saunders proposed Capt. Farquharson, as vice-president, in the place of Mr. Price who was away, and Mr. Henderson as Hon. Secretary, as Mr. Coles felt he was too far away to meet the interests of all. Eulogistic references were made to both these gentlemen. Captain Farquharson having always showed much zeal in all questions of sport and towards the Kennel Club, and Mr Henderson had not only rendered Yeoman service according to the retiring Secretary but he had held an acting office on previous occasions. Both these gentlemen were unanimously eleeted and with a hearty vote to the Chair the meeting closed but not without an enthusiastie offer of thanks to Mr. Coles who was not only the originator, but the promoter of the Kennel Club, and to whom was due its present satisfactory position. Mr. Coles duly returned thanks to Mr. Henderson and all members, who had given him their most cordial eo-operation.

PLANTING NOTES.

THE DISTRIBUTION OF PLAGUE VACCINE IN INDIA.—Bombay, 28th April.—5,147 doses of plague vaccine were sent out from the Plague Research Laboratory, Parel, last week. Of these over 2,000 went to Gurdaspur and Sialkot District, 1,407 to Simla for the Punjab, 1,000 to Karachi, and 593 to the German East Africa Government.—*Madras Mail.*

"GAMPOLA AND THE COFFEE REGIONS," was the title adopted by Sir Emerson Tennent for his principal chapter on the Planting Enterprise; but in his day there was not even a bridge over the Mahaweliganga and the ferries at Gampola and Katugastota were great obstacles to traffic, only swept away by Sir Henry Ward.—Mr. Cottam elsewhere tells us a good deal about the estates now found on every side of Gampola and makes interesting comparisons and references to the past of a more recent day than Tennent's.

CARDAMOM CULTIVATION. — Considerable fears were entertained that the planting of cardamoms had of late years been overdone in Ceylon and that our present Directory returns would show a very heavy excess over the last record. We hasten at the earliest possible moment to say that the Directory returns do not bear out this view—that the increased acreage is comparativcly moderate and that, so far as Ceylon is concerned, we do not think there is any fear of overdoing this product. The case may be different in Southern India as a whole, although Travancore does not show increased crops.

THE STANDARD TEA COMPANY OF CEYLON, LIMITED.

TENTH REPORT OF THE DIRECTORS.

To be submitted at the general meeting, to be held on Thursday, 25th April, 1901, at noon, at the offices of the Company.

The Directors submit Statement of Accounts to 31st December, 1900.

The Profit and Loss Account shows a profit on the working of the Estates in Ceylon of £14,085 3s 9d, which, with the amount brought forward from last year, less interest and home charges, shows a sum of £12,948 1s 3d available for division. In August, 1900, the Directors, under the powers entrnsted to them, distributed an interim dividend for the six months ending 30th June, 1900, of 5 per cent (10 per cent per annum), absorbing £2,975. They now recommend a Dividend at the rate of 10 per cent (making 15 per cent for the year) absorbing £5,950; the placing £1,400 against reserve, and £1,400 against depreciation; and the carrying forward to the next year £1,223 1s 3d.

The Coffee crop was 225 cwt.; it realised about £700.

The Tea crop was 1,129,753 lb., against 918,148 lb. in 1899.

The average Exchange for the Company as drawers in Colombo was 1/4 7-32 against 1/4 9-32 in 1899, and 1/4 5-32 in 1898.

Prices for Ceylon Teas were again generally lower this last season. Of the Company's Teas produced during 1900; those from the St. Leonard's factory sold at about the same average price as the 1899 Teas; those from Gordon, 1d per lb. lower; those from Gouravilla, $\frac{7}{8}$ per lb. lower.

The Company's properties at the close of 1900 were 3,466 acres, with 2,150 acres of Tea considered in full bearing, viz.:—

	Acres.	Tea bearing. Acres.
In Udapussellawa—St. Leonards and Coneygar...	902	530
Liddesdale..	814	200
Eskdale ..	240	227
Gordon ..	386	304
Tulloes ..	419	275
In Up. Maskeliya—Gouravilla and Up. Cruden	705	614

There are also 318 acres Tea in partial bearing, and some 41 acres in addition planted with Tea. Mr. Robert Kay-Shuttleworth. the Director, who retires by rotation, being eligible, offers himself for re-election.

By order, A TRAFFORD BROOKE, Secretary.

25, Fenchurch Street, London, 11th April, 1901.

KELANI VALLEY TEA ASSOCIATION, LIMITED.

REPORT OF THE BOARD OF DIRECTORS.

To be presented to the shareholders at their fifteenth ordinary general meeting, to be held at the Office of the Company, on Monday, 15th April, 1901, at 12 noon.

The Directors beg to submit to the shareholders the report and accounts of the Company, duly audited, for the year ending 31st December, 1900. The total crops from the Company's four estates amounted to 662,248 lb. against 575,255 lb. in 1899; the average price realised was 5·794d per lb. against 7d, and the average rate of exchange was 1s 4 27-64d as compared with 1 4 25-64d for the previous year. Owing to the very depressed condition of the Tea Market during the last six months of the past season, the profit earned for the year under review compares most unfavourably with that secnred in previous years, but with an improving market, a natural shortfall in crops, and the steps now being generally taken to further reduce output and improve quality, your directors have good reason to expect that very different results will be shewn for the current, and, it is to be hoped, succeeding seasons.

Including £419 2s 5d brought forward from 1899, the net profit for the past year amounts to £1,019 14s, from which has to be deducted the Interim Dividend of three per cent, £562 19s paid in September last, leaving £456 15s, available, and this sum it is proposed to carry forward to next season's account.

Debentures to the amount of £2,100, which matured on the 1st January, 1901, have been renewed for a further period of five yeas at five per cent per annum.

Two vacancies have occurred on the Board, one caused by the resignation of the Hon. D A C Scott, on account of ill-health, the other by the regretted death of Mr. Donald Andrew.

It is not proposed at present to fill the first-named vacancy, but, to occupy the seat of their deceased colleague, Mr. Donald Andrew, your Directors have appointed Mr. George Gray Anderson, who, in accordance with the articles of Association, retires from the Board at this time, and being eilgible, offers himself for re-election.

Mr. J B Laurie, C.A., also offers himself for re-election as Auditor.

G. W. PAINE, Chairman.

16, Philpot Lane, London, E.C., 3rd April, 1901.

THE EASTERN PRODUCE AND ESTATES COMPANY, LTD.

Report, to be presented at the Fourteenth Ordinary General Meeting, to be held at Winchester House, Old Broad Street, at 12 o'clock noon, on the 24th April, 1901.

The Directors submit Report and Balance Sheet for the year ending 31st December, 1900.

The profit for the year is £19,723 17s 1d, which, added to £9,807 7s 8d, balance from last account, amounts to £29,531 4 9

From this has to be deducted:—			
Interest on Debentures	£3,937 10 0		
Debentures for £7,500 drawn and paid off, with bonus of 5 per cent, on 31st Dec. 1900	7,875 0 0		
Interim Dividend of 2½ per cent on Preferred and Ordinary Share Capital, paid 5th Nov. 1900	7,475 1 6		
		19,287 11 6	
leaving a balance of ... which it is proposed to apportion as follows:—		10,243 13 3	
Final Dividend on the Preferred Shares of 2½ per cent, making 5 per cent for the year, and on the Ordinary Shares of 1 per cent, making 3½ per cent for the year	3,001 6 6		
Balance to be carried forward as provision for retirement of Debentures in the current year	7,242 6 9		
		£10,243 13 3	

It may not be out of place to remind the Shareholders that of the balance of £80,000 Debentures, now outstanding, in terms of the issue only £30,000 have to be paid off compulsorily out of profits by

annual drawings of not less than £7,500. As shown in the schedule below the Company, on 31st December last, and 10,960 acres under Tea cultivation of which 10,093 were over four years old. The yield of Tea in 1900 was 4,045,146 lh, the average gross sale price being 6·5d as compared with 7·29d in 1899. To this fall of about ¾d per lb, which corresponds closely to the general average decline in price of Ceylon tea for the same period the Company's diminished profit for the past year is almost wholly due. In the face of so serious a decline in value due to over production in India and Ceylon no efforts by estate proprietors are being spared both independently and in combination to restrict the output of Tea hy finer or more careful plucking and hy other methods which have commended themselves to the Joint Tea Associations of both countries. At the same time the efforts to promote the further consumption of Indian and Ceylon tea outside the United Kingdom are heing actively continued with the same encouraging success as heretofore. The average rate of exchange for the year was 1s 4 7-16d as compared with 1s 4⅛d in 1899.

In view of the exceptional conditions affeoting the profits in 1900, the amount written off for depreciation of buildings and machinery has been calculated at one half the scale hitherto adopted.

It is with much regret that the Directors have to inform the Shareholders of the death, in Decemher last of their valned colleague and chairman, Mr C J Liudsay Nicholson. The vacancy therehy occasioned on the Board has heen filled hy the appointment of Mr G A Talbot, who in accordance with the Company's Articles of Association will retire at the General Meeting and will he proposed for re-election. In accordance with the Articles of Association, two of the Directors, Mr David Reid and Mr Norman W Grieve, retire from office, and being eligihle, offer themselves for re-election. The retiring Auditors, Messrs Welton, Jones & Co., offer themselves for re-election.

RALPH A. CAMERON,
Chairman and Managing Director.

—41, Eastcheap, E. C., 10th April 1901.

,, Forest, Grass and uncultivated Land	4,543
Total ..	16,532

NYASSALAND COFFEE CO., LTD.

The report of the Directors for the past year is as follows:

ACREAGE.

468 acres estimated as in cultivation.
2,908 do Reserve.

Total 3,376 acres more or less.

The Direotors beg to submit the accounts for the year ending 31st Decemher, 1900, from which it will he seen that season's working has resulted in a defioit of R20,569·76, thus further increasing the indebtedness of the Company to the Agents and Secretaries, Messrs. Carson & Co.

The total orop secured amonuted to 896 bushels parchment coffee, but owing to abnormally dry weather experience while the orop was on the trees the ont-tnrn was very unsatisfactory, the proportion of light and damaged beans being nnnsually large Of the 633 acres described in last report as under cultivation, a careful analysis made by the Company's Manager shows that 121,736 trees equal to say 100 acres are in hearing, and 177,860 trees equal to say 148 acres are of one and two years old the difference say 385 acres representing the vacancies in the cultivated area eqnal to 220 acres, and 165 acres actnally abandoned. The Manager's Estimate of Expenditnre for the current year is £995 19s 6d, against an estimated crop of 10 tons, which may possibly yield £400, and the season's working will thus result in a deficit of £595 19s 6d. The 1901 crop is to be gathered from 100 acres in hearing, assnming that the 148 acres of yonng coffee trees yield at the same rate in 1902, our crop for that year shonld amonnt to say 25 tons worth say £1,000, if this is obtained there would be a slight profit on the 1902 working, with prospects of larger crops and increased profits in succeeding years as the vacancies supplied up during the recent rains amounting to say 220 acres come into bearing. Scarcity of lahour has precluded the Manager from keeping the land clean, and he ascribes the large number of failures to the plants being choked hy weeds.

The Manager writes under date 11th January :— "I am planting rubher in most of the clearings this month."

As will he seen from the Balance Sheet the Company was indebted to Messrs. Carson & Co. as at the 31st Decemher to the extent of R25149·21, and a further snm of R9,091·29 has heen advanced since that date, making a total of R34,240·50. As intimated to the shareholders in copies of letters which were circnlated by order of the Directors, Mesrs. Carson & Co. have demurred to financing the Company after 31st March last, and failing some scheme being adopted with a view of providing funds for the liqnidation of their advances and for the carrying on of the Company, they will take steps to recover the amount due to them hy such means as they think advisahle, and by a forced sale of the Company's property if necessary. In the latter alternative the return to the shareholders of the capital invested will prohahly he very small, and it is nrged that they should in their own interests support the scheme put forward by the Directors for carrying on the Company.

In terms of the memorandum and articles of Association of the Company, Mr W Shakespeare retires from the Directorate and does not offer himself for re-election. The appointment of an Auditor for the current year rests with the meeting.

THE CRAIGHEAD TEA COMPANY.

The Directors have the pleasure to snbmit the Balance Sheet and Accounts of the Company for the year ending 31st December 1900, dnly andited,

The mortgage was reduced to £3,600 hy the payment of the second instalment of £450 on the 30th June last. This sum is dehited to profit and loss acconnt, and is an ample charge for depre-ciation.

To complete the withering shed and to meet the cost of an oil engine, a new roller and drying machine, amonnting in all to £1,173 15s 5d, which has been debited to Estates Acconnt, one hundred of the unissned six per cent Preference Shares, ranking for dividend from the 1st July last, were offered to and subscribed for shareholders at par.

The increased accommodation and new machinery provided will enable the Manager to deal satisfactorily with the increased yield from the younger fields now coming into bearing.

The total yield, excluding 6,500 lb. made from purchased leaf, was 395,105 lb. Tea, and the gross average price obtained in London was 6·85d per lb. Last year the crop was 342,250 lb. Tea, and the gross average was 7·82d per lb.

	£ s d	£ s d
The Net Profit for the year amounted to	2,272 6 3	
To which has to be added the Balance last year of	636 9 3	
		2,908 15 6
Interest on the Mortgage has been paid	191 5 0	
The Second Instalment of the Mortgage (£4,500) has been paid	450 0 0	
Dividend on the Six per cent. Preference Shares for the year has been paid	451 16 0	
An Interim Dividend of 2½ per cent. on the Ordinary Shares, free of Income Tax, has been paid	572 15 0	
It is proposed—		
To pay a final Dividend of 2½ per cent., free of Income Tax, on the Ordinary Shares, which will require	572 15 0	
And to carry forward the Balance of	670 4 6	
		£2,908 15 6

Colonel Robert Hugh Wallace, the Director who retires on this occasion, being eligible, offers himself for re-election.

Mr. J. Hamilton Alston, the Auditor, also retires, and offers himself for re-election.

By Order of the Board, ROBERTSON, BOIS & Co.,
Agents and Secretaries.

London, 10th April 1901.

The approximate acreages are as follows :—

EDERAPOLA TEA COMPANY OF CEYLON LIMITED.

REPORT OF THE BOARD OF DIRECTORS.

To be presented to the shareholders at their fifth ordinary general meeting, to be held at the Office of the Company, 16, Philpot Lane, London, E.C., on Wednesday, 8th May, 1901, at noon.

The Directors beg to submit to the shareholders the report and accounts of the Company, duly audited for the year ending 31st December, 1900.

Inclusive of 22,097 lb. made tea from bought leaf, the total out-turn from the three factories amounted to 554,430 lb. showing an increase of 88,281 lb. compared with last season.

The average price realised was 5·803d. per lb. as against 6·959d. per lb. last year, and the average rate of exchange was 1/4 27/64ths, the same rate as that for 1899.

Your Directors have to inform you that the formal agreement between the Company and the contractors engaged in Plumbago mining at Ardross, referred to in last report, was duly completed, and considerable progress has been made and expenditure incurred by the miners in tunneling, though the output of plumbago up to the present has been small.

The low prices current in the tea market for the latter part of the past year are responsible for the shrinkage in the profit earned, but there is every reason to expect that, consequent on the steps now being generally taken both in Ceylon and India to restrict output and improve quality, the results for the current year will be more satisfactory.

The net Profit for the year amounts to £1,389 9s 8d., which, with £138 7s 0d brought forward from last year, gives £1,527 16s 8d to be now dealt with, and this it is proposed to apportion as follows :—

Amounts as above		£1,527 16 8
Interim dividend of 3 per cent (free of Income Tax) paid in September, absorbed	£765 0 0	
To write off expenditure for the year on Development Account	341 1 7	
		1,106 1 7
To carry forward to next account		£421 15 1

Mr. James Bett, having accepted an appointment in Ceylon, has resigned his seat at the Board, but it is not at present intended to fill the vacancy thus created.

In accordance with the articles of Association, Mr. George W Paine retires from the Board at this time, and, being eligible, offers himself for re-election.

Messrs. Cape and Dalgleish, C.A., also offer themselves for re-election as Auditors.

G W PAINE,
Chairman.

16, Philpot Lane, London, E.C., 18th April, 1901.

BURNSIDE TEA COMPANY OF CEYLON, (LTD.)

REPORT OF THE BOARD OF DIRECTORS.

To be presented to the Shareholders at their Fifth Annual Ordinary Meeting, to be held at the Office of the Company, 16, Philpot Lane, London, E.C., on Tuesday, 7th May, 1901, at 11 a.m.

The Directors beg to submit the Shareholders the Report and Accounts of the Company duly audited for the year ending 31st December, 1900.

The total crop secured from the four Estates was 402,113 lb. Tea as against 378,608 lb for last year, and 52½ maunds of Tea seed were obtained and sold, as against 62 maunds in 1899.

The average price realized for Midlothian Tea was 7·679d per lb; for the Burnside Group, 5·982d per lb; and for the whole crop, 6·297d per lb, as against 7 3-16d per lb for last season; and the average rate of exchange was 1/4 29-64d against 1/4 13-32d.

The results for the half-year ending 30th June last fully justified your Directors in paying an Interim Dividend of 2 per cent., but the fall in the Market for Tea during the last half of the year so seriously affected the position, that instead of the profit estimated, a loss on the working has been realized of £139 15s 4d, and the final result, as shewn in the Balance Sheet, is a deficit of £324 15s 4d, carried forward to next account.

In view of the efforts now being made, both in Ceylon and India, to restrict output and to improve the quality of the Tea produced, your Directors expect that the results for the current year will be very different, and they feel sure that the Superintendents of the Company's Estates will do all in their power, by careful and economical working, to reduce the cost of production.

In accordance with the Articles of Association Mr George Gray Anderson retires from the Board at this time and, being eligible, offers himself for re-election.

Messrs Cape & Dalgeish, C.A., also offer themselves for re-election as Auditors.—By order of the Board,

LYALL, ANDERSON & Co.,
Agents and Secretaries,

16, Philpot Lane, London, E.C., April 19, 1901.

NUWARA ELIYA ESTATES COMPANY, LIMITED.

REPORT OF THE DIRECTORS.

The Directors beg to submit the Accounts of the Company to 31st December, 1900, to which is appended the Certificate of the Auditors.

The Crop Accounnt shows a working profit of £23,623 6s 11d, from which has been written off, as nsual, the expenditure during the season on additions to Buildings and Machinery, of £2,352 14s 3d, leaving a credit of £21,270 12s 8d, against £20,271 16s 1d in 1899.

The Profit and Loss Account, incldng the sum of £2,599 0 10d brought forward from the previous season, shows a credit of £20,861 2s 3d. From this amount £2,000 has been written off the cost of the Estates, and £962 15s 2d has been used to finally close the "Cost of Sundry Leases" Account.

There remains for distribution the sum of..		£17,898 7 1
An Interim Dividend of 3 per cent free of Income Tax, was paid on 11th October, 1900, absorbing	£6,000 0 0	
It is now proposed to pay a final Dividend of 4 per cent, free of Income Tax, making 7 per cent for the year, which will absorb a further... ...	8,000 0 0	
		£14,000 0 0
And to carry forward the balance of		...£3,898 7 1

The weather during the year was favourable to yield, and the Crop of Tea from the Company's Estates was 1,458,911 lb. The average net price realized was 8·66d against 8·62d in 1899.

The average rate of Exchange for the year was 1s 4⅛d per Rupee. The cost of placing the crop free on board Steamer, or delivering to buyers in Colombo, was 4·82d per lb., which cost includes Commission to Superintendents, the rent of leased lands, as also the upkeep of 172 acres Tea not in bearing.

The following table shows the resnlts of the working of the different Estates for the past year :—

Estate.	Acreage in bearing in 1900. Partial.		Crop.	Average yield per bearing acre.	Net price realized per lb. Tea.	Profit per bearing acre.	
			lb.	lb.	d.	£	s d
Park ..	242	22	172,128	652	9·50	14	6 8

Naseby ..	176	15	101,779	532	8·34	6	0 1
Pedro ..	345	143	312,722	640	8·20	10	0 3
Concordia ...	288	132	220,693	525	9·17	8	15 9
Court Lodge..	302	66	200,711	545	9·23	10	16 8
Hethersett ...	367	25	221,501	565	7·84	6	13 0
	2,020	423	1,458,911	597	8·66	9	13 5

The yield from Tea in full bearing was 644 lb. per acre, and that of Tea in partial bearing 371 lb. per acre, as compared with 605 lb. and 362 lb. respectively in the previous year.

With young Tea coming into bearing in 1901, the acreage of the Company's properties stands as under :—

	Acres.	Acres.
Tea in full bearing ...	2,045	
do do leased lands ..	98	
do partial bearing ..	400	
do not yet in bearing ...	72	
Total land nnder cultivation with Tea		2,615
Jungle, Patna and Scrub, and Fuel Trees, &c.		432
		3,047

The Reports received from Ceylon point to the Estates being in excellent condition, and the Directors desire to record their appreciation of the good work done by the Planting Staff and by the Company's Agents.

The retiring Directors are Mr. Alexander Thomson and Mr. W Megginson, who, being eligible, offer themselves for re-election.

Messrs. Cooper Brothers & Co., Chartered Accountants, offer themselves for re-election as Auditors of the Company.

By order of the Directors,
FRITH, SANDS & Co.,
London, 19th April, 1901. Secretaries.

THE RANGALLA TEA COMPANY OF CEYLON, LTD.

REPORT OF THE DIRECTORS

for the year ending 31st December, 1900, to be submitted at the annual general meeting of shareholders to be held at the Office of the Company, on Monday, 29th April, 1901, at 11-30 a.m.

The Directors beg to submit the Balance Sheet and Profit and Loss Account for the year 1900.

The net profit for the year amounts to		£1,458 12 11
To which has to be added the balance brought forward from 1899 ..		333 19 8
		£1,792 12 7
An Interim Dividend of two per cent was paid on 10th September, 1900, absorbing ..	£440 0 0	
And the Directors now propose to deal with the balance as follows :—		
1. In writing off from cost of Properties, as Depreciation of Machinery, &c, ..	£500 0 0	
2. In payment of a Final Dividend (free of Income Tax) of two per cent (making four per cent for the year)	440 0 0	
3. In carrying forward the balance of ..	412 12 7	
		£1,792 12

The tea crop amounted to 218,572 lb., and the cardamoms to 1,828 lb. (or 1,664 lb. net), as against the original estimates of 220,000 lb. and 4,000 lb. respectively. The bought leaf was 17,770 lb., making a total for the year of 236,342 lb. of tea. The sales of tea show a net average price per lb. of 6·46 pence, being equal to say, 39 cent per lb., the cost being 5·04d, or 30 cents per lb. f. o. b. Exchange for the Company's drafts during the year has averaged 1s 4 39-64d, as against exchange for 1899 of 1s 4 9-16d.

The following table gives the acreage of the estates for the last five yeears :—

	1896.	1897.	1898.	1899.	1900
Tea in full bearing	591½	591½	591½	591½	673
Tea in partial bearing ..	63	63	90	90	22
Tea not in bearing.	61½	61½	34½	34½	21
Cardamoms ..	55	56	56	55	46
Cardamoms not in bearing ..	—	—	10	14	38
Grass and Felled Timber ..	25	25	25	25	25
Forest and Waste Land ..	444	444	434	430	416
	1,241	1,241	1,241	1,241	1,241

The following is a Statement of the tea and cardamom crops, with the yield of tea per acre for the same period :—

	Tea.	Cardamoms.	Yield of Tea per Acre.
	lb.	lb.	lb.
1896 ..	228,360	4,842	380
1897 ..	212,555	8,291	360
1898 ...	206,620	4,026	349
1899 ..	211,361	4,211	357
1900 ..	218,572	1,828	325

The prospects for the current year are so far satisfactory, the estimated yield being 235,000 lb. of made tea and 3,000 lb dry cardamoms. According to advices from Ceylon, the yield for the first two months of the present year was 5,000 lb. made tea in excess of the corresponding period last season.

Mr. William Keswick, M.P., retires from the Board, in accordance with the Articles of Association, and, being eligible, offers himself for re-election.

The Auditors, Messrs. W B Peat & Co., also offer themselves for re-appointment.—By order of the Board, W. H. BARTLETT, Secretary.

London, 19th April, 1901.

THE YATIYANTOTA CEYLON TEA COMPANY, LIMITED.

REPORT OF THE DIRECTORS

to be submitted at the fourth annual general meeting of shareholders, to be held at the London Commercial Sale Rooms, 30 to 34, Mincing Lane, London, E.C., on Thursday, the 25th April, at 12 noon :—

The Directors now beg to submit their report, and the duly audited accounts of the Company, for the year ended 31st December, 1900.

The plucking area, in full and partial bearing, was 2,854 acres, from which crops were secured amounting to 1,470,590 lb. In addition, 5,835 lb were made from purchased leaf, giving a total crop, as shewn in the Estates' Working Account, of 1,476,425 lb. Of this quantity, 701,430 lb were sold in Colombo, and 774,995 lb were shipped to London; the net average realized for the whole being 4·56d per lb. Including purchased leaf, the average cost, f.o.b. (or delivered to buyers in Colombo) was 3·40d per lb, and the average rate of exchange for the year was 1s 4 7-32d per rupee.

Tho following is a comparative statement of the past three year's working :—

Year.	Acreage plucked, Mature, and in partial bearing.	Crop secured from Company's Estate.	Yield per Acre.	Average Rate of Exchange per Rupee.	Cost of Crop per lb.	Net Average sale Price per lb.
		lbs.	lbs.	s. d.	d.	d.
1898	2.240	1,135,794	507	1 4 5-64	3·62	5 35
1899	2,376	1.343,387	565	1 4 5-16	3·48	5·65
1900	2,854	1,470,590	515	1 4 7-32	3·40	4·58

The lower yield per acre last year is due to the large proportion of young tea not in full bearing, viz, 500 acres out of the plucking area of 2,854 acres. The Directors regret that the result of the year's working shows a considerable falling off as compared with that of 1899, but it will be seen from the above figures that this is attributable to the fact that the Company's teas, in common with those of all low-country properties, have shown a very marked decline in value, especially during the last six months of the year,

The net profit for the year amounts ...	£6,753 4	2
To which has to be added balance from 1899 account ..	2,896 11	1
	£9,649 15	3
Dividends have been paid as follows :—		
On the preference shares at 6 per cent per annum—		
On 1st July, 1900. and 1st January, 1901, viz :— ..	2,700 0	0
On the ordinary shares—		
In October, 1900, an interim dividend of 2 per cent was paid, which absorbed	1,800 0	0
	£4,500 0	0
Leaving now to be dealt with ..	5,149 15	3
This the Directors propose to apportion as follows :—		
(1) In payment of a final dividend on the ordinary capital of 2 per cent (free of income tax), making in all 4 per cent for the year..	£1,800 0	0
(2) In writing off cost of properties, including depreciation of Machinery and buildings ...	1,000 0	0
(3) In carrying forward to 1901 the balance of	2,349 15	3
	£5,149 15	3

The following are details of the acreage of the different properties as on 1st January, 1901 :—

	Acreage under Tea.			
Estate.	Bearing.	Partial Bearing.	Total.	Forest Reserves, &c.
Polatagama	687	104	791	251
Weoya and New Polatagama	632	95	727	345
Walpola	821	50	871	145
Rondura	496	85	601*	629
	2,636	334	2,990	1,370

* 20 acres not yet in bearing

The Directors trust that the steps which are now being generally taken to reduce output, in which on behalf of the Company they have signified their willingness to join, will result in again placing the tea industry on a satisfactory basis, and that the accounts for the current year will admit of a better return to the shareholders. In terms of the Articles of Association, Mr C Young retires from the Board, and, being eligible, offers himself for re-election. Messrs. Cape & Dalgleish, C.A., offer themselves for re-election as Auditors of the Company.

GENERAL CEYLON TEA ESTATES, LTD.

The Directors beg to submit herewith the Accounts of the Company and their Report for the year ending December 31st, 1900, showing a profit of £8,560 12s 4d.

After allowance for debenture interest and other charges, there remains a sum of £713 17s 3d. at the credit of profit and loss, to which has been added a balance of £1,779 6s 8d. brought forward, from the previous year making a total of £2,493 3s 11d. out of which the directors have written off £2,000 on account of depreciation of plant and machinery, and propose to carry forward the balance of £493 3s 11d. The crops from the Company's estates amounted to 2,525,088 lb. tea, exclusive of bought leaf, against an estimate of 2,532 000 lb. 2,974 bushels of coffee and 214 cwts of cocoa. The tea cost sold in London, 5.14d, and realised 5.79d per lb. The exchange for the year averaged 1s 4 11-32d. The yield per acre was 505 lb. over the fields in full bearing.

The present cultivated acreage is as follows:—			
Tea in bearing	...	...	4,933
In partial bearing	..	...	348
Not in bearing	..	..	545
Cocoa	..	..	126
Coffee	..	..	118
Total cultivated area		..	6,070 acres.

The past year, has been one of very severe trial to the tea enterprise in India and Ceylon. Prices fell towards the end of the year to a rate unprecedented in the enterprise for all but the most flavoury teas which only two of the Company's estates produce. Hence in spite of the increased crop harvested the result cannot but be considered a disappointment to shareholders. In December the Chairman Mr James Sinclair, went out to Ceylon to visit the estates and has just returned to England. He reports most favourably on the appearance and condition of the properties, which he considers compare well with other estates in the same districts. A fair and reasonable price for tea, is all that appears to be required to enable the company to make substantial profits.

The Directors regret losing the services of Mr. A Melville White, who has acted as General Manager in Ceylon since the inception of the Company, through his retirement from the Colony, and they wish to record their appreciation of his services during his tenure of the office.

Mr. F L Clements, a well-known planter of much experience, has been appointed to manage the Company's affairs in Ceylon.

As will be seen by the Balance Sheet, your Directors have waived their right, under Clause 94 of the Articles of Association, to a commission on the amount paid for Debenture Interest.

Mr. J H Carson resigned his seat on the Board during the year owing to having taken up his residence in Scotland, and his consequent inability to attend Board Meetings. The Directors do not propose filling the vacancy caused by his retirement.

Mr. T C Owen, the Director retiring by rotation, being eligible, offers himself for re-election.

Messrs. Broads, Paterson & Co., the Auditors to the Company, retire, and, being eligible, offer themselves for re-election.

James Sinclair, Thomas J Lawrance; Directors.
Rowe, White & Co., Secretaries. April, 23rd 1901.

REPORT OF THE COMMITTEE.

16, Philpot Lane, London, E.C., 18th April 1901.

The Committee appointed by the Shareholders after several meetings and a long interview with the representative of the Vendor Company and subsequent meeting with the Board on various occasions, unanimously arrived at the scheme set forth on the next page.

As it was necessary for the consent to be obtained of all the Vendor Proprietors, Mr Sinclair when in Ceylon secured that of most of those resident there, but others living in England and holding a large interest declined to agree, consequently the scheme could not be proceeded with. Mr Sinclair only returned at the end of March therefore there has been no time for the Committee to prepare any other scheme, but they are of opinion that some reduction and re-arrangement of Capital is necessary and if re-appointed would endeavour to arrive at one with the Directors and submit the same to the Shareholders at a meeting to be called for that purpose.

The Committee wish to acknowledge that every assistance has been given to them by the Directors.—A Horatio Jones, J F Kimmel, W Murray.

HEADS OF SCHEME.

The arrears of preference interest, due to 31st December, 1,900, to be satisfied by an issue of "surplus certificates" for the amount due. These to bear no interest, and to be repayable out of surplus profits after provision for debenture interest, depreciation (£2,000) and expenses and maximum interest in both classes of preference shares. All preference shares to be entitled to 5 per cent interest instead of 6 per cent as from 1st January, 1901. The preference shares to be divided into two classes—namely, preference and deferred preference. The former to take the place of those held by non-vendors, the latter of those held by vendors and sellers of the estates.

The following represents approximately the holders of Vendor and other Shares respectively. The figures might require a slight alteration on a careful scrutiny:—

	Shares.	£	
Non-Vendors	11,841	59,205	to be 4 per cent Preference.
Vendors	14,013	70,065	to be 4 per cent Deferred Preference
	25,854	129,270	

The first charge is a payment of 4 per cent on the preference, amounting to £2,368, which claim is cumulative against the deferred preference. After this, 4 per cent, or as much as is available to be paid on the £70,065 deferred preference shares, requiring £2,802. Should profits be available beyond this, dividends to be paid on both classes of shares pari passu until they receive a maximum of 5 per cent. These totals would come to substantially less than the present preference shares can claim, and thus the ordinary shareholders would be advantaged. Payments would then be as follows:—Debenture interest, £7,000; expenses, £1,200; depreciation, £2,000; 4 per cent on preference shares, £2,368; 4 per cent on deferred preference, £2,802; and additional 1 per cent on both, £1,292, making £16,662. The ordinary shareholders are not to receive more than 6 per cent until the debentures are redeemed or re-arranged. No reserve or sinking fund must be created out of profits until 5 per cent dividend on both classes of preference shares has been paid. The committee recommend that an additional director should be appointed by the non-vendor shareholders at the next general meeting.

THE AUGUSTA TEA ESTATES COMPANY, LIMITED.

FOURTH ANNUAL REPORT.

The Directors beg to submit the Audited Accounts for the year closing 31st December, 1900. The Profit and Loss Account shows a balance of £168 2s 5d after paying fixed charges, and out of this amount the Preference Dividend has been paid. The low price at which tea has been selling during the twelve months has very much reduced the profit; at the same time the Directors are able to charge all Machinery and building expenses to revenue, and although nothing is written off for Depreciation this year, expenditure under these headings has not been curtailed to the detriment of the Company's property.

The quantity of tea manufactured has been 152,607 lb., of which 121,764 lb. have been sold in London at an average price of 5·78d per lb., and 29,873 lb. in Colombo at an average of 26·18 cents per lb.

The average sale price for the crop is equivalent to 5·68d per lb. London, against 7d per lb. the previous year. The average rate of Exchage has been 1s 4 7-16d, and the cost of production 24·80 cents. or 4d per lb. f. o. b. Colombo, inclusive of manure, costing 1·70 cents per lb. on the Company's tea crop.

By the Articles of Association, Mr. Charles A. Reiss retires by rotation from the Board, and, being eligible, offers himself for re-election.

The Auditors, Messrs. Singleton, Fabian & Co., also offer themselves for re-election.

Charles A. Reiss, Thomas J. Lawrance, Directors.
Albin B. Tomkins, Secretary.
London, 9th April, 1901.

CEYLON TEA PLANTATIONS COMPANY LIMITED.

Report of the Directors to be submitted at the fourteenth annual ordinary general meeting of shareholders, to be held at the Office of the Company, on Tuesday, 30th April, 1901.

The Directors have the pleasure to submit the General Balance Sheet and Profit and Loss Account for the year ending 31st December, 1900, duly audited.

	£ s. d.	£ s. d.
The net amount at credit of Profit and Loss Account, including balance brought forward at 30th December, 1899, and after providing for General Expenses, Directors' Fees, Income Tax, &c., is		47,367 8 11
Dividends on the 7 per cent. Preference Shares were paid for 1900 (less Income Tax) amounting to ..	5,415	
An Interim Dividend of 7 per cent on the Ordinary Shares was paid 28th October, 1900, amounting to ..	11,716 12 0	
It is proposed to pay a final Dividend of 8 per cent on the Ordioary Shares (making 15 per cent in all, free of Income Tax, which will absorb	13,390 8 0	
To write off for Depreciation ..	10,000 0 0	
And to carry forward to next year a balance of	6,845 9 6	
		£47,367 18 11

Owing to the largely increased production of British-grown tea being in excess of market requirements, the past year has been the most unfavourable one on record for producers generally. The results, however, of this Company's working have been such as to enable the Directors to recommend the payment of a dividend of 15 per cent on the ordinary shares, for the fourteenth consecutive year.

The Reserve Fund stands at £100,000, and it is not proposed to further add to this at present, but the sum of £10,000 has been set aside for depreciation.

The purchase of Pitaratmalie estate in the Haputale District was concluded during the year, and this fine property stands in the Company's Books at £40,580. The acreage of the estate is as under :—

	Acres.
Tea in bearing	501
Tea not in bearing	183
Grass Lands, Ravines, &c. ..	193
Forest	728
Total ..	1,605

The yield of tea from the Company's Estates was 526 lb. per acre as against 485 lb. the previous year.

The crop for 1900 was as under :—

Estate Tea.	Bought Leaf Tea	Tea Manufactured for others.	Total.
lb.	lb.	lb.	lb.
4,432,132	481,656	449,104	5,362,892

The gross price realised for the teas sold in London was 7·36d as against 8·10d last year, and the rate of exchange comes out at the same as last year, viz. 1s 4 19-64d.

The coconut crop was disappointing and considerably below estimates, owing to an unfavourable season. The present year, it is confidently expected, will shew a marked increase. The crop was 1,389,418 nuts as against 1,416,843 the previous year.

The Board have to record with deep regret the death of their colleague, Mr. Henry Tod, who was a Director of the Company from its foundation. Mr. William Herbert Anderson has been elected to the vacancy thereby created and you will be asked to confirm his appointment.

The Directors again cordially desire to express their appreciation of the services rendered by the various officers of the Company in Ceylon and London.

Under Clause No. 69 of the Articles of Association Mr. G A Talbot retires on this occasion from the Board and being eligible, offers himself for re-election,

The Auditors, Messrs. Harper Brothers, Chartered Accountants, also retire from office and offer themselves for re-election.—By Order of the Board,

WM. JOHNSTON, Secretary.

London, April 22nd, 1901.

THE RAGALLA TEA ESTATES, LIMITED.

REPORT OF THE DIRECTORS

to be submitted to the shareholders at the Sixth annual ordinary general meeting, to be held at 30, Mincing Lone, E.C., on Tuesday, May 7th, 1901, at 12 o'clock noon.

The Directors beg to submit their Report, and also Statement of Accounts, duly audited, for the period of 12 months ending 31st December last—

Shewing a net Profit for that period, after writing off £700 for depreciation, of	£4,498 19 9	
Add the balance of last account ..	93 8 7	
		4,592 8 4
Out of which the following dividends have been paid :—		
1900, 1st July—Preference Shares ..	£1,050 0 0	
1901, 1st January ..	1,050 0 0	
		2,100 0 0
		2,492 8 4
From which the Directors recommend a dividend of 6 per cent on the Ordinary Shares		2,340 0 0
Leaving a balance to carry forward of		£152 8 4

The Directors are glad to report that the anticipations of the Chairman at the last general meeting have been fully realised, and notwithstanding the low prices current in the tea market, the accounts justify them in recommending a dividend of 6 per cent on the ordinary shares, after making provision to the extent of £700 for depreciation.

The tea crops for the season amounted to 634,208 lb., and the net average price after deducting the usual charges was 7·68d per lb. A small amount of coffee, 27 cwt., was also secured.

The following are the acreages of the Company's Estates :—

Name.	Tea.	Coffee.	Timber	Patna, &c.	Total.
Ragalla and Halgran Oya,	911	—	177	302	1,390
Kelburne	742	10	165	64	981
	1,653	10	342	366	2,371

and it is estimated that the tea crop for the current season will be 750,000 lb.

The Directors have arranged a further issue of £12,000 of debentures to pay off the existing loan

on current account. It will be of interest to the shareholders to know that the Company's properties, which cost according to the annexed balance sheet £106,865 0s 4d, were valued in March last by an independent valuer on behalf of the Board at £167,500.

Under Clause 97 of the Articles of Association Mr. C Hannen retires from the Board, and being eligible offers himself for re-election.

The appointment of Auditors rest with the shareholders, and Messrs. Fuller, Wise & Fisher offer themselves for re-election.

C. E. STRACHAN, and C. HANNEN, Directors; M. P. EVANS & Co., Secretaries.

25th April, 1901.

POONAGALLA VALLEY CEYLON COMPANY, LIMITED.

REPORT OF THE BOARD OF DIRECTORS.

To be presented to the Shareholders at their Fifth Annual Ordinary Meeting, to be held at the Office of the Company. 16, Philpot Lane. London, E.C., on Tuesday, the 7th May, 1901, at 12 noon.

The Directors beg to submit to the Shareholders the Report and Accounts of the Company, duly audited, for the year ending 31st December, 1900.

The net profit for the year after providing for Debenture Interest and other charges, amounts to £474 8s 10d, which with £191 13s 10d brought forward from last accounts, gives £666 2s 8d from which has to be deducted the Interim Dividend of 2 per cent paid in September, amounting to £450, leaving available £216 2s 8d which it is proposed to carry forward to next account.

To those familiar with the conditions which obtained in the Tea Market for the latter part of the past year this diminution in the profit earned will not cause much surprise, but the prospects of the season now entered upon are, from various causes, more favorable, and your Directors hope that their next Report will confirm this view.

The following figures furnish a comparison between the season now closed and the preceding year :—

	1900	1899
Total Tea Crop secured	480,886 lb.	302,614 lb.
Total Coffee Crop secured	231 bushels	960 bushels
Average Price realised for Tea	6·544d per lb.	7·509d per lb
Average rate of Exchange	1/4 13-32d per Rupee	1/4 19-64d per Rupee

The increase in the Tea Crop is partly accounted for by the acquisition of Cattou Estate, comprising 147 acres of tea, and a considerable area of young tea which has come into bearing during the year.

The acreage of the five properties owned by the Company, viz :—Lunugalla, Udahena, Cabragalla, Poonagalla and Catton Estates is now as follows :—

Tea in bearing ..	...	1,237 acres.
Tea and Coffee ...	...	53¾ do
Coffee	..	18 do
Fuel Clearings ..	..	201½ do
Jungle Patna and Scrub	...	1,244½ do
	Total	2,754¾ acres.

The Central Factory at Poonagalla is now completed in every detail, and this, in conjunction with the extensive system of wire shoots connecting the various estates, is proving of great advantage to the economical working of the properties.

The Chairman has recently returned from one of his periodical visits to Ceylon, and reports most favourably of the condition and appearance of the different estates, an opinion fully confirmed by the visiting Agent, Mr. R. Morison.

In accordance with the Articles of Association, Mr. George G. Audersou retires from the Board, and, being eligible, offers himself for re-election.

Messrs. Cape and Dalgleish, C.A., also offer themselves for re-election as Auditors.—By order of the Board, LYALL ANDERSON & Co.,

Agents and Secretaries.

16, Philpot Lane, London, E.C., 20th April, 1901.

THE GALAHA CEYLON TEA ESTATES AND AGENCY COMPANY, LTD.

The report of the directors, to be submitted to the shareholders at the fourth annual ordinary general meeting, states that the gross profit for the season after providing for depreciation on machinery, &o. is £8,017 9s 3d; and balance of last account, £42 13s 9d total, £8,060 3s. From this has to be deducted: Interest on £55,000 debentures at 5 per cent per annum, £2,750; dividends on £60,000 preference share, at 6 per cent per annum, £3,600. London charges; Fees to trustees, directors, and auditors, £550; interest on loan, £629 10s 10d; income tax, insurance, &o., £119 17s 6d. Leaving a balance to carry forward, £110 14s 8d. The tea crop during the season, including 15,200lb from bought leaf, amounted to 1,170,436lb and the cardamom crop was 15,546lb. This company, in common with others, has suffered from the extreme depression which ruled in the tea market during a considerable part of the year, and the directors regret that they are, therefore, unable to declare a dividend on the ordinary shares. They are pleased, however, to report an improvement in the prices recently obtained. The company's teas meet with continued favour, their general uniformity in character and quality being highly appreciated by the trade, but the directors have decided to raise still further the standard of quality, believing that this policy will have beneficial results, although it will necessarily entail a higher cost of production and reduced output. As the company found it necessary to incur certain expenses in connection with the tramway and factory, which were not anticipated when they purchased the properties, Mr. C E Strachan, the vendor, being the only holder of ordinary shares, voluntarily contributed after the last meeting the sum of £3,400 to cover same, and the directors have placed that amount to the credit of the reserve, bringing up that fund to £5,700. On December 31 last the company had under cultivation in tea 2,867 acres, and in cardamoms 235 acres. Mr. W L Strachan having resigned his seat on the board in consequence of his departure for Ceylon, the Board appointed Mr. J. H. Strachan in his place for the residue of his term of office. Mr. J. H. Strachan now retires and, being eligible, offers himself for re-election.—*Home and Colonial Mail*, April 26.

CHEAP TEA.—Tea sweepings (for the manufacture of caffeine), when mixed with assafetida, can now be imported duty free into the United States by a decision of the Treasury Department. By the ruling permitting this, it is expected that refunds to a considerable amount will be made. The Treasury Department declined for a long time to permit the importation of tea sweepings to be classified in any way, holding that the Pure Tea Act excluded such merchandise, although it is not designed for consumption as tea. The first concession that was made to the importers was to allow the importation, upon condition that sufficient assafetida should be mixed with the tea sweepings. Then the courts decided that the mixture can be imported as a crude drug.—*Retail Druggist.*

THE KANDAPOLLA TEA COMPANY, LTD.

The report of the Directors for the year ending 31st December, 1900, states that the profit and loss account shows a profit on the working of the estates of £4,400 19s 2d; interest £66 12s 11d: doubtful Coast advances recovered, £7 17s 2d; transfer fees, 10s; brought forward from last year, £182 8s 3d equal £4,658 7s 6d. The Directors have paid the interest on the debentures viz., £1,575; dividend on the preference shares for the year 1899, £1,878; home charges as per account, £36 13s 11d; leaving a balance to be disposed of £836 13s 7d. The Directors propose to place to depreciation of machinery account, £250; carrying forward the balance £586 13s 7d.

The result of the year's working, is, on the whole, satisfactory, taking into account the fall in the average price of Ceylon teas. The estimates for the year were based upon a yield of 480,000 lb. The crop resulted in a total of 484,379 lb., an increase of 4,379 lb. As compared with the preceding year the improvement is 34,334 lb, and as compared with the yield for 1898, the increase is 114,3851b. During the year 110 acres have been manured chiefly with non-stimulating artificial manures, as recommended by Mr. Bamber, also 105 acres have been treated by applying Basic Slag. The cost of this has been included in the current expenditure. The cost of production averages 34·31 cents per lb. of made tea. The amount realised by sale, works out at 47·51 cents gross, the gross profit being 13·20 cents per lb., as compared with 14·20 per lb. last year. The estimates for the current year were prepared before the scheme for reduction of output of Indian and Ceylon teas was brought forward, and will have to be revised. The Directors propose to cordially co-operate in any scheme of united action which is supported by both India and eylon, provided that sufficient support is forthcoming to assure success. The labour supply and coast advances are reported as in a satisfactory position on all the estates belonging to the Company. The buildings and machinery have also been maintained in their usual good order and repair. With a view to necessary renewals and the provisions of a machine on one estate for the manufacture of green teas, the Board have, for the first time, decided to write down 5 per cent. from the value of machinery. A bonus of £100 has been paid to the superintendents, as shown in the accounts.

Mr. R. A. Bosanquet, the Director who retires by rotation, being eligible, offers himself for re-election.

The appointment of Auditors rests with the shareholders.

THE BATTALGALLA ESTATE COMPANY, LIMITED.

THE REPORT OF THE DIRECTORS

for the past year states that they are pleased to be able to give again a generally satisfactory account.

The increased production has necessitated a considerable outlay for new machinery, but the Factory is now thoroughly equipped to cope with the larger output, and no further expenditure is likely to be incurred under this head for some years to come. The quantity manufactured shows a considerable increase on the past year, totalling 274,556 lb, against 224,803 lb in 1899. The average selling price in London has been 8·38d per lb, against 8·43d in 1899, and in Colombo 36 cents against 37·04 cents in 1899. The total crop averaged a selling price of 7·85d, against 8·22d last year. London sales were 169,285 lb, netting £5,128 12s 2d, and Colombo sales 104,925 lb, realizing R37,737·95. This compares with 191,350 lb, netting £5,835 7s, and 32,600 lb, realising R12,075·20 in 1899 in London and Colombo respectively. Exchange for drafts has averaged 1s 4 7-16d, against 1s 4 13-32d in the preceding year. An interim dividend of 5 per cent, on the shares, free of income tax, was paid in September last, and there is now a balance at credit of profit and loss account of £766 14s 1d, from which the Directors propose to pay a further dividend of 5 per cent, free of income tax, absorbing £750, and to carry forward £16 4s 1d. In accordance with the Articles of Association, Mr. C A Reiss retires by rotation, and, being eligible, offers himself for re-election. The Directors are very sensible of the services rendered to the Company by their estate Superintendent, Mr G C R Norman, who has handled a very large crop with unceasing attention and efficiency. In tendering him and his assistants their very best thanks, the Directors desire also to express their appreciation of the valuable services rendered to the Company by their Colombo Agents, Messrs. E Benham & Co.

BANDARAPOLA CEYLON COMPANY LIMITED.

REPORT OF THE BOARD OF DIRECTORS

To be presented to the Shareholders at their Eighth Annual Ordinary Meeting, to be held at the Office of the Company, on Wednesday, 8th May, 1901, at 3 o'clock, p.m:

The Directors beg to submit to the Shareholders the Accounts and Balance Sheet for the year ending 31st December, 1900, with Auditor's Certificate attached.

After payment of Debenture Interest and all other charges, there remains a net profit for the year of £822 13s., which with £211 18s. 5d, brought forward from last Accounts, gives a total sum of £1,034 11s. 5d. to be dealt with.

It is proposed to write off the Capital Expenditure incurred during the year, viz., £626 13s. 1d., and to carry forward the balance of £407 18s. 5d. to next Accounts.

In view of the period of severe depression through which the Tea Industry has been passing, the serious shrinkage in profits disclosed by the Accounts now published will not be altogether unexpected, but as a result of the steps already taken—in common with other Proprietors—to restrict the output and improve the quality of the Tea prodnced, your Directors confidently look for better results during the current year.

The crops secured during last season amounted to 487,432 lb. Tea (including 8,850 lb. from bought leaf). and 267 cwts. 1 qr. 13 lb. Cocoa, being 36,827 lb. and 28 cwts. 2 qr. 7 lb. respectively less than 1899. The average return from all Tea in full and partial bearing was 612 lbs. per acre, and the average price realized was 5·512d. against 6·633d. during the previous twelve months.

A few acres of land have been acquired during the year, and the holdings of the Company are now approximately as follows:—

Tea in bearing ..	...	782 acres.
Tea not in bearing ..	..	6 ,,
Cocoa in bearing ..	..	224 ,,
Grass, Ravines, &c. ..	..	12 ,,
Reserve, Jungle, &c ..	..	525 ,,
Total Acreage ..	..	1,549 acres.

The Board have with much regret to record the death of Mr. Hugh Fraser, who had filled the post of Managing Director of the Company since its initiation.

To occupy the seat thus unfortunately rendered vacant, the Board, as empowered by the articles of Association, have elected Mr. George Gray Anderson a Director of the the Company.

On the death of Mr. Fraser, it was deemed advisable to appoint a Visiting Agent to furnish periodical reports on the Company's property, and this post

was offered to, and accepted by, Mr. Joseph Fraser. The latter gentleman paid his first visit of inspection at the beginning of the present year, and his Report is of a satisfactory character, being summarised in the remark that "the general appearance of the Estate is highly satisfactory, and the agricultnral condition creditable to Mr. Anderson." In accordance with the Articles of association, Mr. C. J. Scott, retires from the Board, and, being eligible, offers himself for re-election. Mr. John Dalgleish, C.A., also offers himself for re-election as Auditor. G. W. PAINE, Chairman.

16 Philpot Lane, London E.C., 20th April, 1901.

THE IMPERIAL CEYLON TEA ESTATES, LIMITED.

REPORT OF THE DIRECTORS

to be submitted at the annual ordinary general meeting of Shareholders, to be held at the Company's offices, 9, Fenchurch Avenue, London, E.C., on Tuesday, the 30th April, 1901, at 3 p.m.

The directors now beg to submit the balance sheet and profit and loss account for the year ending 31st December, 1900.

The nett profit, after payment of debenture and other interest for the year, amounts to		£2,326	11 11
To which has to be added the balance brought forward from 1899		658	5 5
		£2,984	17 4
This the directors propose to deal with as follows :—			
(1) In writing off from cost of Properties, as Depreciation of Machinery, &c.	£500 0 0		
(2) In payment of a dividend of 2½ per cent (free of Income Tax) on the paid-up share capital of the Company ..	2,250 0 0		
(3) In carrying forward to next year the balance of	234 17 4		
		£2,984	17 4

The following table gives the acreage, and results for the year :—

Estate.	Acreage in full and partial bearing.	Tea Crop lb.	Yield per acre.
Binoya ...	441	194,780	442
Edinburgh ..	362	188,309	520
Friedland ..	161	62,278	387
Mottingham ...	221	105,089	475
St. Vigeans ..	185	82,358	445
	1,370	632,814	462
Nonpareil	81	18,235 Bt.leaf 4,765	—
	1,451	655,814	462

	Cost of Crop per lb. in cents	Net Price realised per lb. in pence.	Working Profit.		
Binoya ..	27.44	5.34	851	16	11
Edinburgh ..	29.27	6.63	2,036	0	1
Friedland ...	28.45	6.72	545	5	3
Mottingham ...	29.88	5.52	289	11	9
St. Vigeans ..	31.48	6.46	462	2	6
Nonpareil ..	29.02	6.03	4,184	16	6
	—	—	Loss 697	19	0
	29.02	6.03	£3,486	17	6

In the above table the Superintendents' Commission has now been inclnded in the cost per lb. of tea, and taken into acconnt in arriving at the working profit.

The deficit in the working of Nonpareil was anticipated, and was provided for when dealing with the balance of profit at the 31st December, 1899, the Nonpareil surplns in that year being represented in the amonnt carried forward. The reports from Ceylon about Nonpareil point to the progress of the yonng tea being quite satisfactory. 38 acres in all have been successfully planted with cardamoms.

The Directors regret the falling off in the profits from the tea-bearing area, bnt this is attribntable to the generally unsatisfactory condition of the tea market during last year.

The total acreage of the estates as on 1st January, 1901, was as follows :—

Acreage nnder Tea.

Estate.	Tea in full bearing.	Tea in partial bearing.	Tea not in bearing.	Total.	Coffee and Cardamoms.	Forest Reserves, &c.	Total Acreage.
Binoya ..	441	—	85	526	—	403	929
Edinburgh ..	306	56	48	410	—	40	450
Friedland ..	161	—	—	161	—	2	163
Mottingham ..	212	9	—	221	—	37	258
St. Vigeans ..	185	—	—	185	—	—	185
Nonpareil ..	36	45	235	316	44	189	549
	1,341	110	368	1,819	44	671	2,534

In accordance with the articles of Association Mr. R S CORBETT retires from the Board at this meeting and, being eligible, offers himself for re-election.

Messrs. W B PEAT & Co., also offers themselves for re-appointment as Auditors to the Company.—By order of the Board, W H BARTLETT,

London, 22nd April, 1901. Secretary.

THE ALLIANCE TEA COMPANY OF CEYLON LIMITED.

REPORT OF THE DIRECTORS

to be submitted at the Annual Ordinary General Meeting of Shareholders tc be held at the Company's Offices, 9, Fenchurch Avenue, London, E.C., on Tuesday, 30th April, 1901, at 11·30 a.m.

The Directors have pleasnre in snbmitting the Balance Sheet and Profit and Loss Account for the year ending 31st December, 1900.

The Nett Profit, after payment of Debentnre and other interest for the year, amonnts to..		£4,659 15 11
To which has to be added the Balance bronght forward from 1899		2,180 18 2
		£6,840 14

An Interim Dividend of 3 per cent was paid on the 2nd October, 1900, absorbing ..	£1,957	16	0
And the Directors now propose to deal with the balance as follows—1. In writing off from Cost of Properties as Depreciation of Machinery &c.	1,000	0	0
2. In payment of a final dividend (free of income tax) of 4 per cent (making 7 per cent for the year)	2,610	8	0
3. In carrying forward to next year the balance of ..	1,272	10	1
	£6,840	14	1

The result of the season's operations is not so favourable as that of the previous year, but will doubtless be considered satisfactory in view of the period of extreme depression through which the Tea Industry has recently been passing.

The following Table gives the Acreages and Results for the year :—

Estate.	Acreage in in full and partial bearing.	Tea Crop lb.	Yield per acre.
Aberdeen ...	316	143,361	397
Calsay ...	352	171,674	488
Dunkeld ...	517	235,106	455
Luccombe ..	550	209,732	381
Thornfield & Gleneagles ...	457	248,087	543
Uda Radella ..	420	202,947	483
	2,657	1,210,907	456

Estate.	Cost of Crop, per lb., in cents	Net price realised per lb. in pence.	Working Profit.
Aberdeen ..	25·05	4·41	201 8 2
Calsay ..	31·62	7·08	1,387 0 7
Dunkeld ..	29·13	5·91	1,156 17 8
Luccombe ...	29·94	5·27	397 5 0
Thornfield & Gleneagles ...	29·27	7·34	2,667 19 9
Uda Radella ...	30·61	8·01	2,564 8 2
	29·42	6·43	£8,374 19 4

In the above Table the Superintendents' Commission has now been included in the cost per lb. of Tea, and taken into account in arriving at the Working Profit.

Uda Radella has done well, but all the other Estates show much reduced profits, the falling off being most marked in the case of the Estates producing low-grade Teas.

The total Acreage of the Estates as on 1st January, 1901, was as follows :—

Estate.	Acreage under Tea. In full bearing.	In partial bearing.	Not in bearing.	Total.	Forest Reserves &c.	Total Acreage.
Aberdeen ..	347	14	—	361	119	480
Calsay ..	342	10	13	365	22	387
Dunkeld ..	517	—	—	517	79	596
Luccombe ...	550	—	—	550	200	750
Thornfield & Gleneagles	457	—	7	464	48	512
Uda Radella ...	380	40	52	472	83	555
Kehelgama ...	—	—	—	—	322	322
	2,593	64	72	2,729	873	3,602

In accordance with the Articles of Association, Mr E J Young retires from the Board at this meeting and, being eligible, offers himself for re-election.

Messrs. W B Peat & Co. also offer themselves for re-appointment as Auditors to the Company.—By order of the Board, W. H. BARTLETT, Secretary.

London, 22nd April, 1901.

PLANTING NOTES.

THE DIRECTORS of the Anglo-Indian Evangelisation Society, which will hold its annual meeting in the Lower Exeter Hall on the 29th inst., are most anxious to send out more men to occupy new fields on the tea estates, among the European employees on the 20,000 miles of railway, and other lonely districts, where it is impossible for the missionaries and ministers of the various denominations to visit or hold meetings. Bishop Welldon, of Calcutta, and all missionaries testify to the good done by this Society.—*British Weekly*, April 25.

ON SOME NEW SPECIES OF EUCALYPTUS.—By R T Baker, F. L. S., Curator, Technological Museum, Sydney, (with Plates) has just reached us from Sydney, the specimens noticed being :—Eucalyptus Vitrea, sp. nov.; White Top Messmate; Eucalyptus Delegatensis, sp. nov.; White Ash, Silver-Topped Mountain Ash; Eucalyptus Intertexta, sp. nov.; Spotted Gum, Gum, Coolabah; Eucalyptus Morrisii, sp. nov.; Grey Mallee; Eucalyptus Vividus, sp. nov.; Green Mallee, Red Mallee, Brown Mallee.

COFFEE PLANTING.—One of the errors, committed by our early coffee planters in both Ceylon and Southern India, was the establishing of small clearings surrounded by heavy jungle in the shape of underwood. The plant, as subsequent experience has shown, should be put down on the most open ground procurable, unmixed with other shrubs; and where there is jungle in the immediate vicinity, it will be as well if a belt of plantain trees were laid down between. On the West Indian islands an idea prevails that many tropical parasites exhibit an aversion to the neighbourhood of plantain trees; the smooth stems and leaves affording no lurking places as other plants. —*Indian Planters' Gazette* April 20.

ALTHOUGH CHINA is so old there's always something new from it. The last is that the Chinese dread decapitation, not because it is painful, for (so far as is known) consciousness ceases at the first cut, but because he starts life in the next world with his head off. This is a serious handicap. But look at the ingenuity of the people? They get over the difficulty by paying the headsman a stiff figure to get hold of the tete and trunk as quickly as possible and then either sew them or gum them together on reaching home. Thus they make sure that if there is an after life their relatives will be at least presentable. Naturally, mistakes occasionally occur, and the nuts are screwed on the wrong way—looking down the vertebral column instead of down the front. A somewhat similar belief (regarding the prudence of dying intact) is to be found in the valley of the Ganges. That's why we blew so many persons away from guns in '57, and why we'd blow them again tomorrow if the necessity arose. Surely man's idea of what comes when consciousness goes is the standing riddle of the ages.—*Sydney Mail*, April 27.

Correspondence.

To the Editor.

COFFEE IN B. C. AFRICA.

III.

SHADE AND BORER &c.

Dear Sir.—Shade mitigates the borer evil to a great extent; the beetles love basking in the sun; but I find they do not object to shade either, although there are a few trees they ovidently avoid, one especially so, which is standiug in 6-year-old coffee which is riddled with borer, but not a coffee tree under "anjowa"—native name—was ever touched. There may be other trees distasteful to the longicorn beetle, and of course, *that tree*, above all others (if otherwise suitable) should be selected as the shade tree for B. C. A.—N. B., by having a variety of shade on a coffee estate, it will soon be found out which trees ought to be selected and planted on account of borer.

I am perfectly well acquainted with a few trees in our jungle which the borer breeds in, and of course, they must be an attraction to the beetles, and should be all felled when opening land for coffee.

We have the branch borer also in B C A, the larva of a white moth that lays its eggs (only one at a time) usually on the budding leaf of a primary in a small web like that of a spider. When the egg hatches, the larva then enters the tender end of the shoot and makes its way along the pith of the branch till it reaches the trunk of the tree, working down the centre, making small air-holes as it goes along. In the course of a few months the ground is reached, where they turn into the chrysalis stage, usually about July or August, and emerge a full-fledged moth in January and February.

This borer is easily detected by the end of the branch, where it begins to work, drying up. They begin to shew up about April and should be destroyed the same as the other borer.

I have never seen a coffee tree over two years old die from the work of this borer, and as they are not very numerous they don't make such a formidable enemy to the coffee as the stag-beetle larva does.

I have found this borer working down the branch of a young forest tree, with a soft centre, just in the same way as in a coffee tree. I have also found the same *red* borer in Ceylon about the edges of the forest; but the damage done there, as well as here, is very slight, although the moth lays about 40 eggs.

By the way I have never hatched this moth, so I may be wrong; but the moth, a sluggish dirty white one, I have often caught amongst the coffee, and it seems identical with the Ceylon one, but I may have to stand corrected; I may be wrong.

I secured at different times the stem of a coffee tree with the borer in it and tried to hatch it; but it always died in the pupa stage—probably through the drying up of the wood. I have also blocked up the hole in a coffee tree in the field with the borer in it, but he always managed to escape.

I suppose I have tired your readers with drought and borer, and shall now turn to an enemy of the coffee tree, which is perhaps not generally known as such in B. C. A. although a most destructive and formidable one, both here and in other countries.

WHITE GRUB.

The fansi or fuuzi is the Maugarga for the common white grub, the larva of the bronze cockchafer, which I am about to try and describe as well as depict the damage it does to our coffee.

The beetle is bright-copper-coloured, about ¾ inch long and ¼ inch broad, and the grub is of a yellowish white colour, and is bluish at the hinder extremity—obtuse and thick. When unearthed, the grub curves into a circle; it must be familiar to all observant planters who are present in the field when the earth is being turned over.

As this is the only cockchafer I have seen in B. C. A which does any harm to coffee, out of about 20 known specimens in the country, there can be no mistake made in identifying it.

When the beetle appears, when it dies, and how long the grub lives in the ground, I cannot say; for I have found beetles ready to fly, fully matured grub, the newly hatched grub, and the pupa all in the same coffee pit; when re-digging for supplies in the months of February, March and April. I should imagine, however, that the beetle only flies at night, and lays from 24 to 30 eggs, about an inch under the surface of the ground; it is said to live and feed on the roots of any plants it comes across in the soil.

However long the grub may live, it does a great amount of damage to coffee, especially to young plants before they have made many roots, by eating them up as fast as they grow.

I have been at war with this grub ever since I came to this country, and it was owing to my representing the terrible amount of damage done to nurseries and coffee in the field that one planter, so far back as 1892 or 1893, brought out a grubber with him, and tried hard to get the turkeys, but he forgot all about the tree roots and stumps in the land.

I remember, I think it was in 1873 or 1874, may have been later perhaps about 1876 or 1878, when leaf disease weakened the coffee so that the leaves after turning yellow blackened at the points, dropped, the wood died back with the crop on it, the blame was all put on this grub. What was not done for grub? Everybody was grubbing, catching beetles by shaking cinchona trees at night, forking the ground, fetching the grub from the roots of the coffee trees, and lime and chemicals were not stinted, but nothing saved the coffee from going out, in spite of every effort made by planters to prevent it. Estates were stinking with manure, scientists were appointed, but nothing which man could devise or apply to the coffee tree stopped the ravages of leaf-disease, (for which there was no remedy, and the weakening and ultimate abandonment of coffee as a remunerative investment, I remember.

As a great deal of light, black, chipped, and empty berry was the result of leaf-disease caused by the weakening of the trees, as the branches died back annually, the roots also decayed; and the white grub was blamed for the damage; so might also our own white grub here be blamed for the same diseased state of our trees and their fruits.

I have not the slightest doubt that the ravages of grub have a little to do with diseased beans; but I cannot make myself believe that a coffee tree either here or elsewhere in good health and vigor, and in its prime, with an abundance of rootlets for grub to feed upon, would ever suffer to the same extent as Ceylon coffee did from leaf disease, or our coffee does lend from a combination of evils to produce an alarming amount of diseased beans, although I am well aware young coffee in the field as well as our nurseries suffer a good deal from root trimming.

This grub is to be found in all cultivated land to a much greater extent than in land which is sterile, and the richer the land is in vegetable nurseries the more numerous they are; instinct leads the beetles to seek the most friable, light, rich soils to lay their eggs, thus becoming the parasite of agriculture.

In coffee nurseries when seedlings and plants are seen to dry up without any visible cause (when search is made) it is usually found to be the work of the white grub. On clearings one year old or so, when plants are seen looking yellow and unhealthy with variegated leaves, blackening the points, in some cases, it is invariably the work of the white grub, but not always so, for when examined sometimes not a grub is to be found at the roots; but when we cut down the plant and examine the stem it is found black-hearted, not necessarily because it has few or no roots, or the tap root turned, but because it is that of a diseased bean, or i

has been scorched in the nursery, when the shade has been too suddenly removed, instead of being thinned off gradually, or it has been scorched in the field. In any case, it should be cut down, when a fine healthy sucker will spring up, *only* if cut below all the diseased spots, many of which are often found in the stem but more frequently at the joints which are unnaturally thick and cankered-looking in most plants.

The natives are well aware of the damage done to coffee plants by the white grub and when I have taken up a dead or dying plant, to examine it, that has been thrown away to make room for a supply, I have had my planters volunteer the information that it was the work of the "*funsi*," also that they are very destructive in their *chineauga*, Indian corn gardens, and, when asked what remedy they adopt, "Oh! none," is the reply, "we kill them with the head of our hoe-handle."

There is great difficulty in getting plants, especially if they are small when put out, to come on in rich hollows the first year, principally owing to the ravages of grubs; but when once the coffee tree gets a sufficient quantity of roots for the grub to feed upon we have our finest coffee there, with a soil almost inexhaustible.

The black grub, another common enemy of all vegetables, the larva of a black moth, does much harm in those hollows (where the wash from the surrounding lands collect) by eating the bark of the coffee plants, and should be destroyed both in nurseries and field.—Yours truly. H. B.

IV.

REMEDY FOR BLACK GRUB.

DEAR SIR,—Young planters, and perhaps old ones, may benefit by my relating what appears to me the only remedy for grub, and the method I have followed ever since I came to this country to get rid of them.

In the first place, when going over a plot for a nursery, make the workmen kill all the white and black grub they discover, or better still give the men a few jam or butter tins to put them into, or have one or two boys for collecting and have them brought home to feed your ducks. This will do an immense amount of good in clearing the ground of a pest and would assuredly render a disappointing nursery, in most instances, a success.

When filling-in the holes in a new clearing it would well repay all planters to give a small reward of some kind for all the grub brought in by the labour force, for it is surprising the quantity they will secure in this way; whereas if no reward is given they are too indifferent to see the utility of master's demand, or order, to kill the grub. If this work is carefully attend to, there will be few supplies wanted and the young plants will not suffer by root trimming which so often proves fatal.

It may be said or imagined by some that the burn will destroy all the grub and other insect life on a new clearing, but this is not the case with the white grub, unless the fire is a very strong one, such as rages in a *virgin forest* clearing, but there are few of these cleared for coffee in B. C. A. and all grass lands are full of grub, and the fires on grass and thin forest land are not strong enough to kill grub two or three inches under the surface, besides the 'fungi' is to be found from a foot to eighteen inches under the surface in free soil.

There are fewer grub in forest than in bush land; that is one of the reasons why coffee makes such rapid progress in new clearings of the former description—and there are so few vacancies.

A coffee clearing that has been grubbed carefully when felling in, usually, with our superior soil and forcing climate, during the rainy months makes rapid progress and looks promising and healthy, if planted with good plants, and early in the season; but after a year or eighteen months' growth, many plants are seen hanging back, looking yellowish, and sickly, and the planter cannot fathom the reason for it. Now I shall tell you what to do; arm a few boys with sharp pointed sticks to dig at the roots of the sickly yellowish plants, in all such patches, and grub will invariably be found to be busily at work and not a root is to be found except the large primary ones, and even they are being barked most carefully by the grub, many of which are sometimes found sticking to the bark, busily at work, when unearthed.

I have seen this myself when watching the boys at work amongst my young coffee after the grub have been removed; the coffee looks worse than before for a time, but soon recovers.

It sometimes happens, however, those patches of sickly-looking coffee is not the work of the grub at all, but weakly black-hearted plants, perhaps the gleanings of a nursery which the coolie reluctantly keeps in his hand till the last; and when good plants are not supplied to him in they go, which is much to be regretted, as they never make healthy trees unless cut down and the diseased part cut off. This plan of cutting down does not always result in a healthy sucker, as it sometimes happens that the disease is in the root portion of the plant, or below where where it is cut, in which case it will never become a good coffee tree, and it will always produce diseased beans, I think, to a much greater extent than coffee trees which have been otherwise weakened or damaged.

I don't think that it will be borne out by experiment that the diseased bean so prevalent amongst our coffee is inherent in our coffee, but that it is caused by our system of cultivation; and that, although diseased beans are planted in a nursery, I believe they will not produce diseased plants, for they don't grow at all as a rule, and any that do spring should never be put out in a clearing.

From the fact that young coffee always produces a sound crop, I think it requires no further proof that the diseased beans are produced through natural causes—I am simply relating my observations, and what experience has made me believe is the truth; but it is more the work of a scientific observer to decide the cause of diseased beans than the planter. After the grub has been removed from young coffee, if other conditions are favourable, a wonderful improvement takes place. I may mention another cause of yellow plants is poor soil, which has not got vegetable humus enough in it to support even grub, and not a single one is to be found near the roots. Of course that land ought never to have been put in coffee, and the sooner it is abandoned, the better for the proprietor.

The heavier the soil is, the fewer grub are to be found in it, and in clayey soils that bind like a brick on the surface I doubt whether any would be found at all, although this sort of soil in B.C.A. produces the soundest coffee.

There is a great deal in the selection of land in this country for coffee; this fact I have only after years of experience found out; this is not my subject, however, in this paper.

When coffee trees attain their full size or come to maturity, or full bearing, say at six years old, I firmly believe that no grub in the soil does the trees any harm. I have dug some 20 or 30 from the roots of one single coffee tree, whereas I have never found more than half a dozen or so here.

The natural enemies of grub are far too numerous here, and coffee estates too scattered, and limited for them to become, for many years at least, a serious pest on our old coffee fields. Shade helps us again here; where we have a carpet of decaying leaves in a shade clearing, it provides the natural and preferable food for such grub, and they fatten and thrive on the humus thus formed instead of seeking live roots to feed upon.

A shade clearing is also an aviary of birds in B.C.A., any many other enemies of the grub, including ants, are to be seen under shade; whereas in an open clearing crows are about the only friend we have got in clearing grub, and they can only get at the grub by following the weeders.

In conclusion, anybody who wants to study grub and its ravages may find much interest in perusing Nietner's little handbook, published by the *Ceylon Observer*, also some further information on grub in

the *Coffee Planters' Manual* and complied by Mr. J. Ferguson, Editor of the *Observer* and *Tropical Agriculturist*.* I am sorry I had not got that little book for reference when writing this paper. Ceylon has many cockchafers, and their larva according to my experience did far more damage (especially in dry low districts) than our *one chafer* in B.C.A. does, and those districts, I know, gave crops of 7 to 10 cwts. per acre for years, without manure (before leaf disease days), and there was not the chipped light and diseased bean the same as here to complain of.

Now I must leave your readers to judge for themselves as to the cause of spotted, light and black beans in our coffee, and hope that this paper may prove of some use to young planters in this, our youngest coffee-growing country. H. B.

COFFEE IN COSTA RICA.

METHODS OF WEEDING, &C.

DEAR SIR,—By way of prelude for purposes of explanation it is as well to mention that the most common distances at which coffee trees are set apart is generally three varas by three, though other distances such as 2½ by three varas and four by 2½ varas are known but are not common, the natural lay of the ground often being the reason given for a distance greater or less than the three varas both ways, (the Spanish vara being 33 inches.)

After

NEW COFFEE IS PLANTED,

the best time being considered the commencement of the rainy season in May the first weeding or shovelling follows as soon as is practicable, to prevent wash from the heavy tropical rains which are the most violent and destructive at this period of the year: supposing the ground to have been ploughed up and harrowed previously during the dry season the first shovelling is the aporca, which is effected entirely by hand labor, and to accomplish which no machine has so far been introduced that will effectively do the two things, firstly the barking up and completely covering of all weeds to the line of coffee trees and secondly the prevention of wash by means of cross dams whose distance one from another is determined by the pitch of the ground, and vary on hill sides from a cross dam at every tree known as labtero system to a cross dam to every four or five trees on ground almost flat, forming what are called cajones or hoxes to translate literally; in new coffee shovelling to the trees in aporcas it is not considered advisable to raise up the ridge higher than 10 or 12 inches on account of burying up the young plants too much. Any less height however is not advisable for the reason that the ground shovelled up packs considerably after a few heavy rains and the following cleaning, the raspa, has to taken into account in which ground is taken from the ridges to the centre of the rows: it is good policy to have special care taken in building the cross dams of sufficient thickness and a few inches higher than the ridges there being the risk of water breaking out and washing in a heavy rain, an idea of which can be formed supposing one to break out at the upper end of a row of coffee trees, in turn breaking through all in its course to the lower end of the row taking with it tons of the best soil in a single rain: on a hillsides where tableros are in vogue the ground to build up the cross dam is taken from the centre of the square of trees and in sufficient quantity to give the bottom of the hole thus made a perfect level, thus giving each tablero a maximum capacity of holding rain water until it soaks into the soil. On flatter ground, where the pitch will allow of doing so, and cross dams can be effective for instance at every second tree, they can be made more secure by taking the ground from the lower instead of the upper side of the dam, thereby lessening the chances of a break out through the levelling of the ground, the water standing back the full length of the cajon before passing over the dam at its lower end. In coffee planted out older than one year ridges are often built up higher than 12 inches, many going as high as 24 inches, though the good results of this are questionable, much mischief being caused to tree abundant in lower branches by excessive piling up of the ground. The aporca described above is all the cleaning done till about July when the ground is pretty sure to be up again in weeds and in need of the second cleaning or raspa, which is also done by hand labor and is the reverse of the aporca in that the weeds are shovelled to the centre of the row and covered with ground, a few boys cleaning around the stems of the trees in advance of the shovellers; this is done to save them from being cut by the shovels in cleaning close to them, a good custom being to reinforce the cross dams at this time with a little additional ground if necessary, there being at all times the danger of a break out in heavy rains.

This second cleaning is considered sufficient till about the middle of October when

THE CROPS

are sure to be showing signs of ripening, when an aporca is repeated, leaving the ground clean and favorable for picking; in January or February at latest a raspa is given, differing from the one done in July in that the weeds are left uncovered, causing them to dry up quickly in a season of the year which is always rainless.

The shovel used is, I believe, peculiar to Costa Rica, being round-nosed, square-backed, slightly indented to the centre, measuring from 14 to 20 inches across, according to numbers and is manufactured principally in U. S. A. Considerable strength and practice are needed to make an expert shoveller and the majority of the working classes begin working at it in their early teens; during the rainy months from May to November shovellers work almost daily from 6 a.m. till 12 and often till 2 p.m. when the rain permits, and it is considered that the work done is a good day's work, when the leader or man who takes the first row sets a good pace and example, for which a little increase in pay is made, all shovellers by custom having to even up their work with that of the leader.

This custom of cleaning is

SOMETIMES VARIED,

a machetea with broad-bladed machetes taking the place of a raspa, though a cleaning in this manner is only effective in the dry season: the machete being very much like the Cuban cane-knife, but with a thinner blade besides having a twisted handle which enables the worker to skim over the surface of the ground lifting very little dirt: covered cleanings of both kinds with shovels though costing more are at the same time more effective, as they annihilate all stubborn weeds and grasses, this not being the case with machetes. The amount of ground that can be gone over in one day working till 2 p.m. varies according to its nature and other conditions; in ground moderately steep, where shovelling is customary and the surface well pulverised, a labourer can do about ⅛ of a manzana or ¼ of an acre, in some cases more, but this can be taken as an average in aporcas. Raspas with shovels and machetes cost 25 and 40 per cent. less than aporcas, the former generally having the preference during the rainy months.

The saying that what is worth doing is worth doing well has no better application than in shovelling, a shovelling badly done causing more loss of ground than if left alone, a state of things which is generally admitted as only needing time to cause the ruin of an estate.

Some adverse critics declare that the roots of the trees are cut and suffer from the shovelling; ocular evidence, however, proves that trees over 30 years old when pulled up have a complete system of roots extending over six feet all round and this often two feet or more below the surface.

* Not forgetting Mr. Haldane's Monograph on "Grub."—ED. *T.A.*

That rain should be induced to soak into the soil instead of running off is considered a point of advantage by many recognised as authorities in such matters; this is one thing accomplished by good shovelling, beside the perfect pulverisation of the surface to a depth of about four inches, added to which the thorough mixing of any class of manures applied to the surface is insured.

The above applies to the interior of the Republic known as the Pacific slope: cultivating with machines has been carried on in newer coffee farms on the Atlantic slope with different success, but here again the soil is very porous almost everywhere, and the native labour which is always preferred in coffee is much more expensive than on the western slope on account of climatic conditions. When prices of coffee were at their zenith a few years ago, several investments were made in coffee farms on the Atlantic slope; results, however, have now shown that labor, seasons of the year, and last but not least that prices in the market are all in favor of Pacific-grown coffee. YOUNG CEYLON.

THE FLOWERING OF BAMBOOS.

Ambegamuwa, May 2.

SIR,—I have just noticed an article in your "Tropical Agriculturist" of April on the "Flowering of Bamboos."

It may interest you to know that a particularly fine clump of bamboos near a bungalow in this district flowered about 2 or 3 months ago. It now looks as if it is going to die, and I suppose there is no doubt but that it will?—Yours etc., X.

[We fear death is inevitable after the flowering, as that result seems always to follow in India. Do the coolies care for the seed?—People in some parts of India often live for weeks on Bamboo seed.—ED. *C.O.*]

CEYLON GREEN TEAS IN AMERICA.

Kandy, 2nd May, 1901.

SIR,—In forwarding the enclosed extract of a letter from Mr. Mackenzie to Mr. Rosling on the subject of Ceylon Green Teas, I would also avail of the opportunity to correct one paragraph in the letter published with my letter of the 26th April, as a clerical error inadvertently crept into the copy. The sentence in the letter should read as follows :—

"I did not go to Chicago this time, because I met down here all the men I wished to see. I send you some papers to show you what Lipton is doing for our Greens in that city. This is evidence of disposition to build a trade, not merely to catch a trade already made by others. Those four stores are the largest in Chicago."—I am, sir, yours faithfully,

A. PHILIP.

EXTRACT OF A LETTER FROM MR. MACKENZIE TO MR. ROSLING, DATED LONDON 12TH APRIL, 1901.

Before leaving New York, I wired to Mr Philip that there was a better demand for our Greens. In fact the supply had run out in America and nearly all known to be afloat were sold. I am more convinced than ever that we have a splendid field in America for our Greens and that we can make them to equal, even to surpass, Japans in liquor. It depends on Ceylon itself, when it can capture the trade. *Business methods.*—A combination of Colombo merchants, to make to standards and regulate prices, would secure much of the business at once. The difficulties now lie with the supply, and the method of supply. Publish again the letter headed "Good advice" which appeared in the *Observer* last August. It foretells the probable pitfalls and difficulties. Abusing me, because I do not and cannot find purchasers for shipments dumped into Toronto market will do no good: I can only advertise, which is of little use without other means. Many Firms have been buying the Greens and shipping them. I found only one besides Salada, amongst the importers, making any special efforts to sell them. *That one* may get disgusted; cease to blend to standards in large quantities, and intending purchasers in the States especially may turn again to Japans. Any Firm undertaking to do the business properly should have support. The American Firms dealing very largely in Japans said to me the day before I left New York, "We are tired of Japans—never want to handle them again. Your Greens are splendid at 15 to 18 cents. But can we get them regularly and to standard in large quantities." I replied, "I cannot say. One Firm has been working on those lines, but I cannot vouch for their continuing to do so. You should try to arrange a contract with them."

(Signed) WM. MACKENZIE.

(*The letter referred to.*)

"If the planter rushes in, manufactures, consigns, and jams the market with green teas, the jobbers will at once do as they have done this year with blacks. They can get along without our teas, and can therefore wait. We will all begin underselling, and thus playing into their hands. As there is no other market for our greens we must keep them here, and Japan will share our loss, to the profit of the wily American jobber. Unsuitable teas do us more harm than good. They are usually consigned, and those familiar with the trade here would not ship them; as a consequence they are sooner or later sold for what they will fetch, and as they are Ceylon greens in name, the price they fetch is taken as the market quotation for all Ceylon green tea. The consignment and 'sacrificing' business is the accepted feature of the black tea trade from Ceylon and India. But that branch of the business is sufficiently robust to continue in existence on the prospect of the gradual extinction of the possible sources of consignment as firm after firm buys its experience and retires *beaten*. But in the case of green tea it is different, and it would not take very much to break the market while in its infancy. At present the principal buyers of green tea use them for packets, and of course have to advertise and push them. Moreover such firms have special outlets for their goods. As these packets become better known and people are educated up to the appearance of the unadulterated and undyed tea, the demand will extend and, when once the grocer can sell it in bulk, the natural merit of the tea and its similiarity to that which consumers are accustomed to will give a great outlet. In the mean time, if such green tea is rushed into this market, the price will be run down to below cost; there will be no money in it for planters or for importers, and the trade will get a serious set-back from being rushed too soon. You will observe that I try to make two points. One is, send only suitable tea, and put a limit on its price. The second is, feed and do not choke the market. While pointing out the difficulties, I entirely agree with you that there is a great future for our greens. In due time rubbish and anything will be taken: but wait till the channel is open before turning on a flood. Rely upon merit at first; remember that Japan has only this one outlet, and in the future the competition for it will be exceedingly fierce, and that they can beat us at making cheap trash. Maintain prices, otherwise it will not pay the planters to persevere. I do not think there is any short cut to a great market."

CEYLON TEA IN FRANCE.

Sir,—I herein enclose copy of letter from Mr. Renton to Mr. Rosling, on the subject of Ceylon Tea in France together with the figures *re* importation of Tea into France.—I am, Sir, yours faithfully, A. PHILIP.

My dear Rosling,—Before returning to Germany I can now give you my impressions of the work in France. I visited the Riviera, the South and the West, and have now been nearly a month in Paris. I find everywhere that, owing to the exhibition, even in some of the smaller provincial towns, Ceylon tea has got to be known, alas, I am sorry to say I fear by name only. In the Vaucluse and in Nimes, Montpellier, Avignon, you get tea at all the Cafés; it is very poor stuff indeed and invariably served with orangeade. I am also sorry to say that in Marseilles at the Café de France, where our tea is supposed to be for sale, tea was so bad that I could hardly drink it, and here also it was served with orangeade.

In the Riviera there is a large quantity of tea taken. Most of the hotels seem to draw their supplies from London, but good tea is sold in cup at nearly all the afternoon Tea Rooms and Confectioners' shops in Mentone, Cannes, Nice, Beaulieu, Pau and Biarritz. I was disappointed to find that our Paris friends were not doing as much with pure Ceylon tea as they led me to expect; there is only one small agency at Mentone and Cannes and two at Monaco; still I find that they send a lot of tea from Paris direct to private customers in the south. In Marseilles, we seem to have made more progress. I saw Ceylon tea in packets for sale in two grocers' shops. In the principal one the whole of the window was given up to Quaker brand teas in packets, and the tea pots similar to those we had at the exhibition. Ceylon tea is also for sale in one Café and one Restaurant, only they don't make it properly. There is a very nice Tea Room which has been established in Marseilles, in the Rue de Noailles, where coffee and cocoa are served as well, but tea seems as much drunk as anything. I asked the proprietor what tea it was and where it came from? He replied "Ceylon," and that he got it direct as the steamers from Ceylon called there!! I feel inclined, however, to believe that it was not Ceylon but Darjeeling; however, it was well made and good tea, which is the main thing. In addition to these retailers there are two wholesale firms who are giving Ceylon tea a good deal of attention, the 1st, * * will not sell more than they can help, but the other * * are inclined to push it; altogether I am very pleased with the result in Marseilles.

I found an English firm at Biarritz who have already been importing tea and who will now give it more attention; they will work all the Basque country and the north of Spain as far as San Sebastian.

In Bordeaux I called on the four principal wholesale houses; the largest, who I thought from their correspondence at the Exhibition seemed inclined to take the matter up in earnest, have now grown very lukewarm, and did not give me much encouragement; but I find since my arrival in Paris they have written to a Broker for samples so that they may prepare an order for the autumn delivery. Two of the other three firms keep it, but only for sale when asked for. An enterprising lady who runs a millinery and dress-making shop seems to do the biggest tea business in Bordeaux; she has one room full of chests of tea, but only gets through about 200 lb. of Ceylon in a year. The grocers in Bordeaux and in the small provincial towns in France do not seem to keep tea, but it is the confectioners and pastry-cooks who have it for sale done up in packets. Everywhere in France I found the so-called Russian tea for sale in packets with the Russian Government bandrole on them; this is looked upon by the public as a sure sign that it is genuine Russian tea. Hence my reason for thinking that we should do well to have a Customs stamp on all Ceylon tea packeted in Ceylon. An English grocer in Bordeaux keeps the tea for sale and so does an English and American Bar which is a funny place to find tea in.

In Paris no doubt most is being done, our friends of the Exhibition * * are keeping up the interest in the article by advertising, by personal canvassers, and by a vigorous campaign among shops, hotels and restaurants. * * tells me that his trade since 1st January, in tea generally, is more than double what it was last year. The * * * have, as you are aware, gone to the expense of engaging Sinhalese boys and have opened a swell tea room in the Rue Canmartin. They have also been asked to run a tea room at the "Infants' Exhibition" which is to be held in the Petit Palais from the 15th of April to the end of July. This Exhibition is for a charitable purpose and the great world of Paris is taking a great interest in it; only, the organisers have exacted very heavy terms for the space. They wanted a rent of 8,000 frs., but in lieu of that the * * * have agreed to give them 20 per cent. of their TAKINGS; they will make no money out of this show but it is a capital advertisement. From the letter I sent you last week, you will see what * * * are doing, and intend doing. With the exception of two wholesale houses and another which I may call wholesale, the Compagnie Coloniale, all the importers of tea are buying our tea more or less. I am sorry the Compagnie Coloniale have avowed to me their intention to do all they can to oppose Ceylon tea; last year at this time they agreed to try it. This Company sells a very fine quality of tea; they do a big trade and they charge a fine price.

I enclose you the statistics of importation of tea into France for 1899 as compared with 1898; this gives the countries of origin. The returns for 1900 are not yet out, and I hear I will not get them until September. What is most striking is the vast increase in the importation from Annam (Indo-China); this tea being from a French Colony comes in practically duty free and I hear that in 1900 the imports were 180,000 kilos. This I cannot believe for I do not believe that there is sufficient acreage under tea in Annam to produce this quantity; can you find out what the acreage there is? because it may be possible that tea is brought down from Foochow and Hankow to Annam and shipped from there as that country's tea.

I am not making any war against China tea. I do not think it politic to tell a man that the tea he buys is rubbish; all I do is to tell him that Ceylon tea is better and that he can improve his China tea by adding Ceylon tea if he does not care to drink Ceylon tea alone, because I think that, where a taste for tea has been established, it will be much easier to get our Ceylon tea taken into consumption; and I know that amongst retailers a good deal of tea is being sold as Annam which is blended with one half Ceylon. My war is against coffee and alcohol.

I enclose copies of the advertisement programme being made this year in France and Paris by two firms, and our friend * * is to do a good deal in the way of advertising as well. I am also giving * * a subsidy for a traveller and demonstrator, who is to go round the provinces within a year and give tea away and also when he can get a grocer willing to take the matter up, he will distribute for a fortnight or a month, say, in front of that grocer's shop, or on the pavement in front of his shop, tea in cup gratis for two or three afternoons in the week. The Ceylon tea house at Versailles is doing very well, and one on a small scale is to be opened on the south side of the river close to the Bon Marché.

I am leaving for Germany: I go to Bremen first and then to Berlin, Magdeburg, and Hamburg. As I shall probably have to go to St. Petersburg in the autumn to see after the start of the tea room there, I leave the East of Prussia and Poland over for the autumn and will take Stettin, Konigsburg, Breslan, Lemberg, and Cracow then.—Yours, &c.,

J. H. RENTON.

NOXIOUS LETTERS ON TEA.

London, April 24, 1901.

Sir,—I am glad to see a protest being made against the attempt on the part of certain individuals, who ought to know better, to advertise themselves by posing as purists in the matter of Ceylon tea.

I should like to ask those gentlemen to say what percentage of the 300,000,000lb of tea imported last year, or of the 250,000,000lb taken for home consumption, consists of the tea which is alleged to be dangerous to health.

In the present day there is a perfect mania for discovering bacilli in everything we eat and drink. I should think it highly probable that even in "Osborne" (or any other) tea a scientist would find bacilli. We are told the air we breathe is full of microbes, and if some of the scientific men who are so mad on the subject were to have their way we should all have to live in hermetically-sealed glass cases, and have our food administered in the form of concentrated lozenges cooked at a temperature of 2,000 deg.

Seriously, however, it is really deplorable that men who have a craze for writing should be allowed to air their fads in the public press, and lead people who are apt to treat everything which appears in *The Times* as gospel truth, to think there is some danger in drinking Ceylon tea, because, forsooth, out of some million and a half packages imported last year a few hundreds possibly of "rubbishy" tea have pased the Customs undetected, or have been condemned as unfit for tea drinking.

I do not for a moment palliate the offience of people who ship inferior tea, as has been done lately to a small extent, but it is very easy to magnify this offence into a serious blot on the Ceylon tea industry, which I maintain does not exist.

I enclose my card, and subscribe myself as

NO RUBBISH.

CACAO PODS AND SEEDS.

DEAR SIR,—As "*Pod*" complains about Mr. Carruthers' diagram of cocoa pods, &c. I now send you an extract from my diary of tests made by me in 1894 and 1900, and since kept as my guide as to what pods to use for planting.—Yours faithfully,

CACAO PLANTER.

1894. Pods from a Young Estate.	Weight	Length.	Round.	Number of Seed.	Wet.	Dry.
					oz.	oz.
1 Forastero Rough and red, grooves yellow when ripe	2 to 9		12	45	5	2¼
2 Condameera Smooth, red, long grooves yellow when ripe	2 to 9		12	29	2½	1¼
3 Hybrid Smooth, red with green grooves, when ripe yellow	2 to 8		11	38	4	2¼
4 Caraccas Rough and red pink grooves, latter when ripe yellow	2 to 8		10	36	3¼	1½
5 Marawa Rough, green, whole pod when ripe yellow	2 to 9		11	40	4	1⅝
6 Condameera Smooth green, whole pod when ripe yellow	2 to 8		11	45	5	2½
Total	12 to —		—	233	23¾	11½
Say Average	2 to —		—	38 5-6	3 5-6	1⅞

1894—Selected *small* pods from an old estate well manured—though I had many 3 lb. pods.

1 Forastero Rough, red, pink grooves, latter yellow when ripe	1 2-16	9½	11	51	4½	2⅛
2 Condameera Smooth, red, pink grooves, latter yellow when ripe	1-13	8½	13½	43	5	2¼
Condameera Smooth and green, whole pod, yellow when ripe	1-3	7	11¾	36	4	1⅛
3 Hybrid Rough red with green grooves, latter yellow when ripe	2-10	11	13½	38	4	2¼
Hybrid Smooth red with green grooves, latter yellow when ripe	1-8	8½	12	26	3½	2
4 Caraccas Rough red, grooves get yellow when ripe, Carracas partially rough red, whole pod pink when ripe	1-4	8	11¾	35	4⅜	2½
5 Marawa Rough, green, yellow grooves when ripe	1-1	7	11½	30	3	1⅝
Marawa Short, smooth, whole, yellow when ripe	1-2	10½	11¼	21	3½	1⅝
6 Forastero Hybrid Short, rough, green grooves, latter yellow when ripe	1-2	7½	12	38	3½	1¾
	1-3	7	11¾	36	4	2½
Total 10 pods	14 to —		—	354	39¾	20⅝
Say average	16½	—	—	35½	4	2 1-16

The last three pods from a dying Forastero tree 12 years old experimented on—

Nov. 1900.	1 pod ripened, though husk thin and soft; 1 pod ripened, though husk thin and soft	7 oz.	—	—	39	2 1¼
		7¼ „	—	—	40	2⅛ 1 5-16
	1 pod ripened, though husk thin and soft	8 „	—	—	42	2⅛ 1 7-16

Among cocoa 10 and 10. The tree gave in last seven years 1,666 large good pods, cut out in November 1900, seed equal to 2 oz. for pod or say 1¾, but cocoa seed last seven years—no pods turned black, but all ripened, though tree was dying for practically four months.—Yours truly,

C. P.

OLD TEA ON DOOROOMADELLA.

Gammaduwa, May 6.

DEAR SIR,—In your foot-note to Mr. H Cottam's interesting letter in your issue of 3rd instant, you ask if the old tea on Dooroomadella is still in existence?

The tea referred to must have been abandoned years ago, how many I do not know, but many of the bushes still exist amongst the patna grass.

The cinchona trees must also have been cut down long ago, as the field is now in heavy chena, but cinchona trees are still growing from many of the original stools.—Yours,

MATALE EAST COR.

THE TEA INDUSTRY: THE OLD REMEDY.

DEAR SIR,—I suppose the familiar *Requiescat in pace* might be adopted as the epitaph over Mr. Rosling's proposal to *rest* ten per cent of our tea land. As one of those who supported the scheme, I regret that it has not had a fair trial—both as a means of improving prices by imposing a check on overproduction which could be promptly withdrawn if new extensions were attempted, and of benefiting the estates by a cessation in the eternal round of plucking and pruning. The primary condition on which the scheme could be tried having failed, through the non-adhesion of an acreage sufficient to reduce appreciably the output of tea—the acceptance of the inevitable is the most practical and philosophic thing to do. The necessity of a reduced output being recognised as a means of recovering prices, even by those who objected to Mr. Rosling's proposal, it remains that an earnest effort should be made to gain this end by more careful plucking and manufacture, as advocated by yourself, Mr. Editor. But what is this but the old remedy? I cannot recall how many years ago it was, but it cannot be less than three years since you issued a most searching list of questions, and elicited a most valuable body of evidence and opinions from practical planters on the best means of ensuring the permanence and progress of the Tea Industry. If you look up the answers to your circular—were they not published in pamphlet form?—you will find that judicious manuring to keep the bush in heart, careful medium plucking, avoidance of hacking, strict attention to the factory by the Superintendent, were the methods suggested; and that your editorial endorsement of judgment in cultivation and plucking, and infinite pains in manufacture, was unmistakable. So we have come back to the old remedies. Let us give them now, after our recent bitter experience, a full and fair trial. Sports and pastimes, like pruning, can be carried to excess, and may tell on the vitality of business. Let not too much be left to the Conductor and Tea-maker—whether plausible Jaffna Tamil or the docile Indian. If they can do all the work, the expense of a *durai* need not be incurred. Let the white man bear his full share of the burden, and all will come right.

PROPRIETOR.

THE KEA-PARROT OF NEW ZEALAND.

15th April, 1901.

DEAR SIR,—Referring to "O. C.'s" letter in the *Observer* of 27th March, I may be able to satisfy him on the subject of the Kea parrot of New Zealand. When I first settled at the North end of the Wakatipu Lake, in Otago, great numbers of Kea-parrots were to be found on my sheep-run, but they confined themselves to the ranges just under the snow line, and fed on hill berries and the fruit of fuschia and other trees in the bush, but I never heard anyone accuse them of being carnivorous birds. About a year after I left New Zealand the depredations of the Keas, on my old sheep-run, began to be talked about, and from living high up on the ranges they took to frequenting the flats bordering on the lake, and their practice was—and is—to alight on the back of a sheep and, with their strong sharp beaks, dig into the back, just over the kindeys, and devour the kidney-fat. That is all they eat, but, of course, that is enough to cause the death of the sheep so mutilated. Many theories have been given as to their sudden change from fruit eaters to carnivoræ, and my own theory may be as probable as any other. It is this. The birds had increased so much in number that their natural food had become scarce, and they had to look around for something else on which to exist. Probably they had begun on the sheep skins which are, usually, hung over a rail near the shepherds' huts, and had picked the small pieces of fat off these, with much satisfaction. Then an occasional dead sheep had given them opportunities of practising their strong beaks, and they thus discovered the situation of what, to them, appears to be a special delicacy—the kidney-fat. From finding out how to get at that on a dead sheep, they proceeded next to look for it on a living one, and thus, step by step, they gained their experience until, now, they are one of the plagues of New Zealand. I may mention that there is nothing singular in this change of habit in these birds. The starling is called "The Farmer's Friend" in Britain, because it lives entirely on grubs, insects, &c, and, for that reason, it was acclimatized in New Zealand. But, in their new home, they increased at such a rate that their ordinary food ran short and they took to eating grain and, now, they are as much of a curse to the New Zealand farmer as rabbits and sparrows are.—Yours truly,

"COSMOPOLITE."

ERRATA.

Page 856—In letter on Cacao Pods and Seeds, signed by "C.P.", in last para *for* "Seed equal to 2 oz. for pod or say $1\frac{3}{4}$, but cocoa seed last seven years," *read* "Seed equal to 2 oz. *per* pod or $1\frac{3}{4}$ *cwt.* Cocoa seed last seven years."

THE OLDEST TEA IN CEYLON AND PIONEERS.

DEAR SIR,—In your issue of the 29th ult. mention is made of the "*Oldest Tea in Ceylon*" planted in 1868-69. I wish to call the attention of yourself and readers to the fact that Captain George Lloyd Williams, of Dooroomadella estate, Matale, obtained seeds and plants of tea from Dr. Thwaites, of Peradeniya Gardens, in 1865, and that the writer became his Superintendent in 1867 and planted out tea plants and made good tea which was distributed in small quantities to Dr. Shipton, Messrs. R B Downall, Walker, Buxton Lawrie, Chippendall and others, in the district of Matale East. Mr. Thos. S Grigson, of Colombo, may also remember the circumstance. Captain Lloyd Williams also obtained 1.000 cinchona officinalis and 1,000 cinchona succirubra from Dr. Thwaites about the same time, and Henry Walker awoke one morning to find himself proprietor of a cinchona plantation and tea bushes planted by—Yours faithfully,

HENRY COTTAM.

P.S.—Mr. Henry Walker, now in Borneo, I believe, bought Dooroomadella from George Wall & Co. and did not know he possessed a cinchona plantation all ready for harvesting at the top of the hill. H. C.

[Mr. Cottam's reminiscences are interesting; we should like to know from a Matale East planter if the old tea (34 years) on Dooroomadella is still in existence? We gave the Loolecondera field preference as continuously worked; but, of course, older tea should be found on Condegalla, Ramboda, where the Messrs. Worms planted a field with China—still existing?—in the "forties"; and in the same decade Mr. Llewellyn of Calcutta sent plants of indigenous Assam to Pen-y-lan; but we suppose they were rooted out for coffee, or ran to jungle. Mr. P D Millie planted some tea in Pundaluoya in 1861; and Mr. A Greig put some on Barra, Rakwana, for Mr. C Shand in 1864.—ED. *T.A.*]

REDUCTION IN OUTPUT OF TEA.

Kandy, May 2.

SIR,—The following cablegram was despatched to London a few days ago:—"Including London figures total 3,500,000 lb."

The above was in reply to the following cablegram received from London in the middle of April:—"Indian 10,000,000 lb. secured, let us know the number Ceylon," followed by a further wire on 22nd April reading "Indians meet tomorrow, give us all the information you have."—I am, Sir, yours faithfully,

A. PHILIP,
Secretary to the Planters' Association of Ceylon.

HAVE WE FOUND THE OLDEST TEA TREE?

Pen-y-lan estate, Dolosbagie, May 5.

DEAR SIR,—Mr. Tringham, of Pen-y-lan estate, Dolosbagie, has preserved one fine specimen of Mr. Llewellyn's tea planted in the "forties." This fine tea tree is probably sixty years old and we measured the stem and found it eight inches in diameter and two feet in circumference; in height it is from 25 to 27 feet and would have been much bigger had not half the roots been cut away in the forming of a side drain near the kitchen of Pen-y-land bungalow.—Yours truly,

H, COTTAM.

[We are indebted to Mr. Tringham for 30 seeds from this old tree—we do not know that there is any special virtue in seed from a very old tree—but they are well worth a trial.—ED. *T.A.*]

PLANTING NOTES.

FOUR TEA COMPANIES: MAIL NEWS.—In our daily and *T. A.* the reports of three companies, and an account of the annual meeting of another, appear tonight. Top of the four is the Balmoral Company, with its solid 12 per cent for the year and £720 to carry forward; Tyspane pays 3 per cent, and has a balance of £176 7s. 3d. which is nearly £40 less than last year, but the Company is making good progress; Kelani Valley paid 3 per cent interim but no final dividend and carries forward £456 15s, the late Mr. Donald Andrew's place on the board being taken by Mr. G G Anderson, who retires but has probably been re-elected. The Panawal Company pays 2 per cent which is creditable, in view of a decrease of £1400 by sales, and and £505 19s. 6d. is placed to reserve. We congratulate the management and all concerned.

TWO SISTER TEA COMPANIES: THE ALLIANCE AND IMPERIAL.—It is strange what a difference the purchase of "one more property" has made to several Tea Companies in Ceylon in absorbing, or destroying, or delaying dividends. We could name several such that would have been all the better off had the Directors not been tempted to add to their estates and responsibilities; but perhaps the most notable is the "Imperial" to which the addition of Nonpareil estate, in West Haputale, has proved a regular "white elephant." We suppose if it had never been purchased that the Company would have regularly given its six to seven per cent equally with the Alliance and that its shares even in these hard times would have been at par in place of 50 per cent below. The figures given elsewhere in the Reports of the two Companies present a notable contrast. Every estate in the roll shows a working profit—such fine Dimbula properties, as Thornfield, Uda Radella and Edinburgh, giving each, over £2,000,—but for Nonpareil, there is the lamentable record of "loss £697 19s 0d." Of course, we do not forget that it had to be turned from an old coffee into a tea estate, and that there are now 316 acres in tea which ought year by year to do much better and 38 acres in cardamoms; but all the same, far better for the Imperial shareholders if their Directors had never touched Nonpareil. Let Directors of other Companies take warning when they are tempted to add still another estate to a prosperous concern.

THE CEYLON GAME PROTECTION SOCIETY MEETING.

This was held in the Nuwara Eliya Board Room shortly after the Kennel Club meeting.

Those present were the Hon. Mr J N Campbell, Messrs. A S Colls, Frank J Hadden, H G Spence, C H Bagot, H H Oliverson, E J S Browne, H W Dickson, John Fraser, C G Wood, C C Herbert, A Hurst, J Wickwar and Thos. Farr, Secretary.

The SECRETARY opened the meeting by stating the difficulty, almost an impossibility, of securing a conviction under the present game laws, which they met today to reconsider; unless a poacher was caught red-handed, no results followed, however weighty the circumstantial evidence might be against him. Mr C H Bagot gave several personal experiences and Major Gordon Reeves wrote to the Secretary, giving an instance in which a delinquent, who admitted to the Magistrate having killed a Sambur and sold the remnants for R35, was only fined R2·50. The presiding Magistrate's name and particulars were unanimously voted to be called for. The Chairman's name was called for before the business of the meeting could be gone into. Messrs. Spence and Bagot were generally called for but the former declined and the latter refused to act.—Mr. Brown, proposed by Mr. Oliverson, was then unanimously voted to the chair when the business of the meeting was gone into:—The minutes of last meeting were confirmed.

THE IMPORTATION OF ANTELOPE.

A long correspondence on the subject was read and owing to the difficulty of catching these it was decided to leave the matter in abeyance.

MR. BAGOT'S RESOLUTION

Was to the effect that no killing of game should take place within limited hours and that even an attempt to shoot at animals within the meaning of the Ordinance should be a penal offence and that the possession of fresh meat of game should be punishable, the proof of legal possession being on the possessor.

RESOLUTION BY MR. FARR.

"That the only way out of the difficulty would be for Government to proclaim all forest, and this was stated by an officer of the Crown to be keenly felt to be a likely necessity by Government and a step to be approved of by their agents."

BRANCH ASSOCIATIONS,

Originating in districts or provinces in which the Government Agents might be induced to take their share in protecting the game of the country, were warmly supported.

THE QUESTION OF WATCHERS.

This was the subject of some discussion as to whether they were "To be or not to be." On Mr. Brown's motion these were considered advisable, if not necessary, in the Bintenne district, towards the support of which the Club has been paying R30 a month, the R M of the districts reporting very good record of services.

Mr. C H BAGOT, addressing the meeting on the difficulty of procuring a conviction, though convincing evidence was adduced, wished to ask the Society to call the attention of Government to the following rule:—"That it shall not be lawful for any person to shoot at any game, unless trespassing in or upon any cultivated land, after dark and before daylight." That the Ordinance 10 of 1891, section 12, did not provid sufficient protection for the preservation of game insomuch as poachers could proceed into Crown forests and kill game between the hours o night, and not be responsible unless actually *caught in the act.* This was the speaker's point of contention and all (the Press included) were asked to support the speaker's resolution to the effect that the game laws should be revised as regards the rules referred to.

Mr. THOS. FARR dwelt on the difficulty arising between the licensed and unlicensed sportsman. It was absolutely impossible to catch the former red-handed, the Ordinance being useless unless Government stretched a point in accordance with Mr. Bagot's suggestion.

Mr. C H BAGOT in further support of the preceding suggestion said that "attempts" to shoot would strengthen the Ordinance, his speech being to the effect that the poacher could not always be seen to hit the game and that he could disclaim all knowledge of its having been slain. Mr Bagot said that he once met a party with guns and dogs hunting in the forest above the Nuwara Eliya Brewery; but, though prosecuted before the Nuwara Eliya court, they were acquitted, no doubt owing to the weakness of the legislation. Referring to the fourth clause of No. 10 of 1891 on

THE POSSESSION OF FRESH MEAT,

Mr BAGOT stated that watchers and aratchis should be empowered to prosecute, but that recent cases, to his knowledge, had been dismissed owing to technicalities.

The SECRETARY, in support of Mr. Bagot's statement, gave

MAJOR GORDON REEVES' EXPERIENCES.

A kangani of his was prosecuted for killing an elk. The Ratemahatmaya, Korale, and Arachchi were interested and even a high Civil Servant was connected in the prosecution. The defendant, replying to the Magistrate stated that the value of elk, which he admitted to have been killed, was R3·50 but, on being questioned, stated he had sold the remainder of the carcase for R35, though he had made sundry presents to gentlemen of the district. Nevertheless an

INADEQUATE SENTENCE

was pronounced, the fine inflicted being only R2·50.

The meeting clamorously called for the name of the Magistrate and particulars, which the Secretary was subsequently authorised to ask for, and censure was proclaimed against those who should have known better than accept such presents, thus conniving at such delinquencies as the Society was so strenuously fighting against. It showed a sorry want of true sport on the part of those who accepted, and their names were much in demand, which, if they had been forthcoming, would have received a vote of censure.

THE WANT OF ADEQUATE LEGISLATION.

A prolonged discussion followed on this question which fully proved the weakness of the Ordinance applying to the possession of fresh meat. It was resolved that anyone in possession of fresh meat should be compelled to prove legal ownership.

BRANCH ASSOCIATIONS.

These were agreed upon to be productive of much good and, in connection with the several roposed Sister-Branches, Mr Shand of Cool-

bawn, Nawalapitiya, was thanked for his kind offer to do all in his power to promote the interests of the Game Protection Society.

THE IMPORTATION OF ANTELOPE.

Mr Farr has not given up hopes of being able to introduce these desirable adjuncts to our game category; but the difficulties were shown to be very great.

LIBERAL SPIRIT OF FOREIGN SPORTSMEN.

The big bags made by visitors which may be accredited to the efforts of the C C P S met with much protestation from all present. The previous donations had been hardly in keeping with the bags made, but, in the last instance of Mr Horsburgh's contribution on behalf of Mons. Dupremont of R20, it was accepted by the Society with very meagre thanks, it being considered a by no means adequate return for the sport enjoyed at the expense of the sporting members of the Colony, this gentleman being credited with a very large return for the trifling fee paid to Government.

In the general sense of the meeting, though no formal resolution was carried, it was unanimously declared that Government should be approached with the object of prohibiting promiscuous visitors indulging in the destruction of Ceylon game fauna without some adequate return. All the resolutions were heartily endorsed. The meeting concluded with thanks to the Chairman.

TEA TRADE IN THE UNITED STATES.

REPORT BY BRITISH AMBASSADOR.

A report was recently made to the British Ambassador at Washington on the tea trade in the United States, and subsequently sent to the Foreign Office. From this report, which has been forwarded by the Colonial Office to the Secretary of the Ceylon Association in London, we take the following:—

"There is now a monthly importation of tea of between nine and ten million pounds. This is an increase of nearly one million pounds per month as compared with twelve months ago, and nearly two million pounds compared with two years ago.

"Taking the figures for the eight months ended February 28 last the amount imported was 78,794,023lb. Of this about 54 per cent. came from China and 37 per cent from Japan. Only a little over 5 per cent was imported from the United Kingdom, British North America, and the East Indies combined.

"The previous year for the same eight months China had about 47 per cent of the trade, Japan about 44 per cent., and the British possessions about 8 per cent.

"China therefore has increased her trade considerably, while all the other countries have sent less.

"The difference may be even greater than is shown by these figures because there is nothing to show from what country the tea imported from British North America came. Part of it may have come from China and Japan.

"Though the quantity of tea drunk per capita in the United States is less than previously, it does not necessarily mean that less tea is going to be consumed. The population is increasing rapidly and large numbers of the immigrants come from non-tea-drinking countries; though they cannot be considered as tea consumers at first, there is no doubt they will in time become so when they or their children adopt the customs of the country. The habit of drinking tea is certainly on the increase, and there will certainly be a very much larger business done in the future than there is at present.

"The demand for Ceylon and Indian qualities is increasing in most parts of the country. With energetic pushing and particular attention being paid to the quality and price preferred there ought to be no difficulty in securing for British dealers a much larger share of the trade.

"If we glance at the prices of tea imported from the several countries it will probably suggest a reason why the sale of that from China has increased so much.

"Prices per pound of tea imported during the eight months ended February 28th:—

From	1901. cents.	1900. cents.	1899. cents.
United Kingdom ..	19·6	19·1	22·8
East Indies ...	13·5	12·6	17·1
British N. America ..	17·2	16·3	16·1
China ..	10·6	12·0	12·4
Japan ..	14·1	12·4	13·7

"It will thus be seen that China has been selling her tea cheaper than her rivals and increasing her trade while other countries have increased their prices and have done a smaller trade.

"The following information supplied by dealers in tea in different parts in the United States may be useful.

"NEW YORK.—The China qualities sell best in the East and the Japan in the West, Formosa included in the China teas. The demand for Ceylon and Indian qualities is increasing. The demand is chiefly for the cheaper grades on account of the duty. The proportion of green tea sold as compared to black is about 1 to 5.

"SAN FRANCISCO.—The China qualities sell best, then Japan, and Ceylon third. The demand for Ceylon tea is increasing; the demand is chiefly for the better qualities. The proportion of green to black is 1 to 3. Demand for green is decreasing.

"NEW ORLEANS.—China tea is the best seller, but demand for Ceylon is slightly increasing. The chief demand is for medium and for better grades, the proportion of green to black is about 1-3 green to 2-3 black.

"PHILADELPHIA.—China and Japan sell best. Never much demand for Ceylon. Demand is greatest for medium grades. Proportion of black to green 5 to 1. Demand for latter is decreasing.

"BALTIMORE.—China sells best. No demand for Ceylon. Demand chiefly for cheaper grades. Proportion of black to green about 5 to 1."—*H & C Mail*, April 26.

PASSION-FRUIT IN NEW SOUTH WALES.—We read in the *Agricultural Gazette* of this Colony that probably no other city in the world consumes in a year anything like the amount of passion-fruit that goes annually into the fruit-salads of Sydney. All attempts to introduce this piquant fruit abroad have thus far ended in failure. The Londoners will hardly look at it. In the United States it is almost unknown. However much we may pity these excellent people,—however much we may wish we might have the pleasure of introducing to them the beauties of the Sydney fruit-salad with its acme of piquancy derived from the passion-fruit, we must admit our defeat up to the present.

THE FOOD WE EAT: APPLES.

[TO THE EDITOR OF THE "SPECTATOR."]

Sir,—*A propos* of apples, there are two old English saws which confirm Mr. Radcliffe Cooke's praise of apples (*Spectator*, April 13th):—

"An apple a day keeps the doctor away."
"Eat an apple going to bed,
You will make your doctor beg his bread."

An experience of some length enables me to support all he says as to the benefit of eating raw apples the last thing at night. A Dr. Searles some years ago wrote to the *Journal of Agriculture*:—"The apple is such a common fruit that few are familiar with its remarkable efficacious properties. Everybody ought to know that the very best thing they can do is to eat apples just before retiring for the night..... The apple is an excellent brain food, because it has more phosphoric acid in easily digested shape than any other vegetable known. It excites the action of the liver, promotes sound and healthy sleep, and thoroughly disinfects the mouth. That is not all. The apple agglutinates the surplus acids of the stomach, helps the kidney secretions..... and is one of the best preventatives known of diseases of the throat. Everybody should be familiar with such knowledge. Next to the orange and lemon, it is the best antidote for the thirst and craving of the person addicted to alcohol or opium."—I am, sir, &c.,

Colwich Vicarage, Staffs. OSMOND DOBREE.

—*Spectator*, April 20.

NOTES ON THE USE OF THE SEED OF THE BAMBOO (DENDROCALAMUS) AS FLOUR.

By W. A. WALLINGER, *Bo. F. S.*

It would not appear to be very generally known that the seed of the bamboo is not only fit for consumption by man, but that, in this corner of India, it is being collected and so consumed to an extent sufficient to ameliorate a very pronounced local scarcity. The *Dictionary of Economic Products, Vol. I.*, contains interesting information on the topic, and the fact that the seed is edible is also referred to in *Agricultural Ledger, No. 17 of 1900.* But the following remarks may, nevertheless, be of some general interest. The fact that there has been an unprecedented deficiency in the rainfall over a tract of country, which is almost invariably well-favoured in this respect, leading in its turn to a sudden seeding of the bamboo, is significant and of interest; but with this aspect of the question I am not at present concerned, except in so far as to incidentally draw attention to the old Brahmin saying: "When the bamboo produces sustenance we must look to Heaven for food." When the seed is ripe, a very slight shaking of the already dry stems is sufficient to induce it to fall plentifully. The ground is either cleared by firing, if the likelihood of being detected is slight; or the seed is collected in cloths spread on the ground to receive it. A very considerable number of the minute pericarps that drop, however, contain no grain; and I have noticed men and women removing these in the reserves by the well-known process of holding baskets over their heads and then pouring the grain slowly on to the ground and allowing the breeze to do the rest. Some bamboo clumps are abandoned altogether as affording insufficent seed for the labour involved.

The collected seed on being brought home is pounded in order to remove the husks. The accompanying specimens may be of value for educational purposes at the Forest School. The original seed is marked No. 1. No. 2 is the husk removed after beating; and No. 3 the seed after this primary process. No. 3 is slightly damped and roughly ground, resulting in the sample No. 4 and the bran No. 5. Finally the coarsely ground seed (No. 4) is re-ground and results in the cooking flour No. 6.

This flour is either mixed with rice or "jowari," or eaten by itself, prepared into the ordinary flat cakes of the country, termed "chapatis" It is said by the natives to be sufficiently nutritious; and the mere fact that it is so largely collected shows it so to be. Nevertheless it would be of interest to ascertain what percentage of proteids the flour contains, and where it would stand in the scale as a nourishing form of diet.

It has been found that two women can collect about 8 lb. of the seed in the day, which, after the removal of the husk and bran, is reduced to 6 lb. This quantity will make 30 cakes 7" in diameter, or sufficient, it is said, to feed an able bodied man for six days. It is interesting to note that the flour is being bartered in local markets by the poor for "chillies" and other condiments; but there is, so far, no recognized market rate. My horse, bullocks, goats and sheep refuse to touch the bran referred to, even when mixed with their ordinary grain. The seed is eaten raw under protest but when cooked, is more appreciated.—*Indian Forester* for May.

THE ROSE GARDEN.

ROSES IN CEYLON.

AT AN ELEVATION OF 5,400 FEET ABOVE SEA LEVEL.

Roses at a high elevation in Ceylon do very well indeed, with but a few exceptions, such as the Hybrid Perpetuals, Jennie Dickson, A K Williams, Reynolds Hole, and a few others. The Hybrid Perpetuals have to be allowed to grow very much as they like, that is to say, no pruning is necessary, only the removal of dead wood, and to let the plant grow on. The plants look straggly by this treatment, but it is the only way to ensure success. Plants that are cut down year after year do not flower properly, and only have a very short life. Among the best are Clio, Robert Duncan, Thomas Wood, Alfonse Suppert, Baron de Bonstettin, Beauty of Waltham, Boule de Neige, and Countess of Oxford. The Victor Verdier tribe all do splendidly and are always in flower. Heinrich Schultheis and its sports are excellent, and Hybrid Teas are without doubt the class above all for this country. As a rule they do better than the Hybrid Perpetuals or Teas, with a few notable exceptions, such as Maman Cochet both pink and white. There is no better Rose grown than this; it simply grows like a weed, and makes very large trees in a year or so from cuttings, and the blooms are enormous and exquisitely formed. To begin to enumerate the Hybrid Teas that do well would be to mention nearly all that can be found in a modern English catalogue. Captain Christy and its sports are in the first rank with the La France tribe, Augustine Guinoisseau and Duchess of Albany being the best of this family. Bessie Brown, Mrs. Grant Baldwin, Kaiserin Augusta Victoria, Mme. Joseph Comber, Mrs Whitney, Souvenir du President Carnot, Shandon, &c., are by far the best Hybrid Teas.

Teas as a class do very well, in the first rank being Maman Cochet, Anna Olivier, Niphetos

(climber), Cleopatra, Perle des Jardins (climber), Duchesse Marie de Rotibor, Emile Gonin, Francisca Kruger, General Bitton, Hon. Edith Gifford, Jean Ducher, Mesdames Baldwin, Berard, and De Watteville, Marie van Houtte, Mrs. E Mawley, Rubens, Safrano, Sappho, and the Souvenir d'un Ami tribe, Zephyr. A lot of the Teas are bad growers, and never make good trees. Noisettes as a class do well. Niel, both yellow and white, Cloth of Gold, L'Idéal, Reve d'Or, W A Richardson, and Lamarque are the best. Both Banksians do well, and soon make extra large trees.

The Bourbon class does not do well, only the Hybrid Bourbon are of any use, such as Mrs Paul, Philemon, Cochet, Purity, and both the climbing and bush Malmaison. The ordinary Bourbons do not flower well. Rosa polyantha, such as Aglaia and Crimson Rambler, grow fast and soon make very large plants.

Chinas do well, but this class as a rule are not very useful, the flowers being very poor and not lasting. The best Chinas are Cora, Duke of York, Duchess, Flora, Mrs Bosanquet, and Red Pet.

The Japanese Rugosa Roses do very well, but have a very straggly growth, and can only be grown as a hedge or back ground.

The Penzance Briars are worthless, and only flower once in a way, though they make good growth. I have all the varieties, but use them as the stock for budding on. Moss Roses are also useless. The only two that flower at all are White Bath and Perpetual Moss, both of very straggly growth and of little or no use.

Roses from seed are very easily raised, and with care good varieties are obtained. The seed ripens all the year round, and is produced freely, if the flower has been fertilised. The writer has raised some fine new sorts from M Neil, Niphetos; Robert Duncan, Thomas Wood, General Jacqueminot, &., and they may be heard of in the Rose world. A CEYLON ROSARIAN.

—*Garden*, April 13.

TEA INSPECTION.

A Visiting Agent writes :—

"How could an Inspector possibly examine all the tea exported? I fancy that is the difficulty. So long as you have buyers, there will be sellers."

To which we reply :—"Don't you see that inspection would be confined to packages bearing unknown marks? No need to touch Directory estates or well-known marks, as the only time tea has been stopped in London is when it was shipped under unknown marks. Think of the grand advertisement it would be to be able to telegraph to the London *Times*:—'Inspector of Tea Exports appointed; standard fixed, below which no tea can leave Ceylon.' It would do more good than fifty answers to Skrine. The Inspector might not reject more than 2 or 3 boxes a year because 'black sheep' and natives would stop shipping rubbish; yet his appointment would be repaid to the honest planter many times over. At present 'the million' at home are being impressed with the idea that "any kind of rubbish can be shipped from Ceylon."

COCONUT PLANTING IN THE NORTH.

During a considerable period, the Pachchillapally district in the Peninsula was the district for coconut planting. In this District there are more coconut estates than in other parts of the North. The best estates, Karampaham, Kotte, Dromore, Ivanhoe and Tanmakeny are situated in this District. A few years back, a new field for coconut planting was found at Vaddukadu and some enterprising men have opened up lands there and have planted them with coconuts. Prominent among those who are planting at Vaddukaddu are Dr. Kandyah, Mr Proctor Casipillai and Mr. Advocate Vanniasinghem. Large tracts have been brought under cultivation and the prospect is reported to be very bright.

The water and soil in Vaddukaddu are alleged to be superior and it is generally believed that, in due time, the district is likely to be a flourishing coconut district, a great rival to the Pachchillapally District. Mr. Proctor Casipillai, who is perhaps the largest and most enterprising speculator, has opened up nearly 300 acres and has applied for more lands. If Vaddukaddu fulfils the expectations formed in respect of it, Mr. Casipillai would be the largest Tamil coconut planter in the North.

The Roman Catholic Mission at Jaffna possesses some valuable estates in the Peninsula. The Melizan Estate, just coming into bearing, is admitted to be a splendid property. But His Lordship Dr. Joulain, the present Catholic Bishop, whose knowledge of the people and the country is perhaps unequalled, has discovered a district suited for coconut planting and which is likely to take the shine out of Pachchillapally and Vaddukaddu. A few years back, His Lordship, favourably impressed with the soil and condition of the land at Mullaitivoe, applied for a block of 500 acres and planted a portion of it with coconuts. The reports we have received of this new plantation are highly satisfactory. The trees are not only in good condition, but compared with those in the old districts they are "giants" and are coming into bearing earlier than in other parts. In view of the excellent water and the peculiar soil, the land is much superior, and as a coconut District, it will, in a short time, become very important and popular.—Jaffna "Patriot," May 10.

PLANTING IN GERMAN EAST AFRICA: GREAT PROGRESS: 25,000 ACRES UNDER COFFEE.

In his report for the year 1900 the British Vice-Consul at Dar-es-Salaam says. — Nearly 600 acres have been planted with Mauritius agave hemp (*Fourcroya gigantea*), and a field railway has been constructed. At the present time some 20,000 leaves, producing about 750 lb of dry fibre, are cut and cleaned daily. The fibre goes through the process known as breaking and scutching the woody stem or boon being cracked and broken up by means of a simple rolling machine. After the bruised leaves have been left in soapy water for one night, they are well rinsed in fresh water and then placed in the sun. When dry as much as possible of the broken wood is shaken out, after which the fibre is beaten by rotating wooden paddles, by which means the remainder is removed. It is then pressed and formed into bales weighing 2½ cwt.

VANILLA.—There are three vanilla plantations near Bagamoyo. Two, Kitopeni and Shambesi, belong to a private company, the third to the Roman Catholic Mission. In the two former are 30,000 vines, each of which bears on an average 20 pods annually. During the drought of 1898 half

the vines died. To prevent a recurrence of such a catastrophe the plantations are now irrigated, the water being fetched a distance of about two miles in pipes. The flowers are fertilised artificially, and the vines are not allowed to grow more than six or seven feet in height. The pods are cured by the wet treatment and are dried in an oven, a temperature of 120 Fahr. being maintained. Some are also sun-dried, being wrapped up in woollen cloth. The trees planted for shading purposes are *Pithecolobium saman* and *Albizzia lebbek*, and as a prop *Jatropha curcas*. Labour is cheap, 3d a day being the price usually paid.

Three or four small vanilla plantations have been started. The largest, on the banks of the Mkulumuzi River, was flooded a few months ago, and most of the vines were lost.

The vines belonging to the Mission are said to be less productive. The prices obtained for 1 lb of vanilla (from 30 to 50 pods) ranges from 1*l* to 3*l*.

BREAD-FRUIT.—A trial has been made by the Mission with the bread-fruit tree which has answered admirably.

COFFEE, ETC.—32 estates have been opened by various German planting companies and private persons in the Hinterland of Tanga and Pangani, and in the highlands of Usambara. About 25,000 acres are under cultivation, 7,500 acres having been planted with coffee, a like number with coconut palms, and 3,260 acres with hemp. Experiments are also being made with ramie, vanilla, cardamoms, Ceara rubber, grape vines, sideroxylon trees, cinnamon, cocoa and tea. Cotton and tobacco have, so far, proved a failure. There are over 5,000,000 coffee shrubs of the Mocha variety (*Coffea Arabica*), one quarter of which are now in bearing. The plantations are situated at an elevation of from 3,500 to 6,000 feet above sea-level. The soil of Usambara appears to be particularly suited to the cultivation of coffee, and the plants come into bearing at two years of age. *Albizzia Lebbek* and *A. Moluccana* are generally used as shade trees, but neither is considered very satisfactory. In some of the estates the shrubs are not shaded at all. Up to the present no signs of sunstroke or canker have been observed.

Hemileia vastatrix broke out in some of the gardens in 1895, and has since made its appearance on one or two occasions. The planters do not, however, consider it a very serious matter, and, after the leaves have been plucked and destroyed, the diseased plants recover. Considerable damage is, at times, done by beetles and field bugs. Very little manure has as yet been used; but the German East Africa Company is following the example of the Guatemala coffee planters, and a mixture of bone meal, sawdust, rotten coffee husks, and lime has been found a good substitute for animal manure which is wanting.

On several of the estates the berries are pulped by machinery (Walker's or Gordon's). Fermenting vats and drying-houses have also been built. Each tree is said to bear on an average ½lb of parchment coffee per annum. The price obtained for the first and second qualities, which are sent to Hamburg, averages 75s per cwt. Inferior coffee is sold locally or in Zanzibar, and fetches about 28 rupees (37s 4d) per cwt. In the following table is shown the total amount of coffee exported from German East Africa since the plants came into bearing :—

Date.			Quantity Cwt.
Jan 1 to	Dec 31	1895 ..	700
Do	do	1896 ..	500
Do	do	1897 ...	1,470
Do	do	1898 ..	2,670
Do	do	1899 ..	1,020
Do	September	1900 ..	1 220

It is believed that next year's crop will be heavy. About 500,000 Liberian coffee shrubs have been planted. The price obtained at Hamburg is, however, not sufficient to pay for the cost of transport, and the gardens are for the most part being allowed to go to weed.

CARDAMOMS.—The cultivation of cardamoms has been taken up by two or three Companies. A sample was sent to Germany at the commencement of the year, but the price obtained (56s per cwt) was disappointing.

GRAPE VINES—10,000 grape vines were planted last year at an altitude of 4,500 feet. They are growing well, but a rust has been noticed on the leaves.

SIDEROXYLON—These handsome and useful trees (the "djohor" of Java) are being planted extensively to mark the garden boundaries.

CINNAMON.—Cinnamon is to be found in many of the estates. A sample which was sold in Zanzibar a few months ago fetched 70 rupees (4*l* 13s 4d) per cwt.

COCOA.—No soil has yet been discovered suitable for the cultivation of cocoa, but there exist a few trees in several of the coffee plantations.

TEA.—Tea grows well; up to the present, however, it has only been planted in small quantities.

LABOUR.—A very important factor in the cultivation of coffee, etc. is, from the planter's point of view, the labour question. The natives of the Tanga and Usambara districts are of little use as workmen, and labourers are usually recruited in the towns of Pangani and Bagamoyo and, in a less degree, on the banks of the Rufiji River. Wanyamwezi and Wasukuma are preferred. It is customary for the men, who receive from 9 to 14 rupees (12s to 18s 8d) per month without food, to bind themselves for six months. There are probably between 3,000 and 4,000 native workmen on the various estates. Asiatics are no longer employed.

A private company has opened a small plantation at Lindi, and a little Liberian coffee is grown near Mikindani.—*Planting Opinion.*

ON A NEW AROMATIC ALDEHYDE OCCURRING IN EUCALYPTUS OILS—By Henry G Smith, F.C.S., Assistant Curator, Technological Museum, Sydney. —We have to acknowledge receipt of a copy of this paper.

THE JUICE OF THE GREEN PINEAPPLE is accredited in Java and throughout the Far East generally, says an exchange, with being a blood poison of the most deadly nature. It is said to be the substance with which Malays poison their creeses and daggers and to be also the finger-nail poison formerly in use among aboriginal Japanese women, almost universally. These women cultivated a nail on each hand to a long, sharp point, and the least scratch from one of these was certain death.—*Medical Times.*

EXPERIMENTAL AGRICULTURAL FARM AND SCHOOL,

We are much interested in learning that the historic estate first opened in coffee by Governor Sir Edward Barnes, and for many years leased and worked by Mr. E. Jeffries in cocoa, coconuts, pepper, and arecanuts, has been sold by the proprietrix, Mrs. Horsford, subject to the lease, to the Ceylon Government and for the avowed purpose of making it the site of a model or experimental Agricultural Farm or Plantation—or both combined—with School, &c. Our information goes to show that Gangaruwa estate, situated near the Botanic Gardens, has been purchased by Government for £8,000, and when taken over will be in charge of the Director of the Gardens. It is purchased subject to Mr. Jeffries' present lease which terminates about two years from now. This will give great scope for experimental work in connection with our Scientific Staff; for, in the Gardens, there is at present no room for such. We also believe the Agricultural School will be once more started at Gangaruwa—that is, in 1903 or so. We cannot too highly commend this latest step of Sir West Ridgeway in the Agricultural and Planting interests of the Colony. Mr. Willis, when he takes possession, should change the name and call his model plantation and farm after the Governor who has done so much for his Department and for Agricultural interests in the widest sense.

COFFEE PLANTING IN SUMATRA.

We are always pleased to hear from our old friend "W.T. McK." who, after leaving troops of friends behind in Ceylon, has been so many years now in Sumatra without making a fortune. He sends us as usual a graphic letter with some useful statistics, showing that his district of "Serdang" has about 10,000 acres uder Liberian coffee. The photograph he sends shows magnificent giant coffee trees (backed by Albizzias) laden with crop; for, of course, the soil is superior to anything we have in Ceylon. But then the market price of "coffee" has, for a long time, been even more disappointing than that of tea!

(*By an ex-Ceylon Planter.**)

NOTES FROM SERDANG, EAST COAST OF SUMATRA.

Some time ago I promised you Liberian coffee figures from here: and now, by the kindness of the Chairman of the Serdang Koffie Planters' Vereeniging, I am enabled to send you a copy of the official figures of the District. By this post I also have the pleasure of sending you a photo, showing coolies picking coffee on Greahan Estate from trees not yet four years old. The gentleman in the hat is the Javanese Head Mandor, a much bigger swell than the head kankani in Ceylon. The lady with the cane is the picking mandor, and the other figures on the ground and up the ladders are members of her picking gang [plump-looking females, not unlike Sinhalese women in size and dress.—ED. *T.A.*] The box she is examining is a framed kerosine oil tin, which, oddly enough, is our standard measure. Our coffee pioneer here, (a genial Italian, rest his soul! his house is like Sheriff's in the old days at Helbodde), discovered that 60 kerosine tins of cherry gave one picul of clean coffee, and that standard has been universally adopted in Serdang.

To practical planters the figures will speak for themselves. When I came here early in 1895 there were three small estates, aggregating about 200,000 plants. The bulk of the district has been planted from '97 onwards. Planting distance varies; but an average may be calculated on of 400 plants to the acre, so that the 4,000,000 plants shown in the table represent roughly 10,000 acres. Three small estates give no return.

Transport is our great difficulty. The far end of the District is 40 kilometres, close on 25 miles, from the railway, over *mud* roads, which, through they harden well enough in the dry season, pull the legs off cattle in wet weather. From where I write it is three hours' driving to Loba Pakam in fine weather: and seven hours if the roads are heavy!! Four years ago we were assured we should have a railway within six months. But at the present rate of progress, the trees, from which the sleepers are to be cut, have not yet started to grow.

Apropos of the coffee figures, it is perhaps worth while repeating the following paragraph from my last notes:—"The old trees of Tanah Abang were planted in 1880 and are 20 years old. They were abandoned for seven years when Giovanni took them up, and all that is now left of them are bearing about four to five katties a year each. Enormous." One katti = 1⅓ lb. Avoird.

The following para is from p. 346 of the *Graphic*, September 8, 1900:—"The Germans have been quick to recognise the possibilities of this region (Uganda), and their enterprise in East Africa is remarkable. Five years ago the home Government appropriated 800,000 marks *for the establishing* of a coffee plantation not far from Tanga. The first year, *I was told*, the yield paid expenses; the third year it equalled half the capital; fourth year, the entire capital; and in the last twelve months the plantation has made a profit of 400,000 marks." The italics are mine. The *Graphic* correspondent is careful to cover himself with "I was told." As to the letter, the wonder is that the young men did not arise, wind him up, carry him out, and bury him. Each of the years is accurately accounted for, so this wonderful plantation must have paid expenses while the plants were still in the nursery! A planter in this district (Serdang), who went to German East Africa two or three years ago, returned here. I hardly think he would have done so if he had realised the prospects as described in the *Graphic*.

A friend recently pointed out to me what he called a "strange omission" in Ballardie's and Owen's, "Buildings." "There are no stables" said he, and I had to draw him a plan for stabling six horses, two carriages, harness-room, and quarters for three syces. Horses and ponies are a necessity in this country: and I think many estates in Ceylon might be better worked if the assistants had ponies to help them from point to point, or to bring them home from work at mid-day after a stiff four or five hours on foot.

Here's to a good New Year to Ceylon. May prices rise, and all proprietors renounce the sweating system! W. T. McK.

* Omitted by printer's carelessness from page 552 *T.A.* of February, 1901.—ED. *T.A.*

* Not certain.

UDAGAMA TEA AND TIMBER COMPANY LIMITED.

REPORT OF DIRECTORS.

The Directors have now to submit their report for the 12 months, ending 31st December, 1900.

TEA.—The estimate for the year was 170,000 lb., but of this only 137,176 lb. were obtained. The Superintendent attributes the deficiency to abnormally wet and windy weather, chiefly during the latter part of the year,

A very wet season was experienced. Frequent floods caused considerable damage to roads and bridges, materially increasing the cost of transport.

Owing to these exceptional causes the Tea cost 30·65 cents per lb., and in consequence of the unusual condition of the markets realized only 25·69 cents the result being a loss of 4·69 cents per lb. or after deducting one or two small assets a net loss of R6,567·32.

The estimate for this year provides for a crop of 160,000 lb. with fine plucking. As the new clearings are now coming into bearing, this should be obtained.

The cost of this Tea should be about 23 cents per lb. and, as the plucking will be fine, with careful manufacture it should sell well.

THE SAW MILLS—at Gintota have worked successfully and showed a profit of R15,461·71. The Directors anticipate an annual profit from this source in future.

The Directors have thought it advisable to write off a sum of R32,858·33 for depreciation of machinery, roads, tools, &c.

A sum of R12,563·00 is due to the preference Shareholders when a sufficient profit has been made to meet it.

It is the duty of the Shareholders to appoint an Auditor for 1901, and a Director in place of Mr H Creasy who retires by rotation, but is eligible for re-election.

Owing to the loss in working of the Company's Tea Estates and the heavy interest payable to the Debenture holders, the Directors regret to inform the Shareholders that the year's working shows a loss of R6,928·75. Unless money can be borrowed at a lower rate of interest, they feel bound to advise that the Company be wound up. One half the loan, secured by debentures, falls due for payment in June next, viz, R75,000, and, unless provision can be made for the paymsnt or renewal of this loan, it will be impossible to carry on the Company, and the debenture holders will be forced to fore-close and take over the property.

SCOTTISH CEYLON TEA COMPANY, LIMITED.

REPORT OF THE BOARD OF DIRECTORS.

To be presented to the Shareholders at their Twelfth Annual Ordinary Meeting, to be held at the office of the Company, on Thursday, 9th May, 1901, at 12 o'clock noon.

The Directors have pleasure in submitting to the Shareholders the Accounts and Balance Sheet for the twelve months ending 31st December, 1900, with Auditor's Certificate attached.

	£ s d	£ s d
The net profits for the year amount to £5,318 14s 1d, which, with £462 16s brought forward from previous Accounts, gives a total to be dealt with of ...		5,781 10 1
An Interim Dividend on the Ordinary Shares of 5 per cent (free of Income Tax), paid in September, 1900, amounts to ...	2,050 0 0	
Dividends on the 7 per cent Preference Shares have also been paid, absorbing ...	630 0 0	
It is now proposed to pay a Final Dividend on the Ordinary Shares of 5 per cent (free of Income Tax) making 10 per cent for the year ...	2,050 0	
To write off the Capital Expenditure incurred during 1900	637 16 8	5,367 16 8
Leaving a balance to carry forward to next Account of		£413 13 5

The total crops secured from the Company's estates during the twelve months amounted to 899,806 lb tea and 48,809 lb cinchona bark, the outturn of tea being 83,806 lb over estimate, and 80,102 lb in excess of the previous year.

In addition to the above, 80,283 lb of tea were manufactured for others, giving a total output from the Company's factories for the year of 980,089 lb.

The yield from the tea-bearing area was 523 lb per acre, against 480 lb in 1899. The rate of exchange was 1s 4 27-64d., against 1s 4⅜d., and the price realised in the London and Colombo markets respectively averaged 6·94d. and 30¼ cents, against 7·71d and 35 cents for the preceding season. The Company's acreage remains unaltered at 1,963 acres, of which 1,720 acres are under tea cultivation.

The past year has been a most unfavourable one for tea producers generally, but it is hoped that the measures that are now being adopted to restrict output, both in Ceylon and India, will have the desired effect of placing the industry on a more satisfactory basis.

The Ceylon Manager, Mr Kerr, resumed charge of the Company's affairs in Ceylon on 1st January last, and reports that the estates are all in excellent order. During his furlough Mr. G M Ballardie again kindly undertook the temporary management in Ceylon, and the Board appreciate the able manner in which the Company's interests have been looked after by that gentleman. The Directors also take this opportunity of expressing their satisfaction with the working of the Company's staff, both in Ceylon and London.

The Directors have to record with much regret the death of their esteemed colleague, Mr. Donald Andrew. It is not at present proposed to fill the vacancy thus created.

In accordance with the Articles of Association, Mr H L Forbes retires from the Board at this time, and, being eligible, offers himself for re-election.

Mr J B Laurie, C.A., also offers himself for re-election as Auditor. H. L. FORBES, Chairman.

London, 27th April, 1901.

THE CEYLON REDUCTION IN OUTPUT.—We have never been great believers in the effect, of an agreement to "rest" so much of our tea, on the London market. Even if Mr. Philip had been able to telegraph 8 or 10 agreed in place of 3½ million lb., we do not think the dealers and others would pay so much attention as they must do to the actual figures of shipment; and the fact, that we have already sent 2½ millions lb. less to London this year than last, should speak volumes as to the greater reduction still to come, owing to fine plucking. It is reassuring to learn, by our Special Telegrams from Calcutta, that the Indian Tea crop must inevitably be short.

SPORT IN CEYLON.—Our columns today afford an unusual supply of interesting reading on Sport in our Highlands, including a long and well-illustrated paper on 'Elk-hunting' by Mr. Thomas Farr, which we take into our Directory and *Tropical Agriculturist* from the "Wide World Magazine" received yesterday; and a special contribution by Mr. H. Brown (now of Nyassaland) on his experiences after Elephant in the Balangoda district.—To supplement these we receive, very opportunely, our representative's description of a visit paid this week to the Horton Plains—so that no one can say our hill-country is not fully dealt with in our present issue.

THE DEVELOPMENT OF THE SIROCCO ENGINEERING WORKS.

The extension of the business of Davidson and Co., Limited, of the Sirocco Engineering Works, Belfast, to the engineering centre of Westminster, where a branch office has been opened at 13, Victoria Street, led to a call a few days since from Mr. F G Maguire, who is the personal director of the London branch. Mr. Maguire's long connection with the firm in India and Ceylon, where he has made many friends, gave rise to a brief but interesting conversation on the subject of the tea industry, and the progress of the tea machinery business founded by Mr. S C Davidson, branches of which, by the way, have been opened in Manchester and Glasgow; and show-rooms are being fitted up in Germany, Austria, and Russia, by specially appointed agents. "It was a case of small beginnings," said Mr. Maguire. "Mr. Davidson, himself a practical tea planter, believed he knew what planters wanted; and he set to work to supply them; the growth of the business has been remarkable. Beginning with an insignificant building, the 'Sirocco' works have developed extensive proportions, while 'Sirocco' machinery is known whereever British-grown tea flourishes, and also in China and Java."

Replying to further questions, he said:—

"The boom in the Jamaica fruit trade has led to their use for refrigerating purposes on Board the British line of steamers engaged in the Jamacia trade. The buildings in which the fruit is stored on arrival at Bristol are also under the controlling action of the 'Sirocco' fans, and if you keep your eye on the events I do not doubt but that you will see the application of the 'Sirocco' fan to many other purposes, such as organ-blowing, elevating grain, tobacco, &c. But with all these developments in directions outside tea we continually keep the needs of tea-planters in view."
—*Home and Colonial Mail*, April 19.

MR. KELWAY BAMBER'S GREEN TEA PROCESS.

Mr. Kelway Bamber is the latest in the field with a tea-manufacturing process which he has protected by patent. It having appeared to him that the present processes of green tea manufacture, as adapted for machinery, are defective, he has sought to supply the defects with the improvements which are the subject of the patent. The invention consists in the application of dry air or air saturated with water or steam alone, or with water and steam and carbonic acid gas, to the tea leaf during the processes of wilting, rolling and drying green tea, also the application of regulating gear so as to enable the operator to supply saturated air, saturated air combined with carbonic acid gas, or dry air, or dry air and carbonic acid gas, at will, to the leaf during each or all of the above operations. The object of the process is to fix and retain the green colour of the leaf and thus prevent the discoloration unavoidable, as claimed by the inventor, in the present process of manufacture, and to prevent breakage and improve the twist of the leaf, thus enhancing the market value of the finished product. Mr. Bamber claims that he improves the present process by (1) admitting into the wilting machine, instead of steam only, dry hot air, or dry air saturated with carbonic acid gas, or hot air

saturated with steam from a boiler or with steam or water from a tank placed in a suitable position, the amount of saturation, by means of the appliances for which patent has been taken out, being regulated at will, until the leaf is wilted, when it is replaced with dry hot air only, or with a mixture of hot air and carbonic acid gas only, to remove the excess of moisture, or until the desirable condition for rolling is obtained. (2) By the application of carbonic acid gas to the leaf during the process of wilting, rolling or drying green tea, *this inert gas having the property of retaning the desirable green colour*, and improving flavour, so enhancing the value of the finished product.

The novelties in the above process claimed by Mr Bamber are (1) the conveyance of dry air, or air saturated or over-saturated with steam or water only, to green tea leaf for the purpose of wilting it. (2) The application of gear to regulate the conveyance of dry air, and the saturation of air employed for wilting green tea leaf. (3) The conveyance of air, carbonic acid gas and steam or water simultaneously or separately into the apparatus for wilting green tea leaf. (4) The application of gear to regulate the conveyance of air containing carbonic acid gas, air alone, or air saturated with moisture and carbonic acid gas to the apparatus for wilting, rolling and drying green tea, alternately or concurrently as desired. (5) The conveyance of carbonic acid gas to green tea leaf and the keeping of the leaf in an atmosphere of carbonic acid gas during all or any of the operations of green tea manufacture. (6) The method or procees of wilting tea leaf and of preventing fermentation or oxidation by the application of carbonic acid gas. (7) The application of carbonic acid gas to wilted leaf, while being rolled and dried, to prevent oxidation.

The invention is a promising one and the application of carbonic acid gas to prevent oxidation is a distinctly scientific advance.—*Indian Gardening and Planting*, May 9.

INDIAN CARDAMOMS DISEASED.

In a report on cardamoms in India, J W Mollison, Deputy Director of Agriculture at Poona, says that a form of disease has appeared in the cardamom crops in most of the Kanara gardens, and is restricting cultivation. No particular indications of disease are presented by the affected plants, but they do not seem to thrive, and the leaves in parts become yellow and wither.

Like any other plant under cultivation, the cardamom degenerates when grown for long periods under exactly the same conditions of soil and climate, and without any change in the methods of propagation and reproduction. The Kanara crops have for a long period been grown with practically no changes in the system of general cultivation, and to these conditions, in Mr. Mollison's opinion, the so-called disease is due. The vigor of the cardamom plant may be renewed from time to time, as may that of any other cultivated plant, by change of seed, change of soil, rotation of crops, and other regenerating influences.

Our information in regard to Mr. Mollison's report does not state to what extent, if any, he estimates the crop shortage on account of the diseased plants. In this market at present there is a fairly plentiful supply of the lower grades of cardamom seed, which are held at from 60 to 70 cents per pound. Large, white Mangalore seeds, however, are rather scarce, and are quoted at from $1 to $1·10 per pound. In the event of any shortage in the supply at primary points, there would, of course, follow an advance in the local market price.

Below will be found a table showing the total imports of cardamom seeds during the fiscal years from 1891 to 1900, inclusive:—

Year.	Pounds.	Year.	Pounds.
1891	.. 41,399	1896	.. 24,540
1892	.. 65,204	1897	.. 34,437
1893	.. 31,315	1898	.. 43,644
1894	.. 25,723	1899	.. 77,076
1895	.. 42,587	1900	.. 45,557

—*New York Drug Reporter*, April 15.

DOLOSBAGE AND ITS ESTATES: NOW AND THEN.

Mr. H. Cottam, who is making a peregrination through his old district, sends us some chatty notes about the changes he notes in different estates. These should prove very interesting to old residents of Dolosbage now away from Ceylon,—for example Messrs. W. Rollo, W. Anderson, Cuthbert, Forbes Laurie, R. Porter, &c. Mr. Cottam is not aware that a special "circular" was issued from the R. B. Gardens, dealing with the Lantana bug, and there can be no good excuse for Dolosbage men not burning off and extirpating the pest, let a worse thing befall them and their tea. We lose sight of old names, through amalgamations. Kellie alone now represents in the Directory:—Fairlie, Hormusjie, Moorootie and Inverugie. We believe in this day of low prices that, for any proprietor of a small tea garden, it should pay him well to use chulas in the preparation of his tea, after the careful, slow, old-fashioned style. The result ought to be worth an extra good price, both for the flavour and keeping powers of the tea: so we have been told by our Rood Lane friends. Of course "chulas" will not do where there is area and quantity.—What does H.C. mean by cracking up a flat for giving 1,300 lb. of *leaf* per acre per annum? That is only 325 lb. of made tea. He surely means 5,200 lb. of leaf? That would indeed be worth writing about, though we see that Mariawatte exceeds this with an average of 5,428 lb. of leaf! (1,357 lb. of made tea) for its 100-acre field.

THE CHINA TEA SEASON is now closed and Messrs. Siemssen & Co. show a total for 1900-01 of 123,566,984 lb. against 115,139,377 lb. in the previous season. The following table gives details:—

TOTAL EXPORT OF TEA SEASON FROM ALL CHINA:

	1899-01 lb	1899-1900 lb
To England	21,268,348	29,297,824
,, The Continent	10,474,124	4,999,347
,, Russia	33,043,881	29,635,815
,, America	50,887,045	43,888,486
,, Australia	6,514,722	6,094,660
,, South Africa	1,378,864	1,223,245
Total lb	123,566,984	115,139,377

[Besides, perhaps 100 million lbs. sent overland to Russia, Thibet and Central Asia generally, including brick tea.—ED. *T.A.*]

A CHANCE FOR TEA IN ITALY.

According to the "Gazzetta degli Esportatori," the trade in tea in Italy at the present time is a monopoly in the hands of one or two firms who supply shopkeepers, and also private customers directly, at extremely high prices, though the quality is not always good. Quite a low quality of tea, the "Gazetta" asserts, is sold at the present time at about 3s 6d the pound. In its opinion, an enterprising firm selling Indian and Ceylon teas, which would open branches in Italy, and content itself with a moderate profit, would soon be able to control the Italian tea market, reaping handsome profits for its enterprise.—*Morning Leader*, May 16.

COCONUT BUTTER IN MANNHEIM.

The manufacture of coconut butter (palmin) is a considerable industry in Mannheim. Palmin is made from the kernel of coconut, and is used as a substitute for butter and lard in cooking. As it does not readily become rancid, it has met with favour in German hospitals and army camps,—*Globe*, May 17.

COLOMBO PRICE CURRENT.

(Furnished by the Chamber of Commerce.)

EXPORTS.

Colombo, 3rd June, 1901.

THE

AGRICULTURAL MAGAZINE,

COLOMBO.

Added as a Supplement Monthly to the "TROPICAL AGRICULTURIST."

The following pages include the Contents of the *Agricultural Magazine* for June :—

Vol. XII.] JUNE, 1901. [No. 12.

FIRST STEPS IN AGRICULTURE.

First Stage—1st Lesson.

BY A. J. B.

IN the following articles I propose to explain in simple language, suitable to the minds of young boys and girls in the country, the elementary principles and practice of agriculture.

In the absence of any easy text-book on agriculture in the State schools of Queensland, these lessons may be found of some use in interesting young people in an industry which must always take first place amongst those of all countries under the sun. It is hard to say what would become of the world and its other industries if agriculture were abandoned.

You have all heard the word "agriculture," and you know that it has something to do with farming. Well, the word agriculture means cultivating a field. But how the field is cultivated, and how the farmers make the beautiful crops of wheat and lucerne and potatoes and other things grow and produce fruit, you do not yet know. You see a man ploughing a field. Why is he ploughing it? That is what I am now going to explain to you. You know the corn and wheat and green stuff for horse feed and vegetables are grown in the soil. But if you were to try and grow these things in the same way as the grass in the bush grows, you would find that your crop would not come to anything. Why is this? You will say that the grass and weeds grow without any ploughing. Their seeds drop on the ground and they grow; why should not potatoes and corn grow just as well? The reason is, that corn and potatoes require a loose soil. And why loose? Because the plants and their roots require air and water, and they can only get air and water when the soil is soft, so that the roots can easily run through it and get the nourishment they require. This nourishment is called plant food. The air can get into a loose soil, and the moisture can rise through it and be sucked up into the plants. Now look at that man ploughing. If you follow him you will see that his plough has stirred up the soil for several inches from the surface. He has thus made a loose bed through which, when he has sown the seed, the little rootlets can easily make their way and draw up all the moisture they need to enable them to grow up vigorous plants. But ploughing alone is not sufficient. Look at the sod the ploughman has turned over. It is like a long cake, scarcely broken. If the seeds were to be sown after he has finished ploughing, they would not grow properly. So the next thing he does is to drag a wooden or iron frame full of long teeth across the ground. This is a harrow, and it does for the field what a garden rake does for a flower garden when it has been dug over. It smooths down and breaks up the clods, and renders the soil soft and friable, and puts it in a proper condition to receive the seeds.

When the field is ploughed and harrowed it becomes a sort of soft sponge. You have seen the rain falling on hard ground. What becomes of

the water? It runs off over the hard soil into some creek or gully or low place on the land, and very little goes into the soil. That little is quite sufficient for the grass whose roots are near the surface, but would not be of much use to plants whose roots go deeper into the soil. So you see that ploughing is necessary to enable the rain water to reach the lowest roots. Now I must tell you something else about the rain water. After a heavy shower of rain you will notice that often a strong westerly wind sets in. Now, a strong wind will dry up the ground more rapidly than a hot sun; and if Nature had not done something to help the poor plants to get the moisture they want, they would all die.

Now I will show you how they get this moisture. Here is a bit of lump sugar. It is quite dry, you see. I dip one end of it into this saucer of water. Now examine the sugar. You see that it is quite wet. Even the dry part I held in my hand is wet. How does this happen? The sugar is full of little passages through which the water creeps up until these passages are all full, and the whole lump is full of water. Just in the same way the soil, after it has been ploughed and harrowed, is full of little passages through which the rain water which lies below the soft soil creeps up and supplies the roots with all they require until another shower falls. When dry weather lasts for a long time the supply of water below the surface becomes exhausted at last, and the poor plants, which cannot live without water, become sickly, and at last die off. But a good farmer is always stirring up the soil between the crops, and by doing this he provides more plant food for them, and the moisture does not pass away so quickly as if he left the soil to itself. Then there is another reason for knocking the soil about, and for digging and raking and hoeing it. You know what weeds are. Weeds are plants, and some of them are very useful; but when they grow amongst garden field crops these plants are in their wrong place. Now look at a paddock full of Sida retusa, which the youngest of you can tell from any other weed. This Sida retusa is a very valuable plant. Its bark is full of fine, strong, silky threads like flax, and these threads are very useful for making ropes. But you know that no flowers or vegetables will grow properly if they are smothered by Sida retusa, so however useful a plant it may be, it becomes a weed because it is in the wrong place, and therefore the farmer and gardener take care to keep it out of their crops.

There are other weeds, such as thistles, which grow in great quantities in the winter, and these must be carefully kept down or they would smother the plants we want to grow. There is another reason why weeds should be kept out of a crop. The wheat and oats and barley and potatoes want a great deal of plant food; but the weeds want just as much, and they thus take away the plant food which would feed the crops, and these are consequently not so good as they would be if there were no weeds.

Now let us see what you have learnt in this lesson. You learned first why the soil in the farm had to be ploughed up, and why it has to be harrowed. Then you discovered what becomes of the rain water which falls on hard ground and on ploughed ground. Furthermore, you learned that the hot sun and the strong wind dry up the land by sucking up the moisture in the same manner as the wind dries a wet pocket handkerchief exposed to it on a clothes line. Then there was something else I showed you. You remember the experiment with the lump of sugar. That showed you that the water deep below the surface is enabled to reach the plants by means of all the little passages through the soft soil. And, lastly, you learned that one reason for constantly stirring the soil is to bring more plant food to the roots of the crop, and the other for the purpose of destroying the weeds, which would, if allowed to grow, either smother the plants you have grown or else use up so much of their food as to prevent them from coming to perfection. One other lesson you must not forget. That is, that even useful plants may become weeds if they interfere with any crops the farmer may be growing.

Many of you have seen fields of wheat, and in some fields you may have noticed quantities of oats mixed with the wheat. Now, oats are very valuable crop when grown by themselves, but when they get into a wheat field they become weeds, which cause great loss to the farmer, because, instead of his crop being all wheat, it is half oats and half wheat, and is of no use to a miller until the oats are taken out of it.

I will now give you a few questions to answer, and remember this, if you carefully attend to these short lessons, you will have no difficulty in answering the questions without looking at a book, and as you advance further into the subject of Agriculture you will be able to answer far more difficult questions as easily as you can answer these eight first ones.

Questions on Lesson I.

1.—What does the word "Agriculture" mean?
2.—Why must the soil be ploughed and harrowed?
3.—What becomes of the rain water which falls on hard ground.
4.—What becomes of it when it falls on ploughed land?
5.—How do the plants obtain moisture from the soil in dry weather? Can you describe an expirement to prove what you say?
6.—What is plant food?
7.—What do you understand by weeds?
8.—Do useful plants ever become weeds?

OCCASIONAL NOTES.

We have to acknowledge with thanks the receipt of a packet of the Kalihara Melon, a plant found in the arid regions of South Africa known as the Kalihara desert. The Hon. F. R. Moor of the Natal House of Assembly, and a Member of the Natal Government, states that this melon is the greatest boon which can be bestowed on an arid region. The value of this melon is as a standby for stock

in an absolutely arid country, or in a country subjected at irregular intervals to long periods of drought. It is said by many travellers to make exist ence possible in districts otherwise uninhabitable.

The Ceylon Veterinary Department is slowly and steadily growing, and we are inclined to think Mr. Sturgess, our Colonial Veterinary Surgeon, is wisely cautious in adopting for his motto "*festina lente*," in a country such as ours: and with a stubbornly conservative people to deal with, it would have been a waste of time and money to attempt to rush the scientific treatment of cattle on those who have for generations past pinned their faith to the epiricism of the native cattle doctor. The scientist from the West has much to learn and much to teach, and to expect to effect an immediate exchange of old-lamps for new is an idle dream that the practical man of sound common sense does not indulge in.

At present we have the following staff composing the newly-formed Department:—Colonial Veterinary Surgeon, G. W. Sturgess, M.R.C.V.S.; Assistant at Kandy, E. T. Hoole, G.B.V.C. Stock; Inspectors at Colombo, E. W. Jayatilleke and P. C. Fernando; at Ratnapura, M. D. Wijayanayake; at Kurunegala, A. M. Fernando; at Jaffna, T. Mahamoot; at Anuradhapura, D. L. Dias.

We take over from that excellent publication, *The Queensland Agricultural Journal*, for April last, the first of a series of papers entitled "First Steps in Agriculture," written in a popular style and intended for "young boys and girls in the country." These papers should prove useful for village schools, and we commend them to the notice of teachers to whom they should serve as ready-made lessons on Agriculture to occupy the attention of themselves and their pupils during an occasional spare hour. In the present lesson it is only necessary to substitute local crops, weeds &c., to bring it home to the children who are being taught.

The alleged cures for snake bite and hydrophobia are legion, but their virtues rest more or less on tradition and have not the testimony of the medical faculty to recommend them. Some time ago Mr. J. Wimalasurendra, Mudaliyar, the well-known worker in metal, addressed a letter to the press in which he claimed to be able to cure snake bite by means of an unfailing remedy—the juice of certain seeds. The juice was to be taken internally in certain doses, and it was mentioned that the so-called snake stone had no virtue unless it had previously soaked up some of this juice. Dr. Andrew Wilson, referring to this communication, expressed his scepticism as to the genuienness of the remedy in view of the seeds being nameless in the letter referred to. We have ourselves failed to elicit further information concerning the identity of the seeds, the name of which, we are assured by the Mudaliyar, he has sworn never to reveal. It is to be hoped, however, that he will not allow the secret to die with him, but will at least impart it to his next of kin, so that the power to save will remain even in the possession of one individual. In a courteous letter, Mr. Wimalasurendra asks that any case of snake bite should be sent to him without delay, so that he may make use of the knowledge he possesses and apply his unfailing remedy.

The *Indian Agriculturist* is responsible for the following:—"The leaf of a variety of Acacia, known in the Deccan (where it grows wild) by the Hindustani name of *Dewana babool*, is declared to possess properties which make it a safe cure for hydrophobia. The leaves are simply ground up, and the juice extracted from them is given to the patient to drink as soon as possible after he has been bitten. It is a nauseating drink, but this need not cause alarm. The decoction should be administered for three mornings in succession, the diet during this period being restricted to plain unleavened bread or boiled rice and curds. The remedy is said to have been tried in a number of cases with unvarying success. Four individuals, who had been bitten by dogs which were unmistakably rabid, and which subsequently bit other men and animals who developed hydrophobia and died, were treated with this decoction, and are still alive and well." Unfortunately a local name of the tree is given. It would have been more satisfactory if the scientific name could have been added as well

---

The following are a few *Errata* in Trimen's Flora:—Plantineae at head of page 388, Part III. should be Plantagineae. On page 268, Part IV., in the botanical description of Amaryllidaceae "ovary superior" should be "ovary inferior." The second part of the Sinhalese names of the two species of Curculigo mentioned on page 269, Part IV., should be bintal and not biutal. On page 858, Part V., line 6, Dimorphocalx should be Dimorphocalyx, and on the previous page, 7 lines from the bottom, Crateeva should be Crataeva.

Andropogon citratus, lemon grass, should not be confused with *A. schoenanthus*, variously known as geranium oil grass, anise-scented grass, &c. It is hardly correct to say that the latter is abundant about Colombo, as Ferguson is quoted by Trimen to have said, Specimens of this grass sent to us by the Government Agent of Jaffna some years ago were identified by Dr. Trimen as of the variety *versicolor* and called anise-scented grass. When crushed the leaves emit an odour of fennel. The grass is said to be common on the Island of Delft.

In the *Ceylon Flora*, Part V., under *A. Citratus*, the sentence "He (*i.e.*, Dr. Watt) adds that it is called &c." makes it appear that lemon grass is used for scenting tea *in Ceylon*, whereas in his Dictionary Watt's remark as to the use of the grass is made without any reference to Ceylon. If used for flavouring tea, it must be in India. The following quotation from the *Agricultural Magazine* for June, 1893, occurs in the contribution to its pages by a correspondent from Bombay: "More than once I was told by ignorant natives that the tea plant was to be seen growing in the vicinity of this city, and some innocently enquired how the leaf was prepared so nicely in Ceylon. The description of the plant they gave me was very unlike the tea bush. At last I had an opportunity of inspecting the so-called

tea, and found it to be no other than the common lemon grass. This is called by many ignorant people here the tea-plant, and its leaves are infused and drunk with milk and sugar. Sometimes it is said these leaves are cut into small bits and dried and mixed with half the quantity of real tea. I experienced the taste of this lemon grass tea, and my curiosity was satisfied once and for ever!"

"Sera," regarding the identity of which Dr. Trimen was a little uncertain, is *A. citratus*. Bushes are frequently grown in kitchen gardens, and the lower portions of the leaves are always used in the cooking of curries. Dr. Watt is incorrect in saying that lemon grass is called pengiun in Ceylon, unless the word is a misprint for pengiri.

ANOTHER NEW FODDER.

We have to thank the overseer of the Kamerang a State Nursery, Queensland, (Mr. G. B. Brooks) for some seeds of the Algaroba or mesquit bean (*Prosopis Juliflora*). This tree is said to thrive and flourish in places liable to be afflicted with droughts, and supplies not only fodder but large crops of beans which are also valuable as stock food, and have a high fattening value, while the tree remains in bearing for some considerable time. The bean belongs to the leguminosae order and sub-order Mimosae. Several varieties of it are scattered over warmer Asia, Africa, and America, and the variety here referred to is found growing freely in Honolulu. It attains to a height of 30 to 40 feet, is armed, and the pods are from 5 to 8 in. long. The value of the pods lies in their being filled between the seeds with a sweet mealy pulp which is very nutritions and is liked by stock. The bean is also reported to be fit for human consumption, and is eaten in various forms where better food is scarce.

Fences made of the timber are reported to have stood in a perfect state of preservation for more than 50 years—the timber resembling *Lignum vitae* in hardness and durability and taking a polish like mahogany. The bark and whole body of the tree is rich in tannin. The gum closely resembles gum arabic. Baron von Mueller, in his work on Select Extra-Tropical Plants, gives a good deal of imformation about the different-species of Prosopis which are some times called cashaw in addition to the names already given. In planting the seeds should be only just covered and not planted deep, or they will take long in germinating. Dr. Watt in his Dictionary also furnishes interesting notes on the genus Prosopis, which he states includes some 18 species of erect trees or shrubs. Regarding *P. dulcis* (the Algaroba or Paray) he says: It produces sweetish succulent pods, 20 to 24 in. long, which are largely used for feeding cattle. It has been introduced into Madras, where it is planted along railway lines, and is known locally as tamarind. *P. Glandulosa*, the mesquit bean, has been successfully introduced into N.-W. India. The tree yield a large quantity of gum used in making jujubes and other sweetmeats. The sweet pulp of the pods, fermented and boiled, is a not unpleasant drink. The beans powdered and mixed with water are used as food in the form of a dried paste. The beans are also used as cattle food. Gamble mentions that the wood is very hard, durable and has a beautiful grain, and is used for furniture and in the manufacture of charcoal. *P. pubescens*, the screw bean or screw mesquit is being grown in the Botanic Gardens, Calcutta. The pods are said to form an important article of food to the natives, and a valuable fodder for cattle, but great caution is necessary in giving them to horses.

Regarding *Prosopis pallida*, Dr. Watt, quoting from Gamble, says that it has been successfully introduced into Ceylon, that its pods contain as much as 90 per cent tannic acid, and that they are imported into Europe under the name of "Algarobilla" or "Balsamocarpon."

[On enquiry the Director, Royal Botanic Gardens, has been good enough to inform us that so far as is known, *P. pallida*—which is the same as juliflora—has never got beyond the Peradeniya Gardens.—ED. *A.M.*]

BIBLE PLANTS OF CEYLON.

Rue (Greek, peganon) is botanically known as *Ruta graveolens*, and belongs to the orange family. As a small and insignificant looking herb one would hardly think it representative of that order. It is mentioned in Luke xi. 42, "But woe unto you Pharisees! for ye tithe mint and rue, and all manner of herbs, and pass over judgment and the love of God: these ought ye to have done, and not to leave the other undone." In the parallel passage Matthew xxiii. 23, Anethon or dill (translated anise) is named instead of rue. Balfour thinks that probably both were mentioned, and each was recorded by a different Evangelist. Both herbs were commonly cultivated in eastern gardens as at present. As its specific name

(graveolens) signifies, rue possesses a powerful odour and a heavy oil is extractable from it. The whole family is characterised by the presence of essential oil, and it is said of one member, the Dittany or Fraxinella (*Dictamnus Fraxinella*) that owing to the large quantity of oily vapour exhaled by it on a warm evening, the air around it becomes inflammable. The odour of rue is considered pleasing by some, but by others most objectionable. It is said to be used as a spice or condiment along with food, and as a flavouring agent in wine, but it is best known in Ceylon as a medicinal plant,—rue oil being a stock remedy for colds and headaches and to allay spasms. This oil is generally prepared here by boiling rue leaves along with coconut oil to which the strong odour is imparted. In England oil of rue is distilled from the fresh leaves and unripe fruit; it has a pale yellow colour, a disagreeable odour and bitter acrid taste. Rue was called by the ancients the Herb of Grace, and Shakespeare refers to it by this name,—

"Here in this place,
I'll set a bank of Rue, sour herb of Grace."

From this we have the word *rue*, meaning the repentance necessary to obtain grace.

Rue is said to grow wild in South Europe and Palestine. It is generally cultivated here as a pot herb.

Mint (Greek, Heduosmon, or Heduosmos, meaning "having a sweet smell") belongs to the genus mentha, of which the most common species found in Syria is said to be *M. sylvestris*. It is commonly cultivated in gardens, is very generally distributed, reaching high altitudes. Mint, like dill and cumin, belongs to the order Labiatae, to which many strong smelling herbs also belong. What is known as field mint (*M. arvensis*) is a variety common in Palestine. Mint and its allies (peppermint, &c.) possess important carminative properties. It was much used as a condiment in ancient times on account of its aromatic properties, in the same way that it is now used for sauce. Pliny mentions it as highly esteemed. It is mentioned in the Bible with other sweet herbs, such as anise or dill, cumin and rue, *e.g.*, "Ye pay tithe of mint and anise and cumin." Matthew xxiii. 23. The giving of the tenth part to God was enjoined on the Jews, and the Pharisees were very particular as to the letter of the law, tithing even the smallest products of the garden. An essential oil of mint is extracted from the plant.

ABOUT MANGOES.

The April number of the *Queensland Agricultural Journal* publishes an interesting article on Mangoes from the pen of Mr. D. O'Connor, and as it contains much information, we take the opportunity of culling from it, to show, among other reasons, how much can be done, and is being done in some places, to improve the quality of fruit.

Probably no fruit in Queensland, remarks Mr. O'Connor, has of late years received as much attention as the mango, and deservedly so, for most persons who have eaten a really good mango regard it as the king of fruits. Comparatively few persons, however, have tasted high-class mangoes; they are still very rare. While a first-class mango might worthily occupy the top of the list of fruits, inferior kinds should be placed near the bottom. Even for cooking purposes a good mango is preferable to an inferior one. This reason alone should be an inducement to growers to cultivate only good varieties. Much may be done by budding and grafting as hereafter described; secondly, by cultivating with care the better forms; and, thirdly, by importing the choicest varieties procurable. The highest class mangoes are not procurable even in India; some care and expense may be necessary in securing the finest. The choicest in India are said to be owned by wealthy natives who guard them with great care. These would probably be unpurchasable, some other means would therefore be necessary to obtain them, possibly by exchange. In India, the home of the mango, it is propagated mainly by one of the following methods:—Firstly, by growing the seed. This is the easiest way and affords some prospect of getting improved varieties, but this seldom occurs. My experience is limited to one instance, the fruit being superior in every respect to the parent; more frequently degeneracy is the case. Secondly, by inarching or grafting by approach. The vigorous plant, called the stock, of suitable size, growing in a pot, is taken to the tree from which a graft is desired, a small branch, the scion, about the size of the stock is selected, a slice about an inch in length is cut nearly half through, and a similar piece cut from the stock; they are then placed carefully together and firmly bound, usually with cotton lamp wick; a coat of varnish, grafting wax or moistened clay is next applied. When the scion and stock have united, the scion is cut off below the stock above the graft. After a reasonable time the little tree is planted in its permanent position. The third is known as "Gootee." In making a gootee a ring of bark is removed from a branch, over this a ring of well-tempered clay is pressed. This is kept in place by a piece of calico cloth or bast wrapt round it. A gootee pot, (a globular earthenware vessel, with a hole in the bottom, through which a cord, having a knot at one end is passed) is suspended above the branch, and filled with water; the other end of the cord is wrapped round the gootee, which is kept moist by the water tickling down. After a few weeks the clay will be full of roots; the branch may then be severed below the gootee and planted. The fourth method may be described as the best. It is called "flute-budding," and is thus described:—The operation is performed in spring. The plants on which the buds are placed is called the stock, and that from which the buds are taken the scion. A ring of bark is peeled off the stock just below the terminal bud, an inch or more as the case may be. A ring of bark is taken from the scion, containing one or more eyes, and of the same length and size as that taken from the stock. The bark with the eyes taken from the scion is then put on the stock, and it should be so placed that its bud

must be exactly underneath a bud on the stock. The bud will attract the sap to the scion bud, and thus promote its growth. After the ring of bark is placed, it is bandaged and mastic applied to any exposed parts of the joinings. Should the diameter of the scion exceed that of the stock, it is easily remedied by cutting off from the scion a longitudinal strip of bark equal in width to the difference. On the other hand should the dimensions of the tube of the scion not correspond with that of the stock, the difference is made good by leaving on the latter a strip of bark of sufficient width to fill up the space not covered over by the tube of the scion. In placing the bud on the stock, care should be taken to make sure that the edges of the back of the stock and the scion coincide all round.

[A description of the method of inarching or grafting by approach as carried out on mangoes in the Bombay Presidency appeared in the *Agricultural Magazine* of August, 1892, under the head "Indian Jottings." In the issue of October last we reprinted a description of the method recommended by Mr. Horace Knight which is very similar to that given above as "flute budding." The notes on mangoes given by Mr. O'Connor, from which we have been quoting, will be concluded in our next issue.—ED. *A.M.*]

FIBRE CULTIVATION IN INDIA.

A considerable amount of attention during recent years has been devoted by Indian planters to the cultivation in that country of indigenous and imported plants from which fibres can be extracted, and the interest shown in this class of products has been increased by the establishment of Government fibre-plantation in Mysore, from which cuttings and plants can be obtained by the private planter. An account of the various plants so far cultivated in India for the sake of their fibres was given recently by Mr. J. Cameron, F.L.S., in a lecture delivered before the Planters' Association of Southern India (*Indian Agriculturist*, February, 1901), from which the following summary has been compiled. The most important of these plants is the so-called sisal hemp (*Agave rigida var sisalana*), which belongs to the *aloe* tribe and is a native of Yucatan, although it is now extensively cultivated in Florida and Bahamas. The Mysore Government imported several thousands of these plants from Florida in 1894, and the latter are now in a flourishing condition and available for the use of planters. The lecturer called attention to the suitability of this plant for cultivation in the scrub and jungle waste places of Mysore, since it grows well under such conditions. The cultivation of the plant is remunerative, especially with the high prices for the fibre which have ruled in London and Liverpool during recent years. The yield of fibre per acre in Yucatan is about half-a-ton, and the average price obtainable may be taken as £25 a ton, although as much as £65 has been paid.

The "China grass" fibre has been grown to a limited extent in the cooler parts of India, but appears to be quite unsuited for cultivation in the plains. At present it has no commercial value, chiefly because of the lack of a machine for cheaply extracting the fibre. Another native plant which yields a fibre which may prove a valuable one is the Ban rhea (*Villebrunea integrifolia*), a plant growing in the sub-tropical Himalayas. The fibre has been examined in the laboratories of the Scientific Department of the Imperial Institute and found to be similar in type to that of China grass but of a much better quality, being more highly resistant to the action of acids and alkalies, and therefore likely to last better.

Of plants which have been introduced into India the Mauritius hemp (*Furcræa gigantea*) seems to be a particularly useful variety. It produces leaves about eight feet in length, which are similar to those of the Agave, and can be manipulated by the same machinery. The plant seems to readily become acclimatised to India, and was observed to have run wild on the Shavory Hills by Dr. Watt in his recent tour through India. This species is suitable, the lecturer stated, for cultivation on abandoned coffee plantations. It yields a fibre similar to the silk-grass, highly resistant to the actions of water, and so suitable for the manufacture of ship's cordage. It has been valued at £27 a ton. A coarser fibre suitable for paper-making is that derived from the Bhabur-grass (*Ischemium angustifolium*) which grows in Northern and Central India. This fibre has already been used in several Indian paper-mills and found to be a satisfactory material for this purpose.

An interesting account of a successful Agave plantation at Pawai, near Bombay, appears in the same number of the journal already referred to. This farm was started on land which had formerly been used for cultivating cocoa and coffee, but had long been abandoned and had run to waste. In this plantation, which is directed by Dr. Suter, the plants are cut when four years old, only the outer leaves being removed, and from these the fibre is immediately extracted by two special machines. The natives operating these machines have to be clothed in absorbent woollen cloth as a protection from the strongly vesicating sap of the leaves. A plentiful supply of water is necessary during the operation of extracting the fibre, as the latter, unless it is immediately well washed, turns brown on exposure to the air. Altogether, the plantation at Pawai gives employment to 250 natives who earn comparatively good wages. It is proposed to commence, in the near future, the manufacture of ammonia and manure from the waste material (amounting to about 97 per cent. of the whole) left after extraction of the fibre.

As a method of utilising the coarser fibres obtained from the stems of trees paper-making seems to be the most satisfactory, and a recent number of the *Indian Forester* (Jan., 1901) contains an account of the native method of making paper from the inner bark of *Broussonetia papyrifera*. The outer bark is first scraped away and then the inner layers peeled off in strips about five feet long which are dried in the sun. These are next boiled in water containing wood ashes, and when they have become somewhat

soft are taken out and beaten into a pulp by means of wooden mallets, any impurities being picked out by hand during the process. The finely divided pulp is next poured into a stretched sheet of cotton through which the water slowly percolates, leaving a sheet of paper pulp. The latter when about half dry is glazed by rubbing with a piece of earthenware. Finally, when quite dry, it is stripped off by means of wooden knives. This forms the common writing paper of Burma. A coarser kind used for packing is also made which is sometimes rendered waterproof by smearing it with melted beeswax. A third kind is also made in a similar manner, but is finished by treating with finely powdered charcoal, so converting it into a paper which can be written on with soft talc pencils.—*Imperial Institute Journal.*

GENERAL ITEMS.

The introduction of synthetic indigo has caused a serious crisis in the Indian indigo trade. Dr. Brunch, chemist to the firm now manufacturing synthetic indigo, lecturing in October last before the German Chemical Society, gave an interesting account of the laborious research of the last twenty years, which were fruitless till 1894. The chief difficulty was in securing an initial material in sufficient quantity, but this has now been found in Naphthalene. By a complicated process this Naphthalene is converted into indigo.

Mr. Wardleworth's lecture on "Jamaica: The Isle of Springs" delievered on March 11th at the Imperial Institute, shews that that colony is alive to its own interests in agricultural matters. Referring to his recent visit to the island, the lecturer stated that the most important feature in the landscape was the coconut palm. Among other products of the palm Mr. Wardleworth said he had tasted excellent butter—quite free from the characteristic flavour of the coconut—from the fruit of tree. Could this be a local product in Jamaica?

Speaking at the Imperial Institute on March 13th, the Duke of Cornwall and York said:— Anything that marks the good work of the Imperial Institute must be of interest to every member of my own family; for it was to commemorate the completion of fifty years of that great and glorious reign—now alas! ended—that this Institute was founded. And I can assure you that our late beloved Queen always had its welfare very near her heart. You know with what assiduous care and keen interest the affairs of the Institute have, from the first days of its existence, been watched over by my dear Father the King; and only recently the Executive Council recorded their grateful recognition of the benefits conferred upon it by His Majesty. Being myself a member of that Council, I naturally take a great interest in the fortunes of the Institute.

A new substitute for leather called "fibroleum," invented in France by M. Brigalant, is described in a report presented to the 'Societe Encouragement by M. Livanche. According to an abstract printed in the *Revue Scientifique*, this product is obtained by chemical treatment of leather waste, which has hitherto been used only for the extracting of the grease that it contains. To quote the abstract: 'The clippings of leather, cut into very small bits, are stored in great vats, where they are macerated in an alkaline solution, which by dissolving the substance that cements the fibres together, leaves them independent. This operation requires great delicacy, for a too concentrated solution or a too prolonged maceration would alter the fibres as well as separate them. The operation, which lasts two to fifteen days, takes place at the ordinary temperature. After washing with cold water the material passes to a special defibrator. The resulting pulp, which is very soft to the touch, is treated in machines similar to those used in paper-making, and the result is a very light, but strong, sheet not more than 1 millimetre (1·250 inch) in thickness. These may be made to adhere, forming sheets varying in thickness from 1 to 10 centimetres (2·5 inch to 4 inches). After treatment in the hydraulic press, these sheets look like leather and have its strength. M. Brigalant has made interesting uses of fibroleum, chiefly in replacing the inferior products that are used in the manufacture of cheap shoes. At present the inventor is making daily 125 to 150 gross of soles, and is putting in machinery sufficient to turn out 1,000 gross a day. Although fibroleum is more absorbtive to water than real leather, its strength and flexibility, as well as its cheapness, make it suitable for all sorts of uses, and M. Livanche thinks that the industry is destined to extend widely."

In view of the increasing price of camphor, a German firm have suggested India and Ceylon as suitable countries for cultivating the camphor tree. The world's requirements of camphor are estimated at 10,400,000 lbs. per annum; of this, under the new administration, about 5,200,000 lbs. will be supplied by Formosa, while about one-third of the whole will be exported from Japan, leaving a diminution in the exports, compared with 1898, of about 3,640,000 lbs.

To prepare sweet potatoes according to the Southern mode, we (*Florida Agriculturist*) are told that they should be peeled and boiled until they are thoroughly but not too well cooked. They should be cut into four pieces lengthwise, and placed in a tin baking pan. Butter and sugar should be placed over the potatoes abundantly before they are put in the oven to bake slowly. After a while, the butter and sugar mingling with the juice of the potatoes form a delicate crust that should be cooked until it has almost reached the point at which it is candy. Under this crust is a thick, rich syrup of the sap of the potatoes, sugar, and butter. Anybody who has eaten sweet potatoes in this way will never be satisfied with any other way of cooking them. The principal merit of this method lies, of course, in having them thoroughly cooked. The fire must be slow, and the cooking must continue until the sugar and butter on top of the potatoes have formed a crust.

The analysis of the sweet potato (according to Dalgety's Review) is as follows :—100 lbs. sweet potato contains 69·32 to 73 11 lbs. water, 1·09 to 1·29 lbs. ash, 1·38 to 2·47 protein or flesh-forming material, ·86 to 1·23 lbs. fibre, 29·73 to 28·46 lbs. nitrogen free extract (starch, sugar, gum, &c.,) and ·43 to ·85 lbs. fat: a total of 27·46 lbs. to 32·49 lbs. dry matter. It thus contains more dry matter and more starchy and sugary food, but less nitrogenous material than the ordinary potato. As a comparison it may be stated that 100 lbs. maize contain 89·1 dry matter, 10·5 protein, and 75 lbs. nitrogen free extract, while 300 lbs. sweet potatoes contain 86·7 dry matter, 4·5 lbs. protein and 75·3 lbs. nitrogen free extract.

In Japan sweet potatoes are preserved by drying thus :—Cleanly washed potatoes are placed in a basket and immersed in boiling water for a short time; when taken out of the basket they are cut into thin slices and spread over mats, exposed to the sun for three or four days. In order to make a superior quality, the skin of the potato is peeled off before slicing.

The *Indian Planters' Gazette* writes :—"The ladybird beetle not having turned out a success for the numerous pests that afflict our tea gardens, we see that the *manthus* has been suggested as a likely ally to wage war with. But there are four *manthi*, though, from its well-known pugnacity, that usually denominated the devout one is probably meant. We have kept this creature in muslin cages, but are not aware that its love of fighting and cannibalistic propensities extend beyond its own species. If, however, it can be trained to turn its attenton to spider, its domestication may be worth attention; but it must be remembered that the insect is as much a vegetarain as a carnivorian, and, though no likely to patronise the bitter tea leaf, would play sad havoc in an adjacent flower or vegetable garden."

Dr. Harvey W. Wiley, of the United States Department of Agriculture, reports that the sunflower is a crop which makes a considerable drain on the elements of soil fertilizers; that one of the most valuable constituents of the plant is the oil, which exists in large quantities in the seeds; that the economic production of sunflowers is now confined almost exclusively to Russia, where it is an agricultural industry of considerable importance; that in the United States it is grown as an ornament and for the production of seeds, which are used chiefly for poultry and bird feeding and for condimental and medicinal properties with farm animals; that the oil of the sunflower seed is not produced commercially in the United States; and that in the cultivation of the sunflower the methods pursued for growing Indian corn are to be followed; and the plant is capable of cultivation over almost as wide an area as Indian corn.

Tomatoes are most helpful to the system when eaten raw, as the volatile oil they contain is dissipated by the heat of cooking. Green vegetables, such as spinach and cabbage, are invaluable as medicinal articles of diet, as they possess blood purifying properties, and act indirectly on the liver. Turnips are nutritious, while the young turnip tops are possessed of tonic properties. Parsley is a blood purifier, and should be eaten both raw and cooked. An almost exclusive diet of fruit and vegetables is supposed to induce purity of complexion.

Says the *Chemist and Druggist*:—We have recently had brought under our notice a fine sample of Egyptian capsicums which have lately made their appearance on this market. The pods are of a bright uniform colour and devoid of the calyx and stalk, are very clean, and have evidently been carefully prepared. They are valued at about 65*s*. per cwt. We have no data bearing upon this sample, but by careful comparison with Natal capsicums the two forms are practically indistinguishable, and it is probable that the sample in question has been grown from Natal seed. In the early part of May last year one of the Mincing Lane brokers included in his spice-catalogue a similar sample from the same country equally well prepared, and valued at the time at 83*s*. per cwt., fine Natal being worth 90*s*. In the catalogue referred to a sample of chillies from the same source was also included, but we do not remember to have seen any further parcels offered since, though we occasionally see quantities from Nyassaland. It is just possible that at no distant date we may receive both capsicums and chillies from the West Indies, as seeds of the commercial varieties were freely distributed through these islands some time since by Dr. D. Morris, late assistant director of Kew Gardens.

LITERARY REGISTER SUPPLEMENT:

AND CEYLON

"NOTES AND QUERIES."

[Under this heading, in future, we mean to give a four or eight page "Supplement" with our *Tropical Agriculturist*, from quarter to quarter, according as there is matter of sufficient value, so to be preserved.]

JULY, 1900.

A LEAF FROM THE PAST:

A FORMER CHIEF JUSTICE OF CEYLON AND THE LORD CHANCELLOR OF ENGLAND; ALSO A LOCAL KING'S ADVOCATE AND A HOME SECRETARY.

A GIFT TO THE SUPREME COURT BY THE LORD CHANCELLOR.—We are glad to learn that the Lord Chancellor has sent as a gift to the Supreme Court an oil-painting of his uncle Sir Hardinge Giffard, a former Procurator Fiscal (i. e. Attorney-General) and Chief Justice of Ceylon. It appears that Lord Halsbury in a conversation with the present Chief Justice when in England expressed his wish to make a replica of an old family portrait and present it to the Supreme Court. The portrait has just arrived and will worthily adorn the walls of the Supreme Court. The thanks of the judges and the legal profession are due to the Lord Chancellor for his graceful present.—Local "Examiner."

The above paragraph from our legal contemporary corrects an error under which we and many in Ceylon have hitherto laboured. We had somehow got the impression that Sir Hardinge Giffard, now Lord Halsbury, and for the third time Lord Chancellor of England, was born in Colombo, and was the son of our former Chief Justice. But, though evidently named after the latter, he is only a nephew. "Who's Who" and "Men of the Time" agree that Lord Halsbury, born in London, September, 1825, is the third son of the late Stanley Lees Giffard, Esq., LL. D., Barrister-at-Law. The founder of the family was a certain Mr. John Giffard, who came into political prominence in Ireland during the troublous closing years of the last century. In a well-known, amusing, but not over-reliable Irish Book of Memoirs, we are told a good deal about John Giffard's climb into notice and a Government office, and how during the process, he came under the scathing sarcasm of Grattan. Of more immediate interest is it to learn that John Giffard's eldest son, Hardinge Giffard, and Mr. Croker of the Admiralty, married two sisters, ladies of Waterford; and that Mr. Croker's good luck and great political influence enabled him to help his brother-in-law, "who, having tried the Irish Bar in vain for several years, has nevertheless become Chief Justice of Ceylon." The writer does not make it very clear to which of the brothers Croker—both in the Admiralty—he refers; but we suppose it must be "John Wilson," of the *Quarterly*, of whose writings Macaulay so often made mince-meat.

Returning to Hardinge Giffard, Barrister, we find that he came out to Ceylon not as Chief Justice, but as "King's Advocate-Fiscal"—an office afterwards designated "Queen's Advocate," and now known as "Attorney-General." From 1811 to 1820, or 1823, Giffard did duty in this post in Colombo and then he succeeded Sir Alexander Johnston, and as Sir Hardinge Giffard, KT., LL. D., served as Chief Justice up to 1827, when he was succeeded by Sir Richard Ottley. Sir H. Giffard embarked for England on March 2nd, 1827; but he cannot have lived long; for in a return of retired Judges on pension made up in 1832, his name does not occur, though those of his two predecessors and successor are given:—

Sir E. Carrington, Knight.—Chief Justice, four years nine months, retired 12th March 1806, pension £1,200 per annum.

Sir A. Johnstone, Knight.—Chief Justice, 17 years, retired 1st March 1819, pension £1,660 per annum.

Sir R. Ottley, Knight.—Chief Justice, 12 years nine months, retired 1st January 1832, pension £1,200 per annum.

Harking back, we must notice that Sir H. Giffard was succeeded in 1820 (or 1823) by a notable man in Henry Matthews, author of "The Diary of an Invalid"—a well-known book in those days—who continued as Advocate-Fiscal till 1827 when he was sworn in as Puisne Justice on the same day as Sir

R. Ottley, became Chief Justice; but, alas, the accomplished writer and judge died at Colombo on May 21st, 1828, his remains being interred in St. Peter's Church, where his son, born in Colombo (then Home Minister) placed a brass plate to his memory. It is a singular fact that two members of the Imperial Cabinet for 1886-92, should thus be closely connected with Ceylon—Lord Chancellor Halsbury and Mr. Matthews, Home Secretary.

We must not forget an interesting passage-at-arms between Chief Justice Giffard and Advocate-Fiscal Matthews during the administration of Lieut Governor Sir James Campbell, K.C.B. It was thus related by our late "senior" and corrected (in the note) by Sir Richard Morgan, himself at the time in Mr. Matthews' office and afterwards Acting Chief Justice :—

During his rule a very curious case of *ex post facto* legislation produced much excitement, at least in the Supreme Court, Sir Hardinge Giffard being judge and Mr. Matthews, (author of "The Diary of an Invalid,") Advocate Fiscal. A rascally Frenchman attempting to fly from his creditors was seized and held in arrest by the Military authorities in defiance of the writ of *Habeas Corpus* issued by the Supreme Court. The Chief Justice was much excited, and told Matthews that in defending such high-handed proceedings he was preparing a bed of thorns for himself. Poor Matthews did not, however, survive to claim the seat of Chief Justice. The brilliant humourist died of atrophy. The Regulation which he drew up at the order of Government served its purpose for the time, though it was subsequently revoked by an Order in Council (not till 1st November 1830, however.) It enacted that it "*was*, is and shall be lawful" to hold any person in custody by warrant of the Governor, such warrant being a sufficient return to any order of Court without the production of the person, We are not aware that any grave collision has taken place between the governing and judicial authorities since this period, unless we include the cyclone in the time of Sir Carpenter Rowe, in consequence of some ill-judged proceeding by which social precedence was conceded to Bishop Chapman, a concession which the Chief Justice sturdily denounced.

We must now bring our notes to an end but, before doing so, would say that it is very pleasant to have the Lord Chancellor recalling the memory of his uncle who, as Chief Justice of Ceylon, was no doubt the great man of his boyhood, he little dreaming then that he himself would be thrice Lord Chancellor. By far the most genial account of Lord Halsbury we have ever seen is that contained in the "People of the Period" which may well be reproduced at a time when he has placed this community under an obligation by sending for our Law Courts a portrait of Sir Hardinge Giffard, Chief Justice. We quote it in full in our daily.

ETYMOLOGY OF AFRICA AND OPHIR.

Dr. Carl Peters' contention that the place name Africa is nothing but the Latin form of the unmeaning Semitic 'loan' place name Ophir, is historically and etymologically untenable. Africa, the name by which the Libya of the Greeks became known to the Romans through the Carthaginians, was at first applied by the former exclusively to the territory, subordinate to Carthage.

. . . . .

As for Ophir, this place name did probably include the south-east cost of Africa, but it equally included the south coast of Arabia, and the whole coast of Western India, with Ceylon, and possibly also the Malayan Peninsula—'Aurea hersonesus,'—of Farther India. The term, in sbort, as used in the Bible, may be compared with tbe Parvaim [compare Sanskrit *purva*, 'Eastern'] of 2 Chronicles iii. 6, and our 'East Indies'; and, less pertinently, with the classical Eous and Panchaia. It occurs as Ophir in Genesis x. 29; 1 Kings ix. 28, x. 11, and xxii. 48, 1 Chron. i. 23, and xxix. 4, 2 Chron. viii. 18, Job xxii. 24, and xxviii. 16, Psalms xlv. 9, and Isaiah xxiii 12, and as Uphaz in Jeremiah x 19, and Daniel x 5; and in all these references excepting Genesis x 29, and 1 Chron. i 23, Ophir and Uphaz are associated with gold. In its Greek form the word is written Oupbir, Ophir, Oppheir, Souphir, Soupheir, Sopbir, Sophira, Sophera, Sophara and Sappbeir. Ptolemy places vi 7, 41, a Sapphara on the southern coast of Arabia, and vii 1, 6, a Soupara on tbe coast of Western India; and vii 1, 15, a Sippara on the eastern coast of India; and there is a 'Sofala thought [Milton meant by Purchas] Ophir' on tbe south-eastern coast of Africa. These four place names are all cognate with Ophir, and not with Africa, which, as has been shown, is quite another word; and I believe the Sonpara placed by Ptolemy on the coast of Western India to be the original Ophir of them all. King Solomon's trade, by means of 'the navy of Hiram,' and 'ships of Tarshish' [Tartessus, *i.e.*, Spain, and compare the term, 'Indiamen'], included imports, expressly invoiced from Ophir [1 Kings x. 11], of 'almug trees and precions stones,' and, not expressly invoiced from Ophir [1 Kings x. 22, and 2, h ron. ix. 21], of 'gold and silver, ivory and apes, and peacocks.' All these are Indian products, the 'almug trees' and the peacocks being exclusively Indian products, and the names used in the original text of the above quotations for ivory and apes and peacocks being every one of them, Indian names Hebrewised:—*shen-habbim* literally tooth of elephant, for ivory, being formed from the Sanskrit *ibha* elephant; *kophim* for apes, being the Sanskrit *kapi*; and *tukkyyim* for peacocks, the Tamil *tokei* or *togei*. This is sufficient to prove that from King Solomon's time, and from the earliest times, the Hebrews knew of India in its trade productions; and in this way at least it was nniversally known to antiquity. Indian teakwood has been discovered in the structural ruins [Mugheir] of the temple of Ur of the haldees. An ancient Babylonian list of clothing mentions *sindhu* or muslin, which Sayce [*Hibbert Lectures, 1887*] identifies with the *sadin* of Judges xiv 12, 13, translated in the English Anthorised Version by sheets, and in the Revised Version by linen garments, and the *sindon* of the Greeks the cendal or sendal of Mediæval Europe; all these denominations signifying Indian stuff. In the original text of Estber i, 6, the wood translated green is *karpas*, the Sanskrit *karpasa*, and Greek *karpasos*, cotton, and instead of the passage reading white, green, and blne *hangings*, it should read white and blue cotton *dharis*, the striped floor-cloths and hangings for which India has always been noted. There is no nndonbted mention of silk in the Old Testament, but silk is rightly supposed to be referred nnder the denomination of *meshi* in Ezekiel xv, 10, 13, translated in both the Authorised and the Revised Versions of our Bible by silk and as *demeshek* in Amos iii, 12, rightly translated by Damascus in our Anthorised Version, and wrongly by silken in the offensive Revised Version. In the Book of Esther, moreover, India is twice [i 1, and viii, 9] referred to by its vernacular name in the Hebrewised form of Hoddn, in Syrac Hondu, in Arabic Hindu, in Persian Hind in Greek *Indika*, all these being variants of the Sanskrit Sindhu literally a river, but especially the river Indus.

The Hebrew place named Ophir has no meaning; but Sonpara [Ptolemy, vii, 1, 6] identified by James Burgess, the emiuent antiquary with the modern Supara, a few miles above Bassein in the Northern Konkan, means the auspicious-far-side, or opposite bank or coast, that is the fair trading coast [compare Surat, *i.e.* Snrashtra, the Fair—merchant—kingdom], to distinguish it possibly from the langerous trading coast, *Ariake And on Peiraton* of the Southern Konkan. Sippara is said to have the same meaning, and both names may be compared with the Greek *Paralia*,* coastland, applied to the broken maritime tract of Attica stretching southward from Mount Hymettus to ape Sunium and the Saronic Sea, to the western coast of halcidice opposite the Pierian shores of Macedonia, and by Ptolemy to the coast of Travancore. The people of Western India, particularly those about the Gulf of Cambay have from the remotest past actively tracked with the south coast ot Arabia, the Persian Gulf, the Red Sea, and the east coast of Africa; and it would be quite natural for them to have carried with them the name of their own famous port of Supara, and applied it to the chief emporia of their trade in the Hadramaut, and the Zanzihar or Black Coast of Africa; the Arabs in the latter country in seeking to give it a meaning in their own tongue twisting it, with but slight change of sound and significance into Sofala at full length, Sofalatn'l Dhahab, the Coast of Gold, an extension of form which indeed seem to emphasise its indication as a variant of Ophir. Finally to this day India is the Sofir, that is, Ophir of the Abyssinians and Egyptian opts. Whatever eastern lands, therefore, may be included in the Biblical Ophir, India of the Hindus is the aboriginal, authentic, definite, and inexpugnable Ophir; while the word Ophir has nothing whatever to do with the word Africa, great as I trust may be the 'golden joys' the dark continent of that name has in store or those pioneers of modern civilisation among whom so high a distinction has been achieved by Dr. Carl Peters.

March 12, 1900. GEORGE BIRDWOOD.

—*Journal of the Society of Arts.*

SHOOT NG NEAR TRINCOMALEE.

A SMALL MIXED BAG AT PERIYAKULAM.

I believe there are many tanks in Ceylon known by the name of Periyakulam, but the one I refer to is about seven and three-quarter miles from Trincomalee. You go along the Nalavile road nearly to the sixth milestone; then turn away to the left, and go for a mile and three-quarters by a sandy jungle road to

THE TANK.

It is a small sheet of water, perhaps, three-quarters of a mile long by seven or eight hnndred yards broad. On the day I am going to tell you about, I went out by bullock cart, arriving at dawn. The first proceeding was to go to the little P. W. D bnngalow on the shores of the tank and get some cooca and hiscuits. I had secured the services of a cooly to carry my cold tea and cartridges, and as soon as I had disposed of my little breakfast we started off along the bund towards the sluice, whence a jungle path leads ronnd to the far side of the tank. Periyakulam, like all Ceylon tanks, is purely artificial; it has a bund which forms one end, and another longer bund going all along one side. There are two sluices, and two sets of paddy fields which are irrigated from the lake. One lot of paddy fields are below the side bund, and the other below the one at the end. Everywhere else the jungle is thick, except for some grassy marshy land beloved of buffaloes, which lies on the opposite side to that along which the bund runs. The sluice at the side is quite at the end corner, close to the jungle, and as this is a quiet deep part of the tank, the crocodiles often come out and lie on the bund just there. Below the sluice and between it and the paddy is a large pool surrounded by jungle trees; this is also beloved of crocodiles, and they often lie out on a little raised path which goes from the bund across this pool to the paddy-fields. On that morning, however, no crocodiles were lying out near the sluice, so we walked across it and took the little jungle path, which goes through the woods at the end round to the open marsh land on the far side.

The tank was high, and most of the open part far too wet for snipe; but further up near a native hut, I knew of a tiny strip of suitable ground, a little patch of old cultivation in fact, where I

EXPECTED A SNIPE OR TWO

to be lying. The fertility of my little patch, by the bye, was entirely dependent on the buffaloes; if the fancy took them to remain round about the hut there would be no snipe, but if they went further into the marsh and left my preserve quiet, I was always certain to find a few birds. To my pleasure, we found the herd of buffaloes that morning disporting themselves near the lake with only their heads and the tops of their backs shewing above the grass and water. The little naked herd-boy was sitting on an old ant-heap which rose from the swamp like an island, watching his charge. Near the native hut are one or two palm trees and a tamarind which serve as a landmark to steer a right course from afar. While keeping to the comparatively dry ground near the jungle we laid as straight a course as possible for the hut and arrived to find everything undisturbed, and a couple of red-wattled lapwings (or "did-he-do-its") in possession of the tiny pool near the palms. There were, however, only two snipe in the patch, bnt they rose easy shots in spite of the gun being barely up, and after snndry explanations on my part to the cooly of the object of a snipe stick, they were at last neatly hung, so as to balance each other at either end of that machine.

A short time after leaving the hut, and while skirting a belt of trees, I heard a jungle cock crow; as the call sounded quite close I went to an opening in the undergrowth opposite where it appeared to come from, and crouched down so as to see under the jungle. I then clapped my hand against my leg so as to imitate the noise made by the wings of a rival cock; and waited almost immediately the bird stalked into my field of vision, and a charge of No. 6 laid him low. To bring jungle fowl right up to one the clapping requires to be very skilfully done, bnt when they are close by it is easy to excite their curiosity by amateur attempts, and so get them to move and show themselves.

Not far from where I shot this cock there is an old ruined tank with the embankments breached; there is still, however, deep water in one or two places. The jungle has encroached right up the old bund, but here and there are gaps among the trees and bushes through which crocodiles issue for their nightly prowls. Near one of these gaps I found

A CROCODILE SITTING ON THE BUND

with his back towards me. Owing to the thickness of the jungle it was impossible to work round to the side of him without making a noise, so I sent

* Paradise—at one time thought to be derived ultimately from either (1) the Sanskrit *para desa*, a far, a foreign country, *para- desi*, corrupted to purdasee being the name given in the Deccan to natives *of:* Hindustan, or (2) from the Sanskrit *purva-desa* [of Purvaim above], Eastern country, familiar in the adjectival form of *parviya*, corrupted to purboe, originally the name given to Hindus living to the east of the Ganges, and then applied to native writers and clerks generally,—is now traced to the Zend *Para-daeza* enclosnre, in Persian *firdauz*, a garden, a park, in Greek the loan word *paradeisos*, and so our Paradise, the Garden of Eden, Heaven, &c., and parvise, the porch under a church tower, or the room above the tower porch, or the cloister close of Cathedrals, that of Chichester being still called Paradise, and of Chester Sprise Gardens.

an "Ubique" bullet into him as he lay, and racked him fore and aft. Of course the shot had very little immediate effect on the tough brute, and he shuffled into the water at a tremendous rate. I then looked about among some trees with damp patches underneath, and put up six or seven snipe; I got shots at five and bagged two. Afterwards seeing no prospects of finding more birds, I started back towards the sluice on my way homewards. When going along the jungle path at the end of the tank I had a bit of luck, a jungle-fowl bolted across, and a quick shot knocked him over —another fine cock bird.

Having crossed the sluice, I looked along the bund and espied a crocodile lying on the top of it, about three hundred yards off. Here was a chance for a stalk. Unfortunately, about 200 yards from the crocodile, a big tree had fallen, blocking up the side of the bund farthest from the tank with a regular abatis. I could not go along the tank side of the bund, as the crocodile had his head that way, nor could I get round the tree, as there was the deep pool below the bund which I mentioned in the first part of this letter. I, therefore, had to make my way inch by inch through the branches in deadly fear lest they should crack or rustle. At last I got through and the crocodile still sunned himself serenely unconscious. The rest was easy and straightforward. The bund was covered with short grass, and I made my way without difficulty to within fifty or sixty yards, when I crawled bit by bit on hands and knees until I was only thirty-five yards away. I then crept very gently up the side of the bund and raised myself little by little till I had a perfect broadside shot. My "Ubique" bullet went through the top of his head, and he shut his jaws, which were wide open when I fired, and lay motionless. To make sure he did not recover and walk away, I cut his throat, and then we went back to the P. W. D. bungalow.

TWO COOLIES FETCHED IN THE CROCODILE

having lashed him with a rope to a suitable pole. They then deposited him, lashed as he was, in the verandah of the bungalow. Three hours later, when there was no one in the bungalow except my old Tamil boy, the crocodile discovered that it was not dead, and after grunting and groaning proceeded to stroll about the verandah pole and all. As my boy was afraid it would get back to the tank, he lashed the crocodile to one of the wooden verandah pillars. As the 12-bore "Ubique" bullet had inflicted a very severe wound to the top of the skull, and as the creature's throat was also cut, I think we may safely deduce that the crocodile is somewhat tenacious of life.

"FLEUR-DE-LYS."

Colombo, 21st March. —*Asian*, May 22.

THE CEYLON CROCODILE.

My short stay in Ceylon has convinced me that excellent sport is to be had crocodile shooting. All the large tanks contain crocodiles, and though they may be easy to approach as compared with deer, they are infinitely harder to bag. Unless a crocodile is hit in exactly the right place it invariably gets back to the water. Either it must be shot through the head or the spine shattered. I do not think the shoulder shot is to be depended upon except with a large calibre rifle. Crocodiles are loathsome reptiles, and one never feels any compunction in shooting them; whereas the pathetic eyes of a wounded cheetah are a very pitiful sight. The more crocodiles that can be shot the better, and quite a soft-hearted man might take pleasure in slaughtering them at every opportunity. Many people when asked will tell you they have shot lots of crocodiles, but on enquiry you find that few if any of them were actually bagged. It is pure nonsense, of course, shooting at corocodiles in deep water, or if they are ashore, only wounding them, so that they escape. This is no sport at all. The crocodile must be properly stalked when it is lying on the shore clear of the water, and hit in a vital spot, so that it cannot wriggle back into the tank. The large ones are, I think, more alert than those which are younger and less experienced; but this is the case with every kind of creature.

I do not think a heavy rifle is required for crocodile shooting; the ·303 is quite suitable. Sufficient penetration combined with perfect accuracy are the main desiderata. The Mark IV. Government bullet is not sufficiently reliable; one of the regular sporting bullets should be used. Out of four crocodiles shot at with the ·303 and Mark IV. bullet I only killed one; and out of three crocodiles I have known of, killed with the ·303 and Mark IV, there was only one case where the bullet may be said to have expanded in a thoroughly satisfactory manner. Even a heavy bullet has to be well placed to kill a crocodile outright. I hit one behind the shoulder with a 10-bore bullet; it struggled back into the water, and rolled about feebly at the surface, getting farther and farther out, so that when it eventually died and sank, the water was too deep to fish it up. If I had placed the ball through its head, it would of course have never moved. The difficulty of crocodile stalking is immensely increased by the frogs, which haunt the edges of tanks. Sometimes when one is stealing along the tank side of a bund, a fat frog will jump into the water with a flop, and there go off in a series of ducks and drakes along the surface, effectually scaring the crocodile if it is within hearing distance.

A good crocodile's skull mounted on a shield makes a very decent trophy, and the skin of a small one mounted with the head on does not look at all bad.

I believe that the crocodile found in Ceylon is *Crocodilus palustris*, but I have no book of reference at hand to make certain. As to the size to which they grow, I have *seen* one which I estimated to be 13 or 14 feet long, but I have found the exuviæ of what must have been a perfect monster; and I fancy that in the larger sheets of water there are a few 17 or 18 feet in length. In the small tanks they run from 6 to 9 feet and in the large tanks crocodiles about 10 feet long are a common size.

A crocodile when it has settled comfortably down to bask in the sun usually has its jaws wide open, possibly with a view to airing its inside. When fatally hit, but not quite dead, they open and shut their jaws spasmodically and wag their heads feebly from side to side.

The cross-country journeys made by crocodiles are invariably done at night, and the early morning and evening are the best times to look for them, though they often lie out when not much disturbed in the middle of the day.

Sometimes one will find little pools in the jungle occupied by crocodiles, especially if they are a good depth in the middle. I have found a good sized crocodile in a water hole, only the size of a large room.

Hornaday, the author of "Two Years in the Jungle," shot a great number of crocodiles with a ·40 cal. Maynard rifle, and his aim was always to shatter the spine. I do not know what particular cartridge his rifle took, but it would probably be 60 grains powder and a 260-grain bullet, at any rate he found it was not powerful enough to cope with the large fish-eaters of 15 or 16 feet long, the ball not having weight enough to cut the vertebræ. The ·303 with soft nose bullet is very much more powerful than any of the ·40 cal. American rifles, and I imagine one should be able to kill the largest crocodiles with it, if the bullet is placed just right. I have killed a crocodile with a 12-bore smooth bore "Ubique," and of course when you can get near enough nothing could be more effective than the large spherical bullet from one of these guns. Crocodiles, however, are often in such positions that they have to be shot at from a considerable distance, so that an extremely accurate single shot or magazine rifle is the best weapon.

LITERARY REGISTER SUPPLEMENT:

AND CEYLON

"NOTES AND QUERIES."

[Under this heading, in future, we mean to give a four or eight page "Supplement" with our *Tropical Agriculturist*, from quarter to quarter, according as there is matter of sufficient value, so to be preserved.]

DECEMBER, 1900.

SINHALESE MANUSCRIPTS IN THE BRITISH MUSEUM.

The work on which Mr. D M de Z Wickremasinghe has been for some time engaged has at last borne fruit in a "Catalogue of the Sinhalese Manuscripts in the British Museum." That this catalogue should be the first of its kind, after Ceylon has been for more than a century a British possession, is certainly not creditable to the British Government or people, and is a proof of the small degree of interest taken by the people of Great Britain in oriental matters generally, and especially in eastern languages. Even Copenhagen had, early in the century, thanks to the enthusiasm of the great scholar Rask, a better collection of Pali and Sinhalese manuscripts than London. Matters have improved of recent years, however; and the collection here catalogued comprises some 150 Manuscripts,—a collection not to be compared, of course, with that in the Colombo Museum; but still a very fair one, containing a few codices of exceptional value. The headings under which the Manuscripts are classified are as follows:—

CHRISTIAN LITERATURE.—Bible.—1.
BUDDHIST LITERATURE.—*Interpretation of the Canon.*—2-13. (12 MSS.) *Interpretation of Extra-Canonical Works in Pali and Sanskrit.*—14-22. (9 MMS.) *Original Works on Buddhism.*—23-32. (10 MSS.)
DEMONOLOGY AND LOCAL CULTS.—33—51. (19 MSS.)
ARTS AND SCIENCES.—*Medicine.*—52—61. (10 MSS.) *Astrology, Divination and Magic.*—62-67. (6 MSS.)
HISTORY.—68-76c. (14 MSS.)
INSCRIPTIONS.—77-79. (3 MSS.)
LANGUAGE.—*Lexicography,*—80-82. (4 MSS.) *Grammar.*—82A-85. (4 MSS.) *Rhetoric and Prosody.*—86-87. (2 MSS.)
GENERAL LITERATURE.—*Poetry.*—88-109. (26 MSS.) *Tales.*—110-125. (17 MSS.)
MANUSCRIPTS OF MIXED CONTENTS.—126-137. (12 MSS).
LETTERS.—138-140. (3 MSS.)

It will be seen by the above list that poetry comes first, followed by demonology and local cults, tales, and history. (The canonical works of Buddhism, being in Páli, do not find a place in this Catalogue.)

In addition to a careful description of each of the Manuscripts, and transcripts of the opening and closing sentences of each, Mr. Wickremasinghe discusses, more or less fully, the subject matter, the author, date of composition, &c., his comments showing much learning and critical acumen, and embodying a mass of valuable information. Some of Mr. Wickremasinghe's statements will no doubt form matter for criticism by scholars; but these columns are hardly the place for such controversy.

We may refer to some of the more generally interesting features of this Catalogue. On p. 39 is described an anti-Christian criticism of certain statements regarding Buddhism and the Solar system, which appeared in a Calendar for 1839 published by the Christian Missionaries of Ceylon." (The language is dubious, but the meaning is obvious.) Of this Mr. Wickremasinghe says:—"It is written in a colloquial but chaste style, devoid of the controversial bitterness which marks this kind of literature at the present day. The writer was probably a Buddhist monk, and, considering his limited knowledge, his arguments are very intelligent. Some of them are, however, very amusing; for example, speaking of the revolution of the earth, he argues that if the earth moves on its own axis, the loose tiles and sand on the roof of houses must fall off into space in the course of its motion!"

On pp. 56-58, we have notes on the earliest mention of the *Parangi* disease in a medical work of uncertain date, named *Yogaratnakaraya.*

On pp. 74-78, the death of Raja Sinha II is stated to have occurred in 1692 or 1692-3

while on page 96, the date is given as 1684. But the Dutch, who ought to know, assert positively that their old enemy died in December, 1687. Again, we are not sure that by the Raja Sinha "who defeated the Portuguese at Colombo," as mentioned in the colophon of the *Kurunegala-vistaraya* (Cat., p. 84) is not meant the second king of that name, and not the first, as is here taken for granted.

There are several references to the mysterious capture and deportation (in 1410 ?) of Vijaya or Vira Bahu by the Chinese, but no further light is thrown on this obscure event in Sinhalese history.

If the dates given on p. 85 could be relied on, they would be of value as well as interest; but we fear that they are untrustworthy. (They record an earthquake in 1679, a flood in 1661, and the death of Raja Sinha I. on 8th March, 1593.)

On pp. 106-107, details are given regarding Alagiyavanna Mohottala, the "poet secretary"; but Mr. Wickremasinghe had not, when he wrote, seen the fresh information, from Portuguese sources, regarding this man, communicated in a paper to the Ceylon Asiatic Society.

Among the "letters" described at the end of the Catalogue is an ola envelope addressed to Joan Gideon Loten, the Dutch governor of Ceylon in 1752-57 : the letter itself is, unfortunately, missing.

In an Introduction Mr. Wickremasinghe gives a most valuable and succinct account of Sinhalese literature from the earliest times down to this century, referring for fuller particulars to the introduction to James Alwis's *Sidat Sangara*, many of the statements in which, however, Mr. Wickremasinghe has had to correct.

This Catalogue does the highest credit to its writer; and to all interested in the history and literature of Ceylon it will prove a veritable treasure-house.

MODERN NUWARA ELIYA.

(From a Correspondent.)

The periodical visitor must admit that outward and visible attempts are being made to improve the place; at least I, after a twelve-years' acquaintance, willingly concede as much, and these brief notes are a short record of how I found Nuwara Eliya during a late visit :—

RAILWAY.—The completion of the projected railway from Nanuoya will, I think, prove generally acceptable to intending visitors, as well as residents, because, even if the rate of transit is not more rapid than now, it may be relied on as more positive, and of greater capacity than the present coach service, which, however, is very well served, in comparison to others of a similar nature. The question, as to whether the propelling power be electrical or steam, is of too technical a nature for more than passing reference in these notes.

ROADS.—Of late, complaints (trivial perhaps) have appeared in the Press about the metalling of the roads, with the resulting inconvenience, cruelty to animals, etc., arising therefrom. Repairs to roads generally cause temporary inconvenience to traffic, and if the Improvement Board could afford it, mechanical rolling would greatly reduce this, due to the less time required. On the whole, I think they are maintained in good order, but the widening out of the roads throughout the town proper is a very necessary and urgent matter. At present they are much too narrow for safety and comfort. Extra width would also facilitate annual repairs. The additional new roads and footpaths now in course of construction, or lately completed, will extend the opportunities for enjoyable walks and drives.

WATERWORKS.—The establishment of these is a great boon, and the supply appears to be all that is desirable, except perhaps in quantity, and that only during the dry season ! On one occasion in March last, and with only a few of the bungalows taking water from the town main, water was not running over the spill, and as the reservoir capacity is practically *nil*, I question if further conservation will not be very necessary. The distributing main will, I hope, prove adequate, but it seems to me to be too small : and if so, the reduction of pressure, and therefore supply at the bungalow taps, will be noticeable when all are connected on to the main. At the intake works, the stand-pipe now permits of the supply-pipe being easily blocked by any mischievous person. The open end should be 8 or 10 feet higher, or, what is better, fitted with a swan-neck, *i.e.*, the end turned downwards to effectually prevent such a possible catastrophe. A very simple provision would have prevented the flooding of intake well, and thus afforded the intended free access to the valves. I do not know if the town main is arranged, so that portable stand-pipes can be attached at various points, and used for Fire Brigade purposes. By this means a very cheap and effective fire extinguishing apparatus could be placed in the hands of the local police. A good water supply necessitates good drainage, and Nuwara Eliya lends itself to this latter very readily, except that the greater part of the plain is of a very absorbent nature. The laying out of part of the plain as a park, and the improved drainage of the same, will materially help the general drainage and health of the town. During the rainy season, the lowering of Lake Gregory spill, at least by one foot, would be an effective aid in the same direction, and without detriment to any other interest. [Indeed ? We recollect that Sir Wm. Gregory was very irate on his last visit to find how low the water was kept, and declared that his design for a really full and attractive lake—a true ornament to Nuwara Eliya—had been entirely spoilt.—ED *L.R.*]

THE POLICE STATION would, I think, be more convenient if removed from its present position to a more central one. In a short time the present station will be far from central (in fact is so even now) as the general town extension is decidedly away from it. It might be more convenient if near the Post office. Perhaps the authorities conclude they can better watch over

the interests of the town from their present super-elevated position, in preference to being "on the spot."

THE POST OFFICE as an institution may generally be taken as an indication of the importance or prosperity of a town, and in the case of Nuwara Eliya this is no exception. The accomodation of the building as a whole may be equal to requirements. Yet this cannot now be said of the portion allotted to the public for enquiry; a small square lobby often crammed with natives of all kinds and castes, having one opening or window for all forms of business. There is much room for needed expansion in this direction, and may it soon become an accompolished fact.

The proposal of Government to establish a complete TELEPHONE SYSTEM will be another step towards bringing Nuwara Eliya up to date; but if established, let us hope, it will be more successful than that now working in Colombo under the same auspices. For business convenience, the use of it will be quickly apparent.

Some consideration appears to have been given towards the adoption of the ELECTRIC LIGHT, but thus far nothing definite has been decided on. I am informed that the greater part of the power required can be obtained from the existing water supply, but that the carrying out of such a scheme might prove too heavy for the existing revenues, but it is also satisfactory to know that further investigations are most probable, and that some day Nuwara Eliya may, and as it should, have its Electric Light

THE HOTELS give another instance of what is instinctively seen ahead in the matter of town growth, for I believe, without exception, all the existing hotels have been extended and improved, so as to be ready for the coming season. In the case of the Grand Hotel many improvements, alterations and minor extensions have been carried out, and a still more extensive addition is to be made shortly, in which the sanitary arrangements will be quite up to date, and far more complete than during any previous time in its history. The position this hotel occupies, is an exceedingly good one, being central and "well connected" in every way. Under the new *regime* instituted since last season, I conclude visitors to this hotel have a good time before them. The "St. Andrews" and "Keena House" are, I believe, also much improved. The position of these is unique in many respects, and it must be a distinct advantage for a Hill Station to have a diversity of hotels, both as regards position, dimensions, and other minor details.

THE HILL CLUB, under gubernatorial patronage, is a men's private Club, and musters about, I think, 450 members. It is splendidly situated, now very comfortable (though the main portion is an old building) and with lately extended accommodation also. Being a limited Company, I suppose they cannot entirely ignore the question of "profit," and I understand that when chambers are available. outsiders have no difficulty in being made honorary members *pro tem*, and in fact the energetic Secretary gladly welcomes at such times those who are so inclined. If this is the case, it might be more correctly classed as a private hotel than club. [Why so? Do not all clubs extend hospitality to temporary visitors introduced by members? —ED. *L.R.*]

In addition to these, many bungalows in part or wholly are available for visitors also during the season. Most of those, now being or recently built, are of a more modern and substantial type than formerly. Judging by the appearance and condition of some existing ones, and owned by well-to-do landlords, I think it time Government stepped in and compelled them to re-build habitable and sanitary residences in their stead. One important feature is specially noticeable in most, viz.. the general absence of a distinct and legible name of each bungalow or house with name of resident. In Indian cantonments, this is, I believe, compulsory and necessity makes it equally so for Nuwara Eliya. Indistinct stencilling of the letters on a piece of tea-box or similar board is hardly in keeping with the assumed character of a Hill Station like Nuwara Eliya. The religious devotee, whether Muhammadan, Hindu, Buddhist or Christian can find houses of prayers suited for their respective faiths. The Established Church, Holy Trinity, has lately been enlarged, but is already considered none too much so.

MODERN SCHOOLS for both boys and girls, and suited for European children are in existence and very ably conducted.

SOME NEW LINES are being built for the working classes near the meat market, and eventually the whole of the shanties and vegetable gardens close by the coaching office should be abolished, and only approved buildings erected in their stead.

The opportunities for AMUSEMENT are very numerous, the racecourse perhaps standing, first with its grand stand, the enclosed space being suited alike for ladies' golf, polo, cricket, football or hockey.

THE UNITED CLUB AND LIBRARY with its tennis and croquet lawns is also within the racecourse bounds, all from their position being very accessible at any time.

In addition to these there are the gentlemen's GOLF LINKS extending over a large part of the plain, and having their own special Pavilion. Bicycling can be enjoyed without any discomfort or fatigue during fine weather and walking facilities, for those who prefer this exercise, are now unlimited.

The lakes and streams provide good FISHING, sailing and rowing. The addition of a few boats for the latter would be a great advantage. Visitors can participate in all or any of these amusements on special terms, etc. The entire place has grown from a comparative village and temporary place of residence to a permanent township, and with increased opportunities for reaching it, will steadily grow in favour not only as a place of permanent residence and holiday resort for Ceylon folk, but also as a Hill Station equally available for India. Let those interested in its development, carry out their schemes in a liberal and substantial manner, and I feel certain such will speedily contri-

bute to the further success of the place as well as prove remunerative to themselves. A new and improved Town Hall is an urgent necessity and must not be overlooked.

"SACRED BOOKS OF THE BUDDHISTS": A REVIEW.

(Specially contributed.)

"*Sacred Books of the Buddhists*—edited by Max Muller, Oxford University Press, Vol. 1, Játaka-málá, translated by J S Speyer, 1895: Vol. 2—Dialogues of the Buddha, translated by Professor Rhys Davids, 1895."

[While the following review from the pen of the best authority in the island was being put in type, the news came of the death of the well-known Oxford Professor whose work is dealt with. The grand old Sanskrit Scholar had seen his best days, and was himself conscious of a failing memory; but his interest in philology and his love of the special studies in which he gained worldwide distinction remained to the end. Not the least of the services he rendered to his adopted country must be reckoned his sturdy defence against German misrepresentation and misjudgment in connection with the Boer war. His keen critical faculty, and his intimate knowledge of British character and of the influences which guide the nation, enabled him to repel with vigour the aspersions cast on the country by those who fancy that the South African war had been of our seeking and that it was inspired by lust of gold or of territory. That was his last, but not least, service to England.—ED. *L. R.*]

Professor Max Müller carried forward his labours as Editor of the Sacred Books of the East by beginning to edit a new series under the patronage of the King of Siam, and under the title of Sacred Books of the Buddhists. Of that series the two volumes before us are the first instalments. Of Professor Max Müller's General Preface it is enough to say that it adds nothing to his high reputation.

The first volume contains translations by Professor J S Speyer of the thirty-four Jataka Stories which are contained in the Jatakamala, a Sanskrit work of the Northern School of Buddhism, ascribed to one Arya Sura, and dating some time before A. D. 700, possibly as early as 400 A. D. The great majority of these stories are identical in substance with stories contained in the Pali Jataka book: many occurring also in the Cariya Pitaka, and in the Buddhavansa.

There is much interest in comparing these with the Pali versions. These are much filled out like the Sinhalese poetical versions of the Kusa Jataka, &c. Like the Pali they are written partly in verse and partly in prose; but the verse part which appears in the Pali only as an occasional quotation is here the larger part. But what is curious is, that while most of the 'gathas' of the Pali appear, though freely altered in the Sanskrit, the narrative slokas of the Pali are not—in any instance we have come across—represented in the Northern version. This, if it is found to be generally the case, will bear out the tradition that the 'gathas' alone are the original substratum of the book, and that all the narrative which surrounds them is "commentary," and may take different shapes in different places and times. The facts are also suggestive as to the Dipavansa tradition that the Vesali heretics played tricks with the Jatakas.

Although the "padding" is often excessive in the Jatakamala, the stories are, as a rule, better told than in the Pali. In Cuddabodhi (Jat. 443) the Sanskrit writer has caught the point of the story while the Pali commentator has missed it. The tale of the Wonderful Pilot again (Supàraga, No. 463) and that of the Lotus stalks (488) were evidently better understood by the Sanskrit than by the Pali writer. But the Monkey's Curse in the last-named reads best in the simplicity of the Pali. Thirteen speakers in succession had uttered each his imprecation on the thief who stole the Bodhisat's lotus-stalks. The monkey's was this, (he knew what it was, the commentator says, to be a snake-charmer's monkey!) "May he wear a garland of flowers and tin earring; may he be forced by blows of a switch to face a snake; and may he go about the streets tightly tied by a string."

The volume which is due to Professor Rhys Davids, consists of a Preface on Buddhist literature in general, and a translation, not of anything new but of the eleven Sutras of the Digha Nikaya, which were published by the Pali Text Society in 1890. In the translation of passages which occur both here and in works which he has formerly translated, (*e.g.* in the beginning of Ambattha Sutta,-Maha Vagga 1-2 22) the Professor has modified his renderings in many places, in accordance with the advance of Pali Study. It is curious that at the same time he should think it necessary repeatedly to point out in his notes some inaccuracy or omission in Professor Childers' Dictionary. It is no disrespect to the reputation of that pioneer of Pali scholarship to say that it is a matter of course that, in the light of present knowledge, Professor Childers' Dictionary should now be far behind the times. The same may be said of Professor Rhys Davids' earlier works.

The chief value of the present work lies in the Preface and in the special introductions. The Preface contains a clear and cogent argument in reference to the date at which the Pitakas, as we have them, must be believed to have been completed; which may be thus abridged:—

The Milinda Panno carries our text back to about the Christian era. The Katha Vatthu, as the early commentators say—and their honesty is guaranteed by the inconsistency of this statement with their theory that the whole canon was the very word of the Buddha—was composed in the time of Asoka about 250 B.C. and this Katha Vatthu presupposes a complete Pitaka. Asoka's own inscriptions, allusions in other inscriptions, and many things in the contents of the Sutras themselves, show that the main parts of the Pitakas were by that time well-known and of recognized

authority. So far the Professor's argument is clear and cogent, and amply carries his conclusion, that the Buddhist literature, in the main, existed *some considerable time before* the end of the third century, B. C. But how long was this considerable time? We believe that the whole may well have taken shape within a century at the longest before that date, and that there is no trustworthy evidence whatever that any of these works existed earlier than that. So that when the Professor ends by adopting, though with caution, Buhler's opinion that these books "are good evidence, certainly for the fifth, probably for the sixth century B. C.," we hold that he has left the region of proof for that of conjecture.

The Introduction to the Kutadanta Sutta contains an interesting excursus on the word Lokayata: and that to Kassapa Sihanada Sutta, one on the Brahman system of Asramas or Four Stages of life, in its relation to the Buddhist view of withdrawal from the world.

ANCIENT RUINS AND ALLEGED VANDALISM AT KOTTE.

[*To the Editor.*]

Colombo, Nov. 6.

SIR,—At a time when the archæology and history of Ceylon are attracting the attention of scholars in foreign lands, it is greatly to be regretted that at home the ancient monuments themselves should be allowed to be wantonly destroyed. As a case in point, I might instance the vandalism that is at present going on at Kotte, for over two centuries the seat of Government. "On the southern side of Kelaniya," runs the classic page of the *Mahawansa*," nigh unto the village of the mighty wood, which containde a large pond and wherein dwelt men of great wisdom and virtue, Alakeswara built the famous city of Jayawardhana Kotte, and adorned it with rows of great ramparts and gates and towers." It is to these fortifications that the attentions of the Philistines have recently been directed.

Surviving the stress of storm and siege of five centuries, still the trace of the massive walls built of huge blocks of cabook stand out clear round the old Sinhalese fort; but at the place where the wall had been best preserved in height and massive proportion it was ruthlessly torn down by a new purchaser of the land, and two rows of coconut plants take up the ground once occupied by the ancient rampart. And daily the huge slabs are removed one by one until even the trace of it has disappeared, entirely in some parts, and unless immediate steps are taken to arrest further ravages, there will in a couple of years not be the faintest trace of it left for purposes of an archæological survey of the ground plan of the ancient city.

The *Rajawaliya* relates how the great Minister Alakeswara to break the power of Arya Chakkrawarti raised the walls of Kotte, threw up massive dams (*amunu*) to keep back the water, and laying in a good supply of provisions to stand a long siege, hanged the tax-collectors, who had been quartered in parts of the country to levy dues in kind for the king of Jaffna, and ended by flooding the country round the city by opening the sluices. These ancient embankments which remain to the present day on the Talangama road about a mile and a half from Kotte are called Parana Amuna (the old dam) and Kuda Amuna (the small dam) respectively.

The old countryside tradition supplementing the *Rajawaliya* tells us how, after building his city, the ambition of Alakeswara to become king, bade Widagama Maha Sami place the crown of Lanka on his head and as he sat on the coronation slab facing the tank, the old Priest gave the state sword which was to have girded the new king into the hands of his *protégé* Prince Parakrama; how the head of Alakeswara rolled into the tank below, and the lad of sixteen was hailed king under the title of Sri Parakrama Bahu VI. The coronation seat, a raised dais composed of slabs of dressed granite, had long escaped the ravages of the villagers being covered with turf. But recently digging near the spot, a rustic accidently struck at the granite basement, and now the stones forming one side of the throne have been removed to a neighbouring temple garden where they are being utilised in the building of a new Vihare. If the proper authorities would wake up, there is still time to get the stones replaced *in situ* and preserve an interesting monument. The old tank, traditionally ascribed to Alakeswara, has so far escaped, being covered over with thick lantana, but this state of things cannot last very long, the stones, &c., will be removed and the place of the tank will know it no more. Both these monuments stand in the old Palace garden still known as the *Pas Mal Peya Watte*, the garden of the five storied palace.* Only one or two broken stumps of stone pillars mark the place of the stately pile where the mighty Parakrama held court. What Portuguese and Dutch invaders spared, the exigencies of the Public Works Department could not do without, and the few perfect stone columns that remained were carted away some years ago to build the bridge at Hendala!!!

Proceeding along the old royal street now disused, the Maligawatte is reached, the site of the three-storied Temple of the Sacred Tooth. Torn down by the fanaticism of Portugal and converted into a Romish Church, it was levelled to the ground, and if we are to credit Pridham, most of the materials removed to build the Dutch Church at Wolfendahl. At last the land came into the hands of the tribe of Genesserie, the Vandal. Not content with selling the pillars, carved capitals, pilasters and dressed slabs lying about, the massive foundations of the palace were attacked on one side and the firmly cemented granite rubble sold and carted away. In the course of these "excavations," the huge iron tripod or lamp on which the lights blazed at festivals was, I understand, unearthed, and other sundries, but where they are at present, the deponent not knowing, cannot say. For a short period operations were suspended, the property being encumbered; the land has however reverted and the work of destruction recommenced. It has entered on a new phase, and the digging has commenced on the hitherto untouched sites of the *Natha*, *Vishnu*, and *Saman Dewales* which supported the Temple of the Tooth, and some beautifully carved granite capitals have been already thrown up. Their fate is not uncertain as the *Maligawatte* is the common quarry of the village. To set out one more instance of the kind, at the village of Pita Kotte, which constituted the outer city, stood the Dagoba and Temple where, according to tradition, before their coronation, the monarchs of Kotte used to ride on horse-back for the ceremony of cutting the Talipot tree, springing into life again like the golden bough of Virgil with the advent of each successive ruler; and the same spot, adds the legend, will see the palm spront again, when a prince of the Sinhalese should be born to wield the sceptre. The Temple had vanished centuries

* Vide *Selalihini Sandesa*.

ago with the other Buddhist buildings, and the *dagoba* which had remained intact, spared alike by conqueror, and by time, has recently been taken in hand by an enterprising villager, and the bricks in the dome are being daily abstracted to build a house which is rising in the neighbourhood. Now, only the basement is alone left of it and that too is fast disappearing. The peasant passing the spot by night, fancies he sees a white figure on a white steed holding his sword aloft, and imagines it the spirit of the unborn monarch, for the belief is general among the peasantry of the lowlands that a prince called Diyasena—as Barbarossa or Arthur—will appear at the supreme moment of his country's fortune, who will alike be national king and Messiah, proof against shot and shell, and that he will revive the glory of the ancient capital, build its walls anew, and that once again a Sinhalese Prince will ride in State to strike the sacred Talipot and be crowned king of a united Lanka. Such is the national dream that clings to the hoary ruin!

The steps leading down from the ancient moat, and many of the stones that paved it have been removed, and the stone lintels, nay the very slabs with which the public buildings had been paved, have been ruthlessly torn out and do duty as door-posts or stepping-stones in private houses. The mamotty of a villager now and again throws up a clay pipe, belonging to the system of underground pipes for supplying water to the city, and no sooner it is thrown up than it is broken. If effective steps are not taken to check this Vandalism, there will, in a short time, be nothing left from which, as I have said before, even to trace the ground plan of the old capital, much less to judge of the style of architecture or the way that the pipes had been laid.

The antiquities under notice being situate in quite a small area, if the Archæological Commissioner, whenever he comes up to Colombo, could arrange to spend an afternoon at Kotte, he would be able to take note of the more important ruins, make some provisions for their preservation, and even see to getting some of the stones, etc. replaced.

It is high time that the Asiatic Society took the initiative in the formation of a Committee for the preservation and restoration of ancient monuments. The presence in such a committee of Agents and Assistant Agents—many of whom take a warm interest in the subject—supported by select local members, would materially add to the strength of the movement, for it is only by such agency it is possible to check villagers from destroying ancient works in inhabited localities, as once they get some visible proof that the Crown is the custodian of the ruins they will be chary of tampering with them.

The passing of the "Antiquities Ordinance" is astep in the right direction, and it is a pity if it is to be emasculated in Committee. Seeingl that the administration of the Ordinance wil, practically be in the hands of the minor headmen the question arises *quis custodiet ipsos custodes?* as that class is the greatest offenders in this respect.

My letter has spun itself out into an unconscionable length, but knowing as I do the antiquarian tendencies and the art-loving traditions of the *Observer*, I make no apology for claiming the hospitality of your columns.

ARISHTANEMI.

MEDICAL SCIENCE IN CEYLON.

The 31st Session of the Ceylon Medical College was opened by Dr. Perry P.C.M.O., on the 4th October, 1900.

Dr. Vanderstraaten then read his paper. "A Brief sketch of the Medical History of Ceylon" which proved of special interest and was very clearly delivered. We give extracts to afford some idea of its scope:—

The Medical History of Ceylon embraces a period of 2,800 years but only a brief sketch will be attempted of the annals—Mythical, Historical, and Official—touching on the most salient and important points connected with the Sinhalese, Dutch, Portuguese, and British periods.

Although Ceylon has been subject to the "many ills flesh is heir to," yet we must thank a merciful Providence who has saved us from great epidemics of fever such as devastated Mauritius in the sixties and those dire afflictions which continue in India as plague and famine.

The reader will not be wearied with statistics. There is a mine of wealth in the archives of the Medical Office, which will repay exploration by any one seeking full information on the diseases endemic or peculiar to Ceylon, such as Parangi, Anchylostomiasis, Leprosy, Elephantiasis, Ceylon Soremouth (sprue), Beri-Beri, Burning of the feet, Malaria and its sequels, etc.

Although we are informed that a system of medicine was known to the Sinhalese more than a thousand years B.C., I will only count it as from 900 B.C., when the great text book, the "Ayur Veda," was compiled by Brahma, a Hindu. This is referred to by the Sinhalese Vedarales or native practitioners who study the commentaries on it called the *Sastras Charaka* and *Susruta*.

The "Ayur Veda" consists of Hymns, Prayers, and Precepts, first preserved by oral tradition, in 100 lectures of 1,000 stanzas each called *Slokas*. These are committed to memory and some are recited aloud by the bedside of the sick by the Vedaralas.

Dr. West in his history of Medicine among the Asiatics says: It contains Anatomical knowledge obtained by dissection, prescriptions of drugs, mineral and vegetable; description of diseases and their treatment.

We can trace the study of Sanitary Science from the most ancient books, the Bible.

Our Saviour and the wise men of old, Moses, Solomon, Mohammed, Brahma and Buddha, inculcated all their sanitary edicts by means of proverbs, or religious dogmas which were binding on the people, being engrafted upon the religious ceremonies and performances. To this day the native practitioners, Sinhalese and Tamil, have recourse to charms, offerings and incantations, and devil ceremonies in propitiating demons or evil spirits, who inflict the various diseases.

There are many good experienced Vedaralas who practice native medicine on the lines laid down in their ancient book, Veda, but the majority are village quacks to whom the words of Job are applicable: "*But ye are forgers of lies, ye are all physicians of no value.*"

In the early part of the 3rd Century, B.C., Asoka was a great Buddhist Sovereign of India. He shewed great sagacity in inscribing new doctrines of love and benevolences on columns or pillars of stone, Sanitary edicts were also thus promulgated, priests were enjoined to educate children and relieve the sick, men as well as animals. Asoka tanght the duty of reverence to parents, love to neighbours, charity, sound moral precepts, and enjoined the wealthy to erect refuges for the blind, destitute and crippled, and hospitals for men and cattle.

These doctrines were first reduced to writing on *olas*, dry palm leaves, in Ceylon. They also taught the sublime doctrine of total annihilation after death, called Nirvana, and of merit here which was to be the reward of all good works.

The Buddhist contractor of some Hospital wards in Colombo assured me that he only charged actual cost price in their contract in order to obtain this reward.

Asoka recognized the sanctity of human life, no living being, human or animal was to be destroyed. He provided wells and resting-places for travellers, and well-equipped bospitals were in charge of skilful Vedaralas or native doctors, they contained all the necessary drugs, mineral and vegetable. (I may say, *en passant*, the list of these drugs will be found in West's book quoted above. Balfour's Cyclopædia of India, O'Shaughnessy's Dispensatory and Waring's Bazaar Medicine of India).

The Malabars or Tamils, who came from India, introduced a work called Vagadam written by Agasteur, *the Great* sage some thousand years B.C. There are in it mysterious poems which were first handed down by oral tradition, and subsequently inscribed on olas. They are said to be very little understood by the Tamil medical men of the present day, who were styled Vyittiyar or Paryari.

The Moorish Practitioners called *Hakim* use the "Vagudam," as well as Arabic authors.

According to the Mahawansa, an ancient historical work in Pali, many of the ancient monarchs of Ceylon practiced medicine and built several large hospitals, then called "medicine honses."

Budha Dasa, who reigned in A.D. 339, was the author of the celebrated Sirartha Saygrabaya in which he related many wonderful cures performed by him.

He built hospitals in every 10 villages, endowing them with 1/40th of the revenue from fields.

He had medical men for his troops, cattle, and elephants. He used to move about with surgical instruments in his waist.

King Ago, 782 A.D. and Dappula II, 795 A.D. built hospitals and asylums for blind and lame, gave paddy crops to cattle and rice, mixed with honey and sugar for use of children. He had a Medical College.

Parakrama Bahu, 1163 A.D., built largest hospital with an attendant, male or female, for each patient; divested of Royal robes he inspected his hospitals four times a month, correctiug the treatment when necessary. He cured a crow of a tumor.

King Pandukabhaye, 437 B.C., employed 150 men to carry corpses to Cemetery, 100 Cemetery-keepers and Sextous, 200 night soil-men, day and night guards and an army of sweepers. (See Burrow's "Buried Cities,")

Portuguese 1505-1656.

From History by Juan Rebeyro, 1685.

Priests and Captains of the Army were in charge of Colombo, Kalutara, Negombo, Batticaloa, Triucomalee, Jaffna and Manaar. They attended to the sick, Surgeons were in charge of the Colombo hospitals. The Portuguese preserved health by adopting native habit of bathing twice daily.

Rebeyro describes Beri Beri, recommended pork, biscuits and toddy. He mentions "Parangi" and called it Neapolitan disease; the natives called it parangieleda or Portuguese sickuess. Fever is briefly mentioned, the remedy being the ordinary

domestic infusion of spices, " Coangtru." He says the vedaralas used always simple "domestic remedies and were good bone settlers.

Small-pox prevailed as an epidemic, Families perished in great numbers. It was called " Deviyankaria," or affair with God. The Sinhalese desertep the affected villages. Dead were left unburied, cheetahs carried away living as well as the dead

---

Dutch Period 1656-1795.

The Leper Asylum, the only monument has inscription on stone, A.D. 1708, and monogram of a Dutch Governor. Governor Van Imhoff 1740 recommended institution to his successor. Accommodation for 400 now.

No record of medical practice among the Army Surgeons. Dutch authors were Stahl, Boerhave and Hoffman. Dutch physicians were no doubt pupils of the above, and noted for knowledge of Botany. Flora of Ceylon described by Linuæus, but the Herbarium was collected by Herman and Hartog in 1671. First European writer on tropical disease was Bontius and Daalmans 1687. In 1739 Doctor Danielsz and apprentice were sent to Kandy to cure King Sri Vijaya Raj Sinha of an ulcer on his leg, In 1659 Knox and his son were captives of the King of Knndy for 20 years ; father died, son escaped 1775. First surgical operation by Kandyan medical man, viz., amputation of leg by red hot knife was in 1775

British Period from 1796.

Henry Marshall, Surgeon to the forces served 1808 to 1821. His "Medical Topography of Ceylon" and " Health of the Troops in the Kandyan Provinces from 1815 to 1820" are in the Colonial Medical Library. Troops: Europeans, Kaffirs. Malays, and Sepoys suffered terribly from malaria, with complication of abscess of liver and dysentery.

Africans or Kaffirs, of Mozambique and Indian Sepoys were in 2nd Ceylon Regiment also Lascars and Pioneers. Kaffirs suffered from consumption besides fever and pocky itch.

In 1812, 1813 and 1814 Famine prevailed; Troops also suffered from want of rice at Minnery ; 53 men of 19th Regiment got fever, 33 died, of 33 Artillery men 11 died ; the convalescents were unfit for duty,

In 1820 there were 32 Military stations. Cordiner relates that 13 miles from Kurunegala, of 70 men of 65th Regiment, one officer and only two men remained after fever.

Small-pox frequently prevailed as an epedemic among natives. Lymph was first introduced from Bombay on threads, and Vaccination was commenced by Army Surgeons in 1802. Mr. Percival, an officer of the 19th Regiment, suggested compulsory Vaccination in 1803, but it was not made legal until 1863, when Sir C. J. MaCarthy was Governor. Dr. Kinnis. Army Surgeon, wrote letters on Small-pox to natives. It is in book form, and was circulated in the Medical Department.

In 1812 the first Botanic Garden was opened in Colombo, and afterwards transferred to Kalutara, being finally established in Paradeniya in 1821. Moon, first Superintendent, published a valuable catalogue now in Library.

In 1817, a great act of humanity was performed in the release of the slaves in the domestic service of Dutch families. It was in consequence of a Petition to the British Government signed by a large number of residents. The writer may be excused for saying that he feels proud to know that the first signatory was his grandfather who died as Registrar of the Supreme Court, and was accorded a State funeral in 1845.

The following notes are in chronological order and as brief as possible :—

1835.—First Medical class established in Military Hospital by Dr. Kevett, Army Surgeon. First pupils were F. W. Ferdinands, P. H. VanCuylenberg, M. B. Misso, Trask, Cleveland, Ebert and E. F. Kelaart. Latter graduated in Europe, became Army Surgeon, serving for years in Ceylon, was first Ceylonese to obtain a British qualification, and was author of the " Prodromus Faunæ Zeylanica."

1839.—First suggestion of the Lunatic Asylum by Governor Sir Steuart Mackenzie. The old Small Pox Hospital, Borella, was converted into a Lunatic Asylum, and used till 1879, when the palatial one at Jawatta was built. Opened in 1847. Dr. Davy was appointed and resigned in 1849. Since then the following officers of C.M.D. had charge :—Ebert, Wambeck, Krickenbeek, VanDort, Vanderstraaten (the writer). Dr. Plaxton came from England in 1878 and resigned in 1886. Dr. Keith acted till Dr. Spence arrived in 1887. Dr. Oorloff acted when the latter was on long leave.

1843.—The following graduates of the Bengal Medical College who were sent to Calcutta by Government returned and entered the Medical Department, viz., Drs. Anthonisz, Loos, Dickman, Kriekenbeek, Oudaatjie, Andree, Wambeek. Drs. Markus, Margenout, and Bruchman came afterwards.

1843.—Colonial Medical Library started.

1847.—Dr. J. B. Misso appointed Portuguese Consul.

1848.—Ice imported ; and Ice machines first introduced 1863.

1845 to 1878.—Fearful epidemics of cholera in the Northern Province. In 44 years, 1841 to 1885, cholera caused 73,400 deaths.

1857.—Select Committee of Legislative Council separating Civil and Military Medical Departments.

1858.—Dr. Elliott first P.C.M.O. died in 1859, Dr. Charsley succeeded. Elliott thought of Medical School then.

1864.—Outbreak of fever in Colombo due to low margins of Colombo Lake during drought.

1865.—Mahara Railway accident : 36 natives and one European killed by collision of ballast train with trolley.

1866.—Municipalities established in Colombo, Kandy and Galle.

1867.—Depopulation of Vanni. Enquiry by Sir R. Robinson entrusted to Dr. Loos.

1867.—Cholera Commission sent to Jaffna, and again in 1877.

1869.—Demolishing of Fort walls and filling up years after of fort ditch. New Hospitals built in many Stations. Palatial barracks for troops and new hospital built on Galle Face.

1870.—Medical School opened ; raised to College 1889.

1872.—Welikada Commission into sanitary condition of that prison.

1873.—The Estate Coolies' Medical Wants Bill was introduced—since amended.

1877 Seaside line to Moratuwa opened ; due to constant agitation, and to whom is also due the extension to Matara by Dr. Anthonisz.

1877.—Dr. Koch, Principal of Medical School, and Dr. J. C. Evarts died of a dissecting wound.

1880.—Clock Tower erected to memory of the late Dr. Koch.

1880.—Two wards built in Colombo Hospital and Clock Tower erected in Galle in honor of Dr. P. D. Anthonisz, who got his C.M.G., and was for 5 years M.L.C. afterwards.

1880.—Polytechnic Exhibition by Dr. Vanderstraaten at the Medical College, Dr. Loos, acting P.C.M.O. Bearer Co. C.V. organized by Dr. Vanderstraaten who retired as Surgeon-Major, 1899.

1884.—Paulusz Hall built at Medical College in memory of R. C. Paulusz, L.C.M.C.

1884.—Silver Casket presented to Sir W. Gregory by Medical Department.

1887.—Parangi Hospital, Sir A. Gordon's, at Metugama W. P., and Balangoda Sab. P.

Ceylon Branch B.M.A., Dr. Anthonisz, President,

1892.—Lady students and doctor appointed.

1895.—Malarial fever Galle and Matara Railway line.

1895.—Foundation of Havelock Hospital by Sir A. Havelock and in

1896.—Opened by Lady Havelock.

1897.—Sir W. Kynsey, Kt., retired. Banquet by Department.

1898.—Dr. Perry assumed duties as P.C.M.O.

CEYLONESE ABROAD.

P. Ohlmus, J. Margenout, G. Andriezen, A. Joseph, J. Garvin, O. Morgan, A. Austin, F. RoosemaleCocq, C. Meerwald, Vanderwert, Ferdinands. *Surgeons in Britain.* W. Fretz, G. Perez, F. Keyt, V. Koch and J. Gabriel. *West Indies*: Surgeon-Col. A. Anthonisz, Cape; C. Loos, Natal; J. Keith temporarily S. Africa; C. Beling, Licensed Practitioner of New York; Surgeon-Col. Bartholomeuz, Surgeon-Major Van-Geyzel, and Surgeon-Lieut. Weinman, Indian Army; M. Wright, Perak; and Sidney Gomes, Borneo; Hugh Keith, Fiji; H. Garvin, W. Australia; C. McIntyre, Handy, Francis and Keegel, also several Medical Assistants at Singapore and Perak.

DIED ABROAD.

Dr. J. Vanderstraaten, St. Helena, fall from a horse; Dr. Evered Schrader, Congo, fever; L. Joseph, Newfoundland; W. Kelaart, Demerara; Surgeon-Major W. Morgan, at sea; Dr. H. Prius, at Christchurch, New Zealand; Dr. James Anthonisz, at sea.

PROGRESS OF MEDICINE IN CEYLON.

From Earliest Times, 900 B.C., to date.

By J. L. VANDERSTRAATEN, Retired Colonial Surgeon, W.P., and Principal Ceylon Medical College.

1900.

SINHALESE SYSTEM OF MEDICINE.—In the early par of the third century B.C. Asoka was the great Buddhist Sovereign of India. He propagated the new doctrines of Buddha by erecting columns or pillars on which were engraved those memorials or edicts, which he was desirous of making generally known; these inscriptions are remarkable monuments of the sagacity and benevolence of that great sovereign, who erected viharas, monasteries, and hospitals thus giving effect to whatever there is of beneficence in Buddhism. From an early period. the priests charged themselves with the duty of educating children and relieving the sick. It is in Ceylon that the Buddist doctrines were first reduced to writing. Theso doctrines recommended the prosperous and wealthy to found refuges for the blind, the destitute, the cripple, the sick and wounded both of man and beast. This was taught to be the surest method of attainiug to the highest degree of perfection and holiness on earth by means of which the future reward of the Buddhist faith might be attained viz. "Nirvana, or an easy departure and utter annihilation." These motives actuate some of the Buddhists to this day and I have learned from reliable authority that the Buddhist contractor of the Planters' and Anthonisz' Wards has actually built these hospitals simply at the cost price of the materials in the hope of obtaining merits here, and Nirvana hereafter. King Asoka also recoguized the sanctity which attaches to human life, and directed that the life of no living being was to be taken; and that wells were to be dug, trees planted, and "caravansaries" erected in public highways for travellers. The medical houses, or hospitals. of that period, were to be provided with all sorts of instruments and medicines consisting of mineral and vegetable drugs, and food; and skilful physicians were appointed to administer them at the expense of the State. Those physicians, or "vedaralas," who had gained a knowledge of Sanskrit committed to memory stanzas and recited them by the bedside of the patient. These stanzas were from the "Ayur-veda," a religious treatise on the science of life and medicine. There are no doubt several very intelligent and trustworthy vedaralas who are Sanskrit scholars and study manuscripts on talipot "olas," or leaves, but there are also a larger number of ignorant impostors in the villages, to whom the words of Job are applicable, "But ye are forgers of lies; ye are all physicians of no value." The TAMIL books of medicine derived for the same source are published in the Tamil and other Dravidian languages. The Tamil practitioners are styled Vrana Vydian and Parikari. The Moors or Mohamedans of Ceylon have their own native practitioners, who blend the Arabic with the Hindu systems of medicine. The recognized physician is called "Hakim." There were many kings of Ceylon who built bospitals and practised medicine themselves, and by their noble example made it an honorable profession. According to the "Mahawansa," Buddha Dasa, who reigned 29 years, from A. D. 339, was the anthor of a medical work called the "Sarrtha Sangraha." Many wonderfnl cures are attributed to him. He bnilt hospitals for every ten villages, and placed medical men in charge of them. They were to receive 1-40th of the revenue derived from fields for their maintenance. He also appointed medical men to attend on his infantry, and veteriuary surgeons to attend on cattle and elephants. Along the roads he bnilt halls for the lame and blind. It is said that, "when he went out of the palace" his surgical instruments were always in his waist. and he operated upon all sick persons whom he met." King Agho, who reigned six years from A.D. 782, caused medicines to be distributed amoug the sick;. and Dappula II, who commenced his reign in A. D 795, is most highly spoken of in this respect, in the following words:—"That most gracions Prince built a hospital at Polonnaruwa. He also in like manner built a hospital at Pandaviya and endowed it with villages which yielded the necessaries of life. He also built in several places halls for the cripples and the blind. In short, he did not leave anything undone which was called meritorious; he even gave growing paddy crops to cattle; and rice mixed with honey and sugar to children."

PORTUGUESE PERIOD.—In the history written by a Portuguese author, Juan Ribeyro in 1685, there is only a very brief description given of the diseases which prevailed in Ceylon at that period, and I can find no allusion to the methods of treatment adopted by medical men of his own nation. The Portuguese priests, and captains of companies appear to have been in medical charge of the garrisons of Colombo, Kalutara, Negombo, Batticaloa, Triucomalee. Jaffna and Mannar. Ribeyro states that most of the Portuguese on their first arrival were subject to bowel complaints, fevers and other diseases to which the natives are not liable. He thought that the Sinhalese retained their health by frequent baths, and states that when he first came out to Ceylon he had two illnesses in the first two years. He then adopted the native habit of bathing twice daily, and during the sixteen snbsequent years he lived here, he never became ill. Frequent bathiug is acknowledged to be one of the best means of preserving health, and is practised by the natives to this day; but it is in strange contradiction to the experience of an old Colonist of 70 years, an Italian, now dead, who attributed his immunity from disease to his never bathing! Ribeyro describes "beri-beri,," as a disease to which Europeans were very liable. He recommended as the best remedy pork and biscuit, with palm wine (toddy?) and smoking, to be persevered in for three months. As a prophylactic against this disease the Captain General, Antoniode Mascarembo. issued an order for everyone in the camp to smoke. Ribeyro states, what we can bear testimony to even now, that no people understand the use of simples better than the Sinhalese, so that with a few herbs or roots, they cnre wounds, ulcers, and swellings, but it is extravagantly stated that "they set broken arms and fractured legs and put those matters to right in a very few days." He also noted the good effects of herbs as antidotes against the bites of snakes and venemous insects. We mnst admit that many "vedaralas" are good bone-setters although they have no proper appliances for preventing shortening of broken limbs. Their method of stuffing a wound and keeping it dilated, when it is connected with a compound fracture (although aromatic, antiseptic and astringent herbs are used to check bleeding and prevent putrefaction,) cannot be approved except as a temporary measure until proper surgical aid is obtained. The historian must have been deluded when he was induced to believe that cancers which are considered

incurable in Europe, were cured in a week in Ceylon. Ribeyro also alludes to the prevalence of smallpox which the natives called "ankaria," or an affair with God, because it appears as if only a miracle can cure it. Riheyro speaks of the habit of betel chewing among the natives Portuguese and Dutch, and thinks it a wholesome practice which purifies the breath, strengthens the gums and cleanses the bowels. The Sinhalese at that time attributed their long and healthy lives to its use, and he confirms it by saying that men and women are seen in Ceylon who have not lost a single tooth. We unfortunately know that the practice of betel chewing has another side to the picture, it produces "betel-chewer's cancer."

Dutch Period.—The Leper Asylum at Hendala is perhaps the only monument of the medical history of Ceylon during the Dutch period which is left to us. There is no authentic record of its foundation beyond an inscription on a stone, "Anno 1708," and a monogram, scarcely decipherable, indicative perhaps of date of huilding and of the original owner of the property on which the institution stands. It is generally believed, on traditional authority that it owes its origin to a philanthropic Dutch lady daughter of a Dutch Governor who unfortunately was herself a leper, and at her death left the property to the Governments, in trust for the pauper lepers of the Colony. In a memorandum made hy Governor Van Imhoff in 1740 he commends this institution to the care of his successor.' Although frequent search was made among the archives of the Government Record office for documents, or information relating to the transfer, none has heen discovered as to how the Government became possessed of a property 16 acres in extent and occupying one of the most heautiful sites in the neighbourhood of Colombo at the month of the Kelani river, admirably adapted, from its sitnation, isolation, and distance from town, for the segregation and treatment of lepers. This hospital is certainly the first in the Colony founded by private benevolence, since paralleled by the foundation of other charitable institutions, especially by the De Soyza family.

There is no certain information available with regard to the state of medical practice in this island during the Dutch period extending from 1656 to 1795. It is reasonable to suppose that there were Army Surgeons among the Dutch, as nnder the British, and that some of these were probably regularly qualified men from the Colleges of Amsterdam, Utrecht, and Leyden,—with the latter of which the name of the great Boerhaave, will ever be connected. It is also interesting to note tbat the first European writer on tropical diseases was a Dutchman named Bontius. There are no records extant to show that any effort was made by the Dutch to teach the science of medicine systematically to the natives but it appears that the Kings of Kandy often requested through the Government, the medical aid of Dutch doctors, which the Dutch Governor of Colombo complied with. The mission of Dr. Danielsz and his apprentice to the court of Kandy in 1739, to cure the King Raja Singha of a bad leg, as recounted in his journal, is replete with interest. The late Dr. Koch, in his introductory lecture delivered at the opening of the session of the medical School in 1872, thus recounts the particulars of that memorahle visit: "Dr. Danielsz went, accompanied by his apprentice, but all he could see of his Royal patient was the ailing limb. Under such circumstances it was impossihle he could adopt any other course of treatment but what consisted of outward dressings. These he tried without any satisfactory results, and alarmed at the consequences of failure, he insisted on his Majesty taking a course of tonics. The decoction was prepared, but the King found it so bitter that he emptied the cup into the royal spittoon, suggesting that the Doctor should employ the more agreeable article of arrack for the conveying of the nauseous potion. Dr. Danielsz hereupon brewed two bottles of bitters, but he prescribed so small a dose of it at a time, (he calls it a small beer-glassful), that His Majesty demanded either a double-dose or to be allowed extra liquor over the bitters. After a good deal of resistance the Doctor was at last compelled to yield, and as he said, he himself was in the habit of taking a "schnap" before meals, his patient also migbt, but positively not beyond the third day. In the meantime the leg was not improving, and the regimen was becoming intolerable, and so Dr. Danielsz was bid prepare to leave Kandy; and if he could not congratulate himself on his professional success, we may yet suppose he was glad enough to escape the attentions of his patient, which now began to assume a form slightly more imperative than was altogether pleasant, and so Dr. Danielsz and his apprentice returned to Colombo, and continued, no doubt, to adorn the profession till the natural close of his not nneventful life."

British Period.—Mr. Henry Marshall, Surgeon to the Forces, who served here from 1808 to 1821 has given us a valuable work on the "Medical Topography of Ceylon, and on the health of the troops employed. in the Kandyan Provinces from 1815 to 1820, with hrief remarks on the prevailing diseases." From this work I have gathered some interesting passages. The troops employed during the early British occupation consisted of Europeans, Kaffirs, Malays, and Natives of India. Marshall says that the individuals of each class preserved a strong pbysical and moral resemblance, using the same food, having similar wants, undergoing the same labor, and suffering the same privations. Each class had particular prevailing diseases according to the effect of the climate, exposure to malarious influence and variations in their food supply. The Europeans suffered from the endemic intermittent and remittent fevers, abscess of the liver, and dysentery, but they were greatly exempted from many diseases to which they are liable in their own country. It was deplorable, says Bertalocci, to see the numerous children of the Ceylonese families reduced and emaciated for want of food, and depending upon parents wbo were in no way ahle to provide for their large families. No substitnte could be found for the staple article of diet for tbe native troops, and consequently privation and exposure led to much suffering. At Minery, between Kandy and Trincomalee, 53 men of the 19th Regiment were attacked with fever 33 died and 20 recovered, but several of them had their constitutions much impaired Of 33 artillerymen, 11 died. In December 1820 there were 32 military stations in the interior, the chief posts being Kandy, Badnlla, Allipoot (15 miles east of Badulla), Ratnapura, Fort King (Attapitiya) and Kurunegala, all of which were hospital-stations. The Rev Mr Cordiner records that a small outpost in 1803, Kottadeniya (13 miles from Kurunegala), was so unhealthy, that of 70 men of the 65th Regiment who marched to it, every one was seized with fever, and within a month Lieutenant Hutchings and two privates were the only persons of the party who remained alive.

The number vaccinated between 1802 and 1812 was 221,082 and it is stated that the efforts of the British Government, to eradicate small-pox by means of vaccination, were so successful that for eleven years the disease did not occnr in Ceylon. The lowcountry Sinbalese when they found hy experience the protective benefits of vaccination crowded in the British settlements to derive its benefits, hut the Kandians, or natives of the hillcountry, who had been at enmity with the Portnguese, Dutch and British still kept aloof from communication with the maritime districts; but, though they did not, nor would not, derive the direct benefits of vaccination they were free from the disease when it had been eradicated by the prophlactic in the lowcountry. They used to drive their small-pox patient into the jungles of the lowcountry.

The administration of the Rt. Hon. Stewart Mackenzie, and the year 1839, was marked in Medical Annals, by the first mention in His Excellency's speech to Council of a Medical School for Ceylon, and of certain measures to be adopted by Government which

afterwards contributed in a very great measure to the efficiency of the Civil Medical Department.

Dr. Kevett, in 1835, was the first who attempted to organize a Medical class. His pupils were the late Mr. Ferdinands of Kandy, E F Kelaart, P H Van-Cuylenburg, M B Misso, Trask, Cleveland, and Ebert of our service. Of this number, Kelaart having obtained the opportunity of a free passage to England as Surgeon's Assistant, accompanied the 78th Highlanders, and returned with a commission as Staff Assistant Surgeon, in 1840. Dr. Kelaart may, therefore be considered as the first Ceylonese who acquired a British medical degree, and his career as a physician and naturalist, was distinguished. His work (contributions to the Zoology of Ceylon) is a monument of his talent and industry.

In 1857 a Select Committee was appointed by the Legislative council to report upon the fixed establishments of the Colony and one of the recommendations made was that the Civil Medical Department should be separated from the Military Medical Department and placed under the control of a Civil Medical Officer, as the existing Civil Department was insufficient for the requirements of the island, and the Military heads of the Department were shifted too often for opportunities to acquire local experience.

A Civil Medical Establishment was proposed, consisting, of a Principal Civil Medical Officer, two Colonial Surgeons, eight Assistant Colonial Surgeons, and twenty-eight Medical Assistants, all with salaries adapted to secure efficiency and ability. Dr Elliott eminent in Ceylon as a public man and well-known for his ability and philanthrophy, was in England when the report was published and he lost no time in applying to the Secretary of State for the Colonies for the new office of Principal Civil Medical Officer, and Mr Labouchere recognized in him the individual suited for the appointment. Although best known as the editor of the leading newspaper in the Island the *Ceylon Observer*, Dr Elliott was known far and wide for his medical skill and was resorted to by rich and poor in their hours of difficulty and trial.

The year 1870 marked a new epoch in the medical history of Ceylon. To Sir Hercules Robinson belongs the credit of sanctioning the inauguration of the Medical School which was raised to the dignity of "College" in 1880, when the late Sir John Douglas K. C. M. G., was Lieutenant-Governor.

LITERARY REGISTER SUPPLEMENT:

AND CEYLON

"NOTES AND QUERIES."

[Under this heading, in future, we mean to give a four or eight page "Supplement" with our *Tropical Agriculturist*, from quarter to quarter, according as there is matter of sufficient value so to be preserved.]

MARCH, 1901.

EARLY SINHALESE LITERATURE.

"ENCYCLOPEDIA OF INDO-ARYAN RESEARCH."

We have been favoured with a copy of Part 10, Vol. 1., of this learned German publication, containing an article on the Literature and Language of the Sinhalese by Wm. Geiger. The introduction is worth translating from the German and quoting, as showing who are our chief learned writers of note:—"The first and last great effort to describe Sinhalese Literature connectedly was undertaken by J. d'Alwis (Grammar of the Sinhalese Language translated . . . Colombo, 1852.) Of publications before that there need only be mentioned Spence Hardy's 'The Language and Literature of the Sinhalese'; also his 'List of Books in the Pali and Sinhalese Languages' Mr. d'Alwis's work, very valuable for that time, is now in many respects antiquated. Even now we are far from being able to give a complete account of the Literature. I can therefore give little more than a list of titles and authors. And even this I could not have done but for the assistance in Ceylon itself of the Mudaliyar Simon de Silva and, after my return, of my indefatigable friend, the Mudaliyar A. Mendis Gunesekara, who, in numerous letters, was ever willing to answer my inquiries. Also, of value to me was Louis de Zoysa's 'Catalogue of Pali, Sinhalese and Sanskrit Manuscripts in the Temple Libraries of Ceylon, Colombo, 1885.' I would also mention a small work in Sinhalese by Rhys Davids, 'Handbook of the Yogāvacara.'"—The author, Mr. Geiger, describes his work very modestly, but really we find nearly 100 quarto pages devoted to the literature, inscriptions and grammar of Ceylon, which must be most interesting to those who have any previous knowledge of the subject. A translation of the whole might be worthy of embodiment in the records of our local Royal Asiatic Society.

PROF. W. GEIGER ON THE LITERATURE AND LANGUAGE OF THE SINHALESE.

On previous occasions we noticed in our columns works by Dr. Wilhelm Geiger, one on his visit to Ceylon, and two others on the dialect of the Rodiyas and on Sinhalese etymology. Now, as further fruit of his mission to our island in 1895-96 we are glad to welcome from the pen of the learned Erlangen professor another valuable work, viz., *Litteratur und Sprache der Singhalesen.* This forms part 10 of vol i. of the *Grundriss der Indo-Arischen Philologie und Altertumskunde* founded by the late lamented Prof. Buhler and continued by Prof. F. Kielhorn with the co-operation of a number of eminent scholars. Dr. Geiger's book consists of nearly 100 pages, in the first 25 of which he treats of the Sinhalese inscriptions and literature in an exceedingly interesting and able manner; though, unfortunately, in dealing with the former he has been hampered by the paucity of material, and for the latter has had to depend largely on the late James Alwis's valuable but not quite reliable Introduction to his translation of the *Sidat Sañgarā.* Mr D. M. de Z. Wickremasinghe's admirable *Catalogue of Sinhalese Manuscripts of the British Museum* (noticed by us recently) reached Dr. Geiger too late (as he mentions at the end of his book) to be utilised by him: otherwise some errors with regard to authorship of works and dates of authors would not have appeared here. In the second part the author deals with the grammar of the Sinhalese language in a masterly fashion, the portion treating of phonology being especially valuable. In the third and final chapter Prof. Geiger shows what is the linguistic character of Sinhalese, the conclusions he arrives at being as follows:—"1. That Sinhalese is an Aryan language. —2. Historical relations declare that the

first Aryan colonists came from the north-west of India.—3. Linguistic grounds also prove that Sinhalese has a prākrit dialect of north-west India as an antecedent: (*a*) Sinhalese is closely allied to Pali. (*b*) It does not however go back to the Pali of the Buddhist books, but to a popular dialect closely connected therewith. (*c*) Sinhalese is allied to the Māhārāstrī. prākrit, even more closely than to Pali. (*d*) Its basis however shows itself in many points more ancient than Māhārāstrī. (*e*) Moreover the comparison with the modern Indo-Aryan popular languages indicates for Sinhalese its place in the western group of dialects, and exhibits Sindhī Gujaratī and especially Marāthi as the most nearly allied languages." An English translation of this valuable work would be welcomed by scholars in Ceylon. We are glad to notice that Prof. Geiger promises us two further works, —one on the Maldive language and the other on the Veddah dialect. We shall await these with much interest.

TROUT FISHING IN CEYLON.

An early morning start and an hour's ride in the train, through some of the most beautiful scenery in the world, brought us to Ohiya station. From there the path leads one through jungle for the first two miles, an ascent of about two thousand feet to the Horton Plains. Another half hour and we catch first sight of the stream, for here it cannot be called more, bounded in as it is by high grass and ferns, and in places unfishable where the rhododendrons overhang. They are in flower just now, a lovely crimson, but although lovely to look at, from a fisherman's point of view they are the curse of the place. Get your cast fairly fixed in one, then you realise for the first time how tough a rhododendron leaf can be. Half an hour's smoke on the bank while your faithful coolie is undoing the tangle is about the only remedy. We are soon at work however, and about one hundred yards lower down I see my friend V—— has hooked the first fish of the day. It has given him excellent sport, but has to be returned to the water, being just under eleven inches, which is the regulation size. We rise several more in this top water, but they are insecurely hooked owing to the difficulty in striking. Rhododendrons again! As we get lower down the water becomes more open, and we each get a nice fish of about one pound.

After two hour's fishing we meet and have a look at our respective catches. V—— has got three, from one pound to one and three quarters, and has returned as many more, while I also have three averaging one and a half pound, and have returned one. Things are looking well for us and we look forward with the keenness of the fisherman to the rest of the day. The water is as clear as gin, the sky a most lovely blue with occasional fleecy clouds blown across from the north-east, and the air has a freshness that recalls Scotland. We are only a few degrees north of the Equator, but our elevation is 7,200 feet above the sea, and that accounts for it.

While we are having our rest and sandwiches we take a look round at the scenery. The plains stretch away to right and left, dotted all over with rhododendrons; this is the only tree that grows in this black Patna soil. Yet here flowers grow in profusion, orchids, ground orchids, and most lovely of all, gentian of the deepest royal blue and golden centre. Here also grows a bamboo, the smallest in the world. It only reaches a height of from one to two feet. There are many more specimens of plant life of interest to those of a more botanical bent. The waving grass of the Patna gives place to stretches of thick jungle.

Our meal over, we set to work again. The next mile of water is, perhaps, the best bit on the river. V—— starts at the Black Bridge, while I go down lower. He begins at once and soon has a nice trout of three quarters of a pound on the bank. Two or three casts later, in almost the same place, a rise and a rush sees him into another. This time a big fish from the way in which he sails slowly up and down the pool, pulling hard, but never showing himself. He begins to feel the strain, however, and is being slowly drawn to the bank, carefully netted and grassed—a perfect beauty in splendid condition, turning the scale at two pounds ten ounces. While V—— has been doing so well I have not been idle, one of two pounds and one of one and three quarters, the latter has given splendid sport, repeated rushes, and at the end of each leaps in the air two feet out of water. He reminds one more of a sea trout than a brown, but ont here the smaller fish generally give the better sport. Large fish, as a rule, content themselves with a feeble rush or two or sulking at the bottom, and are soon beguiled into the net. There are exceptions, however, as not unfrequently a trout more wary than the rest succeeds in making good his escape by twining your cast round some sunken root or snag. From this all your gentle persuasion fails to dislodge him and results in loss of cast and fly.

We are now at the Red Bridge, below the Rest House, and here the river which has gradually been gathering in size, begins to assume a different aspect. A long, deep stretch, terminating in a series of water-falls and rocky pools brings us to Chimney and Atherton's Pool, a huge piece of water nearly half a mile long and in places one hundred yards across. That the smaller stream two miles above should have reached such large dimensions here, seems incredible, there being no tributaries, but such is the case. This piece of lake-like water teems with good fish, but they are very hard to move and after having fished it carefully, we have to confess to neither of us having had a rise. Another small waterfall takes us to the Round Pool; this also contains big fish, one having been seen sporting himself of between seven and eight pounds. I rise and hook a fish here, which after an exciting time, owing to the weeds being so thick, I manage to creel: a pretty trout of just one pound. The river here takes a turn at right angles, and for the next mile or so we have a fine stretch of water consisting of long deep pools and still runs. Yet for some reason or another we fail to make any addition to our catch; the few we do rise coming short, and in a half-hearted way that is most annoying.

We decide to wait and see what the evening may do for us. The sun is getting low and nearly off the water, the hills here rising somewhat abruptly. We are resting beside a big pool, and have not long to wait before we see a rise, and another, and then another, and soon it becomes general. But they are too far out for our light ten-foot rods, and appear to be small, so we leave them to their enjoyment and come to an ideal piece of water, a steep bank covered with ferns and bushes on the far side. First cast V—— has hooked his fish at the top of the run and tries to keep him out of the pool, but he is too lusty, and makes the reel scream as he dashes away taking out some twenty yards of line. From his fighting powers he must be a heavy fish; but no, he has shown himself, and will not be more than one and half pound. He is not tired yet, however, and takes one or two leaps, and a few more rushes which get shorter and shorter and he is safely landed nearly two pounds, a real fighter, the capture of which lingers long in the memory. Meanwhile, I have been fishing over a rapid rush of water with a stony and rock-strewn bed, whence out rush two fishes at my fly. I strike some-

what wildly at this unexpected assault and find that I have hooked one of them. The other hesitates a second or two in bewilderment, and then on seeing the antics of its companion goes out of sight at its best speed. I land my fish after some excellent fun in the heavy waters, and find it to weigh one and a quarter pound. As it is now getting dark and we are about two miles from the Rest House, we hand out rods over to our coolies and set out. On our arrival, fairly tired and contented with the day's fun we count our catch and find that V—— has accounted for six, weighing nine pounds six ounces, and I for seven weighing ten pounds four ounces.

I awoke V—— in the morning, and we start off. To reach the water we intend fishing this morning we have to walk three miles down stream to below "Baker's Falls." This water is open for the first time this year, having been stocked with fry three years before, so we expect great things and know all fish caught will be above the average size. In Tiger Pool I hook my first and have him safely landed before V—— even had as much as a rise. Luck seems to have deserted him this morning for he fishes steadily without result for nearly an hour, during which time I have landed another weighing three pounds ten ounces, and measuring twenty inches in length. This proves eventually to be the best fish of the outing. V—— owned afterwards to having had a fair number of rises, but had missed striking at the right moment; but the story of one fish he did get might be told. He raised him at the tail of a pool in shallowish water. He appeared to be hooked all right, but to our dismay, for I had just come up, the hook came back and the fish remained where he was. I shall never forget V——'s face as I saw him staring up at his fly. He cast again almost immediately, and re-hooked his fish with the same result. I won't attempt to repeat his language after this fresh misfortune, but think it best to clear out as he looks at me as if I were responsible. As we came back a couple of hours later to breakfast at the Rest House before going to the train we re-pass the same pool; V—— insists on casting again. Strange as it may seem the same fish rose again, and this time after a good fight was safely landed. He bore the marks in his mouths where he had been previously hooked. There is some satisfaction in catching a fish of this sort. As time is now short we make for the Rest House and find our morning catch to be five in all, none under two pounds. My luck stopped after catching my big fish so that my contribution is two, while V—— secure the remaining three. A fair morning's sport on the whole.

On our way to the station we have a look at the Stew Ponds which are some little way from the stream. The top pond contains brown trout and the lower rainbow. They appear to be thriving well and there are some little fellows already five inches long. Our streams have to be stocked annually with fry in this way, the ova being got out from home. Unfortunately our trout have not been known to breed as yet naturally, they are probably not acclimatised. Experiments are to be made this year, however, and let us hope with good results. We have to tear ourselves away and have a tremendous rush to the station.

CEYLON AND TEA IN 1319.

From a copy sent us of *The Morning Post*, Monday, January 4th, 1819, we quote as follows:—

The London Tea Company, 83, Newgate-street, respectfully inform the public that the East India Company's sale has just closed; and they are happy to add that they have supplied themselves with a large assortment of the finest and strongest-flavoured TEAS, selected with more than ordinary care, and, they flatter themselves, with their usual discrimination. They now, therefore, with the utmost degree of confidence, offer them to the public, on the same moderate terms for which the business of their house has always been distinguished, satisfied that a single trial will convince the most sceptical that they cannot be supplied with tea so good, at their respective prices, by any other house in the trade, old or new. Orders, with remittances, instantly attended to, and forwarded to every part of the United Kingdom.

CAUTION TO TEA-DEALERS.

A case of an important nature to the public, and to all tea-dealers in general, was investigated last week at the Hatton-garden Police Office. It was an information brought by the Excise against a grocer in Somers Town, for exposing for sale a quantity of imitation tea. The case, which was heard before Mr Sergeant Sellon and another Magistrate, occupied the attention of the Court for three hours. Mr Bolland appeared as Counsel for the Excise, and Mr Adolphus for the defendant. After the examination of a number of witnesses, it turned out that the parties who gave the information to the Excise had employed a person to go from the shop of one grocer to another where, under pretence of transacting business, parcels of imitation tea were deposited. It further appeared, that a fellow named Bachelor was employed by the informers to prepare the imitation tea! These facts being fully established, the information was of course quashed, and we understand that it is the intention of the defendant in this infamous case to prosecute the informing parties for a conspiracy.

CEYLON.

(from the Ceylon "Gazette" of August 8.)

Yesterday evening on the Parade in Slave Island a very handsome pair of colours was presented by Lady Brownrigg to the Native Militia lately raised for service in the Interior. The following spirited address was given by her Ladyship in writing to Don Alvis Mudaliyar of the Governor's Gate, who interpreted it in Sinhalese to the troops:—

"In presenting this standard to the Militia of Ceylon, I have great pleasure in expressing how much gratified I have been by the favourable reports of your attention to the necessary exercise to enable you to take the field with effect.

"Every well-disposed man, who wishes for the happiness of his country and the safety of his family, must feel anxious to rally round this standard, and while their Governor is devoting every moment and thought of his life to put down the rebellion, and unite this island under one government, the caste of fighting men will all step forward, and show the utmost diligence and zeal to support his measures and obtain the grand object of his unceasing endeavours—that of restoring peace and prosperity to Ceylon.

"I present this standard to you with every wish for your health and success, never doubting that the motto, which I have chosen, will be your guide during your service."

The motto to which her Ladyship alluded was "Duty and Honour," embroidered on the colours; Captain De Bussche received the colours from Lady Brownrigg, and presented them to the Muhandiram of the 1st company, who spoke in Sinhalese the following reply to her Ladyship's address:—

"We are always ready to serve the King of England, and particularly under a Governor who has been always so kind to us. If the Kandyans knew how good the Governor was, they would not make war upon him, but we are willing to serve him with our lives against them. We beg to offer our best and humble thanks to her Ladyship and his Excellency for these very beautiful colours."

The Commandant and all the Officers of the Garrison, with most of the Civilians, were upon the ground, and almost all the ladies of Colombo graced the ceremony with their presence.

It is several months since a corps of 100 Natives were embodied, trained, and sent into the interior; Lieutenant-Colonel Cother, Lieutenant Colonel Hook, and some other officers, spoke so favourably of their behaviour, that His Excellency the Governor was induced to order a similar levy upon a more extensive scale. Six native officers, muhandirams, 22 sergeants, aratjes ; 38 corporals, canganis ; 545 privates, ascoryns, have been in training for fourteen days, and their progress has been so rapid, that two muhandirams eight aratjes, fourteen canganis, and 200 lascoryns marched this morning for the interior.

The whole of this corps consists of volunteers raised with great expedition by Deane. whose official duties as Collector of Colombo have been much increased by the Kandyan Rebellion, and who in this and every other extraordinary service incidental to the war, has exerted himself with a zeal and energy that deserve the warmest acknowledgments from Government.—*Morning Post*, January 8th, 1819.

[This seems to show that the Sinhalese made good soldiers.—ED. *L.R.*]

CEYLON.

"CEYLON GOVERNMENT GAZETTE'—JULY 4.

From Badulla accounts have been received to the 23rd ultimo, and we are sorry to learn that some more casualties have occurred in that neigbourhood. On the 16th ultimo, while the Hon. Company's 18th Native Infantry were halting at Passara for refreshment, Lieut Wilkinson sent into Badulla a small party to announce their arrival. This party consisted of six Europeans, six Malays and esix Caffres. They had not been used to go quite to Badulla, but to meet the escort half-way, and so were not aware of there being, within two miles of Badulla, a patch of jungle, which was a favourite lurking-place of the rebels. When they approached this spot a heavy fire was opened upon them by the Kandians from their ambuscade close by, and two fine soldiers of the 73rd Regiment, James Sutherland and William Chandler, were unfortunately killed upon the spot. The gallant conduct of the rest of the party well deserves public notice and approbation. They were resolved not to abandon their comrades even in death, nor to suffer their bodies to be insulted by a barbarous enemy. Lance-corporal M'Laughan, with another European, and four native soldiers, volunteered to fight their way to Badulla, where they might procure assistance. The remaining two Enropeans and eight natives formed themselves into a circle round the dead bodies, which they had previously removed to a spot of open ground ; while the corporal and his companions made their way good to Badulla, followed and constantly fired at by numerous rebels. The determined band posted round the bodies was assailed for upwards of two hours by strong parties of Kandians, who urged on by their chiefs from the hills, for they always keep at a distance themselves, advanced within 150 or 200 yards, and poured in volleys of musketry. The cool intrepidity of the soldiers was shown in the judicious reserve of their fire, for they never returned more than two shots at a time, which were sufficient to keep off the dastardly enemy, until Lieut Burns, with a detachment drove them all into the jungle, and the bodies were brought off and interred in Badulla.

A Kandian servant of one of the headmen, with the Pretender, came in lately to Badulla and gave, on the 22nd ultimo, some curious information respecting the movements and situations of the Pretender, and Keppitipola, and their chief followers, whom he left on the 16th ultimo, between Donattokappola and Materratta, probably in the very place observed a week after by Colonel Kelly. He confirms the account of Keppitipola's suffering from dysentery ; and adds that little hope was entertained of his recovery ; he was so weak as to be unable to walk. He states that the Pretender is not a Malabar, or any relation to the Royal Family, but as many others have asserted, a Sinhalese of the Seven Korles who had been a priest.

Nothing of any consequence has occurred lately in Saffragam, or the Seven Korles. The last accounts from Lieutenant-Colonel Hook were dated the 30th ultimo. He had taken two rebels, who were immediately to be tried before a Court-Martial.

July 11th.—By this morning's post we hear from Kandy that a numerous meeting of the rebels took place at Hanguranketty on the 5th instant, when it was resolved to make a grand attack on the post of Godamoone. On the 7th and 8th this design was put into execution in a true Kandian style. The Pretender, Keppitipola, and several other chieftains, took their position on a hill about two miles off, and about 5,000 rebels made the assault premeditated. They began each day about noon and continued till near midnight, but their fire was at such a distance that not a single man in Godamoone was hurt, nor is it thought that many of the assailants suffered in their dastardly attempt.

We are sorry to announce an accident which has befallen Leiutenant Emslie, of the 83rd Regiment. On the morning of the 2nd instant, when this officer was returning with a party to his post at Gampola, information was brought to him by a Kandian that the path in front was obstructed by elephants. Having halted his party, with a soldier's firelock in his hand he advanced alone, and on turning an angle of the road, he suddenly came in contact with four elephants, at the largest of which he fired. In an instant Mr Emslie was knocked down, and under the enraged animal. In this terrible situation he only recollected the appearance of the brute's preparing, as it were, to destroy him, and hearing the report of a musket, which was fortunately fired by a man who had followed him. Mr Emslie was found by his party lying among some ferns by the road side, almost insensible, extremely bruised, and unable to move, having received severe contusions on the face, chest, and left thigh. Without loss of time he was carried to Kandy, and we are happy to say sanguine hopes are entertained of his recovery.

PRODUCTION AND CONSUMPTION OF INDIAN AND CEYLON TEA.

13, Rood Lane,
London, E.C.

Dear Sirs,

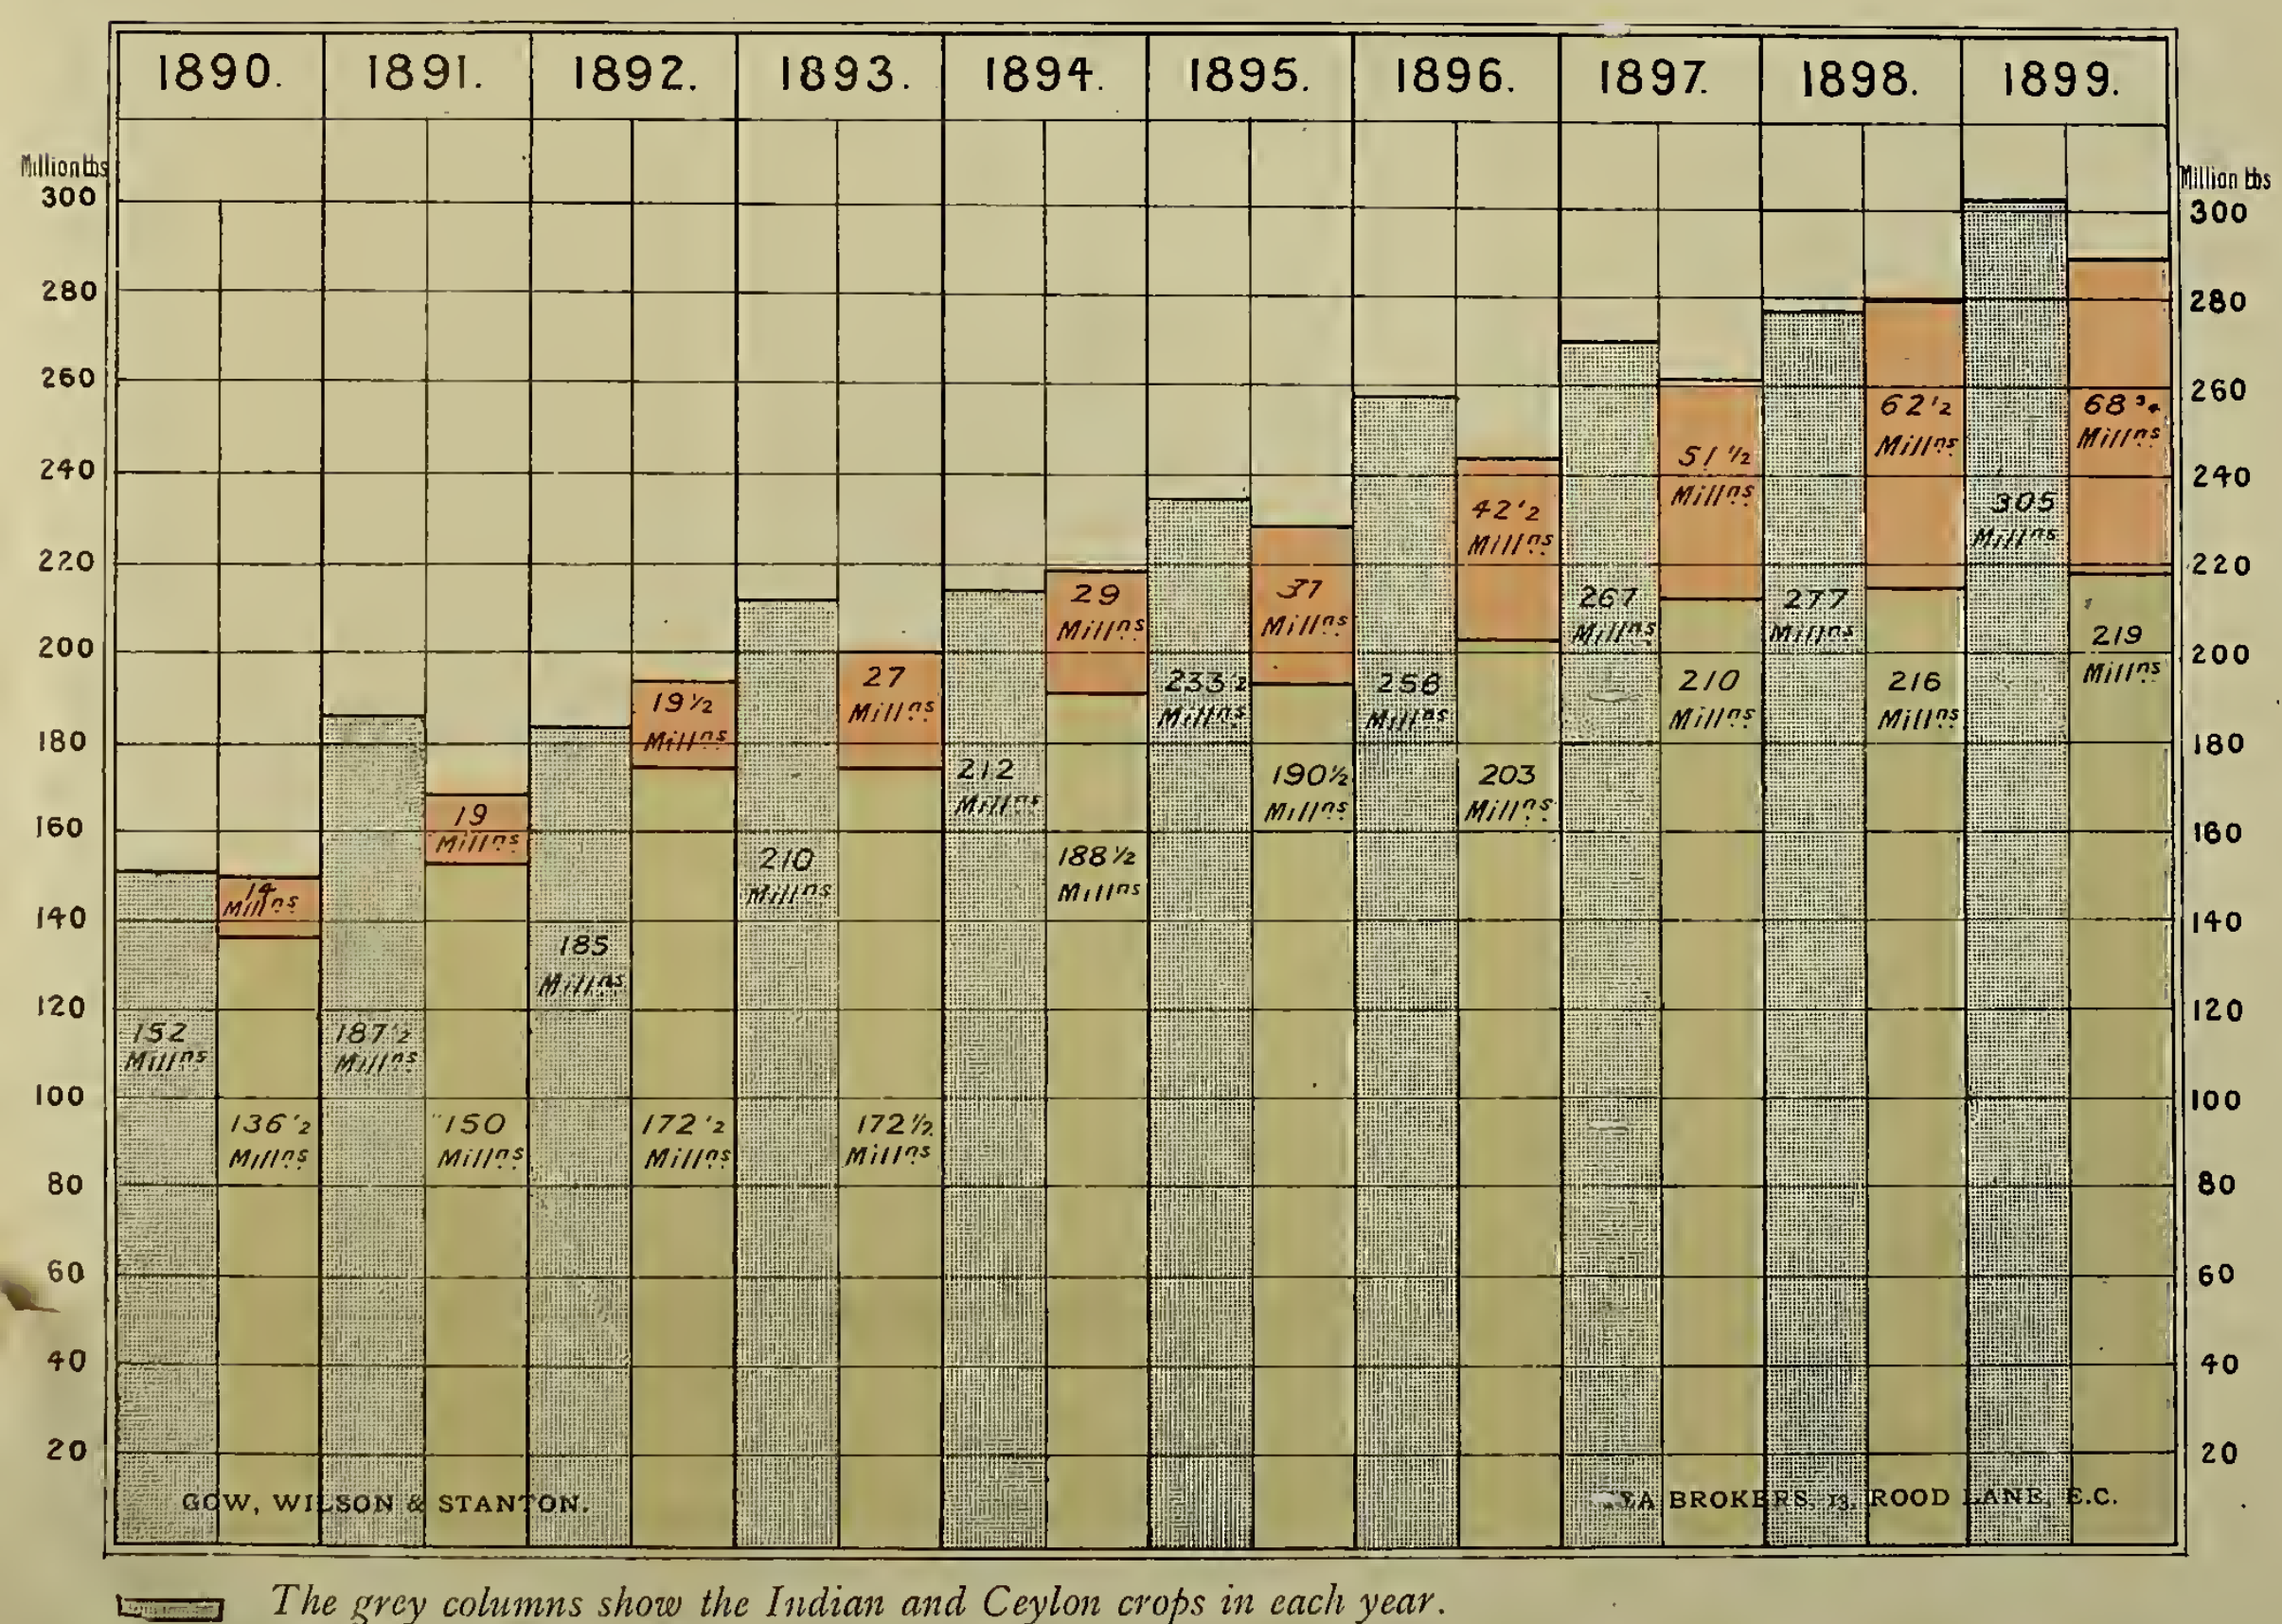
The increase in the output of Tea from India and Ceylon last year was so heavy that we venture to offer a few remarks upon the necessity of making strenuous efforts for the further development of new outlets, in order to effectually cope with the anticipated surplus of this year's crop.

We are, Dear Sirs, Yours faithfully,

GOW, WILSON & STANTON,

June, 1900.

Diagram showing the quantity of TEA exported from INDIA and CEYLON in each of the past ten years; also the quantity consumed in the United Kingdom and taken by other countries.



The grey columns show the Indian and Ceylon crops in each year.
The blue columns show the Home consumption.
The red columns show the quantities taken by countries outside Great Britain.

The diagram illustrates the expansion in production and consumption of British grown Tea. Through the development of new outlets demand fairly kept pace with supply until 1899, when the output exceeded consumption by fully 17 million lbs., a condition which does not augur well for prospects in the immediate future.

In 1899 the production of Indian and Ceylon Tea exceeded that of 1898 by 28 million lbs., the total produced being 305 million lbs.

The world's consumption of Indian and Ceylon Tea last year increased only 9 million lbs., the total consumed being 288 million lbs.

Large areas of land in India were placed under Tea cultivation a few years ago when Exchange was very low. This land is now commencing to bear leaf, and has been the chief cause of the increase in the 1899 crop from India. This is likely to continue during the next few years.

The 1899 crop from Ceylon was the heaviest on record, and during the first four months of this year the increase had already amounted to 11 million lbs. This excessive increase is probably due in great measure to the extensive use of manure. The use of artificial means to still further enlarge the output is very questionable policy, especially under existing circumstances.

Again; have producers asked themselves the question, whether manuring will develop in the bushes, permanent strength and vigour sufficient to withstand the strain of continual plucking, specially in the event of over-production reducing prices so low that artificial manure can no longer be afforded?

Another question naturally arises: Who is to buy the Tea and at what price? No producer wishes a lower level of prices, and yet this is the sure way to obtain it. Production is increasing too fast. Consumption is unable to keep pace with it, in spite of all the efforts to capture new markets and to develop those already acquired.

True, a fall in price may develop Foreign markets with greater rapidity, but no relief through increased consumption at Home can be expected from this cause, because the retail price has already been advanced *Twopence per lb.* through the additional duty.

For years past, over-supply has been promptly dealt with by a fractional drop in price, such a decline invariably stimulating consumption. Now, however, increased supply cannot be dealt with in this manner, because, were the price to fall even as much as the duty has been increased the *retail price* would then be only what it was before the duty was raised.

How absolutely necessary then to raise all possible funds for exploiting new markets and to redouble our efforts in those already using British grown tea.

The foreign outlet which for many years has received the greatest attention and energy from India and Ceylon, as well as by far the most pecuniary assistance is North America, and as a result, the Black Tea Market in this continent has been practically

captured; but out of a total consumption of 111 million lbs., about 75 million lbs. consist of Green and uncolored Tea. Should not India and Ceylon be able to supply this enormous demand?

Suitable Tea can be made, and if we want the North American market, let us supply it with the kind of Tea most appreciated, similar to the Oolongs, Japans, and Greens which form nearly three-fourths of its consumption.

It is unlikely that the Green Tea drinkers of North America will be converted into Black Tea drinkers; why then not supply them with the Green and unfermented Tea which they want and are ready to buy?

Even if no better price could be obtained for such Tea than for Black, it appears advisable to cultivate this trade, because for every pound made the production of Black Tea is reduced by an equal quantity. This would minimise the danger of over supply of such Teas as are sold in the United Kingdom, and consequently increase competition.

The Ceylon Fund has been allowing planters over 1½d. per lb. as a bonus to produce this class of Tea, and both Mr. Mackenzie, the Ceylon Commissioner, and Mr. Blechynden, the late Indian Commissioner, appointed to exploit North America, believe that the great outlet in the United States will be for Tea of this description.

This bonus will go far to obviate any loss which might be entailed in selling, while the "Thirty Committee" would doubtless continue to foster its manufacture if prospects continued favourable for its ultimate success. At the same time it must not be forgotten that if once a commencement were made in this direction, great possibilities exist for a profitable trade in other markets, such as South America, where Green Tea is largely used as well as Maté or Paraguay Tea, besides North Africa, Persia and the neighbouring parts of Asia.

The fact that British grown Tea is so largely displacing black China Tea in almost every market hitherto attacked, is sufficient argument to warrant the belief that the Green Tea monopolies of China and Japan can be assailed with equal success, and that by this means an enormous outlet may be opened for the surplus produce of India and Ceylon.

Surely British energy and resource are capable of suiting their superabundant produce to the requirements of Foreign markets, when by some change in manufacture they can not only attack such important outlets with every probability of success, but by the act of so doing immediately relieve that very pressure which is proving so injurious to their own interests, and a cause of much anxiety as to the very existence of not a few Tea properties.

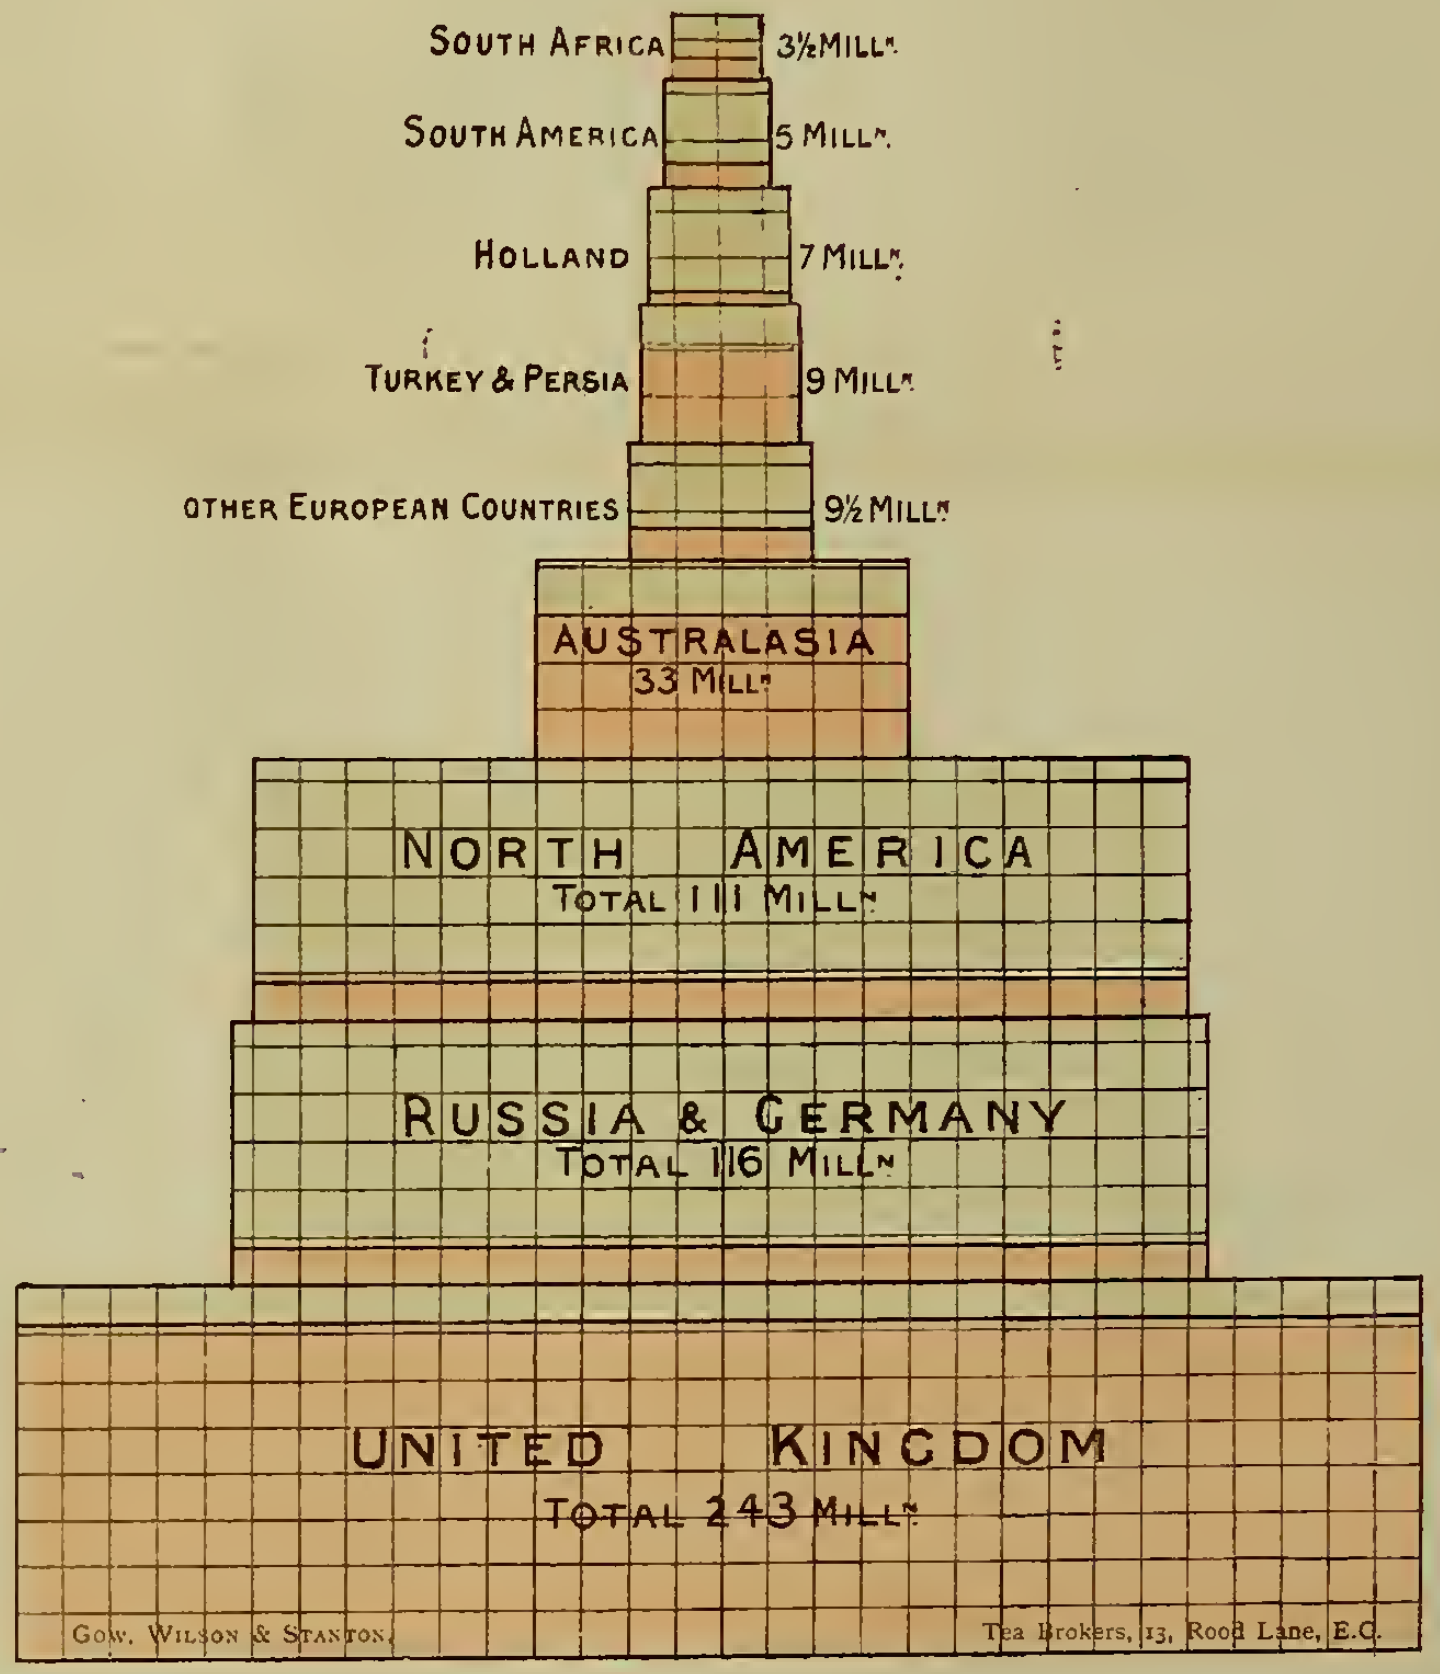
The diagram on the last page gives a history of the consumption of Tea in the most important consuming countries of the world in the years 1890 and 1899, showing the rapid way in which British grown Tea has displaced other growths in many important markets. The United Kingdom has naturally led the way, and has been closely followed by her Colonies, as shown by the increase in Australasia, while the taste for Indian and Ceylon Tea has developed considerably in North America as well as Russia.

It is important to remember that a very large proportion of China Tea which was formerly used in the Australian Colonies has now been displaced, so that it is doubtful whether the same rapid increase can take place in these Colonies as has been the case in the past. The only large field for the displacement of Black China Tea appears now to be Russia, which is gradually increasing its taste for the produce of India and Ceylon; while the world's markets for Green and uncolored Tea still remain to be exploited.

The displacement of China Tea by Indian and Ceylon and the development of the taste for British grown Tea during recent years.

1890.

1899.



Each square represents One Million pounds of Tea consumed, China, etc., being shewn in blue and British grown Tea in red.

COFFEE AND PEPPER EXPORTS FROM WESTERN INDIA.

To the Editor "Ceylon Observer," Colombo. Tellicherry, 24th Sept. 1900.

DEAR SIR,—I have the pleasure to furnish you with my Annual Statement of Exports of Coffee and Pepper for the year ending 30th June, 1900, the total figures of which approximately represent what the crops of these products in India, for the year in question, amounted to. As usual, I further show the distribution of shipments to various ports, and have added the figures relating to exports for the three previous years for the purpose of comparison.

COFFEE.—The crop for the past year was a disappointing one, being some 47 per cent less than that of 1898-99 and almost half of this was shipped from the port of Mangalore alone. Of the total quantity shipped cwts 1,27,331 may be regarded as plantation, and the balance cwts 81,013 as native coffee. The prices fluctuated to such an extent that I find it impossible to arrive at an average value of the coffee exported, and a large quantity was being held over in London at 30th June in hopes of it obtaining a better price, which has to some degree been realized.

I am glad to be able to add, that the reports that are being received from the planting districts, give promise of good crops for the coming season, and I trust that the quantity of coffee exported the season before last may be reached if not surpassed: and in view of better prices at home our planting friends have a right to look forward for brighter prospects in the immediate future.

PEPPER.—The total exports of this spice amounted to cwts 1,68,001 or some 29 per cent less than was shipped last year, the value of which at an average of R37-8-0 per cwt. being an increase of R5 per cwt on last year's value, amounts to R63,00,037-8-0. Tellicherry still continues to be the chief port of export for this spice, which is now being planted up to a considerable extent in the coffee districts as a bye-product.—I am, dear sir, Yours faithfully,

RALPH TATHAM, Agent, Arbuthnot & Co.

MESSRS. ARBUTHNOT & COMPANY'S ANNUAL STATEMENT OF EXPORTS OF COFFEE AND PEPPER FROM SOUTHERN INDIA DURING THE SEASON ENDING 30TH JUNE 1900.
