PREFACE.

SINCE the publication in 1871 of my first Catalogue of the Plants under cultivation in the Garden, the collection, by the constant introduction of new plants, mostly procured by exchange with kindred institutions, has been increased, exclusive of florists' flowers, from 6,000 to 8,500 species.

The rapid increase necessitated a new edition of the Catalogue. In the new issue, instead of the former alphabetical arrangement, I have adopted the natural arrangement, which brings together all the plants that are nearest related to each other and have a similarity, enabling the student of botany, particularly in this Colony, to become soon acquainted with them.

To facilitate to non-botanists the finding of a particular plant, an index of the orders and genera has been attached; also the list of English names of the plants, where such exist. This will be useful, particularly to those amateurs who know the English names and may be desirous of becoming acquainted with the botanical ones.

I have added again the abbreviations of the names of the botanic authorities annexed to the genera and species of the plants, which would be unintelligible to a great many persons in the Colony if the full names of the authors were not given.

For the foreign recipients of this Catalogue, I think it is not without interest if I preface it with a brief description of our climate, its extremes, the difficulty we have to contend with in regard to acclimatizing introduced plants, especially those from tropical, frigid, or Alpine zones (as their well-doing depends entirely upon the climate), and the plants from other parts of the globe which will become accustomed to our climate, and those which will not thrive outdoors.

Our summer season includes the months of December, January, and February, when the temperature on the plains frequently exceeds 100° in the shade, and 130° to 140° in the sun. In 1876 the thermometer registered in December $114^{\circ} 2'$ in the shade, and $162^{\circ} 6'$ in the sun. This degree of heat has only been exceeded on two former occasions, viz., in 1865, when the thermometer registered, on the 9th January, $116^{\circ} 3'$, and the 14th January, 1862, when the reading was 115° in the shade and 165° in the sun. Such a temperature produces very injurious

effects on the introduced plants, especially those from cooler climes, and leaves even injurious traces on the native vegetation.

During the blowing of a hot wind the thermometer and the wet bulb thermometer show often a difference of 30° to 40° , and it is that which enables persons to bear the heat of our summer and carry out their usual pursuits in the field or elsewhere, which in a tropical climate would be impossible.

The changes of temperature during the summer are often very sudden, so that in a short time the thermometer falls from 90° or 100° to 60° or 70° .

Our summer months are characterized by great heat, hot winds, and dryness. Often not a drop of rain falls for eight or ten weeks, and it is during this time that not only the indigenous but the acclimatized vegetation suffers materially. The ground becomes so hot and cracks, that even the occurrence of a heavy fall of rain serves only to clear the leaves from dust, as it evaporates as quickly as it falls.

The autumn season includes in Australia the months of March, April, and May, and is one of our genial and beautiful parts of the year. The temperature falls rapidly, only reaching 70° to 90° in the shade, the mean being $64^{\circ} 6'$; and in the month of May it is only $58^{\circ} 2'$. The northern winds become cooler, the solar radiation is considerably reduced, and heavy dews begin to fall at night. The indigenous vegetation, which has suffered through the summer, awakes to new life, and trees and shrubs put forth fresh growth, while the leaves of the European deciduous trees and shrubs get their autumnal tints and drop.

June, July, and August constitute our winter, our rainy season, which is usually marked by frequent rain and strong winds; but it happens also often that we have to content ourselves with remarkable dry winters, the mean temperature during the three months being 54° to $55^{\circ} 7'$. Heavy hoar frosts and frosts appear often during night. The lowest temperature registered in 1876 and '77, during the month of July, has been 30° and 28° , the lowest experienced in the plains near Adelaide. Such heavy frosts have most disastrous effects upon the tropical and subtropical plants in the gardens.

The spring season, the most genial and most beautiful in South Australia, not surpassed in any other part of the world, includes the months of September, October, and November, the mean temperature during the first two months being 60° to 70° .

At this time of the year, the gardens are in their best floral beauty—trees, shrubs, perennials, annuals, emulate each other in regard to their flowers, which are of such size, richness in color, and perfection as a

northern gardener can scarcely imagine. But early-appearing hot winds in November destroy those floral beauties in the course of a few hours.

The average fall of rain during the year in the plains of Adelaide is 19in. to 21in.; but the distribution is unequal, even on plains not far apart, each showing a great difference in the rainfall.

In the Mount Lofty Ranges, about eight miles distant from Adelaide, the average of rainfall is 40·677in.

According to our indefatigable Government Astronomer, Charles Todd, C.M.G., the lowest rainfalls have been:—In 1850, when only 11·644in. fell; in 1859, 11·647; in 1857, 12·650in.; in 1854, 13·437in., and in 1871, 14·926in. The highest fall near Adelaide was in 1875, when 31·455in. fell.

This climatic sketch refers only to the plains around Adelaide. In the southern parts, and in the hills, the temperature is much cooler, and the rainfall, as already mentioned, much heavier.

From the foregoing it can be imagined that not all the plants from other countries will thrive with us.

The Alpine and tropical ones suffer not only from our dry atmosphere, but the latter also from the cold during the winter months. In the hills the Alpine plants and those of other cool countries grow exceedingly well, but the tropical ones are destroyed by the frosts, which in such localities are even severer than on the plains.

Not many European and North American forest trees prosper with us in the plains. Only the elm, plane, ash, chestnut, poplar, locust tree grow vigorously, while the oak, lime, birch, horse chestnut, maple, thrive only slowly, and suffer materially from the drought. All the attempts to grow the beautiful beech tree in the plains have failed, and even in the hills it grows only slowly, while the other trees mentioned thrive most luxuriantly in those localities.

It is the same with the coniferous trees. The most vigorous growing European pines on the plains are only *Pinus halepensis* Mill., *Pinaster*, Ait., and *Pinea* Linn. All other kinds show only a very moderate growth. *Pinus sylvestris*, Linn. and the genera *Picea* and *Abies* are of a lingering growth, while *Pinus Larix* Linn. succumbs to the slightest hot winds and droughts. Of this fine tree not one specimen is met with in South Australia.

Of the Californian coniferous trees only such as appear at an elevation of 1,000 to 2,000 feet do remarkably well in the plains of South Australia, especially *Pinus insignis* Dougl., which reaches often in the course of ten to twelve years a height of 40 to 50 feet, with a stem of 5 feet in circumference. The *Cupressus* and *Thuja*s thrive also

luxuriantly with us, although some kinds of the first seem to have a short duration of life in South Australia, especially *Cupressus macrocarpa Hartw.*, which, after a very rapid growth, dies suddenly when about twelve to sixteen years old. *Wellingtonia gigantea* does not delight in our climate, although growing the first year tolerably well, but later it ceases to grow, and dies slowly.

Very few of the Himalayan conifers prosper in the plains, especially such as appear at an elevation of 7,000 to 8,000 feet, viz., *Abies Smithiana* Loud., *Brunoniana* Lindl., *Picea Pindrow* Loud., *Webbiana* Loud., *Pinus Gerardiana*, Wall., *excelsa* Wall., &c. Their growth is very slow, and they succumb in a few years to the droughts and hot winds. Only *Cedrus Deodara* Roxb. and *Pinus longifolia* Roxb. doing well with us, although *Cedrus Deodara* in their native state appear at an elevation of from 5,000 to 12,000 feet.

Still more difficult is the existence of the Japan conifers. None will prosper luxuriantly out of doors with us. *Thuioopsis*, *Retinospora*, *Chamaecyparis*, *Cryptomeria* are of a lingering growth, and much injured by hot winds and droughts. The beautiful umbrella pine *Sciadopitys verticillata Siebold*. can scarcely be kept alive indoors. None of the *Taxus*, may they be natives of Europe, America, or East India, prosper with us.

I have already pointed out that some of the tropical trees and shrubs do not object to our climate, and thrive tolerably well. I will only mention the most noteworthy.

Of the Chinese and Japanese flora *Paulownia imperialis Siebold*, *Laurus Camphora Willd.*, *Broussonetia papyrifera Vent.*, *Stillingia sebifera Michx.*, *Aralia papyrifera Hook.*, *Koelreuteria paniculata Laxm.*, *Sophora japonica Linn.*, *Eriobotrya japonica Lindl.*, *Rhus succedanea Linn.*, *Hibiscus rosa sinensis Linn.*, *Euonymus japonicus, Linn., radicans Zucc.*, &c.; but the handsome Japanese maple, *Acer polymorphum Spack.*, in its numerous varieties, despise our climate entirely. They even will not grow in our greenhouses.

From the East Indian flora the following genera thrive well with us in the open air, viz.:—*Erythrina*, *Rhaphiolepis*, *Bauhinia*, *Lagerstroemia*, *Guillandia*, *Poinciana Gillesii Hook.* *Poinciana pulcherrima Linn.* is too tender.

The Chinese, Japanese, and East Indian Alpine plants, viz., camellias, rhododendrons, azaleas, as already mentioned, will not stand our dry and hot summers out of doors, but find a genial climate in the hills and gullies, at an elevation of 1,000 to 2,000 feet, where they reach the same perfection that we are used to see them at home.

From the South American flora *Jacaranda mimosaeifolia* Don., *Myroxylon peruiiferum* Knth., *Brugmansia*, *Begonias*, and *Tecomas*.

Only some of the African palms prosper with us in the open ground, viz., the date palm, *Phœnix dactylifera*, Linn., *reclinata* Jacq., *Chamaerops humilis* Linn., *Palmetto Michx.* From tropical Australia, *Corypha australis* R. Br., and from other tropics *Sabal Blackburnia* Glzbr., *Chamaerops Fortunii*.

The South Australian climate suits all the succulent plants which develop out of doors to great perfection, especially *Yuccas*, *Aloes*, *Agaves*, *Fourcroyas*. *Aloe americana*, *mexicana*, and *Fourcroya* flower generally in their twelfth year after planting, their flower-spikes reaching the size and height (30 to 40 feet) as I have met them during my travels in South America. Of the *Cactæae* the same may be said, as only the smaller kinds want protection in summer from the scorching sun's rays, and in winter from the heavy rains.

The growth and well-doing of the perennials, more particularly those of cooler climes, are very problematical. Only such as root deeply in the ground will withstand our dry summer. We do not succeed with the perennial *Phloxes* (although the annual *Phloxes* do remarkably well, even throughout the summer months), *Delphiniums*, *Campanulas*, and *Aconitums*; in fact, most of our handsome European perennials succumb to our summer.

The annuals in general grow most luxuriantly during the winter and part of the spring months, and arrive at great perfection, especially the stocks, which reach so extraordinary a size as at home would be considered an exaggeration if described. But our climate is fatal to the handsome and favorite autumn flower the China Aster, which, even in a very favorable season, will only produce small insignificant flowers; and, strange to say, all its endless varieties, viz., quilled, Victoria, pæony-flowered, chrysanthemum asters go back to the original type.

Also the handsome *Dahlias* will not prosper on the plains, their flowers being only small, and suffering from the slightest hot wind; but in the hills they attain perfection.

Indeed the aspect of our gardens during the summer months would be a very dreary one if it was not for the *Petunias*, *Verbenas*, *Zinnias*, *Zonale Pelargoniums*, *Tagetes*, *Amaranths*, and *Gomphrenas*. These annuals develop their flowers, with a little help of water, to perfection unknown at home. Of the splendour of the oleanders, which bloom during the summer months, no northern gardener can have any conception. The masses, size, colour, and fragrance of their flowers surpass those produced in their native country; and these lovely plants are in bloom during all our summer months.

The roses will attain similar perfection if we have a favorable season; but, alas, this happens very rarely. The roses have to contend against two enemies, viz., the rose blight and the hot winds. The first scourge can be mitigated by cleaning, but against the hot winds we have no remedy. No flower is more injuriously affected by hot winds; and the small buds are even destroyed by only moderately hot winds, appearing as if a fire had run over them. The dark-colored flowers suffer most. The rose season in 1877 of South Australia has never been surpassed. The roses were free of blight, and the atmosphere throughout September and October being cool, with a cloudy sky and occasional showers, produced a profusion of flowers not uncommonly five to six inches in diameter.

Bulbous and tuberous plants from the Cape thrive with us as vigorously as in their native country, chiefly the *Gladiolus*, *Brunswigias*, *Haemanthus*, *Watsonias*, *Ixias*, *Babianas*, *Ornithogalums*, &c. The same is the case with *Hippeastrums*, *Amaryllis*, *Crinums*, *Pancratiums*, *Alstroemerias*, &c., from any part of the globe. Not so, however, with the *Liliums*. Only *Lilium candidum*, *longiflorum* Thunb., and *eximium* Siebol., thrive well with us out of doors, while all other species, especially those from Japan, will not prosper in the open ground. The same dislike to our climate has also *Fritillaria imperialis* Linn., which never produces flowers, and the bulb dies within a year or two after its introduction. The tulips and hyacinths also find our climate in the plains unsuitable. The tulip bulbs will produce flowers for a year or two, but they gradually dwindle away after the second year. Hyacinths produce good flowers the first year, but afterwards the bulbs divide into numerous suckers, which produce no flowers until they are separated and planted, requiring two or three years before they again flower, again to divide into numerous offsets.

Ranunculus and *Anemones* produce the first year splendid flowers, especially the former; but the *Anemone* tubers show the same decay as the tulips, and dwindle away often already the second year. The *Ranunculus* begin to fail the third or fourth year. *Narcissus*, *Tacettas* and various other kinds delight in our climate, and attain to great perfection, except the varieties of *Narcissus poeticus*.

In the plains it is impossible to grow ferns out of doors—not even the few South Australian species, which are found growing in the hills and gullies, unless planted in very shady, moist, and protected places.

Regarding the plants grown under glass, the summer months of South Australia are not at all genial to the luxuriant growth of orchids, on account of the dry and hot atmosphere. To grow them on wooden blocks is not practicable at all. Though the orchid-houses be kept close,

shady, and damp, the hot air, especially in a fierce-blowing hot wind, will penetrate into the house and injure their air-roots, if growing on blocks, thus checking the growth of the plants materially, so that some time elapses before the roots show young growth again. The only prevention is to grow the plants in orchid-pots in sphagnum for the protection of the roots. During the summer months great attention is required for the plants in the stoves, conservatories, palm and green houses. To protect the plants from the burning rays of the sun the houses must be shaded by blinds. In fact, the effects of the sun on the glass act like a burning-glass, so that the leaves of the plants exposed to the sun's rays are burned in a very short time. On days when the thermometer shows 130° to 140° in the sun, every precaution is necessary to keep the temperature down in the houses.

With the exception of the intertropical fruits, although there are only a few of these, all fruits from other parts of the globe thrive most luxuriantly in South Australia, and come to such perfection in size, and frequently in flavor, as is hardly known in other countries; and many fruits are found to improve materially by the change, as the climatic conditions often succeed in modifying and improving their condition. On the plains grow apples, pears, apricots, peaches, nectarines, oranges, citrons, lemons, plums, cherries, figs, almonds, mulberries, olives, and grapes; while in the hills and gullies besides are grown strawberries, raspberries, gooseberries, currants, walnuts, chestnuts, filberts, &c.

The apples grow to great sizes, but do not always possess the same fine flavour as at home, and contain more acidity. The apple trees suffer much from the attack of the American blight, for which no radical remedy is at present known. The trees which grow in the hills or in rich soil suffer most, and succumb at last to this scourge. The pears grow to perfection, and maintain the same flavor as in the old country.

The fruit of the peaches, apricots, plums, reach to a size and contain a flavor unknown in Europe. The cherries do not attain the perfection of home. All the stone-fruit producing trees are short-lived, especially those of the peach, which live scarcely fourteen to sixteen years. This early decline may be owing to the quick, luxuriant growth and early and excessive bearing, circumstances which produce over-stimulation and early exhaustion.

It often happens that by a fierce, hot north wind the parts of fruit, viz., apples, pears, plums, apricots, and peaches, on the plains, which are exposed to the north become quite black, and are, in the true sense of the word, "baked." Such days we are experiencing at the present time. During the last eight days the reading of the thermometer has

been from 98° to 110° in the shade; but on the 10th of January it was scarcely endurable. At about 3 o'clock p.m. the thermometer registered at the Botanic Garden 116° in the shade and 166° in the sun. That such a temperature must prove very destructive to our introduced plants can easily be imagined. In fact, the leaves of trees and shrubs have the appearance as if a fire had run over them.

The finest grapes are grown in the plains and the slopes of the Mount Lofty range facing the plains. Here they grow to a great size, the summer months ripen them to the greatest perfection; and the South Australian wine must obtain a high character in foreign markets. For the last five years the oidium has made its appearance in our vineyards, but not with such bad results as in Europe. Also the *Phylloxera* has appeared in the vineyards of our neighbour Colony, Victoria, and may, it is feared, also attack our vineyards. From this it will be seen that the Australian vignerons, like the European, have to contend against the two greatest scourges which can invade a vine-growing country.

The cultivation of the olive is a great success, and the oil considered perfect.

All vegetables can be grown during the autumn and winter on the plains; but in no comparison so successfully as in the hills, where are raised the finest vegetables and other culinary herbs throughout the year in great abundance. Cauliflowers two feet in diameter are often seen in the market—cabbages, asparagus, turnips, artichokes, leeks, onions, beet, carrots, potatoes, endive, lettuce, celery, cucumbers, water and sweet melons growing to an extraordinary size, and of the finest flavor.

The cucumbers and water and sweet melons grow most luxuriantly on virgin soil, but if grown on the same spot several years running (although manured) the fruit degenerate in size and flavour, and ultimately produce no fruit at all.

That South Australian cereals are considered to be the finest grown in the world is pretty well known.

When a new comer visits for the first time our Agricultural and Horticultural Shows, and observes the fine display of the splendid flowers, fruits, vegetables, and cereals in their utmost perfection, he must consider South Australia a favored land; and it is, indeed, surprising, that our fickle climate, with its extremes, droughts, hot winds, can produce such developed specimens of Nature's gifts.

R. SCHOMBURGK, PHIL. DR., Director.

January 20th, 1878.

ABBREVIATIONS.

AUTHORITIES QUOTED.

[Those marked * are dead.]

- Adans Adanson, M., a French botanist.*
Ait. Aiton, W. D., Director of Kew Garden.*

Ex Officio Members.

THE SPEAKER | THE MAYOR OF ADELAIDE
THE PRESIDENT of the AGRICULTURAL and HORTICULTURAL SOCIETY.

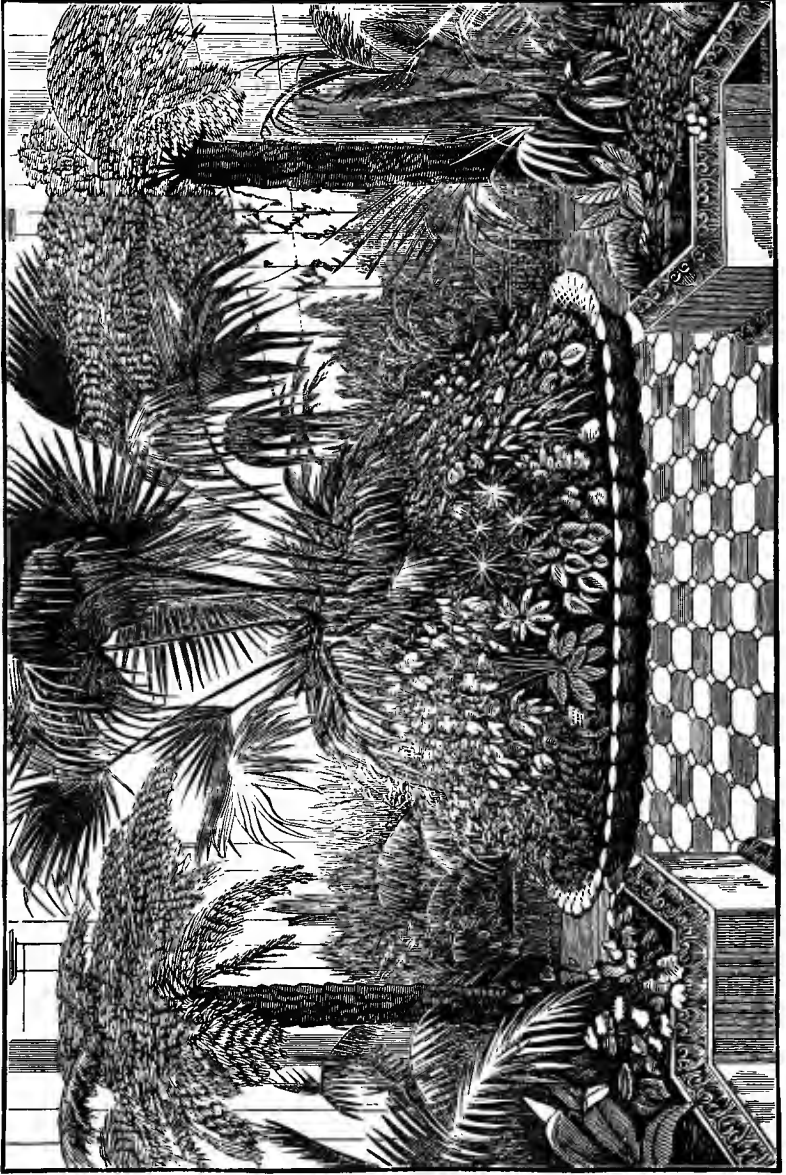

DISTRIBUTION OF PLANTS.

The Director is alone authorized to furnish plants, seeds, and cuttings, to public establishments and private persons, subject to the following rules:—

1. Plants valuable in agriculture, medicine, or arts, and specimens required for artistic, scientific, educational, or benevolent purposes, gratuitously supplied.

2. No new ornamental plants to be distributed by root or cutting until two years in the garden.

3. Such plants of this description, as they can be spared, will be offered in exchange for animals, plants, and seeds.
