Puttalam is quite out of the track of the pleasure-seeker or the globe-trotter either: but for all that it is not much of a place when you get there. No wonder the old Malay resthouse-keeper enquired, in a confidential way, why I had come; and when I told him just to have a look at the place, I could see that he did not believe a word of it. People no doubt sometimes go mad, but such an aggravated form of mental disease as enduring a night journey in the bullock coach, to revel at the grey dawn in the natural beauties of that salt-pan has never before been known, and you would have stamped yourself as an idiot to have believed it. So, I guess, the old fellow argued, and doubtless credited me with some saner motive.

What a night of horrors that ride was from 6 p.m. to 5 a.m.—for it was impossible to sit or lie, and what with the jerks that almost dislocated your neck, and the bumps which your head got, life was not worth the living. Then there were the mysterious stoppages, with a clatter that went on for ten or twenty minutes over the delivery of a mail bag, and "such" a bag which had to be found, and by and by another bag was received, then a shout to the cattle, and a plunge into darkness. We crossed a ferry at midnight, and before doing so, waited heaven only knows how long. A fellow who spoke English assured me that there was no unusual delay. They had to allow "the more previous coach" to get on. He was quite willing to converse, but I was not—felt more inclined to swear. The cattle in the coach did well. They went off with a wild rush, then trotted, then into a walk, and so it was kept up, doing four miles an hour easily.

It was an added horror to find the resthouse shut up; but in a little the old boy in charge shuffled around, prepared an early meal, filled the bath, flapped about a handkerchief as a pretence for dusting, went off to the bazaar for the breakfast, and seemed to bring in his purchases in instalments—a tin of jam now, beef next time, fish after—thus making the most of it. He told me that his visitors usually travelled with their own servants and supplies, and all we had to do was to collect the resthouse charges, hence his chronic melancholy.

When the breakfast was being collected I took a look round the place, and was soon satisfied. The whole population seemed Moors. There was a mosque, of course, with the rigged-up mast fluttering with flap; a big Moorish school was in full swing, the scholars grinding at Arabic; the trees were stunted and all growing the one way, and there was a strong

dry salt wind meeting you at every corner in quite a blustering way. The wind came off the Puttalam lake, and had an odour which wanted freshness, an ancient fish-like smell. I walked out to the "npu pullam"—the salt pans—a whitened desolation, and saw on my way back a half-dried tank. I was struck, however, by the healthy appearance of both man and beast, especially the pariah dogs, which were the biggest and best cared for I have ever seen. Usually the pariah is "high in bone and low in flesh," a brute of furtive look and habit, ever anticipating a stone or stick: and its readiness to howl if you but move your hand, sadly evidencing the hard struggle for existence which is the sum of his life. These dogs, however, were big and well nourished, were friendly and wanted to be patted, and were not the white-toothed snarling outcasts that usually are seen. In walking through the bazaar you were not always on the watch for an unexpected rush, for they allowed you to pass on your way unheeded, and seemed wholly to have forgotten the habits of the pariah. The town seemed very clean, and if there be a Local Board it has some credit for its work. But to get back to civilisation was what bothered. To go through another night journey was a horror to anticipate, and was happily avoided by a special having been put on, and our getting under weigh at 1 p.m. Eight hours at Puttalam seemed long enough, and by starting at midday we had a chance to see the road which we missed the previous night in the darkness. As we got along towards Chilaw, the small prickly scrub gave place for bigger jungle till by and bye we touched forest, and the flourishing plantations of young coconuts was evidence enough that we had passed into the region of direct rainfall. The weather, although cloudless, was very cool, and as the cart was a really comfortable one, we were prepared to enjoy the ever-changing scenery. Tracts of green, glimpses of water and clumps of forest, and the graceful coconut, all helped to charm; and when night fell the young moon shone out, it was even more beautiful than day, and more than a reward for the weariness of travel. At 11 p.m. when Chilaw was reached, the place was all astir with lights and bustle. It was some play the Catholics had got up, but ten hours in a cart, did not predispose you for aught but bed. The Chilaw resthouse, is very comfortable, nicely situated and cool in the extreme. At the one side you look toward the sea, can watch the spray shoot up and hear the beat of the waves on the beach: at the other side, toward the town, there is a mixed mass of waving ponds, houses, a bit of road and the glitter of the back water here and there. If you want to be reminded of Ceylon life, you may be, but if your wish to be at rest then the sea view will give it and the ozone-laden air will add its virtues. I hear much of coconuts, and the value of them and very likely all is true; but meanwhile it has been a pleasure to have been among them, and with that I am content.

TEA, COFFEE, AND CINCHONA CULTIVATION IN INDIA.—From the Government of India we have received a bulky volume of "Agricultural Statistics of British India for the years 1894-95," consisting for the most part of elaborate tables, with an explanatory memorandum prefixed. Of special interest to us in Ceylon are the tables of tea, coffee, and cinchona cultivation in each district of each province and in the native states in 1893 and 1894, and the progress in each product from 1885 to 1894. In 1893 the total area under tea in India was 395,839½ acres; and in 1894 it had increased to 422,551 acres. The highest average yield per acre from mature plants was obtained in Jalpaiguri, viz. 555.9 lb. in 1893, and 541.3 lb. in 1894. The total acreage under coffee in India in 1893 was 258,984.14 acres, and in 1894 it was 277,881.94 acres. In 1893-94 there were 11,235 acres under cinchona in India; but in 1894-95 the acreage had decreased to 8,710.

HYBRID COFFEE.

We recently made some enquiries of a scientific friend regarding the interesting question of coffee hybrids. In sending us the answers that we print below, our correspondent remarks: "I hope the answers will draw a fuller discussion on this very interesting subject. No one appears to have studied the life history of the coffee flower, and without that it is impossible to say what its nature is. We know that it is hemephrolite and fugacious. But we do not know if self or cross-pollination is favoured by the sexual organs. The fact of its being a highly-scented flower seems to point to the latter alternative. Some short-lived flowers are self-fertilised while the flower (corolla) is still in bud. [This also occasionally takes place with coffee.—E.P.] My own opinion is that the coffee flower must be to some extent pregated with foreign pollen. The bushes swarm with bees and smaller insects directly the flowers open."

Question.—Will a hybrid coffee plant, if perfectly isolated, give seed true to name and properties of hybrid?

Answer.—A coffee hybrid may not seed at all. Some hybrids are quite sterile, while the majority are less fertile than pure-bred species. But some are as fertile as the pure-bred plants. It is not known if a coffee hybrid has ever been produced—naturally or otherwise.

Q.—What are the best means of effecting isolation?

A.—To cultivate the hybrids separately from the pure-breds and to induce flowering at a slightly different season.

Q.—Would not the best method to perpetuate the hybrid be to graft it on to the pure-bred stock?

A.—It is by careful selection of the fittest, especially in the seed, that the hybrid element in a plant is best preserved. Hybrids have usually a tendency to revert to the conditions of their ancestral stock. Mere grafting would not protect a hybrid from the fertilising influence of pure-breds.

Being convinced that our correspondent had failed to grasp the meaning of our last question, we put it again in a different form and at greater length. The following is the answer:—

"I'm afraid I misunderstood your original question re the preservation of kind by grafting. But as now put, your meaning is very clear. As the desirable qualities possessed by an individual plant are not always (indeed rarely) reproduced from seed, it is usual to propagate such an individual by the insertion of buds, cuttings, layers and grafts. By these modes of propagation the actual characteristics of the kind are reproduced and multiplied. The coffee bush can be readily propagated by the insertion of cuttings and layers, so that there is no necessity (unless for a particular purpose) to undertake the more laborious process of grafting. It is also feared that grafted bushes would get broken by the wind on most estates. But however that may be, the fact remains that special qualities in habit, growth, size or yield, may in each case be retained by divisional propagation. Where grafting is desirable, with all materials at hand, a man and boy, earning together about Rs. 12 per mensem, could easily turn out 100 grafts a day; and if a little pressure was put on, 150. But taking the smaller estimate, 3,000 grafts for 12 rupees is not a heavy matter."

A natural query arises: how about the Brooke-Mockett hybrid? From the above it would seem clear that high cropping powers cannot be expected from hybrids. The greatest advantage to be derived would be perhaps to get a tree nearly equal to Arabica in cropping powers, with the hardier constitution of Liberian. Further, that if a good hybrid is obtained, it is beyond all question that the safest way to propagate it true to name would be by cuttings or grafts, etc.

We do not ourselves claim to be an authority in any way on this question, but we would suggest that an easier and certainly much surer way of obtaining an extra-good strain of coffee would be by the methods so successfully employed at home in obtaining "pedigree" wheat. Devote a small and isolated field to seed-bearing alone. Rigorously cut

out all poor croppers, and bestow the best and most thorough cultivation possible to the remainder. Note carefully the heaviest croppers, and among these, those freest from disease of any kind. Pick from the latter only, and plant from this seed another seed-field. The process could be developed *ad infinitum*, with a gradually better result each generation. Another way would be to mark the biggest and healthiest croppers throughout the estate, and when pruning, or at some other convenient time, make cuttings or layers and plant these in as isolated a spot as possible. The seed from the best of these should be something quite out of the common, we believe.

We have invited other scientific correspondents to give us their views on Hybrid Coffee, and we should besides be very glad to hear also from practical planters on the same subject.—*Planting Opinion*, Sept. 12.

VARIOUS PLANTING NOTES.

COFFEE AND TEA CULTIVATION IN MADRAS.—We read in the *Madras Mail* that the total number of tea plantations in the Madras Presidency, exclusive of Native States, on the 31st December, 1895, according to official returns, was 107, which employed 4,366 persons permanently throughout the year, and 604 temporarily during the busy season. The area under mature plants was 6,083 acres, and under immature plants 712 acres. 1,940 acres have been taken up for planting but have not yet been planted. The quantity of uncurd leaf grown was 27,70,881 lb., and the quantity of leaf manufactured during the year was 645,658 lb. Of the 107 plantations 99 were on the Nilgiris, with a total area of 6,015 acres under cultivation and 200 acres taken up but not yet planted. The quantity of leaf cured was 579,680 lb. The number of coffee plantations in the Presidency, exclusive of Native States, was 13,033, which employed 19,902 persons permanently during the year and 15,366 persons temporarily. 54,921 acres were under mature plants and 9,032 under immature plants. 59,968 acres have been taken up but not yet cultivated. The total yield for the year was 11,005,137 lb. There were 498 plantations on the Nilgiris with a total area of 24,869 acres. In this District 53,116 acres have been newly taken up but not yet planted. The yield in this District was 7,507,280 lb.

CINCHONA CULTIVATION IN MADRAS.—The total area under cinchona cultivation in the Madras Presidency during the year 1895-96, according to official returns, was 2,595-96 acres; but this is much less than the actual area as many of the planters have failed to furnish the required information. The largest area was on the Nilgiris 1,935-50 acres (but the figures according to the village accounts are 7,226-11 acres), with 2,461,803 mature and 505,209 immature trees. The outturn for the year is given at 402,909 lb. The area cultivated in Malabar was 618-50 acres with 261,350 mature and 11,000 immature trees. The outturn of bark was 308,439 lb. In Madura the area under cinchona was 4,495 acres. The plantations in this District are left to grow wild and are not barked, as it is not found profitable to work them. In Travancore 1,479 acres were under cultivation, with 798,674 mature and 296,000 immature trees. The outturn of bark was 506,350 lb. All the plantations in Cochin have been destroyed. The area of the Government cinchona plantations is 800-48 acres, containing 1,475,193 mature and 155,805 immature trees. The outturn of bark for the year was 229,700 lb. The quantity of bark harvested during any year in these plantations is regulated by the requirements of the factory and bears no relation to the amount which would be taken.

PRECIOUS STONES.

BY PROF. HENRY A. MIERS, M.A., F.R.S.

From the earliest times certain minerals, which are conspicuous for their beauty, have been prized for decorative purposes: the brilliant green hue of malachite, the deep blue of lapis lazuli, and the rich colour of red jasper would naturally attract early attention. But these particular minerals are not numbered among the true precious stones; they do not possess the remarkable qualities which endow the diamond, the ruby, or the topaz with their peculiar attractiveness. The two essential qualities, namely, brilliancy and hardness, are only possessed by certain rare minerals; a brilliancy which makes them unrivalled for ornamental purposes, and a hardness which protects them from wear and tear, and makes them practically indestructible.

It is difficult, in a town like London, where every jeweller's shop is ablaze with diamonds, to realize that large and good stones possessing these qualities are so rare; that thousands of natives are toiling in the river beds of India, Burmah and Ceylon, washing out from the gravel or the sand the little blue and red pebbles which are to be converted by the lapidary's art into brilliant jewels of sapphire and ruby. Even in that wonderful pit at Kimberley, where half the diamonds of the world seem to have been crowded together for the use of man, although, perhaps, ten tons of diamonds, worth more than £50,000, have been extracted in 25 years, yet those which weigh more than an ounce each may be counted on the fingers.

It is in the qualities of hardness and brilliancy that such minerals as malachite and lapis lazuli fail; owing to their comparative softness, they would not, if cut and polished, possess the sharp edges and brilliant surface of the emerald or sapphire, and would soon become dull and rounded by friction, even by the friction of ordinary dust. Again, since they are opaque, they can never flash like the sapphire or the emerald; and yet it is quite a mistake to suppose that the necessary qualities are confined to those few stones which are familiar to everyone, such as the diamond, ruby, sapphire, emerald, garnet, and amethyst. There are many others though they are not so well known I think we may fairly assert that such minerals as tourmaline, jasper, peridot, spinel and chrysoberyl, though their names may be familiar, are not stones which would be recognised by any but those who are in some sense experts; while other minerals, such as sphene, andalusite, anixnite, idocrase, and diopside are possibly almost unknown to most people even by the reputation. Yet all these minerals possess qualities of transparency, hardness, and beauty of colour which render them extraordinarily interesting and attractive as precious stones. (A number of faceted stones cut from the less known mineral were thrown upon the screen by reflected light.)

Take first the hardness. A few years ago, the hardness of stones was a very important character in the eyes of the mineralogist; it was one of the characters by which they were invariably identified, and a distinguished German mineralogist drew up a table by means of which the hardness of minerals can be compared. Any stone is said to be harder than the minerals of this scale which it can scratch, and softer than those by which it can be scratched. In the right hand column the gem-stones are arranged according to their hardness.

MOHS' SCALE OF HARDNESS.

- | | | |

| 10. Diamond | .. | ... | { Diamond. |

Among precious stones diamond stands out pre-eminent as the hardest of all known substances. Ruby and sapphire are scratched by diamond alone, while chrysoberyl, topaz, and spinel scratch all the remaining stones, although they do themselves yield to the scratch of ruby and sapphire. The hardness is a character still generally utilised by the expert when he is in doubt; in experienced hands it has some value. By long practice it is possible to form a very close estimate of the hardness of a given stone, and that often, not by scratch of the other minerals in the scale, but by the feel of the stone against a file; the resistance offered by the stone to the file is taken as a measure of its hardness. It is not a character capable of any accurate measurement, neither is it to be recommended for use by inexperienced persons. I hope to show, as I go on, that we have now accurate methods of testing at our disposal which render the trial of hardness quite unnecessary. But, none the less, the character is one of great importance as investing the stone with durability; all the precious stones, except moonstone, opal sphen, have at least the hardness of quartz, and can barely be scratched by metals, even by hard steel.

Take, next, the quality of brilliancy. This depends upon two things—firstly, the manner in which rays of light are affected when they enter or leave the stone, and, secondly, the manner in which this action can be intensified by the art of the lapidary.

When light passes from one transparent substance to another it is bent or refracted as every one knows from the bent appearance of a stick plunged into water. Consider, now, a ray of light falling upon the surface of a transparent stone; a portion of the light is reflected, but a portion enters the stone. In passing from air into the stone, it is refracted inwards. When, on the other hand, it passes from a transparent stone into air, its course is reversed, and the emerging ray is refracted outwards or towards the surface. It is, however, with the emerging as with the entering light—the beam is sub-divided, only a portion is refracted out, another portion of the light is reflected within the stone.

It is very clear, then that of the light travelling in different directions within a diamond, a far larger proportion is internally reflected than is the case with any other stone. We shall see presently that it is this property which gives the diamond its consummate brilliancy.

Another effect produced by refraction is, as every one knows, the separation of ordinary light into rays of different colours—it is seen in any prism of glass. This property is known as the "dispersion" of light; and a stone which possesses great dispersion will exhibit a beautiful play of spectral colours—will exhibit a high degree of what is called fire. In this respect again the diamond is pre-eminent; its dispersion is nearly twice as great as that of other stones.

All these optical properties are beautifully shown by those unworked jewels of which the smooth facets have been produced by nature; I mean the crystals of the various minerals. The beauty of natural crystals of transparent minerals is largely due to the optical effects which I have just been describing.

The beautiful specimens of rock crystal, calc spar, topaz, emerald, and other stones which adorn mineral collections are sufficient evidence of these properties. But it is very certain that natural crystals, although they possess a beauty of form which is all their own, are not by a long way so brilliant as the faceted stones which are cut from them by the art of the lapidary; that a natural diamond is not so lustrous as a faceted brilliant.

In fact, many of the finest gem stones present a very mean and sordid aspect before they have passed through the hands of the lapidary; one has only to compare the dull and unattractive appearance of a parcel of rough rubies, sapphires or diamonds, with the finished jewels displayed in the jeweller's windows to see how much these owe to the lapidary's art.

In re-cutting the Koh-i-noor it was thought advisable to spend £3,000 on the process and to reduce its weight from 185 to 106 carats. When the great Pitt diamond was cut its weight was reduced from 410 carats to 137; and the fragments and dust removed were valued at £8,000; but the extent to which the stone was improved is indicated in the fact that having been purchased for £20,000, it was after cutting sold for £135,000.

To understand how the cutting of a precious stone adds to its brilliancy, we have only to trace the course of the rays within the stone, and consider how it can best be faceted in order that the light which enters in various directions on the upper side, or crown, may be reflected internally from facet to facet on the under side of the stone with as little loss as possible, and may be finally thrown out from the front of the stone. For this purpose the facets must be so arranged that as much of the light as possible within the crystal shall meet the facets at an inclination exceeding the angle of total reflection. A brilliant with its 58 facets is one of the forms which experience has shown to be best adapted for the purpose. How little of the light goes through a stone so faceted, and, therefore, how much of it is totally reflected internally, is easily shown by holding the stone in a strong beam of light; first so that the light is reflected, and then so that the light shall, if possible, be transmitted. In the latter case, the stone merely throws a dark shadow, indicating that little light, if any, has passed through it.

A faceted stone is always cut from a single crystal, and not from an ordinary lump of the mineral, which is generally a mass of crystals. The chief reason why jewels are cut from natural crystals is that these, by virtue of their crystalline nature, are remarkably homogeneous, and therefore clear and limpid when free from cracks and flaws. A stone which is not homogeneous can never have the purity and limpid brilliancy of a single crystal, for at every point of contact of one part with another reflexion takes place. Among minerals used as precious stones which are not crystals, may be mentioned the opal. The opal probably owes its peculiar beauty to the very fact that it is filled with minute cracks or cavities, each of which contributes some tint of colour by reason of its extreme thinness, just as the colours of a soap-bubble are due to the thinness of its film.

Or take the agate. Here the stone consists of layers of different materials differently coloured. Its beauty is of a totally different nature from that of clear crystals, which it can never rival in brilliancy. Stones like the agate are generally classed apart as semi-precious stones, and their interest depends upon beauty of structure or colour, or possibly to a large extent upon their rarity. The turquoise, for example, is a very rare stone, which is apparently absolutely uncrystallised, but possesses great beauty of colour, and is therefore much prized. The same is true of carnelian. On the present occasion we are not concerned with those opaque or curiously structured minerals whose beauty resides almost solely in their colour.

Those who have had no practical acquaintance with minerals, have little idea how variable and

accidental are their colours. They may scarcely realise that the ruby and the sapphire are the same mineral, and that this mineral also occurs, and is used in jewellery, absolutely colourless when it is known as a sapphire, green as the so-called Oriental emerald and yellow as the so-called Oriental topaz, that topaz itself may be yellow, brown, blue, or colourless; that zircons range from colourless through almost all conceivable shades of brown and green, and that even diamond has been found green, red and blue.

When we came to consider the properties by which precious stones are recognised, I shall say little or nothing about colour, for it is of little value as a criterion. There are, for example, certain red stones which the most skilful experts cannot by their colour alone refer with certainty to ruby, garnet or spinel. It might be expected that a noteworthy difference in chemical composition would accompany this difference of colour, or that the pigment could be ascertained by analysis. In reality, this is scarcely ever the case. It is fairly certain that the emerald owes its colour to the presence of chromium, but the variation in the analyses of precious stones cannot generally be attributed to anything indicated by the variation of colour.

The chemical composition, though of great general importance in mineralogy, is of little practical value in the discrimination of precious stones, since it is usually impossible to sacrifice a sufficient quantity for chemical analysis. If we are dealing with a faceted stone, not even the smallest portion can be utilised, for fear of injuring it.

There is, however, one remarkable optical property, which is ultimately related to the chemical composition. As is well-known, many substances possess the property of absorbing certain rays of light. When the solar spectrum produced by a limping ordinary daylight through a slit, and transmitting it through a prism, is passed through the glowing vapour of certain substances, particular rays of light are absorbed, and their absence from the emerging light is manifested by corresponding dark bands in the spectrum. The instrument by which the observations are made is the spectroscope. It is well-known to most people that the solar spectrum itself contains certain dark bands of this sort, which are produced by vapours that can be identified by the position of the bands in the spectrum; and thus it is possible to ascertain something regarding the chemical constitution of the sun and certain of the heavenly bodies. Now, a precisely similar effect is produced by certain elements if present in a mineral, by merely transmitting the light through a piece of it. Thus, transparent minerals which contain the rare element didymium, betray the presence of that element as soon as they are viewed through a spectroscope by ordinary daylight; the spectrum is seen to be traversed by black bands in the green, which are quite characteristic.

Among gem stones there are two which possess this curious property. One is the variety of red garnet, known as almandine, and the other is the jargon. The almandine produces characteristic bands in the green, and the jargon in the red, green and blue portion of the spectrum. To see these remarkable absorption spectra, to which attention was first called, I think, by my friend, Professor Church, it is not necessary to look through the stone, it is quite sufficient to place it in a strong light, and look at it through an ordinary pocket spectroscope; the light which enters the instrument consists largely of rays which have penetrated the stone, and been reflected from the facets at the back. These rays produce the absorption spectrum. In this way we are enabled to identify a jargon or an almandine merely by looking at it. There is no test so simple or so easy of application. It is curious that the almandine, or iron-aluminium garnet, is the only garnet which presents an absorptive spectrum, and it is not yet certain to what element the bands are due. In the case of jargon, they are supposed to be caused by the presence of some uranium compound in the mineral. All the almandine garnets which I have examined, and nearly all the jargons, show these characteristic absorption spectra.

By way of summary, I have thought it desirable to indicate the general characters of precious stones in a diagram, which exhibits some of their relationships and also some of their differences in a graphic manner.

Opal, which is a comparatively light mineral, has a low refractive power; zircon or jargon is a heavy mineral, and has a high refractive power. Let now the refractive power of any mineral (as measured by its refractive index for yellow light) be represented by a corresponding length set off from left to right, and let its density (as measured by its specific gravity) be represented by a corresponding length measured downwards. Fixing in this way a point corresponding to opal, and another representing the character of zircon, draw a straight line from the one to the other. It will then be found that the points which, by their position on the diagram, represent the specific gravity and refractive index of the various minerals, will be very nearly upon this line; that is to say, as the refractive index of precious stones increases, so also does their density, and the two increase together in a remarkably regular manner.

It appears that these minerals which, by their high refractive power, possess the greatest brilliancy, possess also the highest specific gravity or weightiness; that the precious stones are therefore all heavy minerals. There is also a rough general correspondence between these characters and the hardness of the stones; the brilliant heavy minerals are also generally speaking hard.

Two remarkable exceptions display themselves. Spinel lies far to the right of the position which it should occupy according to its specific gravity; it possesses an extraordinarily high refractive index, and is, therefore, an extremely brilliant gem stone. On the other hand, a glance at the scale of hardness shows that it is, unfortunately, one of the possible gem stones, and that in this respect it is not very well fitted for jewellery.

Diamond is still more remarkable; its refractive index places it at the extreme right of the diagram, with a refractive power, and therefore a brilliancy, greater than that of any other stone; at the same time its hardness exceeds that of any mineral, and this combination of qualities renders it the chief among gem stones, unequalled for brilliancy and durability, although not a heavy mineral. Moreover in dispersion, and therefore in fire, it stands alone. Minerals which are heavier than zircon, such as the metallic sulphides and iron-glance, are unsuitable for gem stones since they are nearly opaque, but they follow the same law, and possess a refractive power still greater than that of zircon or even diamond.

There is one other stone which is exceptional but in less degree and in the other direction, namely, topaz, whose refractive index is not 1.7, as it should be by its position on the line due to the specific gravity, but 1.62; the point corresponding to topaz must therefore be placed a short distance to the left of the line. It is curious that these three exceptional stones lie on the same horizontal line, having all the same specific gravity 3.5.

In mentioning the specific gravity I have introduced a property which is not essential to win esteem for a precious stone, but one which is of great value in its identification.

We have next then to consider those properties by which precious stones may in practice be most readily recognised. The table shows very clearly that specific gravity is one such property. The meaning of specific gravity is easily explained. A piece of tourmaline of any size weighs three times as much as an equal volume of pure water at 4° C., the specific gravity of tourmaline is therefore said to be 3; a piece of almandine garnet of any size weighs four times as much as an equal volume of water under the same conditions, and the specific gravity of garnet is therefore 4.

Now any substance immersed in water loses in weight by an amount exactly equal to that of the water displaced. Hence to ascertain the specific

gravity it is only necessary to suspend the stone by a fine thread to the beam of a balance and weigh it first in air, and then immersed in water. The first weighing gives the weight of the stone itself, the difference between the first weighing and the second gives the weight of the displaced water; hence the specific gravity is found at once by dividing the weight of the stone by this difference. For very small stones, where the weights concerned are slight, it is necessary to use a refined chemical balance. But for ordinary stones a well made Westphal balance is sufficient.

The Westphal balance is constructed on the principle of the common steel yard. At one end of the beam is a counterweight, at the other end the stone is suspended; the beam is divided into ten equal parts. A weight can be suspended on the beam, and its action, of course, varies with its position on the beam; at the tenth division from the centre it has a value ten times as great as at the first division.

The specific gravity is then found as follows:—First, counterpoise the counterweight. Let this require a weight, A, on the right hand side of the beam. Next, find the weight necessary to restore equilibrium when the stone is suspended from the beam. Let this be B. Then A—B is the weight of the stone in air. Next, raise the vessel of distilled water below the stone until it is immersed. If C be the weight now required to restore equilibrium, C—B is the loss of weight in water.

and, finally, the specific gravity is $\frac{A - B}{C - B}$.

This process is known as "hydrostatic weighing," and can be applied to any stone, except such as are very small. Great precautions must be taken, in order to determine the specific gravity with accuracy. Especially it is necessary to free the stone from all adhering bubbles of air. For this reason the process of hydrostatic weighing is a somewhat laborious one.

Now, in order to identify a mineral, it ought to be unnecessary to determine exactly the specific gravity, provided that means can be devised for showing that its specific gravity is the same as that of some known substance. For purposes of identification, a comparative method is often quite as efficacious, and much more easy than actual measurement. This may now be done by means of certain heavy liquids.

Wood floats in water because it is lighter than water; iron sinks because it is heavier; but a substance which possessed exactly the specific gravity of water would neither float nor sink, but would remain suspended in the water like a balloon in mid air. Take, then, a liquid which is heavy—the most convenient is methylene iodide, whose specific gravity is 3.3—a fragment of zircon will sink in this, and a fragment of tourmaline will float, but a fragment of the mineral angite, whose specific gravity is also 3.3, will exactly remain suspended.

This liquid, then enables one to say with certainty whether a given stone has a specific gravity greater or less than 3.3; in the one case it will sink, in the other it will float.

But methylene iodide further possesses the valuable property of mixing easily with benzene, which is a very light liquid. Every drop of benzene added reduces the specific gravity of the mixture, which can thus easily be made to range between that of chrysolite and that of opal. To identify any one of the stones which lie between those limits on the diagram, it is only necessary to drop it into a test tube or small vessel containing methylene iodide—the stone will float—benzene is added drop by drop, the mixture being kept well stirred until a point is reached at which the stone neither sinks nor floats. Then different fragments of mineral possessing specific gravities between 3.3 and 2.5 are taken in order of increasing density and dropped into the liquid; the stone under examination possess a specific gravity between that of the last which floated, and the first which sinks, and the limits may, if necessary, be further narrowed by comparing it with other mineral fragments of known density intermediate between those two. One great advantage of this

method is that the size of the fragment does not affect the result; a minute fragment only just large enough to be visible is equally convenient; in fact is more convenient than a larger one.

If a stone in the rough is under examination, a mine chip can easily be taken from it, and used for the experiment in the most satisfactory manner. The method is moreover extremely sensitive; a mere drop of benzene added to a considerable volume of the liquid is sufficient to send to the bottom a stone which was previously floating.

So much for stones whose density is less than that of chrysolite. As regards the denser minerals, it was until a short time back impossible to test them by any such method they all sank in the heaviest liquid available. But now, thanks to the fortunate discovery by Dr. Retgers of the remarkable properties of thallium-silver nitrate, all the known gem stones may be distinguished by a similar process.

This salt, which may be prepared by fusing together in equal molecular proportions nitrate of silver and nitrate of thallium, possess the remarkable property of fusing at a temperature far below that of either of its constituents, and well below that of boiling water, while at the same time the fused salt possesses a specific gravity greater than that of zircon. The salt fuses at 75° C. to a clear colourless liquid in which zircon just floats; it further possesses the useful property of being miscible in all proportions with water, so that the specific gravity can be reduced to any desired extent by adding water, just as that of methylene iodide was reduced by adding benzene. The substance can be kept liquid by maintaining it at a temperature above 75° C., and this may easily be done by immersing the vessel in which it is obtained in water heated to near the boiling point.

In these two liquids then we have the means of producing a liquid of any required density for the discrimination of gem-stones, since we can obtain from one or the other a liquid in which any precious stone will be exactly suspended.

The nitrate might be used by itself to include the whole series, but it is more convenient to use the methylene iodide when possible, both because it can be employed at ordinary temperatures and because it is cheaper than the nitrate.

Both substances darken on exposure to light, and should be both kept and used in the dark as far as possible; they are easily freed from the liquid employed to dilute them. The benzene readily evaporates spontaneously from the methylene iodide, and the water can be driven off from the diluted thallium-silver nitrate by boiling.—*Journal of the Society of Arts*, Aug. 11.

THE BANANA TRADE OF FIJI.

In a recent article we suggested that the future export of fruit from this colony would require to be conducted on ever improving conditions if the hold we at present possess in the Colonial markets is to be maintained. We also indicated the nature of the competition we had to encounter by reason of the superior facilities that were being offered by the Colonial governments with the intention of encouraging growers to build up a permanent fruit industry. It would be well, that, that the people of this colony—no less the commercially interested than the actual producer, for the whole fruit industry is inextricably associated with the one interest with the other—let no opportunity escape them to keep abreast with their neighbours, in assisting the producers in every way possible, by facilitating despatch and by all other conceivable means. Our largest export of bananas in any one single year was equal to 803,629 bunches in 1892, and since that year the decline in shipments has been very marked, specially to Australia. No doubt the circum-

scribed purchasing power of those colonies, consequent upon the evils left in the trial of the Bunking Crisis, had much to do with the decline, but was not wholly responsible for it. We have to look nearer home for the causes which led to the great reduction of the output, and opened the door, so to speak, for our neighbours to avail themselves of our neglected opportunities. Meantime Queensland, New Hebrides, Rarotonga, Norfolk Island, and the Friendly Islands have stepped into the breach, which we through our clumsiness so obligingly left open, with the result that, now the colony is inclined to re-enter the arena with new vigor, it has a strong competition to encounter. Notwithstanding this, however, with the excellent quality of our fruit, for which it is famed, with fast and direct communication, and with the experience which we have gained in the hard school of adversity, the probability is that we shall regain our former position in the trade; while the addition competition, generally spoken of as the soul of business, which we have now to face, should lend a zest to the campaign to which before we were strangers. It is needless to recount all our previous shortcomings in connection with this trade; sufficient to say they were many and varied. The principal of these however were over-shipment, non-grading, neglect of seasons, rough handling, and the practice of shippers breaking up their shipments into various consignments, and so permitting the fruit grown on one plantation to enter into competition when it reached the open market, the one consignment with the other in the same city. All these mistakes of former years will require to be carefully guarded against or, at any rate, mitigated as much as foresight can suggest. Of times of old when fruit has been rushed into, say, the Sydney market, if such an act of vandalism could have been justified, it would have been largely to the advantage of shippers if half the fruit had been thrown overboard, and by this rough mode a glutted market would have been avoided. Producers will have to guard as much as possible that the markets are not flooded with fruit. The difficulty is not easy of solution, but from past experience we are aware that it would be preferable that the fruit should be permitted to rot on the plantation rather than that it should go forward to a market that is over-supplied. Manufacturers, of course, have a large advantage over fruit producers, but they are ever on the watch to prevent their goods flooding a market—and the output of their wares is restricted accordingly. Nevertheless the same law, that of supply and demand, governs the sale of both produce and manufacture. The difficulty to be coped with, would be very much minimized were cable communication practicable, so as to admit of the early receipt of the state of the various markets. Possibly the proposed Pacific cable will be completed and at our disposal by the end of 1898; meantime it is imperative that reliable information as to the requirements of the market should reach the colony at the earliest possible moment. How this is to be obtained is a matter for consideration. To be effectual, the information requires not only despatch but it must be unimpeachable, and to secure this, it would appear to be necessary that the services of smart business men be retained on behalf of the colony at the three centres of Sydney, Auckland, and Melbourne. And if it then be deemed necessary in the interest of the industry to secure the aid of these gentlemen, their services

should be availed of to regulate the markets in so far as consignments from this colony are concerned in their respective circuits, by Fiji shippers consigning the whole of the fruit to their charge. It must not be forgotten that, while only a fair price is what is aimed at by these extra-precautions regulating shipments, if they are neglected then it would be better that there was no fruit trade in so far as Fiji be concerned. Make no mistake, as soon as a single bunch goes into the market more than it can consume, then the market becomes at once demoralised—hence unprofitable. And it were well in the interest of the industry that the colony is once more endeavouring to build up, without it is to be of an ephemeral character, that the producers and exporters meet together and form some kind of a co-operative combination in Suva, in order that they may regulate shipments on some business lines. We are aware, of course, that efforts in this direction have been made before, and that success has not been achieved; had it been otherwise the decline in our former fruit enterprises would not have occurred. Possibly too much has been aimed at, and hence the failure. Nevertheless, like errors may be avoided on this occasion, and the industry, as it presents itself at this time, is so much the richer in that it is fortified with those results already ascertained—and paid for. As the matter stands at present we have indicated that the trade to be reconstructed on a permanent basis requires to be regulated at the port of shipment and the port of delivery, and the sooner this is accomplished the better it will be for those more particularly interested before the volume of business attains proportions that will materially hamper the position. Now is the time, while shipments are curtailed, to formulate future proceedings, legislative or otherwise. We mention legislative, because in the interest of the industry the suggested meeting of producers and shippers may deem it advisable to ask the Government to provide the funds necessary to the appointment of supervising agents in the colonies—and this would possibly entail a small export duty on each bunch or case of fruit. As regards the regulation of the shipments at this end, the expenses should be no more than each shipper could well afford to liquidate out of his private pocket. Were the system adopted that all fruit put on board ship—never mind by whom appraised on a general average principle according to grade of fruit which might for convenience sake be graded in the colonies) and the whole shipment dealt with as one venture, there would be little room for dissatisfaction on the part of any shipper, as the proceeds of the whole cargo would be divided according to its grade. If an exporter sent second-class fruit, he would only receive account sales for second-class fruit—and so on. Either some such plan as here suggested must be adopted or the fruit industry has a much harder experience to undergo before success is attained.

Further remarks on this subject are held over for another opportunity.—*Fiji Times*, Sept. 5.

In our last article we suggested that the rough handling of bananas had much to do in contributing to the undoing of past ventures; that where profits were wont to be looked forward to the actual result in very many instances was ruinous, alike to individual as to the industry as a whole. Rough handling yielded its part and is largely responsible for collapse that followed after the zenith year

—1892. The rough and tumble of that year brought the climax to a trade that should otherwise have been a remunerative and permanent industry; in place of which plantations were abandoned, the service of numbers of vessels and employees was dispensed with, trade restricted, and the large ocean steamers engaged in the transport were replaced by smaller ones or altogether withdrawn, the Colony's revenue suffered a shrinkage and altogether the country lost prestige. This is only a modified sketch of the past. What are the conditions to be observed in connection with this industry for the future? The same errors are surely not to be again repeated. The whole history in connection with the fruit industry the world over, instructs us that good varieties of fruit carefully grown, tenderly handled and forwarded to market in good condition, will always command a purchaser. It will be well, then, to bear this in mind in all future transactions.

As a rule the ordinary citizen has a good deal of respect for what is termed vested interests—why, we have never bothered ourselves to understand. Even the publican, when the prohibitionists, who surround him, are of opinion that the air would be purer by the closing of it, it may be *The White Lion* or the *Honest Lawyer*, is up in arms at once with "No! You don't respect my vested interests, please." And the landlord is generally pretty safe behind his barrier of vested interests. Nevertheless, we would like to know what the vested interests of the Sydney fruit merchant comprise, and by what right he insists on receiving bananas in naked bunches in place of well-protected cases. If it be because it has been the custom to so receive the fruit it must have originated in our past carelessness in having forwarded it to him in an unprotected condition. Notwithstanding this barrier cry of "Custom! Custom!" it is quite time that the practice was discontinued, more especially as we are aware that so soon as the Sydney dealer receives the fruit, a large portion of it is at once put up in cases for country customers. In fact the work that ought to have been performed on the plantation is done in Sydney. This is one of the anomalies in connection with the trade that requires attention. The fruit is grown in Fiji, carried perhaps a mile to the river or beach, put on board some small craft, then into the larger stream, carried to Sydney, put on the wharf there, then transferred to cart, dumped down in a store, and then—the packing process commences. And at whose cost is all this damage entailed to the fruit en route debited but to the producer—and the middle man benefits by the transaction. Had the fruit been packed on the plantation no waste or destruction would have entailed, and the interests of the producer and consumer would have been conserved. Possibly, and we have our doubts about it, it might serve the interests of a few people in Fiji to so send their produce to market, but that the practice should be longer continued as a general custom is very much to be deprecated. After all, the city of Sydney,

DEAFNESS. An essay describing a really genuine Cure for Deafness, Ringing in Ears, &c., no matter how severe or long-standing, will be sent post free.—Artificial Eardrums and similar appliances entirely superseded. Address THOMAS KEMPE, VICTORIA CHAMBERS, 19, SOUTHAMPTON BUILDINGS, HOLBORN LONDON.

while its consumption of bananas may be comparatively large, still its 300,000 of population is small in comparison to the large number of cities and towns which draw their supplies from the Sydney emporium. The population of Australia, leaving Queensland out of the question, amounts to close upon 3,000,000.

If this barrier of Custom which presents itself is inimical to the profitable conduct of the trade, the sooner it is broken down the better it will be for all concerned. If the middle men of Sydney will not co-operate with the shippers of this colony in their efforts to put fruit on the market on more practical economic conditions then they will only have themselves to blame if other means are taken to reach the consumer without their assistance. By last mail we are in receipt of advices from Sydney—"Don't send any bananas in cases. If you do so they will not realise charges." It would be well, then, if the exporters were to meet together and consider this matter in all its detail. The necessity, under any circumstances, of casing a large portion of the fruit is shown by it being done when it arrives in the colonies. As we are all aware in this country much of the finest fruit fall off the bunches and never reaches the consumer, without it happens to be the colonial wharf longer. Again, much of the best fruit is on the smaller bunches which are not considered of full size in the market acceptance of the term but, cut up and sent to market in cases, the fruit would be much appreciated by the consumer, and, at the same time, the waste which is at present entailed would be avoided and the extra profit that must accrue would also be much appreciated by the producer. It is the timely consideration of all these small details in economic working conditions that make the difference between profit and loss, and as the contest for position in the market goes on apace, it were well that they be not disregarded until too late in the day.—*Fiji Times*, Aug. 8.

VARIOUS PLANTING NOTES.

MACHINE-MADE TEA IN CHINA.—A Colonial merchant in sending us an order writes:—"Certain friends in China have asked me to send them the best books on the above subject as they seem to think there is a chance of making tea in China by machinery. I can't say I share my friends views, but I must comply with their request nevertheless. The Chinese will never use machinery as long as the tea gardens are owned and managed by Chinese."

TOMATO, A FRUIT OR VEGETABLE.—The Tomato, from a botanical standpoint, is a fruit. It is also used as a dessert fruit by many people. In regard to exhibiting this vegetable product, it has been found convenient by most societies to include it with the vegetables or salads, and the decision of the judges in your case was by no means extraordinary. In the *Rules of Judging*, issued by the Royal Horticultural Society, which for the present should be the recognised authority for the settlement of such points, is the following:—"Tomatos are only recognised as dessert fruits where specifically admitted by the particular schedule, thus:—'Tomatos admissible.'"—*Gardener's Chronicle*, Aug. 15.

The Best Soaps for Warm Climates are CALVERT'S TOILET SOAP (6d. Tablets) and PRICKLY-HEAT SOAP (6d. and 1s. bars), pleasantly perfumed, for Bath or Toilet containing 10 per cent. of Pure Carbolic. Very serviceable as preventives of Prickly-heat and other skin irritation. Sold at Chemists, Stores, &c.

F. C. CALVERT & CO., Manchester.

INDIAN TEA SALES.

From *Watson, Sibthorp & Co.'s Tea Report*

CALCUTTA, Sept. 16th, 1896.

32,231 packages changed hands in the sales held on the 10th instant. The market was quiet and prices for all grades of tea were again lower, full rates alone being obtained for a few lots of choice tea. There was a good demand for outside markets and buyers secured about 6,000 packages.

The average price of the 32,231 packages sold is As. 7-6 or about 8½d. per lb. as compared with 24,123 packages sold on the 12th September 1895 at As. 8-4 or about 8½d per lb. and 18,967 packages sold on the 13th September 1894 at As. 8-9 or nearly 9½d per lb.

The exports from 1st April to 14th September from here to Great Britain are 57,079,453 lb. as compared with 55,709,797 lb. at the corresponding period last season and 54,951,184 lb. in 1894.

NOTE.—Last sale's average was As. 7-8 or nearly 8½d.

TELEGRAMS.—Reuter telegraphed from London on the 7th instant—"Type" 7½d, on the 8th instant—"Type" 7½d, on the 10th—Offered 29,000, sold 25,500 packages. Generally very firm with full rates. Average 10d. "Type" 7 7-16d, and on the 4th—"Type" 7 9-16d.

EXCHANGE.—Document bills, 6 months' sight, 1s 2½d.

FREIGHT.—Steamer—£1-3-9 per ton of 50 c. ft.

(From *William Moran & Co.'s Market Report*.)

CALCUTTA, Sept. 16th, 1896.

TEA.—The sale of the 3rd instant, comprised 19,725 chests, of which 19,491 sold. Prices generally were rather weaker, finest kinds selling about half-an-anna lower and medium sorts showing a similar or rather greater decline. Common descriptions were slightly easier. On the 10th a large quantity was brought forward, 32,910 chests being offered of which 32,493 found buyers. Fine teas were steady and common descriptions very firm. Medium sorts again were rather lower.

Total quantity of Tea passed through Calcutta from 1st April to 14th September.

PRODUCTION OF ESSENTIAL OILS IN SICILY.—Ceylon is, to some extent interested in the following information:—

Owing however, to the measures taken of late to guarantee the genuineness of the Sicilian essential oils, these have redeemed their character and regained their place on foreign markets. The value of the volatile oil depends wholly on the variety of the citrus whence it is expressed, and that squeezed from the peel of the bergamot is the most highly prized; that of the lemon coming next, while the orange essence only occupies the third place in the scale of values. The quantity of essential oils shipped to all countries during 1895 was 37,911 kilogrammes, valued at 588,085 lire (lire—9 9-16d), and the large proportion of 32,010 kilogrammes out of this quantity was taken by Great Britain, the value of the same being 224,070. The figures for 1894 were—total 52,422 kilogrammes, worth 733,908 liras; and to Great Britain 45,626 kilogrammes, valued at 638,764 lire. It should however, be mentioned here that in this instance at least the custom-house valuation is apparently greatly in excess of the actual market value of these essences.—*Journal of the Society of Arts*, Aug. 21.

(COLOMBO PRICE CURRENT.

Furnished by the Chamber of Commerce).

Colombo, Sept. 21st, 1896.

EXCHANGE ON LONDON: CLOSING RATES, Bank Selling Rates:—On demand 1/2 1/4 to 5/32; 4 months' sight 1/2 5/32 to 7/32; 6 months' sight 1/2 3/16.

THE AGRICULTURAL MAGAZINE, COLOMBO.

Added as a Supplement Monthly to the "TROPICAL AGRICULTURIST."

The following pages include the Contents of the *Agricultural Magazine* for October:—

Vol. VIII.]

OCTOBER, 1896.

[No. 4.

SEASON NOTES.

ESTERN PROVINCE—Yala paddy crop ripenings and harvesting has commenced. Fruit and vegetable are reported to be scarce in the Kalutara and Negombo districts.

Central Province.—Yala crops are ripening and are being harvested and in some places fields being sown for Maha.

Stock.—Foot and mouth disease is reported from Udahehaheta in the Nuwara Eliya district.

Northern Province.—Work in paddy fields retarded by want of rain. Outturn of dry grain unsatisfactory owing to the drought—tobacco fields continue low.

Southern Province.—Yala crops reaped and the yield middling except in the Hitudum Pattu when it is poor owing to unseasonable weather. Fruit and vegetables reported scarce in the Galle and Hambantota districts.

Eastern Province.—Crops being harvested, other in ear, results satisfactory.

Stock.—Foot and mouth disease is reported from Batticaloa.

North-Central Province.—Yala crops have been reaped with satisfactory results.

Stock.—Foot and mouth disease in all palatas, cattle plague in all palatas except Tamaukaduwa.

Sabaragamuwa Province.—Yala crop being harvested, prospects fairly good, and ploughing and sowing for the Maha proceeding.

Greatest amount of rainfall in any hours—
on the 1st of October, 3:02 inches.

Recorded by M. W. K. BANDARA.

A SUPPLY OF SEEDS AND PLANTS FOR NATIVE CULTIVATORS.

If it is asked how the Government through the Agricultural Branch of the Department of Public Instruction could best help the native cultivator, we would be inclined to say that it is by giving him facilities for procuring seeds and plants. What are the means at present available to him for securing these? Practically none. There is in fact no place within easy reach of the cultivator where the most ordinary seeds and plants which yield food products could be procured. Seeds of grain crops and seeds and plants of fruit trees are what the cultivator may be said to be most in need

of Now, without going beyond Ceylon, we believe that if the cultivator in one district or province found a ready means for obtaining seeds and plants from another district or province he will thereby materially benefit himself. It is well-known that in certain remote districts where the food supply is deficient, jak and breadfruit are practically unknown as articles of diet, though the trees producing these fruits should thrive well in such places. We remember hearing some time ago that a revenue officer, who is well-known for the interest he takes in the welfare of the poorer village population, went the length of offering rewards to those who planted these trees in their gardens.

We should imagine that a workable scheme for supplying the want which we have indicated above, could be formulated in connection with the work of the Colombo School of Agriculture. This institution might be made a sort of central depôt where different kinds of seeds and plants of food-yielding trees—both indigenous and introduced species and varieties—could be procured by would-be growers. Nurseries and seedstores for keeping up a supply of such plants and seeds as would be specially suitable for cultivation by the natives, would, of course, have to be established, and to this end the school will need to be properly equipped and furnished with the necessary funds. The benefits of exchange of seed paddy are two well-known to be stated here, and yet the practice is but little adopted by paddy cultivators in the island. In this connection we may refer to the successful experiments that were carried out some years ago by Mr. William Jansz of Galle, and which conclusively proved that better crops could be obtained by sowing "fresh" seed.

There are also many foreign varieties of paddy, unknown in Ceylon, which can with advantage be introduced into the island. The introduction of the variety known as Carolina paddy many years ago was admitted as a distinct gain to paddy cultivation in Ceylon. We believe that the agricultural society (now alas defunct) which flourished in the forties, did good work by introducing new forms of economic vegetation into the island.

If such a scheme as we have suggested is adopted, and a central depôt be established at the Colombo School of Agriculture where seeds and plants could be offered on easy terms to intending cultivators—who at present know not how or where to obtain them—a great advance will have been made in the improvement of grain cultivation and the encouragement of fruit culture in the island.

OCCASIONAL NOTES.

We have received more than one application for the locally manufactured type of plough referred to in our last issue, and at present six ploughs are being made to order. One of these locally-made implements is now being used on the Havelock Racecourse, and is doing its work well.

The small crop of grapes from the vineyard attached to the School of Agriculture was taken in early in September, the bunches numbering about 250. Those who had an opportunity of tasting the fruit passed a favourable opinion on the quality of the grapes. It is to be hoped that the experiment in viticulture will be continued till the

vines reach the "full-bearing" period, when a final decision as to the prospects of the "extensive" cultivation of foreign grapes in Ceylon may arrived at.

The Government Agricultural Instructorships were suppressed at the end of August. It is to be hoped, however, that the vote for maintaining these posts will not lapse, for if the scheme initiated by Mr. H. W. Green—the well-intentioned and zealous promoter of agricultural education in Ceylon—has been found to be barren of results, there is all the more reason that a more practical scheme should be formulated for the improvement of native agriculture, to take the place of that which has been withdrawn. An initial failure does not justify the complete abandonment of a good cause, but as the old rhyme teaches us, demands a second and third trials.

We would direct the attention of our readers to the first of Mr. Zanetti's paper on "The Fruit Tree" which appears in the present issue—We have no doubt that all fruit-growers will join us in offering our thanks to the writer for placing his practical and useful knowledge at our disposal. We may mention that we have already had many applications for the past numbers of the magazine which contained Mr. Zanetti's remarks on "Pruning,"—a proof of the usefulness of his contributions.

Mr. W. A. de Silva, late headmaster of the School of Agriculture, and a qualified Veterinary Surgeon, has severed his connection with the school and accepted service under the Municipal Council of Colombo. As an Inspector of Cattle, Meat, and Milk, &c., Mr. de Silva should find ample scope for his veterinary attainments, and duties congenial to his tastes. Mr. Hoole, late 2nd assistant teacher, the second old boy of the school who has qualified as a Veterinary Surgeon, has been appointed an assistant to the Colonial Veterinary Surgeon and stationed at Anuradhpura. The school is therefore the poorer by the loss of two teachers whose places on the staff it will not be easy to fill.

The first sessional examination of forestry students was held about the middle of August, the subjects in which they were examined being Sylviculture, Morphological Botany, Mathematics (Euclid, Algebra, Trigonometry and Arithmetic), Forest Law and Surveying.

Applications for rhea cuttings from the school still continue to come in, so that before long we shall probably be in a position to arrive at a decision as to the prospects of remunerative cultivation of this much valued fibre-plant in Ceylon.

THE FOREST LAWS OF CEYLON.

(Continued).

The chief objects of the Ordinance No. 10 of 1885 would be best explained by a few extracts from Mr. Vincent's Report. In his introductory chapter on the future management and working of Forest administration, Mr. Vincent points out the evil effects of not protecting our forests. He says: "Where there is no effective forest conser-

vancy, increasing population soon finds that there are no forests to supply its wants, or that there is no soil suitable for the extension of cultivation. The latter may be said already to be the case in Ceylon, for I may say with absolute correctness, that unless the reserves at over 5,000 feet elevation are encroached on, there is no forest land between 2,000 and 5,000 feet left for capital to open out. And why? Because chena clearings have swallowed up all the forests which were not in times past required for immediate sale. It is not that all the forest has been cleared for coffee, and that thus the enterprise has found its own limits, but large though the extent of coffee estates is, the map shows that immense areas, now only covered with lantana, would be available for fresh development of the enterprise had any foresight or care been shown in preventing forest destruction. It is not a mere matter of opinion, but one that is repeatedly confirmed by officials and official documents, that, owing to the apathy of Government, various claims, such as those put forward under tombu register extracts or under old Sannas: also to rights of paddy land appurtenances, to communal rights, to proprietary and occupancy rights under Ordinance No. 12 of 1840 &c. have been allowed to exist unrecorded and undefined. Under colour of these claims, people have been permitted unquestioned to devastate vast areas of the finest forest, not only in the Central Province, but throughout the moist zone. In some places, I am informed, the forest cleared has been land that Europeans had applied for, and which was about to be surveyed for sale. Having a detailed survey of the Central Province we can estimate accurately what small areas of forests are left uncleared, and what large ones are only covered with scrub. Areas of forest are still left in the moist zone, but when we come to select our reserves for the small local consumption of softwoods and fuel, we shall find that little is available in suitable situations, those forests best situated having been sold or cleared, and that to secure the small quantity of fuel required for our railway, artificial plantations have to be made." The chena cultivation question has been the subject of constant complaint and has been dealt with by almost every Governor since the time of Sir Henry Ward. The question is one of considerable difficulty. One of the main objects of the Ordinance was to introduce a system which has been found to work well in similar circumstances in British Burmah.

The position of the Crown in regard to forests is also explained by Mr. Vincent, and it would be as well to quote his very words on this subject "The position of the state," says Mr. Vincent, with regard to its forests and waste lands is often misunderstood, and the Crown is too frequently regarded as a private landholder, instead of as a trustee with a large and valuable public property which it has to manage for the general good, and to protect against the innumerable forms of trespass to which state forest property is everywhere exposed. Such has certainly been the mistaken position assumed in administering the forest law of Ceylon and although the legislature may give extensive, protective powers, judicial decisions have usually thrown all the advantage on to the other side. In endeavouring to punish forest offences, the courts have regarded the Crown

not as a trustee for the whole nation, but as a landholder whose endeavours to protect an unjust monopoly ought to be thwarted in every way. The real object of the state is to administer its national trust to the best possible advantage, to own State Forest Domains for the permanent public benefit, protecting the public property against individual trespass. We wish to form reserves of timber and fuel, at the same time protecting the property of the nation and improving it. The Legislature has, not only in the Timber Ordinance, but in almost every other law, put large powers into the hands of the Executive Government, which it is trusted to exercise with due discretion. The state has a powerful monopoly, which, if not carefully administered and protected, may, as has already to a great extent happened in Ceylon, be gradually broken up and infringed on, so as to be of comparatively small value. General public interests then suffer to benefit only a few individuals, who take advantage of the incomplete state of the law, and the ill-defined rights which it confers. The forest question can only receive proper treatment when regarded from the standpoint of a large national property, handed to us by the past generation, and which we are also bound to maintain in unimpaired productiveness for the benefit of the present and future generations." To give effect to this view was the present ordinance specially designed.

(To be continued.)

THE FRUIT TREE.

Fruit plants may be said to be composed of four principal parts: roots, stem, leaves and flowers. Plants originate from seeds, which germinate when put into the ground, under the influence of air, heat and moisture, giving rise to two organs: one of these, the root, has an inclination to avoid the light and bury itself in the soil, while the other, the stem, on the contrary, seeks the light and grows above the surface of the ground.

The tap root which is formed by the germination of the seed, grows in most cases vertically into the soil: it carries numerous branches, which after lengthening, become thick and woody in the second year and spread themselves in the soil laterally as well as vertically. On these branches will be found the minute root—hairs which have the powers of absorbing the nourishing matter in the soil.

The important functions of the roots being recognised, it is evident that in the cultivation of fruit trees, we must be careful to favour their development, and this is done by preparing for them a very free and well fertilized soil. Generally the growth of the roots is in proportion to that of the stem. We may conclude from this, that the more numerous are the roots, the more branches the stem will carry, and *viceversa*.

The stem is the support of the leaves and all other aerial organs of the plant. It is so to speak a communicating channel, through which the substances absorbed by the roots reach the leaves, and the organic food elaborated by the leaves is distributed through the entire system of the plant.—At a certain height the stem will produce

branches which again subdivide to form primary and secondary branches.

The leaves appear on the stem and its ramifications; and through them respiration and the absorption of gases from the air is carried on. Buds are formed in the angles of leaf and stem or branch, and in some cases at the end of shoots. These buds contains rudiments of new shoots or new flowers. Those of shoots are thin and pointed, (called by the fruit culturist buds for wood); buds containing flowers (buds for fruit) are thicker and of a roundish appearance.—Fruit growers make use of buds as reproducers of varieties by inserting them on plants grown from seeds.—While the leaves of the plant absorb the gases and moisture contained in the atmosphere, the roots take in water and dissolved food substances from the soil which are necessary to vegetation. This dissolved food absorbed by the roots, ascends by the stem up to the leaves. Once arrived at the leaves and in contact with the gases absorbed by them, and under the influence of heat and particularly of light, it undergoes a sensible change, becoming more concentrated and acquiring new properties. In this form it descends from the leaves and becomes distributed throughout the plant. This liquid is the one which essentially helps in the nourishment and development of plants or trees.

Fruit trees are propagated by seed or by division. The propagation by seed is the natural course by which all plants can be propagated, but through this means we will only obtain plants true to the species, though not necessarily true to the variety, since when seed-grown they are subject to certain modifications of character. As an example a mango tree grown simply by seed, may not turn out in wood, leaves, flowers and fruit, identical in character with the tree from which the seed was obtained. Propagation by division is an artificial course adopted by man. Its object and result is to exactly reproduce the characters of the variety in all its parts. This mode of propagation is carried on by means of cuttings, by under layers, or by the method of budding and grafting. From the facts above mentioned it is evident that the fruit-grower will depend on the seed only to reproduce good healthy subjects on which to graft the variety he intends to cultivate.

(To be continued.)

THE INSPECTION OF MEAT.

BY G. W. STURGEON, M.R.C.V.S., &c., Government Veterinary Surgeon.

III.

Abnormal Appearance of Flesh.—(continued.)

Yellow Flesh.—Is generally seen as the result of Jaundice.

Dark or Magenta Coloured Flesh.—A very dark appearance of the flesh is usually indicative of some grave blood disease, and it becomes more marked after exposure to air for a short time. It is also seen when animals have died from strangulation or suffocation, or severe forms of fever. It should be classed as unmarketable.

Green Flesh.—Is indicative, in most cases, of putrefaction or mortification and almost always

associated with a bad odour. Occasionally the stomach is lacerated by the butcher when being removed and the contents escape and stain the surrounding tissues green—the trick of stripping being then practised to remove it.

Odours.—Particular kinds of food impart an odour to the flesh. Too liberal feeding with turnips gives to the flesh a peculiar smell—also in cases where the animal has been choked by a turnip the odour is especially pronounced. Medicines such as turpentine or ether give an odour to the flesh. The odour of urine is given to the meat in cases of urine poisoning. Meat may contact unpleasant odours from some bad smelling matter or gas being present in or near to the slaughter-house especially those odours arising from the close proximity of closets, cesspools or latrines.

Effects of Cold upon Flesh.—Frozen flesh has a damp, cold feel and is generally stained a light pink colour due to the effect upon the colouring matter of the blood, and muscles. Frozen meat should be carefully examined and the carcass or joints deeply cut into, because unless a carcass has become quite cold at the time of freezing, the outside becomes frozen and the interior does not, consequently it soon putrefies and is worthless. Frozen mutton is generally admitted to be preferable to frozen beef—in the former case the carcass is frozen whole while the carcass of beef is cut into a number of parts thus losing more of its nutritive qualities.

SERICULTURE.

The Muga silkworm, *Antheraea assama*, is a wild form next in commercial importance to the Tusser. The insect is met with chiefly in Assam, but is also found in North Burma. It is to a certain extent domesticated in Assam, as it is often reared in houses; but the best cocoons are obtained only from those that are allowed to form on the trees.

The Muga is a multivoltine worm producing five broods a year. The full grown worm is nearly five inches in length and is as thick as the forefinger. It is of a green colour, the under part being of a darker shade; while the back is of a lighter green. The body is composed of ten rings each with four hairy red moles; a brown and yellow stripe extends midway down each side from the tail to within two rings of the head and below it the breathing holes are marked by a row of seven black points; the head and claws are light brown and the holders dark green with black prickles. When in a wild state and feeding on the trunk of a tree, the worms often descend by the branch when they have exhausted the supply of leaves on one tree and resort to another. They always prefer young trees, apparently because old trees are often infested by ants. They feed from eight o'clock in the morning till near noon and from three till sunset. A complete cycle of the Muga worm lasts for about 54 days in warm months and 81 days in the cold season.

Hatching	..	7	...	10	days,
Worm	..	26	..	40	"
Spinning Cocoon	4	..	7		"
In the Cocoon	14	..	21		"
As a Moth	3	..	3		"

The cocoon of the Muga is large and thin, and fawn coloured: it is about $1\frac{3}{4}$ inches long and one inch in diameter.

! The export of Muga silk from India is principally in the form of *thread* which are sent to the Persian Gulf.

Dr. Watt in his Dictionary gives the following as the food plants of the Muga worm on the authority of Sir. D. Brandis :—

- 1 Cinnamomum Obtusifolium
- 2 Cylicopodaphne nitida.
- 3 Michelia Champaca Sinhalense, Sapu.
- 4 Machilus Odoratissima.
- 5 Symplocos Paudiflora.
- 6 Litsœa Citrata.
- 7 L. Polyantha.
- 8 L. Salicifolia.

W. A. D. S.

BEE-HIVES.

Albert Gale, a well-known writer on Apiculture, has devoted a series of articles to this subject, which have appeared on the Agricultural Gazette of New South Wales. For much of the information given below we are indebted to this authority, who states that he has written with the object of giving instruction not to professional bee-keepers but to beginners, particularly to those in remote place where carriage and other concomitant troubles one always standing in the way of the enthusiastic amateur. Originally bees, like the wild bees of the present day, constructed their combs among rocks and caves and such like places where natural shelter was afforded them. The development of artificial homes for bees was very slow. Those used in Egypt even now, are sundried earthen tubes, about 4 feet long. The same style of hive is said to be the one adopted by the Japanese and the hill tribes of North India. From these sundried clay pots to the old fashioned straw hive development was very slow. For obtaining the honey both from the clay pots and the straw hive "fire and brim stone" were the persuasive arguments used to induce the little busy bee to yield up its laboriously—gathered stores to satisfy the cravings of the bee-keeper. For long this barbarous system, which is in vague even at the present day in Ceylon, continued to be practised till some humane individual came to the conclusion that something might be done to save the valuable lives of the inmates of the hive. It was Nutt who invented the straw super which was improved upon by 'Neighbours,' Pettitt's and Taylor's bell-glass supers. About 1864, *The Times* (London) Bee-master strongly recommended "Pettitt's Hexagonal" as improved by himself, and by the introduction of 6 slides for the purpose of communication between the broodchamber over the super. But later on he discarded it for the Ayrshire Box-hive. Pettitt's "Temple-hive" with its 4 bell-glasses from which the drones were effectually excluded, seems to have been one of the first wooden structures for bee-keeping having any pretensions to use and ornament used in England.

In 1848 the Rev. Mr. Drieron, published his Theory and Practice of Bee-culture, in which he described his method of removing the combs without their being entirely destroyed. His method was by a moveable top-bar to which the bees attached the comb, and also attached it to

the sides of the hive from where it had to be removed by the application of the knife. This was the germ from which sprang the moveable bar-frames.

The Rev. L. L. Langstroth, constructed a hive on the plan of the folding hives used by the celebrated Huber for the purpose of verifying some of his (Huber's) valuable discoveries. The use of the Huber hive had convinced Langstroth that a hive could that should give the bee-keeper a complete control of the combs without enraging the bees. The cutting of the combs from their attachment to the sides and bottom of the hive was the great drawback in Drierron's invention, and Drierrons' moveable top-bar speedily gave place to Langstroth's moveable frame.

The various forms of hives now in use are all more or less modifications of the Langstroth. Whatever the pattern, model, or size the material most suitable is soft, porous, light wood. The wood should be well-seasoned so that there may be no hoisting or shrinking with atmospheric changes. Among other hives besides the Langstroth or Langstroth Simplicity, are the Gallup, Heddon, Quinby, Berlepch, Long-Idea &c, as modifications thereof.

The Heddon hives, though of most approved Structure, are only suitable for very experienced bee-keepers. It requires a skilled mechanic to make them, and they are far more difficult in manipulating than the Langstroth.

The Langstroth hive has stood the best of nearly half a century and it is the most generally used.

Prof. Cook has said of it, "It left the hands of the great master in so perfect a form that even the details remain unchanged by many of our first bee-keepers."

Anyone, says Mr. Gale, who has a fair amount of skill with tools can make a Langstroth live. The following hints are given to guide the amateur bee-keeper in constructing his own hive after the Langstroth type:—

The wood used should be soft, light and well-seasoned, and the only thing that is imperative in the construction is that the measurements must be rigidly adhered to, otherwise there will be no end of trouble in the manipulating of the bees. Many a beekeeper who has been his own carpenter has given up beekeeping in disgust, because, in the construction of the home-made hives, there has been a want of care in giving bee-space—quarter of an inch—truebee space is $\frac{3}{16}$ inch.

The wood in kerosine and other packing cases is more or less suitable. For the colder districts the sides of the first named are too thin. The smell of kerosine is quickly evaporated by placing the cases in the full glare of the sun. The most suitable thickness is one inch or a little less if no planing is to be done. The ends must always be of inch wood or of sufficient thickness to admit of a rebate (rabbet) for the moveable frames to hang freely. The ends of kerosine cases, though not an inch thick, answers very well for the purpose.

The brood chamber or body of the hive is $9\frac{1}{2}$ in deep if a moveable bottom is used, but if the bottom be a fixture (though a moveable bottom is always preferred) it should be 10 in deep. For an eight-framed hive the ends must be $14\frac{1}{4}$ in—

that is if the sides are to be nailed to the ends—but if the ends are to be nailed to the sides an allowance must be made for the thickness of the sides. The sides must be 20 in outside measurement. Therefore a piece of timber 6 ft \times 10 in is sufficient to make a brood chamber or a full size super. From such a piece of timber, first cut off 28 $\frac{1}{2}$ in (if the sides are to be nailed to the ends, and it is always better so to do) and work a rebate (sabbet) $\frac{3}{8}$ in plus the thickness of the top bar of the moveable frame, and the top bar of such a frame should be at least $\frac{1}{2}$ in thick, afterwards cutting into two equal parts. Each one will thus be 14 $\frac{1}{2}$ \times 10 in.

An easier and simpler way of making the rebate, although not so workmanlike, is to plant a strip along the end piece of the frame and fasten it with fine nails.

A full-sized super is the same measurement as the brood chamber. It will be noticed that if a moveable bottom board be used the depth of the bar-frame will be 9 $\frac{1}{4}$ in, thus coming flush with the base of the end piece of the frame, and showing no bee-space—a cleat to form the bee-space is fastened on the bottom board. Half-sized supers for shallow frames are the same measurements in all except in depth.

Since the above was written we have had an opportunity of conferring with a gentleman who has had much experience in bee-keeping, and carried on apiculture in Ceylon with much success. He places great importance on the structure of the hive best suited for Ceylon bees, and though the hives adopted by him were constructed after the modern type of frame hives there are some important alterations which have been made to suit local conditions. This gentleman is having a hive built for us according to his own plan, and we hope to be able to induce him to describe its construction, and, if possible, also to detail his experience in bee-keeping, in a future issue.

MILK AND MILK PRODUCTS.

(BY MR. JAMES MOLLISON),

Superintendent, Government Farms, Bombay.

The food given to milch cattle influences the quality of the milk to a considerable extent. Succulent food undoubtedly causes increased secretion, but at the same time it lowers the percentage of total solids. The morning's milk is usually not so concentrated as the evening's milk, but on the other hand the morning yield is greater. It is not clear why this increased yield should be associated with a diminution in the percentage of solids, unless we presume that the longer period which generally elapses, between the evening and morning milking permits of fuller and freer secretion than the shorter interval between morning and evening. The observations taken at the Poona Government Farm show about one per cent. difference of total solids in favour of the evening's milk which, is however, more than counterbalanced by the increased yield in the morning.

The butter fat exists in milk as butter globules of various sizes easily discernible under the microscope. The butter globules are of lower specific gravity than the other constituents of milk. Consequently if the milk is set in a vessel, the butter

fat rises to the surface to form cream which can be separated by skimming. In the milk the casein also exists in suspension in minute globules. In fresh milk the casein neither tends to rise nor sink because it has absorbed part of the water of milk and is thereby softened and swollen, so that it is more evenly diffused through the water of milk. The sugar of milk is in solution; the mineral matter is partly in solution and partly held in suspension. It consists mostly of phosphates and common salt. The ash constituents are oxides of iron and alumina, magnesia, potash, soda, lime and phosphoric acid.

Milk rapidly undergoes change, particularly if the day temperature is high. The changes are induced by bacterial ferments which thrive in the milk because it is almost a perfect food. The most common change which occurs in the souring of milk is brought about by the conversion of sugar of milk (lactose) into lactic acid. The curdling of milk is an accompaniment of the lactic fermentation. This curdling can be accomplished artificially by means of an organic or mineral acid, or, as in cheesemaking, by precipitating the casein by the use of rennet. The active principle in rennet is the digestive agent found in the fourth stomach of a calf. It not only curdles the casein but also induces other changes which lactic acid cannot induce. The change of lactose into lactic acid is merely a molecular one and is due to growth of the *bacterium lactis*, an organism plentiful in the air of a dairy but particularly where a dairy is not kept scrupulously clean. Immediately milk is drawn from the udder it is subject to contamination. The chemical changes which then take place are directly caused by ferments induced by contamination. The temperature of the milk as it is drawn from the udder is just the temperature at which the reproduction of microbes takes place most rapidly.

If milk is cooled immediately bacterial growth is checked and will not again become active until the milk slowly warms, which it will do if the temperature of the dairy is higher than that of cooled milk. If the temperature is high, the milk will not keep long; if it is low the milk will remain sweet a considerable period. Milk which has been boiled and then rapidly cooled and afterwards kept in a cool clean place will keep longer than milk not so heated; but if the surroundings of the dairy are unsanitary, and the dairy is within range of any unwholesome smell or other unhealthy influence, the milk is bound to become tainted in a manner which probably will make it dangerous for human food. Milk sours quickly in India during the hot season and also during the first part of the monsoon. During the early rains the atmosphere is close and sultry, and though the heat is not exceptionally oppressive, there is "thunder in the air," and any atmospheric electrical disturbance has a material effect in causing milk to sour quickly.

Milk as it is secreted may be contaminated by deleterious substances in the food; moreover a diseased cow may yield milk which may be impregnated with disease germs and may therefore be the means of causing contagion, but as it leaves the udder it contains no fermentative bacetrin. A few hours after milking the number of bacterial germs found in a cubic inch of milk is almost incredible, particularly if the temperature favours

reproduction. The bacteria which cause fermentative changes in milk can be destroyed or at least their development and activity can be stayed in many ways.

Boracic acid, carbonate of soda and saltpetre are all used as milk preservatives, the first being the most effective. These agents do not destroy fermentative organisms, but only check their development.

If the udders of the cows and the hand of the milker are clean, if the milk vessels have been thoroughly washed and well scalded, if the cows are milked in a pure atmosphere and if the udders are not inflamed or otherwise diseased, it is clear that the danger of organisms entering the milk is minimized.

But fermentative bacteria always exist in the air and it is practically impossible to prevent milk coming in contact with them; therefore other precautions to prevent fermentative changes are necessary.

Heat will kill all organisms in milk. If the heat applied is high enough, milk will be sterilized. Boiling will kill all bacteria. If boiled milk is kept out of contact with the air it will keep indefinitely. Preserved or condensed milk is prepared by evaporating milk to which sugar has been added until the mixture acquires the consistence of syrup. Whilst hot it is hermetically sealed in tins and keeps good for years. A high temperature kills the ferments of milk, a low temperature interrupts their activity if it does not actually destroy them. Milk, kept frozen, will keep good for months, whilst a mean temperature of 35° to 40° F. is sufficiently low to keep it good for days. A maximum day temperature of 55° F. will enable milk to be kept good sufficiently long to allow all the fat globules to rise to the surface. Whilst if the mean day temperature is 70° F. or higher the lactic ferment is so active, that lactic acid is formed in sufficient quantity to curdle the casein in a very short time, and the curdling entangles the butter fat globules so that they cannot rise to the surface.

"NITRAGIN," OR THE USE OF PURE CULTIVATION OF BACTERIA FOR LEGUMINOUS CROPS.

Hellriegel's celebrated experiments have already been referred to. Briefly to recapitulate these: in the course of his experiments, Hellriegel found that the assimilation of the free nitrogen of the atmosphere was concurrent with the development on the roots of certain leguminous plants—of nodules which were subsequently found to contain specific micro-organisms or Bacteria; but that when these were absent, growth of the plant was stunted, and assimilation of free nitrogen did not take place. Further, that development—of the nodules could, speaking generally, be induced in sterilised sand supplied with purely mineral food, but containing no nitrogen, provided there were then added to it the watery extract from a fertile soil: but that in the case of certain plants, *e. g.* lupins, the extract from an ordinary fertile soil did not suffice, though that of a soil in which the particular

crop experimented on had been previously growing well was effectual in producing development of the nodules on the roots.

Working on the lines thus enunciated by Hellriegel, Nobbe carried the inquiry a step further, and he reasoned from the observations made, more particularly in the case of lupins, that it was very probable that each plant possessed its particular kind of nodule, or, rather, that the nodules of particular plants contained bacteria peculiar to themselves, and that hence what was necessary was to seek to ensure for the plant grown the presence of the particular organisms that favoured the assimilation by it of the free nitrogen contained in the atmosphere.

Nobbe accordingly started from the other side of the question, and taking the nodules which he found on particular leguminous plants, he set to work to eliminate the specific organisms and to obtain them in a pure state. It had been known, as I have already pointed out, that the growth of certain leguminous plants like lupins, which would not thrive on ordinary fertile soils, could be induced by mixing with the soil other soil from where lupins, for example had been growing well.

But it was also known to Nobbe that this transference of soil, besides being costly and inconvenient, had disadvantages connected with it, for not only were the specific organisms that might be favourable present, but there might be others that were distinctly unfavourable or destructive; while fungoid diseases, parasitic growths, and other elements of a nature prejudicial to the development of the plant might also be simultaneously imported. He sought, therefore, to avoid this by obtaining, *in the pure state*, the specific organisms which was believed to act favourably in the case of each leguminous crop, and apart from the disadvantages that might attend the presence of unfavourable elements.

The method adopted by Nobbe and Hiltner was that known as "pure cultivation." The contents of the particular plants were used for inoculating, in the usual way, a plate of specially prepared gelatine, and the organisms were cultivated on it. A second plate was inoculated from one of the colonies so formed, and the organisms again cultivated. This was repeated successively until, finally, a "pure cultivation" was obtained of the organisms believed to be the one peculiar to the particular plant, and the one by means of which nodules were formed and the plant was enabled to assimilate the free nitrogen of the atmosphere.

On examining microscopically the organisms obtained from the nodules of different leguminous plants, Nobbe could not, however, discover any external appearances which specially characterized one or the other, or which distinguished one from another.

Indeed, up to the present, it has not been possible to say, as the result of microscopical examination, that a particular organism is the one particular to peas, to clover, to lucerne or to any leguminous plant. Still, seeing it was known that in order to get lupins to grow, inoculation with a soil on which lupins had thriven was necessary, but that inoculation with soil where peas, for instance, had grown, was not effectual, Nobbe was led to conclude that, though there might be no external differences in the

appearances of the organisms of the two plants, yet the organisms might have undergone some alterations during the symbiosis with the particular plant, which rendered its action different in each case. He therefore pursued the investigation further in this direction.

CORRESPONDENCE.

Sir,—Mr. W. Nock's remarks on this subject, are very welcome, and at our next opportunity will follow his advice and watch results. I believe the number of bunches on the vines in this last crop, was not such as to fear it affecting the future of the plants; I have seen so many good results from thinning of fruit in general, to neglect the operation or doubt of its usefulness. If it has been proved that doing so will improve the remaining fruit, not only in flavour (especially where saccharine matters are concerned) but also in appearance and still further hasten the maturing of the fruit, this is not, I believe, exactly wanted here, where grapes takes very little more than half the time to mature than it takes in other countries and I must say to great disadvantage of flavour. I have not seen any thinning of the berries in the Continent, nor in Australia, probably I have not seen enough, as there is plenty to see and learn in this cultivation. In countries, where vine growing is done generally on a large scale this could not be attempted. In England where hot-houses and other artificial aids are applied for this cultivation, it is I am aware the practice, and I am quite persuaded that if carefully done by a very light and steady hand, it would benefit the remaining berries. Amateurs or prize fruit growers, should certainly do it for the sake of fine specimen on a small scale, but I don't think the operation as described by Mr. Nock, could be done when vines are grown for market purposes and as a condition *sine qua non*.

Referring to those perfect grapes seen by you in the fruit shops of London, they might not have undergone this thinning process, but more likely owed their lovely appearance to nature, the variety they belonged to and the soil that nursed them.

The Golden Chasellas, that gave us that little fruit this time, is one of the very few varieties allowed to pass as table grapes, having small berries in compact bunches; almost all the others, and the best (every Muscat, Ladies-finger, Gross Colman, etc.) have large bunches with large berries well distributed and ventilated; I could not make up my mind to thin any of these bunches by removing some of their berries, but certainly would remove a whole bunch (when too many on the vine). In removing the number of bunches on a vine I would take care to remove the highest first, the nourishing fluid losing a good deal in water during its run along the wood and before reaching them.

Those vine growers in Victoria who own and cultivate from 10 to 50 acres of table grapes only, and supply a produce which is generally accepted as the pride of Melbourne fruit shops, do not thin their berries but remove bunches here and there, when too heavy a crop is maturing. Such produce they attain by the good varieties they deal with

and good cultivation. The words of Mr. F. M. Bailey, recorded by you on the thinning of fruit, should certainly be studied by all fruit-growers and his advice strictly followed; I do not think, though that his remarks *re*-fruit in the Queensland markets, includes the grapes. It seems to me, this as well as other fruit in bunches, should not be dealt in bulk with others in the thinning question. According to Mr. Nock's remarks it is also evident, that it is an operation which requires training and quite different from thinning of other fruit.

I have with me a volume of 950 pages on viticulture, written by Dr. E. Pollaci, Professor of Botany at Rome's Viticultural College, the leading authority of the day in the Continent. I do not think he would have dealt with the subject, where all those details are given regarding the attentions to be paid to the grapes while maturing, and yet not say a single word in reference to the thinning of berries, though he advises removing whole bunches.

I am, Yours truly,
C. ZANETTI.

REPORT OF MR. C. DRIEBERG, B.A., F.H.A.S.,
SUPERINTENDENT OF THE COLOMBO
SCHOOL OF AGRICULTURE.

The School.

The number of students on the roll was 24, about the same as in previous years, and on the results of the final examination three of the senior students were awarded certificates of merit by the Department. The forestry class, which had been instituted as a sort of nucleus of the proposed School of Forestry, had unfortunately to be given up when Mr. Broun, the Conservator of Forests, went away on leave, as satisfactory arrangements could not be made for its continuance. I am aware that there has been some correspondence between Government, the Director of Public Instruction, and the Conservator of Forests, relative to the cost of the proposed forestry course at the School of Agriculture, and I trust that something definite and favourable to Mr. Broun's scheme has been arrived at by this.

With regard to the veterinary lectures, I would again emphasize the importance of establishing a small hospital or infirmary for animals, to provide students with the means of acquiring some practical experience in veterinary science. The course must always remain incomplete without such means. The hospital, which need not—and indeed had better not—be on these premises, would be almost self-supporting if economically worked on the lines of the infirmary attached to the Bombay Veterinary College and in connection with the Society for the Prevention of Cruelty to Animals.

Agricultural Instructors

During the year I was given the opportunity of visiting some of the stations to which agricultural instructors had been appointed. Before that I had officially no concern with the work of the instructors. The appointments of these officers are generally made on the recommendation or at the request of Government Agents or Assistant Government Agents, who have special schemes of an agricultural nature to be carried out by

the instructors. Such are the appointments of the instructors in the Province of Sabaragamuwa.

The application for an agricultural instructor by a revenue officer may be taken as a guarantee that the operations of the instructor will be closely supervised, with the result that efficient work of a special kind will be done. There are some instructors, however, who, having perhaps been originally appointed on the application of an Agent or Assistant Agent, are at present (owing to changes in the service) left, so to speak, without a patron, and the work of such has generally little to commend it. The position of an instructor is a difficult one. He is appointed on a salary of about R30 or R40 a month, and is expected to establish a model garden, getting, if possible, the help of the boys of the nearest village school, where he has also to teach the Agricultural Primer published by the Department; the place to which he is appointed is generally a remote one, and without strong official patronage there is little opportunity for his doing useful work; he frequently experiences difficulty in obtaining a suitable site for his garden, and having secured one, all the necessary expenses of cultivation have to be met by him; there is generally no market for his produce; and, what with lodging and boarding himself, he finds, if he attempts to maintain a well-stocked garden of any pretensions, that he is out of pocket at the end of each season. But when an instructor receives no help or encouragement from the higher officials and villagers show no interest in his work, and when he finds that his garden is not regularly inspected, he would appear to lose heart, and begin to think that it would be best to try and save something for himself from his salary, while keeping up an inexpensive show of a few plots stocked with easily grown native vegetables. The experiment of sending out Government paid agricultural instructors has, I think, in the main proved a failure, and been the indirect means of bringing much discredit on the School. Whatever may have been the original intention of the appointments (presumably the popularizing of an improved system of paddy cultivation) and the provision for maintaining the work of the instructors at a satisfactory standard, it cannot be denied that their continuance is not justified by present circumstances. In saying this I do not mean to deprecate the appointment of instructors for special work under the direct control of revenue officers. It is for the present sufficient, I think, that the Government provides the means of a cheap agricultural education to the natives of the country without also providing so-called instructors, who, with vaguely defined duties of doubtful utility, need special arrangements for the inspection of their work. The expenditure on maintaining instructors would, in my opinion, be better utilized in the encouragement of native agriculture by the offering of awards for superior produce and stock and careful cultivation, in connection with a scheme for holding agricultural shows, which are recognized in rural economy as strong incentives to activity, a ready means of testing the possibilities of soil and climate and the capabilities of the cultivator, and as convenient centres of

communication where much useful knowledge is disseminated.

The Government Dairy.

On 1st January the dairy herd was composed of 79 cows, 46 calves, 1 stud bull, and 2 draught bullocks. During the year 7 Sind cows and a stud bull of the same herd were purchased locally for R1,250.

At a public sale held at the dairy on 12th July the following animals and utensils were sold: 12 cows, 15 calves, a butter churn, and a milk churn. The amount realized by the sale, after deducting all expenses connected therewith, was R1,267.23.

During the year the number of calves was increased by 44, and 10 succumbed to ordinary calf ailments. So that on 31st December the herd was composed of 74 cows (64 Sind and 10 Coast cows), 65 calves (33 male and 32 female), 2 stud bulls, and 2 draught bulls, the total number of animals in the herd thus aggregating 143.

The net profits on dairy produce for the first half-year were only about R70, the working during some of the months resulting in heavy loss, as, for instance, in March, when the loss was nearly R280. This is solely to be attributed to the effects of the outbreak of "murrain" in the previous year, which threw the machinery of the dairy completely out of gear, both by the loss of cows and calves, and by the large number of abortions which followed the outbreak.

During the second half-year the net profits on dairy produce per month exceeded R300, and it is fair to assume that in ordinary working years under normal conditions the annual profits should be about double what they were last year. Indeed the profits of the year, a little over R2,000, are practically the profits on the second half-year's working, and approximate to the net returns during the first seven months of the dairy's existence (June to December, 1893), nearly R2,500. It will in many ways be interesting to compare the working of the Ceylon Government Dairy with that of the Poona Government Dairy. The Superintendent of the latter Institution, Mr. James Mollison, rendered me much help in the first stocking of our dairy, and I have also taken the Poona Dairy as my model in many particulars. It is strange to find how similar have been the experiences of the two institutions, as will be seen on perusal of the extracts from Mr. Mollison's last report given below:—

The financial results are shown in the appended balance sheet. The profit for the year is R266-11-6, as against R2,254-13-2 last year.

The reason why the margin of profit is so small is due to a very serious outbreak of rinderpest during the year. If reference is made to appendix V., it will be seen that 54 cattle died during the year; of these, 1 cow (our best Aden) was poisoned (intentionally I believe), 1 cow died from inflammation of the lungs, and a few calves were lost, as they ordinarily will be. There were 34 deaths due directly to rinderpest, and some calves which recovered from disease died from after-effects. They never recovered their strength though well cared for. The indirect loss due to diminished milk yield in the healthy cattle was probably more than that from death. The disease first broke out amongst unweaned calves, and these had necessarily to be separated from their dams.

The maternal instincts of Indian cattle are very strong, and the effect of separation from the calves upon the milk yield, especially of the buffaloes, was remarkable. The cattle were in full milk at the time, the whole herd giving about 700 lb. daily. A week after the rinderpest appeared the daily yield was about 450 lb., representing a daily loss of R18. It seems to be practically impossible to wean calves at birth from Indian milk cattle unless done when the heifer has her first calf, but the above results point to the necessity of doing so if possible. The carcasses of the cattle that died were all burnt. This, with medicines, cost R266.

The number of deaths was about 70 per cent of affected cases.

* * * *

Cows advanced in pregnancy were hopeless cases. Symptoms of abortion became apparent, and inversion of the uterus resulted in every case. We had a post-mortem examination on one of these cases, and the fœtus was found to have characteristic rinderpest symptoms.

As far as I could judge, careful veterinary treatment did very little good. The most effective medicine was carbolic acid given in gruel, its influence being a healing one on the highly inflamed membranes of the intestines. I believe the cure of cases to have been chiefly due to careful nursing and to drenching the animals with good gruel. The gruel consisted of linseed boiled with rice, fresh separated milk, and water. We got rid of the disease by segregation.

* * * *

The dairy produce from about 70 milch cattle was sold for R15,303, cattle food, fodder, and grazing cost R10,968. There was a stock of fodder on hand at the end of the year worth R1,507. If the dairy herd keeps healthy, there will be no difficulty in any year in making the dairy a profitable institution. The price of dairy produce supplied to the Commissariat Department for sick soldiers in hospitals is lower than the rates charged to the public. The latter rates are fixed purposely higher than the rates of private dairymen in Poona. Yet we could sell to private families to a much greater extent than is done now if there was an available supply, which there is not.

It would appear from Mr. Mollison's report that the milk produced by the healthy cattle during the prevalence of cattle plague was sold, but this was not permitted at the dairy, which had been declared an infected area by the Municipal authorities; so that the loss occasioned by the reduction in the output of milk has to be increased by the value of the produce of the healthy cows, which, in terms of a local Government regulation, had to be thrown away. The total loss to the dairy in this way has been estimated at R8,000. For purposes of comparison, I may mention that the loss in cattle to the dairy through cattle plague was 17 cows, 18 calves, and 2 bulls, or 37 in all; while the profits including the revenue from sale of cattle in 1894 (the year of the murrain) was R364.88. The dairy practically supplies only Government institutions with milk at the rate of 18 cents per bottle of 26 oz., but when there is any surplus of milk this is sold to the public at 20 cents. There are constant applications for milk from the dairy on the part of the public (proving that a good business could be done in this direction), while the dairy authorities are frequently asked to select and purchase cows for private parties.

At least one dairy has been established on the lines of the Government Dairy, and there is a likelihood of more springing up now that greater confidence is being engendered by the success of the Government establishment. As already stated, the revenue from sale of cattle last year was R1,267.23. If this amount be added to the net profits on dairy produce alone (R2,161.50), we get the total of R3,428.73 as the net profits on the transactions of the dairy for the past year.

In concluding this part of my report I must not omit to place on record the good work done by Mr. Rodrigo, the Manager of the Dairy.

GENERAL ITEMS.

To clean cereal seed before sowing, it is a good plan to shake it in a sieve with meshes small enough to retain the cereal seed but permits most weed seed to go through.

To prevent crows pulling up newly sown corn it is advised that after placing the seed in a box, boiling water should be poured over to heat it and a small quantity of liquid coal tar sprinkled. The mass should be shoveled until the tar is well distributed over each seed; then dry it off thoroughly by sprinkling on some fine dry plaster or earth, and working the mass over until every seed is covered over with the drying substance.

The N. S. W. Agricultural Gazette states that the explanation given with regard to the splitting of the skin of fruits is that is caused by a sudden rapid increase in the growth of the fruit which is not accompanied by a corresponding growth of the skin. This often takes place when rain falls after a long dry spell, during which the natural growth of the fruit is checked. The remedy, therefore, is to apply water to the trees when it is seen they are beginning to suffer from drought, and so maintained a constant and regular growth of the fruit."

In bulletin No. 24 of the Texas experiment station, the following occurs under the head of "measures to destroy the ticks." Almost any greasy or oily substance applied to the parts affected will destroy them. I failed with a decoction of tobacco, and also with crude petroleum. A combination of lard and sulphur or lard and kerosine gives good results. Kerosine emulsion of 10 per cent does fairly well. At one time I entertained a high opinion of this preparation, but later experiences have failed to fully satisfy the demands.

We have found nothing that gives so general satisfaction as several brands of sheep dip that are on the market. These were applied at 2 per cent strength in water. The ones employed by us were Cannon's Hayward's, and Little's. There are others, perhaps, of equal value. The qualities that these possess are efficiency, cheapness, ease of application, mixable with water, non-poisonous, non-irritating or injurious to eyes, skin, or hair, stability, uniformity of strength, non-corrosive to apparatus for application, and no heating required.

[No. 5.

COFFEE GROWING IN PERU

Since more engaging attention: *Engineering* of August 21st has an interesting paper with "Estimates" referring to coffee planting in the valleys of the Chanchamayo and Perené, about which, a great deal can be learned in "Old

Colonist"'s book. I send you the paper for reproduction. "Old Colonist" will especially agree with the writer in describing Peru as one of the most favoured of countries in natural resources and climate—and only wanting an able Governor—a "Porfirio Dias" who has done so much for Mexico—to release her from being the victim of "political jackals"! The want of a proper labour supply is another drawback owing to the inveterate laziness of the *Cholas* (Indo-Spanish) who might do much to develop their country if they would only work. As it is, however, the estimates given for coffee gardens—on a small scale, however—shew such returns as would pay back all the capital outlay in the 6th year and leave an annual income thereafter of over £800 sterling from 20,000 coffee trees covering 10 "hectares"* of a "Chacra" or coffee garden.

Four weedings or clearings a year are provided for and yet the coffee trees are only given 20 years of life if kept clear of weeds! Surely with care, 40 years might be counted on.

The valleys of the Chanchamayo and Perené, which were described in *Engineering*, vol. lviii., pages 474 and 507, are developing such importance as a coffee growing region that it may be of interest to give an outline of the work of developing *chacras* in that part of the world. The following details have been gleaned from several of the persons interested in coffee culture in the Chanchamayo valley, and as all the districts on the eastern slope of the Peruvian Andes are worked in the same manner, the one illustration will apply to the whole territory.

To claim land for the purpose of cultivating it for coffee or other produce, it is necessary to "denounce" it before the Prefect of the Department. The person requiring the land must make his own survey and send in a plan with his petition. The land is divided into lots of fifty hectares (about 123½ acres), and the smallest claim that will be entertained is for one lot. On the other hand, if more than a certain number of lots are required, the petition must be made direct to the National Government.

There is no fee required, but the "denouncements" are usually written upon stamped paper, which, although not compulsory, saves considerable trouble in the future. It is also well to know how to shake hands with the officials properly, for they can do much to smooth the path of a land hunter and can place no end of obstacles in his way, if the interchange of animal magnetism is not carried out, through some metallic conductor, the colour of which has much to do with the intensity of the interest developed. One of the greatest impediments to the rapid development of the district is the want of official maps. The Government has utterly neglected this most important duty, and there is naturally a certain want of confidence among the people who would take up land, because they are afraid that in the future, when the boundaries have to be adjusted, the independent surveys will be found to have mixed up neighbouring properties. The Government does not even take measurements at the time of giving Possession of the land to the claimant, so that the dividing lines have to be adjusted by the parties themselves. It is therefore more than probable that, as the district becomes more thickly populated, quarrels as to location of dividing lines will arise, and the lawyers will reap a rich harvest as soon as the season for litigation comes around.

Peruvians are for ever complaining of the poverty of the country, notwithstanding the fact that it is one of the most favoured in natural resources and climate. They have no one to blame but themselves. The Government at the capital is too busy fomenting or combating internal quarrels, and the interest of the people, who are really keeping the Republic alive, are relegated to the charge of tiptaking officialdom

* The hectare equals 2.471 English acres.

whose combination of craft and ignorance is sufficient to ruin the richest nation on the face of the earth. When Peru finds her Porfirio Diaz as Mexico has done, she will advance, but as long as she is the victim of political jackals she cannot hope to take the position among nations that her undoubted natural wealth should give her.

The configuration of the Chanchamayo valley is admirably suited to the cultivation of coffee. On the slopes of the hills the temperature is just that required, and there is very little liability of the water lodging at the roots of the trees during the rainy season. In flat lands the humidity caused by too much moisture is detrimental to coffee plants, hence the advisability of selecting territory that has sufficient slope to insure perfect drainage. A sharp declivity is also bad, because the heavy rains cut away the subsoil rapidly and soon render the cleared hillsides sterile.

Deep soil is also necessary for the coffee plant, in order that its roots may develop to their fullest extent. For this reason the lands lying immediately on the banks of the Chanchamayo river are unsuited to the cultivation of coffee, the soil being clayey and shallow. Besides this, the low valley lands abound in ants, which would soon attack and devour all the young plants.

Water is plentiful, as can readily be understood, and it can be conducted to nearly all the hill slopes with but little trouble or expense. Therefore, while for coffee cultivation artificial irrigation is unnecessary, or, in fact, not of much value, it can be utilised for other plants, such as those used for immediate consumption; and those intending to take up lands should always keep in mind that the water will have to be used for power when the time comes to put up machinery, &c., for preparing the coffee for market. At present all the machinery in the valley of the Chanchamayo is driven by water power, of which there is an abundance in the different rivers and streams.

The rains are heavy during the months of December, January, February and March; mists known as *aguaceros* are experienced in October, November, April, and May, and the other four months are completely dry: not dry as is known in England, but so dry that everything is parched up as if subjected to the heat of a great oven, the coffee plants lying solely by the moisture they are able to take up by their deep roots.

The question of labour is one that will have to be seriously faced very soon. Even now, at the very beginning of the development of the district, it has become necessary to enlist *chacra* hands in the more distant towns of Huancayo, Jauja, and Tarma, because the labour element of La Merced has thinned out considerably, and many of the workmen (?) prefer to live in a state of idleness than to do anything to help along the rising industry of coffee culture. The *cholas* (mixture of Indian and Spanish) who are brought from the towns on the sides of the mountains cannot stand the change of climate, and are for ever pining to get back to their homes again. It is really aggravating to see this human species sauntering about with their hands thrust in their pockets, totally oblivious to the fact that if they withdrew them and worked they would better themselves. They are a lazy lot, and will only work when they are captured like wild beasts and sent to the capital handcuffed, for the purpose of filling the ranks of the different regiments. Then they become abject slaves, and fight without really knowing what they are killing each other for. The sooner their generation passes away the better it will be for the country's welfare. Compared with the *chuncho*, or full-breed Indian, they are worthless as hands in clearing territory for coffee. The latter know how to use the axe and machete with great skill, and are used to work in the dense woods. However, as the *chunchos* are so few, the others are acceptable on the principle that they are better than nothing.

Their pay varies according to the distance they have to come, and ranges from 50 cents to one sol

per day. There also exists a certain custom of giving them three *copas*, or drinks of *chacta*, per day. *Chacta* is a strong liquor made from the sugar cane, before which the whiskey of the Indian outposts in the States would have to retire to the list of temperance beverages. They are also provided with a place to sleep in. The food they provide themselves; but if the owner of the *chacra* engages to supply them, he deducts 25 cents per day from their money. The *chuncho*, as has been stated, are much more to be preferred as workmen when preparing the land. They are perfectly acclimated, since they inhabit the adjacent forest, and they have not that constant anxiety to go to their homes. Arrangements with one or more of them can be made to clear a certain area of land, they taking in exchange all kinds of trinkets and articles, among which the shot-gun is the most highly prized. They also require their own *copas* of *chacta*, but do not require sleeping quarters, as they go to their homes every night.

When a *chuncho* takes a contract to clear a certain piece of land, he takes his own time to do it. When he goes to work, he does not play with the axe or machete—he works hard: but he may not turn up again for a day or two. If there are any shot-guns mentioned in the contract, however, the *chuncho* knows no rest until his work is finished and he receives the coveted prize. One difficulty with them is their language. But few of them understand Spanish, and it is necessary to have an interpreter: unless, indeed, the subject discussed is *chacta*, and then they can make themselves better understood by signs than they could through the most eloquent intermediary.

Referring to their love of the shot-gun, it can be said that they know the use of it very well, and some of them would be considered fair marksmen. They are, as is natural born hunters, and make good camp suppliers if they do not take into their heads to leave for parts unknown, with the shot-gun loaded them for the purpose of hunting. One of them, who understood Spanish, was asked how he managed to bring down a *pavo del monte* (Mountain Turkey) so soon after leaving camp. He immediately went through a species of performance illustrating his crawling through the undergrowth until he saw the bird. He then sat down and gave a perfect imitation of the turkey calling its mate. He wound up the exhibition by saying "*Cara blanca* (whitface) tries to go to Turkey. Turkey knows too much, so *cara blanca* has to travel very far, and when he makes a noise off goes the bird. I see my bird and then call him. He comes to be shot, and—boom!—down he goes. *Cara blanca es tonto.*" The latter remarks are not complimentary to the paleface, being capable of abbreviation into Anglo-Saxon monosyllables.

Taking the work of the *cholo* by day hire and that of the *chuncho* by contract, there is an appreciable difference in favour of the latter, not counting the fact that there is a saving also in the trouble of superintendence. It is therefore a great pity that their number is so small, as their service could be utilised to great advantage.

There is another way of accomplishing the work of establishing coffee *chacras*, which is adopted by those having capital and who do not wish to undertake the work of clearing and planting themselves. It is by the employment of what are known as *mejoreros*. The *mejoreros* are men to whom the lands are handed over for a term of four years. They are also given the necessary tools, and are supplied with food during the whole period. At the end of the time stated they return the *chacra* to the owner in a perfect state of cultivation, the trees being sufficiently advanced to bear their first crop. The owner then pays them at the rate of 15 cents per plant, first deducting all the advances made for food, &c., nothing being omitted. A strict account of the advances is kept by both parties, and the balance is handed over to the *mejorero*.

There are some *mejoreros* who will take charge of the land for six years and not require any advances in the shape of provisions, &c., their profit being obtained from the crops between the fourth and sixth years. This, as can be imagined, is a good arrangement for the *mejorero*, as he will receive a large sum from the sale of the coffee. It would naturally be supposed that those men would open up their own *chacras* and permanently enjoy the fruits of their labour, but very seldom is this the case. When they have a number of *chacras* on hand, the deductions on account of provisions, &c., are very small, and they then make a handsome profit.

From an economical point of view, the employment of *mejoreros* appears much the cheaper way of obtaining a fully developed *chacra* with the least amount of attention; but it also has its drawbacks, due in the main part to the instability of the people with whom one has to deal. The operations necessary to prepare the land for the cultivation of coffee are as follows: First, the *rocc* or felling of trees and cutting away of the undergrowth is done. This is the most laborious work, and needs men that not only know the use of the axe and machete, but also those accustomed to working where there are numerous venomous snakes and insects. The *chaupco*, or cutting up the branches and preparing the brush for firing, is then gone through. When the dry months set in, and everything is like tinder, the fire is applied and the whole area well burned. The ground is then cleared and the *calles* or streets formed, so that the plants can be located at equal distance from one another in regular order.

There are usually a large number of tree trunks left unburned, and these have to be cleared away, and also the roots extracted where necessary. The number of men employed will depend entirely upon the area it is proposed to put under cultivation, and it is difficult to figure with any degree of approximation the amount of labour that can be counted upon from the *cholas*. Their willingness to work is in inverse ratio to the cube of their capacity to absorb *chaeta* and sleep.

As the burning can only be carried on during the dry months, the work of clearing generally extends over the whole year; but that time is not lost, because the young plants are maturing in their nursery in the meantime.

Taking 50 cents per day as a basis for labour, the estimates of the different processes would be:

	Soles.
<i>Rocc</i> and <i>chaupco</i> per hectare (about 2½ acres)	65
Burning the rubbish	.. 12
Making streets in which to plant the young trees	.. 25

(The gold value of the sole is 2s. 21.)

When the above operations are performed, the land is ready for the *almacigo*, or transplanting the young trees. It is not customary to sow the seeds direct first because one year would be lost and secondly, as the fruit contains two seeds, the sprouts would have to be separated when they had developed, a process that would disturb and perhaps destroy the roots of the plant left standing. The seeds are therefore sown in a selected piece of ground before the clearing of the land is started, and the plants are ready, as has been stated, by the time that work is finished. The seed should be planted where there is no shade, because if the young plants are developed under the cover of the branches of other trees, they must be placed in a similar position when transplanted, otherwise they will suffer from the change to the light and direct rays of the sun. The distance generally fixed between the trees in the *streets* is 2 metres, so that each hectare will contain 2,000 plants.

The seed is the cherry, which contains two beans, each of which develops into a plant. These can be purchased at the rate of ten soles per quintal (21s 3d per 100 lb.). The expense of the nursery is very small, as the seeds are sown close together until the time for transplanting arrives. It is usually

estimated that the plants cost one cent each. The transplanting is done at the beginning of the rainy season, that is in November or the early part of December, and is a delicate operation, as the young shoots are very tender and will not stand much handling or rough usage.

The grounds, when planted, need four cleanings per year, which is estimated at 40 soles per hectare per annum. The harvest time commences in April and concludes about the end of August. The cost of collecting the fruit and preparing the coffee for the market averages about 80 cents for quintal (10½d. per 100 lb.), the machinery, tanks, &c., being considered in the general estimate.

The first crop of coffee is taken in the fourth year, and averages 1½ lb. per tree. After that the average of 2 lb. may be considered a fair one, as in some years they give less and in others much more.

After being cleaned, the coffee of this particular district holds good for about three months, after which it begins to bleach and get parched. It is therefore necessary to ship it at once to market. The prices paid in La Merced, at present, vary between 26 and 28 soles per quintal (Spanish), but it is best to place the figure at 26 soles for the purpose of estimating. The cost of production may be stated at 12 soles, without reckoning interest on the capital. The life of a tree is about 20 years, that is, if it is constantly attended and kept clear of weeds, &c.

Taking 10 hectares as a *chacra* containing 20,000 trees, it will be seen how much expense is necessary to put it under cultivation, and how much profit there will be in five years, by the following estimates, which are based upon the practice of the district:—

	Soles.
<i>Rocc</i> and <i>chaupco</i> 10 hectares at 65 soles	650.00
Burning " " " " 12 " "	120.00
" Street " making " " 25 " "	250.00
Cultivating and transplanting 20,000 plants at 1c	200.000
Cleaning land, &c., four years at 40 soles	1,600.00
Harvesting and preparing 700 quintals at 80c.	560.00
Construction of house	100.00
Tools, &c.	200.00
Construction and repair of roads ..	250.00
Maintenance, five years at 35 soles per month	2100.00
	6030.00

Dividing the invested capital into four parts, and considering it at simple interest of 18 per cent. (the present bank rate):

	S.	S
Interest on first portion ..	1507.50	= 271.35
" second " ..	3286.35	= 591.54
" third " ..	5385.39	= 969.37
" fourth " ..	7862.26	= 1415.20
	Total interests	3247.46
	Capital	6030.00
		9277.46
		Quintals.
Product of 20,000 plants at 1½ lb., fourth year		= 300
Product of 20,000 plants at 2 lb., fifth year		= 400
		700
		S.
700 quintals at 26s.	=	18,200.00
Capital and interest	=	9,277.46
		8,922.54
	Net profit ..	8,922.54

For the years following the fifth the annual figures would be as follows:—

	S.
Cleaning (weeding) land ..	400 00
Harvesting, &c., 400 quintals at 80c.	320 00
Tools, &c. ..	25 00
Road repairing ..	50 00
Maintenance ..	420 00

	1215 00
Interest at 18 per cent. ..	218 70

	1433 70
Product of 20,000 plants at 2 lb. =	S
400 quintals at 26s. ..	10,400 00
Total expense for one year ..	1,433 70

Profit ..	8,966 00

It will now be seen that by employing the *mejorero's* services there is a large saving, for they will have to pay the latter 3,000s. for 20,000 plants in their third year, and will not have all the expense stated in the above estimate.

Contracting the land out of his possession after six years would mean that the *mejorero* obtains a large profit, for the expenses would be 10,711.16s., while the receipts for coffee would reach 28,600.00, showing a clear profit of 17,888.84 soles.

The sale of the coffee at a La Merced is practically compulsory, because there the people have facilities of sending it on mule-back to Tarma, or to Arroya, where it is transferred to the train for shipment to Callao. To endeavour to send the coffee direct to the shipping port would under the present circumstances be simple madness, as the competition of the carriers would soon ruin any one who made the attempt, unless he was backed by plenty of capital. It is sad to see a territory so rich utterly neglected by a Government that is striving to keep its head above the sea of financial difficulties in which Peru has been drifting. Nothing has been done to improve the means of communication with the outer world, and therefore there are no inducements offered to people to go and take advantage of the resources that lie within a comparatively short distance of the coast line. The district is developing, it is true, but it is doing so against all the drawbacks that could possibly be encountered: an indifferent Government playing into the hands of those who place obstacles in the way of advancement, in order to reap all the benefits of the labour of others.

(To be concluded.)

CARDAMOMS IN COORG.

The Cardamom cultivated in Coorg is the *Elettaria Cardamomum*, and although the trade, so far as native cured fruit is concerned, is steadily falling, still the cardamom is an important article to the people and is certainly the cause of much thought and anxiety to the Administrators of this little Province.

I will not give any botanical description of the cardamom in this article nor will I refer to the other kinds which are not utilised, but endeavour to give an idea of the habitat of the plant and the methods of curing it followed by the people, with a few remarks on the state of the cardamom trade.

The cardamom grows best on the Western and Northern slopes of the ghats at an elevation of from 3,000 to 5,000 feet above the sea. Here the full burst of the monsoon strikes the steep sides of the hills and the rainfall reaches as much as 300 inches in some parts. It grows spontaneously but is one of those peculiar plants, the seed of which lies dormant till induced to germinate by the occurrence of certain conditions. One of these is the admission of light. Cardamoms will only be found in the dense evergreen forest, and the ordinary method of inducing them to appear is to open a small space in the forest by felling one or two very large trees. Not only does this admit the light but the fall of the trees shakes the ground and breaks the surface. So thoroughly is the necessity for the shaking of the ground believed in, that when a plot is selected, all undergrowth, small trees, &c. which might interfere with or break the fall of the gaint selected for destruction, are cleared away so that the tree may descend with all its weight and momentum: and to intensify the effect the tree is always felled so as to face down hill. As these plots are almost

invariably situated on the steepest hills, the effect of the fall of one of the enormous trees so common in the Ghat Forests must be very grand.

A Cardamom Estate is called a "male" and the ordinary method of cultivating a "male" among the Coorgs, is to open out a certain number of these plots within the limits of the same. The plots are necessarily small, for only a limited amount of light is required and a plot too large, in addition to admitting too much light, would also allow of evaporation from the soil to an injurious extent. In the leases given for "males", the maximum size of each plot is fixed at one-sixth of an acre and at least thirty feet of forest must be left between any two plots. As a rule not more than two trees are felled and oftener only one. The felling generally takes place in February or March in the year and by the rains the young plants shoot up. They require weeding at least once before they begin to yield, which takes place in the third year. The plant continues to bear for seven or eight years, the fourth and fifth and sixth of its age being its best. When it begins to cease bearing, either a new plot is selected or another tree is felled which seems to give a fresh start to the plant.

The position of these "males" is generally so remote and inaccessible that the picking of the crop is undoubtedly no easy task. In fact, the Coorgs lose a large proportion of the crop, for the fruit begins to ripen as early as July, while they never attempt to pick before well into September. The tremendous rainfall not only, in itself, deters them from penetrating the hills, but renders the numerous streams and torrents impassable. Indeed, on the exposed slopes of the Ghats, life wood scarcely be liveable in the height of the monsoon. As it is, the leeches in these forests throughout the autumn and cold weather months must be seen to be appreciated, and in addition to these drawbacks, the steepness of the hills is such that walking is difficult. When climbing about these "males" one can quite comprehend the feelings of a fly walking of the side of a house.

The cardamoms are picked and sun-dried. If the male is far from the village, the drying takes place on the spot, otherwise the capsules are taken home. Four days sunning is sufficient, care being taken that they do not get wet and that they are not over exposed, as this latter would cause the capsules to burst. But beyond this open air drying, no further curing takes place. The fruit stalks are rubbed or picked off. In this part of the process, it is wonderful the number of capsules a practised hand will clean in any given time. The capsules are then assorted according to size and colour and stored away till disposed of. But a better system of both cultivation and curing has been introduced into Coorg by an English planter in the ghats. I am much indebted to Mr. Finlayson for his having put at my disposal the necessary information concerning his treatment of cardamoms. In the first place, the cardamom plant is raised from seed in a nursery and the plants are put out in a compact plantation, instead of being allowed to grow spontaneously in scattered clearings. The first step is to prepare the area which is to be made into a cardamom plantation. This is done by thinning the shade. The amount of thinning can only be determined on the spot and is guided by experience. The aspect chosen is generally North or North West and the most favourable places are the moist hollows and ravines. The undergrowth is cleared, and planting is done in June and July, from nursery plants raised from seed, supplemented by bulbs from old stools, Mr. Finlayson prefers the latter as growing better. The plants are put out at 7 feet by 7 feet, not deep in the soil. The plants are put into shallow pits which have been filled with surface mould, the soil is pressed round the half exposed bulb and the plant tied to a stake.

These Cardamoms yield a small crop the third year after being put out and they do not come into full bearing until the fifth year, thus there is

no advantage in time in this method of cultivation. The yield then is about half a seer to each plant. Thus an acre would give about 475 seers, or say 950 pounds; under half a ton. The picking lasts from July to January, September and December being the busiest months. The first crop always yields the largest fruit.

Before proceeding to give Mr. Finlayson's method of curing, I will venture on a comparison of the advantages resulting from the two systems of cultivation, the native one by means of isolated and scattered openings in the forest, and the English one of a regular plantation. As to the former, the only advantage that can be claimed, and I am not certain that the claim should be allowed—is that it does less harm to the forest which, as the Ghaut Forests should be preserved for climatic reasons, is a very important point. Mr. Dickinson, whose knowledge of the conditions of cardamom cultivation owing to his personal inspection of the males and ghat forests is unique, is in favour of the native method on the ground of less damage being done to the forest. He argues that the partial clearing of the high forest over a comparatively large area accompanied by the removal of the undergrowth, tends to set up scouring and that the soil will be all washed away. But the drawback to the native system is the difficulty of supervising the work and of enforcing the rules as to the size of the plots and the width of the belt of forest to be left between each plot, and though it is in the interest of the male holder not to open the forest to too great an extent, it is a question whether, with the low prices ruling in the cardamom market, the urgent necessity of raising a large crop will not, and does not, tempt male holders into over-felling, leaving the future to look after itself. Where a forest has been over-felled under the native system, the damage is practically irreparable. It is with very great diffidence that I differ from one so well up in the subject as Mr. Dickinson, but I have seen both systems of cultivation and taking all the conditions obtaining, I am decidedly in favour of the English method of cultivation, as it is more easily and effectually supervised, it concentrates the damage done into a smaller area, the crop is more easily and more cheaply picked and the whole working of the estate more in accordance with science.

Mr. Finlayson dries the capsules partly by exposure to the sun and partly by artificial heat. The former is the better method, but, owing to the uncertainty of the weather, the latter, in the end, pays better. The cardamoms are bleached by exposing them to the dew for a couple of nights and then fumigating them with sulphur. Mr. Finlayson is naturally somewhat reticent as to the process his cardamoms pass through, for the supply is large and the market restricted and the competition from Ceylon, Travancore and Mysore is keen. Before picking, the capsules are carefully sorted and clipped. I am unable to give the cost of cultivating, picking and curing the cardamom under this system. It is finally packed in boxes and sent to the market.

The price of cardamoms has been steadily diminishing of late years, Rs. 14 to perhaps in a few instances Rs. 18, per maund of 28 lbs., is the average selling price of native cured cardamoms. The English cured sell from Rs. 1-8-0 to Rs. 2-4-0 per lb. The system in force in the days of the Coorg Rajas as regards the disposal of cardamoms was that the whole crop was handed in to the Government, who paid the cultivators a fixed price per maund and sold the crop for itself. The price paid was from Rs. 12 to Rs. 20, per maund. This was continued after the annexation of Coorg until 1846, when the males were put up to auction and they are now leased, tenders being invited for a certain period of years. There is another class of male in Coorg the Jama male—the holders of which have a right to the produce on payment of rent which is assessed on the estimated yield.

The prospects of the native cardamom cultivators are extremely gloomy. Owing to several causes, the cultivators have been having a bad time of it lately. Falling prices, the enfranchisement of their slaves which necessitates payment of labour, and bad seasons, have all combined to render it impossible for many of the lessees to pay the rent they covenanted to six years ago. So bad has been their condition that the Local Government has had to allow a large number to resign and the condition attached to the acceptance of the resignation *viz.*, the payment of all arrears, has been found difficult to enforce.

It is a matter of extreme regret that a comparatively large number of families should lose their principal means of livelihood, but it is useless for the State to endeavour to oppose the laws of economics. Want of capital prevents these small male holders from cultivating and curing their cardamoms in a paying way. The outturn is so poor in quality that it necessarily fetches a very low price when the beautifully cured capsule of the English grower is competing with it, and the problem will soon work itself out with this result, that the producers of native cured cardamoms will become fewer and fewer, until the produce they put on the market only suffices for the demand. For, strange to say, despite its inferior value and condition, there is still a demand for this kind and always will be, as long as there are people who, though desirous of purchasing, can only afford to pay low prices and must therefore, perforce, put up with an inferior article. The slow extinction of the male holder is a serious loss to the Forest Revenue, but, I fear, go he must, and the Department must look around for some fresh source of revenue to make us the deficit.

G. H. FOSTER.

Indian Forester.

SILK FROM TIMBER.

Applied science is rapidly undermining the few scraps of sentiment that are still associated with our daily life. The scents that we fondly imagine to be distilled from the sweet breathing children of Flora are in reality extracts from coal tar, and even worse. The raspberry flavour in our confectionery is a product of benzol, with a name about thirty syllablos in length; essence of pineapple is just acetate of some dreadful hydrocarbon compound. Finally, our silks and satins, once spun from the dainty gossamer of the silkworm, are henceforth to be got (paradoxically) from cotton, sawdust, timber, wood pulp, and such like unsentimental sources. The Society of Chemical industry met and gloated over this last fact the other evening. The process has already made such strides in France that many of the extra-gorgeous silks in Regent Street this season are said to be spun from liquid timber. Science is never content with equalling nature; she likes to go one better, and so the new timber silks are much more glossy than those of the ancient worm and take richer shades of (aniline) dye. It is interesting to learn, however, that in nearly every detail of his new silk-making process the chemical engineer has simply imitated nature. The gossamer of the silkworm, the spider, and the rest of the spinning invertebrates is really nothing but a kind of natural liquid gum or varnish exuded from fine pores of microscopic aperture. If you want to see how a sticky liquid can be drawn out into threads you have only to dip a needle into treacle or syrup, and pull it gently out again, slightly twisting the sticky thread at the same time. Only, the sticky threads that ooze out of the spinning ducts of the silkworm are so fine that you can hardly see them without a lens, and they have the advantage of instantly drying into a delicate elastic fibre. When a considerable number of these are twisted together we get the well-known filament which the silkworm uses to wrap round her cocoon and the spider to weave her web.

Now the chemist has imitated this sticky fluid which is so easily drawn into microscopic threads and instantaneously dries as it escapes into the air. He first of all prepares a kind of gun-cotton by treating cotton or wool-fibre with nitro-sulphuric acid, just as if he were going to make smokeless powder, or celluloid, or other lovely modern product. Then he stews this in cylinders for some ours with alcohol and ether, which practically converts it into collodion. The latter emerges as a sticky fluid, like thick gum. This is pumped through pipes to spinning machines, and emerges at each machine from a fine glass nipple. Each nipple answers to one of the pores of the silkworm. Some ten or twelve delicate threads are drawn from these nipples, combined together and spun into a thread no thicker than human hair. You have now a fine tough thread composed of a sort of dried gelatine, which is somewhat akin to the nitro-gelatine employed for blasting purposes. It would never do for ladies to go about in explosive or at least highly inflammable stuff of this sort for obvious reasons. So the "silk" is next, "de-nitrified," which puts it all right, and it is then stretched and "ironed" until it takes on even a higher gloss than the natural article. Then it is handed over as yarn to the weaver, and we need not follow its further progress, which ends in the costumer's window. All this seems to clover that one can hardly believe it. But there is the silk actually on the market. It is nearly as strong as natural silk and a great deal cheaper, although we don't suppose ladies will find the difference in their dressmaking bills. The home of this novel manufacture is at present at Besancon, in France, but they are building large mills for it in Lancashire.

TO THE EDITOR OF THE "DAILY GRAPHIC."

Sir,—I have read with interest your leader on "Silk from Wood," but unless the process you refer to is very different from the last two or three patents taken out, I am afraid it will prove a fiasco. I speak from experience, having used for the last thirty-five years silk of all sorts and I maintain that it is impossible to get an artificial silk yarn out of wood pulp.

The process is very ingenious, and the results in the "yarn" are very good, and, as you say, take the dye better almost than the real article. You say "English ladies are even now adorned with artificial silk." I doubt this very much. Would you be surprised to hear that we have given sample orders months ago for this or similar yarn, and cannot get it? Not that orders are too plentiful, but that the yarn cannot, and has not, been produced in mercantile quantities.

As to the price quoted, it does not compare very favourably with silk, which, as every one knows, is at almost the very lowest point ever known. Had this patent come out about 1871-5, when silk (say *Ital. Organ*) was at 44s. per lb., instead of now at 17s. 6d. to 18s. 6d., it might have had a change. But, apart from the price, the main value of silk is the length of its fibre, and consequently its strength. Your estimate of 4.5 to 5.5, weight for weight and length for length, I take to be quite out of the question. There are a great many objections to this yarn. It is practically gun-cotton. What about a lady getting her dress on fire? The fibre—if you call it fibre—is so short that when once creased the mark will always be there; and there are many other objections that perhaps only a practical manufacturer can appreciate.

I may say that personally I have no prejudice against the yarn. If it fulfils all the objects the makers say it will I shall be only too glad to use it. But I have never yet seen a "silk purse made out of a sow's ear."—Yours faithfully, A. NORRIS. Manchester.—*Daily Graphic.*

THE LAST CINNAMON SALES.

We are glad to find from the particulars which have come to hand by the last mail of the quarterly sale held in London on the 31st ultimo, that the prices of our famous spices were fully maintained. It is more than a year now since there was a great rebound upward, mainly caused by speculation, when the lower sorts of cinnamon fetched unprecedented prices—at any rate, prices which were unheard of for 20 years at least—and even shot ahead of the finest growths, which had always commanded top prices in the London market. It was this last circumstance which placed beyond doubt that the rise in prices, of the inferior sorts certainly, was artificial, and suggested fears that the sales would be repudiated on prompt day. Whether any sales proved to be bogus on settling day or not, we have not been able to ascertain; but it was satisfactory to note that the apprehensions regarding the demoralization of the market and the violent oscillation of the pendulum backward, were not realized. If the artificial prices were not maintained at the following sale, the prices did not slip below normal; there was no throwing back on the market of lots which had secured fancy bids, with the result of disorganization and loss of confidence in the trade. On the contrary, inferior sorts made a distinct advance on the prices which had ruled for years, and this advance has been maintained since, at every subsequent sale; while the finer sorts have held their ground, if they have not shown an appreciable advance. Indeed, the present relation in prices paid for fine cinnamon and ordinary, strikes us as more natural and reasonable than that which had obtained for years, and which secured for carefully-prepared fine quills about double the price which the identical bark, not so skilfully manipulated, fetched. The conclusion we draw from the establishment of this relative position, and from the maintenance of fair prices for the commoner kinds of cinnamon, is that there is now a healthy and growing demand which keeps pace with the supply, and that long-suffering cinnamon proprietors have at last turned the corner, from which a better outlook is visible.

The quantity of spice offered for sale last month was not heavy—only 779 bales; but then the August sales are always light; and, though the figures compare badly with those for May, when the offerings were as high as 1,743 bales, they were better than those for August last year, when the quantity brought to the hammer was only 677 bales. Almost the whole quantity offered found buyers in the room, and the few bales that remained, we have little doubt, were, as usual, disposed of privately at current figures. These prices were satisfactory all round—no sort or quality showing a decline, while most qualities showed an advance. The Goluapokuna mark asserted its prescriptive right to head the list, with 1s 4d for its firsts. This is the same figure as its firsts fetched at the previous quarterly sale; but last month its fourths realized better prices than at the May sales held on 1st June. The highest qualities of Wester Seaton, Kimbulpitiya, and Mudaliyar Rajepakse's marks secured an advance of a penny, and the advance was maintained in the lower qualities; so that there must have been good competition for the finest growths. That is not unusual; but the maintenance of high prices, and even an advance, for the ordinary sorts is a pro-

misising feature, and the more so as these have been offered "unworked." The tyranny of London Agents and Dock Companies, in insisting on undoing every bale and tying it up again, and charging exorbitantly for the damage done in the name of "working"—has at last been fairly overcome. For not only have common and ordinary sorts been offered and sold unworked, but also some fine spice which fetched a shilling and upwards for its firsts. It remains that the leading marks should now insist on their spice too being offered, without needless and expensive manipulation, on samples drawn from a bale of each quality. The saving should mean again of $\frac{1}{2}$ d to 1d a lb.; for, apart from the charge for working these, is the loss in broken cinnamon which is boxed and sold at less than the lowest qualities. We append a report on the sale from a leading firm in the trade, from which it will be seen that the stocks are very low:—

London, Sept. 2, 1896.

CINNAMON—The quarterly auctions were held on Monday last when the very small total of 779 bales Ceylon was presented, against 1,743 bales at the sales of 1st June and 667 bales at this period last year.

There was a full attendance of the trade and with good competition about 720 bales were hammered, ordinary and medium qualities realizing full last sale's prices to $\frac{3}{4}$ d per lb. advance, whilst fine descriptions—of which about 300 bales were catalogued—sold well, chiefly at an average rise of 1d per lb. good to fine "Firsts" at 1s to 1s 4d, "Seconds" 10d to 1s 2d, "Thirds" 10d to 1s 1d, and "Fourths" 9d to 11d per lb. The "unworked" cinnamon, fair to fine first sort brought 10d to 1s 1d, second sort 9d to 1s, Third sort 9d to 10 $\frac{1}{2}$ d, Fourth sort 9d to 9 $\frac{3}{4}$ d, and Fifth sort 8 $\frac{1}{2}$ d to 9d per lb. Only 35 bags chips in sale and sold at 3d with fair clippings at 8 $\frac{1}{2}$ d per lb.

The stock of Ceylon is 2,031 bales against 2,333 bales in 1895, 2,066 bales in 1894 and 3,707 bales in 1893.

The next auctions will be held on 30th November.

ORIGINAL RESEARCH AMONGST PLANTERS.

Almost all great inventions and discoveries have been made by members of those industries which have been thus benefited by them. Our planting industry promises to be no exception to this rule, and we have already had the singular pleasure of drawing prominent notice to the results of original research in more than one direction. We now are glad to draw attention to what promises to be some extremely valuable investigations into the intimate relation that exists between the condition of coffee soils and leaf-diseased trees. It is not our present object to dwell at length on the details of the subject, but a short summary, sketching out the lines on which these researches have been carried, will sure to be of much interest to both coffee and tea-planters, as the causes that induce disease in coffee will also be found powerful factors in the health of tea-plants.

Naturally enough any explanation of the causes of a disease that has hitherto baffled all attempts, practical and scientific, at either prevention or cure, will be first received with much doubt. And this is a very proper and scientific attitude to adopt towards all theories of a novel nature and far-reaching in their effects. Our investigator, a practical planter of some little experience, has throughout his career taken a great and absorbing interest in the scientific side of planting. Before long this gentleman, whose name

we are not just now in a position to disclose, became possessed of a number of representative analyses of the soils of the different coffee districts of South India. Having had some experience with scientific English agriculture, the marked difference between the nature of the Indian and English soils at once struck his attention. Apart from the fact, now generally known, of their great poverty in plant-food, he noted that almost one and all were also markedly deficient in the property of allowing the free passage of atmospheric air within their pores. Nor was this difficult to understand, as the proportion of their harmful iron and alumina constituents was unusually great. The importance of this may not be at first sight apparent to the ordinary reader, but it is simple enough in reality. The roots of plants cannot thrive without a free supply of oxygen; and in fact, experiments have demonstrated beyond question that oxygen is an essential of the life of plant-roots; deprived of this element, they invariably die, though furnished with abundance of all other necessities to their well-being. Now there are certain forms of iron that have a great affinity for oxygen, and it is in this harmful form that by far the greater proportion of the iron in our coffee soils is found. To put it plainly, the iron in our soils is unruined, and until it has rusted is naturally a great absorber of oxygen. For, as everyone knows, rust is merely a combination of iron and oxygen. Here it will be seen that we have two rivals for oxygen in the soil: the plant roots and the unruined iron, and the metal being the stronger of the two, the roots are starved of their great essential and consequently the plant cannot thrive. Thus far it is very clear and simple, but the matter does not end here. Another essential to plant life is nitrogen, and it is well known that this element cannot be taken up, except by legumes, in its free state. The manner in which such plants as coffee take it up is in the ready digested form of nitrates. Nitrates are formed by the action of certain bacteria which live in the soil, nitrates being the vegetable matter in the soil that has (after passing through certain processes) been absorbed by them and passed out in the ordinary course of nature. These bacteria are living organisms and they cannot do without oxygen. It is easy to see, therefore, that in soils where large quantities of unruined iron take up the bulk of the oxygen these unhappy bacteria cannot thrive, and naturally can do but very little to convert the dead nitrogenous matter into food available to plants. In agriculture at home this has been recognised for ages past, and through tillage has got to be looked upon as one of the first essentials to achieve success. The conditions that obtain in plantation culture unhappily do not allow this to be carried out with any attempt at completeness, so that the malign influences of the airless soils are left almost unchecked. This is not all. The valuable nitrates are, as we all know, extremely soluble, and therefore are washed out of the soil in huge quantities by every heavy rain. Now iron in its unruined form effects a combination with nitrates that is especially soluble and liable to be easily carried away by rain. But when duly exposed to the air and sufficiently rusted it forms a combination that can resist in great measure the washing effects of even tropical rainfall.

Knowing all this—which has been set forth here for those unfamiliar with the subject—our investigator fell to considering the matter further. If these soils can neither manufacture nor retain

nitrates in sufficient quantities, the coffee growing therein must suffer from want of nitrogen. If so, the analysis of the sap would undoubtedly show this. Analyses were therefore made of sap from trees grown respectively in soils poor in air and consequently in nitrates, and also from trees grown in rich well-aerated soils. The results were striking. In the first case, the analysis revealed a woeful deficiency in the necessary compounds of nitrogen; in the latter an abundance of these indispensable constituents was found. To be successful in its attacks, disease must, as a very general rule, find assistance in the weakened constitution of its victim. Coffee trees whose sap is poor in nitrogen are, and must be, deficient in vital power, consequently easy victims to the fell approaches of the germs of leaf-disease. To support this further, the sap of leaf-diseased trees was found to be extremely poor in nitrogen, and the same state was revealed in the soils from which it was drawn. Clearly then, there is shown to be a most striking and close connection between the physical and chemical conditions of the soil and the constitution of the plants growing therein, and therefore between the soil and leaf-disease.

To sum up briefly, leaf-disease attacks weakened and unhealthy trees (as shown by after-effects of heavy cropping) far more severely than those of a robust and vigorous constitution. Coffee cannot remain in full vigour without an abundance of nitro-carbons in its sap. These compounds of nitrogen must be derived from nitrates in the soil. Nitrates cannot be formed without the action of bacteria on vegetable matter in the soil. These bacteria cannot thrive without an abundance of oxygen. The majority of our Indian coffee soils contain a very large proportion of unruined iron, which is a most greedy absorber of oxygen. To reverse the argument. Naturally the want of oxygen results in a lack of bacteria; without bacteria nitrates cannot be formed; owing to lack of nitrates the sap of the coffee tree is deficient in nitro-carbons; as a result of this again the vigour of the tree is impaired, and thus can present no effectual resistance to the attacks of the everpresent germs of leaf-disease.—Q. E. D.

Such is, in brief, the theory of the relation between assimilable nitrogen and leaf-disease, which we hope very shortly to publish in all detail. Some of our practical readers may demur at the importance we have attached to the above: what benefit can be derived from knowing the cause of the disease without being told the cure? Let these doubters be patient: on the correct diagnosis of a disease depends altogether the success of the treatment applied. Once the true cause of leaf-disease is fully demonstrated, the cure will follow as a matter of course and certainty.—*Planting Opinion*, Sept. 12.

PROSPECTS OF INDIAN TEA.

The rapid strides that have recently been made in the consumption of Indian tea in America and Australia would seem to justify the assumption that the conversion of our cousins to a taste for our teas will not take a tithe of the time which elapsed ere the average of 5lb. per head of the population of Great Britain was reached. It must be remembered that, with the exception of the outturn of the Assam Company, no Indian teas worth mentioning were put upon the London market until 1862, and certainly they were not calculated to recommend themselves to

public favour. Scarcely two factories pursued the same method of manufacture, in consequence of which there was so little uniformity that the dealers and brokers were in despair, and it was not until 1866 that Indians really began to attract attention in Mincing Lane, but for the subsequent three years dealers purchased Indians merely for blending with the lower class of Chinas. From 1869 a demand gradually arose for the unadulterated article, from which time home consumption has steadily increased; and, though there is a considerable section of the public who still cling to the higher class of Chinas, such as that vended by Twinings, Newman and other well known houses, even they are gradually veering round in favour of Indians. We may take it for granted therefore that within the next two years the demand for Great Britain alone, reckoning on the last census, will amount to 185 million pounds. Next in order of tea-drinking nations comes Russia, but as the upper and middle classes are supplied with the best Caravan tea from China, it would not be safe to calculate upon eventually securing more than one third of the population as our customers, which would give a consumption at 5lb. per head of 155 million pounds and taking the remaining population of Europe at 251 millions, reckoning at the rate of 2lb. per head, we arrive at a demand of 812 million pounds. We place the consumption of Continental nations at 2lb., as the majority are coffee and cocoa drinkers. What can be done here after in the way of conversion must remain an open question, at least for the present; but we have not yet secured even the 2lb. per head be it remembered. Turning to the American Continent, we have to deal with a population of 133 millions, but at present China holds the monopoly of supplying the states on the Pacific Sea-board, leaving us about two-thirds in the Canadas and Atlantic States, which ere the end of the century is reached (if we are to judge by Mr. Blechynden), should create a demand for an additional 220 million pounds. Australasia with its 4 millions may be taken as an assured market at the extreme consumption of that of the United Kingdom, so that 20 millions will be needed for those colonies in the near future, bringing the total demand, say, within the next four years up to 1,082 million pounds, the actual outturn last season being but 135 million pounds. With regard to the population of Asia, estimated to number 854 millions, we must first deduct that of China 400 millions as also Siam, Cambodia and the Malayan Peninsula, for already tea cultivation is attracting attention in these countries, and, with an almost unlimited supply of the very best seed procurable from the Shan States and Northern Tonquin between the parallel of 22° and 30°, these will not only supply their own requirements, but eventually enter into rivalry with us. This will leave us but Persia, Central Asia and Asiatic Turkey to deal with, which may be taken at one pound per head, or 100 million pounds, which is about the estimated outturn from Ceylon, 1896-97, and therefore need not enter into our calculations. Can these possible markets be secured? We believe that to the extent we have put down they can be, but not without the most energetic and prompt measures, and money must be freely, though not necessarily extravagantly, expended in establishing agencies in every centre offering prospects of success. Presuming that the securing of this supply can be accomplished within the next four years we have now to consider what means we have for meeting the demand. The Tea Association do not publish their revised estimate until the end of August, and as much depends upon the vagaries of the remainder of the season these estimates are not reliable there being a discrepancy last year of 3 million pounds in the August estimate and 5 millions between that made in the spring and that realised. We shall be on the safe side, therefore, if we take the outturn of Indians this season at 140 millions and Ceylons at 120, in all 260 million pounds, barely enough to meet requirements, if the American and Colonial demand is sustained at the rate

of the past six months. From all we have been able to glean the extensions this year in both producing countries amounts to 30,000 acres which four years hence may bring the outturn up to about 200 million pounds against a possible requirement of 1,082 million pounds as mentioned above. We abstain from entering into such side issues as the coolie problem, box-supply freights etc., which are purely matters for the planters' and agents consideration; but have endeavoured to show what markets exist or may be created, and what the prospects are of meeting an estimated demand, taking our figures from official statistics, and merely confining our remarks to the next four years, and it seems to us that the dread of over production of Indian teas is a nightmare afflicting timid investors haunted by extreme pessimist forebodings. Sales up to date have been promising enough to indicate a successful season, despite the grumbling indulged in at the abnormal weather experienced during the spring, and it would be a wise policy to devote a liberal portion of the forthcoming dividends to exploiting the markets we have glanced at. A careful consideration of the figures we adduce will, we think, convince most people that, so far from there being danger of over-production, the probabilities lie in the opposite direction, but action, and united action, must be taken at once so as to secure outlets, for it will require fully four years to educate Continental nations. The present growing demand has, however, to be carefully watched, for there is just the possibility that our teas are being taken, as other novelties, merely to satisfy curiosity, though our own opinion is that the patronage is genuine and will become permanent. Planters and investors may regard with equanimity the attempts of rival countries for labour is cheap enough here to defy competition, except, perhaps, in S.E. Asia and Java, but even there the price of labour is higher than with us. At the same time resort should be had to every possible contrivance towards minimising hand work, even in the minutest details; and a good substantial prize might be offered for a picking machine, for with this problem solved the cost of production could be brought down to some two annas. Our remarks have been suggested by the adverse criticism of the *Saturday Review* upon the launching of the Consolidated Tea and Lands Company, Limited; and, though, considering the scheme has been brought out in London, the prospectus might have entered more into details of the actual planting prospects, to those better acquainted with agricultural pursuits as pursued in India than our London contemporary or the *Madras Mail*, which endorses the views of the home paper, the enterprise promises fair enough, while the price asked for the property appears by no means extravagant. It is amusing to note that the *Mail* heads his article "A Mammoth Planting Concern." That is commercial India all over and men here cannot apparently understand dealing in other than petty investments with capital ranging about a couple of lakhs of rupees. We are at issue with the *Mail* on the matter of large versus small companies, for it is now beyond question that all the vexation and obstruction thrown in the way of developing our resources emanates from Westminster; hence, big companies could exercise Parliamentary pressure on the India Office, while the Mannikins would be snubbed.—*Indian Planters' Gazette*, Sept. 5.

PLANTING NOTES FROM EAST HAPUTALE.

Sept. 16.

In this district of late we have experienced rough stormy weather, the wind veering all round the compass. And we have had only two or three fugitive showers since I last wrote you, one giving us a little over one inch of rain. We have still hot dry weather here and there is not much tea making going on, on this side of Haputale just now. I have never seen the brooks lower than they now are, and the patanas are again becoming brown and burnt up with

fierce suns, the skies day by day being without a cloud. We are anxiously awaiting the advent of the North-East monsoon. When the steady rains of the North East monsoon are with us, there will be, I am informed, a good deal of land planted with tea. Some of these clearings are from patanas—poor scrub lands and light chenas. Planters should be very cautious how they select lands for tea plantations. I am quite aware some kinds of patana soil will grow good tea. For the last quarter of a century I have seen both very fine coffee trees and of late years tea trees growing on Nayabedde estate near the road, the soil there being of a kind of peat, deep-lying and well-drained. This kind of bog soil is formed by the slow decay of some kind of vegetable matter which takes place during many years, I might say centuries. Where I now reside, we have five or six acres of rich dark soil patana land, which, if well drained, would grow tea well and profitably for years. There are other kinds of patana lands suitable for tea plantation, but great care should be taken in these days to select only proper and suitable lands, and as a rule to eschew lands growing light scrub and with a scanty growth of jungle trees on it.

Let it be remembered that poor lands that would pay a Tamby or Sinhalese to cultivate with tea or coffee, would bring loss and failure to a European. I am not one of those "tropicals" that believe in the restoration of coffee cultivation, while the red fungus can be seen on most old coffee trees, still swarming on some estates in East Haputale. Before this fungus reached coffee estates attacks of white and black bug were experienced at long intervals; but after a time or season they left the coffee trees. But with the fatal fungus came the green bug to complete the destruction caused by the fungus.

Nevertheless on suitable lands, coffee might be planted now, with the sober expectation of getting crops—half a dozen or so—before the trees are prevented from bearing well by various enemies of one kind or other; and the present price of coffee, and the local consumption of the fragrant berry seems to favour the idea of coffee planting on the hillsides of Ceylon, providing such lands are good chenas or forest lands, if the *vastatrix* fungus ever leaves Ceylon. Then there is no reason why coffee should not be successfully grown again, but I have felt the sad effects of the dire fungus, and would not depend on coffee cultivation while it exists as at present.

THE CHICAGO EXPOSITION.

ARRIVAL OF MEDALS AND CERTIFICATES.

The Hon. W. W. Mitchell in his capacity of Agent to the Hon. Sir J. J. Grinlinton, Special Commissioner of the Ceylon Government at the Great Chicago Exhibition, has received the medals and certificates awarded to Ceylon Exhibitors. In all 106 medals and certificates have come to hand. It is a little late in the day, but the medal and certificates are handsome works of art and well worth waiting for. Each medal is contained in an aluminium case, rather broader than a cigarette case, the medal itself being fixed in a frame of black velvet which moves inside the case like the page of a book and which enables each side of the medal to be easily inspected. On one face the medal, which is of bronze, bears in relief a representation of the landing of

Christopher Columbus on the shores of the New World, and on the other, of which the design is in harmony, the inscription—"World's Columbian Exposition in commemoration of the four hundredth anniversary of the landing of Columbus," and then the dates "MDCCCXCII—MDC-CCIII C. E. Barber *fecit.*" The name of the recipient is stamped in relief on each medal. The diploma is a beautiful work of art and well-worth of "the greatest show on earth." It measures 36×25 inches. The design is a very elaborate one. At the top is a proscenium through which in the background is seen a view of the Exposition building. On one side Columbia and the bison are depicted and on the other representatives of the youth of the Anglo Saxon, the American, Indian and the negro races. Allegorical figures beautifully draped surround the centrepiece, while at the foot is a representation of a galley carrying as shields the arms of the different nations and in which allegorical figures are depicted. In the centre, the nature of the exhibit, the exhibitor's name and the award are given—they are engraved in every case and not written. The diploma which is a triumph of the engraver's art was executed at the engraving bureau of the U. S. A. Treasury. The Hon. W. W. Mitchell, forwarded the medals and certificates today to the recipients of these honours, the list of which is as follows:—

AGRICULTURE.

GROUP 6.

Charles De Soysa, Colombo; D. P. Dias, Kandy; J. Gauder, Colombo; Julian Heyzer, Colombo; The Orient Co., Ltd.; Vavasour & Co.

GROUP 8.

Aberdeen, Aneombra, Ardlaw and Wishford, Blair Athol, Broadoak, and Brunswiek estates; Buchanan, Frazer & Co., Bunyan, Charley Valley, Claremont, Columbia, Court Lodge, Dambatenne, Damblagolla, Dunkeld, Dunnottar, Gartmore, Gigranella, Glendevon, and Glentarf estates, Hon. Sir J. J. Grinlinton (for the Ceylon Government), Henfold, Hethersett, Holmwood, Invery, Kintyre, and Kurunduoya estates, F. G. A. Lane (for Blair Athol estate), Laymastotte, and Lynsted estates, Maekwood & Co. W Waddon Martyn, Mincing Lane and Mousakanda estates, North Matale estate (Land and Produce Company), Oononagala estate, Oriental Bank Estates Company, Ovoca, Pedro, Poop-rassie, Portswood, Rahatungoda, Rookwood, St. Clair, Tillyrie, Udaradella, Vellaioya (no diploma received), Westhall and Yapame estates.

GROUP 9.

Ceylon Government (Hon. Sir J. J. Grinlinton) and the Orient Company, Ltd.

GROUP 14.

Hon. Sir J. J. Grinlinton (for the Ceylon Government.)

GROUP 16.

Government of Ceylon.

GROUP 18.

Colombo Oil Mills (G. and W. Leechman & Co.) Charles De Soysa, Clark Spence & Co. Hon. Sir J. J. Grinlinton (for the Ceylon Government) and Mackwood & Co.

FORESTRY.

GROUP 19.

Leechman & Co., The Government of Ceylon (the Hon. Sir J. J. Grinlinton.)

MINES AND MINING.

GROUP 46.

Darley, Butler & Co., Jacob de Mel, M. A. Fernando, and the Ceylon Government.

MANUFACTURES.

GROUP 87.

C.P. Hayley & Co., and the Oriental Estates Co.

GROUP 88.

Crystal Hill Estate and Julian Heyzer.

GROUP 91.

The Hon. Sir J. J. Grinlinton.

GROUP 96.

Ceylon Government (Hon. Sir J. J. Grinlinton)
the Hon. Sir J. J. Grinlinton.

GROUP 97.

S. L. O. Lebbe Marikar.

GROUP 98.

D. D. de Silva & Co., A. H. Ismail, P. T. Meera Lebbe Marikar, O. L. Mohamad Macan Marikar, A. L. M. Mohama Mahamed, A. T. Ma'hamed Baay, M. A. Perera, and the Ceylon Government per the Hon. Sir J. J. Grinlinton.

GROUP 101.

Colombo Oil Mills Company.

GROUP 102.

Ceylon Spinning and Weaving Company, and the Ceylon Government (per the Hon. Sir J. J. Grinlinton.)

GROUP 104.

Government of Ceylon (Hon. Sir J. J. Grinlinton.)

GROUP 110.

Hon. Sir J. J. Grinlinton (for the Ceylon Government.)

GROUP 115.

Colombo Oil Mills Company.

GROUP 118.

Ceylon Government.

LIBERAL ARTS.

GROUP 149.

Lady De Soysa, Hon. Sir J. J. Grinlinton (for the Ceylon Government), Kumarihami, Lady Havelock, Wennapua Boarding School, and Convent of the Holy Family.

GROUP 150.

Charles' de' Silva, C. Don Bastian, and G. H. Perera.

GROUP 151.

W. L. H. Skene.

GROUP 152.

H. F. Tomalin.

GROUP 155.

Government of Ceylon.

GROUP 157.

Hon. Sir J. J. Grinlinton.

THE PINEHILL ESTATES CO., LD.

GENERAL MEETING.

PRESENT:—Messrs F. M. Mackwood in the chair, H. St. C. Bowle Evans, R. E. Prance, C. G. Ryan and J. A. MacGillivray.

Represented by Proxy were:—Messrs. J. Masterman, J. N. Layton, J. D. Dryer, R. Trimen, T. B. Hughes, G. T. Worsley, Mrs. J. F. Kennedy, Mrs. M. C. Layton, Miss Jane Nicol, C. J. S. Nicol, Mrs. E. L. Owen, Mrs. G. Prance, Mrs. M. F. Thorne, Mrs. A. J. S. Hughes.

Proposed by the CHAIRMAN and seconded by Mr. C. G. RYAN:—That the directors be authorised out of the purchase money arising out of the sale of the Nabaketiya Estate, amounting to R190,000, to refund to each shareholder of the Company a sum of forty rupees per share in reduction of the capital amount subscribed in respect of such share.—Carried unanimously.

Proposed by the CHAIRMAN and seconded by Mr. R. E. PRANCE:—That the capital of the Company be reduced from R355,000 in 3,550 shares of

R100 each (being the amount to which the capital of the Company was increased by special resolution passed on the 19th May 1894, and confirmed on the 16th June, 1894,) to R213,000 in 3,550 shares of R60 each.—Carried unanimously.

The CHAIRMAN explained the proposals of the directors for the disposal of the balance of R50,840, re-purchase money, viz.: 1st, to pay R14,300 to the reserve fund, bringing it up R21,300 = 10 per cent of the reduced capital; 2nd, to lay aside R17,000, provision for purchase of new land and bringing into cultivation, the amount to be placed to a special reserve fund; 3rd, that a sum of R10,540 be provided for extension of factory and for new machinery on Wavahoena and for an assistant's bungalow on Pine Hill; 4th, that at the next declaration of interim dividends probable in January next, the residue equal to R9,000, be divided as a bonus amongst the shareholders, subject to the advice of the solicitors of the Company.

Proposed by Mr. C. G. RYAN and seconded by Mr. BOWLE-EVANS:—That the proposal of the directors be adopted.—Carried unanimously.

This having closed the formal business, Mr. RYAN drew attention to the prices the Pine Hill teas were fetching, which he considered much lower than they ought to be.

The CHAIRMAN replied that the directors had already insisted upon better prices being obtained; otherwise there was no alternative, but to have a change.

THE FINANCIAL POSITION OF THE INDIAN TEA INDUSTRY.

Referring to Mr. Seton's table of results of working of Indian tea companies, the *Produce Markets Review* says: "An interesting table has been published by Mr. George Seton, 120, Bishopsgate Street Within, showing in detail the working of forty Indian tea-growing companies registered in London in the season 1895. The total paid-up capital of these taken together is £4,076,488, and the acreage under tea 107,013 acres; of which 90,759 are mature and 14,254 bear young plants. The cost per acre is £38, and the crop 463 lb. per acre, or 42,928,295 lb. in all. The expenses are £1,265,469, or 9.70d per lb. and the total receipts £1,660,529, or 9.27d per lb. leaving a profit of £395,090, or 2.20d, the ratio of expenses to receipts averaging 76 per cent. The profit per mature acre is £4 5s 2d, or 9.69 per cent on the capital. The dividends paid were £323,074, or 8 per cent., and the amount carried forward and standing to the credit of reserve is £369,441, or 9.06 per cent on the capital. In taking the average profit some very remarkable results are lost sight of. One company makes 5.21d per pound and six make over 3d per pound. Taken as a whole the London Indian tea planting companies are thus very prosperous, which is more than can be said for the various branches of the distributive trade. It is a significant fact also that these established companies have comparatively little maturing in young plants, as they see that the danger confronting the industry in India and Ceylon is over-production. The smaller companies, not having London registered offices, no doubt are hard at work extending, and with this in view the established companies would do well to add handsomely to reserves while times remain good, and to curtail expenses as far as practicable."

The *Grocer* says: "The annual statement prepared by Mr. Seton of the working of forty Indian tea companies during the season 1895 has just been published, and gives some very interesting results. The actual sale-weight of the crop as raised by these companies amounted to 42,928,295 lb., which was an increase of 3,315,450 lb. in comparison with the aggregate of 39,612,645 lb. for the season

1894, as printed in the *Grocer* of October last. The companies and their planters contributing most largely to the production of tea in the past season were as follows: Assam, with 3,225,189lb; Jokai (Assam), with 3,063,651lb; Dooars, with 2,987,136lb; Assam Frontier, with 2,396,053lb; Land Mortgage Bank, with 2,179,187lb; and the Brahm-pootra Company, with 2,175,178lb. The gardens producing the next largest quantities of tea, say between 1,304,921lb and 1,714,689lb, were those belonging to the Singlo, Upper Assam, Cachar and Dooars, Chargola, Llungla (Sylhet), Dooma, and Jorehaut companies. The plantations which turned out crops varying from about 410,000lb to a little over 930,000lb each were those known as the Chubwa, Sephinjuri Bheel, Jhanzie, Moabund, Majnli, Allynugger, Attaree Khat, British Indian, Noakacharee, Dolco, Borelli, Derby, Darjeeling, Longai Valley Eastern Assam, Lebong, Indian of Cachar, Scottish, Assam, Moran, Tingri, Chandpore, and Dejo tea estates. The minor growths gathered were by the Endogram, Boroka, Hunwal, and Balijan planter, who had not in all cases the unenviable reputation of paying the smallest dividends. The best of these were indeed paid by Assam, Jorehaut, Brahm-pootra, Chandpore, Lebong, Moabund, Rajmai, and Sephinjuri Bheel companies, whose distributions of profits on their ordinary shares were at the rate of from 15 per cent. to 20 per cent. Others, such as the Dooars, Derby, Attaree Khat, Balijan, Doom Dooma, Jhanzie, Jokai (Assam), Moran, and Tingri proprietors, returned dividends of 10 per cent. to 12½ per cent. Less successful owners and growers of Indian tea did not pay more than 5 per cent. to 8 per cent. out of their year's net earnings; and there were some whose payments were at the poorer rate of 2½ per cent. to 4 per cent. on their paid-up capital. This, for the whole of the forty companies, reached the sum of £4,076,488, and the total area under cultivation (including young and matured plants) covered fully 107,000 acres. The cost per acre varied greatly, ranging from £19 to £79. The expenses of cultivating and managing the different estates swallowed up from 4.34 pence to 10.33 pence for every pound (avoirdupois) of tea produced; and whilst the prices realised were from 6.7 pence to 13.62 pence per lb., the actual profit fluctuated from 0.31 to 5.21 pence for the same quantity of drinkable tea. The yields per acre, of course, differed widely, according to circumstances of locality, management, weather, time of gathering, &c., and were calculated at from 282lb to as much as 685lb per mature acre, running up in two instances to 936lb and 1,045lb for a similar breadth of plants. All this indicates a high state of prosperity for the British Indian tea companies, and they may look forward to achieving still greater success in their industrial enterprise, as there is a constantly increasing demand for their produce in the home country as well as in the colonies."—*H. and C. Mail*, Sept. 4.

TEA AND COFFEE COMPANIES REGISTERED.

DIGALLA CEYLON TEA ESTATE COMPANY, LIMITED.

Registered August 5th by Murray & Co., 11, Birch-lane, E.C., with a capital of £25,000 in £10 shares. Object, to adopt an agreement with R. B. Reid for the purchase of the Digalla Tea Estate, Kelany Valley, District, Ceylon, and to plant, grow, and produce tea, coffee, cinchona, cocoa, &c. The directors are H. K. Rutherford, G. A. Talbot, and R. B. Reid. Qualification, £250. Registered office: 21, Mincing-lane, E.C.

BRITISH CEYLON TEA ESTATES COMPANY, LIMITED.

Registered July 31, by Warner and Seligman, 21, Great Winchester-street, E.C., with a capital of £160,000 in £5 shares. Object, to adopt and carry into effect an agreement expressed to be made between George L. Davies of the one part and this company of the other part; to acquire by purchase or otherwise any grants or leases from Government, and to pur-

chase, take on lease or in exchange, hire, or otherwise acquire from any other company or companies, person or persons, any tea or other estates or lands or property of any description situate in Ceylon, British India, or elsewhere, or any right or interest therein, or any rights or privileges (including any copyrights or trade marks) which may be deemed necessary or convenient for the purposes of the company; to cultivate tea, coffee, cinchona, rice, coca, cocoa, coconuts, and other produce, and to carry on the business of tea and coffee planter in all its branches; to carry on and work the business of cultivators of and dealers in every kind of vegetable, mineral, and other produce of the soil; to prepare, manufacture, and render marketable any such produce, either in its prepared, manufactured, or raw state, and either by wholesale or retail; to construct and maintain buildings, sawmills, roads, rail, and tramways, &c. The signatories are:—

DUNSINANE TEA COMPANY, LIMITED.

Registered August 28, by Murray, Hutchins, Sterling and Murray, 11 Birch-lane, E. C., with a capital of £100,000 in £10 shares. Object, to adopt and carry into effect an agreement expressed to be made between W. R. Arbuthnot and P. M. Anstruther of the one part and this company of the other part for the acquisition by purchase or otherwise, as a going concern, of the tea estate known as Dunsinane, Kotmalie Korale, in the Nuwara Eliya district, Central Province, Ceylon, to develop and turn to account the said property in such manner as the company shall see fit, and to carry on business as planters and growers of and dealers in tea, coffee, cinchona, cocoa, cardamoms, rice, &c.; to work mines or quarries, and to find, wind, get, work, crush, smelt, manufacture, or otherwise deal with ores, metals, minerals, oils, precious and other stones or deposits or products, and, generally, to carry on the business of mining in all its branches; to build, maintain, and work tea factories, coffee-cring mills, roads, tramways, and other works, matters, and things of any kind; to acquire and turn to account patents, &c.; to undertake the office of trustee, executor, &c.; as merchants, exporters, importers, traders, engineers, and any other trades, businesses, or undertakings whatsoever; and to transact all kinds of financial business. SARAPIQUI ESTATES COMPANY, LIMITED.

Registered August 28th, by J. Ballantine, 21, Cornhill, E.C., with a capital of £120,000 in £1 shares. Object, to adopt and carry into effect an agreement expressed to be made between G. Rothe of the first part, the Sarapique Syndicate, Limited, of the 2nd part, and this company of the third part, for the acquisition by purchase or otherwise, as a going concern, of certain estates situate in the Republic of Costa Rica, belonging to G. Rothe, to develop, cultivate, and deal with the said properties in such manner as company shall see fit, and to carry on business as coffee planters, growers, exporters, and merchants, as also of such other trees, plants, crops, and produce as can or may be grown or produced on the property of the company and to prepare, treat, and fit the same for market and to sell, ship, and dispose of the same; to construct and maintain any roads, buildings, works, ways, rail and tram roads, wharves, piers, docks,

factories, ware houses, electric works, &c.; to turn to account the lands, estates, properties, &c., of the company by clearing, draining, irrigating, fencing, planting, and building thereon; as farmers and graziers, stock-raisers, &c. to lay out towns and villages, and to promote immigration thereto; to acquire and turn to account any patents, &c. —H. and C. Mail, Sept. 4.

PLANTING AND PRODUCE.

TEA IN NORWAY.—If we may judge by the complaints made by British tourists in Norway and Sweden, there is room for the development of the tea trade in those countries. Indian and Ceylon tea are not to be met with in the ordinary way, and the art of brewing tea is sadly neglected. Coffee is in favour much more than tea.

BRAZIL AS A TEA GROWING COUNTRY.—Some Brazilian planters, we learn, are very much impressed with the idea that tea could be successfully and profitably grown in Brazil, and experiments on a somewhat extended scale have been talked of. The idea is not a new one. Some British capitalists had the suggestion under consideration not very long ago, and one well known firm of enterprising tea agents visited the country to see how far the prospect was hopeful. We do not know the conclusion arrived at, but we should imagine that there were difficulties in the way. Allowing that the conditions of soil and labour were favourable there would be the question of security and title, matters of considerable importance where British capitalists are concerned. The three principal coffee producing provinces of Brazil, viz., Rio de Janeiro, Minas Geraes, and Sao Paula are in about the same latitude as Central Australia, and therefore much further south than Java.

PLANTING IN BRITISH CENTRAL AFRICA.—The report of Sir Harry Johnson on the British Central African Protectorate for the year 1895 is very satisfactory.

One of the most interesting parts of the report describes the development of the coffee planting industry, which is carried on in the Shire Province, in Angoniland, and in the Marimbo district. It is to the coffee planting that the Commissioner of Nyassaland ascribes the prosperous change that has recently been experienced in that part of Africa. Tea has been introduced, while tobacco is a great success. As regards the labour question, the population statistics, which Sir Harry Johnson has been at some pains to compile are of great interest and value. The total of European population is 289, of which nearly half is in Blentyre. The native population is estimated at about 850,000. These figures, taken with the the not very encouraging statistics as to the health of the territory, make it clear that the European hill settlements must always remain islands in the ocean of an enormous native population in the plains. "We must encourage," says the report, "the unchecked increase of the negro population," for ultimately the whole future of Central Africa depends on the natives themselves. "Given abundance of native labour, and the financial security of the Protectorate is established." And again, "It only needs a sufficiency of native labour to make this country relatively healthy" (that is, by the clearance of jungle and the drainage of marshes) "and amazingly rich." Sir Harry Johnston sees that this can only be done by just and liberal treatment of the natives. Unskilled native labour at present only receives some 3s a month, and skilled labour only very occasionally reaches as much as £40 a year.

COOLY LABOUR IN BRITISH COLONIES.—Mr. Chamberlain has been interesting himself about coolie labour on the sugar estates not only of Natal but in the West Indies, and a despatch has been sent to the various governors of the colonies concerned. In the West Indies very stringent laws protect the coolie labourers, but he suffers considerably from the tyranny of the "babajees," who treat low caste men with a very high hand, and fleese them freely. Coolies frequently contrive to save money, and are to be met with amongst the shopkeeper class. In British Guiana there have been instances of coolies amassing wealth and owning racehorses, but while labour as in demand in India it seems strange that so many coolies are found willing to go to colonies, where they are treated as inferiors by negroes, and have at any rate until they are used to the country, to put up with very much that is repugnant to their feelings. In the early sixties a large proportion of the coolie labourers on the sugar plantations in British Guiana were mutineers from India, who had left their country for their country's good as well as their own. They were a rough lot, and occasionally made things lively for the planters. Owing, however, to the large proportion of negroes in the colony no very serious mischief occurred.—H & C Mail Sept. 4th.

INDIA AND CEYLON TEAS IN AMERICA.

NEW YORK, Aug. 19.

The market for the past week has shown a better feeling than for some time and more sales are reported; some arrivals of new season Indias show good liquor with fine appearance of leaf and have met with ready sale at full rates. Ceylons, medium and lower grades, are plentiful and sell at easier prices, while good liquoring, well made, tippy teas are somewhat scarce and wanted. Cable advices from abroad report that the stock of India teas is lower in London by 2,000,000 lb. than at the same date last year, while shipments from Calcutta last month were 3,000,000 lb. behind that of 1895, which in itself is sufficient to boom prices of India teas, were it not that the spot stock of Ceylons in London is several millions in excess of that of a year ago; but, judging from all information obtainable, the buyer who carefully looks at his stock and replenishes before a very long time, will probably find that he has not lost anything.

A dispatch from Victoria, B. C., says: Despite the arrival in the field of Nippon Yusen Kaisha as the fourth competitor for Oriental trade to British Columbia and Puget Sound ports, there will be no cutting of tea cargo rates this year, and no sailing ships will be chartered. A combination is announced between Central Pacific, Northern Pacific, Oregon Railway and Navigation companies and the Japanese line of steamers, and a uniform rate of $1\frac{1}{2}$ $\text{\$}$ lb. has been agreed upon.—*American Grocer*, Aug. 19.

MADAGASCAR.

London, Sept. 10.—Twenty thousand natives are ravaging the northern district of Madagascar.—*Australian Paper*.

BRITISH GUIANA AND ITS RESOURCES.—By the Author of "Sardinia and its Resources." (G. Philip and Son.)—This is a seasonable book, for it tells us something of the value of a country about which there is not a little trouble just now. It produces sugar, but not to much profit, though the writer discerns signs of improvement. It furnishes gold, and that in no small quantities. The yield has grown from 250 oz. in 1884 to 110,432 oz. in 1894. Of course it is the opportunity of digging for gold, not of growing sugar, that our Venezuelan friends are anxious to grab. There is a timber trade, but it is not flourishing. As to the natural attractions of the place, the vegetation is magnificent, especially in orchids and palms. The climate is indifferent, but in worse repute than it deserves. The annual rain-fall is 80 inches; the thermometer never falls below 70 degrees; the death-rate is 38 per 1,000.—*Spectator*.

FOREST AND SOILS.

The value of underbrush must not be underrated. Although its mothers young trees, it is useful to forests of larger growth. The amount of mineral matter which a tree absorbs is insignificant. Water is the essential element. In checking evaporation and retarding the flow, undergrowth is often necessary. But the smaller amount of dead wood in a forest the better, since it breeds many kinds of insects, some of which may invade the living trees. The material resulting from decay, however, enriches the soil, so that it is better to burn the dead wood which cannot be utilised. In that way the soil is enriched just the same, the insects are disposed of and the underbrush is not seriously disturbed.

Prof. F. H. Storer, in *Agriculture*, says: "Within porous soils nitrate are doubtless formed rather freely, and, as is well-known, the nitrates are easily washed out from soils, and are liable to go to waste after every rain that is long continued. They are, in fact, leached out of the soil, and the manure from which they come rapidly wastes away. It is said to be a matter of old and familiar observation in Germany, that in sandy regions, in seasons that are particularly wet, the soil may finally be so thoroughly leached that it becomes unfruitful. When we consider the facts that nitrates are easily washed out of the soil, that they are absolutely essential to plant growth, and that they are continually produced, during the period of growth, from humus, by the action of nitrifying bacteria, we can appreciate the damage to light soils by fire. Land thus damaged needs very careful tillage and green manuring before it can produce a crop of consequence."—*Journal of the Society of Arts*, Aug. 28.

THE DUMONT COFFEE COMPANY, LTD.

(Under Acts 1862 to 1890.)

This Company is formed for the purpose of acquiring, carrying on, and developing the celebrated Coffee Estates of the Companhia Agricola Fazanda

Dumont, situate in the district of Ribeirae Preto, in the State of Sao Paulo, United States of Brazil.

Taking the profits of 1895 as a basis, although not half the planted area was yielding crops £127,453 3 6
Less Debenture, Int. .. £22,000 0 0
,, Preference, Int. .. £30,000 0 0
£52,000 0 0

Balance £75,453 3 6
for Dividend and Reserve.

The purchase price has been fixed at £1,200,000, payable two-thirds in cash; balance and debentures; preference and ordinary in equal proportion.

The Company take over the estates as from 1st January, 1896, and are entitled to the profits earned during the current year. These are estimated at about £142,000, and will be used for providing working Capital, for forming a Reserving account, and for the payment of interest on the debentures, and a dividend to the preference and ordinary shareholders from the dates of payment of the instalments up to 31st December, 1896. It will be noted that the average profit of 1894 and 1895 is sufficient to pay the debenture interest and preference dividends more than twice over.

THE BANDARAPOLA CEYLON COMPANY.—The first we believe among the Ceylon Tea Companies in London to declare an interim dividend has been the Bandarapola Ceylon Company. The directors of the Company, as will be seen from the letter which we publish elsewhere, have declared an interim dividend at the rate of 10 per cent per annum (free of income tax) for the half-year ending June 30th last. We heartily congratulate the shareholders.

SCIENTIFIC EXPERT FOR THE TEA INDUSTRY.

(From an Occasional Correspondent.)

Some time ago you published a discussion that took place at a meeting of the Indian Tea Association regarding the appointment of a scientific expert. One speaker animadverted rather severely on the niggardly manner in which the Government of India had always dealt with this question, and not without just reason. Though the United States and France contribute largely, Denmark spends annually £11,000, and all our colonies give liberally towards agricultural colleges and scientific research, it must be borne in mind that the British Board of Agriculture, even in the face of severe and long-continued depression, has never supported agricultural education and investigation to anything approaching the extent its importance demands, or as the countries named and others have. May our Indian Government be induced to follow the better example and not that of the mother country hereafter. The tea industry is a great industry and if its members act with unanimity, and sustained energy it ought in these times to be all-powerful in such matters. No doubt with the cost of pushing new markets, a still more urgent matter for the present, there may be difficulty in paying a competent expert adequately, and retaining his services long enough, unaided. I am not, however, so sanguine of very much being soon accomplished, beyond what has already been and may yet be done by the so-called "rule of thumb" of practical observation and experiments in manufacture, because I do not believe that chemistry is calculated to do so much for tea as in some other processes of manufacture. Tea-making does not, I consider, come within the realm of science so fully as is generally supposed, one reason being it is very seriously affected by the uncontrollable influences of atmosphere and weather in the open field. Still, it is but right that practical men should have the aid of the more skilled scientists, and in the course of years—possibly very soon—this might be productive of great results even in manufacture. Neither may science be enabled readily to do much in the way of cure and eradication of blights, but it could not fail to add to our knowledge and do something. Scientific and minute and careful observation of the life, history, and habits of most of the parasites that affect tea have been made and recorded by Wood-Mason, Cotes, Dudgeon, and others, most interesting, doubtless, but I have not heard of any practical benefit derived. The effective practical remedy is to increase the constitutional vigour of the bushes and thus give them power to resist and grow out of pests, or perhaps develop new varieties of disease-resisting plants. But I believe it is in the direction of analysis of soils to ascertain what elements are wanting and what manure or application is necessary to yield or improve the quality of the tea that most is to be expected. In regard to this it is to be feared practical planters are entirely in the dark, and experimenting, while difficult and costly, is likely to be of little avail. Of course in regard to manuring according to soil for vigorous, healthy plant growth generally, a competent analytical agricultural chemist could not fail also to be of the greatest service. This latter branch of manuring does not seem so urgent for tea, which is not an exhaustive crop as far as rude growth of the plant and leaves, irrespective of quality, is concerned, certainly not so much so as the extension of new markets meanwhile. Even should there be no excess of nitrogen in the rainfall in tea countries (and upon this doubt would seem to be thrown by more recent analysis), the cheapest form to supply it is in green-manuring, and for this the unusual abundance of leguminous herbs, plants, shrubs, and even trees (*papilionacæ* is peculiarly favourable, they having all the capacity of fixing and utilising the free nitrogen of the air. It will be long, I feel convinced, before it can prove profitable to ap-

ply artificial manures, except those, should such be discovered, productive of quality. Unfortunately, in many parts, the supply of local manure is very limited and poor, and if it were in greater abundance the cost of transit would be prohibitive. Hence the importance of green-manuring and top dressing, little more being practicable in many cases. The indigo planters have always had the reputation of being good cultivators, but indigo being one of the family of *Leguminosæ* is in their favour.

One speaker who took part in the discussion referred to is reported to have said that the subject of a scientific expert for tea had been discussed at a meeting of the Royal Society, and that Dr. Voelcker had stated that scientific inquiry should extend over a period of twenty years. I doubt very much if ever this subject has been under consideration by the Royal Society, and am certain if Dr. Voelcker ever expressed an opinion of the kind he would have assigned a much longer period. The same speaker asks "how many proprietors of tea gardens could be found who were so considerate for posterity as to spend large sums of money annually from which they themselves could derive no benefit." But with a long-lived plant like tea especially, this is just what must be done in the interests of present proprietors as much as that of posterity. There is often short-sighted procedure in regard to the management of tea property that is quite as much opposed to the interests of the present owners as of posterity if rightly viewed. This applies equally to the conquering of new markets as to the employment of scientific experts. The fruits of such efforts should all be anticipated, or the absence of them discounted, in estimating the present value of tea property. All who can in any measure realise the difficulties attending the chemical investigation of tea culture and manufacture, and the nature of scientific research in connection with agricultural chemistry in this country, so far from considering twenty years too long, must have good reason to fear that would not prove long enough to obtain really valuable results, not to speak of exhausting the subject. We have but to think of the conflicting opinions and results of agricultural chemists in different countries. Sir John Bennet Lawes has since 1843 been carefully conducting most elaborate scientific experiments in agricultural chemistry in all its departments on his ancestral property at Rothamsted, aided by that eminent chemist Dr. (now Sir Henry) Gilbert, with a thoroughly equipped laboratory and a staff of scientific and practical assistants, at a cost to himself of thousands of pounds annually. They do not consider their investigations yet exhausted. So far from it, Sir John B. Lawes in 1889 set aside £100,000 under the necessary trust deed to secure the continuance of those experiments after his death. Such is his opinion of the time required for such research and the duty to posterity in such a cause.

But we must not for all this be discouraged. The chemistry of tea may be considered practically an unexplored field. There will be all that has been accomplished in agricultural chemistry, and in connection with the arts and manufactures up-to-date to aid us at the outset. And if practical planters have all thought out, and worked up to the points at which they come to a standstill, and the scientific expert be well directed and put on the track, much may possibly be achieved in a short time.

Of course there is much in regard to such research that proves rather interesting than of practical utility. It is interesting to determine the amount of nitrogen in the rainfall, the loss of nitrogen by drainage, the life history of pests and parasites, possibly also the conditions of the atmosphere that are suffered to mysteriously affect quality but unfortunately those matters are beyond the control of science. Recently German chemists have claimed the discovery of a method of inoculating the soil, by which it is secured that the conditions under which leguminous plants can fully assimilate the nitrogen of the air shall always be fully present. To this inoculating material they have given the name "nitragin." If there prove to be

any practical benefit in this it could be applied to green manuring for tea. The same with many other discoveries.

Allusion was also made in the discussion to Mr. Bamber, the scientific expert who was appointed by the Indian Tea Association a few years ago. He doubtless made the best of his time and opportunities. His report was a valuable contribution to the literature of tea, and is now the standard work on tea generally, though he stamps with his approval at least one, in my opinion, vital fallacy in tropical cultivation. He gave all the varied opinions ever held or expressed by planters on different subjects, and he described or referred to all the blights and pests to which tea is subject, but without aiding as to their eradication or cure. Neither was much added to the knowledge of the chemistry of tea, and I fear there was little or nothing contributed towards improvement in the practice of manufacture. He gave the undigested results of some manuring experiments—some of them of old date—by planters as furnished to him. His attention never seems to have been directed by the Association to ascertaining the mineral elements required to produce quality, or to even visit the district conspicuous above others for quality. But I repeat that Mr. Bamber acting under the orders of the Tea Association, did all what was possible in the time, and for this he should have full credit. Allusion was also made to Dr. Watt and his having done "much good work in a short time." Dr. Watt I know as a botanist and an able writer. He may have some knowledge of chemistry also, but I am unaware if he be an agricultural chemist or a practical agriculturist. He has done something for tea by his investigating into the damage to the lead linings and tea from the use of unseasoned and otherwise unsuitable wood for chests.

In addition to the noble example of Sir John B. Lawes, much is being done at home, I believe, entirely by private enterprise unaided by Government. The next of importance is perhaps the experimental station of the Royal Agricultural Society of England at Woburn, aided by the Duke of Bedford, and conducted by Dr. Voelcker. Experiments are carried on a smaller scale at Newton-le-Willows, and by the more enterprising farmers' associations as in Eastern Ross. Most laudable and beneficial have been the unaided efforts of Mr. Findlay, of Fifeshire, in the rearing of new varieties of disease-resisting potatoes. All this should prove an incentive to the great tea industry.

Ceylon also as usual bids fair to set India another example. Not only a scientific expert, but technical schools for instruction in tea manufacture are being advocated for the island.

The Indian tea industry ought to have a competent agricultural chemist who is an enthusiast in his profession with a well-equipped laboratory and an efficient staff of assistants. These should be liberally supported as a permanent institution. In regard to such an investigation no half measures can suffice. They can only prove a delusion and a snare.

It is to be hoped, therefore, that the Indian Tea Association and tea industry may make an unanimous and lasting effort worthy of so great a cause, and that, as recommended, the Government may be induced to provide half the funds thus required in the interests of an industry that contributes so much towards the prosperity of India and the empire generally.—*H. & C. Mail*, Sept. 4.

PLANTING AND PRODUCE.

THE GLORY HAS DEPARTED.—The excitement that used to attend the race of the China tea clipper has gone, so far as this country is concerned, and if a cable from New York contains reliable information it is much the same in regard to America. From New York we learn that the British steamer "Hankow" arrived from China on Sunday. She and the steamer "Glenogle" left China at the same time in Juno loaded with tea, and the "Glenogle" arrived on

Wednesday. Captain Orr, of the "Hankow," when told of the arrival of the "Glenogle," said: "I received instructions from the company's office in London to keep up a speed of only 10½ knots an hour. I could have done 14 knots, and might then have beaten the "Glenogle." The "Hankow" is owned by Messrs. W. Milburn and Company, of London.

POPULARISING INDIAN TEA.—The connection between a church organ and Indian tea does not seem very near at a first glance, but in Dover they contrive to bring it about. At St. James's Church there a new organ is wanted, and a somewhat novel way of providing the necessary funds has been taken. According to the rector, in this month's parish magazine, a number of the parishioners, rich and poor, have taken up the sale of tea, which is sent home by a well-wisher in India, the profits going towards the fund, which has already reached a considerable sum.

PRODUCE AND THE TRADE RETURNS.—According to the Board of Trade returns for August there is a diminution in the import of tea as compared with August, 1895, amounting to £324,908. Of this India's share in the decline is £216,500 and Ceylon's £77,000. Cocoa fell off the value of £76,886. Less sugar by £210,000 came to us this August, Peru being the only source from which we obtained more than last year. The greatest falling off was in the arrivals from Germany and the Philippine Islands. The quantity of wheat (5,153,000 cwt.) compares with 9,966,000 cwt. in 1895 and 8,717,000 cwt. in 1894. The United States sent 2,286,000 cwt. or only 353,000 cwt. less than last year, but from Russia, the Argentine Republic, the British East Indies, and Australasia there came in the aggregate only 1,652,000 cwt. compared with 6,428,000 cwt. last year. The statistical position of wheat would seem, therefore, to be favourable to a rise in price but for the recent heavy shipments from the United States. It must be borne in mind that the figures for August, 1895, were unusually high, and that this year August had only 25 working days compared with 26 last year.

A PLEA FOR COFFEE.—Mr. David Strang, a "coffee specialist," of Southland Steam Coffee and Spice Mills, Invercargill, New Zealand, writes with reference to the decline in the consumption of coffee: "Perhaps the reason why the consumption of coffee is on the decline is that manufacturers have not given it any special consideration. If the trade were taken up by a few specialists, on the same lines as the cocoa trade is run, it would, in my opinion, increase the sale. I have gone to a lot of trouble and expense in machinery and other matters to get coffee up in several forms to suit the various tastes (best raw materials only being used), and the public have the following variety to choose from: Raw coffee, roasted coffee, pure ground coffee, pure coffee with pure chicory only, patent soluble coffee powder, made instantly with boiling water or milk, and patent 'Koff' coffee, being pure coffee and chicory with a small proportion of specially prepared pure cocoa."

A NEW RUBBER INDUSTRY.—The new rubber industry at Lagos affords one of the most remarkable instances of the rapid development of an industry that has taken place in recent years in any British colony. It owes its existence to a wild plant which was only discovered in Lagos within the last two or three years says the *Kew Bulletin*. It was found to be new as a source of rubber, although there is now reason to believe it had yielded some of that formerly exported from the Gold Coast. At the present time Kicksia rubber from Lagos has established itself as a commercial article in great demand. The exports in January, 1895, were 21,131 lb. of the value of £1,214. This was practically the beginning of the industry. In December, 1895, the exports had increased to 948,000 lb. of the value of £51,438 9s 4d. From a recent return, communicated to Kew by the Government of Lagos, the total exports during the year 1895 amounted to 5,069,501 lb. (2,263 tons) of the value of 269,892 13s 10d. This considerable industry has therefore been called into existence within twelve months. The rubber is purely a forest product, and

the collection and preparation of it have been effected by means of native labour. The success of the industry is another indication of the undeveloped resources of our West African Colonies.—*H. and C. Mail*, Sept. 11.

THE BRAZILIAN COFFEE TRADE.

AN INDUSTRY WHICH HAS NOT HAD FROM
BRITISH CAPITAL ALL THE ATTENTION
IT DESERVES.

A correspondent writes:—The wide disparity between their financial standing as nations and their commercial resources must often have struck all but the most superficial observers of the South American republics. The Argentine Republic, Brazil, Uruguay, and Paraguay have all passed through a more or less acute crisis in their national finances, and are now all at varying stages of convalescence. Brazil, which from the point of view of national finance, probably occupies the worst position, must be awarded, in any comparison based on commercial resources and potential national riches, only the best place of any of the republics on the South American continent. It may be some such considerations as these which have produced the recent strength in South American securities. New agricultural industries, the constant extension of existing sources of revenue, and the almost boundless territorial possessions of Argentina and Brazil are all matters which may well for a moment lead investors to disregard Government mismanagement of national finances, and look rather to the immense success which in so many South American fields has over and over again attended private enterprise.

The Brazilian coffee industry is a case in point. A fertile soil and every natural opportunity have combined to produce a trade which numbers among those engaged in it the wealthiest men in Brazil. A constant stream of immigration from Europe keeps up a supply of healthy labour. Spaniards, Scandinavians, but principally Italians and Germans, are annually landed in their thousands in Brazil, and rapidly absorbed into the multitudes engaged on the great coffee estates of San Paulo. The State of that name contains a population of more than 2,000,000, at least one-third of which is foreign by birth. Of the 160,000 souls comprising the population of the city of San Paulo, the capital of the State, probably one-half are foreigners. The State itself produces three-fourths of the entire coffee crop of Brazil, or, on the estimates of the export for 1896, receives about £15,000,000 annually from this single industry. It is obvious that an industry of this kind and magnitude cannot be considered as anything but one of the staple resources of the country where it is carried on, and this the coffee trade is, in fact, to Brazil.

The English-owned San Paulo Railway connects the great inland network of Railways in the State of San Paulo with the sea at the port of Santos. As a result of recent negotiations with the State and Federal Governments this line is about to spend from £1,500,000 to £2,000,000 in doubling its track and in building new stations and warehouses to meet the ever-increasing demands of the coffee trade upon it. Needless to say, various London banks trading in Brazil have branches in San Paulo and at Santos, its port; and it is very certain that the abandonment of the business done

by them in the coffee province would have a very considerable influence for the worse upon their dividends. San Paulo's prosperity rests upon the coffee trade; but it is notorious that while German, Italian, and American capital has been freely invested in coffee estates, English capital has not, up to the present, shown any inclination to flow in the direction of that outlet. This apparent want of enterprise may arise from lack of opportunity of knowing the truth about the coffee industry. German labour may attract German capital and Italian immigration Italian capital; while the American, well aware of the enormous imports of Brazilian coffee into the United States, is not slow to invest his capital at the fountain head of the trade.

Still, with the tenure of property absolutely protected, and a public peace which is only occasionally disturbed by brawls between the various races congregated in the State, it is not to be wondered at that British capital is now moving to a much greater extent than has in the past been the case in the direction of Brazilian coffee estates. A loan of £80,000 on a portion of one of the estates is a comparatively small transaction. What may in time come to pass will probably be the placing of some of the larger estates entirely in English hands, with English capital behind them. Given a productive estate, with a good plant and railway service of its own, as well as a good connection with the State lines, well stocked with trees, with facilities for the planting of more as the business extends, and—what is most important—a good record of increasing profits in the past, and British capital would not be slow to avail itself of the opportunity of investment. A venture of this kind would offer a security almost equal to that of real property in this country, with potentialities of profit infinitely greater. A Brazilian coffee company, capitalised in a fair proportion to the extent of the property acquired, ought to be able to pay a steady dividend of 15 per cent. on its ordinary shares, and to create a strong reserve fund at the same time.—*Financial News*, Sept 9.

TEA IN AUSTRALIA.

Teas.—A little demand for Ceylons; 200 chests sold at 5½d, and 100 chests of fine sold at 1s, 250 quarter-chests of Kaisow buds also placed; 500 half-chests of Indian sold. The second sales of new season Foo Chow teas, ex Sikh, were held on 27th August, by Messrs. Geo. Crespin and Son and Messrs. Fraser and Co. The biddings were not brisk, and results were disappointing to importers, prices ruling low. At the two auction sales 3,893 chests and half-chests sold up to 9½d for S.O.P., Panyongs to 6½d. At the auction held on the 1st September, 676 packages were offered, 409 packages selling up to the following prices: For pekoe, 10d; broken pekoe, 10½d; broken orange pekoe, 10½d; pekoe souchong, 6½d. The Acme packages sold up to 10½d.—*Leader*, Sept. 5.

SCIENTIFIC EXPERT FOR THE TEA INDUSTRY.—An occasional correspondent in the *Home and Colonial Mail* has contributed an interesting article on this subject which we quote on another page. The writer does not consider that tea-making comes within the realm of science so fully as is generally supposed, but at the same time he thinks it right that practical men should have the aid of skilled scientists and that this might be productive of great results even in manufacture. Complimentary reference is made to Ceylon in the course of the article.

COFFEE AND RUBBER CULTIVATION IN CEYLON.

Coffee and rubber are, at this moment, the two tropical products, the supply of which is in no danger of exceeding the demand, and at profitable prices. Attention has been very prominently drawn by us in the columns of the *London Times* to the falling-off and scarcity in the supply of coffee—and in connection therewith to the small encouragement there is for extending the cultivation of tea beyond India, Ceylon, and perhaps Java. We do not at all want home capitalists to be led into the foolishness of embarking their money for the opening of tea gardens whether in Africa, South or Central America or elsewhere. We doubt, indeed, whether our Java neighbours would not do better in keeping to coffee and cinchona; but that is their outlook. On the other hand in respect of our old staple, coffee, there is strong encouragement to extend the culture, and one result of the attention drawn to the subject is that we find new and influential Companies brought before the British public for the promotion of coffee cultivation in Brazil as well as Costa Rica. With both of these, well-known leading Ceylon planters—Messrs. H. K. Rutherford, J. Huntley Thring, J. L. Shand and G. A. Talbot—are connected as Directors; and there can be little doubt that the result will be a considerable impetus to production. The pity is that with a product so much in demand as coffee, a special effort cannot be made to revive the culture in Ceylon on a considerable scale. We by no means lose sight of what is being done to conserve the area planted in Uva, notably Haputale; and still more do we recognise the enterprise which has marked the cultivation of a good-sized clearing of Liberian coffee in the Kelani Valley. May a full measure of success attend the experiment. But what is wanted to ensure further and wider attention to coffee, is surely that all interested in the product here, in India and at the Straits should unite to support the mission to import the ladybird beetles from Queensland to prey on the “bug” and other enemies of coffee. When this is done, there may be justification for new clearings in the hill-country as well as the lowlands.

But to turn to the other product, India-rubber, we can at once with a clear conscience urge its wider culture in our island as a subsidiary product to tea, if not in separate clearings. The demand for rubber in Europe and the United States is increasing every day. The uses for it are multiplying in all directions. The “Cycle” industry alone has created an immense demand. All the supply from the primeval forests of Africa as well as from the basin of the Amazon is not equal to the demand and must year by year now, become less so. One source of supply, Madagascar, is for a time cut off; and the exports from India and the Eastern Archipelago are not increasing. The price of raw rubber is firm if not steadily upwards. It is under these circumstances that we would urge increased attention to the species most desirable for cultivation in Ceylon. Some of the kinds originally tried here—the Ceara for instance—did not succeed so well as was anticipated, although possibly, sufficient time was not allowed for a fair trial. On the other hand, there are certain species, the *Landolphia* may be specified, which are likely to give a handsome return. It would be well if the Committee of the Planters’ Association made

inquiries as to what may be generally recommended to planters inclined to take up the cultivation. We know that British manufacturers of rubber goods are getting anxious about their supplies; and one large Company—the North British, alluded to in our letter from Glasgow,—may be sending out a Commissioner enroute to examine and report on likely new sources of supply, as well as to urge extended cultivation wherever practicable. Under such circumstances, Ceylon ought not to be behind in competing as a producing country—more especially because to diversify and divide our tea gardens with some suitable as well as profitable product, would be one of the best means of ensuring the continued prosperity of the great staple of our planting districts.

MARKET FOR TEA SHARES.

Sept. 10, 1896.

Business during the past week has been rather brisker than for the last week or two, the Stock Exchange official list showing as many as seven or eight different markings in one day. Prices on the whole keep firm, with a slight upward tendency.

Mincing Lane Market keeps steady, and biddings have been fairly active, teas with quality making very good prices.

CEYLON SHARES.

C. T. P. Co. Ordinary have changed hands down to 29½, with shares now offering at 29½.

Associated Company shares have again changed hands, the Ordinary and Prefs. together at 10½, and the Prefs. alone at 10½.

Dimbula Valley Ordinary have changed hands at 6½ and 6¾, with possibly a few more shares to be had at the higher figure. There is no business to report in the Prefs., but shares might probably be had at a little over 6½.

Eastern Produce and Estates Ordinary are again said to have been done at 6¾.

Ouvah coffee have been done at 12½.—*Home and Colonial Mail.*

THE SUPPLY OF RUBBER.

The following article is from the *Manchester Guardian* of Sept. 11th. It shows that although Western Africa has greatly increased its export of rubber of late years, yet there is some danger of the supply henceforward falling off:—

“It is fortunate for the prospects of the cycle industry that the new supply of india-rubber from Lagos promises to be abundant. The “Kew Bulletin” publishes the latest intelligence of this fresh colonial product, which affords one of the most remarkable instances of rapid development of natural resources in our times. The “Kickxia Africana,” wild forest-plant growing abundantly in the interior of Lagos from which the new rubber is derived, differs considerably from the tree furnishing the Brazilian rubber. It was discovered in Lagos in the latter half of 1894, and the first exports of any consequence were made in January, 1895. In that month the shipments amounted to 21,131 lb., valued at £1,213. Thenceforward there was a steady increase month by month, and in October last the quantity reached 1,059,158 lb., and the value £57,117, the returns for November and December showing only a slight decrease. In the whole of last year—the first of the existence of this trade—the exports from Lagos were 5,069,504 lb., of which the declared value was £269,892. The collection and preparation of this raw product are carried on entirely by means of native labour, and, although for a

time difficulties arose out of the claims of forest rights and transit dues on the part of the local chiefs, these appear to have been surmounted. Writing in the early part of this year to Mr. Thiselton-Dyer, of the Royal Gardens, Kew, the Acting Governor of Lagos stated that, according to prevailing opinion there, a considerable falling off in the export of india-rubber from the colony would be witnessed in 1896. He added, however, that no one was competent to give a trustworthy opinion on the subject. The production of rubber from the "*Kickxia Africana*" in Lagos was preceded by its manufacture from a similar plant in the Gold Coast Colony a few years earlier, where attention was first drawn to it in 1882 by Sir Alfred Maloney, then the Governor. In that colony the export, though declining a little after its initiation, is now well maintained, the amount imported from the colony into the United Kingdom last year having been valued at £246,160, besides that sent to the Continent and the United States."

INSECT PESTS.

TO THE EDITOR OF "INDIAN PLANTERS' GAZETTE."

DEAR SIR,—May I, through the medium of your Journal, remind planters and others interested in agriculture that we are still, at the Indian Museum, carrying on our efforts to identify the chief insect-pests of this country—as well as the chief natural enemies of these insect-pests—in the hope of ultimately producing systematic registers, or rolls, of the animals that affect each particular kind of crop whether by ravaging the crop or by preying upon the ravagers; and may I appeal to planters to kindly continue and extend their assistance to us in this enterprise by contributions of specimens and field notes. Such specimens should be addressed to the Superintendent of the Indian Museum.

In return for this assistance we can only hold out the final hope of providing a more or less complete account of the animals (chiefly insect) that affect—whether adversely or beneficially—each particular kind of crop or industry. We cannot test the value of insecticides or undertake the work of an agricultural experiment station, though we shall of course be happy to communicate, so far as we are able, the published results of exterminant experiments undertaken in countries where agricultural stations exist.

—Yours faithfully,

A. ALCOCK,

Superintendent, Indian Museum.

—*Indian Planters' Gazette*, Sept. 16.

THE DYEING PROPERTIES OF JAKWOOD.

The Agriculture Ledger, 1896, No. 4, contains the following paper:—

The Constituents of *Artocarpus Integrifolia*. Part I. Contribution from the Clothworker's Research Laboratory, Dyeing Department, Yorkshire College, by Arthur George Perkin, F.R.S.E., and Frank Cope, Reprinted from the Transactions of the Chemical Society, 1895.

From this we quote as follows:—

Artocarpus integrifolia is the well-known jack-fruit tree, belonging to the Urticaceæ, a large tree cultivated throughout India, Burma, and Ceylon, except in the north. When freshly cut, the heart-wood is yellow, but this, on long exposure to air, gradually darkens, finally becoming of a mahogany colour. It is largely used for carpentry, furniture, etc., being considered one of the most handsome furniture woods used in the country, and is stated to be exported to Europe for this purpose. The rasped wood is used by the natives of India and Java as a yellow dye, in conjunction with alum, for colouring the robes of the Burmese priests, also for dyeing silk, and for general purposes.

A sample of this wood was brought to England by Mr. John Ingleby, late Chief Surveyor* of the Northern and North Central Provinces of Ceylon, who introduced it to the notice of Messrs. Wood and Bedford, of Leeds. This firm being anxious to test its utility as a dye-stuff, and, moreover, being struck by its resemblance to old fustic (*Morus tinctoria*), imported a considerable quantity from Ceylon, and to them our best thanks are due for a supply of material for the carrying out of this investigation.

A characteristic property of this dyewood, by which it may be distinguished from either old fustic or any other natural yellow dye-stuff that has come under our notice, is as follows. If an aqueous decoction be treated with dilute alkali, a yellow solution is obtained, and this, if gently warmed, assumes a beautiful blue tint, which, on standing, rapidly becomes green, and finally brown-yellow.

In a former communication (Perkin and Pate, this vol., 649) it was shown that though morin yielded acid compounds very similar to those produced from quercetin and other allied colouring matters, it differed from these in that during the formation of its sulphuric acid compound 1 mol. of water is eliminated. In order, therefore, to be quite certain that the colouring matter of jackwood was really morin, its solution in boiling acetic acid was treated with sulphuric acid. On cooling, an orange-red, crystalline mass separated, which was collected, washed with acetic acid, and dried at 110 deg.

The composition of the sulphuric acid compound, and a comparison of this and the hydrobromic acid derivative with those of morin obtained from old fustic, left no doubt as to their identity. The colouring matter of jack-wood is therefore morin.

Attempts to prepare acetyl and other derivatives have yielded at present unsatisfactory results, and this is no doubt due to its instability in the presence of most reagents. It is our intention to continue the study of this most interesting substance, but this work will of necessity be slow, for its isolation from the dyewood in any quantity will entail considerable time and labour.

As morin has been previously only known to exist in old fustic, and as this dye-stuff contains also a second colouring matter, maclurin, it was necessary to determine whether the latter also existed in jack-wood. Various tests, however, showed no indication of the presence of this substance; but in order to be quite certain, it seemed best to prove this indirectly by examining old fustic according to the methods employed with jack-wood.

A boiling aqueous extract of old fustic was therefore treated with lead acetate, the precipitate collected, and the filtrate, after removal of lead in the usual manner, evaporated to a small bulk. The dark-coloured liquid thus obtained was treated with excess of salt, filtered, the filtrate extracted with ethylic acetate, and the extract evaporated. The resulting sticky product showed no signs of crystallisation, and it was therefore dissolved in dilute acetic acid and allowed to stand some hours. A light yellow precipitate gradually separated, which was collected and purified by crystallisation in a similar manner, and this was found from its dyeing and other properties to be identical with maclurin. With lead acetate solution, it yielded a precipitate, but was not entirely thrown down in this way, and its isolation from old fustic in the above manner is due to the fact that its lead compound at first formed, is partially decomposed by the acetic acid which is simultaneously liberated from the lead acetate. On the other hand, morin is entirely precipitated by this reagent.

Jack-wood thus treated as here shown yields no substance having the properties of maclurin, and its non-existence in this dye-stuff is thus conclusively proved. Morin is consequently the sole colouring matter of jack-wood, and the cyanomaclurin which it contains occupies the place of the maclurin in old fustic.

As the dilute acetic acid filtrate from the precipitated maclurin (see above) appeared to contain

* Indian Civil Service.

a second substance, it was evaporated to dryness, a dark-coloured sticky residue being thus obtained. When boiled with dilute alkalis, and aqueous solution of this product darkened somewhat in colour, but did not yield the characteristic blue tint formed when cyanomaclurin is thus treated. In a similar manner to the latter, however, it was decomposed by boiling dilute acids with formation of a red-brown precipitate, and evidently consisted of a substance not hitherto known to exist in old fustic. It gives no precipitate with lead acetate solution, and is therefore distinct from the tannic acid which according to Lowe (*Fresenius Zeitschrift für Analytische Chemie*, 14, 127), is present in this dye-stuff in conjunction with morin and maclurin. This substance will be submitted to examination.

DYEING PROPERTIES.

As was to be expected from the results of its chemical examination, jack-wood dyes shades very similar to those of old fustic, that is, olive-yellow with chromium, dull yellow with aluminium, and a brighter yellow with tin mordant. The results obtained, however, are somewhat disappointing when it is considered that its sole colouring matter is morin, for this by itself dyes fine bright shades, whereas those yielded by the wood are duller in comparison. This must be accounted for as due to the brown decomposition products of cyanomaclurin which are probably formed to a slight extent during the dyeing operation, and also exist in the free state in the dye stuff itself.

Experiments showed that the sample of jack-wood here examined contained only about one-third of the colouring matter of old fustic. It is, however, probable that this represents a poor quality, for that brought originally from Ceylon by Mr. Ingleby was found equal to old fustic in dyeing power.

TEA PROSPECTS.

TO THE EDITOR, "INDIAN PLANTERS' GAZETTE."

SIR,—It must be reassuring to all those interested in Indian tea to have read in your issue of 5th instaut, the bright prospects held out for this product. In these pessimistic times not a few of our older planters look askance and gravely shake their heads at the pending ruin shortly to overtake the industry. And now that so many mammoth gardens are being opened out, the anticipated catastrophe cannot be delayed much longer. "What," they say, "can be done with all this tea? Where can people be found to drink it? And where can markets be secured to relieve us of these extra million pounds?"

However, Mr. Editor, as these ill-omened prophecies have filled the air for well nigh twenty years, they can, like the witches in Macbeth, only affect those of gloomy and dark imagination, those whose judgment is swayed by a despondent phantasy, and now that "Capital's" letter has appeared in your columns, these wiseacres must feel not a little disconcerted at this gleam of hope and sunshine thrown out to encourage a vast and growing industry.

Had we no faith in British energy and no confidence in the rising importance of India as a field for commercial enterprise, we could not at this moment proudly look back at the marvellous development which has taken place in this industry during the last decade. From occupying a place of mere secondary importance, Indian tea has advanced with leaps and bounds and is now recognised as one of the prime factors in the export trade of the Empire and, if according to "Capital," within the next four years by "using the most energetic and prompt measures," it is possible to create a demand for Indian and Ceylon teas to the extent of over one thousand million pounds, then it is safe to predict that tea is yet a long way off from even the zenith of its greatness.

We all note with interest the active measures now being taken in opening out the American market and the satisfactory results obtained by Mr. Blechynden's exertions in that quarter. But at the same time, the Association ought to bear in mind that

America is not the only market in the world that has to be opened out for our teas. Attention ought to be drawn to Russia, Persia, Turkey and Central Asia with all their teeming millions of people. Why should not agencies and depôts be established in these countries? Why should these people be denied the luxury of knowing what it is to drink a good cup of Indian tea? Let them but acquire the taste for our soothing beverage and they will find that life is well worth living. Besides, the continued use of our teas, will soon convince them that the Indian leaf has got properties peculiar to itself and cannot be surpassed or even equalled by that of any other country.

Prompt action ought at once to be taken to secure these outlets for our trade and every garden ought to contribute its share in helping to forward the works. Were the necessary funds forthcoming there would be no difficulty in securing first class men with a business capacity and knowledge suitable for advancing the interests of Indian teas in those centres now referred to. A PLANTER.

—*Indian Planters' Gazette*, Sept. 19.

THE NEW LONDON TEA MARKET (LIMITED.)

A winding-up order having been made against this company on July 29th last, the creditors and contributories met yesterday before Mr. A. S. Cully, Assistant Official Receiver, at the Board of Trade offices, Carey-street, Lincoln's-inn, for the purpose of appointing a liquidator. The circumstances connected with the company were of a somewhat peculiar nature.

Having disposed of the proofs, the Chairman said that approximate accounts had been furnished showing liabilities £6,429, of which £3,825 were unsecured, with assets £10. The deficiency as regards contributories was returned at £5,161. The company was incorporated on October 14, 1892, with a nominal capital of £5,000, divided into 2,250 proprietors' shares of £2 each, and 500 deferred shares of £1 each. It was formed for the purpose of buying and selling tea on commission. The promoter of the company was Mr. W. B. Neale, who entered into an agreement with the majority of the signatories whereby he was appointed managing agent of the company for ten years at a salary of £300 per annum. Under the articles of association Mr. Neale was entitled to exercise alone all the powers conferred on the directors. The agreement also provided that the consideration of the services rendered by him in connexion with the formation of the company, the latter were to pay him £875, to be satisfied by the issue of 250 proprietors' shares fully-paid up, and 500 deferred shares credited with 15s paid. The company started operations with a paid-up capital of £60, the working capital being provided by an advance of cash on deposit to the extent of £300. Mr. Neale acted as managing agent down to March 31, 1894, exercising sole control over the affairs of the company. On April 2 following his office was terminated by the appointment of a board of directors. The accounts appeared to have been very imperfectly kept while Mr. Neale acted as managing agent, and when the board of directors was appointed the company's position was not disclosed. A statement prepared in October, 1894, showed that a deficiency of £908 existed in March previously. The Company's operations from March, 1894, to December 31 following appeared from accounts presented to the shareholders on April 30, 1895, to have resulted in a loss of £76. The purchases of tea for that period

were represented at £19,497, and the sales at £18,444. An examination of the books during the preparation of the accounts referred to disclosed the fact that grave irregularities had been committed, and, as a result of further investigation, the bookkeeper was suspended, and Mr. Neale quitted the company's service. The latter subsequently agreed to pay £500 in discharge of any claim the company might have against him and, £200 was paid on account thereof, and the Company assigned the balance to a creditor for £200. In June, 1895, Mr. R. Sefton became the manager, and during his occupation of that office a number of what were termed "swopping" transactions were carried out; The nature of these dealings, which were represented as *bona fide* sales and purchases, appeared to have been an exchange of tea at fictitious values, in order to obtain increased advances upon the warrants. The result of these operations was that the company paid larger commissions and bonuses to the manager than he was entitled to, and the stock of tea (the warrants for which were held by the banks against advances) was largely over-valued. When any of the tea was sold the deficiency in the value had to be made up the Company before the warrants could be released from the bank. The accounts at December 31, 1895, presented in May last, showed a net loss for the year of £119, the purchases of tea being represented at £23,749, and the sales at £23,352. Inasmuch as the stock estimated at £3,939, was, in consequence of the "swopping" transactions, highly over-valued, the actual loss was much greater. The chairman of the Company (Mr. E. A. R. Ewen) had financially assisted the concern from time to time, and was now a creditor for nearly £1,200. The failure of the company was attributed by its officials to—(1) losses incurred through "swopping" transactions; (2) misapplication and misappropriation of the company's funds; and (3) mismanagement and bad debts. In concluding the chairman said that the registration of such a company was an abuse of the Companies Acts. It enabled the promoter (Mr. Neale) to trade without any personal liability, and at the same time to secure an income of £300 a year. That gentleman also received £875 in shares, and it was very difficult to see what consideration the company obtained for them, and he reaped the benefit of the business at the expense of the creditors. His nominees, to whom the shares were allotted, were appointed directors. The case was one which called for an investigation of a public nature, and the Official Receiver was determined that the utmost publicity should be given to it, and he therefore proposed to apply to the Court for an order to examine the persons connected with the company.

At the meeting of creditors no quorum was present, and an adjournment until the 21st was taken, the Chairman intimating that, in the event of no resolution being then passed, the matter would remain in the Official Receiver's hands.

The shareholders decided to leave the case with the Official Receiver, and the proceedings terminated.—London *Times*, Sept. 13.

THE LADY-BIRDS AGAIN.

One of the late issues of the *Ceylon Observer* contains some interesting notes on the Lady-Bird question. Incidentally reference is made to Professor Marshall Ward's distaste to the entire abandonment of Ceylon's first great staple, coffee. It will be remembered that this scientist, now permanently attached to the Scientific Staff of Cambridge University, first won his spurs by his

careful working out of the Life History of *Hemileia vastatrix*. The following letters are then published on the difficulty of obtaining the lady-birds without their particular parasites. * * *

Mr. Ferguson then brings forward an admirable suggestion that, as most probably sufficient funds would not be obtainable among Ceylon coffee planters alone to defray necessary expenses, coffee men in South India, the Straits and Borneo should all come forward and help. We suppose that it is practically impossible to accurately gauge the annual loss caused by bug, but it must run to a very big figure indeed, certainly many times and probable cost of temporarily securing Professor Kœbele's services, some R15,000 at most. In urging the matter on our readers we are not advocating any general appeal for scientific aid of indeterminate value to the coffee industry. It is a very plain and business-like scheme. We think no one will accuse us of the slightest exaggeration if we put the annual loss of crop in South India from bug at half a lakh of rupees. From all the accounts hitherto published of the Kœbele experiments at Honolulu, bug can be absolutely wiped out. At a cost of some R15,000 at most, we would have a very good chance of effecting the same cleansing process in South India. The question is this: whether it is worth our while to spend R15,000 now and once for all, in order to save ourselves an annual loss of R50,000? There is of course no absolute *certainty* of the experiment proving quite so successful as it has in Hawaii, but there are very excellent chances of it so doing.

There is further every probability that if the Ceylon and Straits planters come forward, as the former are almost certain to do, the estimated R15,000 will be reduced to half that amount. It would certainly do no harm if the U.P.A. put itself into communication with the Ceylon P.A., and instituted enquiries as to the exact cost of the proposed investigations, and what portion of this the Island would be prepared to give. While committing ourselves to nothing, it would tend to clear the ground and bring matters to a head.

We had thought, when we first took up the subject, that the importation and subsequent distribution of these lady-birds would be a very simple matter. We consequently wrote for a consignment of the best varieties to be sent us from Queensland, which were promised us in due course. Up to date, however, we have heard nothing further from Australia, and now being no more conversant with the difficulties of the situation are almost glad that so far our efforts have been abortive. The lady-birds required have, it seems, certain parasites, which it imported with them, would render it impossible to obtain their necessary multiplication. To divest them of these unwelcome *attachés* requires special and trained aid.

Further, it appears that personal attention on the voyage out—as the insects must be kept on ice to preserve them in their dormant condition—is almost indispensable. Lastly, before successful distribution can be hoped for, they must be carefully watched and attended to for many weeks by trained scientists.

It is without doubt partly owing to these difficulties that Mr. H. O. Newport, whose name is so closely connected with the question in South India, has decided it would be better not to attempt any importation at all. It will be remembered that in his valuable paper read before the U. P. A., he advocated the encouragement of certain indigenous varieties that he discovered

eeding on the bug, and recommended that the services of a Government expert be called for to pursue his investigations. It is with diffidence that we venture to disagree with Mr. Newport in this matter, to which he has now for so many months given his closest attention. Yet we think that the very face of the species being indigenous militates against their value. They have all the conditions required for their speedy multiplications and consequent destruction of bug, so why is bug found at all in South Indian coffee? What is the factor that preserves the balance of nature in this instance? We would make a shrewd guess in suggesting that the presence of parasites will probably be found to have a great deal to do with it. We are strongly of the opinion that if Government aid be invoked at all, it should primarily be directed towards the importation of those varieties which have achieved such signal success in Hawaii. The matter, we think, is however essentially one for experiment—argument is more or less out of place. In conclusion we trust Mr. Newport will continue his important investigations, whether Government aid be obtained or not: the value of such original research cannot easily be over-estimated.

We may mention here that the late Dr. Nietner, in "The Coffee Tree and its Enemies" advertised elsewhere, published a description of the *Chilocorus circumdatas*, a kind of lady-bird parasite feeding on the Brown or Scaly Bug, generally called the Black Bug, *Lecanium coffea*. The work was printed in Ceylon in 1886.

Since writing the above we notice two communications of interest in the *Ceylon Observer*, the first one being a letter from Mr. Ernest Green, the author of the coming book on the Coccidæ of Ceylon, on the subject of the fund. * * *

The next is a letter from the inevitable wet-blanket, whose remarks however it is only fair to publish as giving the other side of the question. Our contemporary, the *Observer*, it is needless to add, attaches but the slightest importance to the views of its correspondent.—*Planting Opinion*, Sept. 26.

BRITISH CENTRAL AFRICA CURRENT CHAT.

Pulping has been in full swing during the last month on all the low elevation estates.

We understand that Messrs. Foulkes and Pigott intend setting up their machine on one of the Lake Nyasa islands and treating *Sanserriera Cylindrica* (Ife Hemp) which is said to be abundant in a wild condition on the Lake Nyasa islands. They have obtained a concession from Government for this purpose.

While most readers of *Life and Work* will be thankful for the medical notes at present appearing we fear some of the remarks will not be appreciated owing to their evident absurdity, e.g. the following:—

"The preparation of palatable coffee is a task which up to the present time has baffled the endeavours of most coffee-planters in British Central Africa," etc.

We have yet to learn that Dr. McVicar has sampled the coffee brewed by "most" coffee-planters in B. C. A. If he has he must have been doing little else since his arrival at Blantyre only some three months ago. Dr. McVicar is evidently anxious to place the results of his specialised training at the disposal of the B. C. A. public and the effort is a laudable one. It is to be hoped therefore that he will not prejudice his readers by indulging in criticisms which are only the result of a three months' experience.

That a planter's coffee may be bad is further not necessarily due either to incompetence or laziness. It may be due, we would suggest, to pressure of

work. We have known missionaries whose coffee would not pass muster at a cooking school but the public put it down not to indolence or incompetence—but to their absorbing zeal for their work. Possibly the public may have been wrong but at any rate they felt it was a charitable verdict and so let it pass.

Civilization among the natives is certainly making headway. Malota, who has a coffee plantation out Midima way, is engaged in building a brick residence there of no mean proportions.

Mr. Schippers is confident that when the people of Holland know more about the possibilities of B. C. A. as a coffee growing country they will not be slow to invest in our staple product.—*Central African Planter*.

CRITICISMS ON BRITISH CENTRAL AFRICA.

We publish in another column a letter written to the *Zanzibar Gazette* in reply to criticisms made by Mr. Rhodes Morgan, Deputy Conservator of Forests, I. F. S. on B. C. A. Mr. Morgan was interviewed by the *Bombay Gazette* and his chief points against the country were (1) that it was malarious, (2) that leaf-disease might break out, (3) that the discovery of gold would ruin our labour supply, (4) that cattle manure was almost impossible to get and artificial manures were out of the question owing to high freights. As the rejoinder points out these criticisms are easily discounted and they shew but a superficial knowledge of this country. The only point which is really serious is the menace to our labour supply should gold be discovered. It is not however likely to be found in B.C.A. and should it be discovered in payable quantities in the B.S.A. Coy's territory a wise Administration could easily frame such regulations as would prevent the disorganization of our labour supply. The B.S.A. Territory, unlike the Rand, has a native population of millions to draw from so that it would not be necessary to recruit labourers in B. C. A. Such criticisms as Mr. Morgan's may do some good in keeping the wrong sort of man out of the country for B. C. A. is no place for "armchair" planters. Under a wise and beneficent government there can be no doubt that B. C. A. will become one of the foremost states in Africa. We have a unique geographical position; the country is at such an elevation as to make it fairly health and development will make it healthier still; we have high plateaus suitable for sanatoriums within easy reach of nearly every part of the protectorate, we have already got telegraphic communication and a railway is certain within the next three years. All that is required is capital and energy, the one without the other will not suffice, but the prospects for the two combined are of the best. In saying "all that is required" we are assuming that we have a government suited to the country. This however is at present by no means the case and the sooner the present provisional form of government is changed for a more permanent one with a properly organised civil service the better for the country. It is rumoured that Sir Harry Johnston will not return and so far we have not heard anyone deplore the possible contingency. If the rumour proves correct we also hope it will mean the end of the present autocratic form of government and the beginning of a new regime.—*Central African Planter* for August.

WYNAAD TEA.—The development of tea in this district is proceeding apace, so fast in fact that a recent Ceylon visitor was sadly seared. He returned to the Island with words of woe and warning, declaring that it would be sheer madness for Ceylon men to think of extending, with Wynaad tea expanding so "visibly." However, while the sun is shining, wise men mean to make their hay, and there is a very brisk enquiry reported for Wynaad tea lands by Island planters, whom a stern Government nonsuits in their own country.—*Planting Opinion*, Sept. 26.

THE DECLINE IN QUININE.

It is said that the unexpected often occurs. The saying proved its truthfulness on Monday in the decline of three cents per ounce in the price of quinine, which was published exclusively in the Reporter of that date. The announcement was quite unexpected, and took the trade completely by surprise. All of the local conditions governing the market had pointed to a firm price and an increased demand as the season of large consumption advanced. Already signs of activity had appeared, and the trade had begun to feel encouraged at the promising outlook. In anticipation of a steady market, purchases were made in London late last week, so it is reported, at a price equal to twenty-five cents laid down here. During Monday the market was demoralized, but the dealers soon became reconciled to the situation and fixed their selling price at twenty-four to twenty-four and one-half cents per ounce, as against twenty-five cents per ounce, the lowest price quoted for bulk by the manufacturers. The prices of dealers and manufacturers now bear the same relation to each other that they did just previous to the advance of Dec. 18, 1895.

The trade is at sea as to the reason for this radical move of the manufacturers, and no explanation has been forthcoming from the latter. All is conjecture, but an analysis of the situation may help to reach a conclusion which time may prove to have been the correct one. It is known that the order to reduce the price came by cable from Germany on Thursday previous to the date set for the new price to take effect. One theory is that at the prices, which the makers had been quoting for eight months, there was a temptation for others to start new works, as it is well known that quinine pays a substantial profit even at present prices; hence, it is argued, it was determined by the manufacturers to anticipate any such move, should one be in contemplation, by lowering the price and thus dissuading any possible maker from entering the lists. It is barely possible that the much-talked-of Java factory is feared, but this seems hardly probable as it will require a long time to establish a new brand of quinine, and nobody knows this better than the manufacturers.

For some time past it has been apparent that a feeling of mutual distrust has existed among the makers. Just how far back this dates, we are unable to state with any degree of accuracy. Certain indications, however, point to about the time of the advance of last December. At that time at least one of the manufacturers booked a large number of unsolicited contracts at twenty-five cents, which were accepted by the consumers as soon as they learned of the contemplated advance, a notice of which, most of them received in the mail following the one that carried the advice of the booking of their contract. This was looked upon at the time as rather sharp practice. All of the manufacturers made large sales and the importations to cover the contracts entered into were very large. During the first three months of this year they amounted to 1,335,328 ounces at New York alone, as against 1,308,959 ounces for the United States during the fiscal year ending June 30, 1895. The importations at New York for the fiscal year ending June 30, 1896, were 2,913,280 ounces, by quarters, as follows: From July 1 to October 1, 1895, 335,810 ounces; October 1, 1895, to January 1, 1896, 929,585 ounces; January 1 to April 1, 1896, 1,335,328 ounces; April 1 to July 1, 313,357 ounces. Into the United States for the

fiscal year ending June 30, 1896, the total importation of quinine and other salts of cinchona, was 3,359,818 ounces, the largest importation in four years. Then, too, the imports of bark show a material increase. When we take these facts into consideration, in connection with what stock of alkaloid is held by dealers, not large, to be sure, the conclusion is forced upon us that the importations were considerably in excess of the demand. Manufacturers have been large buyers of bark at all of the sales in Amsterdam for several months, and they have probably overstocked themselves, and they have ascertained that there was too great a difference between their price and the price quoted by dealers, who possessed just enough, both here and in London, to control the market. Much of the stock in outside hands is high priced, even that held by late purchasers, hence this latest move of the manufacturers may be considered a master stroke to enable them to market their product and effectively bottle up the dealers or force them to sell at a loss. At the same time it will probably have the result of putting a stop to the leak within their own ranks abroad, if they have thoroughly satisfied themselves that it really existed, and it may discourage the practice of filling up the consuming trade beyond their requirements by persuading them that the price was likely to advance. Another decline is not improbable.

We append tables which picture clearly the situation from a statistical standpoint:—

AMSTERDAM BARK SALES.

	Ounces in bark offered	Ounces in bark sold	Price paid per unit Cent
1895			
January ..	1,148,222	765,314	98

PLANTING AND PRODUCE.

THE DECLINE OF BRITISH AND INDIAN TRADE WITH CENTRAL RUSSIAN ASIA.—An official report from our representative at Khorassan on British and Indian trade with Central Russian Asia, or what is left of this trade, will shortly be issued. The heavy Customs duties levied all along the Russian frontier line from the Caspian to the Pamirs are proving an all but impassable barrier for the British merchant. The green tea trade, which used to reach Russian Turkestan and Khiva from China by Bombay and Persia, is now taking the Batoum route. Piece goods cannot cross the frontier, though right up to the Russian line, British and Indian piece goods carry all before them, in spite of Russian competition. Black tea still takes the old route by India, though Russia is now growing her own tea successfully on the hills around Batoum, but our consul at Meshed thinks that this cannot compete with good Indian tea if that is sent to Khorassan. At the same time trade beyond our north-western Indian frontier, where it does not come into contact with Russian Customs duties, is increasing, and this is especially the case with imports from the countries beyond Cashmere and from Afghanistan. In Chinese Turkestan there are no import or export duties. But the main change in trade in the last few years in this region is that British merchandise now finds its way into Central Asia not through Afghanistan, as it formerly did, but through Cashmere, thanks to the Russian barriers on the northern frontier of Afghanistan.

SOME REASONS WHY.—It is not surprising that the coffee planters of Madras are inquiring into the question why the consumption of coffee has declined of late years, and is still on the down grade, while teas have increased so much in popular favour. There are several reasons for this, and briefly, they may be summed up as follows:—Coffee is not easily made, it is not so easy to procure pure as it should be, and few cooks of British training know how to turn coffee into anything else but a liquid mess from which the flavour has departed. But in the comparison with tea there are other causes to take into account. Coffee planting as an industry has no representation in London. It would be idle to deny that the tea industries of India and Ceylon have benefited immensely by the organisations here which have fostered the development of tea planting, and in various ways stimulated interest in British grown tea. At the Royal Colonial Institute, the Society of Arts, and elsewhere there have been valuable and instructive papers read about tea. Its praises have been chanted loud and frequently. Advertisement in all shapes is necessary in these times, and the tea industry has benefited enormously by the advertisement, it has received not only from the organisation we have mentioned, but by the many forms of dealers who advertise. Coffee planters, on the other hand, have nothing to tickle the public with. There is no special mark or brand of coffee known outside the trade. The public do not care a rap whether the coffee they drink is Brazilian or Mysore. There is a distinct opening for coffee specialists at home who would make and advertise certain blends or select certain districts. The coffee planters would find organisation and representation at home useful, but even then we doubt very much if coffee will ever prove a serious rival to tea, because of the difficulty the humble consumer finds in making it ready for use as compared with tea. As the medical faculty has been quite impartial in its attacks on tea and coffee neither product scores over this point. The art of coffee making is either a lost one or it has never been found in these islands. A Coffee Planters' Association in London, representing the interests of coffee growers in India, Ceylon or any other British possession, might find some useful occupation, and help to give the fillip to the con-

receiving good value for his money but he is supporting a British industry. Those who attach weight to sentiments of this kind say that this feeling has been very pronounced in the case of Indian Ceylon tea. That there is no feeling of this kind where coffee is concerned receives an illustration this week by the publication of the prospectus of the Dumont Coffee Company, Limited, in the names of Messrs. P. R. Buchanan, H. K. Rufford, and other gentlemen interested in Indian Ceylon tea, appear as directors of a Brazilian coffee company. If this prospectus referred to a country for the cultivation of tea, say, in China or in America, such susceptibilities might be ruffled, but applied to coffee it is a point which calls for special comment. Coffee planters have not classed topographical or geographical considerations, but they would have found it very difficult to do so. Puerile as the idea may seem to some, and difficult as it is to carry it to any practical end, it nevertheless serves as an instance marking one of the disadvantages under which the coffee planter suffers. The consumer of tea whose inclinations are in favour of fervid patriotism is proud of the result that he is drinking tea produced in the British Empire, and although his feelings might be hurt if he were paying more for it, and getting less value in the case of Indian and Ceylon tea, he congratulates himself that he is fostering the economy and sentiment at the same time. In the case of coffee there is nothing of this kind. The description of coffee is as good as another that a consumer without special knowledge, who only knows that the cup of coffee placed before him is better than by some one who knows how to accomplish it, but who outside this aspiration cares naught for the berry comes from. Perhaps coffee planters should consider whether it is worth while to work up a sentiment on the subject.

"FUTURES" IN PRODUCE.—An English translation of the book entitled "The Ruin of the World's Culture and Trade," by Dr. G. Rühlmann, professor of political economy at Zurich, has just been published by Messrs. Sampson Low & Co. The volume has been annotated and supplied with a preface by Charles W. Smith, a Liverpool broker. In the preface it is urged that the demonetisation of silver has no way affected prices, but that it is the "futures" dealings in "futures" which have been the cause of the phenomenal fall. It is apparently contended that the interests of the speculators tend to make such transactions continuously "bear" conditions, regardless of the actual economic or statistical position of the particular commodity relieved occasionally by a "corner" equally disadvantageous to producer and consumer. Indeed, it appears to be contended that the fall in silver itself is due to dealings in "futures" in that metal. Mr. Smith and Dr. Rühlmann appear to believe in the possibility of and an international agreement to prevent gambling in "futures." Such an agreement would not prevent competitive importation of Argentine and Indian wheat for sale at reduced prices whenever exchange fell; nor could it, as matters stand, prevent actual sales of silver at reduced prices for the express purpose of lowering the exchanges.

THE DIMINISHING TEA TRADE OF CHINA.—The British Acting Consul at Kiukiang reports that a great feature of the season has been the large increased export to Russia and the continued decrease in shipments to England. British growths in India and Ceylon have almost ousted China from the London market, and the merchant for even a smaller export to England during the present season.

DOCK DUES ON PRODUCE.—The notice of an increase in dock dues on the part of the dock companies caused some excitement amongst London merchants.

spirits, teas, tobacco, and wines. Some of the leading wharfmasters have arranged to put lighters alongside the incoming vessels to take charge of goods at once on their arrival, instead of storing them on the quays.

AWKWARD FOR THE DOCK COMPANIES.—Referring to the subject of dock charges, Messrs. Cayzer, Irvine and Co., the proprietors of the Clan line of steamers, have quietly inaugurated a new scheme for the unloading of their vessels, which, if imitated to any considerable extent, may seriously affect both dockers and dock owners. The matter has been brought to a head by the recent action of the London Docks Committee in raising their charges for landing cargo on the dock quays. One example will suffice. The dock charges on a Calcutta cargo amount to 5s a ton in London, as compared with 1s 10d a ton at Liverpool; but whereas at Liverpool the consignee pays the landing charges, the London consignees refuse to do so, as they wish to warehouse their cargo at their own wharves. Finding that the consignees cannot be coerced, the dock companies are seeking to impose the extra charges on the shipowners. But the latter declare that it is impossible for them to pay a sum which is in many cases equal to half the current freights, and Messrs. Cayzer, Irvine, and Co. have decided to avoid the docks altogether, pending an amicable adjustment of the dispute. Thus the "Clan Macneil" discharged at Mill Hole Pier and the "Clan Macleod" at Butler's Wharf, while the "Clan Macintosh," following the example of the "Clan Matheson" and the "Clan Ross" is now unloading "overside." These vessels have all arrived since the beginning of the present month. The "Clan Fraser," which is next due, will discharge in the river, and arrangements have also been made for handling the cargo of the "Clan Forbes," the "Clan Cameron," and the "Clan Grant" without the ships entering dock. This new departure has caused some delay and inconvenience, but it is believed that when the staff become accustomed to the new system as good despatch will be secured as at the docks, and when the projected deep-sea wharves are erected the greater portion of the London traffic should be dealt with much more cheaply than under existing dock arrangements. The object which the dock companies have in view is said to be to force consignees to warehouse goods at the docks instead of standing to private wharves, where the charges are more reasonable.—*Home and Colonial Mail*, Sept 18.

GOVERNMENT CINCHONA PLANTATIONS, NILGIRIS.

From the annual Administration report on the Government Cinchona Plantations, Nilgiris, for the year ending 31st March 1896, by Mr. D. Hooper, Government Quinologist, Government Cinchona Plantations, &c., Nilgiris, we make the following extracts:—

GENERAL CONDITION.—(a) *Dodabetta.*—This plantation, in the opinion of Dr. King, is the most valuable of all those possessed by Government on these hills in consequence of the large number of crown bark or quinine yielding trees growing there. The natural situation of the plantation after a trial of thirty-five years has proved itself to be adapted for the successful growth of this kind of cinchona, and one of the elements of success might be attributed to the good management of the estates under the present Superintendent. Ninety-one thousand and four hundred pounds of bark were collected during the year from the coppicing of 12½ acres and various thinnings. The severe frost of January, which killed over 3,000 trees in No. I plot, rendered compulsory the harvesting of a large quantity of bark from this part of the estate. It has become difficult to know where to take the crop on Dodabetta, as some of the oldest trees still respond to high cultivation by giving richer bark, and in very few plots are there any trees in such a sickly condi-

years, and the bark of which contains a maximum amount of quinine owing to the liberal application of manure to the land about two years previously. A row of these trees is cut out, and the bark harvested, and the stumps of the trees trimmed as in ordinary coppicing. The next row of trees is left standing, but the alternate rows are all cut down until the boundary of the plot is reached. The trees that are left continue to grow, and the hark thickens, and at the same time they afford shade for the young coppice shoots. When the shoots are sufficiently advanced, the old trees in their turn will be ready to be coppiced and barked, and the succeeding coppice shoots will have shade and protection provided for them. It has been found that the entire coppicing of a plot often results in failure due to the absence of suitable protection for the young shoots.

(b) *Nedivattam.*—A large quantity of dry bark, amounting to 91,600 lb., was taken during the year from different varieties of cinchona trees growing on this plantation. There is a great variation in the weight of bark yielded by the different species; for instance, the succirubra trees on the old plots yielded on an average 33 lb. of green bark per tree, some large magnifolia 27½ lb., the officinalis 9½ lb., and some young hybrid 2½ lb. A number of the older succirubra and magnifolia trees were cut down, not so much for their bark, which does not perceptibly increase in value after a certain age, but for their wood, of which a large stock is needed for fuel in the factory. Over 8,000 renewals were put out during the year, and about 38,000 failures were restored in the younger portions of the estate.

(c) *Pykara.*—(1) *Hooker.*—The young trees on this estate are doing very well; but some of the larger trees on the ridge have a sickly appearance. Some of the trees that were coppiced in 1894, because of their dying condition, have thrown out shoots; but these appear to be unhealthy, and some have died out. The part of the estate, where these trees have been growing, is in an exposed position, and the soil is not of the best description. A belt of blue gums will be allowed to grow up and form a shelter for this plot, and the land will be well manured before any serious work is again undertaken here. Seven thousand seven hundred and fifty officinalis plants were put out during the year.

(2) *Wood.*—In accordance with the suggestion of Dr. King, who inspected this estate in July, and an order from Government (G. O., No. 5141, Revenue, dated 19th December 1895), instructions were issued to abandon this estate. All the trees were cut down uprooted, and the bark was harvested before the end of the year. A fire broke out in the estate in February and cleared the ground of the leaves and twigs of cinchona, and thus made the work of abandonment complete. The number of trees uprooted were 29,484 hybrids and 110 succirubras, and the amount of bark taken from them was 130,025 lb. of green hybrid bark and 1,320 lb. of red bark.

MANURE.—All the estates are well provided with manure. The Dodabetta estate received 1,487 cartloads from Ootacamund in addition to 300 loads from the cattle sheds. Three hundred loads of manure were put out at Pykara and 100 loads at Nedivattam. A ton of Trichinopoly phosphate in powder was last year applied to the land where some of the young plants needed a tonic. The poverty of Nilgiri soil in phosphoric acid has often been made the subject of remark, and the addition of phosphatic manure to land planted up with cinchona is now regarded as necessary.

A few interesting experiments were made on some green bark trees at Nedivattam, which showed to what extent the bark is enriched by good cultivation. In the year 1890 some five years old trees in plot 14 were manured and trenched, and a sample of the bark taken at the time gave 3.73 per cent. of sulphate

Again, in 1890, plot 21 was trenched and manured; the trees were eight years old and their bark yielded 3.23 per cent. of sulphate of quinine. In 1891 the land was subjected to deep digging, and in 1895 the bark from the trees analysed 6.68 per cent. of sulphate. A sample of bark from plot 27 which had been treated in a similar manner as plots 14 and 21 gave 5.22 per cent. of quinine, which is above the average composition of crown barks.

The analyses of some barks from the Dodabetta Plantation show that, in some cases, the stimulating effect of the manure is only temporary. A large number of trees were some years ago manured with fish, cattle dung and bone meal. The best results were obtained in plot 30, where fish had been applied in the proportion of 2½ pounds to a tree. The barks were analysed in 1890, or two years after the manure had been put down. No manure has been given to this plot since that time; but to see if the richness had been maintained, a sample of the bark was analysed in October 1895, with the result that there was a decided diminution of alkaloids.

The following are the analyses referred to:—

	1890.	1895.
Quinine	6.27	4.01
Cinchonidine.. ..	1.39	.68
Quinidine11	.12
Cinchonine20	.23
Amorphous24	.37
	8.21	5.41

Sulphate of quinine	8.43	5.39
---------------------	------	------

NURSERIES.—All the nurseries were well stocked with seedlings and Plants of *Cinchona officinalis*.

CROP.—The quantity of bark harvested during the year was as under:—

	DODABETTA.	
	lb.	lb.
Crown bark	91,400	91,400
NEDIVATTAM.		
Crown bark	37,015	
Red bark	30,359	
Hybrid bark	27,226	
		94,600
PYKARA—(WOOD).		
Red bark	440	
Hybrid bark	43,260	
		43,700
Total		229,700

There remained in stock at the beginning of the year 195,129 lb. of bark; this, with the quantity harvested during the year, made 421,829 lb. Of this quantity 234,457 lb. were disposed of during the year, detailed thus—

	lb.
Used in the factory for the manufacture of quinine and febrifuge.. ..	233,800
Supplied to Bombay Medical Stores	500
Supplied to private parties	157
Total	234,457

leaving 190,372 lb. in stock in the godowns at the close of the year.

FACTORY.—The manufacture of quinine and febrifuge was carried on continuously during the year until the end of February, when the fusel oil ran out. At the usual rate of consumption the oil would have lasted to April; but in October the work of the factory was very much increased, and the chemical were used in larger quantities than was foreseen at the beginning of the year. The fusel oil was ordered in November, and request was made to have it sent out by the end of February; but it has only just arrived.

The following statistics exhibit the outturn and sales of quinine and febrifuge since the manufacture was first commenced in June 1889, or during the past seven years:—

	OUTPUT.	
	Quinine.	Febrifuge.
1889-90	234	357
1890-91	2,928	1,050
1891-92	4,425	3,174
1892-93	4,933	3,139
1893-94	2,000	5,775
1894-95	4,770	1,756
1895-96	3,600	2,284

	SALES.	
	Quinine.	Febrifuge.
1889-90	234	7
1890-91	1,356	200
1891-92	3,344	3,017
1892-93	3,204	2,608
1893-94	2,536	3,513
1894-95	3,631	3,956
1895-96	5,644	2,666

The rate at which quinine was sold during the past official year was R14 a pound for Medical Stores and R16 for the public.

Taking the rate of R14 per pound for quinine and R10 for febrifuge, the value of the stock at the close of the year was R56,221, calculated thus:—

2,880 lb. of quinine at R14 per lb. ..	40,320
1,564 lb. 12 oz. of febrifuge at R10 per lb. ..	15,640
21 lb. 12 oz. of cinchonidine sulphas at R12 per lb. ..	261
Total	56,221

Government has recently decided to raise the price of quinine to R18 a pound for sale to the Medical Stores and the public, but the price of febrifuge will remain the same for the official year 1896-97.

QUININE.—The quantity of quinine turned out at the factory at Nedivattam was 3,600 lb., there remained in stock at the end of the previous year 4,984 lb., making in all 8,584 lb. Of this, 5,644 lb. were distributed as follows:—

Issued to the Medical Stores Department, Madras ..	1,000
Do. do. Bombay..	1,080
Do. do. Bengal ..	1,500
Sold to the Local Fund dispensaries and Municipal hospitals	2,064
Sold to Superintendents of District Jails ..	
Sold to the public	
Sold to the Native States of Mysore Pudukkottai, Karbhari-Janjera	
Issued for paper packets of quinine powders to Collectors, Post offices, &c. ..	
Total	5,644

and there thus remained in stock at the end of the year 2,880 lb., excluding dryage.

As evidence of the expansion of the distribution of quinine by this office during the past official year, quinine was asked for and sent out to the Native State of Karbhari-Janjera in Scinde (north-west of India), to Tinnevely (south), to Bombay (west), to Ganjam (east). The Bengal Government has taken 1,500 lb. of quinine for Calcutta and the Medical Storekeeper, Main Mir. The Province of Burma, too, has drawn its supply of quinine from Madras.

FEBRIFUGE.—The quantity of febrifuge manufactured at the factory during the past official year was 2,284 lb., there remained in stock at the beginning of the year 1,946 lb., making in all 4,230 lb. Of this quantity, 2,666 lb. were disposed of as follows:—

Issued to the Medical Stores Department Madras..	500
Do. do. Bombay..	1,500
Issued to Local Fund and Municipal dispensaries, Sold to Native States and to the public ..	666
Total	2,666

and there thus remained at the end of the year 1,564 lb

In G.O., No. 2382, Local and Municipal, dated the 17th November 1894, communicated to this office under G. O., No. 4720, Revenue, of the 1st December 1894, Government ruled that Local Fund and Municipal hospitals should, from the commencement of the official year 1895—96, obtain their quinine and supplies of other medicine independently of the Madras Medical Stores Department, and that the quinine and febrifuge required should be obtained by these institutions from the Cinchona Department. This office therefore has practically been doing the work hitherto carried on by the Medical Stores Department, Madras, by distributing the quinine and febrifuge indented for by the several Local Fund and Municipal dispensaries, and by recovering and adjusting separately the value of each indent. This has added very materially to the work at the Head office, for, in addition to the above, the despatch of quinine powders to Collectors and Forest officials and Post offices, the sending out of quinine and febrifuge to the Medical Stores Departments of Madras, Bombay and Calcutta, and the public, was attended to. The unusual pressure of work in the office was cheerfully borne by Mr. D. Campbell, the Manager and his staff, who performed their duties most diligently during the year. The Manager was also in charge of the accounts and correspondence of the Gardens during Mr. Jamieson's illness and until the appointment of the new Curator in February.

THE QUINOLOGIST'S REPORT.—This report is not submitted separately this year; many of the results obtained from the experiments made in the laboratory will be found in other portions of this and the Administration report of the Government Gardens.

MISCELLANEOUS.—(a) *Purchase of fresh Cinchona seed.*—In last year's report it was pointed out that cinchona plants now raised from the oldest officinalis trees, and those of the purest type, are not so vigorous or lasting as plants raised from seed taken from those trees ten or twelve years ago. A disease similar to canker sets in when the young plants are about two years old and just when they are ready for planting out. For this reason it appeared desirable that some fresh seed should be obtained from the home of the cinchonas in South America. The Secretary of State referred this question to the Director of the Royal Gardens, Kew, who discouraged the idea of securing seed from South America, and suggested that it might be supplied by the Jamaica Plantations where crown bark trees are almost naturalized and seed freely. The Director of Public Gardens and Plantations, Jamaica, reported through the Colonial office, that he would do his utmost to comply with the request for ten pounds of seed; but considering the question of the probable supply from there, he thought it not at all likely that quantity could be supplied, as the seed to be of any value should be obtained from mature trees; and it is extremely light, the number of trees that would be required to give such a large amount was probably larger than they possessed of that kind. About two pounds of seeds have been received from Jamaica, and they will be carefully sown in the glass houses in the Government Gardens.

(b) **ALKALOIDAL COMPOSITION OF BARK WHEN KEPT IN STORE FOR A NUMBER OF YEARS.**—In March last the District and Medical Sanitary officer, Kistna, sent some powdered cinchona bark which he had received from the Treasury Deputy Collector of the district in whose office it had stored away for the past seventeen years, and he asked for an opinion on its condition before using it. An analysis showed its composition to be 5.4 per cent of total alkaloids and 1.1 per cent of quinine, a result which corresponded with the composition of succirubra bark; and as the bark did not appear to have deteriorated, the District Medical officer was informed that he could safely use it for medical purposes.

Reference to the Quinologist's report for 1885—86 shows that even mouldy bark in a state of powder does not deteriorate when kept in a damp situation for nearly a year.

(c) **ISSUE OF QUININE POWDERS TO THE COLLECTORATES.**—The number of packets issued during the past year has been 2,638, of which 2,399 went to the Collectorates and 239 were sold to the public, against 1,805 packets disposed of in the previous year. These figures show an improvement, considering that the scheme has had to compete with the sale of the powders by Postmasters. In accordance with paragraph 2 of G. O., No. 224, Revenue, dated the 7th March 1893, a separate report on this matter will be sent in on the receipt of the necessary information from the Collectors—*vide* also paragraph 2 of G. O., No. 129, dated the 20th March 1896.

(d) **SUPPLY OF QUININE POWDERS TO THE PROVINCE OF COORG.**—In September last the Chief Commissioner of Coorg, acting on the advice of the Civil Surgeon of the Province, proposed to Government that quinine powders might be sold at the different Post offices in Coorg, where there were no dispensaries. The envelopes for these powders were printed in Canarese and English. In January last five packets of 102 powders each were sent to each of the twenty-two Post office, in the Coorg Province, but, so far, no indents from the Postmasters of this district have been received.

(e) **ISSUE OF QUININE POWDERS FOR SALE BY THE POSTAL AGENCY.**—It having been finally decided by Government that the permanent advance of these packets to Postmasters should be five and the minimum indents three (G.O., No. 356, Revenue, dated 12th June 1895), the necessary amount of quinine powders in July was sent to the 315 Post offices in the five districts selected by the Board of Revenue, viz., Ganjam, Vazagapatam, Cuddapah, Kurnool and Malabar. In G.O., No. 4148, dated the 21st October 1895, Revenue a report was called for on the results of sales by the Postmasters up to the 30th November, 1895. This was done, and in G.O., No., 11, Revenue dated the 11th January 1896, Government considered that the experiment was on the whole a success, and that the introduction of the system into the other districts should not be delayed. In conjunction with the Postmaster-General, arrangements were made for supply of the quinine powders to the remaining fifteen districts in the Madras Presidency. After obtaining the necessary printed covers from the Government Press, Madras, the permanent advance was sent in March to 334 Post offices in the Telugu districts of Anantapur, Kistna, Godavari and Nellore. The distribution of quinine powders to the Tamil districts of the Presidency is now going on. It is estimated that the number of packets issued as permanent advances to Postmasters and to Collectors has been 6,053—

To first five districts	..	1,635	
„ four Telugu districts	..	1,670	
„ Coorg..	..	110	
			3,415
Issued to Collectors, &c.	..		2,638
			<hr/>
			Total .. 6,053

In addition to this number, indents were sent in subsequently by Postmasters for 664 packets, and these, if added to the above, would make the total number of packets issued in the year to be 6,717 packets or 679,858 powders.

DISTRIBUTION OF QUININE IN BOTTLES.—In October last the Deputy Collector, Godavari, addressed this office regarding some bottles of quinine which had been sent to him by the District Forest-officer. Quinine in bottles is not so popular with the people in the district as the powders now being sold by him, and he wished to know if it could be sold by public auction. He was informed that, rather than sell it by auction, it would be preferable to send it to this office for making up into powders.

SUPPLY OF QUININE TO THE BURMA GOVERNMENT.—The issue of three hundred-weight of quinine made up in five-grain powders to the Burmese Administration could not be effected before the close of the previous official year 1894-95, owing to the delay of the Chief Commissioner in selecting the form of envelope to be adopted. As soon as the Superintendent, Government Press, supplied the necessary

covers printed in Burmese and English, the three hundred-weight of quinine in five-grain powders or 479,906 powders were sent in August, September and October last, to the Superintendent of the Central Jail, Rangoon, and the value, viz., Rs. 5,073-10-0 was adjusted through the Accountant-General in the accounts for the year.

(i) VISIT OF DR. G. KING TO THE NILGIRIS.—In June last Brigade-Surgeon-Lieutenant-Colonel G. King of the Botanic Gardens, Calcutta, was invited, through the Government of Bengal, to conduct a thorough examination of the several Government Cinchona Plantations on the Nilgiris and the quinine factory at Nedivattam, and to report on their general condition their value, and the best way in which they should be worked in the future. Dr. King arrived in Ootacamund on the 20th July 1895, and inspected all the plantations in company with Mr. Lawson, and conferred with Government about the future organisation of the Botanical and Cinchona Departments. Dr. King was able, during his visit, to complete his report on the results of the inspection, and he left the Hills on the 8th August.

(j) DEATH OF MR. LAWSON.—It is with great regret that the death of Mr. M. A. Lawson, Government Botanist and Director of the Cinchona Plantations, has to be recorded. Mr. Lawson assumed charge of the Cinchona Plantations and Government Gardens and Parks on the 18th June 1883, and the designation of Government Botanist and Director was given to him on the 1st April 1886. Mr. Lawson had unusual ability which he exhibited in every department of his office. In January 1895 he intimated his intention to retire from service, and at the close of the year his health, which had been most robust during the whole of his Indian career, began to fail. In February last he reluctantly placed himself under medical care, and was removed to Madras, where he died after an operation on the 14th February 1896.

APPENDIX.

Report on the Cinchona Plantations and Factory of the Madras Government.

1. I have, during my present visit to the Nilgiri Hills, gone over and carefully examined the plantations at Dodabetta and Nedivattam and the one near the Pykara river named the Hooker estate. I visited these estates originally in 1871 and, in company with the late Mr. McIvor and Mr. Broughton, made a prolonged and minute inspection of them. And again in 1878 I made an equally thorough inspection of them in connection with Commission appointed by Government to enquire into their condition and prospects. During my present inspection I have therefore had the advantage of the knowledge and experience acquired during these earlier visits.

2. Government are familiar, from the reports of the Director, with the composition (as regards the kinds of cinchona grown) of these plantations. It is therefore unnecessary for me to do more than remind you generally that on the four plantations practically only three kinds of cinchona are cultivated. The Dodabetta plantation is essentially one of crown (or *officinalis*) bark, there being more than half a million trees of that sort on it and only about sixty thousand of the sort known as "hybrid"; while there are no trees whatever of the red bark (*cinchona succirubra*). The Nedivattam plantation, on the other hand, consists of about a quart of a million hybrid trees of 89,000 crown barks, and of 25,000 red barks. The Hooker plantations is composed of 373,000 crown barks, 293,000 hybrids and 2,300 red barks; while the Wood plantation consists of about 12,000 hybrids. Distributed over all four estates there are 1,188 trees of various kinds of cinchona which have been raised from seeds from time to time sent out by the India Office for experimental cultivation. These are now cultivated merely as curiosities, as they have all been proved to be without value as sources of quinine on the Nilgiri Hills. I therefore omit them from further consideration. As Government are aware it has from a very early period in the history of the cultivation of the medicinal cinchonas

in these hills been known and recognised that the best bark to grow for the manufacture of quinine is the crown or *officinalis* sort. It has been equally well-known that the red or *succiruba* bark is one which contains a larger proportion of the inferior alkaloids, cinchonidine and cinchonine; and which, while affording an excellent raw material for the manufacture of cinchona febrifuge, is an inferior raw material for quinine. The sorts known as hybrids are trees which, while inferior as quinine yielders, to the crown barks, are superior to red barks. For various reasons the cultivation of these hybrids was much favoured by the late Mr. McIvor, and it is this fact which accounts for the large proportion of them which still exists on the Government estates. Experience since Mr. McIvor's time has proved that these hybrids are, in the Nilgiris, short lived trees; and that their bark, by reason of the presence in it of so much cinchonidine and cinchonine, is as a raw material for quinine manufacture much inferior to crown bark. The latter is, moreover, also much more hardy than hybrid. The policy of Mr. Lawson has therefore been steadily to reduce the numbers of both hybrids and red barks in the estates, and to replant the areas cleared of these with crown barks. This policy has been carried out to such an extent that at present there are on the four Government estates only about 27,952 red barks and 653,323 hybrids, as against 1,031,005 crown barks. Of this policy I entirely approve, and I would recommend its continuance until the estates contain nothing but crown barks. With the object, however, of keeping up the strain of the latter which appears to have slightly deteriorated of recent years I would support the recommendation made to Government by the Director to the effect that arrangements should be made for the importation from the natural home of the crown bark in the forests of Loja in the province of Ecuador of a few pounds of good fresh seed of that species.

3. From the preceding remarks it will appear that the Dodabetta plantation is the most valuable of the four and that the Hooker plantation ranks next in value. The Nedivattam plantation has, from the preponderance upon it of hybrid and red barks, a considerably less value at present; but, if the policy be carried out of replacing these by crown barks, it may soon become equally valuable with the two previously mentioned. And at present it is of great importance from the presence on it of the Quinine and Febrifuge Factory. The Wood plantation is, both as regards extent and composition, the least valuable of all four. It consists at present of a small patch (27 acres) of hybrid bark trees; it is inconveniently separated from the other three by the Pykara stream; and in fact the chief argument for its retention appears to be that there is on it a bungalow fit for a European Superintendent to live in, whereas on the Hooker estate there is no such accommodation. The patch of cinchona on the Wood estate is so small, and so exposed to the ravages of game that I would root it up and abandon it. I shall, however, refer to this matter more fully in a subsequent paragraph.

MANAGEMENT AND MODE OF WORKING THE PLANTATIONS.—Up to the dates of my previous visits (1871 and 1878) the only method of taking the bark crop which had received anything like a fair trial was that of stripping and renewal under either moss or grass. Coppicing had hardly been tried. In my memorandum submitted to the Cinchona Committee in 1878 (pages 33 and 35) I recommended that coppicing should be resorted to in conjunction with stripping and mossing. Since Mr. Lawson became Director of the Estates, the system of coppice after stripping and mossing has been regularly followed, and the result has been successful. It has been proved that trees which had been reduced to a weak and unhealthy condition from repeated decortication send up from their stools, when coppiced, healthy and vigorous shoots which in turn yield bark of quite as good quality as the original stems. The scheme of working followed by the present Director has

been to allow the coppice shoots to acquire sufficient size to afford shade to the soil; and, when this has been secured, either to fill up vacancies or to replant entirely with seedling crown barks, removing the coppice when the seedlings have grown large enough to afford shade to each other. This plan is, in my opinion, an excellent one. It is founded on the principle that, in growing cinchonas on these hills, the surface of the soil must be protected both from the direct rays of the sun and from the wash that is the inevitable result of heavy rain fall on bare soil. Another prominent feature in the mode of cultivation which has of late years been followed is the cultivation of weeds and their utilization as green manure. During my visit to these plantations in 1878 I was struck, as was also Dr Bidie, by the absolute freedom from weeds in certain parts of the plantation, and by the consequent denudation of the superficial soil by the wash of heavy showers; and I called attention to the matter in my evidence before the Committee (page 31). The same facts had evidently impressed Mr. Lawson for the soil of the Dodabetta plantation which used to be conspicuously bare is now well covered with a fair crop of surface-rooting weeds. The plantations at Nedivattam and the Hooker estate are all fairly well covered with weeds of a good type, with the exception of a few barren patches which are now under treatment. Mr. Lawson has also carried out extensively the system of digging trenches near the trees which serve as receptacles for any soil which may be washed into them by the rain, also for surface soil which may be scraped into them, and for green weeds which may be buried in them. The results of this system of pitting or trenching appears to have been excellent. The manure of all cattle living in the estates has also for years been carefully conserved and spread on the patches most in want of nutriment. A considerable quantity of bazaar manure has also been carted from Ootacamund for the Dodabetta plantation.

5. WORKING EXPENDITURE ON THE PLANTATION.—The cost of European establishment is high in proportion to the annual disbursement on cool labour. This is due to three causes:—

(1) to the fact that the plantations are broken up into so many detached pieces;

(2) to the entertainment of a whole-time officer as Quinologist;

(3) to the fact that the plantation is, from unavoidable causes, worked below its full producing power. The latter cause would be removed by any successful endeavour to increase the demand for quinine and febrifuge. The rapid spread of the sale of quinine in small doses at Post offices and other public offices appears to offer a new outlet for an indefinite amount of the former drug. The cool labour does not appear to me to be costly and I can suggest no way in which rates might be reduced.

6. FACTORY.—The factory is organised on the same lines as that of the Bengal Government, the process of extraction of quinine depending on the use of fusel-oil and of kerosine. The grinding of the bark is done by a Carter's disintegrator of which the motor power is a vortex turbine which, owing to deficiency of water during the dry season, can be worked only half the year. The disintegrator is, however, capable of grinding 4,000 lb. of bark per day; and, as it can be worked for 150 days in the year, 600,000 pounds of bark can be annually ground, an amount which is more than thrice as great as the vats in the factory are capable of converting into the quinine of febrifuge. The factory buildings are, however, capable of extension whenever more vats are required to meet the demand for their output. At present the vats are capable of turning out annually only 4,800 lb. of quinine and about 3,000 of febrifuge—amounts which up to date have exceeded the demand. Should the demand exceed the present grinding power of the disintegrator, arrangements can, the Director assures me, be made for leading water from another stream so as to increase the number of working days and the output of ground bark by

one-third. The factory is thus in all its departments capable of expansion. The present accommodation for storage for bark is ample and it also is capable of expansion.

FUEL.—Fuel for the factory is at present obtained from a shola behind the Hooker estate and about two and a half miles distant from the factory. This shola was made over to the Director by a former Conservator of Forests with the distinct intention that it should be worked *coppice fashion* as a source of fuel for the factory. The policy of coppicing standing forest with the object at once of utilizing the timber on it and of providing for its reproduction by coppice is largely followed in France, and it forms the basis of a well-known and highly accredited system of treatment. Of late, however, this policy does not appear to have commended itself to the forest authorities on these hills, and I understand the question is now under consideration whether the above-mentioned shola should not be resumed by the Forest department and the Director compelled to buy fuel for the quinine factory. If this arrangement be carried out, the Forest department propose, as I am informed, to supply *Eucalyptus* fuel at a cost of R6 per thousand pounds, at a spot over ten miles distant from the factory. The rate of carriage to the factory from this spot would, the Director says, be R2 per thousand pounds. The cost of fuel from the present source of supply he estimates as at Re. 1 per thousand pounds. The proposed increase would therefore form a not inconsiderable addition to the net cost of the output of the factory. I must say, I think, it would be a mistake to increase the net cost in this adventitious way. The object of the maintenance of the quinine factory is the good of the whole population of the country and the allotment to the factory of a piece of natural forest to be exploited in the interest of the Cinchona rather than of the Forest department does not appear to me to violate any principle of political economy. If the management of the shola in question by the Director were to involve its destruction, there might be a case against its remaining in his hands; but conversion into coppice, not destruction, is the idea of his treatment of it. I would, however, with the view of preventing inconvenience from changes in forest policy in future, strongly recommend that as large an area as possible of the land in the cinchona reserves which is unsuitable for crown barks should be utilized for the production of fuel for the factory. I may mention that, on the Sikkim plantation, there is a large area of forest at the entire disposal of Cinchona department, and that there is besides a fuel plantation which now covers 300 acres, and which is being annually extended during the seasons when plantation work is slack.

8. GRAZING.—Attached to each of the plantations there is a certain amount of grass land on which the plantation cattle and also the cattle belonging to the estate coolies are allowed to graze. Such land carries no timber and can be of no use for strictly forest purposes. These cattle are kraaled at night, and their dung is carefully collected as manure which is of great use in the improvement of the poorer parts of the plantation. I think it would be a great mistake to diminish the area of these plantation grazing grounds. If any change is to be made, it should, in my opinion, be in the direction of extension rather than of contraction. I would however strictly prohibit the grazing of cattle in sholas.

9. RAVAGES OF GAME.—There is no doubt whatever that young plants and young coppice of crown barks and of crown bark hybrids are much eaten down by sambur and jungle sheep. This is nothing new. The late Mr. McIvor complained bitterly of it to me in 1871 and showed me large areas of young planting which had been practically ruined by the ravages of these animals. I also heard loud complaints about the matter during my visit in 1878. During my present visit I have questioned the Superintendents and some of the natives, resident on the various plantations, and I have seen for myself ample evi-

dences of the evil. In fact any body can see an excellent example of it by examining the margin of the plantation at the distance of a few hundred yards of the Director's bungalow at Nedivattam. And the mischief is even greater on the Wood estate than at Nedivattam. Fencing appears to afford little or no protection against this kind of game, and the only efficient way of protecting the young plantations and coppice is by shooting the deer. For many years there has been on the Cinchona establishment one shikari whose duty it is to frighten the game of the three plantations of Nedivattam, Hooker and Wood. I have read the memorial of the Game Preservation Association and the comments of the Director and of the Collector of the Nilgiris thereon. And much as I sympathise with the objects of the Association, I must say that the grievances complained of by it are chiefly matters of the past. I fail to see how the proceedings of a single shikari, spread over three such large areas, can be very destructive to game. And I cannot understand how, in the face of the existing evidence, both oral and ocular, it can be contended that game in the neighbourhood of the Cinchona plantations has been virtually exterminated. This is not the opinion of a large cinchona and tea planter in the neighbourhood who assured me the other day that sambur and jungle sheep literally swarm at a distance of 3½ mile from Nedivattam. As the subject, however, appears to have elicited some warmth of feeling, I would suggest that the Wood plantation, where game most abound and where there are only 27 acres of cinchona, should be abandoned; the cinchona, being first uprooted and its bark taken to the factory. I cannot recommend the dismissal of the shikari, but I would restrict him (as at present) to the actual area of the Government estates.

10. ACCOUNTS.—There annually appears in the report of the Director a statement showing the capital and revenue accounts of the plantations from the commencement up to the date of the report. In this return the disbursements of each year are given in one column with interest at 4½ per cent. There are also columns in which the surplus and deficit each year are stated. Up to the end of last year the total deficit is stated to amount to Rs. 641,288-3-6. If the yearly accounts were to be stated like those of a joint stock company this deficit would stand as the capital or as a liability of the company. I cannot, however, understand how the large deficit just named is arrived at. In Captain Campbell Walker's report (p. 16) on the plantation, he gives Rs. 13,04,360 as the Accountant-General's calculation of the total cost of the estates, plus annual interest to the end of the official year 1875-76. During the seven succeeding years such large quantities of bark were sold in England that the surplus of receipts over expenditure during these years amounted in round numbers to Rs. 18,39,000; in other words the receipts of the plantations at the end of the year 1882-83 had exceeded the total expenditure on them from the beginning, plus interest, by the sum of Rs. 5,34,640. The actual expenditure up to the latter date should, therefore, surely have been considered as wiped out, and the plantations should have been credited with the difference, i.e., with the sum of Rs. 5,34,640. From 1882-83 until the present time, the plantation has been worked at an unusual loss. The net receipts for these twelve years were Rs. 6,85,172 and the net expenditure was (exclusive of interest) Rs. 9,66,816. If the surplus prior to 1883-84 be added to the receipts since that date, the amount comes to more than 12 lakhs of rupees, as against less than 10 lakhs of expenditure. If 2 lakhs be allowed for interest (a sum which surely must be considered as ample) the capital cost of the estates has really been extinguished, and no annual charge for interest is really admissible. It is utterly disheartening for any man to have to work under a financial disability (even although it be only imaginary) such as the Director of these plantations has hitherto done. I venture therefore to recommend that, from 1st April 1895, a new departure should be taken in the accounts; that the charge for interest should disappear, and that a stock account, debit and credit cash account and balance sheet should

be annually given. In this way the exact results of the year's working would be shown within the compass of a single page.

11. THE RESOURCES OF THE PLANTATION.—I need hardly remind you that since the suspension during the official year 1883-84 of the practice of selling the bark produced on the estates, these plantations have not been worked up to their full producing power. They have in fact been very lightly cropped; and, even since the manufacture of quinine was begun, the demand for that drug has never yet been equal to anything like the producing power of the plantation. The natural increment of the bark of many trees therefore remains on the trees as an undrawn dividend. The result of this light cropping and of the judicious method of cultivation, and of collecting the bark which have been followed during the past 12 years, is that the plantations are now in a much better condition than they were when I went over them in 1878. An examination of some of the figures given in the Director's report for the official year which ended on 31st March last gives an idea of the present actual condition of the plantation. I find that, during the year 1894-95, 6,720 crown bark trees were coppiced on Dodabetta and the yield of dry bark from them was 51,522 lb. On Nedivattam 4,713 trees were coppiced with a yield of 17,081 lb.; and on Hooker estate, the 6,949 trees which were coppiced yielded 27,008 lb. of dry bark. This is at the average rate of about 5 1-5th lb per tree. The Director assures me that the trees for coppicing were not selected because of their size. On the contrary, they were selected as trees which had, from repeated stripping and mousing, begun to show signs of weak health, and they were coppiced in order that they might have an opportunity of springing afresh from their cut-stumps. In the language of French forestry the trees were coppiced as part of a *coup de regeneration*. Trees to the number of 18,382, cut as a measure of arboricultural improvement (and which, owing to their sickly state, yielded bark of poor quality from which not more than 3 per cent. of quinine may be expected) thus yielded 95,611 lb. of dry crown bark. After deducting these trees, there remained of crown barks on the Government plantations (according to the returns) more than a million trees, some in excellent and the others for the most part in fair health. If the proportion of the bark on the trees that remain be in proportion to that of those which were coppiced last year, the crown bark trees on the three Government estates carry a grand total of 6 million pounds of dry bark. These results which have so surprised me that I have had all the calculation checked are seen at a glance in the following table:—

	Trees up-rooted during 1894-95.	Bark yielded.	Trees left at 1st April 1895.	Bark left at 1st April 1895.
Dodabetta	.. 6,720	51,522	568,295	4,357,090
Nedivattam	.. 4,713	17,081	89,666	324,970
Hooker	.. 6,949	27,008	373,044	1,449,064

Total.. 18,382 95,611 1,031,005 6,131,124

From the foregoing calculation I have entirely omitted the 663,328 hybrid trees which, according to the Director's returns, existed on the four plantations at 1st April last. If the bark on these be calculated as equal, when coppiced to four pounds per tree, there is an addition to the resources of the plantation of about 2½ million pounds of bark. The total amount of bark which the plantation would yield, if coppiced at once, is, according to these estimates, therefore over 8½ million pounds.

It is probable, however, that calculation founded on the number of trees may be fallacious; for the numbers are continually being altered by death and accident; and it is impossible, short of an annual census (which would cost more than it would be worth) to esti-

mate accurately the number of trees that actually exist. It may be advisable therefore to cut down these figures by half and to reckon $4\frac{1}{2}$ million instead of $8\frac{1}{2}$ million pounds of dry bark as the quantity that would be obtained were the whole plantation coppiced now. On the other hand it must be recollected that the trees, if worked on a rotation of twenty years, would yield during that period repeated crops of bark by the stripping and mosing process prior to their finally being coppiced. As a check on these calculations based on *the number of the trees* on the plantation, I shall now give a calculation based on the yield per acre. Captain Campbell Walker's survey showed the actual area to be 848.74 acres. Since the date of his report the Wood estate has been reduced from 72 acres to 27, being a diminution of 45 acres. The acreage of the other estates remains exactly the same, and the whole area now under Cinchona may be therefore taken roughly at 800 acres. Statistics show that the average yield on Dodabetta of an acre, when coppiced, is about 4,000 lb. (excluding root bark) and that the amount of bark yielded by the same acre by stripping and grassing subsequently to 1880 and prior to coppicing appears, from the few areas of which an accurate record has been kept, to be about 1,450 lb. The total yield of the whole plantation, if coppiced at once, would therefore according to these figures be 800 by 4,000 equal to 3,200,000 lb. of dry bark. And the amount obtainable by stripping over a period of twenty years would, at 1,450 lb. per acre, stand thus:— $800 \times 1,450 = 1,160,000$ pounds of dry bark.

The actual stock of bark of all kinds in the plantation thus comes out as 4,360,000 lb.

13. ANNUAL OUTFURN OF BARK AND QUININE.—The calculation per acre appears to me to afford a safer basis for estimating the amount of bark which can annually be taken as the normal crop; in other words of estimating the amount of dividend which may be drawn from the estate without encroaching on the capital. The oldest trees on the plantation are now about thirty-three years of age, and experiments in coppicing show that good returns in the way of crop can be obtained from coppice shoots from twelve to fifteen years old. The Director is of opinion, and in this I agree, that twenty years may safely be taken as the rotation on which the plantation may be worked. On this basis, the annual crop would, therefore, be 218,000 lb. from which there could be extracted (at $3\frac{1}{2}$ per cent.) 7,630 lb. of quinine. But the bark contains a certain percentage of Cinchonidine, Cinchonine and Amorphous quinine; there would, in addition, therefore be a considerable quantity of Cinchona febrifuge.

SUGGESTIONS FOR FUTURE MANAGEMENT.—In view of the early retirement of Mr. Lawson, the question of future management is a pressing one. There are, it appears to me, two arrangements which might be made, and these are *first* to find a successor for Mr. Lawson, who will perform exactly the same duties as he does; *second* to dissociate the appointment of Government Botanist from that of Superintendent of the cinchona plantations and factory. The *second* is the arrangement favoured by Mr. Lawson, who has addressed Government on the subject. Mr. Lawson's proposal is that a skilled Botanist should be got out from England who should have his headquarters in Madras (where the Government Herbarium should be located) and who should fulfil the functions of Government Botanist and of referee and adviser to Government on all matters connected with scientific horticulture; who should lecture on Botany in the Madras Colleges and act as Examiner in Botany in the University; and part of whose recognised duty it should be to carry out the botanical exploration of the Presidency—many parts of which towards the west and south are still, from a scientific point of view, very imperfectly known. In my own opinion, this proposal is probably the better of the two, but it is the more costly. Against the first scheme there is this to be said: that it will not be easy to get a man of Mr. Lawson's calibre and previous experience to accept the appointment on the scale of pay at present sanctioned for him. It is in fact

extremely improbable that a gentleman who had been a professor of Botany in a great English University, and who has had many years experience of the management of a Botanic garden (Mr. Lawson held charge of the Oxford garden for fourteen years) would be secured by the Secretary of State as Mr. Lawson's successor. Against the second scheme the chief objection is its cost. A Government Botanist, with functions as above described, could not, I fear, be obtained even on the salary now paid to Mr. Lawson; far less on the salary (R400 rising to R600 per mensem) suggested by Mr. Lawson. The superintendence of the Cinchona plantations has, moreover, to be provided for. This would have to be considered by Government in connection with the arrangement by which a whole-time officer is entertained as Quinologist; and that is not one of the matters referred to in the Government Order under which I submit the present report. The qualifications of the officer who may be selected to succeed Mr. Lawson in charge of the plantations and factory should, in my opinion, be as follows: he should be an educated man with a sufficient knowledge of agriculture and horticulture, both theoretical and practical, so as to put him on a higher level, in this respect, than any of his subordinates. It might, and I dare say, would be impossible to get a man with a special knowledge of cinchona cultivation; but a man who has general horticultural knowledge and experience would, if he had the advantage of a little tuition under Mr. Lawson, soon pick up the peculiarities of the culture in cinchona. I consider a knowledge of this sort as more necessary for the new Superintendent than a knowledge of Chemistry. For the plantation has now passed beyond the stage when the continued guidance of a quinological expert is necessary. Most of the chemical problems which are likely henceforward to present themselves ought, if not at once certainly after a few months experience, to be capable of solution by an ordinary chemical expert in Madras or elsewhere. I do not mean in the least to decry chemical knowledge, which no doubt will be of great use in working the factory. All I mean to say is that for the management of the plantation (in its present condition and of the factory, *as a joint charge*, a knowledge of horticulture is of more importance than a knowledge of Chemistry. One qualification which the Superintendent of these plantations should most certainly possess is a capacity for estate management and for the organization and control of labour. A most important point for the future management of these plantations will be to secure a continuity of policy. This can never be done if the management be sometimes vested in hands of an officer of one department and sometimes in the hands of another department—neither being experts. The best thing to do would be to secure a man of capacity, energy and tact, and to make it worth his while to remain on in the appointment long enough to accumulate special experience and knowledge, and to utilize that knowledge and experience in the interests of Government. These estates are, in my opinion, a valuable property. The present Director has made it his policy to conserve and to nurse them, and to bring them into a condition under which they can be worked on a definite system. He has succeeded, it appears to me, in putting the Dodabetta plantation into such a condition. Much progress towards this end has been made on the Hooker estate. But the Nedivattam plantation, from having been originally planted out without proper regard to the separation of varieties, is still in a backward condition. The new Superintendent should, in my opinion, carry out Mr. Lawson's policy. Anything like the reversal of policy and general *boulevardment* of current arrangements which so often characterises a change of management is much to be deprecated for these estates. For their future value and their continuity as a source of bark will depend greatly on the way in which they are worked during the next few years. If judiciously treated they may at once be counted upon for the annual supply of 7,630 lb. of sulphate of quinine besides a large quantity of cinchona febrifuge as a by-product. In making the estimates of the resources

and normal outturn of the plantation which are given in paragraphs 10 and 11 of this report, I have intentionally taken the lowest figures. I would, however, have no hesitation in taking a larger annual crop than 218,000 lb. of bark should it be necessary to do so in order to meet a demand. And, if the growth and health of the trees continues as good as at present, I see no reason why, in a year or two, 300,000 lb. of dry bark might not be taken as the normal annual yield.

In my own opinion the consumption of quinine in India is bound to increase rapidly; and not many years will, in my opinion, elapse before the resources of the Nilgiri plantation will (as those of the Sikkim plantation are now) strained to the utmost to meet the demand. The object which the Secretary of State declared to be that with which Government introduced the cultivation of chinchona into India was "to put the only efficient remedy for the commonest and most fatal of Indian diseases within the reach of the poorest;" and that object appears to be in the point of being realized.

IMPORTS OF TEA.

—Indian Planters' Gazette, Sept. 26.

INDIA AND CEYLON TEA IN AMERICA.

In the New York *American Grocer*, the leading trade journal of that great country, are now appearing weekly a series of most taking advertisements, evidently the sensible idea of the above gentlemen [Messrs. Blechynden and Mackenzie]. The advertisement is a full page one, facing the leading article, well executed cuts from photos give views of the various stages of tea, from growth to manufacture, and underneath is the following letter press showing a convincing contrast between the two articles now offered for American consumption.

TEA IN AMERICA.

New York, Sept. 9.

The dull business was made more pronounced by two and a half holidays. The market drags except on choice Formosa Oolong. Old crop in buyer's favor. No change in other sorts. The auction this week includes some new crop Moynne and Congou, and is awaited with interest. Today at noon the Montgomery Auction and Commission Company will sell 5,535 packages, viz: 354 half-chests Moynne, all new season; 288 half-chests and boxes Pingsuey; 899 half-chests Congou, including seasons 1896-97; 131 packages India, Java and Ceylon; 716 half-chests and boxes Amoy, a desirable assortment; 1,111 half-chests Foochow, and attractive offering, including the "Knn Wo" chop; 2,036 half-chests and boxes Formosa, all new crop, and including an attractive invoice of true summer character.—*American Grocer*.

INDIAN AND CEYLON TEAS.

The Cultivation and Manufacture of these Teas explains their extraordinary quality.

MARK THE CONTRAST:

INDIAN AND CEYLON.

LANDS.—New and Fertile.

GARDENS.—Large, well planted, central modern factories, daily manufacture of leaf.

MANUFACTURE.—Modern, up-to date, especially devised machines for twisting and drying leaf, *untouched by hand*.

PURITY.—Full standard; never rejected from any port.

CHINA AND JAPAN.

LANDS.—Exhausted centuries ago, fed with poisonous fertilisers.

GARDENS.—Small, scattered; leaf kept in family dwelling houses, with pigs and poultry till marketed.

MANUFACTURE.—Ancient; barbarous; leaf twisted by the hands of semi-nude moist Mongolians, amidst the sordid surroundings of a Chinese dwelling. No factory inspection and much *Sweating*.

IMPURITY.—Adulterated, colored, faced, "Lie Tea." Rejected on these grounds daily. A shipment recently rejected at New York was admitted through a Western Port of Entry. See daily papers, Importer's Confessions in Petition to Congress.

RESULT:—

1894.	1895.
Imports.	
lb.	lb.

Increased Consumption; 5,379,542 9,283,141

The following statistics culled from the same source show the growth in the import of tea from 1880 to the current year inclusive.

THE FLUSH-WORM IN CEYLON.—*Planting Opinion*, of Sept. 26, says:—Ceylon planters, ever mindful of the awful ruin that swept over their coffee-plantations, are keenly on the watch to detect any similar fungoid or insect pests on their tea. Hitherto, beyond a slight attack of elopeltis or mosquito-blight, we believe Island tea has kept remarkably free from all blights and diseases that are such serious factors in Indiau gardens. But to come to the point, we noticed some weeks ago in a Ceylon exchange, the *Observer*, an enquiry as to the nature of a certain caterpillar that rolled itself up in tender flush. This query having been reproduced in the *Tropical Agriculturist*, we think it worth pointing out that this caterpillar is very probably what is known on the Nilgiris as flush-worm. Ceylon tea-planters would do well to keep this insect severely in check by specially picking and burning or otherwise destroying the affected leaf, as on the Nilgiris this pest is the direct cause of by no means inconsiderable loss of flush. A common method on some estates is simply to instruct the pickers to crush the rolled up leaves in their fingers, but as this is slurred over in nine cases out of ten, the remedy is obviously a very incomplete one. Merely picking the leaf and dropping it on the ground is of little use, as the caterpillar will usually manage to secure a fresh habitat,

COCONUT PLANTING IN BRITISH CENTRAL AFRICA.

In Ceylon Europeans are more and more engaging in Coconut planting at the lower elevations and the question arises, can we here not do something in the same line! By "here" we do not refer to Nyasaland but to the Zambesi and lower Shire districts, for although the *Gazette* may prove that coconuts grow at Jimbe's on Lake Nyasa, we are afraid, it would find it very difficult to persuade planters that they can be grown lucratively there, or anywhere else, in the interior. It may be objected that the only other place is the Portuguese littoral and it is to it we refer. We are aware that this is a formidable objection owing to the well-known "dog in the manger" policy of the usual Portuguese authorities, but we ask if it would not be possible, with the help of our government, to get such concessions or make such contracts would leave absolutely no room for abuses. Were such the case we believe coconut plantations would be as successful on the East Coast as they are in Ceylon and other countries and as the market for copra and coir is a good one there is every inducement for capital to see what can be done in the way of adding to the producing capacity of East Africa. The chief commercial products from the coconut are its oil, yielded by the kernal which when broken up into small pieces and dried is called *copra*, and its fibre. The fibre is usually divided into two classes—"bristle" and "mat" fibre—the former being worth from £30 per ton and the latter about £20 per ton. A third class of fibre, composed of the refuse, is worth about £10 per ton. Nuts are sometimes got about the fifth year but full bearing does not commence till the seventh to the twelfth year and the yield, under favourable circumstances, continues increasing up to the twentieth year. The residual matter, after the oil has been expressed from the kernal called *ponac*, is well esteemed as a manure for coffee and would probably find a ready market in B. C. A.—*Central African Planter* for Aug.

INDIAN TEA ASSOCIATION.

CALCUTTA, Sept. 2.

Proceedings of a Meeting of the General Committee held on the 2nd Sept:— * * *

A letter dated 27th July was read from the Honorary Secretary, Central Travancore Planters' Association, remitting R1,413-14 6 as a contribution to the American Market Fund. Mr. Acworth mentioned in this letter that every tea estate in the district has contributed. An acknowledgment had been sent conveying the Committee's best thanks for the hearty support still continued to be given by the Central Travancore Planters' Association to the efforts for the extension of the Indian tea trade in America.

Letters of 17th and 24th July and 7th August from the Secretary, India Tea Association, London, also in connection with the American Market Fund, which had been previously circulated, were now brought up for consideration. The Committee noted that Sir Henry Truman Wood had at length received the medals and diplomas of the various tea companies and estates represented at the Chicago Exhibition, which had been distributed to all the companies having offices in London the remainder having been sent by the India Office to Calcutta. In response to a request from the London Committee, a sum of £1,000 had been remitted on the 1st instant. The total amount of contributions paid and promised up to date was reported as R99,288-10 0, and the balance in the Bank of Bengal after making the above remittance was R45,886-15 1, the outstandings being in process of collection. * * *

The Committee next proceeded to consider a memorandum prepared by the Secretary, Bengal Chamber of Commerce, with reference to a proposal recently made in the House of Commons for the abolition of duty on British-grown tea, the discussion on which had been postponed at the last Meeting. It was decided that very little could be done on this side beyond supporting any efforts which might be made by the Committee of the Association in London and supplying them with all necessary information. Copies of the memorandum were to be sent home and the attention of the London Committee strongly drawn to the matter urging them to keep the agitation on the subject alive.

The next matter for consideration was a letter, dated 11th August, from Brigade-Surgeon-Lieutenant Colonel W. A. Crawford Ro., Honorary Secretary, Pasteur Institute of India, Simla, forwarding proceedings of a meeting held at Simla on the 10th August, to decide the question of the establishment in India of a Pasteur Institute, for the investigation and combatting of infectious diseases affecting the population of India and for the solution of economic problems.

Also letter of 24th August from Surgeon-Lieutenant Colonel G. S. Ranking, M.D., Honorary Secretary, Bengal Branch, Pasteur Institute of India, asking for an early consideration of the former letter and expressing the hope that substantial aid would be afforded by the mercantile community towards the foundation and maintenance of the Institute. Dr. Ranking asked for a donation of R20,000 and an annual subsidy of R15,000. The Committee gathered that the fixing of the site in Bengal, in favour of which they had recorded a resolution at their last meeting, was more or less dependent on the amount of local support received.

After giving the papers before them due consideration, the General Committee decided to contribute a donation of R5,000 from the funds of the Association towards the establishment of the Institute on the understanding that it was to be located in Bengal and have the support of Government.

As the establishment of the Institute commended itself to the Committee as being an object meriting support from the Mercantile Community, the majority of whom were more or less interested in the welfare of labour directly or indirectly in connection with tea gardens, coal mines, or (ute mills, it was decided to ask the Committee of the Bengal Chamber of Commerce to circulate a subscription list amongst its members which would cover the whole of the ground, and which the Committee felt would be a better plan than for the various Associations to solicit subscriptions each from its own members as in the latter case, firms would in many cases be asked to subscribe three times over.

With regard to the request for an annual subsidy of R15,000 made by the Honorary Secretary, Bengal Branch of the Institute, the Committee felt that no guarantee whatever could be given as to this by the Indian Tea Association as such. If the Institute proved itself of real value, it would no doubt receive support and a suggestion was made that a considerable annual sum might reasonably be expected from the tea industry by the fixing of a small fee on each coolie inoculated. This fee might yield an income of R10,000 on the supposition that one-third of the number of coolies proceeding to the tea districts were inoculated. * * *

Read letter No. 3,719 of 11th August from the Officiating Director of Land Records and Agriculture, Assam, enquiring if any explanation could be given with regard to the fall in the average prices of Assam and Surma Valley teas during 1895-96, as against the average prices in 1894-95. This letter had been replied to, stating that the crop of 1894 was a fine one as regards quality, while that of 1895 was not so, the weather not being seasonable, and this naturally had an unfavourable effect upon prices. * * *

The Secretary of the Association in London having stated that it would be worth while to send home

a monthly telegram advising the state of the weather and the prospect of the crops in the principal tea districts, it was decided to arrange a telegraph code for the purpose of reports on the different crops in the following districts:—Assam, Cachar, Sylhet, Dooars, Terai and Darjeeling. The Assam Branch were making arrangements with their district Committees to supply the information direct to the Association in Calcutta, and telegrams were being received regularly from the Honorary Secretary, Cachar Branch. It was decided to communicate with the Darjeeling and Dooars Sub-Committee with a view to obtaining regular telegrams from the Dooars, Terai and Darjeeling districts.

Considered letters of 20th and 31st August and 2nd September from Messrs. Williamson, Magor and Co., stating that their attention had lately been drawn to several cases in which chests had been found on inspection at the London Warehouse to be as much as from 18 to 24lb. short of the invoice weight, and giving particulars of the shipments. They feared that the thefts of tea which had been stopped by the vigilance of the Police last year were commencing and suggested that the attention of the Commissioner of Police should be called to the matter. It was decided that the information furnished by Messrs. Williamson, Magor and Co. should be communicated to Sir John Lambert with a request that the same vigilance on the part of the Police which had such good results last year should be maintained during the present season.

The Committee had before them extracts from the *Planter* on the subject of slack packing of tea at the gardens, both of which contained many useful hints. The remarks on the economic side of the question of slack packing, they considered, were deserving of attention, as slack packing necessitated 11 to 12 per cent. more packages than were actually required, meaning a considerable extra expenditure on the garden.

Considered letter of 13th August from Messrs. Duncan Brothers & Co, giving extracts from a letter addressed to them by an experienced Assam planter as to the manner in which tea chests were stowed and handled on board the River Steamers, which he considered had much to do with the damage now being complained of. A further letter of 23th August had also been received from Messrs. Balmer, Lawrie & Co., with reference to tea chests which have arrived in a disgracefully damaged state from Dibrugarh via Goalundo. In this case the boxes were all made of good half-inch wood and could only have been damaged by rough usage, and Messrs. Balmer, Lawrie & Co. were of opinion that it was the result of the boxes being thrown into the hold in the course of shipment. It was decided to follow up the letters already written to the Assam and Cachar Branches on the subject of damage to tea in transit by placing before them the substance of the letters now received, and it was also agreed to address the River Steamer Companies with reference to the matter, as proof had been now obtained that a certain amount of damage accrued to tea on board the River Steamers.

Considered letter No. 1116-96 of 5th August from the Secretary, Bengal Chamber of commerce, asking to be furnished with a copy of the report of the Sub-committee on the handling of packages of tea in the Port commissioners, Warehouse and Jetties which had been done in due course, and also further letter No. 1237-69 of 1st September, thanking the committee for the information given, and asking if the committee of the chamber could be kept informed from time to time as to any action taken by the general committee in connection with the handling or shipment of tea. This was agreed to.

Considered file of replies received to the Committee's Circular No. 335 O of 14 August with reference to a suggestion made that shippers of tea should issue a circular to the Liners, stating that they authorise and direct steamer officers to refuse any and every chest they were not perfectly satisfied with, and that they would guarantee that no line would suffer or lose shipment of tea owing to the strictness of its officers. The general consensus of replies received was against the adoption of the sug-

gestion, various objections being raised to it and the Committee had consequently no alternative but to allow the matter to drop.

--*Indian Planters' Gazette.*

HOPE FOR THE CHINA TEA TRADE.

In another column will be found a letter and an article reproduced from the *Foochow Echo* in which an important announcement is made, namely, that foreign machinery and foreign methods have at length been introduced in the preparation of tea in one of the districts near Foochow. The commencement is a small one and how the experiment will result remains to be seen. The machinery has been got up to Peeling without opposition, but whether immunity from mandarin obstruction will continue to be enjoyed is doubtful. There can be no doubt, however, that if the adoption of foreign methods were officially approved they would speedily become general and a great revival in the tea trade would result, notwithstanding the heavy taxation to which the article is subjected, amounting in all, it is said, to 40 per cent. If at the same time that foreign methods are introduced the taxation were either wholly abolished or reduced to a moderate amount the China tea trade would soon regain its ancient glory and wealth would once more flow into the districts that have become impoverished by the loss of their principal industry. If foreign capital were allowed to be freely invested in the interior we would soon have numerous planting companies established whose prospects would be even brighter than that of the Shanghai cotton companies from which so much is expected. Following its usual policy, however, China would probably object to foreigners acquiring any vested interest beyond the treaty ports. In the case of the Foochow enter-

prise Mr. Fraser has presumably been enabled to make some special arrangement to permit of his establishing himself at Peeling, but on this point the local paper is silent. In any case, however, the introduction of foreign machinery and foreign methods affords a ray of hope brighter than any that merchants interested in the China tea trade have enjoyed for many years.

IMPROVEMENT OF TEA MAKING AT FOCHOW: INTRODUCTION OF THE INDIAN METHOD.

The following letter appears in the *Foochow Echo* of the 12th September:—

Dear Sir,—It has been a subject of remark during the past few weeks that you have maintained a mysterious silence regarding the crisis, if I may so call it, that has come about in the Foochow tea trade. The purport of this letter is quite as much to induce you to break that silence and if possible to draw forth some opinion from you as to our prospects, as to furnish you readers with the news, which cannot fail to be of interest to all.

Mr. Fraser, of the firm of Fraser, Ramsay & Co., after visiting the tea gardens of India and Ceylon and making himself acquainted with the methods adopted in those countries of picking and curing tea, has managed to introduce them into one of the tea districts here and with such marked success that a prosperous future for the Foochow tea trade seems assured. So far, what has been done is merely an experiment, but the most satisfactory results have been obtained, that is to say, teas of the prettiest make and appearance have been produced, drawing a strong dark liquor, with an infused leaf of the approved bright golden colour. What more is required? We are at once placed in a position to compete with Indian and Ceylon growers in the great consuming markets of Great Britain and Australia.

No difficulty was found in starting a company locally for the purchase of machinery and for otherwise pushing the adoption of the new method of making tea among the Chinese. The name of the Company is the "Foochow Tea Improvement Company."

Over and above this, I hear that there is quite a little undercurrent of excitement going on in the foreign hong. Of course with such a conservative people as the Chinese it is unlikely that more than a small proportion of the Congou crop will be made in the new fashion for a year or two, but in the meantime it is understood that some of the foreign hong are already vying with one another to get this small proportion into their own clutches. All sorts of inducements are being offered, which the Canton and Chin-chew hong-men will not relish. Liberal advances are to be made to intending operators in this new fashioned tea, and extensive godown-room is to be placed at their disposal. The novel (to Foochow) method of selling the tea by auction has been proposed—the advancing Foreign Hong to be the auctioneers, who further proffer their services to ship any teas, for which satisfactory prices are not bid, to the consuming markets of the world on owners' account. There is nothing like taking time by the forelock.

Pray, Mr. Editor, let us have your views, or those of any of your contributors who may care to favour us with theirs.—I am, dear sir, yours truly, T.

Upon this the *Echo* makes the following comments:—

We find ourselves forestalled by our correspondent "T" in being the first to make public an important piece of news, the introduction into this province of the Indian method of making tea. We were asked by some of our subscribers not to publish anything we might hear about it for a time, and it is only within the last few days that we have been released from our undertaking to abide by the request. Although the thought may have been quite original on Mr. Fraser's part, it was not altogether a new one. The idea of its feasibility had occurred to more than one of our resident merchants, but was abandoned by reason of the difficulties attending the introduction appearing to them insurmountable. It

may be guessed that the foremost difficulty was the certain strong opposition of the Chinese, high and low. It was reserved for Mr. Fraser to do what others had feared to attempt, and if all goes well, as the result of his first experiment seems to predict, his name will be handed down to posterity as the reviver of our moribund tea trade. Mr. Fraser followed up the conception of the idea by going to the gardens and factories of India and Ceylon and learning for himself all that he could about tea cultivation and tea curing in those countries. On his return to China he brought with him a tea rolling machine, which was no doubt to be followed by other machinery necessary to complete the curing on Indian principles. The rolling machine was landed, but now came the question of the difficulties which dreamers of the scheme had looked upon as insurmountable, Mr. Fraser reckoned up and circumvented them. He had his establishment at Peeling and managed to get all his machinery up to that district, piecemeal, without ruffling either the tender susceptibilities of the sleepy officials or the local population. Instead of hiring a score or two of Foochow coolies rush the machinery up *en bloc*, which would have created suspicion, ill feeling, and possibly trouble, he had it carried up at intervals, bit by bit, by local coolies sent down from Peeling for the purpose, and they arrived with their burdens without attracting any special attention. Thus this formidable difficulty, as it was considered, was overcome by a little fact and good management. It was promptly set up and brought into play with the satisfactory results mentioned by "T," namely, in pretty dry leaf, nice strong and dark liquoring waters (so much liked by the English masses), and infusions of the approved bright bronze coloured infusions being produced. But before describing the result we ought first to have mentioned that the Chinese mode of picking of, withering, and fermenting had all to be altered. This was quickly taught, and it is said by the Chinese that these preliminary processes apart from the use of the rolling machinery, are sufficient to produce the made tea with all the characteristics of that shipped from India and Ceylon. Experts who have seen these teas declare them to be wonderfully good but Mr. Fraser and his friends, believing that machine made teas will be far superior, have formed themselves into a company, and several influential merchants have joined them, for the purpose of importing all the machinery necessary. We wish the company all possible success.

The Foochow tea trade continues to decline so rapidly, excepting for its specialities, that all interested in the port at all must welcome warmly any move that is likely to revive it, and should give all the encouragement they can to Mr. Fraser and his friends, in the expense and trouble they are going to, to keep the trade alive.

Having furnished our readers with a brief sketch of what is going on in this new departure in the history of the China tea trade, we willingly comply with our correspondent "T's" wish that we should give our views on the subject. We have to say that we are only deterred from boldly asserting that Foochow has a future before it by the thought of the cruelly heavy export duty, likin, and other taxes we have to submit to, which together amount to fully 40 per cent, on the average cost of the season's crop. Given that we are successful in making tea that will be as readily saleable as those of India and Ceylon in the great consuming markets, how can we look for a prosperous trade with such a handicap as this 40 per cent to add on to our first cost?—*Hongkong Weekly Press*, Sept. 18.

IMPROVEMENTS IN THE FOCHOW TEA TRADE.

Our most important news is that an experiment has been made in making Foochow tea on Indian methods and that it has proved successful. If this can be carried out on an extensive scale it will be a great thing for Foochow. Our teas as at present made become each year more difficult of sale in London and Australia. The trial was initiated by Mr. Fraser, of the firm of Fraser, Ramsay & Co., and on its

being found to be successful a company was formed for the purpose of procuring machinery and otherwise bringing about the change as quickly as possible. I have not heard of any trouble having been met with at Pacling where the first machine was set up, and it is to be hoped that none will be encountered when other machines are taken to other districts in the early spring. We have always been led to believe that anything in the way of machinery which is supposed to lessen the demand for labour would lead to rioting, but we may have been gulled. We must hope for the best, many of the Chinese amongst us have entered into it warmly, but I must add, on the other hand, that many stand aloof. The new-make will, no doubt, cost more, but then it will sell at a higher price. Anyhow, from the outset we shall have teas that are saleable, which is not the case with us at present. If the cost is too high at the beginning, that is a matter that will right itself later on. The terribly heavy duties and likin we have to pay alone stand in the way of a sanguine view being taken of the future of the trade, for there is no doubt about the determination of the enterprising company to make the thing a success.—*N.-C. Herald*, Sept. 18.

NYASSALAND NOTES.

Rumour has it that the Ceylon planters have got terribly afraid of this country owing to reports of our climate being so fearfully bad as to be called by some deadly to the poor martyrs white men, whose misfortune compels them to live here.

I see by a late *Observer* that some Nyassaland correspondent asserts that Mr. Owen who was sent over here by Mr. Carson nearly died from blackwater fever; also that the late A. T. Miller died from the same complaint. Now I am in a position to contradict this statement as untrue, Mr. Owen had fever certainly off and on during his short stay here; no doubt the malaria he absorbed on his journey up the Shiré came out when the hills were reached, as it does on nearly everybody who comes here, so he finished it and cleared. Regarding Mr. Miller's death, I assure you he died from an internal complaint and had no fever during his 6 months in Nyassaland. Fever is common enough here I don't pretend to deny, but it is mostly brought on by men's own fault. Except the introductory fever dose, which few escape and as few if any die; from it is easier cured, of a much milder type and not nearly so obstinate and dangerous as Ceylon lowcountry fever: in fact it is thought so little of by old residents that they don't seem to mind it in the least; and for my own part I would rather have 24 hours Nyassaland fever than a severe cold, which I have by the way at present, and it has stuck to me for 10 days and I can't shake it off. If our country was so deadly as represented, why have we so many ladies amongst us? One gentleman replied to me: "Oh! they never get ill." I can count 18 to 20 of the fair sex in the country, and never heard of any of them being seriously ill: those I have seen looked well, and two or three after 7 or 8 years' residence look blooming and much improved by these residence in B.C.A.

There is, however, a form of fever more unknown in Ceylon, and by the way unknown here until about 4 years ago, viz. blackwater, which has proved fatal in many cases, mostly for want of proper nursing and knowledge of how the disease should be treated. I have seen several cases and have had the complaint twice myself, and if properly treated is not in my opinion so

serious as people would like to make out. It is as well, we are thankful that this form of fever is not very common and has, as far as my knowledge goes, only been contracted by those engaged in opening up Coffee estates, and living in or visiting unhealthy parts of the country. Upon the whole the country cannot be called healthy for Europeans any more than many of the districts in Ceylon were, before they were opened up, and during the opening of large tracts of country for tea and coffee. I would rather have ten doses of Nyassaland fever than one Kurnnegala attack, and I have experienced both. My advice to Ceylon men is not to come here if they are afraid of a dose of malarial fever or what is commonly called here a "belious attack" as common in the Ceylon mountain zone as here. This year has proved a very unhealthy one for both Europeans and natives; it has been worse than I have known it for several years back, and has proved fatal to a few as you would see by the sad deaths of the brothers Buchanan whose loss is much felt and greatly bemoaned by all.

The Nyassaland Co.'s Superintendent is not going to lose time this year, for he has already knocked down nearly 200 acres, and has over 300 labourers at work; so who can say labour is scarcer here? Distant reserves of labour have hardly been tapped yet, but facilities are now offered for getting labour from a distance which did not exist a year or two ago: for instance the Agent of the B.C.A.A. stationed in Augoniland about 100 miles away, is sending down large numbers to work on coffee estates this year, and the supply is likely to continue as there is an enormous population to recruit from. They only stay from 3 to 6 and 8 months. We hope, however, that better pay will induce them to engage for a longer period.

The two assistants Messrs. Moggridge and Robins have been at work on the Company's land for some months, and seem like Mr. Crabbe to like the country and tackle work with a proper spirit—apparently the proper stamp of men for this much abused country. Several new estates are being opened up in Mlanji this year, besides the Nyassaland Co.'s, viz., Messrs. Cox, Austin, and Wils's lands: they are all busy with nurseries and new clearings.

We must have a railway in a few years or we shall be in a terrible box for want of transport facilities. A survey has been made to connect the Shiré Highlands with the river at Chirimo, our port of embarkation (where steamers call) for the coast, and it is reported that no difficulties in the way of engineering exist along the trace: so we hope to be served by a railway in due course.

Transport has been reduced: I am sending coffee home to London for £5 per ton, £2 10s by river, and £2 10s by Reunion Line.

Tea seems to do very well here: I have as good a growth at 3 years as any I ever saw in Ceylon at 300ft. The soil and climate seem to suit it admirably. The flavour (for I have made it frequently of late) resembles very much some tea I made at Tommagong, in the Udapnssellawa district. The aroma is excellent and it flushes freely, so we need not despair of having a paying product should leaf-disease ever appear on our coffee.

We have a terrible pest in borer in Mlanji district, and it is worse this year than I have seen it before, in fact it is as bad as I have ever seen it anywhere except in Travancore.

We have the two borers here—one the *Zeuzera* coffee red borer from the larva of a white moth with steel-blue spots common in the Uva district of Ceylon. This does not do so much damage as the other, produced from the larvæ of the long-corn beetle, the Indian white borer. They are very numerous and destructive, especially when the soil is of a deep chocolate or black loam rich in humus. They begin to hatch about March and assume the chrysalis form about July and August. For the last four months I have had a few boys catching the borers, and they sometimes bring in 20 to 30 per diem besides what they kill in the trees by means of a small wire pushed into the hole where the borer enters the tree; they are worst on coffee 3 and 4 years old.

The black and white grub from the cockchafer beetles are not so numerous as I have seen them in Ceylon, although common enough. Crickets and locusts of various kinds are about the only other enemies our coffee has, but they don't seem to do much harm except to young plants by cutting them down during the dry season.

Black and white bug are both to be seen upon orange, soursop and guava trees at times, and I have seen an occasional coffee tree with bug; but it does seem to cast or spread, probably due to the ever present ladybird beetle of which we have two or three specimens.

Nyassaland planters are going crazy about shade for coffee, and it is being experimented with by several. My observations don't support the theory that shade is required for coffee here, specially having forest trees on a new clearing as some are doing. We have some very good indigenous forest trees suitable (deep feeders that don't seem to hurt coffee) such as mahogany, malombwi, and some of the *Albizia* family, locally named kalatta, sopa, aquaranyana, and chickwani: the latter four have feathery leaves which close up at night, and are very deep feeders, nevertheless they should all be felled when a clearing is being made for coffee, and young plants (to whatever kind is thought suitable by those who want shade, planted out at regular intervals, or a set distance apart after coffee is a year or so old, as young coffee plants certainly hang back when planted under standing forest shade of any kind.

I am not a believer in shade, at least in Mlanji, with our rainfall well distributed at an elevation of from 200 to 300 ft.

Our two driest months are October and November, and I have never known less than 1 or 2 in. of rain, or the thermometer rise more than 96°, and that only for one or two days just before the break of our rainy season towards the end of November. I have never seen healthy coffee dropping or losing its leaves here from drought, as I have seen in Lower Matale and elsewhere in Ceylon. Further my observations go to prove that shaded coffee here does not make wood, nor does it crop so well as that in the open. I can understand going in for shade where coffee gives little of no crop without it. Shade is in any climate undoubtedly beneficial, as an agent for manuring by means of the leaves which are continually falling, and helps to replace the ingredients removed from the soil by the coffee tree; but as I have said suitable shade must be selected. Coffee is not, however, such an exhausting crop that it cannot be grown without manuring on almost any kind of forest soil for at least for 8 years.

I remember seeing some very fine coffee under shade of the small wild fig tree *Ficus indica*

in Lower Matale; but I was told that the coffee gathered from it was very little, compared with the rest of the estate. The unshaded coffee never looked so vigorous and green: it cropped well, while the shaded coffee did not do, although it certainly promised to last much longer.

I took charge of an estate once which was one cover of jak trees planted as shade; the place had not given a decent crop for years; so I set to work and lopped the jaks to a top, giving the coffee a good pruning. The result was double the crop next year. Although jak is considered good shade for coffee by most low-country Ceylon planters, I never thought so; At all events jaks should be thinned out of all the leaves and smaller branches or twigs once a year and buried as a green manure, to make it worthy of the name of a shade tree for any plant growing on the same ground.

Weeding in Nyassaland is not so serious an item of expenditure as in Ceylon. Although we hear some familiar friends here such as the Spanish needle and white weed. They are not troublesome except during the rainy season from November to April, during which time the growth of everything is marvellous. Some discussion has taken place lately in one planting paper as to whether coffee will or is paying in Nyassaland—the outcome of a letter written by Mr. Simpson, a Chirimo and Mlanji trader, who apparently has made some mistake in his mode of cultivation the same as some of his neighbours. In fact the three oldest estates in Mlanji have not got fair play to my personal knowledge, Mr. Simpson included, because they were allowed to grow up to 5 and 6 ft. high, then hacked down before blossoming, and in some instances with crops set on the upper branches, where the sap naturally flows to, impoverishing the lower primaries, that could hardly be expected to blossom again. The trees were allowed to nourish magnificent suckers, 2 and 3 feet high, to be again cut or pruned off: under such circumstances how could coffee yield good crops?

A Ceylon planter asked a gentleman, African planter, why he let his coffee grow up like blue gums, especially when his estate was wind-blown. His reply was: "the more wood and bigger tree gave more crops. After being persuaded that he was mistaken, a general stampede of knife-men were seen rushing to attack the coffee trees, and down they went to 2½ ft. I am sure any experienced coffee planter will agree with me that it would be better to allow estates to grow as native coffee than subject them to such treatment.

Another cause of poor crops such as Mr. Simpson records is owing to planting up old native gardens. Only a few years old chena land, which Ceylon men of experience know, only yields one or two crops, then struggles for existence, unless manured. This is the case with the generality of lands, although some fine coffee yielding good crops is to be found on alluvial deposits without manure.

To sum up with, I have just finished. Gathering a 5 cwt. per acre crop from a field 3 years old, which was virgin forest, but unfortunately the acreage is small, the trees look as if they had borne no crop, and I expect at least 6 or 7 cwt. next year.

Nyassaland planters are mostly a hard-headed, stubborn lot of men, above taking the advice of anybody. Consequently their experience is dearly bought: in fact they are a queer lot,

who are not very particular about the veracity of the statements they make; it is said to be the effect of the African climate!

I must now close with the promise to myself that I shall not be so long silent again. H. B.

NOTES FROM OUR LONDON LETTER.

London, Sept. 18.

LAND AND LIMITED COMPANIES.

In conversation with a gentleman of large experience in the Ceylon tea trade we discussed your remarks relative to the effect of most of the planting lands in that island passing into the possession of limited companies. That authority remarked:—"There can be no doubt that, should ever another crisis occur in Ceylon, there would be little hope of its being pulled through as former occasions of the kind have been. The loss would fall on a multitude of shareholders, whose individual stakes would be relatively small. How many of these would be likely to put their shoulders to the wheel in the way Ceylon planters have hitherto done to put things straight again. They would simply remark that the colony might go to Hongkong for what they cared. And besides that, it is little generally known how much of the capital that has been and is being subscribed towards these daily starting Indian Tea Companies and Ceylon Tea Companies is passing into private keeping. I could mention one City firm who, it has been asserted, has bagged £250,000 by its 'bringing out' of such companies. It is to be hoped that a stop will soon be put to this sort of thing; but so long as the British public rushes madly after shares in these companies, they will be accommodated by those who are making pretty pickings out of the job."

The remarks made above respecting the course of the dispute between the Dock Companies and the shipping interest had been written before the *Times* of this morning came to hand. That issue contained the information quoted in full below. Reference had been made to the rumour that the Dock Committee were seeking negotiation with the shipowners, but it was not possible for the writer to give information as to the terms on which such *rapprochement* was being sought. The extract now given will show you that the dock companies are prepared to retire from the position at first assumed by them—a position which, it is variously estimated, must have compelled the raising of freights to London by from 2s to 4s the ton.

BURGLARY AT THE PREMISES OF THE CEYLON TEA COMPANY.

The premises of the Ceylon Tea Company in Southwark Street, Borough, were broken into for the second time last week. Two of the three safes were broken open and £5 in silver stolen, as were also twenty nickel watches, the last being an item one would scarcely expect to have a place in the safes of a Tea Company. A third safe resisted the efforts of the thieves. It is two years since the last burglary on these premises occurred, when five men were captured and received sentence for their offence.

THE DIMBULA VALLEY COMPANY

has declared an *interim* dividend for the three months ended June 30th at the rate of 10 per cent. per annum on its ordinary shares. It seems to be somewhat out of the usual course to declare a dividend on so short a term, but we

presume that the profits have accumulated so rapidly, that the directors are anxious to get rid of them without delay. The Highland Tea Company of Ceylon is another Company that has declared its *interim* dividend. This is for the half-year ended June 30th; and is at the rate of 8 per cent per annum, to be paid free of income tax.

COFFEE PLANTING IN PERAK.

From the Kuala Kangsar Monthly Report for July, in the *Perak Government Gazette* of Sept. 25, we take the following:—

The Gaggis and Waterloo estates, under the able management of Sir Graeme Elphinstone, are being rapidly opened up. On the former over six hundred acres have been planted in coconuts and coffee, and three hundred acres on the latter have been felled, and holed and the necessary drains and roads in a great measure graded and completed.

The Liberian three years old coffee on Waterloo is looking splendid, and a fair crop will be picked off the old Arabian trees.

A great many Malays have begun to open up small five acre blocks in coffee. I have allowed them to take a crop of *padi* off the land the first year, as I do not think it is in my power to prevent them. A great deal of rubbish has been written on this subject by officers who know nothing about what they are writing. I think Government should once for all lay down whether this is to be allowed or not, having obtained the opinion of an experienced practical planter first.

Sir Graeme Elphinstone's new estate called "Ravenwood," near Sungai Siput, is being opened up by Mr. Forrest. Sir Graeme and a Mr. Thomas have applied for another 500 acres of land on the other side of the main road to the new estate. The Monthly Report for September has the following:—

In my report for July I made a mistake in the name of Sir Graeme Elphinstone's new estate, it "Heawood," and not "Ravenwood" as stated.

During the current month I have had applications for 1,200 acres of coffee and coconut land, viz:—500 from Sir Graeme Elphinstone and Dumraez Thomas, Esq., near Sungai Siput; 500 from Sir Graeme Elphinstone and Mr. Solomon Ramanathan, near Jenalek, on the Patani road; and 200 from Mr. Solomon Ramanathan in the Chua valley. I have strongly recommended these three applications, and hope the Government will grant them, and that at an early date.

The following figures shew the amount of work done by Sir Graeme in opening up in 1896:—In coffee:—on "Waterloo," 6 acres; on "Rumah Papan," 255 acres; on "Heawood," 20 acres. In coffee and coconuts:—on "Gaggis," 277 acres. Total 558 acres.

In addition to the above, by the end of the year, Sir Graeme intends to open up another 117 acres on "Heawood," and 90 acres more on "Gaggis," making more than 750 acres in the year.

If the new applications are granted Sir Graeme intends to fell 20 acres on each and plant in the nurseries at once.

ROYAL GARDENS KEW.—The Bulletin of Miscellaneous Information for March and April has the following contents:—Botany of Formosa; New Rubber Industry in Lagos; Coffee Planting in Lagos; Botanical Enterprise in East Africa; Myrrh and Bdellium; Miscellaneous Notes—Mr. R. Derry, Mr. A. Parsons, Mr. C. Wakely, Mr. W. Binder, Botanical Magazine, Relief House, Palm House Heating, Douglas Spruce Spar, Pelican, Blackthorn fishhooks, *Strobilanthes callosus*, and Mr. Littledale's Tibetan Plants.

SUPPLY OF TEA CHESTS.

As the manufacturing season draws to a close and Managers become busy with their estimates, the annual recurring anxiety as to the supply of tea boxes for the ensuing season manifests itself, and though the majority of planters are apt to adopt the motto "*après moi le déluge*" in reference to the matter, there can be little doubt that, as years go on, the difficulty of procuring an adequate supply of seasoned wood, locally, will intensify. We are willing to admit that timber, like coal in Assam, is plentiful enough, but the getting either out to a market at a reasonable cost is the hitch. We noted in our issue of the 19th that a Ceylon firm were getting a consignment of pine shooks from the Baltic and our correspondent expressed surprise thereat, venturing on the assertion that India could supply Ceylon with all her requirements, but if we experience a difficulty in meeting our own wants, we most assuredly cannot export. Of course we know that the forests in the tea districts are not the only ones in the country, and that were the Southern India timber tracts thrown open unreservedly, Ceylon could obtain ample wood from the Palghat jungles, but teak from its weight and difficulty of working, is by no means the best fitted wood for tea chests, irrespective of the powerful smell when not thoroughly seasoned, and all other suitable timber is being more jealously conserved, and very rightly so, year by year, by Government, the Forest Department apparently having at length fully awakened to the importance of securing the rainfall.

Some two years ago we suggested that an attempt might well be made to obtain pine or fir from the Siberian forests *via* Vladivostock, but can we wait until the Railway puts that port in connection with those forests? And would it not be more satisfactory to open negotiations with the "lumberers" of British Columbia *via* Vancouver? The forests of Northern Canada along the line of the Pacific Railway could, for a long time to come, furnish India and Ceylon with tea shooks, and our planters might find a new market by tapping that of the dominion from the north, without sending their teas all across the Atlantic, in most cases *via* the United Kingdom, with all the drawbacks of transshipments and passing through the hands of half a dozen sets of middlemen. Could the pine woods of Northern Asia or America be opened up freely for the tea trade requirements, we might be content to wait until some enterprising firm set about initiating the project without casting about for some novel material for our boxes. We have heard it advanced that pine is too fragile to stand the rough treatment our tea chests are subjected to, but the tea interest is sufficiently strong now to insist upon more careful handling and, moreover, the breakages among the kerosine oil cases are so few, comparatively, as to show the wood, though light, is stout and strong enough if ordinary care is observed in its treatment. Whether some more suitable material could be devised for packing our teas, those mostly concerned must think out for themselves. Many suggestions have been made and experiments tried, but somehow all return to the lead lined wooden chest, though should a trade be opened with Central Asia no doubt the packs made from pulp would be found the best that could be adopted, though when the question of opening up a trade in that direction crops up, we are inclined to think that a better chance of accomplishing success lies in the Persian Gulf route to the Kerbha River, than up the difficult passes and over the rough mountain roads of Turkistan or through Cabul to Samareand. There is no doubt that the wood of Indian tea chests is far too heavy, and no advantage is gained in using it, for the complaints from Australia last season regarding broken boxes showed that we certainly gain nothing in strength; a comparison between a China and Assam chest is remarkable. True the former is strengthened by being cased in paper, mats and split cauo, but when we come to look closely into matters, there is no doubt that Chinaman's actual box is decidedly a far superior article to our

own, chiefly because the material employed admits of being more easily worked up, and were we to adopt the light pine in lieu of the thick heavy wood at present in vogue, we should get a better chest and one thoroughly seasoned, hearing in consequence less about loose packing. With the low rates of freight now ruling it would no doubt pay to send one of the four-masters with gunnies and rice to San Francisco for disposal there on ship's account, then letting, her run up to Vancouver for a cargo of pine (either in logs or planks) for this.—*Indian Planter's Gazette*, Sept. 26.

 THE PINE HILL ESTATES COMPANY,
LIMITED.

An ordinary general meeting of the shareholders of this Company, was held at the Company's offices, No. 20, Baillie Street, at 12-30 today.

Present:—Messrs. H. St. C. Bowle Evans in the chair, R. E. Prance, J. A. McGillivray, C. C. Herbert, F. W. Bois, representing Mrs. M. E. Bois and C. G. Ryan.

Representing by proxy were Messrs. John Masterman and F. M. Mackwood, Mrs. M. F. Thorne, Mrs. G. Prance, Mrs. A. G. S. Hughes and Mrs. E. L. Beven.

Proposed by Mr. H. ST. C. BOWLE EVANS, seconded by Mr. C. C. HERBERT and carried that the report of the directors be adopted.

Proposed by Mr. C. C. HERBERT, seconded by Mr. C. G. RYAN and carried that a final dividend of 4 per cent on the paid up capital of the Company be paid at once making a total of 7 per cent for the year.

Proposed by Mr. C. G. RYAN, seconded by Mr. C. C. HERBERT and carried that Mr. H. St. C. Bowle Evans be re-elected a director of the Company.

Proposed by Mr. F. W. BOIS, seconded by Mr. J. A. MCGILLIVRAY and carried that Mr. John Guthrie be re-elected auditor for season 1896-97 on same fees as before.

The CHAIRMAN then went on to say that the directors regretted that a dividend of 7 per cent only could be declared, but that the profits for the current season (1896-97) would, they hoped, enable them to declare a good dividend, as if the crop netted 50c per lb. a 16 per cent dividend would be realised. He also pointed out that by the figures shown in the Report, Pine Hill and Wavahena has earned 13½ per cent for the past season and Nahakettia only a little over 2 per cent and it was therefore owing to Nahakettia that the dividend was so small. Nahakettia, he was glad to say, had been sold, and the Company's position, with the large Reserve Fund amounting to 10 per cent of the reduced Capital, was, the Directors considered, a very sound one.

After the above business was concluded the meeting resolved itself into an extraordinary general meeting and confirmed the following special resolutions:—

1st.—That the Directors be authorised out of the purchase money arising out of the sale of the Nahakettia Estate, amounting to R190,000, to refund to each Shareholder of the Company a sum of Forty Rupees per share in reduction of the Capital amount subscribed in respect of such share.

2nd.—That the Capital of the Company be reduced from R355,000 in 3,550 share of R100 each (being the amount to which the Capital of the Company was increased by special resolution passed on the 19th May, 1894, and confirmed on the 16th June, 1894,) to R213,000 in 3,550 shares of R60 each.

The meeting closed with a vote of thanks to the chair.

The following is the report by the Directors:—

Your Directors submit their Annual Report and accounts for the 12 months ending 30th June, 1896.

The Tea Crop from the 3 Estates was 5,209 lb. over the estimate, but the estimated 250 bushels of parchment Coffee from Nahakettia Estate was represented by 85 bushels only.

Pine Hill and Wavahena Tea Crop	amounted to ..	117,723 lb.
Out-turn purchased Tea	do. ..	14,261 „
Nahakettia	do. ..	112,485 „

The working profit for the season amounted to R25,880.78, contributed as follows:—R21,601.51 by Pine Hill and Wavahena and R4,279.27 by Nahakettia.

The amount available for dividend after payment of the interim dividend of 3 per cent on 21st Feb. 1896, stands at R15,296.78 equal to an additional 4 per cent or 7 per cent for the year—which your directors propose to deal with as follows:—

To payment of dividend at the rate of		
4 per cent ..	R13,946.00	
Leaving a balance to be carried forward ..	„	1,380.78

R15,296.78

Since closing the accounts, the sale of Nahakettia Estate for the sum of R100,000 has been completed, showing an apparent profit of R6,417.56 over the amount it stands at in the Company's books, but the actual profit cannot yet be ascertained, on account of claims for short area, involving survey costs, a claim for sale commission, and also heavy costs to pay for the expense and trouble of writing down the Company's Capital from R355,000 in 3,550 shares of R100 each to R213,000 in 3,550 shares of R60 each.

The Directors do not add anything to Reserve Fund from profits as a sum of R14,300 from the Nahakettia sale money is added thereto.

The estimated Estates' crop for season		
1896-97 is put at ..	150,000 lb. tea.	
and from purchased leaf ..	15,000 do.	
		165,000

According to the Articles of Association, Mr. H. St. C. Bowle Evans retires from the Directorate, but is eligible for re-election.

WHO DISCOVERED THE TEA PLANT IN INDIA?

TO THE EDITOR OF THE "ENGLISHMAN."

SIR,—As one who many years ago entered on this *vexata questio* and endeavoured to solve it, I am interested in what your "Special Commissioner" has so graphically said on the subject in your impression (Dat Edition of this morning.)

The destruction by fire of my library of rare and valuable books on India in 1882, and the—to me irreparable—loss of my MMS. on History, Natural History and Shikar, prevents my being able to verify my statements by referring to the authorities on which they are based, and I have, therefore, to trust more or less to memory which at best cannot be considered as absolutely reliable. At page 145 of my "Historical and Topographical Sketch of Calcutta," which originally appeared in your "Saturday Evening Journal" more than twenty years ago, occurs the following footnote:—

"In this year (1825) the tea plant was discovered in India. It was found in the district of Tejpur, Assam, by Major R. Bruce and his brother, Mr. C. A. Bruce. Various other persons claim this honour, but it is generally allowed that the brothers Bruce were really the discoverers of the tea plant in this country."

Subsequently I gathered additional evidence on the subject, and wrote a paper on it, which was reproduced in Wymann's "Tea Encyclopædia." I think it was there satisfactorily established that the late Major R. Bruce was the actual discoverer of the indigenous tea plant in India. Not having Mr. Wymann's work at hand to refer to, I am unable to

forward a copy of the said article; but, as the subject is of some interest to those connected with the tea industry in India, you may be disposed to publish it from the above book should it be in your Editorial Library.

In connection with this subject I may state that as the tea plant is not found in a wild state in China, and is indigenous to India, ergo, botanists are wrong in designating it *Thea Chinensis*; the above specific name ought once more, I submit, to be changed to *Indica*, in accordance with the recognised rules of scientific nomenclature. But it is said that a myth is as difficult to kill as a cat, aye, and more so, and this scientific misnomer, if I may be permitted to so call it is likely to be perpetuated. The Buddhist legend about the tea plant being carried from India to China by a priest* is evidently based on historical facts.

H. JAMES RAINEY.

Rainey Villa, Khulna, Sept. 21.

LANTANA—THE FOREST'S FRIEND!

I think "Velleda," though he jested on the subject of *Lantana* in your March issue, may like to read the annexed extract from the Coorg Annual Report for 1894-95. Mr. Lawrie effectually disposes of the "Forester's friend" theory, and clearly shows that, though *Lantana* "takes possession of the soil," it does not later on protect the young plants of valuable species as "Velleda" thinks.

It may interest your readers to know that in Berar, where the *Lantana* was an undoubted pest, steady work for three seasons at an expenditure of some Rs. 17,000 has practically eradicated the shrub, and all that is now needed is the destruction for a few years to come of seedlings and any plants overlooked in the first clearing. The expenditure in the future will be trifling, as one very satisfactory feature observed is the absence of shoots from roots left in ground, and the comparatively few seedlings observable after two years' careful work.

I may mention the fact that the Central Provinces Forest Administration has warmly supported Berar in eradicating *Lantana*, and has carefully destroyed any isolated shrubs found in Betul and Nimar. All these shrubs were apparently sown by birds which love the sweet fruit borne by *Lantana Scandens*.

C. BAGSHAWE.

P. S.—May I warn your Bombay readers of the danger of introducing *Lantana* hedges. I hear this is being done in the little hill station of Panchgani, and I fear it is certain (as it did in the case of Chikalda, which is much like Panchgani) to lead up to very insanitary conditions.

Extract from Coorg Forest Report, 1895-95, by A. E. Lawrie, Deputy Conservator of Forests.

"I am sorry I cannot endorse the opinion of my predecessor regarding seedlings of *matti biti* and *hona*, found under impenetrable clumps of *Lantana*. One has only got to see a stretch of *Lantana* in all its glory, and it will not take long to find that these light-loving seedlings stand absolutely no chance. Even sandal itself cannot stand very thick *Lantana*. Lately I have had a few lines opened through dense *Lantana* where sandal had been sown some five years ago, and which were known to have germinated excellently, and for two years were not lost sight of, but in the third were completely covered over with *Lantana* and entirely lost sight of. In these lines, for every one weedy sandal nearly a hundred dry rotted stams were found from three to four feet high. *Lantana* as a nurse growing and as a hedge no doubt is very good; the stems if not burnt rise some feet up and then curve down on either side, allowing a fair amount of side light to reach any seedling springing up under it, and here the seedlings shoot a head protected from cattle and other animals. The other great drawback to *Lantana* and which makes it anything but the Forester's friend is in the matter of fires; for once a fire enters a *Lantana* stretch the entire area is bound to be gutted. In any case, if it can be prevented, *Lantana* should not be allowed to take unlimited possession of the ground.

* Perhaps Theosophists would be disposed to claim him to be one of their mysterious Mahatmas.

GOVERNMENT BOTANICAL GARDENS,
SAHARANPUR AND MUSSOORIE.

From the report on the progress and condition of the Government Botanical Gardens, Saharanpur and Mussoorie, for the year ending 31st March 1896, we make the following extracts:—

CULTIVATION: FRUIT CULTURE.

Crop.—The mango crop, the chief and most profitable of the fruit crops of the country in a good year for that fruit, was for the second season in succession extremely light. The trees flowered fairly well, but owing to the presence of insect blight they did not set fruit so plentifully as the show of blossom would lead one to expect.

It may not be quite in place to draw comparisons between the past and current season in a report supposed to be only dealing with the past one, but I cannot help remarking, even at the risk of it being considered so, on the profuse manner in which the mango blossomed this spring. Almost every tree met with was laden with blossom from top to bottom and so profusely in many instances that the foliage was entirely hidden by the flowers. Notwithstanding the great show of blossom, the crop of fruit during the coming season will be again light. Insect blight was not present to any great extent, 10: were there unseasonable showers of rain while the trees were in flower: therefore I can only account for the lightness of the current crop to the extreme dryness of the air caused by the prolonged drought, having possibly withered up the organs of fructification before fertilisation could be effected.

Bers, lichees, loquats, peaches, pears, plums and oranges yielded average crops, but the yield of limes, lemons and grapes were considerably below the average.

The amount realized by the sale of fruit was Rs. 1,355-8-0, or Rs. 69-7-0 more than was realized from the same source in the previous year.

AMERICAN DEWBERRY (*Rubus trivialis*).—This useful small fruit is gradually becoming better known to growers of fruit in this country. During the past year 147 plants were distributed against 30 plants in the previous year, as noted in former reports the fruit is of little use for dessert, but it furnishes an excellent preserve and on that account alone is well worth growing.

The plants forming the garden plantation of dewberry were all raised from seed, it had been noticed during the past season or two that the quality and yield of fruit of individual plants varied considerably. A selection of offsets from the largest fruited and most prolific bearers was therefore made during the past cold season and transplanted to a new plot of ground. When the newly made plantation comes into bearing the quality and yield of fruit is certain to be fairly even and better than is now produced by many of the seedling plants forming the old plantation.

ARABIAN DATE PALM (*Phoenix doctylifera*).—Since submission of the last annual report 25 plants of the Arabian Date Palm have been killed by the palm borer, *Rhynchophorus ferrugineus*, but the mortality would not have been quite so great if the plants had been allowed to linger on until they died.

With a view of trying to completely eradicate the pest every individual plant was carefully examined and all plants that were suspected of harbouring the pest were uprooted and burned. Many of the plants looked fairly healthy when uprooted and in such cases the only sign of the presence of the insect was premature withering of the lower leaves of the plants. As all suspected plants were found when uprooted to be attacked by the borer, premature decay of the lower leaves has proved to be a sure sign of the commencement of an attack. In future as soon as premature loss of the lower leaves is noticed plants showing such symptoms will be at once uprooted and burned.

Three of the plants are for the first time carrying a crop of fruit, but as it will not ripen until towards the middle of the current summer, comment on its quality will have to stand over to the next annual report.

AVOCADO PEAR (*Persca gratissima*).—In the garden report for the year 1892 mention is made at paragraph 52 of the thriving and promising condition of three specimens of this tropical fruit tree.

Last season one of these specimens bore and ripened a few fruits for the first time. I was absent on furlough when the fruit was in season, but the native head gardener describes it as being similar in size and shape to a good specimen of the common pear and pale green in colour when fully ripe. To his taste the pulp proved insipid and nauseous and far from agreeable. The fruit is described in works of reference as being highly esteemed in the West Indies and tropical America, though strangers at first do not like it. It is never eaten as gathered from the tree, but is always flavoured with spice, lime-juice or pepper and salt. When its own peculiar flavour is disguised by the addition of these adjuncts all lovers of fruit are said to soon acquire a taste for it.

THE AVOCADO, OR ALLIGATOR PEAR as it is also called, is not likely to become a common fruit tree in Northern India; but as it is a nice evergreen and ornamental at all seasons of the year, it is deserving of a place in the garden on that account alone.

The seeds are also said to be of economic value by yielding a deep indelible black stain useful for marking linen.

BER (*Zizyphus jujuba*).—The Mauritius variety of jujub plum, made mention of at paragraph 54 of last annual report, were transferred from pots to the open ground early in the cold weather. The plants have not made much progress since being planted out, but they look strong and healthy and give every promise of making good growth as soon as the monsoon rains begin.

BLACKBERRY EVERBEARING (*Rubus fruticosus*).—This fruit-bearing bush still gives promise of being as well adapted for culture in this climate as its congener the dewberry. The plants mentioned at paragraph 57 of the last annual report as having been planted alongside of the latter have made excellent progress. One of the largest plants bore a few fruits this season for the first time, but as they were picked off by birds before they were fully ripe I can unfortunately offer no remarks upon its quality.

For the present all that can be said of it is that it gives every promise of being a success, but it will have to undergo observation for another season before more reliable information can be given about it.

FIG (*Ficus carica*).—The Japanese figs continue to make the same slow progress as reported of these varieties in former reports.

A few of the plants are bearing a small crop of fruit this season, but as it will not ripen until sometime after the date of the despatch of this report comment on the quality of the fruit will have to stand over until submission of the next annual report.

LOQUAT (*Eriobotrya Japonica*).—The small plantation of loquat plants raised from seeds received from the Governor of Malta has not made such good progress as anticipated when it was reported on in paragraph 61 of the last annual report.

Several of the plants died last season, but all blanks have been filled up from the reserve of plants maintained in pots.

The Malta strain of loquat looks robust and apparently as well adapted to this climate as our own as long as it is under pot cultivation, but when transferred from pots to the ground it gradually falls into an unthrifty condition and dies off. The soil of the plantation is of good average quality, so at present I am at a loss to account for the Malta kind doing so badly. The tree is a native of Japan, and the Malta strain in common with our own must have originally been introduced from the former country. It is therefore curious why a tree of common origin should be found delicate in India after undergoing a course of cultivation for a series of years in Malta.

ORANGE (*Citrus aurantium*).—A very fine variety of the Malta blood orange fruited last season for the first time. The plant was received in 1888 from Dr. Bonavia when Superintendent of the Jail at Etawah, with the remark that it was a layer of a variety of

Malta orange taken from a tree in the habit of bearing fruit out of season. The plant made very slow growth for many years, but during the past two seasons it has made better progress and now stands as a specimen 8 feet high and about the same in spread.

The fruit is much smaller than that of the common Malta blood orange, but deeper in colour and of much finer flavour. Its slow rate of growth and shy bearing habit is certainly not a recommendation, but when it is worked on the lime stock it may prove as quick growing and prolific as other varieties of Malta orange.

A few plants have been raised by budding it upon the common sour lime, and as soon as ready these will be permanently planted for future observation.

As most of the varieties of oranges of recent introduction have been fully described in former reports there is nothing further of general interest to add under the head of this fruit.

PEACH (*Amygdalus persica*).—Seeds of a variety of peach were presented to the gardens two years ago by a native gardener under the name of Gujarati peach. He described it as being a dwarf bushy form of the tree never exceeding a height of 3 or 4 feet when fully grown, and judging from the present appearance of the plants his description is likely to prove correct.

The plants are now two years old, and although only standing about one foot high they flowered most profusely this season and set fruit. The latter unfortunately dropped before ripening owing to shifting the plants from the small sized pots they were in when they flowered to pots of larger size. I am therefore not in a position to pass an opinion upon the value of the variety, but as it is so distinct in habit from all other forms of peach its progress will be closely observed and communicated in future reports.

There is nothing of interest to place on record regarding other recently introduced kinds. Bidwell's early peach is one of the best of these, but for general planting no variety is more reliable than the selected forms of the common peach of this district. Attention is therefore constantly devoted to keeping up a large stock of young plants of the best forms of these for distribution.

PEAR (*Pyrus communis*).—The two varieties of pears, viz., the "La Conte" and "Kieffer," introduced a few years ago from Florida, again bore a small crop of fruit.

Mr. F. W. Seers, who was officiating as Superintendent of the garden when the fruit was in season, in a note he left behind him, states that owing to the attacks of hornets, pilfering and other causes, he was not able to secure a single specimen of either of the varieties ripened naturally upon the tree. The fruit he tasted was gathered while hard and green and artificially ripened under cover. In spite of having been matured under such conditions he says it ripened after having been kept for a period of ten days to perfection and was of very superior quality.

In paragraph 73 of the last annual report I stated that I considered the "La Conte" pear to be one of the best introductions in the shape of fruits secured by the garden in recent years. The "Kieffer" variety had not fruited when that report was written, but as Mr. Seers considered the fruit it produced last season to be as good, if not better, than that of the "La Conte," both pears are without question a great advance upon the common country variety and both cannot be too strongly recommended for general culture on the plains.

A fair stock of young plants of both varieties is available for distribution grafted upon the country variety of pear. It has to be proved yet if the latter is the best procurable stock for these Florida pears, but as it has a strong root and is possessed of much natural vigour, I see no reason why it should not prove to be as good a stock as can be found.

Persimmon (*Diospyros Kaki*).—This is another of the recently introduced fruits to which attention has been paid by the garden.

Mr. Seers, the Officiating Superintendent, reports that several trees bore a few fruits last season, but unfortunately with one exception they all dropped while in an immature state.

He describes the specimen which attained to maturity as bearing a close resemblance in shape and colour to an obtuse conical tomato. Measured with a tape the circumference was eight inches, length from base upward four inches, and colour reddish orange.

Sir Edward Buck, Secretary to the Government of India, Revenue and Agricultural Department, happened to be on a visit to the garden when the matured specimen of fruit was gathered and it was submitted to him by Mr. Seers for an expression of opinion and I believe he pronounced it to be very good.

As several of the trees are carrying good crops of fruit this season I hope to be in a position to give further information about this fruit in the next annual report.

A small stock of seedling plants are available for distribution, but it will be some time hence before the gardens can supply plants in unlimited quantity.

PLUM (*Prunus domestica*).—The varieties of plums made mention of in former reports as having been introduced from Florida and Japan continue to grow very slowly and so far give no promise of bearing.

Unfortunately they are not planted in a position for giving them a fair test. The plot of ground they occupy consists of good soil, but it is much overshadowed by other trees. It is intended during the current season to plant a few plants of each of the new kinds in a more open spot and note the result.

VINE (*Vitis vinifera*).—The vine plantation planted in 1893 is making fair progress, but as this fruit bears so poorly in this district, the care and attention given to the plantation has only been sufficient to cause the plants to furnish enough wood to meet the demand for plants and cuttings which is made upon the gardens by other districts.

As plants and cuttings command a fair price, the garden realizes more revenue and is really doing more good for the country at large by only studying to meet the demand for plants and cuttings than by solely devoting its attention to cultivating the vine for the fruit it might yield.

WINEBERRY (*Rubus phoeniculusius*).—I regret having to report the total loss of all the plants of this new fruit.

In the last two annual reports I noted its evident dislike to the excess of moisture we have in the atmosphere and soil during the monsoon season. Four plants of the original large batch of seedlings proved strong enough to last through two rainy seasons, but the heavy rainfall of the past monsoon proved to be more than the plants could stand, so they all died off from the effects of damp.

The fruit of the wineberry, though much praised by the New York seedsmen who placed the seed upon the market, is, I believe, of little value; therefore the total loss of the plant is of minor importance.

VEGETABLE AND FARM CULTURE.

95. The leading standard varieties of summer and winter season vegetables were grown on the same scale as in former years.

96. As vegetables are grown by this garden chiefly for seed, cultivation was largely confined to kinds that have been proved to give good or fair results from acclimatized stock. It is not claimed that the latter is better than imported seeds of the same kinds, but by constant selection, it has been found it can be kept up to a fair standard of quality, can be sold much cheaper, and in the case of some kinds practically gives as good results as the more expensive imported stock; this branch of garden work is therefore on the whole of considerable economic usefulness.

97. The list which follows is a detail of the chief kinds grown and weight of seed harvested of each. I may add that the bulk of the seed collected was disposed of by sale or by free issue to soldiers' garden.

Cow PEA (*Vigna Catjang var.*).—Although I mentioned this plant in last year's report, I think it desirable to again draw attention to it.

The plant furnishes excellent forage for cattle in the rains, while the young pods can be used as a table vegetable and form a good substitute for French beans.

A large supply of seed was harvested last season, most of which is available for distribution.

CARROTT, SHORT WHITE (*Daucus Carota*).—Mention is made at paragraph 95 of the last annual report of the introduction of this new form of carrot.

Roots of the new variety were planted out with a view of raising acclimatized seed, but I regret to say they failed to flower: so the variety has for the present been lost.

CLOVER EGYPTIAN (*Trifolium Alexandrinum*).—A supply of seed of a clover was sent by the Director of Land Records and Agriculture, N.-W. P. and Oudh, under cover of his No. 1889, dated 23rd November 1895, for trial and report.

The variety was not received under a distinctive name, but it proved to be Egyptian Clover, a kind experimented with here in the years 1884 and 1885.

The crop much resembled lucerne, but I consider it far from being equal to the latter as a fodder. It bears cropping fairly well in the early part of the cold season, but as it begins to wither when the hot season has fairly set in, and usually completely dies off in the rains, it is therefore not possessed of the perennial habit of lucerne, and for this reason is much inferior to it for cultivation in India.

106. A small supply of seed has been gathered, part of which is available for trial in other districts, but I can only recommend it to be tried in districts higher up in the Panjab where the climate is cooler and drier than here.

107. **BEAN, IRVINE'S HYBRID PERENNIAL** (*Phaseolus sp.*).—Mention is made of the introduction of this bean at paragraph 98 of the last annual report.

108. When last reported on the plants had died down to the ground, but as there was life in the fleshy root when the report in question was written, it was hoped that these would ultimately sprout and give a crop.

109. A few of the roots made an attempt to grow but the shoots they produced never looked healthy, and, after struggling on in an unhealthy state for some time, the plants all gradually died off.

110. In America this bean is held in high estimation, but it does not appear to be suited to the climate of this country.

Sugar Cane (*Saccharum officinarum*).—No seeds were received from any source during the past year, so it was not possible to repeat the attempts of past seasons to raise this crop from true seed.

A small supply of canes, representing the varieties cultivated in the neighbourhood of Lucknow, was received from the Superintendent of the Government Horticultural Gardens, Lucknow, and are now under culture in this garden.

As several of the kinds are distinct and look superior to the varieties grown by the zamindars of this district, their attention will be drawn to the Lucknow sorts as soon as the garden is possessed of sufficient stock for distribution.

SISAL HEMP (*Agave rigida var Sisalana*).—The Sisal hemp appears to have found a congenial home in this climate. The plants are growing vigorously and have made as much growth as the two common Agaves of the district could have shown in the same length of time since date of planting.

A small quantity of the fibre was prepared and submitted to the Reporter on Economic Products to the Government of India for an opinion.

He declared it short and deficient in strength, but this was due to extracting it from the leaves before the latter had attained to maturity. When the leaves are fully matured I have no doubt it will show improvement both in length and strength.

The plants are freely producing offsets or suckers, most of which are available for distribution.

As the plant is seldom asked for by the public I would suggest that jails, which make a speciality of cultivating the common Agaves for the production of fibre for the manufacture of matting, be informed by circular that plants of the Sisal hemp are available for trial on payment of freight.

RHEA (*Boehmeria nivea*).—A considerable number of requests were received during the year for seeds, cuttings and roots of this fibre plant; also for information as to how to grow it, all of which were met with as far as possible.

A company has lately been started in Bombay to work a newly discovered process for cleaning and preparing the fibre for the spinner. The attention it has attracted has awakened renewed interest in the plant, and as the demand for it is likely to increase, arrangements will be made during the current season to further the increase the area under it in order to meet the anticipated increased demand.

I have not much hope of ever seeing the plant become a paying crop in the comparatively dry climate of the North-Western Provinces, but this is no reason why the garden should not do all that lies in its power to assist would-be growers in providing themselves with a supply of plants for experiments.

RUM PLANT (*Strobilanthes flaccifolius*).—Last year I noted that this plant (the wild indigo of Assam) had completely failed under trial in the open ground, but that it would probably succeed under shade.

In consequence of the total loss of the plants that were planted out, the stock was reduced to a single pot specimen. A fresh stock of plants is gradually being got together from cuttings supplied by the surviving plant, but as they are not sufficiently strong for the ground they are at present being nursed in pots. As soon as these plants are ready for the ground, they will be planted out under shade and the result duly noted in a future report.

SACALINE (*Polygonum sachalinense*).—I noted in the last annual report that the growth of this new forage plant had been slow and after another season of trial the same remark still applies to it.

The plants are fairly healthy, but instead of producing shoots from 12 to 14 feet high as claimed for it by the seedman who advertised the seed, the greatest length of stalk so far produced has not exceeded 2 feet.

As the roots become older and stronger, the length of stalk may increase, but it gives little present promise of ever proving a good forage plant in this climate.

ARBORICULTURE.

Services were, as usual, rendered by the Superintendent of the garden to the Board by advising, inspection and aiding it in every possible manner to improve and advance the road arboriculture of the district.

In accordance with orders conveyed by the Director of Land Records and Agriculture, North-Western Provinces and Oudh, in his letter No. 258—V.-164, dated the 7th November 1895, an experiment was made with a paint recommended by the Reporter on Economic Products to the Government of India for preventing the attacks of white ants upon growing trees.

For the information of all who may feel interested in remedies for destroying white ants, I have thought it desirable to here give the recommendation for the trial of the paint in detail, followed by a report on the result of an experiment made with it on a few trees on one of the Saharanpur roads.

“EXTRACT FROM THE AGRICULTURAL LEDGER, SERIES 1895, NO. 9.

“Paint used against white ants.

“During a brief visit to the Native State of Gondal, the writer recently gave this subject considerable attention. There seemed to be no doubt that His Highness the Thakore Sahib, by his enlightened action in this matter, had effected a radical improvement. The trees throughout his State were all painted as described, and not a single tree could be found showing the mud encasements so characteristic of the presence of white ants. And very possibly, as a consequence of the care bestowed on these trees, they were healthy and vigorous, while those in neighbouring States were sickly and badly attacked with white ants. In consequence of these observations the writer asked for information as to the composition of the paint which had been used. He was informed that the red colour was merely to indicate

the fact that the trees had been painted, and that it was for the most part red ochre. The useful ingredients were said to be as follows:—

- 1 part dekamali gum (the resin of *Gardenia gummifera*).
- 2 parts asafetida,
- 2 parts bazar aloes.
- 2 parts castor-oil cake.

“These are well pounded, mixed and kept in water for about a fortnight. When thoroughly united, and what may be called decomposed into a thickened compound, water is added in order to bring it to the consistency of paint and the colouring matter then added. The mixture is now ready for use, and if thoroughly applied for about two feet will check not only the attacks of white ants, but of red ants and other insect pests. Its effect will last for two years or more. The cost of the preparation comes to about 4 to 5 rupees per 100 trees. But according to the information furnished from Gondal, it refuses to possess no special properties; from other parts of India the reputation is very general that it is of great value. The red ochre, added to the above preparation, may not only be useful as indicating the trees that have been painted, but give a useful consistency, if it does not serve to mechanically hold the other ingredients.”

The paint was prepared according to the directions given by the Economic Reporter to Government and applied to a number of mango, shisham and siris trees on the Sirsawa road that were badly attacked by white ants. Before applying the paint the coating of earthy matter deposited upon the trunks of the trees by the ants was removed, and in all instances where the earthy deposit was entirely removed the paint has, so far, had the effect of preventing further attacks by the ants upon the trees. In a few cases the men employed on the work of painting overlooked strips of earthy deposit lying in hollow channels on several of the trunks of trees operated upon. The strips of earthy deposit overlooked were painted over together with the cleaned portion of the trunk but the ants took no notice of the paint when applied to the outside of their earthy runs, and therefore made use of the strips that were left as passages to communicate with the upper portion of the trunk, where they continued their attacks as before the application of the paint. The experiment has therefore proved that the paint is an effective against the attacks of white ants if applied directly to the bark of attacked trees, but that it is of little use if applied without first entirely removing all earthy ant deposit from the trees.

The trees experimented upon were 29 full grown specimens averaging from 2½ to 3½ feet in diameter. Ingredients for paint to the value of Rs. 13-3-0 were purchased, but as the full quantity was not used, the actual cost of painting the 29 trees operated on was Rs. 7 or at the rate of 3 annas 10 pies per tree nearly. I therefore consider the paint too expensive for extended use on large sized trees, but its cost would not be prohibitive for use on young trees or saplings. In districts where it is found exceedingly difficult to establish the commonest and hardiest of roadside trees owing to the presence of white ants, the paint would, I feel sure, prove most useful.

EXORIC PLANTATION.

There is little to place on record under this head this season. Owing to the prolonged drought some of the species of trees under trial in common with many other timber trees throughout the garden have shown considerable difficulty in throwing out new foliage this year, but with this exception the trees are making as good progress as can be desired.

The Eucalyptus trees continue to yield a steady income by the sale of leaves for making up the decoction used for cleansing the boilers of locomotives.

The quantity of leaves thus disposed of during the year was 50 maunds, or exactly the same weight as sold last year. As the leaf is sold at the rate of R2 per maund, R100 was realized from this source.

MUSSOORIE GARDEN.

Great assistance was as usual rendered by this garden to the parent institution at Saharanpur by furnishing it with supplies of fruit trees, orchids,

bulbs and roots of various kinds, seeds of Himalayan trees and shrubs, &c., for exchange purposes with kindred institutions in all parts of the globe.

A considerable number of fruit trees comprising apples, apricots, pears and plums were permanently planted out last cold season.

The plots of ground where planting has been done were formerly used for growing such crops as Indian Corn and various kinds of Cucurbitaceous vegetables for seed for distributions through the larger institution at Saharanpur; but as the latter finds it can produce a sufficiency of such seeds to meet all possible demands, it was considered it would in the end prove more profitable to extend the area permanently under fruit, and almost entirely do away with the cultivation of seed crops.

Owing to the heavy rainfall in the year 1894 and early part of 1895 a considerable part of the wood-work of the green-houses gave way to the action of damp. The decayed parts were, however, lately replaced with new material, so the houses again stand in a fair state of repair.

APPLE (*Pyrus malus*).—The overseer of the garden reports that a few fruits were produced last year for the first time by a variety of apple introduced a few years ago from Japan. He describes the fruit as being of medium size, rich golden yellow in colour, flesh mealy, juicy, and of a very pleasant sub-acid flavour.

The variety is remarkable for its dwarf bushy habit. It has been under cultivation in the garden for about 5 years, but the largest plants are not above four feet high, and as they are bushy in proportion to their height they have more of the appearance of dwarf bushy shrubs than of apple trees. If the variety proves to be a prolific bearer, it should, owing to the small amount of space it occupies, prove useful for planting in gardens of limited area.

I am somewhat disappointed with the Bismack apple, a variety specially noticed in former reports owing to the many special merits claimed for it by the European Horticultural Press when it was introduced.

I have not had an opportunity of examining and sampling the fruit in a ripe state, but Mr. F. W. Scrrs, who officiated as garden Superintendent during the greater part of the time I was on furlough last year, describes it as follows:—

“The Bismack apple produces a large handsome, taking looking fruit with an attractive and somewhat peculiar scent all its own, but to a certain extent the apple is a fraud as it remains distinctly tart when quite ripe, and is only suited for cooking.”

One of the special merits claimed for the above apple by its raiser was its adaptability for culture and bearing in hot climates. With a view of testing this special claim a specimen was planted at Saharanpur. It has made far better growth than those at Mussoorie, but so far it has failed to ripen fruit.

CHESTNUT GIANT OF JAPAN (*Castanea vesca*).—This plant still continues to make very slow progress. The plants are in a healthy condition, but as they only make a few inches of growth in the course of a season the soil and climate does not seem favourable for promoting good average growth. I therefore fear that this variety of sweet chestnut must be looked upon as a failure at Mussoorie.

DEWBERRY (*Rubus trivialis*).—A few plants of this small fruit were sent from Saharanpur two years ago to the Mussoorie garden for trial. They have made rapid growth for the time they have been planted and are reported by the Overseer to be bearing an abundant crop of fruit this season. This bush can therefore be recommended with confidence for culture both on the hills and plains.

PEAR (*Pyrus communis*).—The Japanese varieties of pears mentioned in former reports still continue to make good progress but as they have not yet attempted to fruit, nothing worthy of note can at present be said about them.

Plants of the two varieties of pears from Florida which have proved such a success at Saharanpur have been planted alongside of the Japanese kind and the progress of which, will be duly noted in future reports.

TREE TOMATO (*Cyphomandra betacea*).—This continues to thrive and bear abundant crops of fruit every year, but as plants and seeds have not been in much request lately, I fear this fruit is not so well-known as it deserves to be.

The plant is utterly useless for culture on the plains, but it thrives admirably in the hills, especially when grown in low well sheltered valleys. It is a rapid grower, of easy culture, and as the fruit travels in good condition to great distance with a minimum of care in packing, it deserves more attention than it has hitherto received. It is in season from September to end of November and even later when frosts hold off, and as fruit is as a ruler scarce everywhere during that period, it would, I am sure, be in good demand if settlers in the hills would take its culture up, and bring it prominently to the notice of dwellers in the plains.

The garden can only cultivate it on a limited scale owing to want of room, but as a good supply of plants and seeds is always on hand, it is in a position to give growers a fair start when they apply to it for aid.

WALNUT (*Juglans regia*).—A variety of walnut raised from seed procured from France some years ago fruited last season for the first time.

The Overseer of the garden reports the nuts to be somewhat hard-shelled, but very much larger than the best of the nuts produced by the old established local varieties.

As the tree is carrying several dozens of nuts this season, I shall soon be in a position to raise a stock of plants of this improved form of the walnut for general distribution.

The single specimen of *Kaghzie* or thin-shelled variety of walnut, noted in former reports as having been raised from seed sent by a Forest Officer from Upper Burma, is making excellent progress, but it will still be some years hence before it may be expected to bear.

JALAP (*Ipomoea purga*).—There is nothing of any importance to record regarding the condition of this medicinal root.

It is still subject to the fungoid disease that appeared upon it some years ago, and owing to its attacks the rate of increase still continues slow.

A supply of tubers will always be available for trial in other hill districts, but I fear the latter can never be produced in quantity within the garden itself.

Saharanpur, the 25th May 1896. W. GOLLAN,
Superintendent, Government Botanical Gardens,
N. W. Provinces.

TEA-PLANTING IN CEYLON.

That delicious cup of tea my friend the tea-planter gave me lent me a mental fillip that was evidently not meant to be wasted on small talk, so I hinted I should like to see his Ceylon photographs. While discussing them, with the pin of judicious curiosity I lured from him the winkle of information which was my aim—namely, an account of life as it is lived by Europeans in this interesting island of the south. So warm was my friend's enthusiasm, that his account of things naturally fell into a dithyrambic rhythm. This I have reduced to its lowest terms for readers of the *P. M. G.*

In Ceylon the development from night to day is very rapid; at second cock-crow, in the twinkling of an eye, or in the life of a cigarette, one may appreciate the change, and the *appuyah* (head servant) is at the manager's door, summoning him to the arena of work, the factory. Around this is the muster-ground for a strong force of Tamils and Cinghalese artisans, among whom his colleague, the assistant manager, is busy distributing the labour of the day. These two are perhaps the only Europeans on the estate, the next in the hierarchy being a native tea-maker, who controls the factory. Below him comes the kangany, who is a kind of headman on the estate owning coolies. At the advent of the manager the sleepy activity of the factory is accelerated into a semblance of bustle. The engine is a spluttering,

withered tea-leaf of yesterday's gathering comes shooting from the first and second floors into boxes, and, when the weights have been duly pencilled on a slate, it is trundled away to the rollers. The engine is moving a "Rapid Roller" holding 270 lb. of leaf, while the 16 foot water-wheel is driving two smaller rollers, which manage 90 lb. between them.

In the tea-room, meanwhile, you may see coolies busy at emptying bins and bulking the tea, *i.e.*, heaping it into a mass and continually throwing the bottom to the top, so that the sample may be as uniform as a slice of well-stirred Christmas pudding. After bulking, the tea is put through a process of extra firing in a desiccator, so that the villain moisture may not lay his spoiling hand on the produce, and is finally stowed in lead-lined chests. By 6.30 the assistant manager has set all the wheels in motion, and after his superior has smiled approval, returned to his light morning meal, the *piec de resistance* of which is a cup of tea. The manager harks back to the bungalow, and gets through some general business and consultations. At 7.30 the ponies are brought round, and a tour of inspection of works in hand is begun. Here are men pruning, or draining, or road-making, and there the leaf is being plucked by some eighty women under the superintendence of kanganyics, who will have somewhat to say to them if the greatest care is not exercised in the operation. And so by 10.30 our manager has earned his breakfast. While he is making the hearty meal which belongs to honest morning endeavour let us watch more closely the women and boys at work. As they move quickly from plant to plant—the average stature of each being half their own height—they take only the two top leaves and the bud, leaving on the tree one leaf from which the new flush is to be thrown. At a good flush each woman will bring in some 30 lb. of leaf in a day of ten hours. In Ceylon gathering goes on all the year round, and every bush is thus handled every ten days. The leaf that has been gathered is laid to wither on horizontal blinds of jute hessian, and on the following morning it has an apple scent and is ready for the next process of rolling, which is to give it the necessary twist. It is rolled for three-quarters of an hour, and then fermented for half an hour, before undergoing another turn of rolling. But the times for withering, rolling, and fermenting vary according to the weather and the quality of the tea. Strong teas must be withered long and rolled hard.

After breakfast arrives the postman with the managerial letters, to which replies are sent at leisure and entrusted to the tapal-runner, or fast-running coolie, carrying a padlocked tin box on his back. A midday siesta follows, and about half-past two the principal works are again visited. Then at four o'clock a horn, called the *kavalkarren*, is blown by the watchman as the signal for a general concentration on the factory of all hands on the estate. This business is one of the pretty sights of the day. My friend's estate at Matale, north of Kandy, the mountain capital, is situated in an amphitheatre of the big volcanic hills typical of the country. Down the slopes come winding the coolies and the women, picturesque with their baskets and scarlet cloths thrown loosely over one shoulder, engirthing the waist, and bunched up behind in the universal mode of the dress-improver. Now follows the last weighing of leaf; the workers stand in blocks, pruners here, roaders there, manurers yonder, while names are entered for the day's work in the register. The manager next goes his final round of the factory, returns to the bungalow, and then pays visits to his friends in the neighbourhood. Bridle-paths are fairly numerous on the estate, and cart roads connect one property with another. In his leisure time for sport he may get some snipe-shooting in December and January over the paddy fields or flat at the foot of the hills, in which is grown inferior rice called paddy. The coolies, too, are now free to go off to the coolie lines, where they live in their exiguous mansions, which they use merely as sleeping-places and as repositories for their scanty belongings. An

ordinary London room would house two dozen of them. Drinking and gambling are strictly forbidden, but both, and especially the latter, are too much for the coolie's powers of resistance, and when he retires to the lines he has long evenings of these illicit enjoyments.

The best of the coolies are promoted for the plantations to the factory. The whole estate of some eight hundred acres is weeded by hand, and this tiresome work is done by the old women and children, the kangany having contracted to put the ground into a proper condition in this respect. The heavy draught work, of course, is done by oxen, which are branded on flank and back with most fantastic designs, a potent charm, according to the superstition of the natives, against rheumatism and other diseases of cattle. Rheumatism is prevalent because the tea plant has a strong predilection for a lightish clay soil, and rejoices if it finds a little disintegrated mica mixed therewith. Wages are paid monthly, but payment—in rupees—is always a month in arrear. This enables the manager to keep a firm hold over his men. Their feelings, however, are good towards their masters, who play the role of doctors and general mentors in all ordinary matters. An ordinary coolie makes his 33 cents a day, his kangany taking another 5 cents per diem for each coolie as head-pay. A woman is paid 25 and a boy 18 or 12 cents. The European has to deal with the Cinghalese, who are the natives; the Veddahs, who are the aborigines and of a dwarfish stature; and the Tamils, who are the immigrant Indians.

The importance of the Ceylon tea industry need be illustrated by one fact only. In the four years 1889-1893 the percentage of the sale of Ceylon tea as compared with that of India and China doubled itself, rising from 15 to 31 per cent. In the island an import duty is imposed on tea, so as to present possible malpractices connected with the export of foreign teas. The Ceylon Tea Fund is an advertising instrument for making Ceylon tea known all over the world, and is supported by subscriptions of 10 cents per 1,000 lb. of green tea-leaf plucked during each period of six months.—*Pull Mall Gazette*, Sept. 12.

MORE LIGHT ON QUININE.

More light has been shed on the quinine situation during the past week, and it now appears that natural distrust was the real cause of the sudden reductions in the price, the first of which occurred Aug. 17 and the second Aug. 21. With this distrust there was presented the difference between the cost of quinine and the selling price of the manufacturers, which was so wide as to afford possible temptation to some of the makers to quietly dispose of portions of their product at a price below that to which all had bound themselves to adhere. That some of the members of the combination have yielded to this temptation and made sales below the established quotation, and otherwise violated the understanding which has controlled the makers for the past two years, is more than suspected by others in the compact, as well as by the trade at large. Fresh goods have been imported from London within the past six months, and goods have been purchased, in this market within a shorter period from at least one of the manufacturers' agents for speculative account, a portion of which was afterward shipped to London. Furthermore, it is known beyond question that some of the members of the combination have been demanding as their allotment of sales a greater proportion of the whole than their generally understood relation to the consuming trade entitled them to, at least in the opinions of their competitors. It is a well known fact that one or more of the manufacturers overstepped the limits of the agreement, in a desire to sell goods, just before the advance of Dec. 18, 1895. Instead of confining sales to quantities sufficient for sixty days' requirements of their customers, beyond which they are bound not to contract to deliver, some of them persuaded the trade to contract for stocks far in excess of these limits. Whether the intent of this

policy was to make a showing of sales which should secure a more liberal percentage in the next allotment, is, of course, not known to the outsiders. But the excessive contracts naturally resulted in heavy importations, and in course of time, when the large consumers realized that they had obligated themselves to take more than they could possibly consume within a reasonable length of time, they offered their surplus on the market at or about twenty-five cents per ounce, just what they had paid for it. This had a tendency to keep the market fairly well supplied, and to give the impression that the "outside" stock, which was supposed to be nearly exhausted, was like the widow's cruse. In spite of the condition of affairs which we have just pictured the demand for quinine had begun to increase when the first reduction in the price was ordered. It was, however, mostly from the jobbing trade throughout the country, rather than from the manufacturers of pills, many of whom were heavily stocked.

What the future has in store for the consumers of quinine no one knows to a certainty. The manufacturers may deem another reduction necessary to accomplish their purpose, which is to remove any possible temptation to some of their number to dispose of goods in violation of the compact. While the stability of the combination may have been threatened by the discoveries which have been made, there does not appear to be any likelihood of its dissolution, as the manufacturers know from bitter experience that their best interests are served by united action both in the purchasing of bark and in marketing the finished product. At the same time prudence dictates a more perfect relation of selling price to cost.

The bark is richer in alkaloid than it used to be, hence the cost of producing is lower than formerly. The bark shipments continue heavy, and at the August sale in Amsterdam, held on Thursday, 85 per cent. of the offerings, which were large, were purchased, but at a decline of 10 per cent. on the price paid at the July sale, which is conclusive evidence that the manufacturers still control the bark situation. A fact worthy of attention is that the price paid at Thursday's sale, two and fifty-five hundredths Dutch cents per unit of quinine was the lowest price ever known. In August, 1895, the sale realized two and six-tenths of a Dutch cent per unit, the lowest price up to that time, while in August, 1894, four and a half Dutch cents per unit was paid.

All that is now wanted on the part of the manufacturers to enable them to reach the goal they set out for two years ago is a little forbearance, coupled with some firmness, as the legitimate stock in second hands is not large.—*Oil Paint and Drug Reporter*.

THE UPPER MASKELIYA ESTATES COMPANY LIMITED.

Minutes of proceedings at the extraordinary general meeting of shareholders held at No. 7, Queen Street, Fort Colombo, on Saturday, 10th Oct. 1896:—

Present:—Mr. W. D. Gibbon, in the chair, and Mr. C. A. Leechman, Directors, and Messrs. G. H. Alston and James Forbes, Mr. C. J. Donald acting as Secretary. The following shareholders were represented by the holders of their Powers of Attorney:—Mr. A. E. Wright, Mrs. A. N. Wright, and Mr. Jas Gibb, by Mr. W. D. Gibbon and Mr. G. W. Carlyon and Mr. T. K. Wright, by Mr. G. H. Alston. Messrs. A. Thomson and W. H. G. Duncan were represented by proxy.

Mr. GIBBON having taken the chair, the notice convening the meeting was read.

The CHAIRMAN stated that the present meeting had been called to confirm the Special Resolution passed at the extraordinary general meeting on 5th September last. The special resolution was then proposed by the CHAIRMAN, seconded by Mr. JAMES FORBES:—“That the share capital of the Company be and the same is hereby increased from R270,000 to R350,000 by the creation of 160 shares of R500 each,”—which was carried.

A vote of thanks to the chair closed the proceedings

Correspondence.

To the Editor.

CEYLON TEA IN RUSSIA.

Nijni Novgorod, Moseow, Aug. 29.

DEAR SIR,—I went to see the big Fair yesterday—a truly wonderful sight, and the place crowded with people from all parts of the world. Mr. Rogivue is advertising Ceylon tea most successfully, and had had many orders from people—some for Siberia. He has well-advertised the teas of Ceylon, and the tea is selling well in Moseow. His tea place at the Fair is very attractive, and a splendid man in charge. We enjoyed Ceylon tea there made in Russian fashion very much and drank success to Ceylon.—Yours in haste,
W. JORDAN.

THE BANDARAPOLA CEYLON COMPANY LIMITED.

16, Philpot Lane, London, E.C. 1st Sept. 1896.

SIR,—We beg to inform you that the Board of Directors of this Company have declared an Interim Dividend at the rate of 10 per cent per annum (free of Income Tax) for the half-year ending 30th June last.—Your obedient servants,

LYALL, ANDERSON & CO.,
Agents and Secretaries for Bandarapola Ceylon Company, Ltd.,

RHEA.

2, Victoria Mansions, Westminster, S.W.,
Sept. 11th 1896.

DEAR SIR,—I see that a great deal is being made of a report by a Mr. B. Ribbentrop Inspector-General of Forests for India, who states that “the difficulty of treating this fibre has at last been overcome by a Mr. Gomess.”

Mr. Ribbentrop may be a very good Inspector of Forests, but as an authority on the treatment of Rhea Fibre, I do not think his opinion is worth much. He seems to be under the delusion that Mr. Gomess is the only person who can degum Rhea; as a matter of fact the Midlands Spinning Company have been employed degumming Rhea for the last two years at their factory at Long-Eaton in Derbyshire and spinning the product into yarns; which find a ready market; the process they are using is that of Mr. H. H. Boyle, whose Patents are our property.

It is one thing to treat Ramie as a Laboratory experiment, but quite another to do so on a commercial scale.

But before you can degum Ramie you have to decorticate the stems so as to remove the fibre—what then is the use of a degumming process unless you can decorticate? Mr. Ribbentrop appears to be ignorant of the fact that Mr. Gomess has no decorticator, how then he successfully treat the plant?

The £5,000 offered as a premium some time ago by the Government of India was for a decorticator and not for a degumming process; this premium was withdrawn because no machine entered for competition was equal to the Government's requirements.

Several decorticators have since been invented but so far as I know none have been successful; to be successful the machine must not only remove the wood but also the bark by the operation, this my machine does, and with labour at 6d per day I can produce a ton fibre equal to China grass at a cost of about 30s per ton, this machine has been seen at work by Mr. J. O. B. Saunders of the *Calcutta Englishman*, and he was so impressed by its value that he com-

municated with the Indian Government with a view to having the offer of the £5,000 premium revived, but in the present state of finances they do not see their way to do so.

I wish Mr. Gomess and every other inventor of a process to degum the fibre every success; there is ample field for all but I do most certainly object to it being given to the world that Mr. Gomess is the first to solve this difficult problem.

I enclose you a report by textile experts as to my decorticator and Mr. Boyle's degumming process, these gentlemen are not inspectors of forests but they at least carry as much authority as experts on Rhea as Mr. Ribbentrop. These reports you are at liberty to print if you wish to do so.

It is self evident that a decorticator joined to an efficient degumming process renders the process complete, but one without the other is useless, if Ramie fibre is to be produced on a commercial scale and at such a price as to enable it to compete with existing fibres.—I am, dear sir, your obedient servant,

J. M. MACDONALD, Managing Director.

CEYLON TEA IN AMERICA.

SIR,—Will you allow me once more to ask for your good offices in the interests of the tea trade with America.

Mr. Mackenzie writes the results of his interviews with the principal tea houses during his late trip to the States.

He says that the dealers “deprecate our packing more than four kinds of tea for America, and they mentioned the following prices:—15 cents (7½d), 20 cents (10d), 30 cents (1s 3d), 40 cents (1s 8d). They would not taste or handle teas running up by single cents per lb.; but thought these prices most suitable for long lines of tea. Life is too short, is the general comment on the English market, with a thousand samples to be tasted weekly.”

One firm had “taken up those teas with misgivings and hesitation, but had now great faith.”

From London I also hear complaints of the “small breaks, and innumerable samples for London trade as well as for America. It is thought that Ceylon will have to suit its teas to what is the universal demand, or lose ground.”

The same firm adds “the number of small lots now offering is very confusing to buyers, and tends to lower the average, and it is difficult to get a continuous supply of teas of average quality. With these expressions of opinion from our best friends, it is surely impolitic on our part not to try and meet the views of the market.—I am, &c.,

Sept. 16th. A. W. S. SACKVILLE.

INSECT ENEMIES OF TEA.

Dartry, Ganipola, Sept. 17.

DEAR SIR,—I send you in a match-box some pooehies I found this morning on a patch of tea, the leaves of which had been completely eaten up by this insect.

If you can tell me the name of the insect and if it is likely to become a scourge, it would be interesting.—Yours faithfully,

J. A. ROBERTS.

[Mr. Staniforth Green, to whom we referred the insects and leaves, writes:—

“The tea leaves sent to me by Mr. Roberts of Dartry estate have been attacked by the same case-bearing caterpillar as the one described in last night's ‘Times of Ceylon,’ under the head of ‘Tea Bushes and Caterpillars.’ With his tea leaves Mr. Roberts has sent some small dipterous flies, bearing some

resemblance to the common house-fly, but much smaller, being about a quarter of an inch in length. These flies come from the eggs deposited by the parent fly under the skin of the caterpillar, and they have undergone all their changes, from the egg to the perfect state, within the caterpillar's case, to the complete destruction of their host. It would be interesting to know how the parent fly, with its soft ovipositor, is able to lodge an egg with success under the skin of the caterpillar. Perhaps it is effected while the caterpillar has its head and shoulders out of its tough case when on the move, or in feeding. There is also an ichneumon-fly that destroys the caterpillar, but being armed with a strong sting-like ovipositor, it would probably, in urging its egg, be able to pierce the tough case. No living caterpillar was discoverable among those sent by Mr. Roberts. All had miserably perished, so that it is to be hoped they will be kept well under through the attacks of their insect enemies, and that the tea tree will never be seriously damaged by them. The fly lays a single egg under or upon the skin of its victim.—Colombo, 2nd Oct.—ED. T.A.]

SCOTTISH CEYLON TEA COMPANY LIMITED.

16, Philpot Lane, London, Sept 19.

SIR,—We beg to inform you that the Board of Directors of this Company have declared an *Interim* Dividend at the rate of 10 per cent. per annum (free of Income Tax) for the half year ending 30th June last, on the body shares.

Your obedient servants,
LYALL, ANDERSON & CO.
Agents & Secretaries.

EDERAPOLLA TEA COMPANY OF CEYLON, LIMITED.

16, Philpot Lane, London, Sept. 22.

SIR,—We beg to inform you that the Board of Directors of this Company have declared an *interim* dividend at the rate of 10 per cent per annum (free of Income Tax) for the half-year ending 30th June last.—Your Obedient Servants,
LYALL ANDERSON & CO.

Agents & Secretaries.

SILK CULTIVATION IN CEYLON.

We-uda, Oct. 10th.

DEAR SIR,—Those of your readers who are interested in Sericulture will be glad to learn that the opinion expressed in my letter of 25th July, with regard to the Bengal silkworms, has proved correct: worms recently reared in Dimbula have produced finer cocoons than in the low-country and without any falling-off as regards their brilliance, the special characteristic of Bengal silk. It remains to be seen what diminution in the number of broods in a year is caused by the colder climate, but even if the reduction is considerable, it will, I think, be fully compensated for by the increased weight of the cocoons.

I hope soon to be able to distribute eggs or young worms of the finest varieties of the annual silkworm from Japan. My stock of mulberry trees is limited, and is required for several species, and it is desirable to ascertain by actual experiment at what elevation the annual worms will give the best result. With this object in view I shall be glad to hear from anyone, in any district over 500 feet elevation, who is willing to make a trial with this species.—Yours faithfully,
PERCY N. BRAINE.

THE NICARAGUAN RUBBER DECREE.

A decree of the government of Nicaragua, restricting the exportation of India-rubber to the produce of cultivated trees, has been translated for the United States department of state by Vice-Consul Henry E. Low, at Managua, as follows:—

To prevent the extinction of the India-rubber trees in the national forests, and to develop their cultivation in plantations, arranged with the bounty laws, the president of the republic decrees:

1. From January 1, 1897, it will be prohibited in all parts of the republic to export India-rubber which has not been cultivated in plantations, arranged in accordance to the laws of March 6, 1883, and March 23, 1887.

2. The foregoing prohibition will last for ten years from the date indicated, and whosoever shall act contrary shall be fined in accordance with the regulations concerning fraud upon the treasury, shall lose for the benefit of the treasury the India-rubber, and besides be fined to the amount of *four times its value*.

3. India-rubber can be exported only coming from regular plantations, formed, as before said, in conformity to the bounty laws of 1883 and 1887, but to verify it the exporters must register their rubber forms, first, in the office of the tax-collector of the district, expressing the number and age of trees. This registration will be gratuitous and must be made every year in the first days of January, to produce the desired effect. The exporters must receive from the tax-collector way bill (a certificate on, and to go with the produce forwarded) made out to order; in order that this document may be endorsed, they must present their registration certificate, and forward a copy of both documents to the minister of finance.

4. Anybody found extracting India-rubber from the national forests will be considered as a smuggler (contrabandist) and will be sentenced and fined as such by authority of the judicial or police department

5. To be presented in the next sitting of the legislature, to be published.

Interviews with Mr. William A. De Long, who was for some years engaged in the India-rubber trade in Nicaragua, and with other rubber-men in New York, have elicited only expressions of the opinion that the enforcement of the above decree will be practically impossible. In some quarters it has been intimated that the government of Nicaragua can ill afford to lose the revenue derived hitherto from the export duty on India-rubber, amounting to 4 cents a pound, or about \$40,000 a year.—*Indiarubber and Guttapercha Journal*, Sept. 10.

THE AMSTERDAM DRUG-MARKET.

Our Amsterdam correspondent reports that the public auctions to be held on October 1st., will include 5,128 bales and 237 cases, weighing together 498,539 kilos, of Java cinchona bark. The total quantity of sulphate of quinine represented is 28,616 kilos., giving an average of 5.83 per cent for the Manufacturing bark. The supply includes 14,288 kilos of Druggists' bark, with 402 kilos of sulphate of quinine.—*Chemist and Druggist*, Sept. 26.

STRANGE STATEMENTS RESPECTING QUININE.

It must be confessed that the current explanations of the motives of the quinine manufacturers' combination in reducing their official price, by two strokes delivered in quick succession, to 11½d per oz. are by no means satisfactory. We referred, in our issue of last week, to the talk of change and the Commercial Sale Rooms; but it is difficult to see how anyone could be so foolhardy as to select the present moment for opening a new quinine works on the Continent, while the notion that the manufacturers' action was inspired by fear of coming competition from the new quinine factory in Java may also be dismissed as improbable. The Java quinine-works will be, at best, a very small factor in the quinine-market for some years to come, and to reduce the price in Europe by nearly 20 per cent before a single ounce of Java-made quinine has yet made its appearance in the open market would be as preposterous as, say, the raising of fortifications round London because of a diplomatic rupture with Venezuela. Another reason, not mentioned by us last week, which has been put forward to account for the action of the combined makers is the competition of the Imperial Quinine-works in London, which are not in the "ring." With all respect to that excellent and now well-established factory, however, we cannot affect to regard it, at present, as a sufficiently serious competitor to the older makers to call for such drastic action on their part as a twopenny-halfpenny reduction on a fourteenpenny article. Moreover, though the Imperial Quinine-works are said, by their selling-agents to have sufficient quinine orders on hand to keep them going for several months, they have never adopted an aggressive "cutting" policy towards the older makers. In fact, they have not even replied to the two reductions announced by the manufacturers' "ring" by lowering their own price.

So much for the current talk concerning the reasons that have inspired the action of the quinine-makers. Now let us inquire whether there are no other motives that may have inspired so serious a step as that of deliberate depreciation of their own stock of quinine by nearly 20 per cent., at a time when nothing but the manufacturers' own initiative could have caused such a depreciation.

It would naturally be expected that the London Agents of the German quinine makers would be the persons most likely to be able to afford information on the policy of their principals. Nothing of the kind. One and all these gentlemen profess to know rather less about that policy than the merest outsider. Their instructions come to them cut and dried, "made, in Germany" without a word of explanation. Thus, child-like and bland, they face their customers, "Story? bless you, Sir, I have none to tell," is the burden of their song. Yet it is an open secret that the policy which led to the establishment of the "concert of quinine-makers" had its mainspring in Germany, and that the directing wires are still pulled from that country. That those who dictate the policy of the "ring" know what they are about is shown by the results of the combination. During its existence the stock of quinine in the London warehouses, in other words, the only large aggregation of second-hand supplies in the world, has been reduced from 3,027,718 oz. (on August 31, 1894) to its present small compass of 1,675,600 oz. The stock

of cinchona bark in London has been similarly reduced, all sources of supply, except Java, have practically run dry, and the quinine-makers can buy their raw material at auction in Amsterdam and London at a figure out of all proportion low compared with the recent selling price of quinine.

Only one thing has been wanting to render the market-supremacy of the "ring" complete, viz.—regulation of the supply of bark. That has failed them hitherto. There are reasons for believing that, although at first sight an abundant supply of cheap raw material must be to the manufacturers' advantage, they would have been quite as well pleased if Java had lived up to the expectations generally entertained of her, by gradually diminishing her output. The makers have been confronted month after month with unmanageably large supplies offered, practically without reserve, at the Amsterdam auctions. There are only some half-dozen customers for these supplies, and they have been gorged to their throats. Said one of the largest German quinine-makers last summer to the present writer, whom he showed over his factory, which was then shut down in order not to heap up unnecessary quinine supplies: "We have told the Java gentlemen that we cannot swallow their stuff at the present rate, and still they keep sending more. We have now threatened them that if they do not bring their output in harmony with the requirements, we shall let the unit at the Amsterdam auctions drop to a figure that will bring them to their senses." But the Java planters are a promiseous mob. They have shown themselves incapable of intelligent co-operation, and they now suffer for their short-comings. Which brings us to our next point—viz., the question why other, and more business-like persons, should not accomplish what the planters have failed to do? The cinchona exports from Java still keep increasing month by month. For the year ending the 30th June, 1896, the total was 9,108,385 half-kilos, as compared with 8,705,057 and 7,428,336 in the two preceding seasons. Moreover, we hear today, from our Amsterdam correspondent, that the August shipments, of which the results was made known in Amsterdam on Wednesday, show a still greater relative increase, the figures being as follows:—

Aug. Half-	1896	1895	1894	1893
kilos ...	979,300	697,000	853,000	636,000

January 1 to

Aug. 30th	6,029,000	5,013,000	5,554,000	5,376,000
-----------	-----------	-----------	-----------	-----------

All expectations of an improvement in the price of bark based upon the diminished exports are therefore at an end for the present. It is said that the heavy shipments of the last few months are due to the unusual character of the monsoon, and that there will be such a falling off during the remainder of the year that 1895 will ultimately take rank as the highest season on record. This, however, is a statement that has been made many times before, and it is difficult to credit it now.

On the other hand, we hear from a well-informed source that the recent reduction in the quinine-price was a deliberate move in the policy of the combined quinine-makers. It is known that sometime ago an expert, on behalf of the Syndicate of quinine-makers and a few others closely connected with the trade, visited all the Java plantations, and prepared an exhaustive report of their capacity. It is supposed that a scheme was subsequently drawn up, and discussed between the quinine Syndicate and the proprietors of the principal plantations in Java, under which the Syndicate undertook

to buy out the plantation owners—lock, stock, and barrel. The negotiations, it is added, reached a point at which it seemed almost certain that at least three-quarters of the Java plantations, including all those of real importance, were about to pass under the control of the Syndicate. At that time, it may be noted, the current price of Java-bark in Amsterdam was about 2·80c per unit per half kilo. At the last moment, however, negotiations fell through. Now it is hinted that the sudden reduction in the price of quinine which followed the breaking-off of the negotiations is due to a definite policy on the part of the quinine Syndicate to depreciate the bark-market to such an extent that the plantation-owners will be forced to come to terms. The first result of the move was seen at last Thursday's Amsterdam auctions, when the unit fell to 2·55c., the lowest point touched since February, 1895, when the lowest unit on record, viz., 2·50c. was reached. If the quinine manufacturers' policy should be successful, we shall probably see a further fall in the unit at the September auctions in Amsterdam, and it may be well that shortly afterwards the formation of a Syndicate to take over the bulk of the Java plantations will be announced. Such a step would give to the quinine-makers almost a few years' monopoly of the market, inasmuch as Ceylon has but little bark left, while the Indian supply is small and partly of poor quality, and neither cultivated nor wild-growing (*Cuprea*) barks from South America can be thrown upon the European market in quantities large enough to affect the quinine-supply at anything like the present unit.

We repeat that this statement comes to us from a well-informed source, but we cannot, of course, guarantee even the partial truth of the assertions. Yet there is nothing inherently improbable about them. Several unsuccessful attempts have previously been made to bring the cinchona supply under control, but none of these were set on foot by an organisation so powerful as the present quinine combination; and it is well known that some of the members of the combination, especially in Germany, have long been anxious to place their business upon a sounder footing. So much is certain, that if the quinine-makers should obtain control of the bulk of the plantations, they will be able to raise their prices to an extent that will richly compensate them for the recent decline.—*Chemist and Druggist.*

PLANTING AND PRODUCE.

INDIA AND ITS PRODUCE.—The recently issued volume by the Government of India of British India for the years 1894-95 consists mainly of elaborate tables, with an explanatory memorandum prefixed. The tables show the tea, coffee, and cinchona cultivation in each district of each province and in the native states in 1893 and 1894, and the progress in each product from 1895 to 1894. In 1893 the total area under tea in India was 395,830½ acres; and in 1894 it had increased to 422,551 acres. The highest average yield per acre from mature plants was obtained in Jalpaiguri, viz., 555·9lb in 1893, and 541·3lb in 1894. The total acreage under coffee in India in 1893 was 258,984·14 acres, and in 1894 it was 277,881·94 acres. In 1893-94 there were 11,235 acres under cinchona in India; but in 1894-95 the acreage had decreased to 8,710. A copy of the annual report of the Secretary to the Chief Commissioner in Assam on the subject of tea culture in that state for 1895 has recently been

received at the Board of Trade from the India Office. As in previous years, in the statement appended to this report, figures are given for each subdivision separately, in addition to the totals for each district. Silchar continues to head the list in regard to the number of tea gardens and the area under tea cultivation and the Dibrugarh subdivision still shows the largest outturn. The total number of gardens at the close of 1895 was 812, against 823 in 1894, showing a decrease of 11 gardens. During the year 15 gardens were newly opened, against 48 in the previous year, 17 were closed against 7 in 1894, and 9 gardens were amalgamated with other gardens against 10 in 1894. Some improvement has taken place in the number of gardens furnishing statistics. Out of 812 gardens, statistics have been furnished in respect of 717 gardens, against 698 in the preceding year: estimates had to be framed for 95 gardens, against 125 in 1894. The Chief Commissioner's thanks are due to those managers and agents, who have furnished the required information. The total increase of 7,218 acres under tea cultivation, as compared with 12,171 acres in 1894 is distributed among all districts except Cachar and Darrang. In Cachar it is stated that new extensions have not kept pace with the areas of old tea abandoned, and in Darrang the decrease is said to be more apparent than real, being due to greater accuracy in the figures for certain gardens for which estimates had to be framed in previous years. The total outturn of tea during the year was 99,524,584lb, as against 94,829,059lb, in 1894, or an increase of 4,695,515lb.

HOW THE CHINA TEA TRADE IS HANDICAPPED.—It is not only that China tea shippers have to meet the successful competition of India and Ceylon teas, but the Chinese Government have helped to destroy the trade, the decay of which they now lament. If the Chinese authorities would abolish duty and admit machinery, the tea trade of China would be permitted a chance of recovering some of its lost ground, but that is not a matter that the planters of India and Ceylon wish to see altered. The perversity of the Chinese officials has no doubt helped to benefit British-grown tea. On the subject of likin the British consul at Fuchan recently wrote: "Even in China the imposition of likin occasionally leads to riots. The likin duty on tea is nominally 2·20 taels per picul but additions bring it up to nearly 2·80 taels. The tax, for reasons known to the officials, is divided into five items called original dues, likin dues, expense of collection, military contribution, and 'loss on touch of silver,' all of which vary in amount. To these have to be added a ferry toll or duty on all teas from the north, and a tax of 3c 'for benevolent purposes' on teas coming from the districts to the west, and one or two extra tolls, so that the total amount does not fall short of 2·80 taels. If the value of tea is taken at 15 taels per picul, with the export duty it has to bear taxation to the amount of 5·30 taels, or about 35 per cent. *ad valorem*, before it leaves China. It may be asked why transit passes are not taken out, which would enable the merchant to bring the tea to the port on a payment of 1·25 taels per picul. The native dealers and growers are afraid of official opposition, and European exporters find it impossible to make the necessary arrangements. (1) The Lo Ti Shui or Octroi office.—This has seven branches which collect annually 30,000 or 40,000 taels on goods taken into Fuchan by road. Like the likin it is under the control of the provincial treasurer."

PLANTING ENTERPRISE IN EAST AFRICA.—There is every reason to believe that the Shiré Highlands will become the seat of an important planting industry. Shiré Highland coffee commands a high price on the London market. At Zanzibar, Sir John Kirk's experimental garden is an object of interest, although the trials of tea do not appear to be satisfactory. An account of the present condition of the garden is contained in the following notes of a recent visit, taken from the *Zanzibar Gazette* of August 28, 1894: "Mr. Crabbe, the Ceylon planter who was passing through here last week on his way to Nyassaland,

paid a special visit to Mbweni for the purpose of noting the condition of the coffee plantations started by Sir John Kirk at the close of his time here. Mr. Crabbe was well pleased with the condition of many of the trees, and as the crop was ripe and falling, he opened some berries and considered some of the beans quite fine. He made several recommendations which were duly transmitted to the Rev. J. Key, who takes great interest in the plantation, but who was unfortunately away from home at the time. The tea, which is now in full blossom and affords a pretty sight, well worth a drive to visit, Mr. Crabbe considered a poor kind and for the leaf hardly worth growing, and he did not recommend its extension. The cacao, he considered planted in too windy a site, but walking about the shamba pointed out many spots on which he thought it could be planted to better advantage."

A NEW USE FOR THE WILD TAMARIND PLANT.—In the botanical section of the British Association, Mr. D. Morris, assistant director of the Royal Gardens, Kew, contributed a paper, which in his absence was read by Mr. Seward, on "The Singular Effect Produced on Certain Animals in the West Indies by Feeding on the Young Shoots, Leaves, Pods, and Seeds of the Wild Tamarind or Jumbai Plant (*Leucæna glauca*, Benth.)" The properties of this plant had received little or no attention in this country. It is commonly found along roadsides and in waste places in tropical America. The plant was much more plentiful in the Bahamas than in Jamaica; it was, in fact, distinctly encouraged in the former islands as a fodder plant. The people were fully aware of the singular effect it produced on horses, causing them to lose the hair from their manes and tails. It also affected mules and donkeys. Its effect on pigs was still more marked. These animals assumed a completely naked condition, and appeared without a single hair on their body. Horses badly affected by jumbai were occasionally seen in the streets of Nassau, where they were known as "cigar-tails." Such dilapidated animals, although apparently healthy, were considerably depreciated in value. They were said to recover when fed exclusively on corn and grass. The new hair was, however, of a different colour and texture, "so the animals were never quite the same." One animal was cited as having lost its hoofs as well, and in consequence it had to be kept in slings until they grew again and hardened. The effects of the jumbai on horses, mules, donkeys, and pigs were regarded as accidental—due to neglect or ignorance. The plant was really encouraged to supply food for cattle, sheep, and goats. The latter greedily devoured it, and were not perceptibly affected by it. It would be noticed that the animals affected were non-ruminants, while those not affected were ruminants. The probable explanation was that the ruminants, by thoroughly mixing the food saliva and slowly digesting it, were enabled to neutralise the action of the poison and escape injury. The seeds probably contained the deleterious principle in a greater degree than any other part of the plant. The effect upon mankind is not stated, but, if it be at all analogous to that upon pigs, the plant should come into use as a homeopathic remedy for baldness.

OPERATIONS IN "FUTURES."—In certain quarters gambling in futures has been seized upon as the disturbing new condition of the produce market. It is, however, a suggestive fact that dealings in "futures" originated in a period of abnormal disturbance in prices consequent on the outbreak of the American Civil War. At the outset, at least, transactions of this nature were simply methods of insurance; the planter in raising his crop was glad of an opportunity of approximately securing beforehand an adequate return for his outlay, and the user of raw materials was equally pleased to have a means of securing ahead a supply of material at a price fairly proportionate to that at which he could contract for the sale of the fabrics. In more recent years this system has extended to the distributor, who, having had to face incalculable variations of exchange, has also insured himself by what are practically operations in exchange "futures." In the

Economic Section of the British Association on Monday, Mr. Elijah Helm, Secretary of the Manchester Chamber of Commerce, read a paper on "Mercantile Markets for Futures." He described the origin and purpose of dealings in futures. It constituted, he said, a method of insurance to producers and distributors against the risks of fluctuating prices, for the system had accentuated the fall of prices of commodities within the last twenty years. Its development had been assisted by the telegraph and the telephone. It could be differentiated from pure gambling. He maintained that the system properly organised and controlled, was, on the whole, economically beneficial, and that the demand for its legislative suppression was not justified. Mr. Charles Stewart, who followed with a paper on cotton futures, described what they were and how they operated in practice. Cotton futures were, he said, "hedged," first as sales, second as purchases. The system of dealing in futures was the natural outcome of the expansion of trade, particularly the future of the development of such by telegraph. The increase in the size of the crops, the small margin of present-day profits, the greater speed in transit, the increased magnitude of producing concerns, and the necessarily greater increase in capital for their requirements, were all demonstrated in the explanations given of the practice. In the course of the discussion it was pointed out that, but for the system described, planters would run serious risks, as they used to do in old times, when every producer sent his cotton to the market at the same time, and so depressed prices; whereas now a planter could sell his cotton whilst the crop was growing.

THE DOCK COMPANIES AND SHIPOWNERS.—The circular issued by the London and India Docks Joint Committee with reference to the arrangement for discharging cargoes on the quays for shipowners, who desire to retain their fixed berths proposes the following terms:—(1) That the shipowners pay to the Joint Committee a sum of six pence per ton weight on all goods discharged within the docks, except those upon which the Joint Committee receive landing charges, and also excluding bulk grain. (2) That the shipowners deliver goods entered for overside delivery, free to the Joint Committee's craft—*i. e.*, on the same terms as to other consignees' craft. (3) With the above alterations, the terms of the existing agreements and arrangements to remain unaltered. In the event of these terms being generally accepted, the committee propose issuing a revised scale of rates for the use of their dry docks at about 10 per cent. below that now in force. Fixed berths, it is added, will be available on similar terms at the Tilbury Docks, as well as at the Victoria and Albert Docks, and to a limited extent and the West India Dock. The charges are calculated on the ton of 2,240 lb weight. In view of the fact, that negotiations are proceeding, the date on which existing agreements and arrangements terminate has been postponed until November 1.

INDIAN PATENTS.

Applications in respect of the undermentioned inventions have been filed, during the week, ending, 26th September 1896, under the provisions of Act, V of 1888.

For improvements in machines for breaking balls of rolled tea leaf and sifting the same.—No. 333 of 1896.—Nathan William Horatio Sharpe, engineer, of 26, Perth road, Stroud green, London, for improvements in machines for breaking balls of rolled tea leaf and sifting the same.

For an invention to be called "Quinlivan's simple and unique machine for hulling paddy into clean or cargo rice by steam, cattle or hand power."—No. 4 of 1896.—Thomas Quinlivan, engineer and miller, residing in the city of Rangoon, of the province of Burma, for an invention to be called "Quinlivan's simple and unique machine for hulling paddy into clean or cargo rice by steam, cattle or hand power." Specification filed 29th July 1896.

COFFEE PLANTING IN BRITISH CENTRAL AFRICA.

(Appendix No. 2 to Sir H. Johnston's Report.)

In 1878 a Mr. Jonathan Duncan was appointed by the Church of Scotland Foreign Mission Committee to join the Mission in what is now British Central Africa as a lay member and horticulturist. Before leaving Edinburgh the present Curator of the Botanical Gardens there gave him three small coffee plants, which he took out with him and planted in the Mission gardens at Blantyre. Prior to this, in 1876, the late Mr. John Buchanan, C.M.G., had joined the same Mission at Blantyre as a lay member, especially in charge of horticultural work. Mr. Buchanan took a special interest in the cultivation of coffee. In the year 1880, the sole survivor of the three plants brought out by Mr. Duncan bore a crop of about 1,000 beans, which were all planted, and from which 400 seedlings were eventually reared in the Blantyre Mission gardens. "In 1883*, from the 400 trees 14½ cwt. of coffee was gathered. The size of the pits in which the trees were planted were 6 feet wide by 3 feet deep. They were filled up with alluvial soil, cow manure, and wood ashes. I believe this accounts for the enormous crop."

In 1879 Mr. Henry Hendersen, a well-known lay member of the Church of Scotland Mission, now dead, who founded the Blantyre Station—who may be said, in fact, to have founded Blantyre, since the selection and purchase of the site was his own doing—brought out with him 56 lbs. of Liberian coffee seed, but the introduction of this variety met with but scant success, and although there are still some survivors traceable to this introduction, it has been found far more profitable to plant the small Mocha coffee which was the kind originally introduced through the medium of the Botanical Gardens at Edinburgh. Later on, varieties of Jamaica coffee were introduced by the Moir Brothers, whilst managers of the African Lakes Company, Mandala. The blue mountain variety thus introduced has succeeded very well in the Shire Highlands, and to a less extent the orange coffee has prospered.

In 1878 Mr. John Buchanan planted some coffee for the Church of Scotland Mission at Zomba, on the Mlungusi stream, close to the present site of the Residency. In 1880 Mr. Buchanan has left the service of the Mission, for whom he had worked four years, and started with first one and then two of his brothers as coffee planters. It was a plucky enterprise, as they had practically no capital, and but for the generosity with which they were helped and supported by Dr. Rankin (their parish minister at Muthill, in Perthshire) they would probably have broken down for want of funds. After Mr. Buchanan left the service of the Mission, nothing further was done by that body as regards coffee planting other than to keep in good order the parent trees, one or two of which are said to be still growing in the Mission grounds at Blantyre. For nearly ten years (1880 to 1890) Mr. Buchanan and his brothers were the only coffee planters in Nyasaland. In my Report on the first three years' administration of this Protectorate I somewhat erroneously gave Mr. Buchanan's name as that of the original introducer of coffee into British Central Africa. This was not quite correct, though it was not wholly incorrect. Mr. John Buchanan arrived in this country two years before Mr. Duncan, and it was on account of his energetic representations to his friends in Scotland interested in botanical work that the Curator of the Edinburgh Botanical Gardens intrusted these three coffee plants to Mr. Jonathan Duncan to convey to Blantyre. This coupled with the long ten years' work as the sole coffee planter in what is now the British Central Africa Protectorate, may fairly entitle Mr. Buchanan to be considered the introducer of coffee culture into British Central Africa, a more potent factor of civilisation, perhaps, than any

other form of commerce or enterprise, and far more wholesome than the feverish rush for minerals. In 1884 Mr. Buchanan returned to Scotland, and wrote an interesting book on his attempts to create coffee plantations in the Shire Highlands.*

In 1886 and 1887 the Buchanan Brothers were much encouraged and helped by Mr. Consul Hawes,† who, finding their finances at a low ebb, and struck with their eagerness to turn their abilities to account, employed them to build the Residency at Zomba, which is still the best and largest—and perhaps, one may add, the most durable—building erected up to the present time in Central Africa, north of the Zambezi and south of the Congo. The Government grounds at Zomba are a portion of Mr. Buchanan's original coffee estate, and were sold by him to the Government for a nominal sum. In 1888 Mr. Buchanan became Acting Consul, and when the Administration of the Protectorate was started in 1891, he received the appointment of Vice-Consul at Blantyre, which he held up to the time of his death. His services in regard to this country were early recognised by Her Majesty's Government, and he received a C.M.G. in 1890. At the time of his death, which took place on the 9th March, 1896, as he was on his way home for a long holiday, he was still by far the most considerable coffee planter in British Central Africa.

At the close of 1889 Mr. Eugene Sharrer arrived in this country to start coffee planting. Mr. Sharrer had previously visited the Shire Highlands before Consul Hawes' return to England in 1889, and had been assisted by the latter to acquire some estates in the Zomba district, and encouraged to start coffee planting. Then ensued the declaration of the British Protectorate and the immigration of British and other European planters became so general as, in the course of a few years, to increase the number of planters in the Shire Province alone to something like 100. Coffee planting was now established as the chief industry of Nyasaland, and undoubtedly it is almost wholly coffee planting which has brought about such a prosperous change in this part of Africa, and has enabled our local revenue to rise from nothing to 20,000*l.* per annum in five years.

Out of the approximate 100 which forms about the present total of the planters, 12 are Europeans of other than British nationality, and consist of 4 Dutchmen, 3 Germans, 1 Frenchman, 1 Italian, 2 Austrian Poles, and 1 Portuguese (recently established in Mhanje.)

Besides these European planters, it is pleasant to be able to record that six natives who have risen, most of them from the position of scholars at the Mission schools, have started and are doing well as coffee planters. One of these men is a native Chief, who surrendered his governing rights to the British Government, and has gone in vigorously for coffee planting. The other natives are George Chokobwino, "David Livingstone," Tom and Sam Makwito (these two were educated at the Lovedale Institute, South Africa), and Donald Malota. In addition to these, I may mention the Chief Mbariku, the senior member of the native Council at Kotakota, on Lake Nyasa (a Muhammadan), who has shown himself intensely interested in all these questions of planting and stock-breeding, and who has started coffee planting on a small scale in the Marimba district. The Church of Scotland Mission, which was the pioneer in the introduction of coffee, but which until quite recently never went in for coffee planting, has now started a small estate worked by its scholars.

The Zambezi Industrial Mission makes coffee planting its principal industry, and hopes in time to become self-supporting from the proceeds of its plantations.

The African Lakes Corporation, though mainly a trading Company, have some flourishing coffee plantations.

Coffee planting is at present almost entirely confined to the Shire Province, and, indeed, to the much more

* I quote from an article on the subject written by Mr. Jonathan Duncan, now a coffee planter in Central Africa, to a local newspaper published at Zomba, the "Central African Planter."

* "The Shire Highlands," published by Blackwood.

† Now Her Majesty's Commissioner and Consul-General in Hawaii.

restricted area of the Shire Highlands. A little is done in Angoniland (Upper Shire and South Nyasa districts), and a very little in the Marimba district. Coffee planting has also been started by the Livingstonia Mission in the North Nyasa district, but at present without any results to be chronicled.

Messrs. Buchanan Brothers have under cultivation about 900 acres of coffee on their various plantations, situated between Zomba on the north and the River Ruo on the south. They have in their employ nine Europeans in various capacities looking after the coffee. They expect to export this year nearly 100 tons.

Mr. E. C. A. Sharrer is the largest owner of estates in all the Protectorate, as is shown by the accompanying map. These amount to an approximate 365,000 acres, of which only about 900 are at present under cultivation with coffee. He employs about nineteen European assistants to look after these estates, and cotton is grown as well as coffee. His plantations being very much younger than those of Buchanan Brothers, his export is comparatively little at present, but I believe he will send home about 20 to 30 tons of the present year's crop.

Mr. Hugh Bloomfield Bradshaw formerly an officer in a cavalry regiment, has some large estates in the Mlanje district. His approximate area under cultivation is 300 acres, and he expects to export about 20 tons of coffee this year.

Messrs. Pettitt Brothers, who came out originally to hunt, took to planting coffee four years ago. They own about 50,000 acres, of which about 300 acres are planted out. Their out-turn this year is expected to reach 20 tons. They employ five European assistants.

Mr. John W. Moir, for many years joint manager of the African Lakes Company, has about 230 acres planted with coffee in the Mlanje district and will probably export a little over 10 tons in the course of the present year. Mr. Moir employs three European assistants.

Mr. Henry Brown also formerly in the service of the African Lakes Company, a planter on Mlanje, will export about 10 tons this year.

Mr. Kasimir Steblecki, an Austrian Pole, has about 200 acres under cultivation, and may export as much this year as 12 tons.

So far as I am aware, no other planter expects his year's output to reach 10 tons, as the other plantations are scarcely old enough to bear more than "maiden" crops. The total export of coffee anticipated during the year 1896 is expected to reach a total of 350 tons.

It is worthy of note that a great interest has been taken lately by Ceylon planters in the prospects of successful coffee cultivation in British Central Africa. There is one Company already established in Ceylon, the Nyasaland Coffee Company, which has acquired valuable estates in the Mlanje district, and is placing a large area under cultivation. I believe, in addition, one or two Englishmen have come here from Ceylon, and are starting coffee planting on their own account.

The ordinary procedure of an average planter on coming into this country is to start planting in the following manner:—

After selecting and purchasing his land, he begins by obtaining labour (this should be about the month of June; it is advisable to commence at that season of the year), and cuts down all the superfluous timber on the land he wishes to plant, and uproots the bush which, together with the timber, he carefully burns and mixes the ashes with the soil. The further clearing of grass &c., is effected by hoeing. The ground is now lined out in regular rows from 6 feet to 7 feet apart, and at equal intervals of not less than 6 feet or 7 feet, pits are dug in these lines with a common hoe, 18 inches wide and 18 inches deep. These pits then are left open for as long as possible (say until September) to "weather," then they are filled up and a bamboo stuck in the centre to mark the place where the coffee plant is to be inserted. Prior to this the planter will either have made a nursery for himself, rearing the young plants from seed, or will have made an arrangement with some neighbouring planter to purchase seedlings already grown. When the rains be-

gin about the latter end of November, he proceeds to plant out the seedlings in the aforesaid pits, taking care that sufficient labour is available at this time of year to keep all the land which he is cultivating free from grass and weeds. The majority of planters up to the present time have contented themselves with erecting a wattle and daub-house with a thatched roof, not caring to build a more substantial or sanitary dwelling until they are sure of some return from their coffee. But the older planters have already built for themselves good substantial brick houses, and some of the newer men, realizing how important it is to health, start house-building at the very commencement on substantial lines. I consider mud houses of one storey and thatched roofs unsanitary. The house is generally damp, as the floor is simply on the ground, and the thatched roof rots with the wet, and the rotting grass seems actually to be the cause of certain forms of sickness. The best kind of house which could be put up rapidly and with little expense would be with corrugated iron (roof and sides), having a timber lining to moderate the great heat coming from the iron during the day-time. Undoubtedly the best kind of house for this climate is one of brick with a corrugated iron roof and timber ceilings. The average amount of ground which a man is able to open up who has at his command sufficient capital to employ 100 men is about 60 or 70 acres of coffee a-year. This would come into bearing with what is called the "maiden crop" after three years.

The estimated total expense of the planting, upkeep, and bringing into bearing of (say) 100 acres, together with the cost of the planter's living in a reasonably comfortable style, should not amount to more than 1,000*l.* This, however, would not cover the expense of erecting a brick house, brick pulping vats, and importing machinery for pulping. If, after the first year, the planter is not desirous of increasing the area under cultivation, and merely contents himself with keeping the plantation clear of weeds, draining it and making roads through it, he should be very well to keep within the above mentioned expenditure of 1,000*l.* until his coffee brings him some return. The third year, generally about the end of June, the crop is ready for picking. This is, of course, one of the busiest times for the planter. The care which is necessary for the proper pulping, and more especially for the preparing of the coffee for shipment, entails considerable trouble in this country, because even during the dry season we are apt to be surprised with occasional showers of rain. Perhaps the best time for shipping coffee from this country is at the end of the very dry month of October.

As regards pulping: The usual process adopted in this country is similar to that in vogue elsewhere. The berry when picked (it is here spoken of as the "cherry") is passed through a pulper, all of which in this Protectorate, with one exception, are worked by hand power. The beans are here separated from the sweet, fleshy envelope which covers them, and are passed into a brick vat where they are left (according to the temperature) for twenty-four to thirty-six hours for fermentation. They are then passed on to a second vat, thoroughly washed, taken out and dried. The pulper in general use in this country is Gordon's cylindrical pulper, but this season one of Walker's twin disc pulpers was imported and proved a great success. Some planters with a very limited maiden crop do not care to go to the expense of purchasing a pulper, and their coffee when picked is generally pulped by hand and dried. From what I can gather the average out-turn of coffee per acre in this Protectorate is from 3 cwt. to 3½ cwt.; there have been exceptional cases where as much as 17 cwt. per acre have been taken, but this result can in no way be taken in making an estimate. In neglected gardens a return as poor as 50 lbs. to 60 lbs. per acre has been realised; but it is generally considered that the above estimate of 3½ cwt. per acre is one which can be relied on if ordinary care is taken of the plantation.

During 1894-95 much greater care was taken in the cultivation of coffee than was hitherto the case. The system of "topping"* was universally adopted, though not to the extent to which it is carried on in Ceylon and India. This will to a greater extent necessitate the training and up-keep of a permanent staff of natives to handle and prune the coffee in a proper manner, otherwise "topping" will do more harm than good. Another measure that has been more adopted than formerly is the replenishing of the soil by manure in some cases, and in others by trenching and forking. The results of these measures will on the one hand tend to reduce the excessive bearing of the maiden crop, but will bring about a more regular system of bearing for a number of years. A great deal of diseased berry was found amongst the 1894-95 crop, due, it is thought, to the early fall of the rains, which brought the coffee prematurely into blossom, leaving the seed to suffer from subsequent droughts. Other persons hold the opinion that empty or diseased berry is caused by the presence of a beetle resembling the ladybird, which has been very prevalent in some districts. The Ceylon planters assert that the cause lies with the well-known green bug, an insect which sucks the sap of the coffee tree, and that the remedy is to be found in shade and good manure.

The coffee sent home in 1895 realised higher prices than those quoted for 1891, and some samples are said to have been bought at the record price of 111s per cwt. The prospects of the coming crop of 1896 are good beyond all previous years, chiefly owing to the abundant rainfall, which has been at least 10 inches above the average.

I attach to this Appendix a sketch map showing the estates, a portion of which are under coffee, or which are intended for the cultivation of coffee. The area covered by this map is the southern portion of the Shire Province.

In drawing up this Appendix on coffee planting I have to acknowledge much assistance from Mr. J. E. McMaster, and have also to mention that all the planters when applied to were ready to supply me with information. H. H. J.

LANTANA—THE FORESTER'S FRIEND?

I do not see why your esteemed correspondent, C. Bagshawe, should accuse me of jostling on this sad subject. Sure nobody can have a more thorough objection to jokes—at times than myself. I am, however, seriously obliged for the interesting extract quoted and can only hope for pardon if I suggest that the real inward gist thereof is precisely what I said in March; *viz.*, that we do not know everything about *Lantana*, and that there is at least room for two opinions as to its possible utility in forests, if rightly used. I am quite ignorant as to who was Mr. Lawrie's predecessor, so have no idea which of the two carries the greater professional weight, but the extract from the Coorg report simply shows that Mr. Lawrie disapproves of *Lantana*, whereas his predecessor held the contrary opinion. Having had under my charge certain of these impenetrable *Lantana* jungles, I certainly never advocated sitting at ease while the *Lantana* over runs the whole country. What I still advocate is using the *Lantana* as a servant, and finding out the conditions in which it can be utilised, instead of going blindly to work trying to exterminate it by sheer expenditure of money. Rs. 17,000 have almost exterminated the plant from Berar, and it is open to Mr. Bagshawe to think that the expenditure in the future will be trifling but, it is also open to others to be less sanguine, and even to anticipate the need for a similar expenditure before say ten years are out. What have they got on the ground in place of the Berar *Lantana*? I do not know the circumstances or Berar, but if it is bare soil, I should be inclined to think the money now too well invested, while if

it is grass, I should be inclined to think a good deal less of the bargain still, for it is my experience that grass is infinitely more dangerous than *Lantana*. The facts disclosed in the Coorg report do not, in my opinion, go any way at all towards disposing of the Forester's-friend theory. All they prove is that a crop of young sandalwood was allowed to be ruined by *Lantana* for want of timely care. This want of timely care is not to imply any fault of the Forests staff being, doubtless, the necessary result of present conditions, but it would be equally unjust to blame the *Lantana*. What was wrong was the treatment thereof. I might venture to suggest that if the Rs. 17,000 spent in Berar had been spent in Coorg, the latter might have been the richer by large areas of sandal saved till it was able to kill out the *Lantana* on its own account, while Berar might have been, as Ingoldsby says, not one penny the worse. VALLEDA.—*Indian Forester*.

PLANTING PROSPECTS IN FIJI.

With its productive soil and, without doubt the healthiest tropical country in the world, Fiji has a magnificent future in store for it, but the pity of it is that its consummation is not somewhat hastened by a little display of wisdom in the directing of its affairs. New blood, in the shape of intelligent, young and energetic men, with a small amount of capital, is sorely needed to settle upon and develop its acres, and money in the shape of a loan to be devoted to the specific purpose of improving its fortunes is of first importance. If the condition of the country is to be improved, coolie labourers require to be imported, and other initial expenses, inseparable with any scheme for encouraging colonisation, require to be provided for. If an addition of desirable colonists is to be secured it will be necessary that the inducements be such that they be sufficiently attractive. Were a dozen or two of planters to arrive here, tomorrow say, from the sugar districts of New South Wales, where they are threatened to be "froze out" by the new tariff conditions of that colony; or, it may be—and many of us fondly hope that such will be the case—that a few gentlemen, learning that Fiji is likely to be famed as a tobacco producing country, were desirous of throwing in their fortunes with us, the question of an adequate supply of labourers would be a very serious matter, and its absence would go a long way to cause them to waver in their preconceived determination of making their home in this country. New people coming here with money in their pockets, bent on a certain purpose, would not appreciate having to wait the best part of a year before their requirements with regard to labour could be satisfied. "Life is too short," they would say, "We'll go and try Queensland or the New Hebrides: both out money and our presence will be welcome there." Again, another drawback to our labour conditions in the employment of coolie labourers, to men of small capital, would be the planking down of the whole cost of their introduction fees before they entered service. For large capitalists and corporations this course would possibly be a matter of supreme indifference, but it would be otherwise with individuals of limited means. To a well-regulated system of labour supply in the hands of the Government, it should not be of supreme importance whether or not the cost of introduction were paid down on the nail or distributed by half-yearly payments over the five years of coolie indentureship. Before, however, the Government could so accommodate the planter it would be necessary that it poss-

* Cutting off the primary shoots of the tree so that its secondaries may develop and come into bearing.

essed the funds to enable it to do so, and a loan for the purpose would be a necessity. A loan for a like purpose sanctioned by the Secretary of State, was recently negotiated on the London market by the Crown Colony of British Guiana. In many other ways the future of the colony requires to be anticipated. For instance—and we are not sure but that the funds of the colony may be of a sufficiently elastic nature to permit of the expense being defrayed out of revenue—the natives at their last annual meeting suggested for the consideration of the Governor, that a commission of one or more be sent to Honolulu to find out the method of preparing dalo there, as the chiefs here, were desirous of adopting so good an example. The same commission might also, with advantage, learn something with reference to rice cultivation, and the profits which accrue. Wrinkles might also, at the same time, be gleaned with respect to sugar-cane growing and manipulation with economies, and the methods pursued with regard to packing and shipping bananas to San Francisco. And if the experiences gleaned were afterwards approved of and deemed advantageous, there is no reason why the Mauritius should not be visited, and this colony instructed what is being done there with the fibre industry, as we are informed that the fibre plant which flourishes so well in this colony is of the same variety as that which is manufactured in Mauritius. And then, why not Cuba be likewise visited. The “prospect” is certainly encouraging enough if we were only a little more enterprising. Wrinkles with regard to sugar could be noted but more particularly with respect to Havannah tobacco and cigar manufacture. The condition of that unfortunate island is such that there should be little difficulty at this time in inducing a small colony of say a dozen tobacco producers and cigar manufacturers to transfer themselves from that fever and war-stricken country to Fiji, were opportunity afforded them. The tobacco industry at Jamaica is not yet, if we remember rightly, forty years old, and was introduced into that country much in the same way as now suggested. All the products we have enumerated are grown here, but the colony requires to glean more exact information regarding their growth and manufacture. In fact we require to be fortified with a lot of technical matters with regard to them which can only be ascertained by some cute messenger whose services require to be retained for the express purpose, and we think the public exchequer should defray the cost. The amount of energy now being displayed by Governments, both small and large, in leaving no stone unturned to keep their people well-posted in all matters affecting their natural products would have been viewed as marvellous a few years ago but is now only regarded in the light of a duty engendered by competition and as absolutely a necessity if the survival of the fittest is to be justified and maintained.

If no ability or inclination be evinced on our part to enter the arena of progress than we have only ourselves to thank for our smugness if other countries march ahead of us. If there be no seed-time on our part then we are perfectly certain there can be no harvest. And it should be plain to all of us that if our progress be not nearly so rapid as our neighbours, its cause must be attributed to our lack of energy and that our non-progressiveness is but a consequent and natural effect.—*Fiji Times*, Sept. 9.

VEGETABLE PRODUCTS OF AMERICA.

From Ratzel's “History of Mankind,” Part XI, we quote the following:—

The climate of America used in the last century to pass for inordinately cold and damp, and the highly premature question, whether it were not detrimental to the development of American humanity, long formed a standing subject of discussion. America embraces very hot and dry regions; but in the north the Arctic climate penetrates so far into the continent that even Labrador, in the latitude of England, is an inhospitable polar country. Cold winters and hot summers characterise the larger part of North America. The southern half of California on the Pacific coast is an Italy-like oasis; but as we proceed inland, with the rising ground the driest portions of the continent soon come into view. It is only to the east of longitude 98° W. that agriculture is practicable without artificial irrigation, and that forests or even groves of any extent are found.

In Mexico, too, and as far as Patagonia, the western region is the driest. Westward of the tributaries of the River Plate we come into a district the steppe-like character of which quite reminds us of that about the sources of the western tributaries of the Mississippi. The Pampas may be called the prairies of South America; the wormwood flats of the north are reproduced in the Chañar steppe at the foot of the Andes, and the desert of Atacama in the Salinas and the Campo del Arenal. But the genuine prairies are the Pampas which from Cordoba to Patagonia, between 29° and 40° S. latitude, cover a soft soil free from shingle—one of the most monotonous grass-steppes in the world. Further southward comes the Patagonian steppe with its rough stony soil.

Between the tropics lies a highly-favoured region of the world. The manifold configuration of the ground offers a rich variety, and above the eternal midsummer of the Amazon and Orinoco lowlands, eternal spring is gorgeous on the lovely middle slopes of the Cordilleras. It is just the regions of the ancient civilization of America which share this good fortune; Mexico, Bogotá, Quito, have perpetually a temperature of early summer, while in Quito the difference between summer and winter is not more than 3°. Near Cuzco the spring is permanent, at least in some charming oases.

Flora and fauna are richly developed, but have supplied fewer cultivable plants and domestic animals than has the Old World. Maize, potatoes, sweet potatoes, tobacco, cacao, *maté*, are all we can name as having acquired importance for mankind; while of animals hardly any can be picked out. Turkeys, the cochineal insect, guinea-pigs, stand at most on the same level as vanilla. The later acquisition for medicine of Peruvian bark and *curare* gives reason to hope that many another valuable product may yet spread from those countries over the world. One can point to a long list of plants of which the settlers have learnt from the Indians, and which have become useful and often indispensable to them, grain-bearing grasses among them—the *zizania* or water-rice of America, and the floating *glycyria*; then the *echinochloa*, cultivated in Mexico like millet, the *Euchlaena lururians*, closely akin to maize, growing wild in Guatemala, and bearing there the name *teosinte*, “the maize of the gods.” Species of *miliun* and *panicum* with edible grains occur in South America. If we add the *quinoa*, the Peruvian grain-bear-

ing plant which holds a position like our buck-wheat, we have a whole list of meal-producing plants, among which, however, only maize in its numerous varieties was generally cultivated in the tropical and temperate regions of north and south. Not until the introduction of domestic animals from Europe was the great wealth of nutritious grasses utilised. Among many races of ancient America, and above all among the more civilized, vegetable diet prevailed over flesh food. To the great wealth of tropical America in palms corresponds in some measure the abundance of useful articles which are produced from them. Even bamboo hardly fulfils so many uses as the *carnahuba* palm of Brazil (*Copernicia cerifera*), which lasts through the worst and longest droughts, remaining always green and juicy. Its root has medicinal properties similar to those of sarsaparilla, and from the stem line strong fibres can be drawn. Its wood can be worked for poles, beams, laths, palings, musical instruments, pipes, and pails. The young leaves, when fresh, afford a nutritious food; the tree further furnishes wine, vinegar, sugar, and a gum, resembling sago, which in times of famine has often been the sole sustenance of the Indians. Besides this, flour, and a whitish fluid like the milk in the coconut, have been obtained from it. The soft fibrous substance in the interior of the leaves and stalk is a substitute for cork. The fruit has a flesh of agreeable flavour, the oily kernels are roasted, ground, and used as coffee. From the dried leaves are made hats, mats, baskets, and brooms, and a kind of wax for candles is also obtained from it. Wax is furnished also by the slender *Ceroxylon andicola*, one of the handsomest of trees with its 200 to 250 feet of height. The Tagua palm gives vegetable ivory—with caoutchouc and Peruvian bark one of the few natural products of South America which have made their way to any large extent into trade. The fan-like leaves of the Brazilian king palm (*Orodoxa regia*), nearly forty feet in length, find a use in various directions. The Mariba palm has edible fruit; the juicy sweet flesh in which its seeds are covered is a great delicacy with the Indians, and a *maximiliana* covered with ripe fruit is not likely to remain long unshared by travellers. Two or three palms in the north of South America furnish cooling drinks such as the Caribs especially love. The Macusi Indians knead the orange-tinted porridge-like pulp of the *mauritia* into a dough which they tie up in the leaves of the mariba palm and take in water. From the dark violet roots of the *turn* palm also, the Indians and Negroes of Guiana brew a cooling drink by the addition of water. In consideration of the many uses to which palms, otherwise of no value, can be put in the way of building, timber roofing material, and so on, the more intelligent among even the Indians long since began to take care of them and plant them, especially the coco-palm and, on the Mosquito coast, the *sugar* palm.

The primeval forest of South and Central America contains edible fruits in abundance—guava, the *ochuba* resembling the winter cherry, *curupa* and *chubupa*, maumee, *chirimoya*, avogado pear, cashew nut, *cirueta*, pine apples, *grenadillas*, the fruits of a passion flower, solanums of all kinds, from the cherry tomato to the pungent chillies which furnish the so-called Cayenne pepper, the indispensable seasoning of all Indian foods. Almost all have spread far beyond the confines of America. North America has a whole list of nut trees, including walnut and hickory.

The nut tree of Colombia rivals the walnuts of Europe and America. Many leguminous trees furnish edible seeds. There are mulberries in North America and on the plateau of Bogota. In higher situations, and in the most southerly parts of South America, there is also an abundance of berries, even in Colombia species of *rubus*. In North America the fruits of two kinds of chestnuts are eaten; there also edible nuts are borne by two species of hazel, and in the south by some witch hazels. Sweet acorns are gathered from the live oaks; in the west the *piñon* has edible oily kernels; the wild papaw or melon tree (*Papaya vulgaris*) furnishes fruit like melons; species of wild plum are widely distributed. In North America various species of the vine grow wild, some very productive and of well-flavoured fruit which are now cultivated in Europe.

Even the far west of North America, and again, in spite of their steppe-character, the plains of South America, are by no means destitute of edible fruits. In the region of the Rocky Mountains and the Great Basin there are plums, cherries, raspberries, blackberries, currants, and gooseberries. In California meal made from the fruit of the *manzanita*-bush is an important article in the economy of the Indians. Schmiedel mentions bread made from the seed of a leguminous plant as being eaten by the Indians of the Pampas. In New Mexico and West Texas there are two species of mulberry and several of vine. Under the name of *panoche* the Indians of California know a saccharine substance of the nature of manna, which is exuded by aphides on the leaves of the reed; and also the sweetish juice of the sugar-pine (*P. Lambertiana*), which, however, tastes, more of turpentine than of sugar. The well-flavoured sugar of the sugar-maple is to the present day of importance for the settlers in the east of North America. Besides the numerous conifers, rich in balsam and resin, we may mention the wax-berry, from the berries of which a wax-like substance is obtained by boiling. For a black dye the North Americans employ the seed of the snallow and the bark of the willow, and for red the roots of *savoyenne* and buffalo-berry. For fishing-lines they use the bast of the maple, the red cedar, or the stalks—as thick as a finger—of a giant oar-weed. Of medicinal herbs there is no lack.

Yuccas and agaves furnish fibrous materials. In old Mexico paper was prepared from the fibers of the maguey and the bast of the indian-rubber tree. At the present day the fiber of the sisal agave of Yucatan is in demand. In the highlands of South America similar materials were afforded by *fourcroya* and the *bromeliaceae*. Caoutchouc is obtained from various trees and creepers; the dried juice of the *Mimosops balata* is used by the Indians of Guiana to smear their arrows; when fresh they drink it like milk: the fruit is equally appreciated by men and monkeys, and the wood, under the name of *boteri*, is one of the favourite building timbers of Venezuela. The resin of the *mani* serves for stilling bow-strings. In the Colombian lowlands all the huts consist of bamboo, which grows in quantities near the Cauca. The flesh of many species of cucumber is eaten, while others provide calabashes, but the favourite kind, called *totuma*, is made from the hollowed-out fruit of the *Crescentia*. The South American Indians paint themselves with annatto from the *uruku* (*Bixa orellana*) and the *genipaba* (*Genipa americana*). Nowhere is nature so well adapted

for the hunting and forest life as in America, and in North America at least full justice has been done to her wealth. It would require a book to recount all the materials used by the Indians. Only a few examples need here be given. The Canadian refreshes himself by chewing the sapwood of the poplar called "La sève"; the juice has a pleasant sweetish taste like water-melons, and acts as a restorative. When snow covers the prairie this is often the only food for horses obtainable in the absence of fodder. The Wintuns of California often fill their stomachs in winter with the sweet bark of the yellow pine. On the upper Saskatchewan, when hunting and fishing fail, the Indian scrapes a lichen, *gyrophora*, and boils it into a nutritious jelly. Among the Yuma tribes the roots of the *mescal* (*Agave deserti*) are roasted and eaten for the sake of their flavour. The stone-pine affords nuts; the *opuntia* and another cactus, the *Pitahaya*, sweet fruits; the locust-tree sweet pods, and, in its seed when crushed, a nutritious meal; *amole* (yucca) edible fruit and tough fibre; palmetto, in its leaf-buds, a substitute for cabbage; the young leaves of *Agave americana*, when cooked, a savoury dish. Leaves of certain *ericaceæ* furnish tea, and the arbutus is mixed with tobacco. Of edible fungi 108 kinds are reckoned in North Carolina alone. The so-called "Indian bread" is a fungus attaining a weight of 30 lb. The tomato is everywhere employed. Vanilla first attained importance through Europeans; but cacao was used and valued in earlier times. The coca of Peru (*Erythroxylon coca*) was known even into Central America as *nayo*; each leaf was separately detached from the stalk with the thumb-nail, and dried in earthen pots over the fire.

Imported plants have become widely distributed, in some degree even those which white settlers did not cultivate. Thus bread-fruit grows wild in some of the West Indian islands, where the indolent and contented negroes require hardly anything further for their sustenance. The cultivation of sugar and cotton in plantations has hardly brought any advantage to the individual Indian, since he lacks capital and organising power; but in Mexico and Central America coffee-planting, which requires only hard work and the hoe, has had a more favourable effect; and the same may be said of tobacco. On the other hand, the Indian has nowhere adapted himself to such forms of cultivation as those of the vine or the olive; nor indeed have the Indians, even when settled for generations, taken to agriculture in the European style as it is carried on in the temperate districts or North America, the Tierras Frias of the Mexican and South American highlands, or on the River Plate, so readily as to cattle-breeding, which has turned them and the half-breeds on the Llanos and Pampas into distinctly pastoral nomads, under the name of *llaneros*, and *gauchos*, and races of horsemen.

SELANGOR PLANTERS' ASSOCIATION.

We have received a copy of the minutes of a general meeting held on Saturday, 26th September.

The following resolution proposed by Mr. GIBSON and seconded by Mr. CAREY was carried unanimously:—

"That the Association should again address the Government on the subject of sales of land by auction in Selangor, with a view to having the State put on the same footing as the rest of the Federated States, where grants of land are given to suitable applicants."

The Chairman laid on the table a draft copy of a Bill entitled "An Ordinance for the Protection of Indian Immigrants," which had been sent to him as a member of the late Labour Commission, by the Colonial Secretary, and he drew the attention of the meeting to various points in the Ordinance. After some discussion it was resolved that the Hon. Secretary should write to the Colonial Secretary asking if the operations of the Ordinance is to be confined to the Colony, and if not whether a certain number of copies could be supplied to the Association, failing which it was agreed that they should be printed in the State and distributed to members.

7. Read letter from the British Resident to the Chairman, forwarding a draft of the "Federal Produce Protection Enactment, 1897," and intimating that the Government will be glad to receive the views of the Selangor Planters' Association. Resolved that the letter be acknowledged and the Government thanked for forwarding the proposed Enactment, which is approved of by the meeting, and that printed copies be sent to all members with a view to ascertaining the general opinion of the planting community.

8. Mr. Huttenbach addressed the meeting on the subject of Government inspection of oil engines, as prime movers, for which a fee is charged, although they are free from the risk and danger attending steam engines. Resolved that the Hon. Secretary enquire as to what is done in other countries before taking any further action in the matter.

ZANZIBAR CLOVES.

There have been signs lately of an impending speculative movement to force up the price of Zanzibar cloves. In the early part of the month a Mincing Lane firm of brokers, who are currently reported to act for a rich "syndicate," actually purchased considerable quantities, although the price did not advance beyond one or two points. It is well known that in the early days of the late Colonel North's "camphor syndicate" the speculators banded together under that *Sobriquet* attempted to corner the clove-market along with the other departments of the Mincing Lane produce-trade to which they turned their attention. The clove speculation was unsuccessful from the beginning—as, indeed, it could hardly help being, considering the enormous supplies of the spice in Europe and the East. It was quickly and quietly dropped, but it is now said that the recent tentative movement was engineered by some members of the old "syndicate" resuscitated. Whatever truth there may be in this statement, a more inopportune time for an upward movement in cloves could hardly be imagined. Sheer over-production has forced down the price of Zanzibar cloves to almost the lowest figure on record. There is no prospect—barring a total failure of the crop or a destruction of the plantations by a hurricane—that there will be any considerable diminution in the supply. The stock in the London public warehouses alone is about 84,000 bales—equal to one and a half year's average output in Zanzibar—and there is no reason whatever for assuming that there will be a marked increase in the consumption. It is rumoured, indeed, that over one-half of this enormous London stock has been quietly bought up by the syndicate, but no convincing evidence is brought forward to bear out that assertion. Clove oil (the chief article of pharmaceutical interest) is now lower in price than it has ever been, and a halfpenny advance in cloves would almost certainly react upon the oil-market.

The chief reason which has been brought forward as a possible cause for a permanent advance in the price of cloves is that, after the recent events in Zanzibar, slavery may be abolished in the Sultanate. As the clove-plantations, which are almost entirely owned by Arabs, are worked by slave-labour, it is thought that the cost of production of the spice would, in that case, be much increased. That

may be so, but in the meantime there is nothing to show that there will be any change in the conditions of labour in Zanzibar yet awhile.

According to a recently-published report of the British Consul at Zanzibar, the production of cloves shows a tendency to increase, in spite of the low prices that have ruled for some years. The total quantities of cloves brought to market in Zanzibar during the past six years (in frazilehs of 35 lb.) have been—

Year.	1890.	1891.	1892.	1893.	1894.	1895.
Zan- zi- bar	124,929	69,388	121,398	108,090	138,691	146,397
Pemba	384,933	324,252	236,211	259,367	372,999	391,460
Total	509,862	393,640	357,609	367,457	511,690	537,857

Not much hope for speculators here. These figures represent the actual quantities brought into Zanzibar from the "Shambas," or plantations, between January 1 and December 31, although the proper season when cloves are picked, dried, and brought to market extends from September to March. They show that the production during 1895 is the largest of the series. The continued heavy crops have caused a glut in the home markets, although shipments at the lower prices are still being made, especially to Bombay, Marseilles, and Hamburg, which three ports, indeed, absorbed most of the consignments during the last half of 1895, London taking comparatively but a small quantity.

In 1895 there were three convictions under the proclamation of the Sultan against the adulteration of cloves. The cloves, which were in these instances imported by British Indians from Pemba, were found to be adulterated with salt, and were seized and publicly burned; and this action has already had a deterrent effect on a practice which was becoming very common.—*Chemist and Druggist*, Sept. 26.

THE DEPRESSION IN GAMBIER.

The gambier market is in a position most unsatisfactory to all concerned, importers, dealers and consumers alike. Usually the last named are pleased at the low prices, but in this instance they hold large stocks, which they cannot make use of, and which they purchased at prices higher than those now prevailing.

The present price is the lowest in many years, if not in the history of the article, some in the trade remembering 3½c. as the lowest price previously reached. The depression is really due to lack of business in the industries which use gambier. Trade has been dull all the year, yet the shipments were maintained about on a par with 1895, and under such circumstances there could be but one result. The situation September 1, showed shipments from Singapore to Atlantic ports, from January 1, 63,000 bales, against 66,000 bales for the same period in 1895. The deliveries were but 49,000 bales, against 91,000 in 1895. The visible supply at Atlantic ports from September 1 to December 31 is placed at 44,000 bales, which includes a stock in store of 12,000 bales, and a stock to arrive of 32,000 bales, not counting steamer lots, either direct or from London. The Hankow arrived September 5, with 2,300 bales direct, and the America from London, September 6, with 1,800 bales, and other lots may follow to swell the visible supply. The deliveries for the last four months were 49,000 bales in 1895, 30,000 bales in 1894, and 25,000 bales in 1893. The visible supply, therefore, for the next four months is 47,800 bales, almost equal to the deliveries for the first eight months of the year. With a falling-off of 42,000 bales over 1895 in the deliveries from January 1 to September 1, it is not to be expected that the deliveries for the next four months will aggregate those for the same period in 1895.

Sales have been made at 2 92½c during the week, and while the market appears a little firmer, it is doubtless due to the non-arrival of the "Falconhurst"

with 8,000 bales. Most of this cost originally 4 to 4½c, and it is a noteworthy fact that consumers have been free sellers of their surplus at the low prices. It cannot be said that there is any immediate prospect of an improvement in values.—*Oil, Paint and Drug Reporter*.

PLANTING AND PRODUCE.

SOME FACTS OF THE TEA TRADE.—The various consular reports from China show that although the decline in the export of tea from the Celestial Empire to Great Britain and her colonies goes on, there are markets in which China still holds the field, and that these have yet to be won by Indian and Ceylon planters. The export of tea from China to Great Britain, Australia, and New Zealand shows a marked decrease. In 1887 the export of tea to Great Britain was over 793,746 piculs. Since that date it has shrunk to less than a third of that amount. The export to Australia was in 1895 less than half that of 1887, and the export of tea to New Zealand has become insignificant. Such are the effects of the competition of India and Ceylon. It is far otherwise with the export of tea from China to Russia. The trade report of the Imperial Maritime Customs states that "the purchase of black tea at exceptionally high prices, both for the Odessa market and for transmission via Kiakhta, were the largest on record." A considerable quantity of tea is also sent to Siberia from Hankow, up the river Han to Fanch'eng, whence it is carried forward overland, in addition to that which passes through Tientsin, the bulk of which consists of black and green brick tea. It is clear that the export to Russia is the mainstay of the China tea trade, and that it is to the development of that branch of it that the small difference between the amounts exported in 1895 and 1894 are due. The Chinese variety of tea is still popular in the United States, but even there the amount imported from China is not so large as formerly, and the trade is a declining one. In 1895 the amount of tea exported from China to the United States was 311,120 piculs, as compared with 403,196 piculs in 1894. The tea trade is one which has been more particularly affected by the events of the last two years. Until recently the whole of the Formosa crop was exported to foreign countries via Amoy. Now that Formosa has become a Japanese possession it is unlikely that this state of things will continue.

THE EFFECT OF LIKIN.—Mr. Cass, in his paper on the Amoy tea trade, forming Annex E to the Trade Report for 1895, drawn up by Mr. Gardner, Her Majesty's consul at that port, states that the tea districts in the neighbourhood of the city in question are among the finest in the world. They have, however, been thrown out of cultivation and almost depopulated owing to the present method of local taxation, notwithstanding the fact that labor is extraordinarily cheap, that the communications (by water) are excellent and that the harbour of Amoy is extremely convenient for shipping. Mr. Cass is of opinion that "as matters stand at present, so far as Amoy is concerned, there will in the near future be no tea to collect either likin or duty upon. Twenty-five years ago 3,000,000 dollars was the annual income of the Amoy tea districts; today it is not 350,000 dollars. Likin has done it."

FOOCHOW AND THE UNITED STATES.—The diminution of the export of tea from Foochow is very marked. In 1893, 54,000,000 lb. were exported; in 1894, 53,030,000 lb.; and in 1895, 48,000,000 lb. The export of brick tea is, however, increasing being 10,000,000 lb. in 1893, 11,000,000 lb. in 1894, and 13,000,000 lb. in 1895. There are some peculiar teas, such as Souchong, and some scented varieties, only obtainable at Foochow, which will always maintain a certain trade. The tea trade of Foochow with Australia is likely to come to an end in the near future, as Indian and Ceylon teas are rapidly displacing those of China in those colonies. There has, however, been a great increase in the export of tea from Foochow to the United States, namely 12,000,000 lb. in 1895, as against

6,000,000 lb. in 1894, but as has already been pointed out the total export of tea from China to the United States has greatly diminished, as Indian and Ceylon growers are doing their best to push their teas in that quarter also. Her Majesty's consul at Foochow remarks on the weight of taxation which is crushing the tea trade there, and states that the dues levied on common teas amount to 30 per cent. on the value.

COFFEE PLANTING ENTERPRISE.—Some financiers in the City have been turning their attention to the coffee planting enterprise, under the impression that it has been unduly neglected so far as British capital is concerned since the unfortunate collapse of the industry in Ceylon nearly twenty years ago. The croakings about over-production of tea and dismal forecasts as to the outlook in the few years time may have assisted in bringing about this flutter of excitement in coffee, but it is mainly due to the success of tea planting as an industry and the desire to emulate it on the same lines. As only about 27 per cent. of the coffee entered for home consumption comes from British possessions, in contrast to 88 per cent. of the tea supply from India and Ceylon, there is a field for an increase in the cultivation of coffee in territory under British rule, provided always that conditions are favourable to placing it on the market at competing prices. The consumption of coffee does not increase, and there seems no prospect of this while tea has so many advantages over it. The hope for British-grown coffee lies in its being able to successfully compete with the product from South America and elsewhere.

THE COFFEE MARKET.—The coffee market is a perplexing problem to gauge, and the element of speculation which enters so largely into the European market consequent on the difficulty of fixing the precise limits of the growing crops, especially in Brazil, is one of the coffee planter's main troubles. Dealing with the subject of coffee prospects at the present time the *Grocer* says: "Certain facts have come to light which tend to confirm the belief that the entire Brazil crop for 1896-97, now in course of being gathered, will turn out to be unprecedentedly heavy, and the aggregate yield of about 1,000,000 bags, predicted as far back as October last, is likely to be attained. It is estimated that this amount will be produced as follows: By a crop in Rio of 4,000,000 bags, one in Santos of 5,000,000 bags, and by yields in Bahia and Victoria of 1,000,000 bags. This will be nearly double the total outturn in 1895-96, when it was not more than 5,489,000 bags of all kinds. Contrast the above figures with those relating to the Brazil coffee crops in the poor, lean years of 1893-94 of 1889-90, and 1887-88, when the quantities raised were respectively confined to, say, 4,300,000 bags, 4,220,000 bags, and 3,042,000 bags—and it will be seen what immense strides have been made in the planting and growth of the Brazil description of coffee within the past nine or ten years. Such an enormous increase in the available supply of coffee, therefore, cannot fail to influence the market in favour of buyers by bringing about a much lower range of prices. It is also argued that, although the promised abundance does not consist of the kind of coffee exactly suited to the tastes of British or European consumers, it is none the less sure to serve as a useful substitute for the higher-priced plantation sorts. Some foreign drinkers of the beverage, whose palates are not so nicely discriminating in their choice between passable or medium qualities and grades of a richer flavour, may discard the former in favour of the latter, especially in view of the greater comparative cheapness of the article. Mention of one or two instances

will suffice to show that there has already been a considerable fall in value since it became known that a thumping crop of Brazil coffee was practically assured for the present season. From 55s and 52s 6d in the middle of last February, down to 50s 6d and 41s recently, there has been a fall in quotations of 4s 6d to 8s 6d per cwt. for September and December deliveries of fair Channel Rio, as recorded by the London Produce Clearing House. 'Good average' Santos has declined in proportion, and from 52s 9d in July the price here has since fallen to 48s, which is a moderate figure: whilst in Havre the same quality of coffee has lately been disposed of in the terminal market at 60½fr, instead of 75fr in June last, and 96fr to 100 fr in September, 1895 and 1894. Regarded thus, the position of coffee just now is one from which the home trade in London may derive real encouragement, as it seems that more reasonable prices for the favourite berry are about to set in and rule for some time to come. Once Brazil coffee grows to be relatively cheap, it will be a pretty true harbinger of easier rates for what are termed 'fancy' coloury sorts. As the depreciation in common coffee goes on, the disparity between that and prices for the finer grades will doubtless appear more marked, and the low valuations in the one case will help to bring down extremely high rates in the other."

COFFEE LOOKING UP.—Another large coffee company. This time in the East. It is called the Malay Peninsula Coffee Company, Limited. It has a capital of £100,000, divided into equal proportions of 6 per cent. cumulative preference and ordinary shares of £1 each, subscriptions being invited for 50,000 preference and 30,000 ordinary. It is acquiring, as going concerns, certain coffee estates, comprising about 10,000 acres of land held on leases for 999 years, in the protected state of the Malay Peninsula. The area now under coffee of various ages aggregates about 1,048 acres of which 538 acres are in full bearing, 108 acres in partial bearing, and 402 acres young plants, which come into bearing in 1897 and 1898. The profits for the year ending October 31, 1895, are certified, at an exchange of 2s 2d, to have amounted to £6,350, and those for the current year are estimated, on an exchange of 2s 2½d, to amount to £7,075. The purchase price is £92,000, of which £72,000 is to be paid in cash and £20,000 in fully-paid ordinary shares. The directors are Sir Alexander Wilson (chairman of the Mercantile Bank of India, Limited), R. J. Boyle (chairman of the Moabund Tea Company, Limited), and D. M. Lumsden (chairman of the Port Dickson Coffee Company, Limited), who will join the board after allotment. It is announced that Mr. Thomas Heslop Hill, the principal proprietor of the estates, has consented to undertake the management of the estates for a period of five years. The following contracts have been entered into: A contract between Thomas Heslop Hill and Thomas David Traill of the one part, and Richard Blamey Magor, as Trustee on behalf of the Company, for the purchase of the Siliau Coffee Estate, dated September 8, 1896. A contract between Thomas Heslop Hill of the one part and Messrs. George Williamson & Co. and D. M. Lumsden of the other part, dated September 22, 1896, with reference to assisting in the formation of the Company.—*H. and C. Mail*, Oct. 2.

DRUG REPORT.

(From the *Chemist and Druggist*.)

London, Oct. 1st.

ARECA-NUTS.—Sixteen bags were offered today, for which 28s per cwt. is asked, but that figure was not obtainable at auction.

CARDAMOMS.—In strong demand, with keen competition. At auction 166 cases were all disposed of at an irregular advance, averaging about 3d per lb., but in some instances much exceeding that figure. The following prices paid:—Ceylon-Mysore, fine pale medium to bold plump, 3s 7d to 3s 8d; medium fair pale 3s 3d to 3s 4d; small to medium yellowish and brown 3s to 3s 2d; small yellowish 2s 8d to 2s 11d; ditto brownish 2s 5d;

DEAFNESS. An essay describing a really genuine Cure for Deafness, Ringing in Ears, &c., no matter how severe or long-standing, will be sent post free.—Artificial Eardrums and similar appliances entirely superseded. Address THOMAS KEMPE, VICTORIA CHAMBERS, 19, SOUTHAMPTON BUILDINGS, HOLBORN LONDON.

medium to bold brownish and split 2s 3d; very small pale and dull brown split 2s 1d to 2s 2d per lb. Ceylon-Malabar, fair round brownish 3s 1d per lb. Seed realized from 3s 1d to 3s 5d per lb. The exports of cardamoms from Ceylon between January 1 and September amounted to 222,096 cwt. The "Wanderer" has brought 39 cases from Ceylon this week.

CUBEBS.—Quite neglected. A parcel of 31 packages fair berries, not stalky, from Bombay, was bought in. The price suggested is 35s per cwt. Five bags small, fair, stalky, slightly damaged, berries sold at 5s per cwt. Of a further supply of 127 bags, 10—bold brown berries, from Singapore, without stalk—realised 25s. per cwt. Cubeb-stalks were apparently unsaleable at any price.

KINO.—The auctions today included about 750 lb. (in 7 cases) of good bright reddish, very stringent African kino. No bids at all were made for it, even when 6s per lb. was suggested, and whole parcel was bought in at nominal rates.

KOLA was in considerable supply today, 73 bags, mostly African, being offered; 2d per lb was refused for one lot, and the bulk was bought in; but a lot of good brown West Indian sold cheaply at 5d per lb. Twenty bags of San Domingo kola, a new and very bold variety, were shown today, and bought in. This appears to be the first time that this kola has been seen in our markets. It is said that between three and four tons have lately been shipped to this country and the Continent.

NUX VOMICA—We have to report an arrival of 351 packages from Madras, and 5 from Amsterdam.

OILS (Essential)—The output of Citronella oil in Singapore in 1895 amounted to 400 cases of 30 21 oz. bottles. Among our imports this week have been 10 cases Patchouli oil from Singapore; 340 cases Camphor oil, of which 280 came direct from Kobe and the rest from Hamburg; and 81 packages Citronella oil, four cases fair pale Nutmeg oil were bought in at 2½d per oz. Fifty-two quart-bottles of Cinnamon oil realised 6d per oz. Lime oil (W. I.) firmly held at 5s per lb. for good distilled or expressed. Lemon-grass oil unaltered. At auction one or two parcels were bought in; on the spot 2d to 2½d per oz is asked, and for October shipment 19-16th d. per oz. e. i. f. has been accepted. Citronella oil is somewhat firmer, with buyers, but no sellers, at 10½d per lb. e. i. f. shipment to end of year. On the spot the price is 1s 1d per lb. for drums and 1s 2d per lb. for tins.

QUININE remained quiet during the early part of the week, but on Tuesday a sale of 10,000 oz. B. & S., or Brunswick second-hand bulk, was reported at the price running up to 10½d per oz., showing a slightly easier tendency today. The market closes with no sellers below 10½d. It is stated that the deliveries of quinine from the London warehouses in September amounted to 110,000 oz. while the arrivals were practically nil. Some quinine made by a new French factory has recently been shown in the market. It is said to compare unfavourably with the standard brands, so far as appearance is concerned.

SENNA.—At today's sales 916 packages of new crop Tinnevelly senna were offered. They met with excellent competition, both on the part of the home and the export trade, and almost the whole sold at full to dearer prices for ordinary and medium grades, while for good qualities, though scarce, the prices realised were hardly so high in proportion. Very common damaged to small dull specky leaves realised ½d to 1d; ordinary small to medium dull to medium greenish 1½d to 2d; fair medium greenish to good medium to bold ditto 2½d to 3½d; fine to bold picked leaves, from 3½d up to 7d per lb. One hundred and twenty-five packages Tinnevelly senna have been received this week.

VANILLA.—About 125 tins, representing about 950 lb. were offered today, and partly sold without much change. Good crystallised Mauritius and Seychelles, 7½ inches to 8 inches 23s 6d to 29s; 5½ inches 7 inches, 23s 6d to 27s 6d; brown from 23s 6d down to 18s, and common qualities at correspondingly lower rates.

INDIAN TEA SALES.

(From *Watson, Sibthorp & Co.'s Tea Report.*)

CALCUTTA, Oct. 14th, 1896.

A quiet tone prevailed in the sales held on the 18th instant. Good liquoring teas were wanted and prices kept fairly steady, but for all other kinds the market was weak and prices generally favored buyers. 24,209 packages changed hands.

Since the season opened on the 21st May last 19 series of sales have been held at which 361,266 packages sold at an average of As. 7-7 or about 8½d per lb. as compared with 302,037 packages sold in 17 sales before the holidays last year at As. 8 or about 8½d per lb. and 311,111 packages sold in 19 sales in 1894 at As. 9-2 or about 9½d per lb. Details annexed.

The average price of the 24,209 packages sold is As. 6-10 or nearly 7½d. per lb. as compared with 21,890 packages sold on the 10th October 1895 at As. 8-3 or nearly 9d per lb. and 23,781 packages sold on the 4th October 1894 at As. 8-5 or nearly 9d per lb.

The exports from 1st April to 10th October from here to Great Britain are 76,902,931 lb. as compared with 68,971,959 lb. at the corresponding period last season and 68,951,733 lb. in 1894.

NOTE.—Last sale's average was As. 7-2 or nearly 8d.

TELEGRAMS.—Reuter telegraphed from London on the 18th instant—Offered 56,000, sold 44,000 packages. Common to medium rather easier. Fine qualities full rates. Average 9½d. "Type" 6½d.

EXCHANGE.—Document bills, 6 months' sight, 1s 2½d.

FREIGHT.—Steamer—£1-6-3 per ton of 50 ft.

(From *William Moran & Co.'s Market Report.*)

CALCUTTA, Oct. 21st, 1896.

On the 1st inst., 25,596 chests were offered and 25,443 sold. Good to finest qualities alone maintained values, while common to medium sorts declined from a quarter to half an anna per pound. On the 8th instant, when 24,505 packages changed hands, common and mediums were again somewhat lower, good to fine showing no change. For Friday next about 30,000 chests are catalogued.

Signs of an early closing are reported from all districts; rain is wanted generally, and without this the manufacturing season will probably come to an end earlier than last year.

Total quantity of Tea passed through Calcutta from 1st April to 19th October.

SMOKERS SHOULD USE

CALVERT'S DENTO-PHENOLENE,

A FRAGRANT LIQUID DENTIFRICE AND MOUTH-WASH.

Editor of *Health* says:—"The most effective preparation for ridding the mouth of the aroma of tobacco, and leaving a pleasant taste." Sold in 1s. 6d., 2s. 6d., and 1 lb. 7s. 6d. bottles, by Chemists, & c.

F. C. CALVERT & CO., MANCHESTER.

THEFTS OF VANILLA IN MEXICO.—A wail comes from Mexico about the prevalence of thefts of vanilla beans, the thieves usually gathering them before fully ripe. So bold have the thieves become and so frequent are their raids that it is claimed the planters contemplate a change of crop, vanilla, owing to the losses by theft, being no longer profitable.—*Oil Paint and Drug Reporter.*

MARKET RATES FOR OLD AND NEW PRODUCTS.

THE AGRICULTURAL MAGAZINE, COLOMBO.

Added as a Supplement Monthly to the "TROPICAL AGRICULTURIST."

The following pages include the Contents of the *Agricultural Magazine* for November:—

Vol. VIII.]

NOVEMBER, 1896.

[No. 5.

SEASON REPORT FOR SEPTEMBER.

WESTERN PROVINCE.—Harvesting of Yala crop going on and preparation for Maha-harvest prospects good. Fruits and vegetables scarce in Kalutara and Negombo. Vegetable supply good but fruit

scarce in Colombo District. Rainfall fairly plentiful.

Central Province.—Yala crop being harvested, good or fair generally, but particularly good in Matale. Yala crop being sown or in early stages of growth. Prospect of dry grains good. Rainfall sufficient in most parts, good supply of fruits and vegetables in Newera Eliya.

Northern Province—The rain in the North was fairly well distributed, though very heavy in some parts. Paddy sowing commenced with the rains. A few cases of murrain reported from kilakumulai in Vavuniya District.

Southern Province.—Maha sowing going on. A good harvest was taken at Tissa. Rain abundant. A few cases of cattle disease.

Eastern Province. Ettala paddy crop in Batticaloa being harvested and yield good. Munmari crop being delayed for want of rain, but has progressed fairly in Trincomalee. Preparation for sowing Indian corn and fine grain in Batticaloa, Tobacco land being manured for next years crop in Trincomalee.

N. W. Province.—Yala crop gathered or being taken in, though slightly interfered with by rain in some parts. Preparation for Maha crop in progress. In Puttalam the rainfall was very

scanty. Crop prospects good in Kurunegalle District. Murrain among cattle.

Province of Uva.—Maha harvest complete; crop good in all parts except Wellassa where damage was done to the paddy fields.

Sowing for Yala going on. Fruits and vegetables scarce.

N. C. Province—Yala harvest still going on—reaping and threshing in progress. Tanks more or less half full, though some small tanks are dry. Health of cattle bad. Murrain in all palatas except Tamankaduwa and hoof and mouth disease general.

Province of Sabaragamuwa.—Yala crop being taken in, harvest good in Kegalle, fair in Ratnapura. Early Maha crops progressing satisfactorily. Dry grain prospects generally good. Cattle free from disease.

RAINFALL TAKEN AT THE SCHOOL OF AGRICULTURE DURING THE MONTH OF OCTOBER, 1896.

Greatest amount of rainfall in any 24 hours—
on the other 15th October, 1.96 inches.

Recorded by M. W. K. BANDARA,

IMPLEMENTS.

A catalogue of the various implements of husbandry used in Ceylon would not occupy much space, and the lack of variety cannot be said to be made up by efficiency. If it be argued that there is nothing that can supercede the so called native plough under certain conditions we are only too ready to admit the contention. But what we hold is that the native plough is not suited to all kinds of land, and its work can be done far better at certain times even on the land which it may be said to be best suited for. Not only are there various forms of ploughs used in modern agriculture—different ploughs for different kinds of land, but there are various forms of tillage implements other than the plough which are used at different stages in the preparation of land for sowing, so as to make that preparation as thorough as possible. Each of these distinct forms of tillage implements has its own special work and one cannot satisfactorily perform the work of the other. In native husbandry there is but one implement for animal power, a simple hoe or one-tined cultivator, for a plough it is not, since it has not the essential element of every plough, viz. the mould-board by which a furrow slice is turned-over. A cultivator is all very well in its place. Indeed it may be said to be indispensable for its special work, but to say that the plough can be superceded by the cultivator is absurd. The operation in native husbandry which is most akin to the work of a properly constructed plough, is the turning over of the sods as a first operation in preparing for sowing. This part of the work is done by manual labour, by means of the mamoty, and the work is no doubt as thorough as it can be and possibly superior in quality to that which would be done by a plough. We are aware that in paddy cultivation the conditions of culture are such as do not greatly favour the use of an iron mould-board plough. There are in fact certain situations of land where it would be impossible at any period to use such an implement, but these are only exceptional cases, and a light mould-board plough, weighing not more than 25 lb, so as to be within the power of village buffaloes to draw, is an implement that should be an acquisition to most cultivators.

The mistake that was made in the attempt to supercede the native plough for ploughing work was to introduce what was a novelty from England. The Howard "Cingalee" plough which was specially designed and constructed to meet the wants of the Ceylon paddy cultivator weighed about 50 lb. and cost over R20. It would have been the better plan to have endeavoured to improve the native implements of husbandry by slow degrees and so to gradually work out a perfect implement. Modern English ploughs have indeed been the outcome of such gradual evolution.

The idea of improving native implements is not a popular one, for the failure of the first attempt to improve the native plough has done much damage to the cause, just as the dismal failure of the Alfred model farm for a long time stood in the way of any attempts being made at dairy farming and stock breeding.

In India much good is resulting from persistent attention to the implement question. The implements now in use by our cultivators should as far possible be modified, and suitable forms of new implements and machines, as would tend to facilitate and improve their work should be introduced. The school of agriculture ought to be given the opportunity of working at the improvement of implements, and by trials with various forms of new implements and machines as are likely to suit local conditions, of a-certaining, which of them are best adapted to the needs of cultivators in Ceylon.

For ploughing up coconut and other lands under "dry" cultivation there is a great demand for light ploughs, and these are now being locally manufactured: an advertisement in the present issue of the Magazine indicates how and at what cost these could be procured. We have had many enquiries about the "planet junior" hand implements (with fittings for various kinds of work) which have been in use at the School of Agriculture. The implements are the best of their kind, and we would refer those who are in want of these handy and useful machines to Messrs. W. H. Davies & Co., who are Agents for the manufacturers.

OCCATIONAL NOTES.

In the present issue will be found the first of a series of papers as the peculiarities of coconut cultivation in India. Most of the information given is taken from the Indian Gazetteers and reproduced in the Watt's Economic Products of India. We have sometimes had enquiries made as to the method of culture in India, and we have no doubt that the authentic information embodied in the account now reproduced will be acceptable to our readers, some of whom will no doubt be inclined to think that more than one of the methods in vogue in N.W. India are very peculiar indeed—at any rate quite unlike anything practised in Ceylon. In future issues we shall refer to the forms of cultivation in vogue in other parts of the Indian peninsula.

The shipment of Homco manure referred to in our last issue has arrived and trials of this fertilizer, which comes to us with such an excellent reputation, have already been begun. Those of our subscribers who may be anxious to give it a trial can have small supplies (of say $\frac{1}{4}$ cwt.) on application to the Superintendent School of Agriculture.

The students of the School of Forestry have gone on tour, for a practical course of instruction, in charge of Mr. Brown the chief conservator of forests. The tour will extend over a month, during which time the forests between Kurunegalle and Dambool will be traversed, while it is expected that Galboda and Newera Eliya will also be included in the tour. We can only wish that the School of Agriculture was as fortunate as its sister institution in having provision made which will enable its students also to travel and so gain that practical acquaintance with Ceylon products as cultivated on a commercial scale, which is so necessary to complete their course of training.

PECULIARITIES OF COCONUT CULTIVATION IN INDIA.

1. BOMBAY.

The coconut palm would seem to be grown almost solely for the "toddy" it produces in the Bombay Presidency. With reference to the Kolaba district it is said that the coconut is the most liquor-yielding palm, and that the moist, sandy soil, brackish water and abundance of fish manure make its growth so vigorous that the yield of juice is much in excess of the wants of the district. The trees are grown within walled or hedged enclosures, sometimes entirely given to coconut palms, in other cases partly planted with mangoes, jack, betel-nut, and other fruit trees. Every garden has one or two wells, from which the trees are watered by a Persian wheel. In starting a cocoa-nut garden, a bed is prepared, and in it, at the beginning of the rainy season, from twenty to forty large, ripe, unhusked nuts are planted 2 feet deep. The bed is kept soaked with water, and after from three to six months the nut begins to sprout. The seedlings are left undisturbed for two years. They are then, at the beginning of the rains, planted in sandy soil in rows about 18 ft. apart, and with a distance of about 15 ft. between the plants. For about a foot and a half round each plant the ground is hollowed 3 or 4 inches deep, and during the dry months the plants are watered daily or once in two days, and once or twice in the year, enriched with fish manure or with a mixture of salt and *nachni*. When nine years old the trees begin to yield nuts twice a year and sometimes thrice, 120 nuts being the yearly average yield from each tree. The trees are then ready to be tapped, each cocoa-palm, when ready for tapping is estimated to represent an average outlay of about R9. The coconut gardens are generally owned by high-caste Hindus, who let the trees to some rich Bhandari who has agreed to supply the owner of the liquor-shops with fermented or distilled juice. The Bhandari pays the owner of the garden R1 a month for every three trees. Of the Thana District it is stated that the seed-nuts are prepared in different ways, the best and oldest tree in the garden being set apart for growing seed-nuts. The nuts take from seven to twelve months to dry on the trees; when dry they are taken down, generally in April or May, or left to drop. When taken down they are either kept in the house for two or three months to let half of the water in the nut dry, or if, the fibrous outer shell is not dry, they are laid on the house-roof or tied to a tree to dry. After the nuts are dry they are sometimes thrown into a well and left there for three months when they sprout. If the nuts are left to drop from the tree, which is the usual practice in Bassein, they are either kept in the house for some time and then left to sprout in a well, or they are buried immediately after they have fallen. When the nuts are ready for planting they are buried either entirely or from one half or two thirds in sweet laud, generally from 1 to 2 feet apart, and sometimes as close as 9 inches. A little grass, rice straw or dry plantain leaves are spread over the nuts to shade them. If white ants get at the nuts the grass is taken away, and some salt or saltish mud mixed with wood ashes and a second layer of earth is laid over the nuts.

Nuts are sometimes planted as late as August, but the regular season is from March to May, when, unless the ground is damp and their inner moisture is enough for their nourishment, the nuts want watering every second or third day until rain falls. The nuts begin to sprout from four to six months after they are planted, and when the seedlings are a year or eighteen months, or, what is better, two years old they are fit for planting. At Bassein the price of seedlings varies from 5d. for a one or one and a half year old seedling, to 6d. (4 annas) for a two year-old plant.

In planting them out the seedlings are set about six yards apart in the 2 feet deep holes, in which about $1\frac{1}{2}$ pounds of wood-ashes have been laid to keep off white-ants, and the garden must be very carefully fenced to keep off cattle. The plants are then watered every second day, if not every day, for the first year; every third day, if not every second day, for the second and third year, and every third day, if possible, for the fourth and fifth year. Watering is then generally stopped, though some Bassein gardeners go on watering grown trees every seventh or eighth day. For two years after they are planted out the young trees are shaded by palm leaves or by growing *mutheli* plantains. During the rains, from its fifth to its tenth year, a ditch is dug round the tree and its roots cut, and little sandbanks are raised round the tree to keep the rainwater from running off. In the ditch round the tree, 22 pounds of powdered dry fish manure is sprinkled and covered with earth, and watered if there is no rain at the time. Besides fish manure the palms get salt-mud covered with the leaves of the croton-oil plant (*Croton Tiglium*) and after five or six days with a layer of earth; or they get a mixture of cow-dung and wood-ashes covered with earth; or night soil, which on the whole is the best manure. Palms suffer from an insect named *bhonga* which gnaws the roots of the tree, and from the large black carpenter-bee which bores the spikes of its half-opened leaves. When a palm is suffering from the attacks of the *bhonga*, a dark red juice oozes from the trunk. When this is noticed, a hole 3 inches sq. is cut in the trunk from 4-6 feet above where the juice is coming out, and is filled with salt, which drives away or kills the insect. To get rid of the boring insect, it is either drawn out by the hand, or it is killed by pouring into the spike assafœtida water or salt water.

Another reference to the yield of the palm in the Bombay Pres. says. "A well-watered and manured tree, in good soil, begins to yield when it is five years old and in bad soil when it is eight or ten years old. A palm varies in height from 50 to 100 feet, and is in greatest vigour between the ages of twenty and forty. It continues to yield till it is eighty, and lives to be a hundred. A good tree yields 3 or 4 times a year, the average number of nuts being about 75." In the report of the Kathiawar district in the Bombay gazette there occurs a short but interesting account of the coconut. At Mahuva in 1875, 1500 acres were planted with 170,000 plants. At Khanderā there is a garden with 7,000 palms, and there are about 2,000 at Bhavnager. A singular fact about the coconut palm is that it grows freely in solid limestone, provided a hole about $3\frac{1}{2}$ feet

deep and 3 in diameter is cut in the rock and filled with mould. All the trees at Gopuate are planted in solid rock.

DR. HENRY TRIMEN F.R.S.

Dr. Trimen, whose sad death occurred on the 17th. October, was no mere botanical enthusiast as many were inclined to think, but a scientific worker, who made use of his special knowledge as far as in him lay for the advancement of the colony's welfare. Indeed it will be long before we find another official with so intimate an acquaintance with our tropical flora not only in its purely botanical, but also in its economic aspects. In classifying and describing the vegetable products of the Island whenever the necessity arose, Dr. Trimen's services were invaluable and he will be sadly missed whenever work of this description has to be done. Besides, as a botanical referee on local questions who is there with Dr. Trimen's experience, and whose authoritative decisions will be accepted? A close worker who allowed himself little recreation, Dr. Trimen was yet a social companion and courteous in the highest degree.

We had the pleasure of being associated with him in dealing with the Ceylon collections for the Imperial Institute in London, and saw something of his wonderful energy and thoroughness of work. Very shortly before his death we had occasion to consult him on a point connected with the teaching of botany, and we would refer to the matter here as being of interest to others. We wrote to the Doctor animadverting on the botanical classification of fruits as given in ordinary text books of botany, remarking how inadequate such a mode of classification was for tropical fruit, and giving examples which presented difficulties. Here is Dr. Trimen's reply, which, while it illustrates the decisive manner in which he was wont to state his opinion on botanical questions, shows at the same time the characteristic humour of his style and conversation:—

Dear,—

You are quite right about the classification of fruits in text books. I have denounced them for years. But as a fact, they may mostly be disregarded, being never employed by working botanist and usually invented for the delectation of the unhappy student. Most of those in the list you give are succulent and several truly "berries" but most would require special description, not falling under particular names. Some have special names: that of the pomegranate is called a "balaustion" in the books. Anybody is at liberty to call it so if he chooses, but he may just as well call it a pomegranate at once, as there is nothing else like it in structure.

You will find correct descriptions of our native fruits in my Flora.

Yours very truly,

HENRY TRIMEN.

"NITRAGIN," OR THE USE OF PURE CULTIVATION BACTERIA FOR LEGUMINOUS CROPS.

The inquiry by Dr. Nobbe took three distinct lines:—

1. What the nature of the process was by which leguminous nodule-possessing plants were enabled to assimilate free atmospheric nitrogen.

2. How the working of the nodules manifested itself in soils of different degrees of richness in nitrogen.

3. Whether the bacteria originating from the nodules of different kinds of leguminous plants were all of one and the same kind, or if each group of leguminous plants had its particular nodule activity.

As to 1, Nobbe concluded that, like the green plant, the bacteria could not by themselves assimilate free nitrogen, but that they were gradually changed in the nodules to a particular form known as "bacteriods," and that it was by virtue of their network arrangement in the cells of the nodules, which presented the largest possible surface to the air, that they were enabled to absorb the free nitrogen of the cell-sap and render it assimilable by the plant.

In regard to the second point, Nobbe found that the working of the nodules attains its full efficiency only when the soluble soil-nitrogen was nearly used up. Accordingly, the more nitrogen that the soil contained capable for being taken up by the plant, the less was the difference between plants that had been inoculated and those that had not. As a consequence of this, quickly growing leguminous plants such as peas, vetches, and the like, that used up the nitrogen of the soil quickly, showed the influence of the inoculation much more rapidly than did clover, lathyrus, &c. In the end, however, the inoculated plants possessed an advantage in that the demands of leguminous plants for nitrogenous food are exceptionally high.

The third question is the one of most importance to us at the present time. Nobbe showed, by his experiments, that though the bacteria from the nodules of leguminous plants of different families were in outward appearance scarcely to be distinguished from one another, yet in their behaviour to plants they showed very marked differences. The bacteria from nodules of the pea, for instance, acted admirably when used for inoculating the pea plant, and also did somewhat less well when used for vetches (which are nearly related to the pea); but they did not do at all when used on clovers, serradella, robinia &c.

Similarly, bacteria from the nodules of red clover, robinia &c., would answer with those kinds of plants from which they originated, but had no action whatever on peas. From this, Nobbe drew the conclusion that every leguminous plant is most influenced by bacteria of its own kind, though bacteria of nearly related kinds can replace one another to a certain extent; but that bacteria from leguminous plants belonging to families widely separated from one another, either from no nodules at all or only small ones with no appreciable influence on the supply of nitrogenous nourishment.

No absolute distinction, however, could be drawn respecting the activity possessed by the bacteria of nodules of different families of leguminous plants. For it was one only of degree. Pure cultivations of unlike origin represented not special kinds but only adoptable forms; these were able in a weaker degree to enter into symbiosis with all the families; these were the *neutral* bacteria. If one such form entered a leguminous root and, while forming nodules in it, increased, its descendants would be influenced by the parent plant so energetically that they would only possess the full power of working in the case of leguminous families of the same kind, but they would lose it more or less for all others. On sowing, therefore, in any particular soil, nodules can only be formed with certainty when the neutral bacteria or the form of bacteria adopted for the particular kind of plant in question are present in sufficient quantity. If in a soil already exhausted more or less, by heavy leguminous cropping of its neutral bacteria, there be put in another leguminous plant which is not closely related to the previous one, there will no longer be the conditions present for the formation of nodules, or else this formation will be so meagre that it has but little value for the nitrogenous nourishment of the plant. Hence, wherever there are no nodule-bacteria in soils, or these are present only in small quantity, the lacking bacteria should be artificially supplied by inoculation of the soil through the medium of the proper "Nitragin" for the crop in question.

In preparing "Nitragin" for commercial use, Nobbe and Hiltner took the "pure cultivation" obtained as already described, transferred it, with suitable precautions, to a glass bottle holding 8 to 10 oz., and containing at the bottom a small quantity of agar-gelatine on which it was then allowed to grow; the bottle was sealed and the contents kept from the light. In this form the "Nitragin" is available for use, and can now be purchased by anyone desirous of trying it.

MILK AND MILK PRODUCTS.

(By MR. JAMES MOLLISON),

Superintendent Government Farms, Bombay.

Milk sours so quickly in India that in order to get fresh cream the use of a De Laval Separator becomes almost compulsory. The separator will be found economical in other ways. By means of a separator the milk, so soon as it is milked, can be separated into its two products—cream and separated milk. The latter soon sours, but the former must be kept to ripen before it can be made into good butter. The separation of whole milk by mechanical power makes a large dairy unnecessary, for no room is required for the numerous vessels otherwise needed for setting the milk. If it is found necessary to raise cream by the ordinary milk-setting process in India, the quicker the cream is made to rise the better the results will be; because even under the most favourable conditions it is improbable that all the cream can be skimmed off before the milk has thickened by turning sour. The loss can be avoided if the milk is maintained at an artificially low temperature by means of ice.

Cream rises quickest in a falling temperature, and to expedite the process on practical lines in India I should recommend that shallow vessels be used, that these be placed in pans containing the coolest well water procurable, or that water be cooled specially for the purpose by allowing it to filter through a series of earthenware chatties. It is well enough known that if porous earthenware vessels are placed on a stand one above the other so that the water passes from one to the other, even though the temperature of the atmosphere is high, evaporation takes place which lowers the temperature of the water so that, that which collects in the lowest vessel is comparatively cool and is ordinarily of sufficiently low temperature to rapidly lower the temperature of new milk, provided the milk is set in its vessel in the water. This is a cheaper method of rapidly cooling milk than the use of ice. There is however one objection. If milk is cooled below the temperature of the surrounding air, it will (like any other cold substance) condense the moisture of the surrounding air and along with this moisture it will absorb any taint or odour existing in that atmosphere. Impure air under these conditions will certainly injure milk. The point therefore to be sure of is that the dairy is thoroughly ventilated and that the air which circulates through it is pure. If on the other hand milk at a comparatively high temperature is exposed to air of a lower temperature the latter will certainly be the absorbent. These statements tend to show that the refrigerator in common use in dairies is of great value. The refrigerator is designed to aerate milk and at the same time to cool it. The refrigerator is essentially a continuous tube ranged like a "worm" inside a frame. Cold water is made to circulate through the continuous tube whilst the milk passes as a thin film over the metal frame; the milk is cooled and at the same time is thoroughly exposed to the atmosphere so that the animal odour which invariably impregnates new milk is driven off. It is at the same time thoroughly exposed to the oxidizing influence of pure air. This refrigerating process is employed to prepare milk for conveyance by road or rail in closed vessels to considerable distances and the milk is undoubtedly all the better for the treatment.

I have found that in hot weather milk so treated is further preserved against any fermentative change if the vessels are covered with hoods of wet canvas. The heat of the sun or of the air evaporates the water from the hood and the heat necessary for volatilization of water is derived partly from the milk which is of course further cooled.

A cool well ventilated dairy kept scrupulously clean is as necessary in India as elsewhere. A well planned and well arranged dairy should, in India, have high walls with a considerable air space between the ceiling and the double tiled roof. Either a cement concrete floor or a stone floor does very well, but the joints of the latter should be well cemented. The walls also should be plastered with cement to a height of three or four feet or tiled, and there should be no underground drain. Milk must necessarily be spilled from time to time on the dairy floor, and if there are crevices in the floor or walls, small

quantities of milk are sure to enter and ferment and cause unsanitary conditions which should be avoided. The windows and doors of the dairy should face the west or north. The main walls should be of considerable thickness and a veranda all round will still further help to keep the dairy cool. If the windows open inwards and wire gauze is stretched upon and tacked to the window frame, ventilation will be secured whilst flies and other insects will be excluded.

SOME PARTICULARS REGARDING RHEA-CULTIVATION.

[Being extracts from a report to the Government of India by James Montgomery Esq. Kangra]
Propogation.

(1) By seed: This course must be adopted in some cases, when the germ of the plants has to be carried over great distances; but probably much disappointment will attend the result. To obtain the seed great care is requisite, and a favourable atmospheric season. For this purpose young spring shoots should be carefully reserved in a well sheltered position. These plants should receive special care and be well manured. During the rainy season they must be kept thoroughly drained, and after that has passed, the ground should be carefully loosened round the plants. If the rains cease early in October, a fair amount of seed may be obtained; but, as far as I can judge, no amount of care can ensure success, so much depending on the season a dry one being most favourable for the full development of the seed. The only method of sowing, which I found successful was on a gentle hot-bed under glass, in March and April; the seed scattered over the surface, covered very thinly with sifted earth, and carefully shaded from the sun, until the plants were about three inches high, when sunlight may be gradually admitted. When sufficiently strong they should be planted out a foot apart every way.

(2) By cuttings of the stems: The stems should be spring-grown ones, allowed to ripen well and not cut until duly ripe. Then divide the ripened portion of the stem where the cuticle has turned fully brown into short lengths, each including three eyes or buds, cut a quarter of an inch below the bottom bud and as much above the top one, and plant with the centre bud level with the surface. If the weather be damp and cloudy, they will readily strike root, otherwise they will require shading for a week or ten days, the soil being kept moist. As with seedlings, I find a foot apart every way the most advantageous distance as very few shoots are thrown up the first year.

(3) By divisions of the roots: This is by far the most advantageous and profitable method. The plants for this purpose should be three or four years old. After gathering the spring crop, dig out each plant, carefully and remove the earth from the roots. I generally put the mass of roots into running water for a short time; this cleanses them thoroughly and enables the gardener to see his work clearly. The tuberous portions of the roots will be found to show a large number of eyes similar to those on a potato.

From these carefully separate portions, each containing five or six eyes; let the cuts be clean and reject all fibrous and decayed matter. Expose these sets to the sun for a couple of hours to dry the surface of the wounds, and then plant six inches deep, and at the full distance of four feet apart every ways. In this way two good crops will be obtained from them the first year.

The soil and situation for plantations.—A rich loam suits the plants best, but they will grow in any kind of soil, provided a full supply of moisture be available, combined with through drainage. The latter is emergently required, particularly during the rainy season, as should the land be retentive and become swampy the plants will shortly decay in a very short period. If the land be poor, a liberal supply of manure is requisite, otherwise the stems will be short and weak, yielding scarcely any fibre. In no part of Upper India can the plant be successfully cultivated unless water for irrigation be available during the dry season. The facilities for obtaining an ample supply of water, combined with the moderate temperature at all seasons, renders this district particularly favourable to the plant.

Cultivation.—Should the land have been stocked with seedlings or cuttings (paragraphs 4 and 5), then in the following spring, after having reaped the first crop of available shoots, every other plant should be transferred to fresh ground, and put down at two feet apart. The following year the same course should be pursued, taking up each alternate root and replanting at four feet apart. After this the plants may well remain undisturbed for four years, hoeing well between after each crop, clearing away weeds, irrigating moderately during the dry season, and supplying manure where necessary. The only manure I had at command has been vegetable, consisting mainly of the leaves and wood portion of the plant itself, and of tree and vegetable leaves, stored up for the purpose, with which I mix a considerable amount of wood-ashes. With the aid of this only I have kept plants growing in the same spot for upwards of six years; but consequent on the then very crowded state of the ground, the stems were short and very weak. I would therefore recommend a thorough removal after four years, the land to be then well ploughed, cleaned and manured.

Gathering the Crop.—The period of reaping will vary slightly according to difference of season. I find that in this district three good crops can be relied on each year;—the first during the latter half of April, the second about the commencement of August; and the third about the end of November. It will be found of much advantage to postpone reaping the second and particularly the third, as long as the condition of the plants will admit. If the third crop be cut in the middle of November, the weather here during the remainder of that month is not sufficiently cold to keep back the new growth; and should the young shoots appear above ground early in January, the frosts which are usual at that period seriously injure them and lessen the spring crop. My own experience indicate that the stems should be gathered so soon as the cuticle shows a clear brown colour for about one third of the length. At this stage, if the soil be good and the plant healthy, the

stems will be clean from butt to point, the leaves of a rich dark green above, and pearly white below, and the branch-buds, at the axil of each leaf-stalk just showing. If gathered earlier than this I find the connection of the fibres very weak, and that a considerable portion separates in the operation of scraping the peel. If allowed a further growth, the axillary branches will have been thrown out, which will cause breakages at every point both in peeling and cleaning.

The average height of stems grown here has been six feet, after cutting off the soft portion at the top. In gathering I supply each coolie with a sharp pruning knife. With this they cut the ripe stems close to the butt; these are removed in bundles by boys to the nearest manure pit. Here the boys cut off nine inches of the top and pass one hand with a gentle pressure from top to butt; this removes every leaf. The stems are then placed in clean water from whence the peelers remove them and separate the peel, which is again thrown into water, from which it is withdrawn as wanted by the men who clean it. These lay three or four strips of peel on a flat board, scrape it a few times on the inner side from butt to point, then turn it over and repeat the scraping, which removes the cuticle: it is then hung up or thrown on clean grass to dry.

Taking the distance of four feet apart for fully bearing plants, an acre will contain (allowing for paths and water channels) 3000 plants: more than this I find to be too crowded and to increase labour while lessening the actual yield during a four year's period. Thus planted the yield will be a steadily increasing one, and the plants will not show any deterioration.

From repeated experimental weighings, I have deduced the following average proceeds from 1,000 freshly cut 6 feet stems:—

		lb.	
Weights as cut	..	286	
do when dried	..	77.5 = 27	p.c
do Fresh peel	..	83 = 29	"
do Dry peel	..	21.5 = 7.5	"
do Fresh wood	..	203 = 71	"
do Dry wood	..	56 = 19.5	"
do Clean dry fibre	..	18.7 = 6.5	"
do Water	..	208.5 = 73	"

If larger stems, from 7 to 8 feet, be taken, the average is less in the weight of peel, but in the outturn of clean fibre it is slightly greater. With small stems from three to four feet, the percentage of peel is markedly greater, but the return of fibre is barely 35 per cent. Moreover, the extra labour in cutting, peeling, and cleaning these small stems is an important consideration.

The crop cut during the rainy season will always contain a large percentage of water, and that of clean fibre be formed rather less, the fibre being also softer than at the other periods of cutting. This I consider due to the fact that at this period the resinous matter in the plant is in a more diluted state, and consequently a greater portion of it is removed during the process of washing and scraping the peel.

I have already expressed my opinion against the use of either immature or small stems as likely to give a result inferior both in quality and quantity: yet I am fully satisfied as to the advisa-

bility of not only sorting the crop, as cut, according to length of stem when necessary, but I would further recommend, that the peel from all stems of five feet and upwards should be divided into two, and the fibre from the upper and lower portions kept distinct. If cultivated as I suggest, the difference in length of the stems at each cutting will be found very small, the monsoon crop always giving the longest stems.

Taking the above as a basis for calculation and knowing that each plant established as I recommend will give at least an average of six stems during the first year, I assume:

3,000 plants × 6 stems × 3 crops × 18 lb.

————— = 972 lb.

1,000

per acre per annum

In earlier estimates, calculating on closely-planted crops and stems four to five feet, I was cautious to restrict my estimate to 750 lb. per acre, but five years' additional experience has shown me that with proper open cultivation 1,000 lb. per acre may be fairly assured.

THE NUTRITIVE PROCESS IN PLANTS.

(PROF. J. REYNOLDS GREEN, D.Sc., F.R.S.)

Carbohydrate reserve materials are not always deposited in the shape of starch grains. The roots of our biennial plants furnish as with examples of another kind of store. If we examine the root of a beet or a mangel wurzel we find that the succulent substance is distinctly sweet to the taste. This sweetness is due to the presence of a solution of cane sugar in the sap. The cells are very turgid with water, and this contains a large percentage of cane sugar. Indeed, the manufacture of sugar for the market from beet-root is, as is well known, of great commercial importance. The sugar here remains in solution, and is not deposited as starch as in the former case. We cannot however, think of it as remaining unchanged after its transit from the leaves. The process of its formation is much like that of the potato at first. But when the leaf starch has been converted into sugar, that sugar is malt sugar as before, and it is transformed into cane sugar after its arrival in the root.

An onion affords us an instance of yet another kind of carbohydrate deposit. Here the fleshy leaves of the bulb, wrapping it so closely round as to form a very solid body, are charged with an accumulation of grape sugar, a third kind, differing from both malt sugar and cane sugar, such as we have seen to occur during the processes already described.

The chief form of deposit in seeds is that of starch, which is the most stable body and the least liable to disturbance. This no doubt is why it is adopted by the plant for this reservoir, as generally a longer time, indeed in some cases a very prolonged period, passes before it is called upon to supply nourishment to the young plants. Carbohydrate material is thus stored in many forms and in various places in the plant. Similarly, nitrogenous material or proteid has its appropriate reservoirs. We have in many seeds, particularly leguminous ones, stores of

this material in the form of definite granular aggregations, which botanists have called *aleurone grains*. If we take for instance the pea or bean, we see that the cells contain embedded in their protoplasm structural elements of two sizes. The larger shows the curious concentric marking peculiar to starch, the smaller show no structure. Instead of turning blue when treated with iodine, they become brown or brownish-yellow. These small grains are the aleurone grains, and are made of proteid. This substance is not all uniform in its properties, indeed, we are familiar with many kinds of proteids, which differ very considerably with regard to the fluids in which they will dissolve. Those proteids which most readily occur to our memory are the albumin or white of egg, the globulin of muscle, the fibrin of blood and so on. Though the vegetable proteids are not met with in the same condition exactly as the animal ones they are nevertheless very much like them in their composition. The aleurone grains of the pea have very striking similarities with the globulin found in muscle. A good deal of the substance is soluble, like that, in a ten per cent. solution of common salt, and salt added to saturation to such a solution of the proteid precipitates it in the form of an amorphous mass. Parts of some aleurone grains are soluble in water, and resemble some of the soluble proteid, of an animal digestion. The albumin of white of egg is very much like a proteid which is found on the underground parts of the asparagus, which must be accordingly called a vegetable albumin.

If we wish to study the deposition of proteids in these vegetable reservoirs, we turn to the seeds rather than to other parts of the plant. In seeds they are very common. The pea and bean have been alluded to; here they occur in conjunction with starch. Other seeds, such as the rape and the linseed, show them associated with oil. In some seeds they are distributed through the whole substance of the embryo; in others they fill the endosperm; in the wheat and barley they occupy a single layer of cells just underneath the outer covering.

In most of the seeds produced by our cultivated plants, the aleurone grains are very simple in structure; indeed they show no structure, being little rounded masses of granular-looking material. In some foreign seeds, particularly the seeds of the castor oil and the Brazil nut, they are much more complicated. In our own flax we have similar ones. Various solvents need to be used to show the structure, which consists of the following parts. There is an oval casing or matrix, part of which dissolves in water, and the rest in 10 per cent solution of common salt. Embedded in it is a large regular crystal of proteid matter, which will only dissolve in a saturated solution of salt. This is known as the crystalloid. Between this and the outside of the grain is a rounded irregular mass of small crystals of the double phosphate of magnesium and calcium, which is known as the globoid. This of course is not proteid though it is always embedded in the grain.

RAPE.

A correspondent to the Ceylon "Observer," has made some enquiries about the cultivation of rape.

In England two forms of rape are distinguished (1) Winter rape (*Coleseed*) *Brassica napus*, and Summer rape (*Colza*) *B. Campestris*. The latter matures faster, though they are both biennial crops. Rape may be said to grow on all soils but best on clay fen or alluvial soils: peaty land suits it very well. The summer rape, however, likes a heavy clay best. The crop grows very rapidly and is ready for eating off as fodder in 12 to 14 weeks. The seed is best drilled 12 to 15 in apart, 4 to 6 lb. being required for one acre. It is said that there is no crop on which sheep feed faster and do better than rape. The leaves are rather liable to attack by fly, and a remedy against this is dusting over with lime, ashes, soot or salt. The seed crop yields from 24 to 36 bushels per acre. Rape seed contains 35 to 40 % of oil. The residue or cake is good for feeding though much inferior to linseed cake. In spite of it being rather bitter to the taste, stock do not dislike it. When mustard seed is found along with rape the cake is only fit for manure for which it is valuable as containing nitrogen in a slowly available condition. Mustard seed commonly occurs with Indian rape seed which is therefore quite unsuitable for feeding purposes. To detect the presence of mustard in rape mix the cake with cold water and leave in a covered vessel: a characteristic smell is soon perceived. Generally rape is first fed and then allowed to seed. On the continent it is commonly grown for green manuring or ploughing its herbage into the soil. Rape oil is extensively used for machinery, lamps &c., but the oil and cake so called are not exclusively obtained from this oil nor are the name *Colza* oil and rape oil used to distinguish the produce of different plants. The seeds of other cruciferous plants are also crushed with rape and *Colza*. In particularly rich soils rape sometimes grows to a height of 3 or 4 feet.

In the "characteristics and composition of feeding stuffs" given in the H. and A. Society's Journal we read of Rape seed (seed of *Brassica napus* and *campestris*):

"It has a greenish mottled appearance and a bitter taste which renders it distasteful to cattle at first. Should be given in small quantities to begin with. Not suited for calves. When given to milch cows the quantity should not exceed 2 or 3 lb. per head per day, or it will give a disagreeable taste to milk and butter. Sometimes very impure. A dangerous impurity is mustard seed. May be detected by steeping in cold water for some hours and noting smell of mustard. Danger may be avoided by steeping the ground cake in boiling water."

The average composition of pure rape cake is given as "albuminoids 31, oil 10, and carbohydrates 30 per cent." Rape is a good deal cultivated in India. In our next we shall refer to the special features of rape cultivation in India.

REPORT OF THE SUPERINTENDENT OF
SCHOOL OF AGRICULTURE FOR 1895.

(To be continued.)

Model Farm.

The subjoined statement shows the transactions of the Model Farm for the past year. The lease of this Crown land was acquired from a private individual, who had been holding it on payment, (out of the Dairy funds,) of a sum of Rs. 4,400 as compensation. A rental of Rs. 1,350 a year is paid to Government for the occupation of the land, and any profits that may accrue after this obligation is fulfilled goes to the credit of the Dairy Fund.

In August Mr. Samaranayaka, an Assistant Master at the School of Agriculture, was detached for service at the Model Farm, where he was to take up his residence in order to better look after the interest of the farm and remain in charge of such of the dairy cattle as might be sent there from time to time. Mr. Samaranayaka, has had on an average about 25 head of cattle under his care at a time, the stock consisting chiefly of dry cows and growing calves. The main source of revenue from the farm is the land under Mauritius grass, and since Mr. Samaranayaka has taken charge of the place better returns than before have been shown.

Grass Land about Dairy.

These lands which supply the dairy cattle with the bulk of their green fodder, the value of which is debited to the dairy, yielded a net return of Rs. 750 during the year.

The financial position of the dairy will be seen at a glance in the following summary:—

	Rs.	c.
Vote from Government in 1893	19,539	12
Special advance in 1894	11,500	0
	31,039	12
Paid in 1893 to revenue	7,627	86
Paid in 1894	1,262	65
Paid in 1895	5,237	35
Balance to be paid	16,911	26
	31,039	12

Balance in hand on December 31, 1895,	R3,114.44
Valuation of stock, building, and utensils,	R15,500

There has been some outcry against the expenditure on the work of the School of Agriculture. If, as I gather from the last Administration Report of the Director, the annual cost of the Agricultural School proper is between Rs. 8,000 and Rs. 9,000, it must be remembered that there is a considerable revenue from its appertinent institutions—the Dairy and Model Farms. The net profits from these establishments were in 1895 (a bad year for the dairy) over Rs. 6,000. In a good working year, when the profits of the dairy should be nearly double what they were last year, and with the agricultural students paying double the fees they have paid hitherto (a measure which came into force from January, 1896), the expenditure on all the establishments under my charge would be practically met by the revenue.

Experimental Cultivation.

An experiment in grape cultivation was begun at the School of Agriculture by arrangement made with Signor Zanetti, an Italian gentleman,

who has had considerable experience in viticulture in Italy and Australia. Nearly an acre of land in the vicinity of the dairy was laid under vines in August, and the plants—720 in number—are being treated after the Continental fashion. The following are the varieties of grapes that are receiving a trial: Gordo Blanco, Lady's Finger, Champion Muscat, Gross Colman, Snow Muscat Marillion (white grapes), Black Prince, Black Ambro (black grapes), and Chassalas d'Or (a golden grape). It is too early to speak definitely with regard to the vineyard at the school, but so far the vines have made fair progress under the system they have been grown, despite the poor soil in which they have been planted and the severe drought they experienced during the latter part of the year. There is yet much to be done in the way of modifying their treatment to suit local conditions, which Signor Zanetti is gradually doing after studying the progress of the plants.

Trials were also made with teosinte or reana (*Enchlyana Luxurians*), "Delft" grass (*Andropogon Schoenanthus*), and different varieties of the cow pea. Teosinte and Delft grass were of course grown only as fodder plants. The yield of the former was at the rate of 15 tons per acre per cutting, or, if five full cuttings could be counted upon in the year, the enormous annual yield of 75 tons per acre. It should be stated, however, that the soil on which the teosinte was grown was a rich black mould. On a poor sand the crop made little growth without manure, and was almost killed out during the dry season.

Delft grass, said to be the prevalent grass on the island of Delft off the northern coast, also proved to be a heavy cropper, yielding at the rate of 8 tons 4 cwt. per acre per cutting; and four or five cuttings a year may be counted upon.

Unfortunately your cattle did not take at all to this grass, objecting apparently to the strong aniscent of the leaves. Delft grass is a close ally of the wild grasses used for hay-making in Western India, and ought to be well suited for that purpose, only that Ceylon stock do not take to hay at all. Even the imported Sind cattle will not touch hay after having eaten Mauritius grass for a time.

Of cow peas, the most satisfactory variety proved to be that known as "the wonderful." Its yield, when grown for fodder, was at the rate of 5½ tons per acre; and cattle took very kindly both to this and to teosinte grass. The legumes are good for human food, and though a little coarse found purchasers. The cow pea is, however, best known as a nitrogen restoring crop, and since I established the plant at the school I have had many applications for seed, while considerable interest has been evinced by our more advanced agriculturists in the question of the assimilation of free nitrogen by certain plants and the important bearing it has on practical agriculture. The study of this question from a local standpoint will no doubt bring out some useful facts. The school has formed further connections with agricultural institutions in India and the Colonies, and the agricultural Magazine continues to be a valuable medium of local and foreign communication.

C. DRIEBERG, B.A., F.H.A.S.,
Superintendent.

Statement showing the receipts, Cost of Maintenance, and Profit of the Government Dairy

Farm during the year 1895.		Amount.	
Date.	Receipts.	Rs.	c.

GENERAL ITEMS.

"Mulch," says the American Agriculturist, "keeps the ground loose and porous, and this causes the moisture in the ground below to be drawn upwards towards the surface. This is especially important in hot dry weather, for at such a time a plant can hardly have too much moisture. How can a large field be mulched? By repeated cultivation. The light coating of soil on the top acts very much as does a regular mulch of straw or leaves, helping plants wonderfully in withstanding drought. Moreover, the stirring of the soil destroys all weedgrowth. . . . Farmers, as a rule, do not do half enough in the way of cultivating their crops when growing. Let them try thorough tillage for one season, and they will be surprised and delighted with the results."

Labour-saving machines used in the preparation of the land and cultivation of crops is one of the chief features in the Agriculture of today. While deep cultivation and subsoiling are of special value in a large proportion of soils, shallow or top-cultivation is not only useful but it becomes in all hot and dry countries imperative for the growth of crops in all kinds of soils. Keeping a fine layer of soil on the surface of the

ground does more than anything else to keep and economise the moisture in the soil. It acts as a mulch, and this is the easiest and cheapest form in which it can be provided. . . . Soil having been once cultivated to a good depth by ploughing and subsoiling, it does not require to be constantly turned over with a plough, but what it needs is the constant stirring and pulverising of the surface. For this purpose several very effective implements have been invented, which like the old fashioned harrow will cultivate a much larger surface with the same strength of team as would be required for ploughing. On some soils and in some seasons rolling is found very beneficial as it tends to compact the soil. . . . Some of these surface cultivating machines act as weeders, while nearly all have the power of producing on the surface finely pulverised soil, which acts as a mulch and prevents the evaporation of moisture from the land.

The following, considered an excellent remedy for sore eyes appears in the Cape Agricultural journal: Sulphate of Zinc, *three drachms*, Liquid Extract of Opium, *three ounces*, to be mixed in *twelve ounces* of rain water.

One ounce of the mixture to half a pint of water; of this two ounces to be syringed (a small glass syringe is best) into the eye.

A correspondent writes: I have used the above for two seasons and find it an unfailing remedy. This season out of thirty head treated, only two or three required a second application. If possible, keep the affected beast (with me mostly young cattle) separate from the herd as it is very contagious.

Referring to Banana or Plantain meal, the *Produce world* says:

The best meal is reported to be made when the fruit is green: just before it ripens. It should be peeled, and then cut into slices—if to be dried in the sun the thinner the better. Steel knives should not be used, silver or nickel are the best; but substitutes may be made of ivory, bone, or even bamboo. After cutting up, the slices may be spread out on a cloth in the sun to dry, or the fruit may be dried in special ovens. When thoroughly dry the slices are ground or pounded into meal or flour, then sifted through a fine sieve, and all particles of fibre or foreign matter removed.

If the fruit is partially ripe it will not dry well; the dry portions will be of a dark colour, and spoil the *quality* of the flour.

Mr. J. W. Crowhurst and F.R.C.V.S. states that in treating warts, particularly when very small and in great numbers, he has found arsenic in the form of Fowler's solution, produce good results. The dose given to cattle is about one tablespoonful once or twice a day for 10 or 15 days.

Mr. Long in answer to Mr. Ascroft stated in the House of Commons that there were 10,753,000 Cattle and 29,775,000 sheep in the United Kingdom at the date of the last return. No official estimate of their value exists, but if £9 per head in the case of cattle, and £1 per head in the case of sheep be taken as a fair average, the value of the cattle would be nearly £97,000,000 and that of the sheep £30,000,000.

* The TROPICAL AGRICULTURIST *

◇ MONTHLY. ◇

Vol. XVI.]

COLOMBO, DECEMBER 1ST, 1896.

[No. 6.

RAMIE, RHEA OR CHINA GRASS FAURE'S NEW PATENT RAMIE FIBRE DECORTICATOR.

NO MORE RIBBONS OR STRIPS.

It is claimed for this machine that it forms the connecting link, so long sought for between the grower of ramie and the spinner and manufacturer of the fibre; and that its effect will be to place ramie on the list of every-day

so long advocated, has been definitely acknowledged to be erroneous, experience having proved that to obtain the full advantages of the many brilliant qualities of the fibre, the stems must be treated in the green state. The chemist has insisted that as little as possible must be done to the green stems by machinery, leaving the main treatment to be carried out by chemicals. The machinist has retorted that the fibre is seriously damaged by chemical process, which take away its strength, its lustre, and its ductility, and that therefore machinery must play the important part; and so for many years the battle has been waged, first one side and then the other gaining the victory.

textiles to be produced and utilized without difficulty in any desired quantity. The battle has been long between the chemist and the machinist concerning the role each has to play in the production of ramie, and until the point has been definitely settled, the fibre, notwithstanding its magnificent qualities—strength, lustre, ductility, capacity for taking colour by printing and dyeing, and for mixing with other fibres, has been under cloud. The manipulation of the stems in the dry state

The problem, commercially considered, has been to obtain a machine, which can carry out economically the following processes without damaging the fibre:

- Remove the woody parts from the green stems;
- Remove the outer skin or cuticle, which has so long baffled all efforts, mechanical and chemical, to remove it;
- Extract as much as possible of the juices of the stems, so as to simplify and cheapen the degumming process. The two former processes are effectively carried out by

hand labour in China, where workmen scrape each stem and remove the skin and the wood, but leave most of the juice in the fibre.

All inventors of ramie decorticators have concentrated their efforts on machines to produce ribbons. Needless to say, the object aimed at has fallen far short of the real necessities of the case, hence the long delays and numerous disappointments with which this fibre is associated. Ramie ribbons have three serious, almost fatal defects: They contain a large percentage of woody matter; they contain the outer skin or cuticle of the stem, which has been the despair of the chemist to solve and remove; and they contain the major portion of the juice which coagulates in drying and becomes gummy.

Mr. Faure has aimed at the construction of a machine to produce *not ribbons but the fibre* in one operation, free from woody matter, from skin, and with the least possible amount of juice in it. His product is equivalent to "China Grass," but in an improved condition, because his machine is much more regular and efficient in its action than the varying hand labour obtainable in China, and because the possibility of adulterating the fibre is done away with. Mr. Faure's first decorticator obtained the gold medal at the last Paris trials. It was the best of the machines exhibited there and tested by actual work with green ramie stems. Being desirous of improving on his first attempt, he has since constructed several decorticating machines, each one showing marked superiority over the preceding ones. A skilled engineer and machine maker, with every facility in his own works and ample means for carrying out his ideas, he had the benefit of another very important advantage, namely, the growing of ramie on his own estate in the Limousin near his works, which enabled him to practically test his ideas by actual experiments on the raw material—a combination of advantages probably not enjoyed by any other inventor of decorticators. Patiently and scientifically he has, step by step, worked out the problem; and the machine illustrated on the previous page represents the results of his several years' labours. It is simple, inexpensive, and does its work admirably.

It is fed by two men, working alternately, each holding in his hand about ten stems. The stems are used in the same condition as cut, with the leaves on. The operation of feeding is as follows: The stems are passed in twice. They enter the machine, leaf ends first, and after having been treated about two-thirds of their length they are withdrawn, an operation easily carried out, and fed in a second time, the thick ends first, so as to complete the operation. It frees the stems from all woody matter and from the outer skin or cuticle and extracts a large portion of the juice, thus producing fibre retaining all its valuable qualities.

The machine, which weights 11 cwts., is simple in construction, very strong and not liable to get out of order. It consists mainly of the framework and driving gear, the decorticating drum carrying beaters, and the feed bed. This latter is the important feature of the machine, by reason of its special contour which varies at different parts to suit the various descriptions of work which the machine has to perform. The first part of the bed is curved outwards, the second is straight, and the third is curved inwards. The ramie stems are fed into the machine over the first part of the bed, where the woody portion becomes immediately broken and partly removed; the strip passes on to the second part, and as the speed of the beaters is considerably greater than that at which the stems are fed into the machine, a scraping effect is produced on the strips, seeing that the distance between the beaters and the surface of the bed is less than the thickness of the strip. This scraping action effects a double purpose; it attacks the outer skin and also all matters extraneous to the fibres. The strips or stricks of filaments then pass down vertically into the machine and the separated matters, viz. most of the woody parts, the skin and gummy substances, are thrown out to a distance by the centrifugal force of the

beater drum. When the stems have entered to within a short distance of their end, the return movement is effected and they are withdrawn. During the withdrawal the following action takes place:—At the inward curve or third part of the bed, the filaments are slightly and gradually grazed by the beater blades, which throw out the coarser of the debris still adhering. The operation is performed with great delicacy; the fibres assume the position of the chord of the curve and are constantly agitated by the beaters. When the fibres arrive at the second part of the bed, as the space between it and the beaters is infinitely reduced, the entire removal of matters still adhering to the fibres is effected, and these latter leave the machine:—white, parallel and free from woody matter, from skin, and from the major portion of the juice. The concave bed or breast is mounted in such a way, that its position to the action of the beaters is easily regulated. The brackets which carry the bed are supported by spiral spring cushions and flexible legs, the object being to obtain a rubbing action between the beaters and the fibre, having for its special object the loosening and removal of the skin or outer cuticle. The elastic bed gives way or vibrates an enormous number of times per minute, and this produces the desired rubbing or "knuckle joint" action between the beaters and the fibres on the bed. The shape of the feed bed causes it to remain clean and free from extraneous matter through the action of the beaters. Clogging is thus rendered impossible. All abnormal strains are avoided, and the machine can be kept at work from morning till night without stoppages for cleaning. The refuse falls underneath the machine and is removed from time to time. In the case of a number of machines working together, an endless band or conveyor, passing under the machines, removes the refuse continuously and so keeps the neighbourhood of the machines perfectly free from it.

Faure's machine is simple in construction, and capable of being easily worked by native labour in the ramie plantations or in works connected therewith. Although simple, it needs to be constructed with the greatest accuracy in order to ensure effective working. The cylinder, carrying the steel beaters is perfectly balanced and accurate in its action; it runs at 400 to 450 revolutions per minute; the surface of the beaters is perfectly parallel with the setting of the feed bed and capable of working close up to it, say within a distance equal to the thickness of a piece of writing paper. The feed bed, the varying profile of which is of such enormous importance in the efficacy of the machine, is made with the greatest of accuracy and of the best materials.

With regard to the production, practical experience shows that two men working at one machine can treat 360 lb. of fresh green stems per hour, or about 32 cwt. per day of ten hours. The amount of dry fibre produced, depends largely on the nature and growth of the stems; the percentage of fibre contained in green stems varies very much according to circumstances. On a 5 per cent. basis, the nett production of dry fibre by each machine per day of ten hours is 180 lb. When the stems are specially good, more than 200 lb. of dry fibre have been produced per machine in ten hours. Under ordinary circumstances a production varying from 160 to 200 lb. of dry fibre in ten hours per machine may be expected.

The apparently small production per machine needs a word of explanation, seeing that decorticating machines are being made professing to treat large quantities of green ramie stems per day, but it must be borne in mind that their production is ribbons not fibre. Ramie ribbons or strips must always be unsatisfactory, and will, no doubt, in time disappear from the market. The buyer has no means of testing their value, the quality or percentage of the fibre, and whether damaged or not by the decorticating machine; hence he will only give a low price for an unknown article, in addition to which they cannot be highly compressed and packed into proper bales as other fibres are. Therefore the

freight on ribbons is unduly high; they also contain a very large percentage of useless material on which freight has to be paid.

Faure's machine produces *Abre*, which will always rank higher in the market even than China grass, by reason of its regularity in condition and quality. The buyer can easily see and test what he is buying; he will therefore be disposed to give it its proper classification and pay its full market value; in addition to which, by reason of the bales being well pressed and containing little else than ramie fibre, the freight and expenses per ton will be at the minimum.

The product of Fauro's ramie fibre machine cannot be compared with the ordinary ribbons or strips. It is an entirely different article, and will fetch a very different price in the market. The machine, when treating good stems, produces about 5 per cent. of waste fibre, that is to say, fibre which escapes from the hands of the workmen. It cannot, however, be correctly classified as waste, seeing that it has excellent value for second quality ramie, and here we would note that in relation to ramie, there is practically no real waste, as the fibre is always saleable. Its qualities of strength and colour are so great that, even for paper-making, the very shortest of the fibre always has excellent value and fetches good prices.

In connection with the question of fibre production and waste, the nature of the growth of the stems must be considered. If they are planted too far apart, the stems have a tendency to unduly throw out branches. Each branch represents a break in the continuity of the fibre of the parent stem. Recent plantings of ramie are being made with the stems much closer together, so as to prevent undue branching and improve the quality of the fibre. Green stems grown in a tropical or subtropical climate give the best results. The growth being quick, the stems carry plenty of fresh green juice, which assists the decortication very much by leaving the fibre freely and carrying with it in its downward course from the beating point of the machine large quantities of extraneous matter. The condition of the stems at the time of treatment also plays an important part. In order to ensure the best possible fibre, the stem should be treated within a few hours of being cut. They should not be over-ripe, as the fibre deteriorates after the stems have arrived at maturity. The best plan is to cut them either just at full maturity or slightly before. The fibre thus obtained excels in whiteness and ductility, retains its full lustre, and shows to the best advantage during subsequent manufacturing operations, such as preparing, combing, spinning, dyeing, &c. Each machine requires about one horse-power to drive it. When a number of machines are working together less power will suffice; thus eight horse-power will drive ten machines.

Faure's patent decorticators were sent last year to Italy, Egypt, Tonquin, &c. and have more than justified the expectations that were raised respecting their action and the quality of fibre they produce.

A few words will not be out of place concerning the disposal of the fibre after leaving the machine. It may be dried at once and then haled, its condition being the same as China grass. Experiments made last season show that steeping the fibre in boiling water for about half an hour and squeezing it thoroughly previous to drying, gives very favourable results, as when dried the fibre is soft and separates freely. The gummy nature of the juice having been seriously modified by boiling, the final degumming process is rendered very easy, cheap, and short. The addition of about 1 per cent. of carbonate of soda to the water may be made if the circumstances are favourable. This partially degums the fibre and does away with any possibility of fermentation or deterioration during the transport to manufacturing countries.

The sole representation of Mr. Faure's interest, both for machines, licenses, and patents has been entrusted to Mr. Thos. Barraclough, of 20 Bucklersbury, London, to whom all applications should be made.

GRAPE FRUIT vs. PUMELOE—A NEW FRUIT FOR ENGLAND;

THE KEW GARDEN AUTHORITIES JUSTIFIED AND THE "FRUIT-GROWER" CONVICTED OF RECKLESS IGNORANCE.

WE regret very much that in the *Tropical Agriculturist* for August last (page 120) we took over a stupid paragraph from the *Fruit-grower* entitled "The Pumeloc in England: The Ignorance of Kew Gardens," which only showed the ignorance of the writer and which was entirely inaccurate in its reference to Kew and especially to Dr. Morris. The paragraph in question pointed out what no one had disputed, that the Pumelo is not a new fruit in England, although the writer erroneously supposed that the authorities at Kew were in ignorance of the fact. In reality, Dr. Morris of Kew Gardens in a letter to the *Saturday Review* had referred to "GRAPE FRUIT"—not Pumelo, from which indeed it differs as much as a fine apple does from a crab. The Grape Fruit is so highly esteemed in the United States that single specimens are retailed at a dollar a piece, and we need scarcely add that the fruit is entirely new to England.

We are glad to be able in this connection to reproduce here an article written by the editor of *Garden and Forest*, the leading horticultural journal in America, which clearly shows the value of Grape Fruit; and this we must give prominently in our monthly periodical in order to correct the blunder made in August; and also because the subject is one of special interest to us in Ceylon. We should like to know if anything has been done at Henaratgoda or Peradeniya—Hakgala is, we presume, too high—to do justice to the Grape Fruit? Meantime we quote as follows:—

GRAPE FRUIT.

Under the title of "The Coming Fruit," Dr. D. Morris, of Kew, not long since wrote to *The Saturday Review*, urging upon the people of the West India Islands to establish groves of Grape-fruit trees of the best quality. When passing through New York in the early part of this year, Dr. Morris was very strongly impressed by the quantity of this fruit which the New York market was demanding, and our readers will, perhaps, remember an article in the present volume of *Garden and Forest*, on page 163, in which he gives a sketch of the origin and history of the Shaddock, Pomelo, Grape-Fruit, Forbidden-fruit and other varieties which belong to this group of Citrus-fruits, and are botanically classified under the species *Citrus decumana*. They are quite distinct botanically from true Oranges, Citrons or other groups of the Orange family, and since they have mostly been raised from seed with little care given to selection, they vary widely in quality. The frost which ruined the Orange groves of Florida has temporarily shortened the supply, and Dr. Morris quotes a paragraph from this paper recalling the sale of small-sized grape-fruit of at least a dollar each, and is, Dr. Morris suggests, probably the highest price ever paid for specimens of the orange tribe.

No doubt, it will be long before there is any over-production of grape-fruit, since the demand for it increases every year, and it is constantly becoming more popular as a breakfast fruit. It is beautiful, is said to have medicinal value, and the more it is used, the more highly it is relished. Beyond question it would be a profitable fruit to raise in the West Indies, and probably the English people will in time prize it more highly than they do now, and furnish an additional outlet for West Indian groves. Since the Florida frost, this country has absorbed almost the whole West India supply, although much

of it has been very inferior in quality. How does it happen that the enterprising orchardists of California have not been awake to the situation? There is no reason why they should not supply the east during a part of the year with all the grape-fruit needed. The limited quantities thus far received from California have lacked weight and juiciness. Wherever the fruit is grown it should be borne in mind that the highest success will only come with the use of the best varieties. There is no need to grow the thick-skinned and bitter sorts, or those with a dry, cottony pulp, when there are varieties both of the apple-shaped and pear-shaped fruits, with silky skin, full of juice and of a most delightful flavour, with just enough bitter to give it piquancy and suggest its tonic quality.—[*Garden and Forest.*]

CAPSICUM, POTATOES, AND SOME OTHER ECONOMIC SOLANACEÆ OF INDIA.

[BY YOGE DRACRI GHOSA, OF THE AGRICULTURAL SOCIETY OF INDIA.]

Of the numerous *Solanaceæ* found in India, Nees von Esenbeck in his synopsis of Indian *Solanaceæ* counts about 45 species as indigenous to India.

Royle, in his illustrations, does not mention more than 44 species, which, excluding the Himalayan species, reduces the number for the plains to about 33; the Himalayan species being—

- | | |
|----------------------|-----------------------|
| 1. Lycium europæum. | 6. S. crassipetalum |
| 2. Atropa acuminata. | 7. S. rubrum. |
| 3. Hyoscyamus niger. | 8. Physalis angulata. |
| 4. Solanum laxum. | 9. Datura ferox. |
| 5. S. Lysimachoides. | 10. Amisodus luridus. |

According, therefore to these authorities, we can rely upon 27 species of *Solanum*, three of *Physalis*, and three of *Datura* as tropical. But there are several other species of this order, although not recognised by the earlier authors as indigenous to India, or more accurately, to the plains of India. For, barring few exceptions, a great many species, which have been known to have been introduced in the plains from foreign countries, are nevertheless found to be growing wild in the colder regions and higher latitudes. If by India we limit ourselves to the plains or even to the peninsula, the statement about indigenous and introduced plants is correct. But if in the term India we include the Himalayan ranges, we must hesitate before we declare a particular species as not indigenous. A species may have been introduced to the plains from foreign countries, say the Dahlia. All our garden Dahlia bulbs are received from Europe, but that is no sufficient reason to say that the Dahlia is not indigenous for Dahlias are pretty common in the hills, and at places where they could not have been introduced. Many indigenous plants and seeds or bulbs of plants, though quite common in the country, are annually imported, because better results are obtained from plant raised from imported seeds. It has not noften been urged that, because there is not to be ordinarily found a Sanskrit name for a plant, it must be an introduced one. But the reverse of this proposition would not hold true, for we know we have a Sanskrit name for tobacco, *tāmrakuta*, but nevertheless it is admittedly an introduced plant. The same may be said of many others. On the other hand, coffee was ordinarily believed to have been unknown to the Hindoos; at least the beverage produced by the infusion of the roasted berries. In the Vedas, however, a beverage is mentioned; which is said to have been used for keeping off sleep, and which was much sought for by the gamblers of the time. It is said to have been prepared from the seeds of a berry named *Bibhidaka*, its other name being *Jāgara* the Wakeful, which grows in the casis of the Desert. The use of coffee as a beverage must have been forgotten, until, introduced by the Arabs under the name of *kawa*, who brought the berries from their own country, not knowing that they were indigenous to India. The cultivation of the coffee plants dates from still later time, but notwithstanding all this, it would not be fair to say that the coffee species is an introduced plant. The ancient Hindoos, even in the Vedic age, or at least in the ages of the *Sutras* and *Smritis* were aware of introduced and foreign plants, and in certain observances they have disallowed foreign articles. However, be that as it may, following the authorities, there altogether 33 species, a few and a very few of them are economically known, the rest being of interest to the botanist or the naturalist.

The foremost of the *Solanaceæ* are the Capsicum or Chillies, sometimes known as Cayenne-pepper. Botanically, six species of this sub-genus pertain to India either as indigenous or as domesticated and cultivated. The whole of this family

or sub-genus may be considered as originally foreign, but that they have since so much adapted themselves to the soil and the climate that several of them have been completely acclimatised or naturalised here, freely flowering, bearing pods, ripening seeds, and self-sowing themselves again. Many individuals of some of the species of this family have been seen in most outlandish places, the seeds having been scattered by birds. Amongst them may be included the *Dhanilanka*, the bird's-eye chilly.

The Genus *Capsicum*, Linnæus Gen. Pl. II 892. is almost identical with Genus N. 338 of Schreb., the same of Pitton de Tournefort and G. Von Miller's Dictionary, 4, p. 411, is as distinct a genus as any other genus. There is, however, much confusion in the nomenclature of the several species, different authors having given different names to the same thing, and it is not unoften to find the same author in different publications having differently named the same plant.

Dr. G Watt counts—

1 *Capsicum annuum*, Linnæus; 2. *C. fastigiatum*, Blume; 3. *C. frutescens*, Linnæus; 4. *C. grossum* of Professor C. L. Willdenow, four species, *Capsicum minimum* of Roxburgh being, according to him, identical with *C. fastigiatum* of Blume and *C. baccatum* of Wallich.

Dr. Watt's, however, is the shortest list of all. Roxburgh counts six, namely:—

1. *Capsicum purpureum*—Roxburgh.
2. *Capsicum annuum*, Willdenow sp. I, 1,050.
3. *Capsicum grossum*, Willdenow sp. I, 1,051.
4. *Capsicum frutescens*, Willdenow sp. I, 1,051.
5. *Capsicum minimum*, Roxburgh and
6. *Capsicum cerasiforme* Willdenow, sp. I, 1,051.

Or, in the other words, he differs from Willdenow in making three species of 1,051 of that author.

It will thus be seen that *C. grossum* is admitted to be a distinct species. It has been acknowledged to be so even in Nees von Esenbeck's standard work. It is also the case with *C. frutescens* of Linnæus, but *C. Chamæcerasus* of Nees von Esenbeck is identically the same as *C. cerasiforme* of Poiret and the *C. purpureum* of Roxburgh. The *C. baccatum* of Linnæus is no doubt the same as *C. frutescens* of Rumphius Herbarium Amboinense.

I. CAPSICUM GROSSUM.

The *kaffrimarie* of the bazaar is cultivated all over India. It bears fruit all the year round, and is identical with the Bellpepper of Firminger. The rind is reflex, and swelled into various shapes. The thick fleshy skin is not quite so acrid and is not unoften used as a pot-herb by itself. In Nepal, which evidently is its home, it is known as *karsini* or *Kharaseni*, indicating the locality whence it was primarily introduced.

All the six species of Roxburgh are cultivated in India: they are indiscriminately called *Lanka* or *Lankamaric* or *Lal maric*. In the bazaar the size, shape, and colour distinguish them, by goat-pepper, bird-pepper, chilly, bell-pepper and Cayenne pepper, the chillies being the smallest-sized fruits. There are a great many varieties of them, some of which are ornamental. The pods are long, straight, of the size of a finger, long, bent, thin, and about an inch long, round, berrylike fruits, and looking more or less like tomatoes; some of them are orange, bright red, pale amber, purple black, yellow, and some are as white as a jasmine. The vernacular names are accordingly *kaffrimarie*, *lal lankamaric*, *holdolankamaric*, *dhanilanka*, and *kulelanka*. White fruits appear as the *kulelanka*, the fruits being of the size of a round Bengal plum. Some however call the *Lankamaric* or the *Lal lankamaric* as *Gach-marie*.

The capsicum is not mentioned in Sanskrit works, and not known to have a Sanskrit name. It does not occur in any of the recent Sanskrit medical works, such as the *Madhava Nidana*. It has therefore been considered as introduced fruit, a fruit which, though now almost naturalised here, was quite recently introduced long after the latest Sanskrit medical work was written.

In the Bombay side of India, it is known as *Goamaric* i.e., pepper from Goa, where it is extensively cultivated, perhaps having been introduced by the Portuguese from Brazil or Chili. In Bengal it is *Gach-marie*, i.e., the tree pepper or shrub pepper, as distinguished from *maric*, the true pepper, and which grows on a creeper. It is also called *lankamaric*, i.e., pepper of Lanka (which is the native name of Ceylon) just because the fruit was first brought to Bengal, as it is supposed, in coasting vessels from Ceylon.

Whatever be its origin, it cannot be denied that it is a great boon to the people of Bengal, whose limited means make the black pepper an expensive article for daily use. The acrid flavour of the pods is the only seasoning which the poor Bengali can afford, in addition to salt, to make his dishes palatable. The capsicum is thus the only cheap condiment available to every one. Nature requires a stimulant, and the capsicum supplies this to the million. It stimulates the secretion of saliva, which is so much needed to the rough balls of *chatu* or the mouthfuls of dry *mudi*. Internally also it accelerates digestion, and the pungent juice clears away the phlegm. It is said to be vermicide, but those who use it to excess are not free from ring worm. It has been used by European physicians as a stomachic, and is not unoften given with other recipes in cholera. It has been used with great success in cases of *Cynanche maligna* (Duncan's Med. Comment., Vol. II, 2-12-1783, and Medical Communications, Vol. III, p. 372, 1790). In the pepsia of drunkards and of gouty subjects, it has been found useful. Used externally its tincture proves valuable in elephantiasis, and also in some cases of rheumatism. Its composition, as ascertained by Bracconnot, is:—

Acrid oil	1.9
Wax with red colouring matter	0.9
Brownish starchy matter	9.0
Gum	6.0
Animalised matter	5.0
Woody fibre	67.8
Salts	9.4
Citrate of Potash	6.0
Phosphate and Chloride of Potash	3.4

Fruit *Capsicum annuum* 100.0 pts.

But Bucholz's analysis gives the proportion of *Capsicum annuum* without seeds to Capsicin or Acrid oil as 25 to 1.

The Capsicum is a paying crop. It requires no special attention, and if properly cured in dried condition, it fetches a handsome price. Fresh pods in the North Western Provinces sell at from half-anna to two annas per seer. It is largely cultivated for trading purposes in East Bengal, which principally supplies the market. In a dry state it sells from 9 Rs. to 12 per maund. In England chillies sell at 30s. per cwt. in quiet and dull markets. The acidity of capsicum is due to the alkaloid mentioned before which, when gently heated, becomes fluid, and at a still higher temperature it dissipates in acrid cough-producing fumes. The volatile alkaloid smells much like conine. By treating Capsicum with petroleum, *Capsicols* may be obtained, which, however, is a doubtful substance, and *Capsicin* or *Capsaicin*. Capsicin is sparingly soluble in petroleum, but dissolves readily and abundantly in fatty oils, ether, etc. Allowed to crystallize, we obtain colourless crystals answering to the empiric formula C₉H₁₁O₂. Capsicin is not a glucoside. It is a powerful rubefacient, and helps to relieve constipation. It is therefore a necessary condiment to natives of Bengal, whose principal strength-giving food is based upon fats, and Capsicin dissolves *ghi*.

It is needless to repeat what is well-known about the uses of Capsicum as a condiment and as a culinary article. It however, is an important ingredient in the preparation known as *kasundi*, or *Achar*, *Chutni*, which is prepared by the Hindoos of

Bengal with some ceremony. It is made up by pounding green mangoes with mustard seeds and some other condiments. Capsicum enters in to the preparation of *Gnappi*, also a condiment specially liked by the Burmese. In the North-Western Provinces, where spirits are largely used by the people of the lower castes, pounded Capsicum is mixed with jaggery and water to form a substitute drink on festive occasions. The pungency of the Capsicum and the sweetness of the jaggery combine to produce in the throat, when drunk, an imitation of the spirituous drinks—a cheap imitation no doubt. It is much used by the poor *Mathahs*, *Dhobis*, *Passis*, *Dharikars*, etc., when they cannot afford the expensive *Mahua Rum*.

Roxburgh distinguishes six species by the following characteristics:—

a.—General appearance and habit of the plant, which is identical in them all. They are all shrubby.

b.—Peduncles which are solitary in all five, except in *C. minimum*, Roxb., which has peduncles in pairs.

c.—Character of the leaves: *C. purpureum*, Roxb. has ovate lanceolate. Such is also the case with *C. annum*, Willd. and *C. frutescens*, Willd.; those of *C. grossum*, Willd. being ovate, oblong, and of *C. minimum*, Roxb. ovate-cordate.

The difference in the shape of the leaves is not a criterion.

d.—As to the fruits or berries: why, this also is variable, *c* and *d*. vary under climate and other conditions specially so in a cultivated species.

It has been often noticed that by cultivation, exclusive of selection, the fruits and leaves vary. It has also been observed that seedlings of one species may approach in these characters to those of other species. Seedlings of the Jack fruit have been known to produce serrated leaves, reminding one of its ally the bread-fruit. What is called the *kafrimarie*, and what the botanists have named *Capsicum grossum* by climatic influences have been seen to bear round berries as well as long pods. The garden varieties of red, orange, purple, etc, coloured berries of ornamental *Capsicum*, may be traced to the *C. grossum* and the *C. minimum* to the other long-podded *Capsicum*s. It would therefore serve the cause of science to reduce the unstable species to one which may have some permanent characteristics to distinguish them from other species of the same genus. The *Capsicum*, if divided under two species, No. I and No. II. would serve our purpose for all ordinary occasions. The horticulturist had better look to the result, and let botanists be content with really stable characteristics.

The Genus *Solanum* or the Night-shade described in Scrib. General N. 337, embraces a much larger number of species of much more diversified characteristics than the *Capsicum*. In an economic point of view, the foremost in the genus stands the Potato. Roxburgh enumerates 16 species under two sections, the unarmed and the armed, as of India, omitting altogether the potato which he neglected evidently fancying it to be neither indigenous to the country nor sufficiently acclimatised or naturalised here as to justify him to enumerate it under indigenous solanaceæ. In dealing with other introduced plants, he has not been quite so particular, such as in the case of tobacco or the *Carica* Papaya, etc, etc., both of which freely ripen seeds and seedlings, and may be found in out-of-the-way places. This can be said of the potato. The potato has not been observed anywhere in India to have grown in a wild state from self-grown seeds, although it bears quite freely tomato-like berries which ripen their seeds also. It would be an observable incident if seedlings of potato could be found anywhere in India bearing the edible tubers. But it ought to be said that seedlings from sugarcane have not been seen growing wild and producing saccharine canes. Be that as it may, the potato dates as far back as the tobacco, and perhaps earlier than the papaya!

Perhaps the climate and the soil, at least of the plains of India, are not quite so well suited to the

potato as those of Peru. It has been seen to grow wild, being also originally introduced from Chili.

Following Roxburgh below are given names of some of the economic Solanaceæ which are indigenous or more or less naturalised in India:—

I. Sec. Unarmed.

1. *Solanum pubescens*, Willd. sp. I. 1026
2. *S. auriculatum*, Willd. sp. I. 1025
3. *S. lycopersicum*, Willd. sp. I. 1033
4. *S. rubrum*, Willd. sp. I. 1034
5. *S. decemdentatum*, Roxb.
6. *S. spirale*, Roxb.

II. Sec. Armed.

7. *S. Melongena*, Willd. sp. I. 1036
8. *S. longum*, Roxb.
9. *S. insanum*, Willd. sp. I. 1037
10. *S. æthiopicum*, Willd. sp. I. 1036
11. *S. diffusum*, Roxb.
12. *S. Jacquini*, Willd. sp. I. 1041
13. *S. indicum*, Willd. sp. I. 1042
14. *S. trilobatum*, Willd. sp. I. 1049
15. *S. nirsutum*, Roxb.
16. *S. stramonifolium*, Jacq.

I. 1 and 2 are subarbarcus.

3, 4 and 5 are annual.

6 is shrubby.

2 is downy.

and 5 is hairy all through.

The arms or thorns, hairs or downs, it must be said, are not persistent characters, at least they do not reproduce themselves in the same degree under climatic and cultivating influences. Thorns have been seen to interchange for hairs or downs, and they have also noticed to change in their number, size and hardness. The thorns are not constant in many other plants, not even in the *Ægle Marmelos* (the Bel-fruit), or the *Zizyphus Jujuba* (the hog-plum), which last is notoriously armed, but specimens perfectly free from thorn are not altogether impossible. The same may be said of certain varieties of *S. Melongena* (the egg-plant) which have been seen not to bear any downy substitute of the thorn. The calyx of *S. longum* of Roxburgh is not invariably armed, though that distinguished author has based his species on this, the character of the leaves and the shape of the fruit. He says:—

“I consider this to be a species distinct from *S. Melongena*, for the fruit is always cylindrical, never changing by the culture into any other form.” Roxburgh no doubt was misled by limiting his observation to the Bengal cultivated egg-plants. In the North-Western Provinces, however, the general shape of *S. Melongena* is more cylindrical than oval or round. The same may be said of *S. insanum*. For ordinary purposes, therefore, these three may be made into one species, leaving the gardener to name his varieties.

Neglecting therefore the arms, we may begin with one continued list of 16 indigenous species of *Solanum*, remembering, however, that the potato counts beyond this number.

1. *S. pubescens* Willd.—This is the same as *S. verbascifolium* of Linnæus and *S. erianthum* of Don's Nepal flora, the *Aras* of the native Kavirajas and the *Gandhira* of the Sanskrit authors. This grows all over India, and flowers almost the whole year round; the berries are of the size of a cherry, and they may be seen all though the year. The bark and the leaves are immediately used, and it is said the berries are cooked in curries. This plant has been seen in favourable places to obtain the size of a small tree. It may be distinguished from the next by the colour of its flowers, which are white, while *S. auriculatum* has lively blue, purple flowers.

2. *S. auriculatum*, Willd.—This is the *S. mauritianum*, Sect. Roxburgh says: “Independently of the colour of the flowers, the stipulæ on axillary leaves render the species readily known; in all other respects it almost exactly resembles the preceding, in that plant there are no stipulæ and the flowers are white.

1 and 2 therefore for ordinary purposes may be put under *S. pubescens*. Variety A (white flower). Variety B. (Blue-purple flower and stipule).

3. *S. lycopersicum*, Willd. ordinarily known as *Pomum Amoris*, *Blackroot* and *Rumphius*.—It is the same as *Lycopersicum amoris*, Monch Sol. esculentum, Mill., the tomato of the gardens. This has, however, been made the basis of a separate genus *Lycopersicum* and the tomato is *L. Gleni* of Tournefort. Some authors, however, have distinguished it into a separate species. But from the description it cannot be doubted that *Lycopersicum cerasiforme* of Danal is none other than the *L. esculentum* of Willd., the *Gadba* Begun of the Bengalee gardeners. Some however distinguish the *L. cerasiforme* as *Solanum pseudo-lycopersicum*, which has been named by Genetia as *Solanum sprinum*. It is questionable whether *Lycopersicum Humboldtii* of Willd. is not identically the *S. lycopersicum* of Roxburgh which Willdenow in another place has described as *Solanum Humboldtii*. Any how all the three species of Tournefort's *Lycopersicum*, i.e., *esculentum*, *2 cerasiforme*. and *3 Humboldtii*, are different names of Lone apple which has been thoroughly acclimatised in India and which has been seen to reproduce itself from self-sown seed.

4. *Solanum rubrum*, Willd. This is undoubtedly the same as *solanum nudiflorum* of the same author, for Roxburgh says "seeds received from Mauritius under the name of *Solanum nudiflorum* (Willd. sp. I. 1035) produce this very plant."

Roxburgh, however, has himself sub-divided this species under—

A. *Erythropyrenum*, Roxb. which is *S. Rumphii* of Dan and *S. asperum* of Hoarnem.

B. *Melanoperenum*, which *S. oleraceum* of Rich. Herb. and *S. Nigrum* of Blume. *Solanum nigrum* of Linnæus, however, is no other than—

- S. rubrum*, Mill.
- S. incertum*, Danal.
- S. Roxburghii*, Danal.
- S. trianguluris*, Lunk.
- S. villosum* Lunk.
- S. nodiflorum*, Jacq.

But *Solanum incertum* of Danal is
S. nigrum of Forsk and
S. miniatum of Bernh

The whole forest of names being thus cleared, the *Solanum nigrum*, Willd. may be said to the scientific name of the native plant *Goraski*, which bears red and black berries. This is the *Moko* of Yunani physicians, who speak somewhat of *Arak-i-moko* infusion decoction or extract of *Moko*, a cooling draught, not unoften prescribed in early stages of insanity. It is *Gad-ka-mai* of lower Bengal, a herbaceous plant growing wild throughout India. It bears diminutive tomato-like berries of the size of a small pea, much eaten by children; in a ripe state it has some sweetish taste. It must not, however, be confounded with the *Mokoye* of the North-Western Provinces, which latter is *Flacourtia montana* of Graham, or *Flacourtia enermes* of Roxburgh.

5. *Solanum decemdentatum* Roxb., identical with *S. decemfidum*, Wall. This said to be a native of China and Singapore, but it has been completely naturalised here, for it ripens its fruits and self-sows itself. It is properly speaking a variety only of *S. rubrum*, Willd. mentioned above. It is from its habit a robust pubescent variety of *S. nigrum*. It is an annual herb, but hairy. Its berries are of the size of a pea, and are smooth and bright red when ripe. It is not unoften difficult to distinguish from *S. nigrum* or *S. rubrum*.

4 and 5 therefore for ordinary purposes may be put under one species, *Solanum rubrum*.

Solanum spirale, Roxb.—This has no economic value, except as a narcotic. The sixth species therefore in an economic point of view is—

6. *Solanum tuberosum* L. Its synonyms are *Lycopersicum tuberosum*, Mill, *Papas americanum*, Baugh, *Papas Pernanorum*, Besel, *Batatas peruvianum*, Park.

The potato.—Its ordinary vernacular name is *Alu*, but the term *Alu* is not restricted to this tuber only. It is not unoften, therefore, that it is distinguished from other edible tubers and roots by the name *Gol alu*, i.e., the ball-shaped *alu*, *Vilati alu* i.e., foreign *alu*. The name of *alu*, therefore,

The Potato.—Its ordinary vernacular name is *Alu*, but the term *Alu* is not restricted to this tuber only. It is not unoften, therefore, that it is distinguished from other edible tubers and roots by the name *Gol alu*, i.e., the ball-shaped *alu*, *Vilati alu*, i.e., foreign *alu*. The name of *alu*, therefore, seems to indicate the class to which this article of food belongs. Thus we have *Cankh alu*, identified by some to be *Pachyrrhizus angulatus* Rich, *Dolichos bulbosus*, L. Dr. G. Watt in his Dictionary of Economic Products says that the tuberous root resembles a turnip in taste and consistence, and that it is eaten both raw and boiled. The *Cankh alu*, however, is never known to be used after being boiled. There is another similar looking tuber which sells in the bazaars, of the N.-W.P. as *Sakarkand*, which is always taken boiled. This *Sakarkand*, when boiled, has the consistence of boiled turnips, but has a much sweeter taste than that of turnips, but wants the flavour of turnips. The *Sakarkand* is, however, distinguished from another edible tuber sold in the Bengal bazaar under the name of *Lal alu* or *Mau alu*, which when boiled is as sweet as the former. This later *Lal alu* or *Mau alu* is sometimes called *Lal Sakarkand alu*, which is no other than *Batatas edulis*, Choisy, *Ipomœa Batatas*, Lank, *Convolvulus esculentus*, Spre., *Convolvulus edulis*, Thumb., *Ipomœa Catesbæi*, Meyer. The vernacular name *Sakarkand alu* literally means the sweet tuber *alu*, for *kand* is the Sanskrit name for a tuber, and is the Sanskrit equivalent of the vernacular term *Alu*, which again may be traced to the Sanskrit name *Ol* (*Amorphophallus campanulatus*, Blume,) which is *jamikand* in the N.-W. P., i.e., the earth tuber. The *Lal alu* or the *Lal Sakarkand alu* is *Batatas edulis* variety *a erythrorrhiza* and the white variety, that is, the *Sula Sakarkand alu* is *B. edulis*, variety *b leucorrhiza*. This last is not unoften confounded with the *Cankh alu*. A great many of the *aluu* class are also called *Alus*, thus we have—

<i>Capdi alu</i> ,	<i>Dolichos globosa</i> , Roxb.
<i>Kham alu</i> ,	<i>D. alata</i> , L.
<i>Garane alu</i> ,	<i>D. purpurea</i> and <i>robella</i> , Roxb.
<i>Mau alu</i> ,	<i>D. aculeata</i> , L.
<i>Susani alu</i> ,	<i>D. fasciculata</i> , Roxb.
<i>Kukur alu</i> ,	<i>D. anguina</i> , Roxb.
<i>Sar alu</i> ,	<i>D. nummularia</i> , Lam.
<i>Kanta alu</i> ,	<i>D. pentaphylla</i> , L.

Parkinson, however, puts the potato under *Batatas peruvianum*, although it has been clearly established that the potato originally belonged to Chili, whence it was introduced to Peru.

(To be continued.)

ARTIFICIAL COFFEE-BEANS.—Artificial whole Coffee has long been known as a commercial commodity, but we were scarcely prepared for the statement recently made by the *West Indian and Commercial Advertiser*, that it is now manufactured to an alarming extent, consisting of the roasted meal of different cereals worked up with dextrin. Two different factories, it is stated, have been established at Cologne, which undertake to furnish the requisite machinery and plant, with directions for making the false Coffee-beans. The apparatus supplied by these wholesale swindlers is capable of turning out more than half-a-ton daily, at a cost of about £1 per cwt., good Coffee having nearly five times this value in the market. The fictitious Coffee is difficult of detection by ordinary examination, especially when a proportion of genuine Coffee is mixed with it.—*The Gardeners' Chronicle*.

THE "LADYBIRD" ENEMY OF
COFFEE-BUG—ADVERSE
CRITICISM.

We are very much indebted to Mr. E. E. Green—specially qualified as he is to write with authority on the subject for the following communication sent by him to our "senior" in England. It will be seen that Mr. Green sees no reason in the adverse criticism recently offered, for refusing to make the experiment proposed of infesting "ladybird" beetles to deal with the green-bug on coffee; but as the expense would be widely distributed, our planters in Mysore, the Straits, &c., if they agreed to join in the employment of Mr. Kœbele, it ought not to cost any individual proprietor more than a few rupees. We are back, therefore, at the point where support for a joint mission should be canvassed for—who will lead the way? Mr. Green writes as follows:—

"Budleigh Salterton, Devon, Oct. 8.—I have just been reading in the *Ceylon Observer* (Overland edition, Sept. 16) an article called 'The Ladybird a Humbug,' by an anonymous correspondent.

"There are one or two points in the article that warrant a little criticism. Your correspondent argues from the fact that because 'scale-bugs' abound in Australia, therefore, the introduction of ladybird beetles from that country must manifestly be useless. This fact does not affect the position at all. In their own country the beetles are hampered by numerous natural enemies and parasites that prevent them from increasing sufficiently to get the upperhand of the more prolific bugs. But when the beetles are removed to some other country, having left their natural enemies behind, they are in a position to increase and multiply unchecked as long as a plentiful supply of their food is forthcoming. And this food being the scale-bug, the failure of food would mean the success of the ladybird experiment.

"It may be said that other natural enemies will find them out in the new country. And so they will—in time, but experience shows us that it is usually a long time before fresh enemies acquire the habit of preying upon the new introduction.

"There is no question whatever about the value of the work effected by the 'Vedalia Ladybird,' which was imported from this same scale-infested Australia. In a comparatively short time this insect practically freed the orange plantations of California from the dreaded 'flute-scale' (*Icerya purchasi*) that had proved so destructive there.

"The partial failure of the experiment in other places requires an examination of the particulars of the individual cases before we can judge of their merits. It appears—your quotations supplied by your correspondent—that ladybird beetles have not given entire satisfaction when employed against the ravages of the 'black scale' (*Lecanium oleæ*). Now this particular bug forms a very hard scale in its later stages which serves as a protection for the large number of eggs de-

posited beneath it,—a fact which may possibly account for its ability to resist the attacks of the beetle.

"Our own chief pest the 'green bug' (*Lecanium viride*) is an especially unprotected insect, the skin of the body remaining soft to the end. In this particular it very closely resembles the species which we are told by Mr. Kœbele has been exterminated in Honolulu through the agency of ladybird beetles—also originally hailing from Australia.

"Your correspondent very justly suggests that 'it would be unwise to incur any extraordinary outlay' in the matter. I do not advocate any extraordinary or even very heavy expenditure. A few cents per acre for all the coffee in the island would produce sufficient funds for the starting of the experiment. The suggested remedy is not of course a certainty,—otherwise there would be no two questions about its immediate adoption. But if nothing should ever be attempted for fear of possible failure there would not be much progress in the world! The possible benefit is enormous,—far out-balancing the expense of a possible failure.

"I notice that one of the critics quoted by your correspondent impugns the value of the ladybird, partly because 'she does not extirpate the fungus.' Surely this is rather unreasonable! I presume the fungus in question to be the sooty growth usually associated with an attack of 'bug.' But if you kill the cause (the bug), the effect (the fungus) will soon pass off. Moreover this fungus is not in itself injurious to the plant. It germinates and subsists solely upon excrementitious matter from the bugs.

"As for your correspondent's concluding remarks upon scientific as opposed to practical work. In many cases the life history of an organism must first be known before a logical remedy can be suggested. It is possible that a scientist—from his special training—may be in a better position to carry out the first part of the work; while the practical agriculturist may best know how to apply the results of the first man's labours."

To which we may add that there is surely a high negative value to be attached to the scientist's work when he is able to indicate—as Thwaites originally did and Marshall Ward later—the fruitlessness of the coffee planter trying to expel the leaf fungus from his fields when once it has taken possession. Now, the fungus is supposed to be in a decaying state itself in Ceylon, while the "green-bug" has long been regarded as a far more serious enemy; and science as well as practice points to a remedy in the "Vedalia ladybird" to be got from Queensland.

FRUIT CULTURE ON THE INDIAN
HILLS.

Some interesting facts regarding fruit culture in the hills are given by the Rev. M. M. Carleton in the last issue of the *National Magazine*, published in Calcutta. Mr. Carleton, who is one of the foremost pioneers of the fruit growing industry in the Himalayas, has made various experiments at Ani, a village in Kulu, 4,500 feet above sea-level and

distant 65 miles from Simla. As regards apples it appears that American and English trees have proved almost a failure. The experiments have now extended over a period of ten years, but though the trees themselves flourish and a few apples are produced the return is of the poorest. The conclusion arrived at is that apple cultivation will not be profitable at a lower altitude than 6,600 feet. Apricots, on the contrary, have proved a remarkable success. The native tree of the Kulu valley is not very prolific, but the Kashmir and English varieties yield fruit after the fourth year in great abundance. Mr. Carleton strongly advocates the extension of the cultivation of these varieties in all the lower hills; and he suggests the introduction into Simla of the American fruit-drying machines. He believes that enterprising persons could establish a very profitable industry in preparing dried apricots for the Indian markets. American grapes at Ani have done extremely well. Fifteen years ago the Black Hamburg variety was tried, but it turned out a failure. Mr. Carleton, six years later, sent to America for a hardy prolific vine grown on the northern limit of grape cultivation, where the spring opens in May and the frost comes in September. He held that this variety would ripen in Kulu before the heavy rain, because spring begins in the valley early in March. He has now a vine eight years old which yields 70 lb. of grapes. He remarks that a few such vines around the houses of intelligent zemindars in the Simla district would give a handsome return in the local market especially in the month of June. There can certainly be no question about the great demand for fresh fruit in Simla during the summer months. Experiments with the European orange have shown that the Maltese variety can be grown in the lower hills as high as 4,500 feet. Mr. Carleton thinks a great industry might spring up if the cultivation of oranges was undertaken. From one tree at Ani, eight years old, he gathered 220 oranges last February, which is the month for plucking the fruit, following the Californian custom of leaving the oranges on her trees until the new leaves appear. Snow does not appear to injure the fruit though it affects the leaves. It is pointed out that oranges sold from the Gujranwalla and other gardens fetch from Rs 5 to Rs 8 per 100, and it is believed that still higher prices could be obtained for the Kulu fruit in the Simla market during April. If this were so one tree yielding 200 oranges annually would give the owner a handsome profit, and that on only 10 feet square of ground. It is evident that grape and orange cultivation in the lower hills could be made a very paying industry, but the natives are not enterprising enough to take the matter up. European energy is needed to show them the way, and in the absence of other agency the Forest Department might well step in and give the movement a helping hand.—*Pioneer*, Oct. 3.

THE CIGAR TRADE AND CEYLON TOBACCO.

The success that has attended the cultivation of tobacco in Borneo cannot fail to make a comparison with the result of similar cultivation in Ceylon an unsatisfactory one. It may well be doubted, we think, if there is anything in the quality of the Ceylon-grown leaf to account for this. Indeed, expert opinion has, we know, reported very favourably upon this. Any facts, therefore, which may throw light

upon our relative failure, and may suggest means whereby it may be redressed, cannot but prove both of interest and of possible value. A correspondent now at home writes us that he has been making some inquiry as to the conditions under which Borneo tobacco has secured the favourable position it has in the London market. He consulted, he writes us, one of the most experienced men in the cigar trade, who told him that one reason why the sale of cigars of Borneo tobacco has become so large is that it has been fostered by the endeavours made to popularize it. Not that these would by themselves have sufficed were the quality not good, but that there was not sufficient difference between this and that of Ceylon grown tobacco to account for the different results obtained in the two cases. He pointed out that success must mainly depend upon the appreciation shown by the million, and not upon the opinion of the limited number who can afford to pay for high-priced cigars. The taste of these last has become so highly cultivated and fastidious that they will tolerate no cigars but those of the highest class and such as have become well-seasoned by careful long keeping and seasoning. It is not these men who are the rulers of the tobacco market. They will willingly buy at prices quite above common reach, but they constitute merely a drop in the ocean of cigar consumers. Where one man will satisfy an exigent taste by paying from 6d to 1s 6d each for his cigars, hundreds are satisfied with those they can purchase for 2d to 3d each. It is this second-class of customers that uses up the vast importations of the tobacco from Borneo and Sumatra. The finer production of Havana and other West Indian growth are reserved for the first alone. The expert went on to remark that, owing to the high duty on imported cigars, these were not within the reach of the generality of smokers. It is true, he said, that an attempt had been made to introduce cheaper cigars manufactured abroad, but that to do this necessitated these being made of the coarser tobaccos, and that their manipulation was unsatisfactory. One of the prime qualifications of a cigar is that it shall burn easily and evenly, and with a residual ash that shall not unexpectedly fall. Foreign-made cigars of the cheaper sort do not, it was said, possess this qualification. The result has followed that a distinct preference is shown for those cigars that are made in home factories from imported leaf. It was acknowledged that in some respects these are not equal to those rolled in the producing country. The leaf dries during the passage to Europe and has to be damped before being made up into cigars. To the *connoisseur* who can afford to pay for the higher priced cigar, this is a bar to their use. But the million is not so exacting. He is willing to sacrifice some degree of refinement in flavour for the facility with which the home-made cigar smokes and the low price at which it can be supplied. Every year shows the British-made cigar ousting its foreign-made competitor. Our correspondent doubts in Ceylon tobacco has been tried in this direction. He believes that were the leaf treated in home factories, and as freely advertised as the Borneo tobacco has been, the issue to the attempt lately made to introduce cigars of Ceylon tobacco to the home public would not have been what it was. He advises, for the reasons set forth, that an attempt should be made to introduce our island leaf to the attention of the home cigar factories.

YEAR BOOK OF THE UNITED STATES
AGRICULTURAL DEPARTMENT.

We have been greatly interested in looking over "The Year Book of the United States Department of Agriculture," with a copy of which we have been duly favoured. So much accustomed to the spread-eagleism with which so many of the descriptive and semi-advertising agricultural journals is conducted in that progressive country, it is refreshing to come across carefully sifted facts and figures showing the actual progress in that—when all deductions are made—really grand, ever advancing commonwealth. This volume of 656 pages comprises only a very minute portion of the annual reports or government publications of the year, an epitome of which is given in the appendix; but it contains the cream of all the most valuable papers bearing on agriculture, written by eminently competent men; reports from the different bureaus and divisions such as, in the opinion of the Secretary, are specially calculated to interest and instruct the farmers of the country; and papers from experts of the agricultural experimental stations, discussing in a popular manner the results of investigations in the science of agriculture, or new developments in farming practice. And with a view to make them attractive as well as instructive these papers, or rather essays, are embellished with many interesting and beautifully executed illustrations. "500,000 copies of this book have been published at an expense to the people," we are told, "of \$400,000." Of the contents we can only give a few samples, sufficiently indicating the nature of the advice tendered to farmers and planters by this paternal government:—Reasons for cultivating the soil, by Milton Whitney—The two freezes (1894-5) in Florida, and what they teach, by H. J. Webber—Some additions to our vegetable dietary, by Frederick V. Coville—The pine-apple industry—Principles of pruning—Small fruit culture—Tree planting in the Western Plains—Relation of forests to farms—The shade tree insect problem—Principal enemies of the grape—Climate, soil characteristics, and irrigation methods of California—Human foods—Treatment for fungous diseases of plants—200 weeds: how to know them and how to kill them—Statistics of principal crops, consumption *per capita* of tea, coffee, wine, &c.

Amongst the numerous plates and text illustrations we specially note:—The main building of the U. S. Department of Agriculture.—Cocoanut grove near Palm Beach, Florida, showing effects of freeze.—Plan of irrigation by terraces, monographic display of southern economic timber trees.—An old orange grove killed down by cold, &c., &c.

We at length get at the truth regarding the fearful freeze in Florida, disastrous enough in all conscience, and ought to make the purely tropical planter thankful that at least he is free from some of the evils which afflict his subtropical brother. But we have no desire to dwell on this calamity which, however, may not be altogether unpreventable if only the tactics adopted by the wise Incas of Peru should be put in practice. These were simply to have always in readiness heaps of damp grass with which to raise a smoke dense enough to carry off the frosts not infrequent upon the high plateau of the Andes. By this simple means the grand old Incas protected their potato fields probably for centuries before the tuber was known in Europe.

In his paper on "some additions to our vegetable dietary" F. V. Coville, Botanist, gives some good grandmotherly advice regarding the

virtues of certain pot. herbs the use of which he says "both in the form of salads and boiled green vegetables is much more prevalent in Europe than America," and he seems to attribute the cadaverous look of many of his countrymen to the lack of this food, or, to quote correctly, "to the lack of this kind of food is due in large part the reputation of Americans as a bilious race." There are more bilious races however, to whom a study of this paper might prove profitable, the persistent beef-eating Europeans and Eurasians to wit. "There seems little doubt in general," says Mr. Coville, "that a wider use of green vegetables in the dietaries of most of our people, particularly those with healthy digestion would be a marked benefit." Yet when he goes on to enumerate and describe the different pot herbs he recommends, we do not find much that is new to us. Indeed, with the single exception of *New Zealand spinach* brought home to England by Captain Cook, there is not a vegetable mentioned but what was familiar to Pliny ages ago. One of the plants mentioned, the Amaran, is commonly used by our estate coolies, and might with advantage be added to the dietary of the dory; while another—the *dock*—we do not think any European could stomach, the "*docken*" as we know it—is one of the most useless and objectionable of weeds. Not even an ass will tackle it, and the good farmer is always bent on eradicating it. The late Dr. Alexander in his "Life among Our Ain Folk," tells us of an excellent old farmer but very wicked man who "banned all the week and delved dockens on Sunday"! Evidently, however, the *garden sorrel* is meant—a near relative of the dock but not possessing much more of a nutritive character.

Another early acquaintance recommended for table use is *Caltha palustris* and though here called a 'cowslip' is none other than the common marsh marigold of Britain, which we were always assured by our grandmothers had certain virtues but we never thought of eating it. We feel more in agreement with the writer, when he speaks of dandelion (*Taraxacum*), which while extensively cultivated around Paris for its tender blanched leaf and relished in many of the colonies as an excellent tonic, it has never been sufficiently appreciated in Britain, except by rabbits.

We cannot afford space to dwell longer on this paper, and would now turn to what is of more universal importance, viz:—

THE STATISTICS OF THE PRINCIPAL CROPS.

Beginning with the staff of life the quantity of wheat raised in 1895, was 467,103,000 bushels compare Britain's 38,348,000, or Australasia's 32,461,000 over 76,000,000 bushels were exported besides \$30,000,000 worth of flour to the U. K.

Of cattle the estimate is 16,137,586 milch cows, and 32,085,409 oxen.

But wheat is by no means the principal crop. There were more than twice the average under corn, producing 2,151,138,580 bushels value \$544,985,534. Oats also figure at \$24,443,537 bushels, and barley \$7,072,744—to say nothing of rye, rice, hay, hops, cotton and fruits, &c.

The canning of fruits is itself a big business, employing 50,881 hands, the wages paid during the year being \$5,243,707, cost of materials used \$18,665,163, total value of product \$29,862,416.

We are told that "The capital employed in this industry was only \$701,388 less than that employed in the creamery and cheese-factory business, while the value of the products exceeded the

combined value of all the windmills, clocks, watches, firearms, mirrors, mats and matting, linen fabrics, and enamelled goods made in the U. S. during the year."

With regard to the cattle industry, it is estimated that three acres of land in the highest state of cultivation will support 5 head of cattle, so that "If the 300,000,000 acres of arable land in the Mississippi Valley were to be devoted to such an extensive system of culture, more cattle could be raised in each year than are consumed in the whole world." There is evidently no fear of London starving just yet. The U. S. in keen competition with Canada, Argentine, and Australia, can be trusted to keep up the supply and down the price.

The future prospects of the farmer are thus concisely put :—

"The farms of the United States average 137 acres each. These farms number 4,564,641 and their average value in the census of 1890 is 2,909. The farm family including hired help, averages six persons. By their own labour, with an additional investment upon each farm of \$200 in implements and \$800 in domestic animals, those families made for themselves during the year, out of the products of the earth, a wholesome and comfortable living. The same farmers have with part of their surplus products, fed all the urban population of the U. S., poor and rich alike. Cereals, meats, vegetables, dairy produce &c., have been supplied to village and city markets in abundance. It is probably safe to say that 40,000,000 of American citizens not living on farms have been so furnished with all the necessities and luxuries known as products of the varied soil and climate of States of the Union.

"During the fiscal year 1895, the U. S. exported to foreign countries domestic commodities merchandise, and products aggregating in value \$743,000,000 of which the agricultural products formed \$553,215,317. Of this total Europe received 79 per cent.

"Thus American agriculture, after feeding itself and all the cities and towns of the U. S., has sold to the outside world over \$500,000,000 worth of products. In the presence of these facts, in the face of these figures, how can any one dare to assert that farming is generally unremunerative? But declaimers declare that the farms of the U. S. are sadly burdened with mortgages. The census, however, develops the fact that on the entire valuation returned for farms there is only a mortgage of 16 per cent."

We would now turn with very special interest to inquire into the capabilities of our beloved cousins in the way of consuming tea. On page 552 we find a table showing the consumption of tea from 1870 to 1896, from which it appears that the taste for tea is not perceptibly increasing—in 1886, the consumption *per caput* was 1.37lb., today it is at the rate of 1.38, while in 1881-1882 it was actually higher viz. 1.54 and 1.47.

Collée is consumed at the rate of 9.22lb. *per capita*. In distilled spirits they are very moderate averaging only 1.12 gallon per head, but in malt liquors the consumption is very ample amounting to 15 gallons *per caput* that is to say for every cup of tea he drinks, Jonathan swigs three glasses of beer! Would that for his own sake and ours he could be induced to reverse the order!

MARKET FOR TEA SHARES.

Thursday Evening, Oct. 1, 1896.

A steadier tone has prevailed during the past week, and in regard more especially to some of the new issues there has been a slight recovery. In one or two quarters, however, some considerable lines have been sold at rather knock-out prices.

Mincing Lane still keeps very firm, notwithstanding considerable supplies placed on the market; the strongest prices, however, seem to rule for the higher class and fine Teas.

FRESH ISSUES.

Consolidated Tea and Lands.—The Firsts were at one time as low as about 5s. premium only, but they are now buyers at 10s. to 15s. premium, with holders asking a higher price. The Seconds stand round about 1½ to 1½ prem.—*H. and C. Mail*, Oct. 2,

THE DUCKWARI (CEYLON) TEA PLANTATION COMPANY, LIMITED.

Report by the Directors to the Sixth Ordinary General Meeting of the Company:—

The Directors beg to submit herewith the Accounts for the year ending June 30th, 1896. In the Statement of the application of the balance of profit in the Report for the twelve months ending June 30th, 1895, the loan from the Ordinary Shareholders was erroneously deducted. The balance of profit for that year was

.. .. .	£1,533 0 2
From which the following only should have been deducted:—	
(1) The Preference Dividends	£840 0 0
(2) The Directors' Fees	890 0 0
Leaving	£643 0 2
to be carried forward, instead of £239 15s. od	
From this balance, further deductions, were made by the Board:	
(1) In payment of a bonus to the Secretary, who had given his services without remuneration, from the foundation of the Company	£200 0 0
(2) In payment of the Chairman's travelling Expenses in Ceylon, in the autumn of 1894	21 18 6
	£221 18 6
Balance	£421 1 8

Inclusive of this last balance, Profit and Loss account on June 30th last, shews a surplus, after writing off 10 per cent. depreciation on value of Machinery and Buildings, of 1,984 5s. 3d., which the Directors propose should be applied as follows:—

(1) In payment of 7 per cent Dividend on Preference Shares	£840 0 0
(2) In payment of 5 per cent Ordinary Shares	400 0 0
(3) In formation of a Reserve Fund	700 0 0
.. .. .	1,940 0 0
Leaving	£44 5 0

to be carried forward to next year.

The returns of Crop have been 206,671 lb. Tea and 5,790 lb. Cardamoms, against 171,674 lb. Tea and 5,966 lb. Cardamoms last season. For the coming year it is estimated the yield will be 210,000 lb. Tea and 6,000 lb. Cardamoms.

£258 16s 11d have been spent during the past twelve months in sundry additions to Factory and Lines. A system of artificial manning is being introduced on some backward portions of the Estates, and very material increases of yield are confidently expected therefrom. Mr. Spenco retires from the Direction by rotation, and, being eligible, offers

himself for re-election. The Auditors, Messrs. Brown, Fleming and Murray, also retire, and offer themselves for re-appointment. P. G. SPENCE, *Chairman*.

R. CROSS ARTKEN, *Secretary*.

17, Philpot Lane, London, September, 1896.

THE CONSOLIDATED ESTATES COMPANY, LIMITED.

Authorized capital £100,000, divided into 5,000 preferred shares of £10 each entitled to a cumulative preferential dividend of 8 per cent., £50,000; 5,000 ordinary shares of £10 each, £50,000; total £100,000.

Fifth annual report of the Shareholders at the general meeting, to be held on Wednesday, the 7th October, 1896, at 34, Great St. Helens, C.C.

The General Managers have the pleasure to submit their Fifth Annual Report and Balance Sheet, together with Statement of Accounts for the Crop Year ending 30th June, 1896.

The Profit and Loss Account shows a balance (including £162 13s. 10d. brought forward from last year) of £6,267 14s. 5d., after paying Interest on the Debentures, and an Interim Dividend of 4 per cent on the Preferred Shares.

Out of this sum the General Managers propose:

To write off the Balance of account for stamps and Legal Expenses in connection with the Estates purchased in 1895, viz. ..	£21	3	
To pay a Balance Dividend of 4 per cent on the Preferred Shares, which will absorb ..	680	0	0
To set aside for redemption of five per cent. of the Debentures at 103	1,751	0	0
To write off from the Factory Extension Account the sum of ..	800		0
To pay a Dividend of 8 per cent on the Ordinary Shares, which will require ..	1,520	0	0
To put to a Reserve Fund the sum of	1,000	0	0
Carrying forward the Balance, viz.	298	11	2
	£6,267	14	5

The following shows the result of the year's working, viz.:-

NET PROCEEDS OF CROP.

	£.	s.	d.
881,484 lb. Tea at an average net price of about 6½d. per lb. realized ..	23,480	6	2
Interest on Account	119	17	0
	23,600	3	2

EXPENDITURE ON ESTATES.

Messrs. George Steuart & Co's drafts—			
R242,962.97 at an average of 1s. 2 7-32d per rupee	14,399	7	
Postages	1	0	
Bonus to Superintendents—			
R4,000 at 1s. 2½d.	237	10	
	14,637	17	8
Net Profit on Cultivation	£8,962	5	6

From the foregoing figures it will be seen that the Season was a very prosperous one, the yield of Tea having exceeded the estimates given in the last Annual Report by about 100,000 lbs., and a considerably larger dividend might have been paid on the Ordinary Shares, but the General Managers strongly advocate a continuance of the Policy indicated in their last Report of making provision in favourable seasons for less prosperous times, partly by liberal extension of cultivation and partly by building up a good Reserve.

The outstanding advances made to coolies (commonly called "Coast advances") amount at Current Exchange to £1,031 8s. 1d. This has been paid out of Revenue, and the Superintendents on the Com-

pany's Estates certify that in their opinion these advances (with trifling exceptions) are all good and recoverable, but it has been thought better not to take credit for them in the Accounts, and the amount therefore practically forms an additional Reserve Fund.

The shareholders are aware that the Company has recently acquired three new Estates on terms which the General Managers believe to be favorable, and to promise satisfactory results, though it will be some years before these Estates are fully developed. For convenience of reference the following approximate particulars of all the Estates now held by the Company are appended:—

Name of Estate	Ceylon District	In Cultivation		Total Acreage
		In Bearing	Recently Planted.	
Wattegodda ..	Dimbula ..	800	.. Nil	
Tallagalla ..	Kalutara ..	270	.. 70	
Ellagalla ..	Matale ..	207	.. 20	
Hoonocotua and Hennewille } ..	Kotmale ..	588	.. 30	
Wariagalla ..				
Rutland ..	Fewbeta ..	414	.. 30	
Knutsford ..	Kalutara ..	104	.. 59	
	Reserve Suitable for Tea	Forest Waste, Water, &c.		
Wattegodda ..	Nil ..	95	.. 895	
Tallagalla ..	144 ..	15	.. 499	
Ellagalla ..	13 ..	205	.. 445	
Hoonocotua and Hennewille } ..	45 ..	50	.. 713	
Wariagalla ..				
Rutland ..	87 ..	64	.. 595	
Knutsford ..	Nil ..	23	.. 186	

* of which 73 acres are planted with Cardamoms and 40 with Cocoa.

The last three Estates having been purchased as from 1st July, 1896, the working of them does not appear in the Accounts now presented, which are for the Crop Year ending 30th June, 1896.

Hoonocotua and Hennewille are now worked as one Estates, which will henceforth be known as "Hoonocotua" only. Knutsford, which adjoins Tallagalla, will now be amalgamated with it, and the two Estates will be called "Tallagalla" only.

The following are the Estimates for the current season's crops:—

	Expenditure, at 1/2½ per Rupee.				Crop. lb. Tea
	R.	£	s	d	
Wattegodde	83,043	4,930	13	7	300,000
Tallagalla	48,336	2,872	18	4	220,000
Ellagalla	27,960	1,660	2	6	85,000
Hoonocotua	71,193	4,227	1	8	250,000
Wariagalla	39,987	2,374	4	6	130,000
Rutland	47,906	2,811	8	4	154,600

Also, 2,500 lb. Cardamoms and 30 cwts. Cocoa from Wariagalla.

The foregoing Estimates have been cautiously framed, as it has not been thought advisable to count on such a favourable season as we have just had. It is to be hoped, therefore, that the Estimates will be fully realized, and in that case the results will be quite satisfactory if the price of Tea is maintained and Exchange does not materially rise.

During last Season about 150 acres were opened up, and a further 130 to 150 acres will be taken in hand this Season. The cost of these extensions, and of an enlargement Factory of on Wariagalla, will be charged to the Factory and Extension Account, but the premium realised on the Debentures and shares issued this year (which has been carried to the credit of the Factory and Extension Account, as arranged) will provide for most of this expenditure, which is estimated at about £1,600, during the current season.

The Preferred Shares to the nominal amount of £13,000, Nos. 1,701—3,000, both inclusive, and Ordinary Shares to the nominal amount of £13,000, Nos. 6,901—8,200, both inclusive, which were issued on 1st July last, and are included in those enumerated in the annexed Balance Sheet, do not participate in

the Dividends now proposed to be paid, these Dividends having been earned during the Crop Year which ended on 30th June last. For the same season the Debentures to the nominal amount of £10,000 Nos. 351-450, will not participate in the next drawing for redemption.

ARBUTHNOT, LATHAM & Co., General Manager.
34, Great St. Helens, E.C., 25th Sept. 1896.

PUTUPAULA TEA ESTATE COMPANY, LIMITED.

The shareholders of this Company are to be congratulated on the eminently satisfactory report adopted at the annual meeting today. The report recommends the payment of a dividend of 10 per cent for the year, besides carrying forward a substantial sum and making permanent improvements on the estate:—

Acreage.—Tea in bearing 391 acres; Tea in partial bearing 30 acres; Tea in under one year 33 acres; Liberian Coffee 10 acres; forest—, grass &c., and waste land, 235 acres. Grand total, 699 acres.

The Directors have pleasure in submitting to the Shareholders the accounts for the past year. The crop amounted to 153,365 lb. tea (against an Estimate of 140,000 lb.) and 30 bbls. Liberian Coffee. The nett average sale price of the former was 44 cents per lb.—The latter realised R174.95. The nett profit of the year amounted to R22,171.41, which with the balance of R2,635.16, brought forward from last year makes the balance at credit of Profit and Loss account R24,806.57. The Directors recommend a dividend of 10 per cent for the year carrying forward R4,806.57, to the current years accounts. A sum of R2,736.88, was spent during the year in manning a portion of the Estate and was charged to expenditure. A sum of R3,217.74, was spent on permanent improvements to buildings and a further sum of R3,500, in opening 30 acres in Tea. These items have been charged to Capital account. The Estimated crop for 1896-97, is 165,000 lb. on an estimated outlay on working account of R45,000, which includes R5,000, for manuring purposes. In terms of the Articles of Association the Directors now retire and Mr. Kingsbury and Mr. Subren offer themselves for re-election. The appointment of an Auditor for the current year will rest with the meeting.—By order of the Directors, ATKIN, SPENCE & Co., Agents and Secretaries.

MARKET FOR TEA SHARES.

Thursday Evening, Oct. 8, 1896.—The general depression in the Stock Markets has reflected itself slightly upon the market for Tea shares, and in some quarters shares have been sold at somewhat easier prices; the general tone, however, in these shares continues fairly strong, and wherever buying takes place prices tend to rise.

Our attention has been drawn to a paragraph in the financial columns of our contemporary *Truth* (September 24), which seems to require notice here.

Truth's Calcutta correspondent gives to investors a warning against being inveigled into purchasing at high prices poor or worn-out Tea gardens, and, we cordially endorse this warning. But we must be allowed to take exception to *Truth's* apparent wholesale condemnation of Tea, conveyed in the concluding sentence of its correspondent's letter, which runs as follows:

"I would warn all capitalists and investors of this grave fact. Bengal has planted out thousands of acres, year by year, also Ceylon. Prices are down, and this year's crops will fall short. Touch nor handle not."

Here we venture to say that the facts are at variance with these statements, as, up to the present, Tea prices this season have been exceptionally good, and although there has been some slight shortage up to

date in the crops, this has been more than compensated for by the much higher prices which have thus far been obtained for the portion of the crop so far sold to date.

Mincing Lane, though slightly easier, keeps, fairly steady, and fine Teas still maintain a high range of price.

FRESH ISSUES.

Consolidated Tea and Lands—We are informed that an official quotation for these shares will very shortly be granted. The Firsts have changed hands at 15s premium, but are now scarcely so high as that. The Seconds, however, still quote £1 premium upwards.

East India and Ceylon shares keep rather sluggish.

Sylhet Co. Shares.—Some may be shortly for sale, and might be open to a fair offer.

PLANTING AND PRODUCE.

THE TEA TRADE OF CENTRAL ASIA.—In the report on Central Asian trade, which appears elsewhere, Vice-Consul Ringler Thomson offers some opinions about the decay of the green tea trade and the respective positions of India and China as competitors in the tea trade of Central Asia. Apropos of this, we notice that Mr. Leslie Rogers, a well-known planter of Northern India, seeks to show in the *Allahabad Pioneer* that in virtue of all that has been done, enterprise to get a footing in the Central Asian markets has not been wanting among the Indian planters, yet their trade has not been an undoubted success. Indian tea exported to Cabul, which is the especial foothold of North Indian desires, was in April and May, 1896 of a value of only R31,445, as against R94,501 during the same period last year; and the same tale is told in regard to most articles of commerce sent to Cabul, to Thibet, or to Western China. Mr. Leslie Rogers maintains that since 1880, when the Afghan War revived the once flourishing green tea trade with Cabul, Meshed, Bokhara, and Samarcand, the planters of Northern India have left not a stone unturned to revive their connection with all these Central Asian markets. Grievances, however, arose for the planters to bear, in the shape of "almost prohibitive restrictions" placed on all trade by both the Amir of Cabul and the new formed Russian Customs Department in Bokhara, and the North Indian planters went in a body to petition Sir James Lyall to get the Government of India to do something in their behalf. Several times, too they have made an effort to get the Amir to receive a delegate at Cabul, and discuss matters personally with His Highness at home, but according to the account, the Amir had "foolish suspicions" as to the real intentions, and on every occasion has declined to admit a trade apostle. Mr. Rogers contends, therefore, that by proceedings such as these, as well as by "keeping up a constant correspondence in the home and Indian papers on the subject," the North Indian planter has not been wanting in enterprise, and that "with little more public spirited support of his interests by the home and Indian Governments he would not compare unfavourably with any other nationality in the race for the markets of Central Asia."

COOLIE LABOUR IN NATAL.—In an article published in the *Globe* on "The British Artisan in Africa" the writer, referring to Natal, says: "It is because the British Artisan has been found unsatisfactory that the people of this most English colony are obliged to fall back upon coolies; and in future indentured coolie artisans will be imported from India. The products of Natal have to compete with cheap and efficient labour elsewhere, and the industries dependent upon labour must keep this fact steadily before them. Let us take tea-planting, which is worked entirely by coolie labour. This industry has to compete with the teas of India, Ceylon, and China. It is not sufficient to raise the quality of the tea to the same level,

but the cost of production must also be comparative. Indirectly and directly, the British Artisan has a good deal to do with tea. Until recently only English mechanics were employed to clean and repair the machinery, and only English artisans were in the carpenters' shop at Nonoti. But they have been replaced by coolies, who are not only cheaper, but more handy and less troublesome. The British workman is frequently spoken of as 'a difficulty' in Natal. There must be something manifestly wrong for a colony so essential English in its tone and warm in its welcome to English settlers to have to come to the decision of importing coolies."—*H. and C. Mail*, Oct. 9.

TEA GROWING IN SOUTH CAROLINA, U. S. A.

Mr. Charles U. Shepard, of Pinehurst, South Carolina, U. S. A., writes under date Sept. 28:—

"My little experimentation with the cultivation of tea in this country has been thus far successful that during almost the entire picking season of 1896 the orders were in excess of stock on hand. I intend increasing my acreage by planting out more gardens of Darjiling and other suitable seed until I reach the limit of the capacity of my factory."

We shall be glad to learn the result of Mr. Shepard's further experiments.

THE NEW DIMBULA COMPANY, LIMITED.

REPORT, SEASON 1895-96.

The Directors, in submitting their eleventh Annual Report, have the pleasure to state that the past season has been satisfactory in all respects.

The yield of Tea exceeded the estimate and the prices were better than in the previous season.

The additions to the Factory and Machinery, referred to in last year's Report, have been carried out, and the Estate is reported in good order.

The area of land in bearing is 2,193 acres, and the Directors have sanctioned the opening of an additional 50 acres during current year.

The accounts now presented show a surplus of £20,433 0s. 5d. after writing off the amount of Tea Extension account, viz., £166 18s. 10d. and the amount of the "Factory and Machinery account," viz., £3,259 0s. 10d. The Directors propose a dividend of 8 per cent. per annum on the "A" and "B" shares and 6 per cent. per annum on the "C" shares for the year ended 30th June last, a moiety of which was paid in March. The Directors also propose an additional dividend of 8 per cent. on all shares, and the placing of £5,000 to the Reserve Fund.

The Ceylon Manager has dealt very efficiently with the Factory extension, with the labour supply, and with the general manufacture, and the Directors desire to express their great satisfaction with the management, and with the work of the staff in Ceylon.—By order of the Board,

A. CRABBE,
Secretary.

THE TEA TRADE WITH CHINESE TURKISTAN.

Many of our readers are planters. It is to them that our leader is addressed. At the same time we would impress upon all who are interested in opening out the trade with Central Asia the necessity of bringing before the Commerce Department the fact that it is their duty to guard and foster our commercial interests along this most promising of our trade routes, which leads over the northern frontiers of Hindustan.

The *Pioneer* has most steadily endeavoured to arouse public attention in the Leh-Yarkand trade. The *Civil and Military Gazette* has followed suit. Those journals of course take up the question from a political as well as from a commercial view. We however—although as citizens we deplore the want of energy of the powers that be—have chiefly to deal with what affects so many of our constituents, and will confine our remarks to the tea trade.

That good Indian-grown tea is preferred to the Chinese article is well-known to travellers who have journeyed over the Keradoram ranges, but the tea must be of the best; it must be suited to the taste of the purchasers. A clean, well-rolled black tea, with a certain proportion of green added, is what appears to be most appreciated, but it will probably be found to be advisable to send samples of both green and black in order to thoroughly test the market.

Leh is not so far distant that any planter need dread the journey, and he might do worse than spend his holiday on a trip through Kashmir and on to Leh, taking with him carefully packed samples of the products of his garden. Now is the time to meet the traders. They are all assembling in Ladakh, and will shortly be *en route* to Srinagar, but we repeat ourselves in hopes of impressing on our readers the fact that the Kashmir Ladakhi and transfrontier tribesmen are connoisseurs; even the poorest will not buy rubbish of the kind formerly exported to Kabul as green tea. To the traveller tea is his one luxury; as soon as the packs are off the ponies a little burtze or other fuel is collected, and the Samovatur is set to boil. The villager, directly he returns from his fields, has his bowl of tea; it is a beverage eminently suited to their tastes. It is true they add salt and other condiments which are not suited to our Western palates, but they declare it brings out the flavour. It is the business of the planter to supply a tea which is capable of having flavour, and not to imagine that "any stuff is good enough for the uncivilized people who live amongst the uplands of the Himalayas."

The distrust of the merchants has to be overcome, for they all know that inferior teas were formerly sent to Central Asia, but this distrust can be overcome by any one who will cater for the taste of his customers and will strictly keep his wares up to standard. The Central Asian trader is generally a Pathan; he is very quick at seeing his own advantage, and would gladly deal at first with a European. He *cannot*, however, afford to make a false step, and must feel that he is sure of his market, and that depends entirely on the goodness and suitability of the tea.

The trader's time is a rough one. After arriving in Leh in the early autumn he has first to recruit his ponies, selling off some and turning others out to graze in the lucerne fields where they gathered strength for the return journey. Whilst this is going on he sells his Yarkand goods and buys coral, piece goods and other articles which are sent up from the Panjab. Then he enters on his dreary march to Yarkand with no chance of changing his carriage *en route*. On arriving there, he has either to retail his goods or hand them over to a middleman who seldom pays until he has sold the stock. Their ideas of trade are peculiar. A Pathan trader who had brought goods from India passed on most of them to a shop-keeper. Wearily he waited for payment. After a year had passed the man who was anxious to be off sued his debtor; the Court decreed that the merchant was entitled to hand over the balance of his goods to the retailer, but that he must wait for payment for the whole lot until he next returned from Leh. Many of the merchants are men of substance; they can afford to wait for their money, and, what is more to the purpose, they can pay in Leh for the goods they require in spite of their difficulties in Chinese Turkistan. We do not advise any European to endeavour to trade in Yarkand or to send their own caravans, but as far up the route as Leh there are no difficulties; either by the Kulu or Srinagar roads the pony-owners will

carry goods by contract. Indeed, when the tea has once been thoroughly introduced, there is little doubt that the traders would buy it in Srinagar. There would be no difficulty in establishing an agency in Kashmir, but at first it will be necessary to work in Leh.

As to the tea trade with Kashmir, most of what is drunk is Indian tea, although the villagers think it is Chinese. The demand is increasing, and will continue to do so, for the people are waxing fat and prosperous. Three to four rupees is not an uncommon price for what is called "Bombay tea." It is supposed to come from China, but is in reality an Indian product. The profit made by the middleman is very great, but the planter would have great difficulty in getting the market into his own hands; still, when prospecting for the Chinese-Turkistan trade, he might find that something could be done in Srinagar. We are inclined to think there are possibilities in both places, for the demand for tea is a large one. Tea reigns supreme; coffee and cocoa are not its rivals; and amongst the Mussalman races it takes the place of beer. In Ladakh *chang*, the beer of the country, is used on festive occasions, but tea is the universal drink.—*Asian*

DESTRUCTION OF TEA FACTORIES BY FIRE.

Within the last few weeks the destruction of two large tea factories by fire have been reported. To those who have seen the splendid buildings now erected on tea estates, it appears most strange how a fire on a big scale can possibly take place. Every precaution is taken to make the factories secure from fire; in fact, it may be said, they are practically fire-proof. Even about old tea-houses, built years ago, means have been adopted so that there should be no chance of any portion catching fire, and yet there remains the fact that fires do take place, and every year one or more tea-houses are burnt to the ground. As a rule, the cause of the fire remains a mystery, *i.e.*, if the fire has broken out in the tea-house itself. Surmises are made, explanations of sorts are given, and eventually after much wasting of pen, ink and paper, and many inspections, the matter is buried, and in course of time allowed to drop. It is true that in the majority of tea-houses a very considerable amount of timber is to be found inside them, in the form of posts, beams, rafters, planks, etc., but these are always so well protected by the adoption of various means that to one acquainted with them, it simply appears marvellous how they can catch fire to such an extent as to set the whole building in a blaze. The roof is all corrugated iron; sparks from the chimneys of the engine and dryers cannot set fire to the building from outside. Doubtless all timber in close proximity to dryers and their funnels get very dry in course of time, but these portions are always protected by a casing of zinc sheeting or some fire-proof substance. In many instances, when a factory has been burnt down, it has been owing to the stacks of firewood outside having been erected too close to the building. In such cases of course, if the stacks, owing to any cause, catch fire, it is practically impossible to save the tea-house: especially if there is the slightest breeze or wind blowing the flames in the direction of the factory; it is simply doomed. Managers and tea-house assistants are most assiduous in their attentions, and we think we may safely say, that no tea-house has ever been burnt down in the last ten years, with a European in charge, inside on duty. It is of course quite impossible for the Manager or Assistant to be always present in the building, unless a special tea-maker is employed, whose duty it is to devote his whole attention to manufacture. Such being the case, we can only attribute a conflagration, except of course in exceptional cases, to either of two causes: (1) Gross negligence, or carelessness, on the part of the natives on duty in the building; or, (2) deliberate setting fire to the building by some native or natives. We are of opinion that many tea-houses have been deliberately set fire to by natives, and if it was possible to bottom the real facts and trace them to their source, it would be found

that natives to satisfy some private or imaginary grudge, have wantonly been the cause of the conflagration. Natives think nothing of incendiarism. A coolie or coolies, perhaps, have a row with the *sahibs*, or with the sirdars, or with their *jat-bhai*, or it may be with all combined Drunk with liquor and mad with rage, to vent their spleen they watch their opportunity and turn incendiaries. There is always a chowkidar supposed to be guarding a factory, but he is generally an invisible force, and, if not actually sound asleep, he is bound to be at the other extremity of the building. The firing process is not a very difficult one. All coolies on a garden know the inside of a tea house pretty well, and exactly where the kind of materials they require lie. The coolie or coolies secure the tea bulking cloths, or hessian withering cloths, or it may be the firing cloths, then collect whatever they can lay hands on in the shape of fuel, it may be tea box shooks, or bits of planking, or firewood. A pile soon made in some spot, either inside or outside the building, where a blaze will set the whole place on fire. Possibly some kerosine oil is poured on, a match is struck and applied, and a memorial bonfire the result. What European is there in the whole of India, who can say he has fathomed the inmost depths of the cussedness of a native. Even if the coolie or coolies did not take all the trouble to go through the elaborate process detailed above, there are hundreds of ways of setting fire to a building, if a man or men are maliciously intent on the job. If they are determined to set a tea-house on fire they will find the way and means, and the building which was considered practically fire-proof will soon be wrapt in flames. All the vigilance of Managers and Assistants, or the ingenuity of engineers and builders, will not avail against such scoundrels. Incendiarism is a common form of revenge in India, and has flourished for ages. The culprit or culprits are seldom caught. If done in secrecy, he or they get off scot-free. After the building has been burnt down to the ground, it is impossible to trace the origin of the fire—the first intimation of which has perhaps been a lurid glare in the sky, if at night, or a wild hubbub and running about of excited coolies if in the day. In the ensuing bustle and confusion everyone, more or less, lose their heads, and the incendiaries, if they have not already cleared off, mix in the crowd, and, perhaps, to evade suspicion falling on them, make a show of helping to extinguish the flames. Even if suspected there is no proof to convict them, unless caught red-handed, and so they escape. The total destruction of a tea-house by fire is always a most serious loss. Even if fully insured, the insurance money goes but a little way to recoup the real loss to the estate. It is the most dire calamity that can possibly happen to a large garden, especially if situated a distance from any neighbouring estate, which might possibly be able to help manufacturing the leaf. If destroyed during the height of the manufacturing season, it simply means the dead loss of some hundreds or thousands of maunds of tea, not covered by insurance. Moreover, it puts the whole working of the garden out of gear, and takes months before the old order is restored and things work smoothly again.—*Indian Planters' Gazette*, Oct. 17

THE AMSTERDAM MARKET.

Further details with regard to the cinchona sales of last Thursday state that the demand for Manufacturing barks was good, but without any inclination to strong competition, and in all cases where importers took up a firm stand the buyers invariably left them alone. This accounts for the fact that 5,122 kilos of quinine in the bark remained unsold. The richest parcel at auction was 132 bales crushed Ledgeriana, containing 11.60 per cent of sulphate of quinine. This lot only realised 30½c, or 5½d per lb. Druggists barks were decidedly firmer all round, and for fine whole and broken quill an advance on the former auctions was paid. Medium grades were also well competed for, but common lots were slow of sale.—*Chemist and Druggist*, Oct. 10.

LEAVES FROM A PLANTER'S NOTE BOOK.

(Contributed by a Planter.)

PLUCKING AND KINDRED MATTERS.

I.

The general rule on all gardens is to pluck two leaves and a bud, or two and a half leaves and a bud. But after the first two flushes are off, and specially when there is an abundance of leaf, the rule is more honoured in the breach than in the observance thereof. Theoretically the rule is supposed to be in force, but practically it is a dead letter. When inspecting the leaf brought in, during the process of spreading it out for withering, I daily find that the major portion of the leaf plucked consists of three to four leaves, for the most part all on one stalk. Managers and Assistants do their best to prevent this, but on large concerns, especially during the height of the season, it is practically impossible to prevent the pluckers bringing in the extra leaves. In fact, the pluckers themselves cannot well be blamed. Outsiders can form no idea what plucking means. Only planters and garden coolies learn from experience what it really is. Plucking is no child's play and is an *art* only learnt by hard-persevering labour. I use the word *art* advisedly, and I feel sure my brother planters will back me up in my assertion that plucking is an *art*, and not merely an art, but, I may almost say, one of the fine arts. The amount of skill required to be a successful plucker is by no means small. Only a planter knows what a cunning hand, and what skilful manipulation is required, before one can become a really first-class plucker. There are pluckers and pluckers, but what a difference between them. A planter is simply delighted when he finds a plucker who *can* pluck. There are no pluckers like women, and amongst women none that will compare with the Nepaïese, or other hill women (Pahariahs), working on the hill gardens in Darjeeling and the Kangra Valley. Men make wretched pluckers; their hands and fingers have not the necessary pliability; they are too hard and coarse. Children pluck fairly well, when they can be persuaded to put their minds to it, and girls often turned out adepts at it. The value of women and girls who can pluck is beyond estimation; they are worth their weight in gold. The study of plucking and pluckers is a most interesting one, and if some of my brother planters will only jot down their experiences, and send their notes down to this journal, I feel sure the Editor will be delighted to insert them. There is an Indian plant, a medicinal herb of great value, which, unless plucked off by one clear cut of the nail, loses its peculiar properties and is rendered valueless. I have sometimes thought that if we really sifted the matter thoroughly it might be somewhat the same with tea. I have a faint kind of idea that the *manner* the leaf is plucked has a deal to do with the quality of the tea manufactured from it. My own belief is that leaf plucked off with one clean cut of the nail, withers better, ferments better, and altogether turns out better tea, than leaf carelessly stripped or broken off the bushes. Some planters may laugh and consider the idea an absurd one, but it is little things like these that sometimes make all the difference. Anyway, to any planter who may possibly have the leisure, which unfortunately I have not, and who will not mind the sweat, the experiment is worth trying. I have read many articles on the subject of plucking my machinery, but I have no doubts as to any mechanical contrivance ever proving a success. Even if a machine was invented that would suit all bushes, and run through a garden plucking or rather cutting off the leaves promiscuously, the results, I much fear, would prove disastrous. Scissors and clippers of kinds have been invented, but after numerous experiments it has been found that, so far, the natural method of plucking by the hand is out and out the best. Everything, I may say, depends on the plucking. Leaf should be taken off *just when ready*, not a day earlier, not a day later. If taken off *just when ready* it makes

all the difference in the outcome. A ripe leaf is doubtful, an overripe one bad, *decidedly bad*. It is an utter impossibility to make tea, much less good tea, out of leaf tough as shoe-leather. Managers and Assistants know exactly when the leaf is ready, and would gladly pluck it, but alas! their hands are tied, and they cannot do the things they would do, for they have not the coolies. Here comes in the question of the labour force, an ever-diminishing quantity—but that's another story, and although it has everything to do with the successful plucking of a garden, we cannot more than touch on the fringe of it here. The simple fact remains, that if tea of good quality is to be made, the only way to turn out such tea is to pluck the leaf *exactly when it is ready*—neither earlier nor later. It is no use having an extensive acreage if the labour force is not sufficient to work it. Managers often get unjustly blamed for things, when the fault is not theirs at all, but lies at the door of others, who shift the blame on to them to find a way of escape for themselves. No fixed rule can be laid down for the plucking of bushes. The majority of gardens contain a mixed *lot* of plants, and they require plucking according to their class. Planters know from experience exactly when their bushes are ready for plucking, and do their utmost to take the leaf off in due season. If, however, owing to sudden rushes of leaf and heavy flushes they do fall behind, it can only be attributed to insufficiency of labour. Naturally the tea manufactured also deteriorates very considerably in quality. The remedy in such cases is *not* in the writing of "stinkers" to already overworked and half-demented men, but in the frank recognition that, it is utterly out of the power of the employs to cope with the extra work, with a short labour force. If there is anything that disheartens a planter, it is the relieving of a "stinker," when he is slaving like a coolie and doing his utmost to pull through the crisis. Theoretical letter, written under a punkah in a nice cool office, are all very well in their way, and most excellent studies for leisure hours in the cold weather, but they don't read well, when perused by a *practical* man working in the sun, or in a tea house, with the temperature at 120. They have the most undesirable effect of rubbing him up the wrong way, and instead of helping to mend matters, only tend to deprive him of all heart and spirits for his work. There is nothing more depressing at such times than one of these "extinguishers" written perhaps by some inexperienced hand, to one who has been through the mill, and is a veteran in the service—to one at any rate who has his wits about him and knows exactly *what* to do and *how* to do it. It is not, however, the Manager alone who suffers. If there is a Tea-maker, or tea-house assistant in charge, he comes in for his share of "the beans." All hands on the garden suffer more or less, noses are put out of joint, and the air is thick with anything but blessings, and all because the leaves will not stop growing, but insist on going *bhanji* and turning into leather. I have stated what the remedy is *not*, the question as to what the remedy *is*, quite a different matter. Solutions without number have been put forward and discussed from time to time, but the problem has not yet been solved, for year after year the same difficulties crop up, the same leaf is plucked, and the same "undesireable" teas are made. Gardens with an adequate and ample supply of coolies to meet all exigencies are not in the category. I do not allude to them, for they invariably send down good teas to the market. It is for gardens short of labour, and practically with no labour at all when most wanted, that the problem has to be solved,—How to pluck with a short labour force and yet make good teas? This is the question, and doubtless the answer will work itself out in time, but at bitter expense. Yearly new gardens are being opened out and large extensions made, but the supply of coolies is not equal to the demand, and in proportion the supply of the class of labourers suitable for garden work is dwindling down gradually but surely. Coolies, more coolies. This is the cry. Who will give us more coolies, and where are they to come from?

Many gardens have not a sufficient labour force to cope with the gardens work at ordinary times, much less when there is a heavy rush of leaf, or a heavy flush on. Then, every soul has to be put on to plucking—men, women and children. All have to ply their fingers and a general ripping off the leaves commences. Stripped off, torn off, broken off their parent stalks anyhow (sometimes stalks and branches are brought in wholesale, the coolies employed on such occasions not being particular), the leaves are brought into the factory to be manufactured. Then indeed it is a pretty sight, and how the heart of the tea-maker doth rejoice, when he picks up stalk after stalk with five and six leaves on it! How he does pray for the long life and prosperity of his beloved Aryan brethren! Then having said his prayers, he sets to think it out how this conglomeration of sticks, stalks and leaves is to be made into tea. Into tea, however, it is made, and when it reaches the market, the brokers make rude remarks about it, and class it as "most undesirable," and, worse than all, sell it off for what it will fetch; and this after all the trouble and worry and bother there has been over the plucking of the leaves to make it. Well, at any rate, quantity has been made if quality has been sacrificed. A big invoice has at any rate been despatched, and we have always been informed that big invoices sell better than small ones. So, perhaps, we shall partly make up for quality by quantity. But alas! when the tea sales are published, we find that the big invoice were sent down, and which we expected to be sold in one lot, has been spilt up and divided into two or more invoices, and apportioned to different brokers, and sold in two or more lots with the result that the teas did not realise the prices we expected for them. On top of this comes a wire. "Teas most disappointing." Telegrams of this type always gladden the heart of a planter, they give him a good appetite, and make him look forward to a substantial bonus at the end of the season and a princely rise of salary? What will the end be if we continue much longer short of labour? Shall we have to employ the heathen Chinese? They are already being largely employed on gardens as carpenters. Why should we not engage families of them and employ their wives and children for plucking and other works? They will cost more than the indigenous native, but if we cannot recruit sufficient labour in India itself, we must engage foreigners. Chinese women would most probably make excellent pluckers. Now that the Chinese are losing their tea trade in their own country, owing to a great extent to their conservatism, if they found a field open for them on our shores, they would doubtless immigrate here in large numbers to the tea districts. Out of China they would not stand on their ancient ways, and would soon come under the yoke of the foreign devil and barbarian so hateful to him in his native land. Calcutta is full of Chinamen; they make most excellent carpenters and shoe-makers, and the men would doubtless make splendid tea-makers. One good quality about them is that they do not require much looking after. Once they understand what they have to do, "John" is all there. The subject of fine or coarse plucking is an exhaustive one, and it is impossible to do it anything like justice in this paper. The remarks here made are only from jottings noted down in his few leisure moments by a hard-worked planter. He lays no claim to literary ability, nor does he deem himself competent to write a learned disquisition on the subject. Doubtless some will appreciate his humble efforts to edify and amuse and, if so, he will not have written in vain. Knowledge is always gained by interchange of thoughts so he lets drop these few crumbs with the hope that some brother-planters will follow his example and begin to contribute their quota to the sum of general knowledge by writing down their thoughts, feelings and experiences in a similar manner. It is impossible for us all to agree on any one subject—there are many ways of looking at an object, and the pictures vary and are as numerous as the points of observation. No two minds think exactly alike—it would not be human nature if they did. But although we differ on minor points, in

essentials all our various and differing thoughts and feelings can be brought into one focus blending in one harmonious whole and forming a kaleidoscopic picture worth the framing and handing down to posterity.—*Indian Planters' Gazette*, Oct. 17.

THE AMSTERDAM CINCHONA AUCTIONS.

Our Amsterdam correspondent, telegraphing on Thursday evening, states that of the 5,365 packages of Java cinchona offered at auction today, 4,338 sold at the average unit of 255c per half kilo, being the same as that of the previous auctions. The English and American manufacturers were the largest buyers, the equivalent of 755 kilos of sulphate of quinine being taken by them. The Auerbach Factory purchased 4,121 kilos, the Brunswick Factory 1,864 kilos, the Mannheim and Amsterdam Factories 3,903 kilos, the Frankfort-on-Maine and Stuttgart Factories 2,774, and various buyers 3,702 kilos. The following are the range of prices:—Manufacturing barks 3½c to 30½c (equal to 2d to 5½d per lb.); Druggists' barks, 9½c to 95½c (equal to 1½d to 1s 5d per lb).—*Chemist and Druggist*, Oct. 3.

OAHU AS A FIELD FOR COFFEE.

In another article we have shown at some length the necessity for inaugurating plans for the development of the Island of Oahu and also to protect and maintain an increased business for Honolulu. A short time ago it was our good fortune to visit the Waianae plantation and while being hospitably entertained by manager Ahrens were given some information in regard to his experience with coffee planting in the Waianae valley. Mr. Ahrens has about 60 acres under cultivation upon which has been planted about 50,000 coffee trees the plants running from one to three years. The estate is about five miles from the sugar mills or Waianae station and is reached by a splendid carriage road of about four miles and the balance of the distance by a well-made trail or bridle path. The cultivated portion is situated on the slope of a gulch backed on the north-east side from the higher elevations by an almost perpendicular mountain. The slopes on either side of the gulch are easy grades and result in a narrow valley of varying widths at the bottom. Mr. Ahrens has made a beautiful place of this gulch. At a convenient spot are located the neat and comfortable homes of the workmen close to which has been erected a private residence for Mr. Ahrens. An abundant supply of pure water oozes out from numerous springs in the hillside which is used for irrigation and household purposes. One of these streams has been diverted into a large swimming pool surrounding which as well as the houses are beautiful flower gardens containing every variety of roses and rare flowers all singularly healthy and free from blight. A large number of limo and orange trees have also been set out and are doing well.

Returning to the coffee plantation as we stated above there are about 50,000 trees growing all healthy and vigorous. The older trees are actually loaded with berries and although not quite three years old will yield this year about seven tons. One three-year old tree for example had 48 primaries and one of these by actual count contained 147 berries. As 700 whole berries make a pound the average to a tree would be very large. Mr. Ahrens considers that nearly all the valleys and gulches on this island are equally well situated for coffee and is confident that if developed in a few years millions of dollars worth might be produced. Anyone wishing to verify these statements can on any Saturday make a round trip to Waianae for \$1.25 and for another dollar for a saddle horse the plantation can be reached in good time to enable the visitor to return to Honolulu the same day. This is but one of many industries that might be taken up in Honolulu.—*The Hawaiian Commercial Journal and Maritime Report*.

COFFEE PLANTING IN SELANGOR.

In his monthly report for August (as given in the *Selangor Government Gazette* of Oct. 9), the District Officer of Klang says:—

During the month Mr. L. Davidson, of Ceylon, visited the district and inspected most of the coffee gardens, including "Highlands" and "Golden Hope" estates as well as Mr. T. H. Hill's 2,500 acres block, Mr. A. Forsyth's estate and the Dato Dagang's 14-year-old coffee. He also visited the Langat River between Kuala Klang and Golden Hope estate and inspected a portion on the right bank of the river within the reserve J, close to the Pedamaran Javanese holdings.

The Acting District Officer, Kuala Langat, reports:—

The area demarcated during the month amounted to 370 acres, which were distributed as follows:—

	A.	R.	P.
Bandar Mukim	..	115	0 0
Klanang Mukim	..	255	1 24

Total .. 370 1 24

Although a larger area than usual has been demarcated, applications are now coming in with a steady rush, and the result is that there are now 874 acres still undemarcated.

Klanang, as will be seen from the above return, is flourishing extremely and coffee land there is already beginning to fetch high prices. Much of the land bordering on the Coast Road at Klanang is really rich and only wants capital and care to produce a first-class berry. The *Tukang Kepala* has several acres of splendid coffee near the junction of the Bandar and Klanang Roads. Native tobacco has from time to time been very successfully grown there by the Javanese. At *Tanjong Duablas* (Telok Besar) I have laid out a new kampong site, and on the whole the present state of agriculture in the district may, I think, be considered satisfactory when the isolated and roadless state of the greater part of the district is taken into consideration.

PLANTING AND PRODUCE.

CEYLON TEA AND THE UNITED STATES MARKET.—From a communication from Mr. William Mackenzie to the chairman of the Ceylon Planters' Association in the Ceylon papers it appears that the packing of more than four kinds of tea for the United States is deprecated, and what are regarded as suitable prices for long lines of tea are quoted, there being an objection to tasting or handling teas running up by single cents per pound. Complaint is also made against small breaks.

TEA MACHINERY FOR CHINA.—As we hear that enquiries are being made from China with reference to tea machinery, we advise those manufacturers who are not already aware of the little peculiarities of the Chinese to act cautiously before imparting information, even if it be in serious contemplation to use tea machinery. There are no patent laws or anything approaching them within the Celestial Empire, and the imitative faculty of the Chinese is well known.

THE DOCKS AND THE SHIPPING COMPANIES.—The London and India Docks Committee has, it is said, concluded an agreement for five years with the Peninsular and Oriental Steam Navigation Company, wherein almost every demand made by the Docks for increased remuneration has been surrendered. Some small payment for special berths is to be made; otherwise all is to be as before.

THE BOTANICAL SURVEY OF INDIA.—Some excellent work has been done by the Director of the Botanical Survey of India during the past twelve months. Thus, one of the botanical collectors, Harsukh, managed to visit Pir Ghal, the highest peak in Waziristan (about 11,500 ft. above the sea), and other localities which have not hitherto been accessible to Europeans, or even to natives of Hindustan. Again, the largest and most important collection made during the Chitral expedition was that of head botanical collector Inayat

Khan. Specimens were collected all along the route as far as Chitral, and excursions were made from several of the camping grounds up to a height of 11,000 or 12,000 feet. The Pamir Boundary Commission was also fruitful in valuable botanical results, due to the exertions of Surgeon-Captain Alcock, who was attached to the Commission as the medical officer and naturalist. It is intended to publish an account of his work in a volume on the natural history of the Pamir Boundary Commission. Further, an inquiry has been initiated in connection with the outbreak of rust in Indian wheat, which is likely to lead to a number of interesting observations on this very important subject.

COFFEE.—According to Messrs. During and Zoon, the European stocks on the 1st inst. showed a decrease of about 700 tons, whilst the visible supply showed an increase of about 23,930 tons, the figures being 82,950 tons and 219,300 tons respectively, against 83,650 tons and 195,370 tons on September 1. The first offers of East Indian colony coffees have made their appearance in our market already, says the *Commercial Record*, but, as usual, no business resulted. There is in our belief hardly another trade where the maxim of "give and take" is more needed and frequently practised than in the East Indian coffee trade. Invariably sellers and buyers are shillings and shillings out at the beginning of the season, but judicious persuasion of the honest broker at both ends of the sea gradually brings the opposing poles into close proximity, and at last business results. A Coorg crop at 95s c.f. and a Neilgherry at 90s c.f., although both hailing from good estates, were found exorbitant here, and bids of about 5s less were proffered by speculative buyers in our market, which, however, met with silent scorn on the part of the Indian planters. In the face of their small yields this year, planters are naturally more stubborn than usual, and will require a lot of work to bring them down to reasonable prices, but at the best the arrival business this year will be, we fear, confined to small limits only, for, according to the latest reports, Chickmigur promises to fall short 50 to 60 per cent. of last year's yield, and Coorg at the very least 30 to 35 per cent. In other districts the prospect are even worse; some are returned at half of their last year's gatherings. It may interest those dealing in these fine East Indian sorts that the total export from Coorg during the year 1895-96 is shown to have been about 3,650 tons. Stocks of light coffees in the principal European ports are about the same as last year, so there is no lack of available stuff, and if Indian planters wish to dispose of their crops on arrival terms, it will be advisable not to hold out for impossible values, or otherwise they might be compelled to run the risk of the market until their gathering has reached the hammer of the London broker.—*H. & C. Mail*, Oct. 16.

A CUP OF TEA.

This was the title of a lecture delivered last week at the Agricultural Hall in connection with the Grocers' Exhibition. The lecturer was Dr. Goodfellow, who dealt with the subject from a general point of view. If the lecturer succeeded in impressing his audience with the importance of using tea to the best advantage by brewing it properly, his lecture will have served a useful purpose. After describing the tea plant and the method of dealing with the leaf, the lecturer said: "The average composition may be taken as follows: General composition of black tea—water, 8.10; theine, 3.35; albumin, 18.01; nitrogenous extractives, 5.82; dextrin and seetin, 1.21; organic acids and oil, 1.04; tannin, 17.02; colouring matter and resin, 3.21; cellulose, 35.89; ash, 6.35—100.00. Green tea differs slightly in composition from black, containing considerably more tannin and slightly more essential oil. A few words on the properties of these bodies will prove of interest,

Theine has the formula $C_8H_{10}N_4O_2$, consisting of carbon and the gases nitrogen, hydrogen, and oxygen in chemical combination. In the pure state it is a white body crystallising in needle-shaped crystals; it has no smell, but possesses a slightly bitter taste; it dissolves freely in hot water. It is classified by many chemists among the vegetable alkaloids, and may be regarded as a powerful stimulant to the circulatory and nervous system; it is therefore the stimulating constituent of tea. Albumin belongs to the proteids or flesh-formers, but as it does not pass into the infusion I need not dwell on its properties and uses. Nitrogenous extractives are unimportant from our point of view, and so are the colouring matters, cellulose and ash. The volatile oil present, however, deserves a few words. It is believed to be produced in tea during the process of preparation, as it has not yet been found in the fresh green leaves. When obtained pure by distillation it is of a yellowish colour, and smells strongly of tea. It is very volatile, and is the constituent which gives to tea its characteristic aroma. It acts as a narcotic on the nervous system. Tannin is the astringent constituent of tea, and is closely allied to the tannin of the oak bark. It has a bitter taste and possesses the property of combining with animal membranes. It has a constipating action on the bowels. It does not dissolve out very rapidly from the tea-leaves, but after about five minutes the rate of solubility increases. The injurious effect of badly prepared infusions of tea are mainly due to the tannin present. Tannin gives a greenish black reaction with chloride of iron and this reagent may be employed to compare qualitatively two samples of tea for tannin acid. There are certain other organic acids present in tea which I am of opinion may exercise a harmful effect on digestion. We are mainly interested tonight, however, with the stimulating constituent of tea, viz., theine. I have already pointed out that theine is composed of carbon, hydrogen, nitrogen, and oxygen, and I have here on a table the result of the ultimate analysis of a portion of theine. It is a very interesting and wonderful subject to consider how these elements are combined to form a body like theine. Carbon is a black solid, hydrogen an inflammable gas, nitrogen a gas with no very striking properties, oxygen is the gas which supports all combustion. These elements, so dissimilar in properties from each other, are combined in suitable proportions to form this white crystallised stimulant. A few experiments with these gases will help to bring home this interesting fact to your minds. Oxygen gas is an invisible, inodorous, and tasteless gas. It will not burn of itself, but causes other bodies to burn with great rapidity. A piece of sulphur, phosphorus, or even iron wire will burn brilliantly in oxygen; and I will now proceed to demonstrate its properties to you. [Dr. Goodfellow here performed a number of striking and brilliant experiments, showing the wonderful powers of oxygen in supporting combustion.] Hydrogen is a light gas, the lightest substance known in fact, and will not support combustion, being in this respect quite unlike oxygen. It burns, however, very readily with a blue flame, producing water, and with air forms explosive mixtures. [The lecturer performed a number of experiments with hydrogen, showing its important properties.] Nitrogen, the other constituent of theine, is also a gas, but it will neither burn nor support combustion. It has few positive properties, its chief use in nature being to dilute the

oxygen of the air, of which it forms 78 per cent. [Experiments were here shown with nitrogen.] These elements then are chemically combined to form theine, the active stimulating constituent of tea. Of the bodies which I have mentioned as composing the tea leaf, theine, tannin, and the volatile oil are the chief found in the infusion. Very few people know how to prepare tea properly. Many believe that unless the liquor be dark it is of inferior quality, while others think the strong acrid taste of the liquid obtained by allowing tea to stand for a long time indicates high quality. These ideas are wrong. The acrid taste is due to tannic acid, a body which is injurious to the system in excessive quantities, and therefore indicates a badly prepared infusion. The chief objects in the making of tea are—(1) to obtain the maximum of theine with the minimum of tannic acid; (2) to develop and bring out the aroma. Now the longer the leaves steep in the water, the greater the quantity of tannin dissolved out. It follows, therefore, that to allow tea to brew too long is a mistake, as the flavour is spoiled by the predominant tannin, and the infusion acquires injurious properties. Further, the aromatic oil is largely lost by evaporation by allowing the tea to stand too long. In order to secure the best results the following plan is recommended. Two earthenware teapots are required, and both should be heated dry in front of the fire. The dry tea should be placed in one of the pots and allowed to remain in the closed warmed teapot for about one minute. This brings out the aroma. Water which has just come to the boil should now be used in the preparation of the beverage, and the whole allowed to stand from three to five minutes according to the kind of tea. At the end of this period the liquor should be poured into the second heated teapot, and is then ready for the table. Recently, many teapots have been invented with the object of achieving the same result without the bother of pouring into a second pot. The principle in many is an arrangement whereby the tea is placed in a separate vessel called the 'infuser,' and boiling water poured on in the usual way. After four or five minutes by a contrivance the infuser is withdrawn to the upper part of the pot, and thus undue soaking is prevented. Tea prepared according to this plan contains a fair quantity of theine and a minimum quantity of tannic acid. The aroma is also well brought out. The leaves should not be used again for a second brew, as a second liquor would contain a large percentage of the tannic and other organic acids most injurious to the digestive system. What are the effects of properly prepared tea taken in moderation? In the ordinary properly prepared infusion the action of the volatile oil and tannin may be neglected, the physiological effects being chiefly due to the theine. Regarded in this light tea is a stimulant to the circulatory system. It quickens the pulse slightly, and accelerates the respiration. The theine also acts specifically on the nervous system, stimulating thought and mental processes. It also acts on the skin, increasing perspiration. In this way it generally acts as a refreshing agent to the whole system, and often acts so specifically on the brain as to cure or palliate nervous headaches. It cools the body, too, by inducing activity of the sweat glands, and its effect is not followed by any marked reaction. But if tea—even properly prepared—be taken regularly in excess, it acts injuriously on the body. It produces hyper-excitability, sleeplessness, trembling of the muscles, palpitation of

the heart, and many chronic nervous ailments are produced by excessive tea-drinking. When tea is badly prepared, so that it contains an excess of tannic acid, the injurious effects are greatly increased—digestion is seriously delayed, the gastric juice partially decomposed, and the mucous membrane of the stomach so altered as to seriously interfere with the absorption of food. Tea is not often adulterated nowadays, the vigilance of the Customs officials being largely responsible for this satisfactory state of affairs. Sometimes exhausted leaves are faced and added to genuine tea, but the practice is very uncommon indeed. Perhaps the most serious evil connected with tea-drinking is the increasing demand for the strongly flavoured teas which are grown on virgin soils without the most careful cultivation. These varieties of teas are usually very rich in organic acids, which may be regarded as the objectionable constituents of the popular beverage; but a very simple test for tannic acid will show the intelligent individual which of two samples of tea contains the less. To each jar add an equal volume of a solution of ferric chloride (chloride of iron), and dilute with equal quantities of water. The solution which gives the strongest greenish hue contains the largest quantity of tannic acid. [Dr. Goodfellow here demonstrated this simple test.] Another evil connected with tea-drinking is the growing custom to make a cup of tea and a little light cereal food, like biscuits, &c., take the place of a good meal. Provided that plenty of food be taken there can be no objection to a cup of properly prepared tea, but it should not be taken before the meal, as the edge is thus taken off the appetite. In conclusion, the cheering qualities of good tea deservedly place it above all temperance beverages and stimulants; but in the enjoyment of the fragrant cup practise moderation, see that the tea itself is of good quality, and exercise a little common sense in its preparation."—*H. and C. Mail*, Oct. 16.

WYNAAD PLANTERS' ASSOCIATION.

At a recent meeting there were present:—Messrs. Abbott, DeFenblanque, Mackinlay, J. S. Malcolm, J. S. Nicolls, R. K. Walker, H. Waddington, and B. Malcolm, Acting Hon. Secretary. Mr. Walker in the Chair.

The Acting Hon. Secretary read a statement, the substance of which has already appeared in the papers, of the Reception of the Deputation from this Association by H. E. the Governor. The Association recorded with great satisfaction the way in which its Deputation had been received by His Excellency and was especially glad to hear that His Excellency had stated that if it were necessary that the Grant towards the upkeep of the main road should be somewhat supplemented. He did not think there would be any difficulty about the matter.

Read letter from Mr. Sanderson to Secretary U P A. regarding the conditions under which coffee is worked in the Port of London; and the steps taken by a Committee on behalf of the trade, with the resulting improvements for future working of this Product recorded with satisfaction.

LIBERIAN COFFEE.—A discussion ensued regarding curing charges on Liberian coffee. It was resolved that the Honorary Secretary be instructed to address the coast firms, pointing out that a large acreage of Liberian coffee is now coming into bearing; and that while this Association is fully aware of the necessity of obtaining special pulpers, it would point

out that there will always be some 25 per cent of this crop sent down in dry cherry for treatment on the coast. That this Association views with alarm the large rise in curing charges. It trusts that it is only a temporary measure; and will be glad to learn what steps the firms are taking for the efficient treatment of this coffee.

KOLA-PLANTING.

Within the last two months several important planters from Brazil, Ecuador, and British Guiana have visited London, and made inquiries about the advisability of starting kola-plantations. These planters mainly take up their European headquarters in Paris, and in that City they have made experiments with kola preparations. One of them, a Brazilian, afterwards also made inquiries in Germany and the United States. He was told that London was the centre of the kola trade, and finally went there. Not being able to obtain any information from the wholesale chocolate-makers, he went to Kew, and also to Messrs. Christy & Co., of Lime Street, where he secured half a ton of kola-nuts for seed. Kola, said this Brazilian, was a most economic crop for the planter. Those with whom he had talked about the matter in Europe had mostly asked him to ship the nuts, surrounded by leaves, in straw baskets, exactly as they have been packed in Africa for centuries. Mr. Thos. Christy, when I called upon him the other day, was enthusiastic about this Brazilian, and further told me that he had also had visits recently from an Ecuadorian and a British Guiana planter, both of whom want to start kola-planting.

The planter from Ecuador went to Germany and New York where he learned that there was a large demand for fresh, kola-nuts, that it was an easy, clean article for a planter, and that the tree grew at a low elevation. Then, coming to London, he pursued his investigations and purchased plants from Messrs. Christy & Co. Kola, he said, is sure to be taken up largely by planters, because no preparation, such as the fermenting of cocoa, or the fermenting, husking and drying of coffee, is necessary. It runs no risk of being spoiled on its way to the coast, and there is no doubt that it is a crop that will become as popular in South America as it is in Africa.

The British Guiana planter's experience is almost identical, and shows that there is a movement in favour of the introduction of kola on plantations in various parts of South America.

The great obstacle to the popularising of kola has hitherto been the want of a palatable preparation which might be taken as a breakfast beverage by the million. Mr. Christy assured me that his "neokola" fills this gap, and that it is in a great measure due to their conviction that the popularisation of kola on cocoa, tea and coffee lines is imminent that these South American planters are disposed to take up kola-growing—*Chemist and Druggist*.

COFFEE PLANTING IN LAGOS.

The curator of the botanic station gives an account in the *Kew Bulletin* of the progress made with coffee planting in Lagos. He says coffee planting is being energetically extended in West Africa. This part of the world is the home of more than one species yielding commercial coffee. Chief amongst these is the Liberian coffee which thrives at sea level. This has long been grown in the native state of Liberia.

Seeds of Liberian coffee were received at Kew in 1872 from a small plantation on the Secoom River near Accra on the Gold Coast. "The plants raised from these seeds at Kew were the first grown in this country. In 1874 and 1876 larger supplies of seed were obtained direct from Liberia, through the kind agency of Mr. James Irvine, of the firm

of James Irvine & Co., of Liverpool. The plants were distributed from Kew to tropical botanic gardens throughout the Empire." Coffee cultivation is now being carried on under European supervision both at the Gold Coast and at Lagos. In the latter colony the industry has originated in the efforts made in that direction at the botanic station established by the Government at Ebute Metta. The distribution of Liberian coffee and other plants from this station have been as high as 13,960 per quarter, or at the rate of 45,000 per annum. In 1892 (although a nominal price only was charged for the plants, and in some cases many distributed free of charge to native chiefs) the total receipts amounted to more than £91.

In 1894 some Arabian coffee in parchment, grown at the botanic station at an elevation of only 2 ft. above the sea, was valued in London at 94s per cwt. It has been shown, however, that the more permanent sort to grow in the lowlands is the Liberian coffee, and samples of this were recently valued at nearly the same price. The curator, Mr. Millen, remarks in his report for the quarter ending December 31st, 1894: "There is no doubt that coffee has a great future before it on the West Coast. If properly cultivated and prepared it should be able to compete with any coffee-growing country."

In the appendix to the report on the botanic station for the quarter ended September 30th, 1895, the following further particulars are furnished respecting the extension of coffee plantations in the colony of Lagos:—

It will probably be interesting to record the advancement made in coffee plantations in this colony, which have originated through the establishment of this botanic station.

When returning from Abeokuta His Excellency the Acting-Governor gave me permission to visit two plantations situated near the Ado River.

The first one I visited was at Soto, and is owned by the Ilaro Estates and Plantations Company, Limited; it was commenced in 1892, and is under the management of Mr. Punch, a European, who took me round and kindly gave me quarters for the night.

Mr. Punch calculates that he has 150 acres under cultivation, which includes 50,000 plants of coffee liberica. These plants are in different stages of growth; 1,200 plants are three years old, and are producing a fine crop of large bold berries; 5,000 trees are two years old, and are in a healthy and flourishing condition. These also are producing berries, and are doing remarkably well when taking into consideration that a crop is not expected much before three years; 9,000 plants were planted out last year, and 36,000 during the present year.

About 1,000 of coffee arabica are planted out, and these have produced good crops of berries of good size.

CACAO is also being grown; 4,500 plants have been planted out, and their appearance is everything that could be desired for young plants.

I next visited the plantations, the property of A. C. Campbell and Co., situated on the other side of the river, and about one hour distant from the town of Ajilete. I visited this plantation in the early part of 1893, and reported on it. At that time preparations were being made for planting out during the rains. I could see a marked improvement since my first visit, and considerable work had been done.

Mr. Campbell offered me every facility, and was pleased to see me visiting the plantation.

He states that he has 160 acres under cultivation, most of these being planted with Liberian coffee, numbering 67,000 plants. They are represented in three stages of growth:—13,000 were planted out in 1893, and are in most flourishing condition; the berries are well matured, and of good size. In 1894, 22,000 were planted out and are doing well; while 32,000 have been planted in their permanent place during the present year. The plants are looking very satisfactory for the time of year.

Here, also, are a few plants of Coffee arabica. They have done so well that Mr. Campbell intends to extend the plantation and plants more of this kind.

NURSERIES.—About 25,000 plants of Coffee liberica are in beds large enough to transplant.

VANILLA (*Vanilla planifolia*).—These were botanic station, and grown in a shady and cool place on the plantation. Here they have made enormous growth, and have been doing so well that Mr. Campbell anticipates planting out an acre with this valuable plant.

KOLA (*Cola acuminata*).—About 600 of these have been planted under the shade of forest trees.

CACAO.—About 300 plants of cacao have also been planted out, to ascertain their suitability for further cultivation.

The plantation is kept in a clean condition, free from weeds; the soil is rich in vegetable matter; it is pure forest land, and several streams pass through the plantation, which are very useful in watering the nurseries.

The work has progressed considerably since my previous visit, and the work carried out by Mr. Campbell is very creditable indeed. This plantation is worked by forty-five labourers.—*H. & C. Mail*, Oct. 16.

MARKET FOR TEA SHARES.

THURSDAY EVENING, October 15, 1896.

A rather steadier tendency has characterised the market in Tea shares for the past week, and in some cases a notable advance has taken place in the shares, especially of the best known old companies.

Mining Lane is again easier, both for Indians and also for Ceylons.

FRESH ISSUES.

Consolidated Teas and Lands, all classes of the shares, are rather easier, with sellers rather than buyers at a little below last price.—*H. and C. Mail*, Oct. 16.

SALE OF QUININE AND CINCHONA.

It is a fact which deserves some attention, that in spite of the greatly increased quantities of quinine in the bark offered at auction in Amsterdam, almost the whole of the supplies continue to find buyers. It is true that the prices are very low, but unless the demand for quinine were not only keeping up, but actually advancing, it would be impossible to dispose at any price the enormous quantities that are now being offered. How great and increasing these quantities are may be seen from the following comparison of the bark and quinine offered at the first eight auctions of the last four years held in Amsterdam:—

	Total pkgs. in 8 sales	Total kilos Bark	Total kilos Quinine	Average con- tents of Bark	Kilos Quinine Sold	Kilos Quinine bought in
1896	48,968	4,528,277	240,309	5.05 to 5.83	262,126	38,183
1895	52,512	4,636,859	225,367	4.63 to 5.17	141,314	84,053
1894	39,951	3,443,031	161,659	4.61 to 5.12	125,727	85,932
1893	46,423	3,930,504	172,982	4.23 to 5.02	97,679	75,303

These increased sales have been made in the face of the fact that it is well known to all buyers that the Java supply is not by any means exhausted.—*Chemist and Druggist*, Oct. 17.

A TEA-DRINKING CEREMONY IN JAPAN.

From an illustrated paper in the September number of the *Far East*, by Mr. Takashima Seta, Professor of English in the Higher Commercial College, Tokyo, entitled "The Chanoyu Ceremony," we make the following extracts:—

Japan, with her long line of history and traditions, is still a problem in divers things to Western people, especially in some of her characteristic institutions which still remain unfathomed despite the pile of information culled by globe-trotters and other prolific writers whose fanciful pens often depict Japanese affairs in colours altogether unnatural. To these writers caprice seems to sway many things. Japanese in such a way as sometimes to thwart all attempts at analysis. Taste, widely different according to country, age and race, should be thoroughly appreciated ere one can gain an insight into the manners and habits of a nation. To judge Japanese institutions by a Western standard of taste or in a matter-of-fact way may perhaps render them incomprehensible, or even absurd. For example the question may naturally arise of what wisdom and practical benefit are those endless formalities in the making and drinking of tea in the Chanoyu ceremony? Certainly, if judged by a cold utilitarian principle, i.e., if tea drinking means no more than drinking tea, this august ceremony will lose all its significance and charm, but the Chanoyu rightly understood means more than a mere gratification of the palate, and its merits must be considered from an æsthetic and also from an ethical point of view. It is an art in the sense that every movement and action in the performance of the ceremony is rendered in compliance with the laws of grace and refinement, while on the other hand it involves an ethical significance, inasmuch as in ancient times it was looked upon as a means of religious discipline. The man who enters into the true spirit of Chanoyu, free from the detractions necessarily entailed by worldly cares and ambitions, however extravagant it may sound to say it, is fitted, in the language of a priest who made much of this ceremony, "to be better disposed to grasp the truths of the Infinite." As to whether Chanoyu was instituted for merely bringing friends together to enjoy a pleasant time over a cup of tea, or whether it was intended to impart to those who took part in it certain sound practical lessons for the conduct of daily life, our readers must draw their own conclusions.

Except to the initiated, the secrets of the ceremony are a veiled mystery. The profound motives, so eloquently set forth by various Chanoyu men in regard to the ceremony, sound rather far-fetched and improbable. Rikiu, the greatest master in this art that ever lived, referred in one of his poems to the fact that Chanoyu meant no more than to boil water, make tea and drink it *properly*. On one occasion when a man quizzed him on the secrets of Chanoyu, Rikiu replied, "Well, there is no particular secret in the ceremony save in making tea agreeable to the palate, in piling charcoal on the brazier so as to make a good fire for boiling the water, in arranging flowers in a vase in a natural way and in making things appear cool in summer and warm in winter." Somewhat-disappointed at the apparently insipid reply the inquirer said, "Woh on earth does not know such a simple explanation as that." Rikiu's happy retort was, "Well if you know it, do it" It sounds paradoxical but is true that "there is no iron law for Chanoyu requiring that such and such forms should be observed, but at the same time, the ceremony should not be performed at random." All the endless round of formalities is, after all, a means to an end. Everything in the ceremony seems strikingly artificial and conventional innumerable laws regulating even every move of the hand and body. There are said to be seventy five manual movements in an ordinary Chanoyu, and over three hundred in the true orthodox ceremony. But the consciousness of being fettered by laws, shows that one has not yet reached a state of proficiency in the art. Freedom and ease are the ultimate end of Chanoyu, so that the slavish adherence to rules in the beginning should finally end in an un-

conscious observance of them. Hence the manners of Chanoyu master should be graceful and polished, and their taste chaste and refined, not because they strive to be thus, but because of the culture received through the Chanoyu practice. It is as much a violation of the spirit of the ceremony to make much ado about the *catechisms* and secret traditions existing in different schools of Chanoyu as to wrangle about the differences of the tenets of different denominations ignoring the very spirit of Christianity. Again losing sight of the main motive of Chanoyu, people are often led to believe that, but for the display of wealth and luxury, the ceremony could not be conducted with any degree of success. The simplicity and unobtrusiveness so beautifully exemplified in Rikiu's whole career may be safely taken as its watchwords. Good fellowship and the absence of social barriers characterize all Chanoyu meetings. In feudal times when people were bloodthirsty and bent on warfare, the prevalence of Chanoyu among the military class, strange as it may appear that the *Samurai* of those days took to this graceful ceremony, exercised no mean influence towards cooling the heat of military ardour.

The Chanoyu ceremony had its origin in Buddhism. About seven hundred years ago a priest of Kyoto named Yeisei brought back to this country from China, where he had been on a mission, some tea seeds which he planted for trial on Mt. Sabori in Chikuzen. A good crop of tea rewarded his labour, whereupon he presented some of the choice leaves to a prominent personage of the time, who relished them as a rare tonic for headache. Meikeishonin, another priest of note in those days, is said to have transplanted some of the shrubs to Mt. Togano with a result that far surpassed his expectations. From that time on, tea has gradually become a popular beverage both among the high and the low. The introduction of the Chanoyu ceremony proper was deferred to a later period, i.e., 1267 A.D., when a set of *Daisu*, the ceremonial tea service, was first brought over from China. Of course in those days the ceremony had nothing of the elaborate character which it presents today. It was then a cherished pastime for the priest in his solitary hours in the monastery, but it had not yet commanded the attention of society at large. Some years after, the *Daisu* referred to above fell into the hands of Ashikaga Takauji who lived in the middle of the fourteenth century, and whose record in history was blotted by his disloyal conduct towards the Emperor in his latter days. Enjoying a short interval of peace, he gave himself up to the pleasures of Chanoyu but soon after the country becoming turbulent, he had to take up arms. Chanoyu shared the vicissitudes of disturbed society for many years, until the final restoration of peace caused its *renaissance*. The golden epoch of the Chanoyu ceremony in the mediæval history of this country, was at the time of Yoshimasa who grasped the reins of power in the middle of the fifteenth century. In 1479, freeing himself from worldly responsibilities, this accomplished general retired to "Ginkakuji," the Silver Storied Temple in Kyoto, in building which no expense was spared. Near the main building he caused to be put up a little apartment where he frequently held Chanoyu meetings with prominent men of the time. Yoshimasa learned Chanoyu under Shuko, a priest of Shomeiji in Kyoto, who for the first time formulated and codified its canons. Under such an impetus the ceremony reached a marvellous degree of popularity. In the course of time numerous schools sprang up, but it is universally recognised that Chanoyu as it is practised today was perfected by Rikiu who introduced divers improvements. Being a man of extraordinary talent, rare intrepidity and ready wit, his life as a Chanoyu artist reads like romance. For the marvellous work he achieved in his profession, he surely deserves the esteem and regard lavished upon him by the men of his time as well as by succeeding generations. Serving first under Nobunaga, and subsequently under Taiko, his works speak more eloquently than volumes of panegyrics. Rising above the grave error of the people of his time, who vied with one another in putting up elegant rooms and collecting costly utensils, this great master inaugu-

rated a model style of architecture and gardeniug, exceedingly simple and modest, but of exquisite taste. To show with what simplicity and economy Chanoyu could be successfully conducted, he planned a room of only two *So* size, or of not much over six feet square, and as utensils he brought over rough looking earthenware pots into service in the ceremony. Oblivious of the true motives of the great master, the people after him prided themselves in securing purposely unshapely looking articles at exorbitant prices!

Of eight different schools of Chanoyu now extant, i. e., the Senke, the Yuraku, the Oribe, the Yabunchi, the Yenshu, the Sekishu, the Kanamori and the Sohen, the most popular is the first named, founded by Rikiu. It goes without saying that each school possesses its own secret traditions, imparted only to the initiated, but to point out and explain their differences and characteristic points is out of the question in these limited pages.

Sosho is the highest honorary title given to those of special attainment in this art, but so few have deserved it, that only five names are mentioned in history upon whom have been conferred this coveted name. The five thus honoured were Shuko, Showo, Rikiu, Oribe and Yenshu, the first being the founder of the so-called Chanoyu, the second, the great promoter of the art in the middle of the sixteenth century, while the last three are the founders of their respective schools. Leaving all prejudice, Rikiu was the greatest of them all, and to him may be ascribed the perfection of the ceremony.

During the Tokugawa dynasty, Chanoyu received such attention that it was made a sort of national ceremony and the lord of each province used to support a professional in this art called "*Chobozu*" or "tea priest," probably so named from his clear shaven head, which was a characteristic of Chanoyu teachers.

THE UTENSILS REQUIRED FOR THE PERFORMANCE OF THE CHANOUYU CEREMONY.

The famous Rikiu once made the apt remark that "it is ridiculous to make so much ado about costly utensils, when all that is required in Chanoyu is only a kettle." Even the very cheapest ware answers the purpose, if one enters into a true enjoyment of the ceremony. Not upon utensils or external environment, but upon the minds of the participants in the ceremony, depends the success of the ceremony. There is an interesting anecdote illustrating this. It happened over sixty years ago that one day the famous Japanese poet Chikusa Arikoto, in a walk in disguise through a street in Kyoto, came across a little hut by the roadside, with a little patch of ground with two or three trees, thoroughly sprinkled with water and looking very refreshing. He saw inside this humble cottage a man practising Chanoyu all by himself. His curiosity being deeply aroused at the strange employment of the inmate, he entered and occosted the man. He was seated in a little space of not more than six feet by three scrupulously clean, and on the wall was hung a screen with a rare autograph by a famous poet. Arikoto entered into conversation with the man on Chanoyu, who finally asked him if he would become his guest at a Chanoyu meeting early the next morning in the forest near by. This strange invitation was at once accepted. Next morning upon coming to the appointed place, Arikoto found three stools beneath a shady tree. The old recluse in a coarse but clean dress received his distinguished guest most cordially, and went through the tea ceremony in a masterly way, the utensils employed on the occasion being of the humblest description such as may be found any day in the kitchen. As the guest was about to drink the tea offered, he heard overhead the sweet notes of a nightingale much to the delight of his host. It is said that the next day when a messenger was despatched with a bounteous present to the hermit, he had disappeared no one knew where.

It would not interest readers to enumerate all the little utensils used in Chanoyu but here we may mention some of the more common and necessary ones to which I shall have occasions to refer in the course of this article.

1. *Kama*, kettle, and *Huro*, a brazier set on the mat.

II. Decorations for a Chanoyu room.—1. Hanging screen—a specimen of writing is preferred to a picture. 2. Flower vase. 3. Double folding screen (to be placed in front of the brazier.) 4. Censer stand. 5. Tobacco fire-box. 6. *Anbon*, an old fashioned lamp with a paper shade.

III. Candle sticks and a hanging lamp.

IV. Utensils for ashes and charcoal.—1. Ash shovel.

2. Feather duster. 3. Charcoal basket. 4. Tonga.

V. Tea set.—1. Tea caddy. 2. *Chasen* (beater). 3. Ladle. 4. *Chashaku* (tea scoop). 5. Tea towel (18 in. by 6 in.) 6. Napkin (purple, yellow, brown or red colour). 7. Cup. 8. Incense case.

VI.—1. Water bucket. 2. Water jar. 3. Slop jar.

VII.—Shlf : Square and Round.

THE TEA CEREMONY PROPER.

About a week beforehand invitations should be issued stating the date and hour, together with the names of the guests to be present on the occasion. Those thus honoured should then wait upon the host a day previous to the time of entertainment to return thanks for the invitation received. In Chanoyu meetings a large number of persons are seldom invited at a time, this probably being necessitated, partly by the limited size of the room and partly by a desire of preventing the possibility of confusion which might mar the enjoyment. Usage prescribes the hours for Chanoyu meetings, viz., early dawn, morning, noon, evening, or any time after meals, but in days of yore the custom was to hold such meetings in the early morning, when nature was still in her freshness and the hubbub of the day had not yet set in. The care and anxiety of the host in working up a Chanoyu meeting can be better imagined than described. He has personally to attend to all the minute details. For example, he should first of all see to it that the room and the surroundings be properly swept and cleaned, that the ladle for the lavatory be changed to a new one, that in winter the garden be carpeted with pine leaves, except on the stepping stones, and that trees as well as the ground be thoroughly sprinkled with water. When snow happens to be on the ground the flakes should not be swept away save on stepping stones. Then again, he should not forget to provide the following articles in the waiting room: cushions, tobacco fire-boxes, braziers (in winter), sandals, umbrellas and clogs (in case of rain), a writing box, bell and a card giving the names of the guests to be invited in the order of their rank. His work is not even then ended, for he should keep his eyes open to make sure that the room is properly arranged, set a kettle on the brazier, hang a screen on the *tokonoma* or place of honour and place the charcoal basket incense case and other necessary articles in their proper places. Meanwhile, at the appointed hour the guests will arrive at the waiting room, when the host makes his appearance in the garden and asks them to come in to the Chanoyu room. The guests will then enter the garden, and each kneeling before the *Tsukubayc* or stone cistern, will wash his hands and mouth (this is, however, dispensed with in a morning meeting) and then make his way towards the place of ceremony. Upon gaining the *Njiriguchi* or crawling-in entrance, which is left half open, the first guest stoops before it and peeps into the room to take in a general survey, then enters or more strictly crawls into the room and advances to the front of the *tokonoma* to examine the screen. While doing this the second guest will be peeping into the apartment following the first, and by the time the latter approaches the side of the *Ro* or fire place to inspect the kettle, the former will be before the *tokonoma*, thus when the first guest takes his seat, the second will be by the side of the *Ro* and the third in front of the *tokonoma*. The rest of the guests will go through a similar routine in their turn. The one in the rear shuts the door after him with a slight noise which serves as a signal that the guests have all entered the room—the host being mean-

while in another room. The host then makes his appearance and expresses in a few words his cordial welcome to the guests, whereupon the head guest makes some complimentary remarks on the neat appearance of the garden. The host then brings forward a charcoal basket and piles some charcoal on the brazier, and when later he burns incense on the fire, the guests will ask the privilege of looking at the incense case. This being finished, a meal is served. One characteristic point in this feast at the *Chanoyu* meeting is that the host waits on the guests himself. Here we might devote a page or two to the particulars of the meal, not so much as to the menu, which is simple so far as courses are concerned, but to the elaborateness of the table etiquette observed on the occasion; we will, however, hurry on to the tea ceremony proper.

Right in this connection, I must crave the reader's indulgence should the ensuing description be found tediously minute, yet I am disposed to trespass on his patience in order to satisfy his curiosity in regard to the intricacies that are involved in the performance of *Chanoyu*.

After the repast, the host asks the guests if they would be pleased to retire for *Nakadachi*, or recess, upon which they temporarily withdraw to the waiting room. Meanwhile the host removes the screen from the *tokonoma* and sets a flower vase in it, containing a few sprays of flowers. After this the kettle is filled with water, and more charcoal piled upon the brazier. This being done, the water jar and tea caddy are brought and arranged on the mat as in Figure 1. Everything is now ready; the host steps out into the garden and beats a gong upon which the guests proceed to the room in the same way they did at first. When they are all seated, the host brings forward a cup, a beater, and a scoop, and sitting in front of the water jar he sets them thus. (Figure 2.) Next in order come a slop-bowl, a lid stand and a ladle. The host makes a bow to the guests, then taking up the cup places it before him. Next he takes the tea caddy from its wrappings which are intended to protect it, and re-arranges the utensils as in Figure 3. The host then wipes the tea-caddy and the lid of the water jar with a piece of cloth which he always carries in his belt. Taking the ladle with his right hand and transferring it to the left, he removes the lid of the kettle and dips out hot water and pours it into the cup. The lid is then set on the kettle, and the ladle on the "lid stand." The *Chasen* (beater) is rinsed in the hot water in the cup and set aside while the cup after being emptied is wiped clean. With the right hand the scoop is held and with the left the tea caddy, the cover of which being removed, is placed at the right of the cup. Finally some powdered tea is measured into the cup. Then scooping out hot water from the kettle, the host pours it into the cup and briskly stirs up the tea with the beater. The foaming tea is now ready for the guests. The head guest respectfully holds the cup in his hands and takes a sip whereupon the host will ask if the tea tastes right. An answer having been received, the host puts the lid on the kettle and sets the ladle against the slop-jar, while the guests in rotation drink a little and examine the cup after drinking. The host then removes the lid of the kettle and lays it on the lid stand, and then places the ladle across the top of the kettle, and awaits the return of the cup from the last guest. When the cup is returned, he lays it before him, and pours some hot water into it and rinses it. He then announces that he would be pleased to offer them the *usucha* (weak tea). With this remark he pours some water from the water jar into the cup for cleaning the beater, after this he empties the water from the cup and wipes the latter with a "tea cloth." Three scoopsful of water are now added to the kettle and the ladle is set against the "lid stand." Just at this juncture, the guests ask the privilege of examining the three articles, viz., the tea caddy, its bag and the tea scoop which after being examined are stowed away. After this the guests and the host may enjoy themselves in

indulging in informal conversation. The meeting is closed with the offering of *usucha* (weak tea) prepared in a manner similar to that described above.

With slowness, to a degree trying to one's nerve, composure and precision the above ceremony is executed, and it is difficult to analyze the impression of one who for the first time beholds this much-spoken-of ceremony of Japan.

HOW TO DRINK THE TEA AT THE PLACE OF CEREMONY.

On reading the following description of the orthodox way of holding the cup and drinking its contents, it is bewildering to think that one should go through all this trouble for the simple refreshment of a cup of tea. The tea may be served in two different styles, viz., the *koicha* (strong tea) and the *usucha* (weak tea); in one the guests drink each a little from the same cup, while in the other a fresh cup of tea is prepared for each individual. The forms to be observed in each case are somewhat different as regards minor points.

As the host offers a cup of tea (*koicha*), the head guest advances a little and taking hold of the cup he sets it in front of him. Next he takes the napkin offered, and lays it by the side of the cup. Resuming his seat, he bows to the rest of the guests, and then begins to do his part. With the right hand he spreads open the napkin on his left palm, and places the cup on it. Touching a side of the cup with his right hand, he respectfully holds up the cup as far as to his eyes—a sign of reverence. This being done, he takes a sip, and after three and a half sips, he wipes with his index finger the part of the cup which his lips have touched and then wipes his soiled finger with a sheet of paper. The cup is then passed to the second guest who receives it with both hands and drinks his portion in the same manner as his predecessor. After the last guest has drunk the last drop of tea, he sets the cup with napkin on the mat and then admires it.

In case of *usucha* (weak tea), while the host is measuring the powdered tea into the cup, the head guest bowing to the one sitting next to him, takes the cake dish in both hands and sets it before him, (by the way, cake is not served in connection with *koicha*). Then spreading open before him, a sheet of paper, he lays a piece of cake on it. The cake dish will then be passed on to the next guest who helps himself to a cake in the same manner. The one taking the last seat, passes back the dish to the head guest who places it where it was before. When a cup of tea is offered, the guest first eats the cake, then takes up the cup with his right hand and lays it on the left palm. If three draughts and a half he drinks the contents, after which he wipes off the part his lips have touched with his first and third fingers.

In the above I have described the general process of *Chanoyu*, leaving out many minute points fearing lest my narrative should become blurred in the intricacy of details. For the sake of clearness let me summarize the programme of an ordinary *Chanoyu* Meeting.

1. Preparations of the host for the meeting.
2. Arrival of the guests at the waiting room.
3. Entrance of the guests in the *roji* i.e. garden.
4. Entrance of the guests to the room.
5. Greeting of the host.
6. Dinner.
7. *Nakadachi* i.e. recess.
8. Second entrance of the guests in the room.
9. The *koicha* ceremony.
10. The *Usucha* ceremony.

—*The Far East* for Sept.

TAKASHIMA SETA.

THE AMSTERDAM MARKET.

Our Amsterdam correspondent writes on October 10th:—"The total exports of cinchona-bark from Java were extremely heavy last month. The figures now are as follows (in half-kilos.):—

	1896	1895	1894	1893
September	1,789,000	816,000	1,071,000	500,000
Jan. to Sept.	7,818,000	5,829,700	6,625,000	5,876,000

—*Chemist and Druggist*, Oct. 17.

SIR HARRY JOHNSTON'S REPORT ON
BRITISH CENTRAL AFRICA.

Our readers are already familiar with the many features of this report from the extracts taken from the home press. But it may be well to recapitulate and notice its main heads after a systematic fashion, and to refer to a few points connected with planting development that have not hitherto received the attention they deserve. The report opens with an analysis of the census—the main results being 289 Europeans, 263 Indians, 23 half-castes, and 844,420 natives. There seems a very fair distribution of the natives over the planting districts, according to the names of the latter; but no doubt, as in India and Ceylon, the natives are congregated in the lowcountry and villages, and that the European planters are for the first time cultivating on the mountain ranges and establishing labourers on the plantations so formed. Sir H. Johnston next discusses the different native tribes, their condition, location and prospects more particularly with reference to their taking up work on the plantations. The question of Indian settlement is considered: the splendid work done by the Sikhs in dealing with the slave traders is well known. Sir H. Johnston had hoped to introduce Indian cultivators; but so far the funds have not been available. Indian traders and surveyors (largely Tamils) are hard at work; and Sir H. Johnston gives an invitation to the Indians, who are not satisfied with Natal and the Transvaal, to try British Central Africa. The section of "health" has been fully mentioned. There is nothing to show that the risks are greater for planting pioneers than they were in the remoter districts of Ceylon, the Wynaad or Coorg in India, in the "forties," "fifties," and even "sixties." The Shiré Highlands are generally as healthy as our own hill country, although the malaria in the valleys and lowlands ("blackwater fever") is apt to invade clearings at the lower elevations. Here is a paragraph which shows that the first great need of the country is a railway from Quilimane to Blantyre (just as was the want in Ceylon—a railway from Colombo to Kandy in the "fifties," at almost any cost, as the master-mind of Sir Henry Ward clearly saw):—

Undoubtedly the chief risks to health on the part of temperate, well-conducted persons, arise, from the journeys to and from the highlands of British Central Africa either up and down the malarial Zambezi Valley, or in the low-lying regions of Lake Nyasa. Places such as Blantyre, Zomba, the Cholo plantations, and the higher Mlanje plantations, and certain settlements in Angouland, are like series of healthy islands in the middle of an unhealthy sea. Chinde and Quilimane, our principal ports, are by no means very dangerous to the health of those who are residing there. If there were means of quick transit between coast and the islands there would be no more risk about settling in British Central Africa for a term of years than there is about going to Ceylon or to such parts of the interior highlands of Brazil as can be rapidly reached by railway from the coast. What we want here is a railway from Quilimane to Blantyre. When this is effected we shall hear very little more of the unhealthiness of British Central Africa, because persons will be able to accomplish in one day the transit from the coast port to the highlands of the Protectorate without spending days and days on a singularly uncomfortable little steamer in the marshes of the Zambezi and Shiré, where the system becomes soaked with malarial poison.

Sir Harry Johnston unsparingly condemns the increasingly large import and use of whiskey as inimical to health. It is still the day of small

things so far as the total import and export trade is concerned. That of imports increased in value from £73,667 in 1894-95 to £82,760 in 1895-6. The total value of exports in the latter year was only £19,668: this includes an increase of £3,200 in coffee on the previous year, while the trade in rubber, oil seeds, beans and wax is increasing; samples of cotton have been approved of; tobacco and tea are being tried on a small scale; while a good deal of attention is to be given to fibres from plants of genus *Sansevieria*, familiar to us in Ceylon. Next to coffee, we think with Sir H. Johnston that indiarubber yielding plants deserve most attention. It is interesting to hear of finds of limestone in many parts; and still more of guano deposits on islands in Lake Nyassa; and of brick-making by the natives.

The postal service and the "general condition of the Protectorate" next claim attention; but there is not much here to detain us; until we come to the consideration of the Labour Question by the Commissioner in the following among other passages:—

The native labour question is almost the most important question which can now claim the attention of those administering the Protectorate. Given abundance of cheap native labour, and the financial security of the Protectorate is established. The European comes here with his capital, which he is ready to employ to almost an unlimited extent if he can get in return black men who will, for a wage, work with their hands, as he cannot do himself, in a tropical sun. It only needs a sufficiency of native labour to make this country relatively healthy and amazingly rich. The cultivation of coffee would be a hundred times more extensive than it is if there were an adequate labour supply. In like manner towns would be built, roads would be laid out, railways could be made, marshes could be drained, river channels could be straightened and deepened, and countless crops could be planted and weeded, if sufficient natives came forward to wield the spade and axe, and pickaxe and hoe. All that needs now to be done is, for the Administration to act as friends of both sides, and introduce the native labourer to the European capitalist. A gentle insistence that the native should contribute his fair share to the revenue of the country by paying his hut tax is all that is necessary on our part to secure his taking that share in life's labour which no human being should evade. At the same time, the Administration is bound to see that the native is fairly treated, that he is fairly paid, and that attention is given to his food and general welfare on the part of his European employer. The system of registering native labourers has worked well, and undoubtedly the intervention of the Administration has secured to the native uniform fairness of treatment which formerly he did not receive when it was left to the will of the employer, whether he was properly paid or cheated out of his earnings under various pretexts. In no part of the world is honesty more obviously the best policy than in Africa in dealing with the negro, who has a very clear sense of justice. The news that such-and-such a man has been unfairly treated by his employer, and has brought back no wages after three months' work, will deter a whole district from furnishing further recruits for the labour market at Blantyre. Fortunately now the native begins to understand that if, his European employer does not treat him fairly, he has redress at the hands of the nearest official.

Native wages are slightly increasing, but are still very low. For unskilled labour, about 3s. a month with or without food (according to the season of the year) is given, and proportionately less for the work of women and children, who are occasionally employed to weed the plantations. Skilled labour—carpenters, masons, brickmakers, clerks, interpreters, overseers, domestic servants, and cooks—receive wages ranking from 4s. a month to 40l. a year.

Some native overseers (originally boys educated at the Missions) are now landowners and planters on their own account. I entertain great hopes of the intellectual development of the negro of central Africa.

Allusion is made to native printers, telegraphists, masons, carpenters, &c.; also to the introduction of cattle, buffaloes and goats from India. Then we are rightly told that "Road-making" comes next to the Labour Question, and mention is made of several roads made, in progress or in contemplation. The more the better for the rapid development of the country. Still more important is the news of the survey party being at work to report on the best railway route between Blantyre and Chirimo at the head of the all-the year round feasible water communication with the rest of the world. It is surprising to note how large a number of steamers of all descriptions are found in the lakes and rivers. Over 100 are specified—from gunboats and passenger steamers to cargo boats—but the total tonnage is not equal to one large ocean-going steamer of the present day. The report concludes with an account of the excellent relations maintained with the German and Portuguese Agent in adjacent territories a fact that reflects the greatest possible credit on Sir Harry Johnston's tact and influence.

But, perhaps the three appendices attached to the report contain information as interesting as any already noticed. The first is on the "Big Game" of the country, a paper principally due to Mr. Sharpe—second in command—and added to by our old acquaintance, Mr. Alex. Whyte. It is of special interest to sportsmen and naturalists. Still more worthy of preservation is the paper in which Sir H. Johnston sums up the history of coffee planting in his state from the day in 1878 when Mr. Duncan, a church of Scotland lay agent, introduced three plants from the Edinburgh Botanical Gardens. The progress in 17 years has been slow as compared with a similar period in Ceylon; but then we speak of 1837 as the beginning of our European enterprise when the export was already 30,000 cwt. The export from British Central Africa this year is exported to reach to 350 tons, or, to take the more universal expression, to 7,000 cwt. But the 100 planters at work are bound to develop the planting and trade rapidly, as the following summary made from the report indicates:—

Names of Proprietors.	Total of Estate.	Planted up to 1896.	Crop 1896.	Employ- years.
	Aeres.	Aeres.	Cwt.	Euro- peans.
Buchanan Bros.	.. —	900	2,000	9
E. C. M. Sharer	.. 365,000	900	600	19
H. B. Bradshaw	.. —	300	400	—
Pettitt Bros.	.. 50,000	300	400	5
J. W. Moir	.. —	230	200	3
H. Brown —	—	200	—
K. Stebleki	.. —	200	240	—
Nyassaland Coffee Co.	.. —	250(?)	—	2
African Lakes Corporation	.. —	—	—	—
Zambezi Industrial Mission —	—	—	—
6 Native Owners	.. —	—	—	—

The map of the Shire Highlands, which accompanies Sir H. Johnston's report, shows very clearly the location of all the estates devoted to coffee planting, as also much Crown or State and not yet taken up. This map as well as

the paper on Coffee in full, we hope to give in the *Tropical Agriculturist* in an early number. Several of the more extensive proprietors come to the country for sport—to hunt—including Messrs. Pettitt Brothers, Sharer, &c. The only reference to any coffee enemy is a mention of "green bug" which "shade" and "good manure" remedies; but the Shire Highland planters will have to get the enemy of the "coccus" (along with the Ceylon, India, the Straits, and Java) from Australia in the Queensland "ladybird" insect. Finally in a third appendix, Sir H. Johnston gives us an account from his point of view—a generally accurate and fair one—of "Missionary work in British Central Africa"; and this we shall reproduce in instalments in our "Day of Rest" column. Considering the close relations already established between Nyassaland and Ceylon, we cannot know too much about the rapidly advancing country so ably administered by Sir Harry Johnston, who has our best wishes for continued success in his good work.

THE NILGIRI AGRI-HORTICULTURAL SOCIETY.

This Society, says *Planting Opinion* of Oct. 24, now consists of some 54 members, and the General Committee is a strong one, bearing such well-known names in the Agri-Horticultural Madras side world as Messrs. C. Gray, T. Griffiths, Generals Baker and Jennings, Messrs. Minchin, Proudlock and Standen. The first show will be held next May. A capital practical start has been made by circulating the following queries, answers to which by members will be published next month:—

QUERIES.

What flowers can be produced at their best, for the Flower Show in May, from an Ootacamund Garden?

What month should *Gladiolus* bulbs be taken up and how long should they be kept out of ground?

What month should Pink and Carnation slips be put down in Ootacamund.

Do *Grevillea* Plants do best planted late or early, in the monsoon.

It does seem a pity that for some cause or other, perhaps undue modesty, the Madras Agri-Horticultural Society has not a real live journal of its own. It does useful work indeed, but to furnish it its value is only very partially appreciated.

MARKET FOR TEA SHARES.

Thursday Evening Oct. 22.—In our appended usual table of tea companies it will be observed that we now place all the companies, whether quoted or unquoted stocks, in one strictly alphabetical list, and we trust this will commend itself to our readers as being more easy for reference.

This table now represents, it will be seen, about 6½ millions of share capital, besides more than a quarter of a million of debenture capital.

Notwithstanding the present inherent weakness of the stock markets, all tea shares of repute have been strong, with a somewhat advancing tendency.

MINING LANE shows some signs of a slight recovery, although prices for the majority of teas remain still rather low.

FRESH ISSUES.

Consolidated Tea and Lands, we now understand are soon to obtain a Stock Exchange special settlement and quotation. There is no business to report in any of the issues.

Empire of India and Ceylon, as notified last week, are shortly to get a quotation.—*H. and C. Mail*, Oct. 23,

THE MOCHA TEA COMPANY.

PROPOSED PURCHASE OF ESTATES.

A special meeting of the Mocha Tea Company was held at the offices of the Company, Prince Street, at noon today, for the purpose of receiving a recommendation from the Directors, as to the proposed purchase of two estates in the Maskeliya district.

Mr. F. W. BOIS presided, and there were also present Mr. W. Moor, Mr. H. G. Bois, and Mr. V. A. Julius; also Mrs. M. E. Bois, Mrs. Hurdwood, Miss W. Bois, and Mr. Henry Bois, as represented by their attorney, Mr. F. W. Bois; and Miss Julius as represented by Mr. V. A. Julius.

The CHAIRMAN, in explaining the objects of the meeting, said, they were called together in consequence of a recommendation from the Directors that the Company should purchase two estates for a sum not exceeding £6,100. The two estates were really to be taken as one. They were brought to the notice of the Company by Mr. J. N. Campbell, who represented the proprietor. Seeing that he was an interested party the Directors thought it best to have the opinion of an independent visiting agent, and consequently they asked Mr. A. C. Bonner to report and value.

This report was then read. It is stated that the two estates could be taken as one. They comprised 200 acres in excellent order. The crop estimated from them was only equal to 275 lb per acre, but with somewhat coarser plucking an additional 75 lb. per acre could be obtained. The average crop for the past four years was equal to 256 lb per acre. The valuation of the estate at nine years purchase was R118,700; and he thought an annual profit of R13,500 might be looked for.

The CHAIRMAN said that taken as a whole the estates did not appear to be in a very fine state. They would notice that Mr. Bonner's valuation was R118,700, but he wished to point out that that included 19 acres which were in dispute. In regard to that he might say that the present owner did not seem to have any proper claim. Therefore they had to make a deduction for this and the valuation became R109,500, and the estimated profits would be about R12,000. He might say that Mr. Campbell thought the estates could be very much improved and worked with a greater return.

It was then proposed by Mr. V. A. JULIUS, seconded by Mr. H. G. BOIS and unanimously agreed to, "that Directors be authorised to purchase the Lanka and Craighill estates in the Maskeliya district for a sum not exceeding £6,100 sterling, and to raise a sum not exceeding R69,000 at 6 per cent. interest to enable them to pay the purchase money."

It was agreed on the motion of the CHAIRMAN that a special general meeting to confirm this formal resolution be held at noon on Saturday, November 7th.

As the meeting broke up the Chairman said he hoped things would turn out as well as they expected.

THE LATE DR. TRIMEN.

In the death of Dr. H. Trimen, the late Director of the Royal Botanic Gardens, Peradeniya, Ceylon and the scientific world have sustained a heavy loss. Not only did he occupy a place in the forefront of authorities on tropical agriculture, but his devotion to duty amidst the distraction and physical suffering of disease must evoke feelings of admiration for the strength of will and character which surmounted these difficulties, and of pity that death took him ere his life's work was done. In the brief compass of

this article it is impossible to indicate all that he was as a scientist and a man. Science was his mistress, but in his case it did not lead him beyond the paths trodden by the generality of mankind; and his sociability and geniality will be a lasting remembrance to a wide circle of devoted friends. On his career, a brilliant one in scientific circles, though to the general public comparatively unknown, we have already touched; but a bald narration compressed into the limits of a paragraph gives but a faint idea of years of conscientious and unremitting work, which has gone to enrich scientific knowledge and have been of immense service in its practical applications. To give our readers an appreciation of Dr. Trimen's life and work, we do not think that we can do better than quote from an article our absent senior wrote on the subject some few months ago:—

"Take Dr. Trimen's latest work: 'THE FLORA OF CEYLON' in three volumes—why, it is impossible to overestimate the value of this work for practical, educational, and scientific purposes in the colony. . . . Dr. Thwaites's great work on Ceylon plants might well be complained of by any 'practical planter' as above his head—being essentially a scientific botanist's book. But Dr. Trimen, while taking care to serve the purposes of science, and to be as full and correct as any reasonable botanist could desire, has added a series of most useful economic notes which simply make his work a treasure-house to the ordinary intelligent readers,—to all in fact who wish to know what can be said about each of our plants (useful and ornamental) and especially about the timber trees and economic products of the island. That the highly accomplished and worthy Director should have persisted in this important undertaking to the sacrifice of his health, if not of all that makes life worth living, speaks highly for his conscientious devotion to duty and deserves the grateful acknowledgement, not only of the Government, but of every right-thinking man in the community. We are equally clear that never before in the history of the island has more attention been given in our Botanic Gardens to every question bearing on the economic as well as scientific side of planting, and tropical agriculture generally, than during the past fifteen years. We speak of that we do know; for, as editor both of daily and monthly issues, we have continuously been made the medium of requests for information, of puzzling questions, of plants forwarded for identification by planters—not to speak of our own many editorial queries—and we have never failed to receive the most prompt and satisfactory attention from Dr. Trimen. . . . We are absolutely clear that no more valuable reports—both from an economic and scientific point of view—reach us from any Botanic or Government Gardens the wide world over, than those that bear the imprint of Peradeniya."

CEYLON TEA SALES IN MELBOURNE.

TEAS.—Locally, on the 1st October, a small catalogue, consisting of 250 packages of Ceylon, was offered at auction, selling up to 8½d. for Pekoe, 6½d. Pekoe fanings, 1s. 2½d. for broken orange Pekoe, 5½d. for Sonehongs, 12½d. for broken Pekoe and 4½d. for siftings. Privately, 700 half-chests of Panyongs sold at 4½d., market firm at this price, and 150 quarter-chests of bnds. A quiet business doing in Ceylon and Indian; 100 packages of the former sold to 1s. for fine; and 130 chests of the latter to 7½s.

THE INDIAN RICE CROP OF 1896.

The Statistical Bureau of the Government of India has issued the following First General Memorandum on the Rice Crop in Bengal, Lower Burma, and Madras, of the season 1896:—

In Bengal the weather was on the whole unfavourable insufficient rain alternating with floods, which resulted in a reduction in the area under cultivation and caused damage to the standing crop over a large area. There was good rain about the middle of September which has slightly improved the prospects of the crop.

The area cropped with winter rice is estimated at 29,597,900 acres against 30,402,500 acres in 1895 and an average of 32,634,100 acres, the decrease being about 2½ and 9½ per cent respectively. This year's crop is estimated at about three-fourths of an average crop, but the estimated outturn is likely to be much reduced as there has been little or no rain in the first half of October.

The area estimated to have been sown with autumn rice amounts to 7,128,500 acres against an average of 7,438,100 acres and an approximate area of 7,050,100 acres in 1895. The outturn is estimated at 67 per cent in 1896, against 78 per cent in 1895, of an average outturn.

In Madras the area reported to have been sown with rice is 3,385,000 acres which is about the average, but is less by 174,000 acres, on nearly 5 per cent, than the area sown in the corresponding period last year. The decrease in area is due to the unfavourable character of the season. The standing crop is reported to be generally in fair condition, though it needs rain in many parts, especially in the northern districts.

In Burma the area sown up to the end of September is reported to be 5,190,912 acres, being an increase of 100,009 acres over last year's area. The increase is due to fallow land being largely brought under cultivation. The area destroyed by floods, &c., is estimated at 83,676 acres, of which 66,352 acres being in the districts of Thongwa and Amherst. The rain up to date has been favourable. The standing crops are reported to be healthy, and the prospects very good.

TEA IN AMERICA.

New York, Sept. 30.

The situation still drags, and is without new feature since our last report. Fine grades of Formosa continue to be well held. On all sorts there is no change to report.

Last week the Montgomery Auction and Commission Company sold 8,671 packages of teas, as follows:—Moyune—24 Hyson, 6 to 6½c; 549 Young Hyson, 6½ to 26c; 177 Imperial, 8 to 20½c; 356 Gunpowder, 10½ to 30½c. Pingsuey—21 Young Hyson; 311 Imperial, 10 to 15c; 1,783 Gunpowder, 7½ to 23c. Japan—32 Nibs, 5½ to 11½c; 46 Caper, 17c; 121 Siftings; 723 Congou, 6½ to 18c; 101 India and Orange Pekoe, 12½ to 16½c. Oolong—356 Foochow, 6½ to 7½c; 985 Amoy, 6½ to 8½c; 2,985 Formosa, 10½ to 32c.—*American Grocer*, Sept. 30

COFFEE GROWING IN HAWAII.—The *Hawaiian Commercial Journal* of Sept. 15, says:—Last week we referred at some length to the possibilities of this Island as a field for coffee and other industries and also gave an account of the success of Mr. Ahrens of Waianae in coffee growing. At that time we had not visited Mr. Ahrens estate and therefore were obliged to confine ourselves to information received at second hand. However, on Saturday last week we had the pleasure of visiting the Waianae coffee fields with a party of ladies and gentlemen from Honolulu, under the direction of Mr. B. F. Dillingham, manager of the O. R. & L. Co., and can even add to the glowing descriptions of the place we had already received. As a result of the visit of Mr. Dillingham party we understand that one or two new coffee plantations will be started in the neighborhood of Honolulu at once.

THE AVERAGE PRICES OF CEYLON TEAS.

The views of any man experienced in the London market tending to throw light on the late downward course of the prices obtained for our teas cannot fail to be of interest. Expression of these is quoted in our London Letter, and although there may be those who may not fully agree with the opinions expressed, there is reason to think that these are worthy of every consideration. Undoubtedly the steady falling off in the quotation of averages that has been noticeable for some years, has not been satisfactory. But if it can be shown, as is alleged, that this falling off is not attributable to want of appreciation shown by the British public for Ceylon teas, undoubtedly the knowledge will be pleasing to us. The expert who favoured our London correspondent with an interview on his topic was able to cite his own experience as evidencing that, although the averages published by Messrs. Gow Wilson and Stanton and others were undoubtedly correct as applied to the whole volume of sale, they did not represent the conditions attending the sales effected by himself or those of many other estate owners. In his own case, he said, the prices he had obtained showed no reduction on those at which he had sold for quite three years past. Indeed they had even slightly improved during the last year of the three. He thought that an explanation of the reduced general average was to be found in the very large quantity of tea coming forward of late from low country estates. He did not consider that this was by any means up to the average of general imports of tea grown on our higher levels, and the prices obtained for them—their bulk being large, caused a reduction in general average, while a particular average would show a steady maintenance of the prices for several years of imports of the higher class. He drew the deduction, he continued, that no evil augury was to be drawn from the present quotation of averages. And the more so, he thought, because, although our low country teas obtained lower prices than those paid for the higher growths, these could be produced much more cheaply than the last, and the growers of both therefore secured equivalent profits. At the same time he admitted that the public quotation of average made, did induce a good deal of apprehension as to the future of the Ceylon tea trade among them not fully instructed on the subject. He would like to see some distinction drawn by the firms making publication between the averages for the two classes of teas. Whether this could be done he declared himself to be ignorant. If it were practicable, he feared that to draw such a distinction must involve such difficulty, and possibly an invidiousness that might be resented by some. We can ourselves see objection to the course this gentleman suggested as desirable. It has not been established, in the first place what should determine the classification between high-grown and low-grown teas. Some might fix the limit at one thousand feet of elevation, others might deem higher or lower altitude a more fitting line of separation. And as the various London tea firms might adopt independent classifications, their average would in such a case show such an amount of variance as to give results even more misleading than are obtained under the existing system of a general average. And after all it is scarcely the outside public that would be either affected or misled by the present quotations. And those who are "in the

know" can sufficiently discriminate for themselves. Proprietors of estates of low elevation, so long as they are satisfied with their returns, will trouble themselves little about average quotations. Similarly, those whose productions are obtained at higher leads would, we should say, be equally satisfied with good results in their balance sheets, and would feel no alarm at the relative decline of the averages publicly quoted.

NOTES FROM OUR LONDON LETTER.

A good many of us find

MESSRS. GOW, WILSON & STANTONS' WEEKLY REPORT

of the tea market somewhat unpleasant reading, for their quotation of Ceylon tea averages has a persistently downward course. Remarking on this to a gentleman of large interest in Ceylon and of great experience with the London tea market, he observed:—"Your doubts can be well understood, and it seems dillicult to account for the droop of quotations. But you must bear in mind that they are of *general* averages only. For myself, and for many other old proprietors in Ceylon, I can only say that we do not experience any reduction in our average. For the last three years mine has remained pretty constant. If anything, my last year's prices were rather better than for the two, preceeding it. But I suspect the decline shown by the brokers' weekly reports to be due to the fact that a lot of lowcountry estates are now coming into full bearing, and that these are sending home a very considerable proportion of the full receipts. Certainly the quality of the teas produced on these is below the standard of my own teas, which, as you know, are grown at a high attitude, and naturally they do not sell for equally high prices as I obtain. But then they are produced far more cheaply than are those grown well up in the hills. I suspect, it is this influx of lower class teas that is accountable for the reduced average of the brokers' publication. So far as the bulk of the tea growers in Ceylon are concerned, I don't believe they have much to grumble at, and I feel sure that the proprietors of the low estates are equally well satisfied with their returns. Sixpence per lb. will pay these last quite as well as ninepence to tenpence will pay me, and certainly I have no reason for complain. Still a good many outsiders who watch the market for investment purposes only may be discouraged by what they see published of these averages. It is to be wished that these were divided for high and low grown teas in the reports, but I don't know if it would be possible to do this. Certainly to do so would entail much extra work, and probably it might be complained that to draw such a distinction publicly would appear invidious. But neither you nor any of your friends need fancy from the reading of these averages that Ceylon tea planting is in a bad way. The enterprise is sound enough, and is paying well all round."

The opportunity of this interview was taken to put a question as to the possible overdoing of THE TEA COMPANY MANIA.

As to this matter the gentleman interviewed said:—"I quite think this is being overdone, and concur with the suggestion that appeared in the *Observer* that it may seriously affect the position of planting industries in Ceylon should it ever unfortunately happen that the island has to pass through a crisis of the kind from which it has before on more than a single occa-

sion suffered. But I don't think there is any chance of this Company-mongering coming to an end. What I cannot understand, however, is how it comes about that men are so anxious to sell the properties they own. Naturally, of course, they are at present able to get top prices for them, taking advantage of the existing "rush." But then when they get their price what are they to do with the money? It is hopeless to expect they can safely invest it here so as to obtain a return upon it equivalent to the income derived from their tea estates. It seems to me that all they can do is to reinvest in tea in some form or other, and I know of cases where, failing every other eligible investment, this has had to be done. And this investment, mind, must be made on terms equivalent to those which secured the high prices for their estates. So that really there seems to be no logic about the transactions that we daily hear of. But in spite of this men will be tempted by the offers made by company promoters, and the practice will be extended until every acre of land cultivated with tea in the island will fall into the possession of limited companies. No cessation of the practice can be hoped for until that area is completely taken up."

THE LATE DR. TRIMEN.

We greatly regretted to read this announcement in the *Times* this week:—"Trimen: on the 16 Oct., at Peradeniya, Ceylon, Henry Trimen, M.B. London, F.R.S., late Director of the Royal Botanical Gardens there, in his 53rd year." We know that Dr. Trimen will be greatly missed among you, as, indeed, he will be here in many social and scientific circles. The following obituary notice has also appeared in the *Times*:—

Mr. Henry Trimen, F.R.S., F.L.S., the eminent botanist, died at his residence in Ceylon on the 16th inst. He was born in London in 1843, was educated at King's College, and graduated M.B. at the University of London in 1865. For a time he was Curator at the Anatomical Museum of King's College and Lecturer on Botany at St. Mary's Hospital Medical School. Entering the Botanical Department of the British Museum as Senior Assistant in 1869, he held that post for ten years. In 1880, he was appointed Director of the Royal Botanic Gardens, Ceylon, which appointment he only quite recently resigned. Dr. Trimen was editor of the *Journal of Botany*, 1872-79; and he was the author of "Flora of Middlesex" (written in conjunction with Mr. Thiselton Dyer); of the botanical portion of "Medicinal Plants," a work in four volumes published 1875-80; of a Systematic Catalogue of the Plants of Ceylon, 1885; and of a "Handbook to the Flora of Ceylon," 1893. He was likewise the author of numerous papers in the Transaction of various learned and scientific societies. He devoted special attention to the economic aspects of botany, particularly to the sources of drugs and other products, especially of tropical countries. Some years ago he was engaged by the Madras Government to report on the botanical and cultural problems presented by the cinchona plantations in the Nilgiri Hills; and he was the means of introducing into cultivation in Ceylon many useful and valuable products of other countries.

The report of the

SCOTTISH TRUST AND LOAN COMPANY OF CEYLON

has been published for the year ended August 31. It states a profit made of £8,711 net. The directors propose to pay a dividend of 5 per cent per annum, free of income tax, (2½ per cent of which was paid as an interim dividend this year) and a bonus of 7½ per cent, also free of income tax. There will remain a balance of £3,086 to carry forward to next account,

THE NEW DIMBULA COMPANY

has declared a dividend of 16 per cent per annum on the A and B shares, and of 14 per cent per annum on the C shares for the year ended June 30.

WILD RICE.

At the request of Dr. G. Watt, C.I.E., Reporter on Economic Products to the Government of India, the Board of Revenue has asked all Collectors and officers in charge of Settlement Parties in Godavari, Kistna and Malabar, the Deputy Director of Agriculture, the Honorary Secretary, Madras Agri-Horticultural Society; the Superintendent, Government Central Museum; and the Principal of the College of Agriculture to favour the Board with any information they can afford as to the existence or otherwise of the *Oryza Coarctata* in the Madras Presidency. The attention of Dr. Watt was first called as regards this grain by the Director-General of Statistics, Mr. J. E. O'Connor, who asked for the former's opinion as to certain grains sold in Karachi, the exact position of which in the classification in trade returns seemed doubtful. As this appeared to be an entirely new article of human food unknown in the series hitherto examined and reported on by Dr. Watt, he obtained a specimen of the plant from the Collector of Customs, Karachi, and it was found to be a species of *Oryza* (rice) not hitherto known to be eaten, and the botany of which even, until very recently, was involved in the greatest obscurity. The plant obtained by Dr. Watt was determined to be the *Oryza Coarctata* of Roxburgh (wild rice), a remarkably interesting species, originally discovered by Dr. Buchanan Hamilton in 1796, and supposed by him to be confined to the estuary of the Ganges. This plant was subsequently described by Griffith as *Oryza riticooides*, the wild grass, and, according to Roxburgh, the grain was never collected as an article of food. The specimen obtained from Karachi is known in the bazaars as *Nanoi*, and is stated to occur in the valley of Indus in the Karachi Collectorate of Sind, and is collected in the months of July and August. The grass (*Suhangah*) producing the grain grows among other kinds of grass on the marshy grounds on the banks of the Indus which are constantly washed by sweet and salt water at ebb and flow tides, respectively. It is gathered by the poorer classes for their own consumption, but is sometimes exchanged for equivalent value in one and other articles offered by petty traders going round the creeks; and two or three maunds of it are thus brought every season to Keti-Bander and a small quantity exported to Karachi. The Collector of Customs, Karachi, states that a noticeable feature about the gathering of the grass is the vast amount of labour and trouble involved, as it is estimated that a man engaged the whole day cannot collect more than four seers. The plant is described as 4 to 6 feet in height, the upright stems rising from a stout creeping rhizome. The grains do not spread out on ripening, but are closely compressed into a long erect spike. Dr. Watt now asks for any information as to the existence of this plant in any other localities besides the estuaries of the Ganges and the Indus, as it would go a long way to confirm its being regarded as truly indigenous. He remarks that the obscurity in which the history of most of India's cultivated plants is involved, is intimately associated with the rise and diversity of the human family. He says that this

curious rice is not at all unlike *Triticum* (wheat), and the resemblance accordingly at once suggests the possibility of its having been the wild grain seen by Aristobulus on the banks of the Indus which he spoke of as being very similar to wheat; so that if that suggestion be correct, we have an interval of 2,000 years between the two recorded observations of the existence of this edible grain. The enquiry, therefore, has a wide significance, and will richly repay whatever attention may be spared to it. Dr. Watt adds that Mr. J. F. Duthie has collected *Oryza Coarctata* at Shikarpur about 200 feet above the level of tidal influence; and this fact suggests the question whether it is cultivated in that locality or whether the presence of salt in the soil allows of its existence in regions now remote from the direct influence of the sea. If that be so, then enquiry is not to be confined to the actual estuaries of the great rivers such as the Nerbudda, Tapti, Colerom Palar, Kistna, Godavari, Mahanadi, &c., but may be extended to all salt-impregnated soils and margins of brine lakes and marshes.—*Madras Times*, Oct. 29.

PLANTING NOTES FROM HAPUTALE.

THE WEATHER. Nov. 2.

Sunny mornings and rainy afternoons, and evenings also, are our present experiences. A whole month has passed away, and we have had only two days, in which rain did not fall in this district, and at times we have been under heavy downpours. During the whole of last month we have had hardly a puff of wind, either from the south-west or north-east. It has been a great calm with us, such as you get in the Norse latitudes—rizzling rain and an entire absence of wind. The mountains of Ceylon supply the lowlying rivers of Ceylon with abundant water, and these mighty rivers when fully replenished serve to irrigate extensive areas of lowlying paddy lands. These abundant rains falling on our hills are not lost: they are most precious, for they give the Sinhalese goyiya his daily bread, and without the mountain zone, Ceylon would be poor indeed.

LAND FOR PLANTING.

Some weeks ago, in a letter which appeared in the *Observer*, Sir G. E. stated that tea estates at a medium elevation in Ceylon do not yield high quality teas, nor can they compete with the low estate hardly above sea-level. This may be the case, but take courage ye owners of medium-lying tea estates: your properties may be nigh a railway and have a good cart road to them, and manures can be cheaply applied to the tea bushes, and the crops of your totums greatly augmented. I read in *Observer* that there are no high-lying forestlands left for sale in our mountain zone. Lots of virgin forest around Trincomalee and in other places are available; but the question seems to me to be just this: Do you wish to grow more tea in Ceylon of an inferior grade or not?

LONDON COMPANIES.

The year about to close is memorable in planting annals. The resident proprietors of tea estates of Ceylon will soon have left us. Companies—large London Tea Companies—have already absorbed most of the tea totums of our island; and these London Tea Companies will henceforth be the real rulers of the tea enterprise of Ceylon. What will they do with it, or for it? Will they look favourably on the Planters' Associations in Ceylon, Parent and District Associations, or try to administer their legitimate influence in this island? Will they support the Volunteer enterprise among

the planters? Well, this I know full well—that planters who are Volunteers will have to go through their martial exercises within a few miles of their totums, and not expect to go to Camp meetings in remote regions far away from their estates.

YOUNG PLANTS.

Looking over your report from the Conservator of Forests in Ceylon, I could not help being surprised to find that so many young tree plants had died soon after planting. Surely our Foresters may learn from *past* experience first to plant only sturdy plants; and secondly to closely see to the planting of these plants *themselves*, and to choose suitable soil for the various kinds of trees they wish to propagate.

PLANTING AND PRODUCE.

INDIAN TEA COMPANIES IN THE UNITED KINGDOM.—We publish elsewhere a list for the compilation of which we are indebted to Mr. George Seton, of the Joint Stock Indian Tea Companies with headquarters within the United Kingdom. The acreage of the properties owned by the various companies, the district, and the capital are given together with the official address, and the names of the directors brought up to date.

PIANOS AND PACKET TEA.—The grocers of Birmingham are sore about an extension of the "present" system in connection with the tea trade in the Midland capital. A retail tea company is offering pianos to those of its customers who purchase a certain quantity of its tea. The idea is to send in a certain number of bags denoting the purchase of the tea, and this system is denounced by the trade as a "growing evil." It has grown to such dimensions that we may look for a gift of a cottage or of a landed estate in time.

HOW ABOUT PORTUGAL.—Should the planters of India and Ceylon desire to push their teas in Portugal the exhibition to be held in Lisbon next year will give them the opportunity. The London Chamber of Commerce recently held a meeting in support of the project which is called the Vasco da Gama and Indian Celebration Exhibition. Sir A. Rollit, M.P., President of the Chamber, was in the chair at the meeting, and letters were read approving the proposal and promising their assistance from the Lord Mayor, the Governor of the Bank of England, Sir Clements Markham, C.B. (President of the Royal Geographical Society), Lord G. Hamilton, M.P. (Secretary of State for India), Sir George Birdwood, and others. The association of the celebration with India, it was pointed out, made it a matter of interest to Britain. A committee was formed to assist the movement, and it was also resolved to request the co-operation of the Foreign and Colonial Department, the Trinity House and other public bodies.

BRAZIL AND ITS COFFEE INDUSTRY.

The financial position of Brazil and the effect on its merchants and planters of the enormous fall in the Brazilian exchange is the subject of much comment in trading circles. Brazil, it is said, has enjoyed for a number of years past a considerable amount of prosperity, owing to the high prices obtained for her coffee and rubber. This, however, means mainly prosperity for the planters and high prices in terms of the paper currency. As the exchange has declined the paper price have risen, and as wages and other costs of production and fixed charges have been paid in paper the producers are said to have been making profits at the rate of 100 to 200 per cent. Of course the continual decline in the exchange must have been proportionately distressing to importers and to the Government and all individuals and companies having gold debts abroad to meet. It may also, under the circumstances, be assumed to have induced a considerable rise in the cost of living, as many other prices, and particularly the prices of imports, have probably advanced in Brazilian currency to some extent, though not equally with the prices of coffee and rubber. But the upward movement, meanwhile seems to have had a remarkable influence in sti-

mulating production in Brazil. During the current season there has been gathered, it is said, the most phenomenally large coffee crop ever grown. Instead of a crop of 5,000,000 to 6,000,000 bags, a yield of from 8,000,000 to 9,000,000 bags is reported. Recent advices from Rio de Janeiro and Santos have indicated that those markets were becoming glutted, and, naturally, prices have fallen. According to some American authorities the prices of coffee still mean a profit (in paper) of 100 per cent. to the planter, as against a profit of 200 per cent. last year. As, however, there appears to be a disposition in New York to utilise the position in Brazil with its depreciated currency as an object lesson against the free coinage of silver, it seems not improbable that this statement is an exaggeration. It is difficult to believe that the expenses of the planters expressed in paper have not risen to some extent with the depreciation of the paper. Any way, dealers and merchants are said to be talking very alarmingly of the decline, and to be doing their utmost to arrest it by sending out adverse reports with regard to the next, or growing coffee crop, with the object of inducing the consuming markets to buy the crop now in hand; and they are attributing the failures reported to the reduced price of coffee.

RUBBER PRODUCTION IN BRAZIL.—The production of rubber has been greatly increased with the constant advance in its paper price. Twenty years ago the Brazilians asserted that they could not produce more than 8,000 tons per annum without killing off the trees, whereas at present they are said to be producing at the rate of 20,000 to 21,000 tons annually. Judging superficially, the case of Brazil seems to offer another striking illustration of the influence of a depreciating currency in artificially stimulating production in particular directions, and of the financial and commercial disorganisation which must eventually result.

VANILLA IN THE WEST INDIES.—Planters in the West Indies are on the look out for new sources of income, and some of them are growing vanilla. A sample of vanilla, grown and cured at the Botanic Gardens, Trinidad, was lately received (says the *Kew Bulletin*) from Mr. J. H. Hart, F.L.S., the superintendent. The pods were produced by plants originally supplied from Kew of what is known as the "Sion House variety" of *Vanilla planifolia*, Andr. In the present instance the quality is not so good as might be desired; but now the right sort is established in the island it might be worth while to carry on further experiments with the view of improving the quality of the produce.—*H. & C. Mail*, Oct. 23.

CURING OF VANILLA—PREPARATION OF PAPAIN.—The *Chemist and Druggist* of Sept. 26, has the following replies to a correspondent:—

E.P. (Fiji).—(1) Curing of Vanilla.—After the pods are plucked they are dipped in boiling water. Next they are packed in hardwood cases, 6 feet long, 4 feet wide, and 2 feet deep. A blanket is first put in the box, then the beans to about the depth of a foot, and a double thickness of blanket on the top of them. The box is then covered with glass, and placed in the sun for a fortnight, during which time the beans ferment, or sweat. Only experience can tell when that process is complete, and the beans are ready for the dry shed. This should be an airy shed, well protected from rain, and not too much exposed to the sun. It should have a series of wire shelves all round it and on the top shelf the beans are placed in single layer, not too crowded. They are turned over every day or second day, and in the course of ten days removed to the second shelf, then to the third, where they remain until they are quite dry and fit for packing. (2) All that we can tell you about the manufacture of Papain is that the juice is pressed out of the fruit, clarified by filtration through a twill bag, and the ferment precipitated by alcohol. It is then dried, but sometimes purified by treatment with water. The supply of papain is more than equal to the demand, and we do not think it would pay you to manufacture it, although it seems probable that it should be more plentifully used by Indian natives, whose caste prejudice prohibits them from using pepsin.

MOCHA TEA COMPANY OF CEYLON LIMITED.

A special general meeting of the shareholders of the Mocha Tea Company of Ceylon, Ltd., was held at noon today in the office of the Agents and Secretaries, Messrs. J. M. Robertson & Co. The meeting, presided over by Mr. F. W. Bois, formally confirmed the following resolution passed at a general meeting on 17th October:—"That the Directors be authorised to purchase the Lanka and Craighill estates in the Maskeliya district for a sum not exceeding £6,100 sterling, and to raise a sum not exceeding R60,000 at 6 per cent interest to enable them to pay the purchase money if the purchase be completed."

COFFEE PLANTING ON HAWAII.

A PROMISING NEW INDUSTRY IN THE HAWAIIAN ISLANDS
SOME FIGURES RELATING TO THE COST OF COFFEE
CULTURE—WHERE VEGETABLES MAY BE PLANTED EVERY
MONTH IN THE YEAR.

The Island of Hawaii, the largest of the Hawaiian Islands, is situated about two hundred miles from the city of Honolulu. Regular lines of steamers connect this island with the city. The only town of importance on Hawaii is Hilo, on the east side of the island, and from whence a finely macadamized road, through the cane-fields and a most luxuriant tropical forest, leads to the celebrated volcano of Kilanea, distant thirty-one miles.

Until within a few years sugar has been the staple product of this island. Now, however, Coffee planting is drawing the attention of small farmers. On both the leeward as well as the windward side of the great mountains Kea and Loa, lays a large tract of land unsuitable for cane growing and which has been found to be eminently suitable for the production of Coffee, ranging from the sea coast up to an elevation of three thousand feet.

Quite a large number of plantations have been started during the last four years and will soon be coming into bearing. The Coffee raised on this island in years past has taken a very high rank, even thought by many to be equal to the best Java or Mocha.

Land or settlement can be had from the Government, and also from private land owners, at prices ranging from \$20 to \$25.00 per acre. The best Coffee lands are, for the most part, covered with a forest growth and require clearing. The land can be cleared, by contract, at prices ranging from \$20 to \$50 per acre.

After the land is cleared and the young trees planted, either from those owning nurseries, or from the nurseries planted by the owner, but little care is necessary except to keep the weeds down, until after the third year, at which time a small crop can be expected, when careful pruning and "handling" is necessary to bring the trees to perfection.

From 750 to 1,200 Coffee trees are set on an acre and will be in full bearing the sixth year after planting, smaller crops being taken the fourth and fifth years. The crop on a good tree should be about three pounds.

The necessary machinery for pulping and hulling costs from \$150 to \$1,500 according to the size. Buildings for the drying and storing are not expensive. The greatest cost in the coffee business is that incurred in picking the ripe berry, which, as the Coffee does not ripen all at once, is rather slow. The berries take from five to seven months to mature.

On the higher lands the small farmer can raise corn and potatoes, as well as all garden vegetables,—enough to supply his family. Planting of these can be done every month in the year, thus giving him a constant succession of crops the year around, while meantime his Coffee is growing and coming into bearing.

A farmer coming here to live should have at least \$3,000 to carry him through. Land can be leased from the Government, with the privilege of purchase, on very reasonable terms. No tax is levied for the next six years on Coffee plantations.

Space in this magazine will not allow to go into all the details of Coffee planting, etc., but the writer of this article will be glad to answer all questions, to any thinking of emigrating here.—D. H. HIRNCOCK, Hilo, Hawaii, Hawaiian Islands.—*Mayflower*, Oct.

TEA IN MELBOURNE.

Ceylon are in favour, and sales made of 200 chests at 7d to 1s 4d, 100 half chests of Panyongs, and 400 chests of Indian. At the auctions on the 15th October, 2,819 packages of Indian were offered, of which 1,920 packages sold up to the following prices:—For Doors pekoe S., 6½d; do. pekoe, 6½d; do. orange P., 7½d; Darjeeling orange P., 1s 1d; do. pekoe, 10½d; do. pekoe S., 6d, golden orange pekoe, 1s 6d; Assam pekoe, 11½d; do. orange P., 9d; do. pekoe S., 7½d; Cachar pekoe, 7½d; do. orange P., 7½d; do. pekoe S., 7½d; do. souchong, 6½d; Terai pekoe, 7d; do. orange P., 7½d; do. pekoe S., 6½d. Also 68 packages of machine-made China realised the following prices;—For broken leaf, 4½d; pekoe S., 5d; pekoe, 7½d; orange pekoe, 11d. The biddings were fairly brisk, and the bulk of the catalogues sold.—*Leader*.

CEYLON LIMITED COMPANIES—THEIR RESERVE FUNDS—AND SOME COLOMBO QUOTATIONS.

A Ceylon proprietor now at home favours us by the present mail with some criticism which we think it well to lay before those concerned and our readers generally. In the first place—looking over the list issued by the Colombo Share Brokers' Association as published in the *Overland Ceylon Observer*—he finds that the London-Ceylon Companies quoted are frequently given very considerably below their proper market standing. We are not quite clear as to whether our friend has compared the Colombo and London quotations for precisely the same date, but presume he must have done so. In any case it can do no harm to rephrase what he says on the subject. He writes:—"Ouvahs are quoted £11½. Now no Ouvah Coffee Company's shares have been so low as £11 10s for ever so long. I know some were sold in September—the very last lot in the market—at £12 5s. Again, Nuwara Eliyas are quoted with you in Colombo at £12½ ex-dividend. I am told it is very difficult to get them at £13 now."

Then as to "Reserve Funds," our critic considers that Ceylon Companies—or rather their Directors—are, as a rule, to blame for not affording clear and full information to their shareholders as to the placing or investment of any and all Reserve Funds. Our correspondent maintains this should be distinctly shown in the Directors' Reports sent out before the annual meetings, so that any shareholder dissatisfied with the securities indicated, might object. He goes on to say:—"There ought to be no hole-and-corner work in any public Company's affairs: see the disturbance on just now about the 'British Farmers' Association, Limited,' as indicated in the *Financial Times* of the 20th-21st October. It is far better that the Directors should act fairly and squarely with the shareholders."

On the general principle, we heartily endorse the views of our critic; but if the attempt is made to apply the censure to any of our Ceylon Companies, we scarcely think the case will hold

good to any important extent. In the first place so few of our Plantation Companies as yet have any considerable reserve funds. They are mostly very young, and, though prosperous, have only begun to think about "reserves." But in the case of the leading as of the oldest of our Tea Companies, we are under the impression that the shareholders have had very full and satisfactory information as to the investment of a considerable reserve, namely in coconut plantation to a certain amount and the balance in Government securities. If this information is not given in the latest Annual Report, we feel sure it was supplied at the meeting in the speech of the Managing Director. Indeed, is this not the usual way of supplying information in reference to reserve funds or securities, or, when not done, questions can always be asked by shareholders at the meeting. Further, are we wrong in supposing that where no special investment is mentioned, it may be taken for granted that any reserve funds are, as a rule, invested in Government, Indian or Colonial first-class securities? Be this as it may, however, now that the time has come when we hope "reserves" will become the rule with all well-regulated Ceylon Tea Plantation Companies, we think our friend's criticism or suggestions may well be taken to heart and the practice be adopted by Directors of taking their shareholders fully into their confidence, as to the use made of the profits placed in reserve—as a guarantee for the maintenance of prosperity. It is certainly indispensable, that such "guarantee" should, in its investment, be, like Caesar's wife, above suspicion, and there is nothing like publicity to secure this end.

LIFE IN GUATEMALA.

THE COFFEE PLANTATIONS: PEON LABOUR: THE MODERN SYSTEM OF CULTURE.

The fact that a co-operative colony, to be composed of young Californians, has been proposed to be started in Guatemala—the most northern of the Central American republics—has directed attention to the existence and social conditions of the colony.

Guatemala is not a bad land to live in, especially in the elevated region devoted to the culture of the coffee plant. But the truth of the matter is that while the climate of the region is delightful and by no means insalubrious there are drawbacks (says a Californian paper) which, from an American point of view, are serious obstacles.

No one who has travelled in any part of Spanish America from Mexico to Patagonia can have failed to recognise and record one bitter fact. The man who goes into any Spanish-American state to till the soil or to labor with his hands has no social future. He is, to all intents and purposes, a peon, a laborer.

The Spanish traditions have not been rooted in the institutions of Central America for nothing. There was a time when the Archbishop of Guatemala was primate of all North America. There are families in Guatemala who can trace back their pedigree for a clear 300 years, and though Guatemala is nominally a republic the American citizen who takes his capital into the country and toils with his hands to amass a competence will find the doors of Guatemala society hopelessly shut against him.

The politician proper reaches his highest development in lands where wealth and aristocratic traditions go hand in hand. In the higher circles of society in Guatemala, Nicaragua, Salvador, Honduras, and Colombia nearly every brainy man is a professional politician.

"The land of Manana" (pronounced Manzan-na) is a country in which nothing is hurried. Everything can be put off till to-morrow. It takes time to think, and nothing is so repugnant to Spanish

American traditions as the feverish haste of the New Englander or the business energy of the Western man.

It is a characteristic of all the representative men of Central America that they absolutely refuse to be hurried. They never jump at a bargain, and their business transactions are marked by a provoking coolness of deliberation strangely at variance with their warmth and energy in the secluded circle of social life.

A word about the coffee plantations of Guatemala may be in order after this introduction.

These plantations lie on the Pacific slope of the country, at a distance from the coast varying from 40 to 100 miles, and at an elevation ranging from 4,000 to 5,000 feet.

There is very little railroad communication and transportation is mostly conducted by the most primitive means.

The present coffee-planters of Guatemala are of all nationalities—English, Americans, Germans, and Spanish-Americans. Many of the old coffee-planters began life in much the same way as the scheme proposed by the would-be colonists. They lived in adobe dwellings and toiled hard to drill the refractory peons into the work of clearing the plantations. The successful coffee-planter of today toils hard, not as a laborer, but as an overseer. For a man to put his hand to the plough would have the same social effect in Guatemala as in the Southern States during the era of slavery.

The modern system of coffee culture in Guatemala, and especially the introduction of machinery, and the gradual enlargement of the coffee area, have devolved upon the planters the necessity of supplying suitable houses for their laborers in place of the old thatched shanties or adobe huts in which these miserable creatures existed. The lumber for these buildings is all imported from San Francisco, and the wooden dwelling of the planters are constructed on a larger scale of the same material. Lumber is an expensive material in Guatemala, and hence a heavy drain is made on capital at the start.

There is no such thing as a coffee trust in Guatemala. Every man runs his own coffee ranch as he pleases. When he wants money he borrows it on the security of his next coffee crop from the agents of bankers in Europe, San Francisco, and New York.

Life on a coffee ranch is not unhealthy, but no white man could perform the work which the peons accomplish in clearing a plantation. The first clearing is a herculean task, and after that the rapid and prodigal growth of weeds and rank vegetation in a tropical climate requires that the work of clearing shall be kept up incessantly. It is the hardest kind of work under the most favorable conditions. There is no cleared land available at the present time, for one reason that it would require so heavy an outlay of capital to accomplish the task, and a coffee plantation left alone for one single month will be so overgrown as to require as thorough a clearing as the original one.

The coffee plant is about five months in development up to the ripening of the berry, but it is five years before the plantation begins to pay.

A certain number of acres of land are cleared by contract labour at about 30c. a day in American money, though the planters keep the figure a secret. After the ground is thoroughly cleared and the coffee planted it will not be till the third year that there is any return at all. In the third year there is a slight return, just enough to pay for the cleaning of the coffee-bean. In the fourth year the crop about pays for sacking and getting it to the port of shipment.

From the fifth year onward, if the seasons are good, there are substantial profits, provided labour is obtainable at a cheap rate; for on coffee plantations cheap labour is everything, and the peons can be very refractory at times. Nature is so prodigal in providing fruits for food and so little is required in the way of clothing or shelter that if a peon

chooses to say he will work "manana" tomorrow he is subject to no inconvenience by the delay, whatever his employer may suffer. In the land of manana there is a tomorrow for the peon as for the proudest Castilian. It is this spirit of procrastination which has driven the most irrepressible American settlers to despair. In the course of time they begin to manana themselves.

The women and children of the peons find employment during the coffee-picking season at a mere pittance of course, but a peon can exist on wages which a sand, shoveler would spurn if starvation started him in the face. The male peons are liable to military service, an element which has to be taken into serious consideration, for Guatemala, like the other Central American republics or the great powers of Europe, is armed to the teeth all the time and her soil is liable to invasion and pillage at any hour.

White men going to Guatemala to settle will soon find that there are three climates. On the coast it is blazing hot; in the higher altitudes, on which the plantations are situated, it is a little warm, but not uncomfortably so; in the highest elevations the climate is an eternal spring.

All kinds of provisions are very dear and tobacco is worthly 1 dol per pound. In Guatemala City wines are cheaply obtainable at the hotels, but bottled beer is worth about 80¢ or 1 dol a bottle. Hotel accommodations are quite high.

Perhaps the most discouraging feature to be settled is the want of transportation facilities; the long distance from the plantations to the towns (often 40 miles or more) and the difficulty of obtaining social recognition. Once this recognition is obtained life is pleasant enough, and there are many dark-eyed damsels of old Castilian stock in Guatemala City whose glances are apt to soften the pangs of exile.

The early coffee crop is ready for picking by December, and the season lasts till May. The plantations near the line of railroad running to the coast at San Jose of course use the railroad, but elsewhere the transportation to Ocos and Champerico is by ox teams and other primitive means. The old-fashioned bongos or boats in which the coffee-bags were shoved off on the beach, amid a tremendous surf, are now replaced by lighters pushed off from long iron piers.

The steamers do not come up to the piers for the reason that the heavy rollers would soon toss them ashore, and the lighters are towed out a mile or more to the steamer's side.

In no way can the extreme conservatism of Guatemala and other Central American republics be better shown than in the rude contrivance by which passengers are swung into the lighters and then into the gangway of the steamers. The traveller who has once gone through the ordeal seldom cares to repeat the experience, save on the direst necessity. *Torres Straits Pilot*, Oct. 3.

NOTES FROM HOME.

LONDON, Oct. 23.

Mr. Wm. Mackenzie, the Ceylon Tea Commissioner, was ready to start once more for America this week; but a difficulty about passage will delay him some days. He deserves credit for facing transit across the Atlantic and back in the cold season; but he is in splendid health, and reports that encouragement is found in certain firms taking up the work of advertising

CEYLON TEA IN AMERICA

on their account. One London firm with branches in the States is doing a good deal, while Messrs. Larkin & Co. of Toronto, who have so often written to the *Observer* on the subject, deserve great credit from the Ceylon planters for their enterprise since they advertise in some 340 Canadian papers. Mr. Mackenzie has induced them to make a beginning across the border in the

States, and their venture in Buffalo—a city of 400,000 people—is reported to be eminently satisfactory, so that we may expect a further extension. Several of the Commissioner's lady lecturers on Ceylon tea have been taken on by firms now interested in the trade—a good sign. At the same time, we are not to expect any very large figures by way of increase of exports to America in 1896: indeed there is a rumour that the published return for 1895 may have to be amended through some exports from Calcutta via London to America having been counted twice, owing to want of clearness at the Customs. It seems that the American Customs statistics do not help in respect of the countries from which different kinds of tea are imported.

Considerable activity over

TEA COMPANY SHARES

prevails in the City, and there is no lack of confidence in Ceylon plantations. Apart from recent purchases and developments, the formation of another new Company, dealing with estates at a comparatively high elevation, is reported; while a merchant recently from your midst (Mr. W. H. Figg) is credited with an AMALGAMATION AND CONSOLIDATION SCHEME which is sure to be very popular at this end, although the outside public are not likely to be appealed to. The Companies to be amalgamated are some of the very prosperous ones in the Kelani district, among the earliest formed and for which Messrs. Whittall & Co. Colombo, are Agents; and at the same time the capital is likely to be changed into sterling. No doubt a popular as well as powerful Company will, in this way, be formed.

It is satisfactory to see the

SCOTTISH TRUST AND LAND CO. OF CEYLON

—after suffering in the coffee days—coming rapidly to the front with its tea, although other products are not ignored: debt and debentures are being cleared off and the lucky shareholders divide 12½ per cent for the year free of income tax. The veteran Chairman,

MR. THOS. DICKSON, SR.,

may well be proud of his steering of this Corporation through the dark times of depression into the present course of prosperity.

THE BRAZILIAN-DUMONT COFFEE COMPANY

—to judge by the market quotations for debentures and shares—is not over-popular in London at present, perhaps, owing to the late financial trouble in Rio; but full confidence is expressed in its being a sound and profitable enterprise for the shareholders, and the following testimony appears in a paragraph in the *Financial Times* this week:—

Dumont Coffee Estate—The sale of the Dumont Coffee Estate to an English Company has caused the *Journal do Commercio* of Rio de Janeiro, to express its regret that so fine a property should be allowed to pass out of Brazilian hands. The *Rio News* while sharing the opinion of the "Journal" as to the value of the estate, which is, it says, "one of the most valuable in Brazil," is glad to see so large an introduction of foreign capital into the country, believing that with more foreign property owners steadier progress will be made.

The

COSTA RICA COFFEE VENTURE

—on which Mr. J. L. Shand reported—is not yet floated, some more capital being considered necessary, though a considerable amount has been subscribed. The increased tightness of the money market may be telling against such

fresh appeals; but an easier time is anticipated after the American Presidential Election is settled. Speaking of the

SARAPIQUI (COSTA RICA) COFFEE SYNDICATE,
it was of interest to me to find in the Secretary the son of a gentleman whose name was very familiar in Ceylon forty years ago as Agents for the Ceylon Railway Company, formed to connect Colombo and Kandy. Mr. Beeston left Ceylon before my time; but his name frequently appeared in print in connection with the winding-up of the company. His son is a nephew of the late Mr. George Steuart of the well-known Colombo House, and his sister—shortly to be married—inherits largely under the will and is interested in Colombo property, so that a visit to Ceylon may be included this winter in the honeymoon trip her husband and herself.

PALLAKELLE ESTATE,
Dumbara, has at length been sold for £38,000, a moderate price seemingly for the large area of the property and the big extent in cultivation; but then cacao there has had a trying time, and tea and coconuts have to be proved, though there is no need to suppose that the purchasers have not made a good bargain, likely to give them large profits from the growth of a variety of products.

With much regret—with little surprise—did I notice the death of

DR. TRIMEN

(at the age of 53) in the London papers the other day. He was so weak and ill when he left London that I doubted his ever returning. Nothing but a determination to finish his book could have carried him out to Peradeniya. I trust he was able to feel that he had accomplished the truly useful mission, on which he had set his heart, and that the third volume of the "Flora of Ceylon" can duly appear with the finishing touches of the author.

I have seen a good deal lately of a relative who has been through the "siege of Bulawayo" and the recent exciting times—not yet quite over—in Mashonaland. He like all other South African Colonists I have seen, looks on Cecil Rhodes as the ablest and most progressive man amongst them and the only one to restore prosperity to the country. With prolonged experience of the Transvaal and Natal, he tells me there is a good field for

CEYLON TEA IN SOUTH AFRICA

although the locally grown tea is in favour so far as it goes. But he is enthusiastic over what the Messrs. MacLure (relatives of well-known Maskeliya coffee and tea planter) have already done in Johannesburg for Ceylon tea, both wholesale and retail. He declares their tea refreshment shops to be superior in attractiveness, attendance, &c., to any he has seen in London. The Messrs. MacLure deserves a vote of thanks from the C. P. A.

I have been interested in a series of papers by Miss E. A. Ormerod (the well-known leading Entomologist) on

"AGRICULTURAL PESTS

with Methods of Prevention;" and have secured the right of reproducing the series *in extenso*, in the *Tropical Agriculturist*; for, although, mainly dealing with agriculture in temperate regions, yet there is much in the information and hints, of value to tropical cultivators—planters and farmers; and the perusal of the eight articles cannot fail to benefit many in India, Ceylon, the Straits, &c.

In reference to the

LADY BIRD EXPERIMENT OF COFFEE

Mr. E. E. Green reports:—"I am writing to America to find out Mr. Koebele's present address. I think he has left the Sandwich Islands, having completed successfully his contract there. As soon as I know his whereabouts I will find out what his terms would be to start the experiment for us."

THE CEYLON TEA AND COCONUT ESTATES COMPANY, LIMITED.

The *Gazette* contains the memorandum and articles of Association of the Ceylon Tea and Coconut Estates Company, Limited, which has been formed to acquire the Perth and Maputugala estate in the Rayigam Korale of the Kalutara District. The original capital of the Company is R50,000, divided into one thousand shares of R500 each. The signatories are:—W. Henry Figg, Herbert Tarrant, H. H. Capper, Frank Capper, by his attorney H. H. Capper, Ada Capper, by her attorney H. H. Capper, Ethel M. Figg, by her attorney H. H. Capper and Katharine Fox Tarrant.

MARKET FOR TEA SHARES.

Thursday, Evening, Oct. 29, 1896.

A steady and increasing business has been in progress the past week in the shares of the Indian tea companies, mostly at advancing prices, and the Stock Exchange official list shows more than one advance in quotations. There is a great deal of investment buying going on in all the shares which stand in best repute.

Mincing Lane keeps rather easy, though there seems to have been something of a steadying in prices during the week just closed. Telegrams from India point to a somewhat early closing in of the cold weather, so that the total crop seems likely, if anything, to tot out slightly short of even the more recent revised estimate.

FRESH ISSUES.—Consolidated Tea and Lands Co. shares are now all quoted in the official list. Special settlement, 4th prox.—*Home and Colonial Mail*, Oct. 30.

THE LANKA PLANTATIONS COMPANY, LIMITED.

DIRECTORS.—Mr. George Allen, Chairman; Mr. William Austin, Mr. Henry Bois, and Mr. Edward Pettit.

AGENTS IN COLOMBO.—Messrs. J. M. Robertson & Co.
SECRETARY.—Mr. Charles M. Robertson.

Authorised capital £200,000, in 15,000 ordinary shares of £10 each and 5,000 preference shares of £10 each, of which only 1,470 have been issued.

Report to be presented at the Sixteenth Ordinary General Meeting of the Lanka Plantations Company, Limited, to be held at the office of the Company, on Wednesday, the 11th November 1896, at 12 o'clock noon, precisely.

1. The Directors now submit their report for the twelve months ending 30th June last, together with the balance sheet and accounts of the Company made up to that date and duly audited.

2. The coffee crop shipped to London was 605 cwt., against 1,371 cwt. last year, and realized £1,57 11s 2d net. The acreage under coffee alone remains at 210 acres, and the trees being still in good heart are receiving careful cultivation.

3. The total crop of cocoa gathered on Yattawatto amounted to 1,355 cwt., against 1,214 cwt. last year, and realised £3,493 1s 3d, the market price being a shade stronger. During the season 51 acres were planted with cocoa, 44 acres of which have been interlined with Liberian coffee which is growing well; and 150 acres of available land adjoining the estate

have been purchased making a total of 192 acres new land. The cost of the land and the new planting are charged to capital account.

4. The tea received from the Company's estates amounted to 646,161 lb., and has been sold at an average of 8-15d per lb. net, realizing £21,967 10s 2d. Last year the Company received 528,018 lb., which was sold at an average of 8d per lb. net, and realized £17,507 3s 2d. Credit is due to the Superintendents for having so well maintained the quality of their teas in spite of increased yield.

5. The following statement shows the acreage and state of cultivation of the Company's estates on the 30th June last:—

Estate.	Coffee.	Tea.	Cocoa.	Grass.	Chena and Patana.	Forest and Timber Trees.	Total.
Ampittiakande } Aruhalla }	50	414	—	4	167	70	705
Fruit Hill	—	225	—	—	12	—	237
Fordyce, Garbawn, Gonagalla and Pannamatta	—	772	—	29	—	135	936
Rappahannock	23	302	—	31	30 $\frac{1}{2}$	87	473 $\frac{1}{2}$
Rillamulle	—	232	—	—	6	20	258
Thotulagalla	137	221	—	4	97	96	555
Yattawatte	—	—	*671	95	267	106	1139

210 2166 671 163 579 $\frac{1}{2}$ 514 1303 $\frac{1}{2}$

* 44 acres interlined with Liberian coffee.

6. The net profits for the past year amounted to £10,708 1s 1d, to which must be added the sum £1,270 18s 10d the balance brought forward from the year 1894-5, making together £11,978 19s 11d.

7. Having already paid a half-year's interim dividend on the six per cent preference shares to the 31st December 1895, amounting less property tax to £426 6s 0d, the Directors recommend the payment of the dividend on these shares to the 30th June last requiring less property tax a similar amount, and having deducted £1,566 the customary 10 per cent from the 10 years of the suspense account, they further recommend a dividend of 10s per share free of income tax (being 5 per cent per annum), on the ordinary shares, amounting to £7,500 carrying forward a balance of £2,060 7s 11d to the next account.

8. The Directors who retire on this occasion are Mr. Henry Bois and Mr. William Austin, who being eligible offer themselves for re-election.

9. Mr. John Smith, the Auditor, also retires and being a shareholder offers himself for re-election.—
By order, C. M. ROBERTSON, Secretary.

12, Fenchurch Street, London, E.C., Oct. 30, 1896.

PLANTING AND PRODUCE.

JAPAN TEA EXPORTATION.—The floods in Japan have played havoc with the season's tea crop, the exports of which, it is estimated, will not be much more than half of the exports last year. According to the latest Japanese papers, only 353,000lb of tea were brought to Yokohama between September 1 and September 15, showing a decrease of 580,000lb compared with the latter half of August. Many miles of railway were washed out by the floods. Only one branch remained intact in the cities of Kobe and Osaka, and freight had to be transferred by this single line as soon as traffic, at the end of September, could be resumed. The important line between Osaka and Kanazaki was still closed when the last steamers left. The prospects are for a speedy recovery of things, so that heavy shipments may be expected next month and throughout the coming winter.

A PHASE OF THE LABOUR QUESTION.—It is anything but gratifying to Indian planters, who are not so exempt as they would wish to be from labour troubles, to know that British Indian labour is received with condescension in countries not under British rule, and that the treatment accorded to the immigrant is anything but good. There

are, of course, thousands of British Indian subjects who, like other emigrants, leave their country for their country's good, and who from labour point of view are useless. These are indifferent where they go so long as they make money. But there must be also many who are a loss to the labour market in India, and would remain at home if they knew what they had to put up with elsewhere. The lot of British Indians in Natal or the West Indies is rosy indeed compared with their life, say, in German East Africa or the Transvaal. The *Times* in its article on Indian affairs deals with the cynical appreciation of the British Indian recently expressed by Major von Wissmann, who in his statement of Germany's policy in Africa was good enough to explain that the greatest obstacle "to Germany's making East Africa what England had made India lay in the thinness of the population." "In order to obtain a denser population recourse might be had to settling the colony with Indians" and certain other Asiatics. Having thus obtained a supply of British Indian subjects to do the work of opening up the country—a work which the Arabs and negroes will not do—Major von Wissmann proposes that "the negroes should be taxed least, the Arabs more, and the Indians most of all." The writer of the *Times* article goes on to say: "Does Major von Wissmann really suppose that so valuable a class of British subjects are to be had by German administrators in East Africa on the terms of his programme?" Perhaps the Major does, for an impression prevails that Indian labour is to be had for the asking in any country or for any purpose. British Indian subjects are even attracted to the Transvaal, that land of promise for alien labour, where they receive characteristic consideration. The Johannesburg correspondent of the *Times*, writing of this treatment, says:—"The Boer Government has decided to bring in a drastic measure dealing with the Asiatic traders in this country. These poor fellows are to be cleared out of their present shops in the towns, and are to be allowed to trade in certain 'locations' only. Ostensibly, the change is to be made on hygienic grounds, but the real motive is that Asiatic traders are, erroneously, looked upon as a curse to the country, who spend no money in it and send all their savings to India. These people work hard and patiently and live upon little. I have had years of experience among the Tamils (a race of Southern India), of whom there are large numbers in Johannesburg, and a more decent, inoffensive people it would be hard to find. They are very proud to call themselves "British subjects of the Queen," and I believe that the Indian Government and India Office have contended that these Indians are British subjects with a right to claim British protection. Many thousands have been admitted into the Transvaal; they have brought goods from India, spent money in acquiring shops in the town, &c., and it is hoped that a gross injustice to these poor Indian traders may be avoided by a timely and judicious word of advice from the British Government to the authorities at Pretoria." Perhaps the Indian Government will exercise some inquiry into the treatment of Indian subjects in countries not under the British flag.—*H. and C. Mail*, Oct. 30.

CENTRAL TEA COMPANY OF CEYLON, LIMITED.

Directors.—J. Sancoft Holmes, Chairman; H. K. Rutherford, and W. H. Anderson.

Secretary.—Sir Wm. Johnston, Bart.

Manager in Ceylon.—H. V. Masefield.

Report of the Directors to be submitted at the First Annual Ordinary General Meeting of Shareholders to be held at 21, Mincing Lane, E.C., on Thursday the 5th November, 1896.

The Directors have the pleasure to submit the General Balance Sheet and Profit and Loss Account for the year ending 30th June, 1896, duly audited.

The net amount at Credit of Profit and Loss Account, after providing for General Expenses, Directors' Fees, Income Tax, &c., is ..	£	s.	d.
	3,091	15	0
Dividends on the 6 per cent Preference Shares were paid for 1895/6 (less Income Tax) amounting to ..	870	0	0
It is proposed to pay a Dividend of 10 per cent (less Income Tax) on the Ordinary Shares which will absorb ..	1,940	2	0
And to carry forward to next year a balance of ..	281	13	0
	£3,091	15	0

The Directors trust the results of the year's working of the Estates may be considered satisfactory by the Shareholders.

The gross average price realized for the tea crop was 8.14d per lb.: and the rate of exchanges 1s 2 5-64th d.

The following is a statement of the acreage and crop from the Company's Estates:—

Estates.	Tea in		Forest, &c.	Crop. lb.
	Bear- ing.	not in Bearing.		
Kabragalla ..	431	42	464	171,227
Somerset ..	221	—	19	95,900
Loxa and Easdale ..	166	—	27	30,587*
Totals ..	818	42	510	297,714

* Note.—Loxa and Easdale crop is for six months only.

Since the formation of the Company, Loxa and Easdale Estates have been purchased. To meet the purchase price of these properties the Directors arranged a temporary loan, and it is now proposed to issue 593 Ordinary Shares at a premium.

Under Clause No. 24 of the Articles of Association, Mr. J. Sancerft Holmes retires on this occasion from the Board, and, being eligible, offers himself for re-election.

It will be necessary to appoint Auditors for 1896/97.

By order of the Board, WM. JOHNSTON, Secretary.
London, 29th Oct. 1896.

A TRIP TO BANANALAND IN WINTER TIME.

BY H. T.

Truly as delightful a trip as any of us Southerners, as we are called in that land, can take; for not only do we escape the cold unsettled weather of Victoria during July and August, but we can bask under tropic sun, strong enough to make us glow under its heat, but tempered at such season by gentle breezes rendering it a pleasure to breathe and live under its rays.

After travelling about North Queensland for six weeks, one cannot help feeling surprised that so comparatively few Victorians take advantage of so pleasant and instructive a mode of escaping our winter, and seeing the tropical beauties of the North. They would find the scenery and the climate a revelation to them, and return with enlightened ideas as to the characteristics of that truly interesting portion of this great continent.

It seems to us that what is to be seen in these parts is not sufficiently advertized and made known, (such as is done for New Zealand), and it is with the view of assisting to supply such want that we have put together a few hasty notes of our experiences.

There are many opportunities of reaching the district of which we write whether by rail to Brisbane and thence by steamer, or by sea direct from Melbourne by the S. N. Co., Howard Smith & Co., or the Adelaide Steam Ship Co. Our experience being by the boats of the first-named Company, we can only speak of them and better coasting steamers than the "Arawatta"

"Aramac," and "Wodonga" could not be desired. The "Wodonga" is the largest and best of the three. Great cleanliness prevails everywhere in it, and the table is abundant and well-served. The only improvement we could suggest is less hurry in getting through the meals, but that seems to arise as much from the American habit of bolting food on the part of the passengers, as from the hurry of the stewards. It would appear as if the native-born were following the States in that particular, as the same fault obtains in the hotels in the North. This haste, in our opinion, accounts, to a great extent, for the number of people one sees with bad teeth. It must however be good for the dentists.

It is needless to say anything of such a well-known place as Brisbane (which is *not* Bananaland), except to mention that, on one of the nights we were there, occurred the severest frost on record, the bulb thermometer on the ground at the Acclimatization Society gardens registering 19 degrees of frost, and great damage was caused thereby to the palms, pineapples and all delicate plants of tropical growth; and we found Mr. Souttar, the general and able Curator of these gardens, lamenting over the sorry sight they presented on our visit to them.

Passing on to the North, somewhat less than four day's steaming brings us to Townsville, allowing for calling at Keppel Bay (landing passengers and cargo for Rockhampton), Bowen and Flat Top, for Mackay passengers.

Townsville being in lat. 15, we are now fairly in the tropics. Like nearly all the coastal towns in Queensland its site has been badly chosen for access by water, the shallow depth even at high tide making it inconvenient for steamers of the "Wodonga's" size to go up the mouth of the river, and cargo and passengers have to be landed by lighters. Of course at present matters are made worse from the disastrous effects of the cyclone in January last, which destroyed a large portion of the breakwater. Had the town however been placed two miles further north there is every indication that much money would have been saved, a safer breakwater constructed, and easier access provided.

Townsville is an interesting place and full of life and bustle for its size, and it might easily be made a handsome city in time to come, if the Municipality or Divisional Board, as such institution is called in these parts, would exercise taste and spend some money in improving and planting with trees the principal streets, as well as clearing away a great many unsightly objects which now offend the eye. Townsville possesses some buildings, notably the offices of Burns, Philip & Co., some insurance companies and banks, &c., but they are bordered by insignificant wood-and-iron structures of the old shanty type which will no doubt disappear in time.

There is a rocky hill bordering on the sea whereon a number of rather neat private residences are perched in positions which look somewhat dangerous for a place exposed to cyclones.

On the north shore, the hospital is finely situated on a rise, and further on is the orphanage in the middle of a nice garden, showing the advantage of the free labour given by the boys, while a mile onwards, the battery at Kissing Point commands the harbour; but the most commanding feature is the Castle Rock standing a little inwards and sloping down to the town at its base. This rock is about 900 feet high and easy of ascent, although few residents ever seem to go up it. From its top the view north and south, seawards as well as inland, is very extensive and fine.

The railway to Hughenden is one of the sources of business to Townsville, opening up as it does connection with the flourishing mining centre of Charters Towers and the squatting districts westwards.

For some months past the chief traffic on this railway has been, unfortunately for the country, the transport from the interior of tick-infested cattle which have been hurried down in thousands to be boiled down for the sake of tallow and hides at the

two meat works in the vicinity of Townsville, which have found it to their advantage to employ their plant in such process for the present.

In fact just now wherever one goes about Townsville there is little else talked of than "ticks," and we were not long there without seeing them, both dead and alive. Bad as this plague is and ruinous as have been the losses caused thereby over a large extent of country, it seems now on the decrease, and old experienced squatters think that they will disappear as quickly as they have come.

And now proceeding further north we rejoin the steamer again for the 200 odd miles to Cairns. The best plan is to go there in one of the big steamers, and return in small coasting boat the "Palmer" which calls at many interesting ports on its voyage. Cairns itself is not pretty, but being surrounded by a range of mountains commencing to rise at about 10 miles inland, the view from the sea is picturesque. The water is very shallow for a long way out, and it is only at high tide the steamers can approach the wharf. When we arrived it was Carnival week, there being races, agricultural show, bazaar, ball, &c., yet at ordinary times it seems a very sleepy place. The streets are wide—too wide—for they are hot made, and the dust is great unless when it rains. There is a Government nursery at Kemerunga where many tropical economical plants can be seen, and where coffee is growing luxuriantly, but it is situated too far from the town, being 9 miles, and a bad road, so that comparatively few people visit it. The sugar plantation and mill of the Messrs. Swallow, formerly of Melbourne, is about the same distance in another direction, and it is well worth visiting. The mill was in full work day and night, with electric light, pressing canes of good quality.

On the Hambleton plantation can be seen about 30 acres of Arabian coffee only planted out 12 months ago and already giving good promise of blossom, while in Mr. W. H. Swallow's garden there are cacao trees, cinnamon, and other tropical products, formerly confined to the East and West Indies, but now bearing evidence of the suitability of the climate and soil of Northern Queensland to produce them all, given the needful labour,—indeed, we think on this account alone there is a promising future for Cairns as the centre and port for the export of such products. On the slopes of the hills and on the table land above the ranges there is any quantity of splendid land awaiting clearing and planting.

There are also now being arranged the erection of one or more central sugar mills under the "Sugar Works Guarantee Act," involving the opening up by farmers of a considerable tract of country lying between 20 and 40 miles of Cairns, in which direction a permanent tramway is now in course of construction. All this is bringing money and population into this district.

The chief attraction of this part of Queensland is to go up the Cairns Railway to see the Boron Roa George and Waterfall, out of all question the finest scenery of its kind to be met with in Australia. The railway in itself is, as is well-known, a remarkable undertaking. For about 8 miles it runs along tolerably level country through dense tropical jungle in parts, then it ascends the Barron Gorge reaching in twelve miles the Falls, 1,200 feet above sea level. In that distance it passes through 15 tunnels of various lengths and traverses many bridges, passing on one of them the Stoney Creek Falls, the spray from the water of which dashes over the bridge in flood time. On another at Surprise Creek the rails pass 70 feet clear above the bed, and passing you look sheer down 1,000 feet into the bed of the Barron. The scene is constantly changing as you wind along the steep sides of the mountains, at some points a magnificent view of the Pacific Ocean discloses itself, at others you look at the ranges on the opposite side of the Gorge, descending precipitously down into the valley for 2,000 feet, all clothed clothed from base to summit with trees and plants and tropical vegetation of all sorts. Then come the Falls themselves facing the line where the river clears the descent of 700 feet to the rocks below.

It would be difficult to overstate the beauty and grandeur of this even when the waters are low, and in flood it must be a grander sight.

At Kuranda station about 1½ mile above the Falls, there is a small but comfortable hotel which accommodates about 10 guests, and here it is desirable to stay for a day or two, walk down to the Falls and view them at leisure. There are also interesting excursions which can be made from Kuranda into the rich agricultural land and heavily timbered scrub of the Upper Barron; while beyond the railway passes into the Herberton country, rich in tin and silver minerals.

A few miles above Kuranda can be seen two small coffee plantations of between four and ten acres each, the trees on which are about four years old, and the yield of last season was very satisfactory and profitable.

As the introduction of Japanese as labourers in these northern latitudes is quite of recent date, it may be of interest to note that we saw about 60 of them working at various occupations, on the Hambleton sugar plantation, and also at Goondi on the Johnstone river. These Japs are not like the stray ones to be seen sometimes in Melbourne, but are sturdy strong fellows evidently accustomed to country work. They are short but broad shouldered and muscular, are quick at picking up their new duties prove quiet and contented subjects filling a place quite unsuited by climate for white labour.

The places of interest touched at by the "Palma" on the return voyage from Cairns to Townsville are too numerous to detail in a sketchy paper such as this, but the Johnstone River will serve as a sample. Nine or ten miles up this river, which can only be entered at high tide, is the township of Geraldton which owes its existence to bananas and sugar. For miles below and above it, the banks are lined with banana plantations all leased, and in some instances purchased, by Chinamen, who, cultivate with success and profit this fruit. Knowing when the steamer is due they have large flat bottomed boats piled with bunches and cases ready for shipment south.

On the occasion of over the "Palma" grounded on a sand bank about a mile from the town, and in spite of the personal exertions of Capt. Clark, who worked like a seaman himself, it was 40 hours before she was got off; meanwhile we had an opportunity of visiting the large sugar mill at Goondi belonging to the Colonial Sugar Refining Company. This mill in addition to passing canes of their own crushes for farmers, who either lease or purchase adjacent land from the Company under a seven years agreement; and from such information as we gathered both from the Company's representatives, and the farmers themselves, the arrangement worked harmoniously and to their mutual advantage.

The dense and impenetrable tropical bush where the country has not been cleared is in itself a sight to see. Palms of all sort vie with native trees to reach the light, while the tree ferns also rear their stateliness, and gigantic creepers clasp all in their embrace, and can be seen at the tree tops 50 or 60 feet above with their cable like ropes coming down to the ground, where ferns of all kinds and sizes from the tiny maidenhair to the huge bird-nest abound. There is no entering such jungle without a way being cut out, and in some places when a track has been opened for access to where some giant of the forest has been felled, it is like entering a tunnel which never sees the sun.

One of the beauty spots the "Palma" called at on her way to Townsville is Mourilyan harbour. The entrance is saw narrow that a stone could be thrown on those on either side of the steamer, but once inside a harbour of great size presents itself surrounded with hills clad with burden from top to the water edge. The remembrance of our short glimpse at this place remains with us as a dream of loveliness.

To conclude these rough notes we quote a remark made by Sir Samuel Griffiths in an able paper of his on Federation recently published in Brisbane, and which we may say has been the main incentive

of our putting them together:—"The present lack of more general acquaintance and intercourse between the different colonies is probably one of the most serious obstacles now existing in the way of Federation.

NOTES FROM THE METROPOLIS.

CEYLON TEA

in sales this week had rather a check through an unexpectedly large offer of "Indians;" but this may be only temporary. More is thought of the talk of a City Syndicate (of the financiers, it is said) banded to send out improved

TEA MACHINERY TO CHINA

with the avowed object of preparing and assorting China tea into Broken Pekoes and Pekoes as well as Souchongs. Many, however, doubt the prospect of success and, indeed, assert that the first man to try to erect such machinery in the interior will soon be "a head the shorter." Possibly, the object is to erect a Factory in a treaty town on the coast. At any rate City men do not often give money without some assurance of practical work. Then there is some talk again of what

JAVA

is going to do with its rich soil, good jât and new factories. This week some Java teas have been selling up to an average of 10d and 11d; but one who ought to know assures me that Java teas are more likely to be a rival to strong "Assams" than to "Ceylons." Still, to increase the quantity of Indian quality is a serious enough prospect, except we got America, Russia and Australasia to take off a great deal more and oust China and Japan.

Mr. G. A. Talbot is off to

BRAZIL

to see for himself the great Dumont Coffee Company's plantations and much interest will be felt in his report: surprise is expressed that the attempt was not made some time ago to get the opinion of the *Observer's* Brazil correspondent, Mr. A. Scott Blacklaw, now one of the oldest European residents and planting authorities from Ceylon.

A visit to the new offices of

THE CEYLON ASSOCIATION

this week carried me up to the topmost story (by a convenient "lift") of a handsome block in Gracechurch-street, where I found Mr. Leake very comfortably located for his business offices, and a commodious, well-lighted chamber allotted to the Association. It is marvellous to see how well and youthful the leading Kandy merchant and planter of the "fifties" and "sixties" continues to be. Any stranger would certainly guess Mr. Leake to be ten to twelve years younger than he actually is. His career has been an exceedingly interesting as well as useful one from school and college days onwards, and I hope it may be my privilege to set it forth in the *Tropical Agriculturist* series of *Pioneers* ere long.

I was very sorry to miss the meeting of the

NEW DIMBULA PLANTATION COMPANY,

which owes so much, primarily to the Ceylon Manager, Mr. Dick-Lauder, and his staff, and next to the Board of Directors with Mr. Herbert Anderson and to the Secretary, Mr. Crabbe. But here is the report of the proceedings at the meeting:—

THE NEW DIMBULA COMPANY, LD.

Report of proceedings of the twelfth ordinary general meeting, held at No. 25, Gracechurch Street,

London, on Wednesday, 21st October, 1896. H. Brooks, Esq., in the chair.

The SECRETARY having read the notice convening the meeting, and the minutes of the last meeting, held on October 23rd 1895.

The CHAIRMAN said: I have now to move that the Report, Balance Sheet and Accounts as presented by the Directors be received and adopted. The Directors with me are all very pleased to have again an opportunity of meeting the shareholders with a Statement of Accounts which cannot fail, I think, to give universal satisfaction. I am pleased to say that in the past season the yield of tea has shown a satisfactory increase upon the previous year, and reached the large total of 960,000 lb. and this is one reason, of course, for the improved condition of our accounts. I may add that it is hoped that in the present season the yield will exceed a million pounds. Another cause of our success in the past season has been the improved price obtained for tea, the average net price of the whole crop having exceeded last year's price by 1½d. per lb. On the other hand, there has been an increase in the cost of about ¾d. per lb. This, however, is largely due to the fact that the whole of the most recently planted tea is now included in the acreage plucked. At the elevation of this estate young tea takes a long time to come to maturity, but we hope as the yield increases, the cost will revert to something near its previous low level. I do not think there are any items in the Accounts which call for special comment from me. They are, I think, put forward in a very clear manner. It may possibly occur to some of the shareholders that a larger dividend might have been paid, but in view of the unusually favorable circumstances of the past season, your Directors think that the most prudent course is to take advantage of the opportunity to add to the Reserve Fund. (Applause.) I took occasion last year to call attention to and to congratulate the shareholders upon the extinction of all arrears of dividends upon the "B" shares, and the payment of a first dividend to the "C" shareholders. We are now launched on our career free of this drag of arrears, and have now completed the first year on the freer conditions, and I am very pleased that we are able to pay such a satisfactory dividend as that which is now recommended, and my earnest wish is that it may be continued to you for many years to come. (Applause.) I have to move that the Report, Balance Sheet and accounts as presented by the Directors be received and adopted.

Sir A. N. BINCH, K.C.M.G., having seconded the motion, Mr. James Anderson stated that he thought the accounts exceedingly satisfactory. He gathered from them that the net profit amounted during the year to £23,852 16s 3d and that the Company had in hand after paying the proposed dividends the sum of £13,702 3s 2d, including the Reserve Account, and that the outstanding liabilities only amounted to a small sum, and that the position of the Company was a very strong one, and he did not see the necessity of adding to the Reserve Fund, but thought it would be more satisfactory if larger dividends were paid. He also referred to the item of Coast Advances which he thought was very small and reflected great credit on the management.

The CHAIRMAN in reply stated that the opinion of the Board was that if they started with a dividend of 16 per cent. they would like to keep it up. They did not want to start with a flourish of trumpets and pay a 20 per cent. dividend and then have to come down to a 16 per cent., that would be rather derogatory; they liked to feel their way a little carefully to begin with, and though there could be possible objection to putting the Company on a solid basis besides this was their first year on the altered conditions of existence, and there were other reasons why they should be prepared with a Reserve Fund.

The resolution was put to the Meeting and carried unanimously.

The CHAIRMAN then moved: That a dividend be declared of 8 per cent., per annum on the "A" and "B" shares, and of 6 per cent., per annum on the "C" shares, for the year ending June 30th, 1896; and that an additional dividend

of 8 per cent., be declared on all shares; that the same be payable on October 22nd less the interim dividends paid in March last, and that £5,000 be placed to the Reserve Fund.

Mr. W. S. BENNETT seconded the motion which was carried unanimously.

Mr. W. S. BENNETT:—I have now to ask the Chairman to put this resolution, and I have a peculiar pleasure in doing so, because Mr. Brooks and I have served together on the Board from the very beginning of the new Company, and therefore, I have great pleasure in proposing, that Mr. Herbert Brooks be re-elected a Director of the Company.

Mr. W. HERBERT ANDERSON seconded the re-election of the Chairman.

The resolution was carried unanimously.

The CHAIRMAN:—Gentlemen, I have to thank you very much for the honour you have done me in re-electing me as a Director. It is not the first time you have re-elected me, I think it is the third or fourth, and each time I have still the same pleasure in thanking you and saying I will continue to do my best as I have done hitherto for the good of the Company.

Mr. HENRY BROOKS proposed:—That Mr. George Sneath be elected Auditor for the ensuing year at a fee of 20 guineas.

Mr. T. A. PARKER.—I shall be glad to second that resolution.

The resolution was carried.

The CHAIRMAN.—The next resolution comes as an annual dish. I think it ought not to be passed over in silence. It is that a vote of thanks be accorded to our Resident Manager and staff in Ceylon. Attention has already been called to the manner in which he has kept down the Coast Advances, and I can say that the Board very closely scrutinise the expenditure in Ceylon, and they can only speak favourably on the question of cost. I am sure his heart is in his work, and he is ably supported by his staff. I have much pleasure in proposing a vote of thanks to the Resident Manager and the Colonial staff.

Mr. J. ANDERSON.—I have great pleasure in seconding this motion. I am sure anyone who has been connected with the Company as long as I have—and that has been from the commencement—and who knows Mr. Dick Lauder personally, must thoroughly appreciate him for the way in which he manages the work of this Company. As I said before, I do not suppose there is any company whose efforts have been attended with so much success, and I am sure a great deal of it is due to the manager on the spot and the staff.

The resolution was carried unanimously.

Mr. J. ANDERSON:—Before we part, I think it our duty to move a vote of thanks to the Chairman and Directors. Everything that they have put before us is satisfactory. I may differ a little with the Chairman and Directors on one point, that is the Reserve Fund, but I think the great success of the Company is largely due to the Chairman and Directors. I have great pleasure in moving a vote of thanks to the Chairman and Directors.

Mr. PARKER:—I have much pleasure in seconding it.

The resolution was put to the meeting and carried unanimously.

The CHAIRMAN:—I must again thank you for the very pleasing compliment. I can assure you it gives us very much pleasure to work for the Company, and it is very pleasing to us that we have so few differences with our shareholders. We are very much obliged to you for your kindness.

The proceedings then terminated.

THE MIDLANDS TEA PLANTATIONS CO. which owns Strathellie, Gneiss Rock, etc., has made a good purchase in

BLACKSTON ESTATE

for £16,500—good, because it rounds off and improves the rest of their property, affording, too, a capital factory for extended operations. Messrs. Gow, Wilson & Stanton are now to offer Mr. T. C. Anderson's

GARTMORE

(Maskeliya) properties by public auction on 26th Nov., with a reserve price of no mean proportions. Indeed, if rumour speaks true, private offers running considerably over £30,000 have already been placed on one side.

THE AGRA OUVAH ESTATES CO., LD.

Minutes of proceedings at the extraordinary general meeting of shareholders of the Agra Onvah Estates Company, Ltd., held at No. 7, Queen Street, Fort, Colombo, on Saturday, 14th Nov. 1896.

Present:—Mr. C. A. Leechman, in the Chair, and Mr. G. H. Alston, Directors; Mr. F. F. Street, Mr. Jas. Forbes and Mr. C. J. Donald.

The following shareholders were represented by the holders of their powers of attorney.—Mr. G. W. Carlyon by Mr. G. H. Alston, Mr. W. H. Figg by Mr. G. H. Alston, Mr. G. C. Walker by Mr. Jas. Forbes.

Mr. LEECHMAN having taken the chair, the notice convening the meeting was read. He then said:—The only business we have to deal with today is to confirm the special resolution passed on 24 October last.

Proposed by the CHAIRMAN:—“That the Share Capital of the Company be and the same is hereby increased from R400,000 to R750,000, by the creation of 700 shares of R500 each.”

This was seconded by Mr. JAS. FORBES and carried *nem. con.*

A NEW DEVELOPMENT IN THE TEA TRADE.

A meeting of the Management Committee of the Birmingham Grocers' Association was held at the offices of the Secretary, Colmore Row, last night, Mr. J. L. Instone presiding.—Mr. J. Norris called attention to what he described as the latest development in the tea trade. A large firm of local tea dealers was offering pianos as an inducement to purchase of their tea. Grocers were exhibiting the pianos in their windows, and he regarded this as a degradation of the trade. The Association had protested against the present system in the trade, and thought they should take some action in this instance.—Councillor Jarvis thought the members of the Association had tied their hands in the matter. They were unfortunately compelled to sell proprietary articles which were accompanied by presents. He understood that the objects of the firm in question in offering the pianos simply meant diverting a portion of the money they spent in advertising. He did not see how they could object to such an arrangement.—The two members of the firm concerned attended the meeting, and explained the circumstances under which they offered the pianos saying it was nothing more or less than an advertisement.—A discussion took place as to whether they would discontinue requesting grocers to exhibit the pianos in their windows, and a promise was given that no further firms should be asked to exhibit them, and that if those who entered into arrangements to do so were willing to break the contract the firm would not object. It was also stated that the value of the tea was exactly the same as before the 100 pianos were offered. A resolution was passed that, having heard the explanation of the originators of the new development, they be requested to consider how far they could meet the wishes of the Association in withdrawing the exhibition of the pianos in grocers' shop windows, and the matter dropped.—*Birmingham Daily Post.*

TEA IN AMERICA.

NEW YORK, Oct. 14.

At last there are signs of improvement in demand and so marked that some varieties, notably low grade Formosas, are up fully 2c per pound. There is no improvement to note in price for green teas, but holders of Japan are much more confident, particularly as the export this year is far below last. Ceylon and India sorts are steady.

Last week the Montgomery Auction and Commission Company sold 6,693 packages of tea, as follows: Moyune—25 Hyson 6½ at 7c; 421 Young Hyson, 6½ at 27½c; 100 Imperial, 7 at 19½c; 199 Gunpowder, 14½ at 34½c. Pingsuey—233 Imperial, 9½ at 15c; 731 Gunpowder, 9 at 23c. Japan—466 Congou, 9 at 17c; 168 India and Orange Pekoe, 11 at 17c; 56 Capers, 11 at 16½c. Oolong—531 Foochow, 6½ at 8c; 3,163 Formosa, 13 at 36½c.

To-day at noon the Montgomery Auction and Commission Company will sell 6,904 packages, viz: 671 packages Moyune, new season's, including attractive chops; 806 boxes Pingsuey, invoices of seasons 1896 and 1897; 5 half-chests Japan; 901 half-chests and boxes Congou, including new season's, and comprising fancy Monings, Ning Chows and desirable Pekoes and Paklings; 24 boxes Capers; 126 packages India, Java and Ceylon, including fancy grades; 423 half-chests Foochow; 3,948 half-chests and boxes Formosa, a very attractive offering, including new season's, fancy invoices of specially selected rich and spicy summer crop and invoices of desirable leaf, heavy drawing teas.—*American Grocer*, Oct. 14.

THE WE-OYA TEA COMPANY, LD.

At a meeting of the shareholders of the above Company held on Thursday, 19th Nov. 1896, the following were present:—

Directors: Mr. E. J. Young, in the chair, Messrs. E. S. Anderson and W. J. Smith.

Messrs. A. Thomson, W. D. Gibbon, G. Vanderspar, E. H. A. Vanderspar, Gordon Pyper, H. Creasy, D. Edwards, and J. H. Starey. Mr. C. J. Donald acted as Secretary.

The following were represented by their attorneys:—Messrs. C. Young, A. Morrison, W. Cookes, Major G. L. Gwatkin, G. C. Walker, J. MacLiesh, J. H. Johnston, J. K. Morrison, and Mrs. E. C. Baillie.

The following were represented by proxies:—Messrs. F. G. A. Lane, W. F. R. Reid, W. P. Metcalfe, Mrs. L. C. Stuart, and Mrs. A. S. Donald.

It was proposed:—"That the We-Oya Tea Company, Ld., be wound up voluntarily,"—which was carried unanimously.

THE LATE DR. TRIMEN, F.R.S.

DR. TRIMEN'S death has attracted much notice in England. One correspondent writes:—

"We were, as you may suppose, much grieved to hear of poor Dr. Trimen's death. There have been several very appreciative notices in the London papers. One from the *Gardener's Chronicle* is good; also a notice of his retirement from the *Kew Bulletin* of July or August last. There will be a notice of his death in the November Bulletin."

The notices are as follows:—

DR. HENEY TRIMEN.

The friends and acquaintances of Dr. Henry Trimen will receive the news of his death with deep sorrow. His modesty, his gentleness, his sympathy, his right-

mindfulness, his sweetness of disposition, and readiness to help, were as remarkable as his extensive botanical attainments. Trimen was educated for the medical profession, and took the degree of Bachelor of Medicine at the University of London. Attaching himself particularly to the study of botany, he became an assistant in the Botanical Department of the British Museum; and on the death of our old correspondent, Dr. Thwaites, in 1882, became Director of the Royal Botanic Garden at Peradeniya, Ceylon. That position he filled till compelled recently by ill-health to relinquish his duties.

Dr. Trimen first attracted attention by the excellent *Flora of Middlesex*, prepared by himself in conjunction with Mr. W. Thiselton-Dyer, the present Director of the Royal Gardens, Kew. That book has formed the model on which all subsequent county floras have been prepared, and the more closely they have approximated to it, the more valuable has been the result.

During the period of his service in the British Museum, Trimen was associated with the late Professor Bentley in the preparation of the standard work on Medical Botany, and also edited the *Journal of Botany*, in which periodical appeared several critical notices from his pen. On his appointment to the directorship of the beautiful garden at Peradeniya, Trimen took up the work left unfinished by Thwaites, and devoted himself to the preparation of a complete flora of the island. Three parts of the *Handbook to the Flora of Ceylon* have appeared, bringing the work down to the Balanophoraceæ, so that the work is well advanced, and we trust material may be in hand for its completion. It is accompanied by an atlas of coloured plates of the more interesting species. Not long since Trimen visited this country to seek medical assistance when his friends were shocked at his condition, and entertained forebodings which the event has only too surely verified. Dr. Trimen died at Peradeniya on 16th inst., in his 53rd year.

It will be a matter of deep regret not merely to the Government of the colony, which he has served so well, but also to the botanical world, that Dr. Trimen was obliged, owing to the serious ill-health, to retire on July 1st last from the post of Director of the Royal Botanic Gardens, Peradeniya, in Ceylon. Dr. Trimen, who was at the time second officer in the Botanical Department of the British Museum, was appointed on the recommendation of Kew to succeed the late Dr. Thwaites in 1879. His administration of Peradeniya, whether from a practical or a scientific point of view, has brought it into the front rank of the great botanical establishments of the world. On this point the following extract may be quoted from an article by Dr. Treub, the Director of the Great Botanic Garden of the Dutch Government at Buitenzorg in Java. This article, originally published in the *Revue des Deux Mondes* for January last, has been translated in the *Smithsonian Report* issued from Washington.

Extract from "A Tropical Botanic Garden," by Dr. Treub, in *Smithsonian Report* for 1890, p. 390:—

"The Royal Garden of Peradeniya, in the island of Ceylon, was founded in 1821. Situated near Kandy, at an altitude of nearly 500 metres [1,600 feet], having a moist and hot climate, occupying more than 60 hectares [150 acres], and connected as it is with the port of Colombo by a railway, the garden of Peradeniya possesses conditions most favourable in every respect. For many years it was under the direction of Dr. Thwaites, a man of real merit, but who thought a botanic garden in a tropical country should be in some manner a reduced copy of the virgin forest. This system, more original than meritorious, excludes any methodical arrangement of plants and necessarily restricts the number of specimens. Dr. H. Trimen, the successor of Dr. Thwaites, as soon as he arrived in Ceylon, realised the disadvantages of the plan of his predecessor. To distribute over an area of 60 hectares, without any order, a great number of plants, for the most part not labelled, was to fatally embarrass the scientific use of the rich collections that had been brought

together. So Dr. Trimen did not hesitate to adopt a new arrangement of plants according to the natural system, and to label them as far as it was possible to do so. With branch establishments upon the plain and upon the mountain, the garden of Peradeniya has before it a brilliant future.

Dr. Trimen has not merely carried out a most efficient and thorough reorganisation of his department, but he has signalled his term of office by the production of three volumes accompanied by an atlas of plates of the long-desired *Handbook of the Flora of Ceylon*. (For notices of these volumes, reference may be made to the *Kew Bulletin* for 1893, pp. 34 and 227, and 1895, p. 236.) A final volume alone remains to complete this valuable work. It is satisfactory to record that Dr. Trimen has been "given by the unanimous vote of the Legislative Council a special allowance in addition to his pension for the last six months of the year in order to complete the scientific work upon which he is now engaged."

Intelligence has reached England of the death, on the 18th inst., at Peradeniya, Ceylon in his fifty-third year, of Dr. Henry Trimen, F.R.S., F.L.S., late Director of the Royal Botanic Gardens, Ceylon. The deceased gentleman was formerly senior assistant in the botanical department of the British Museum, prior to which he had acted as lecturer on botany at St. Mary's Hospital Medical School. He was also for many years editor of the *Journal of Botany*. In conjunction with Bentley he wrote "Medicinal Plants," a work much valued by pharmacists and he was one of the authors of Trimen and Dyer's "Flora of Middlesex." Of late years he had been engaged in writing a "Handbook to the Flora of Ceylon," three volumes of which have already been published.

The friends of Dr. Trimen who saw him during his last visit to England—a twelvemonth ago last summer—would not be altogether unprepared for a serious turn in the malady, or rather maladies, from which he suffered; yet the news of his death on the 16th inst. came as a surprise, even to those best acquainted with his condition. For several years he suffered from deafness, which at length became absolute, and then gradual paralysis of the lower limbs set in. This terminated not long since in utter helplessness so far as his legs were concerned, and functional complications arising, he succumbed sooner than was expected. He bore his afflictions with wonderful fortitude, and even cheerfulness; and his only desire was to be spared to complete his great work, the "Handbook to the Flora of Ceylon." But this was not to be. It is to be hoped, however, that a competent botanist will be found to complete this important and admirably-planned publication.

Henry Trimen was born in London in 1843, and educated at King's College. In 1865 he graduated M.B., but he never practised medicine. His favourite study was botany, and he at first specially devoted himself to the British flora and the sources of vegetable drugs. In 1867 he was appointed Lecturer on Botany at St. Mary's Hospital Medical School; and in 1869, he entered the Botanical Department of the British Museum as senior assistant. In the meantime he had published a number of contributions to British botany, chiefly relating to the flora of Surrey, of Hampshire and especially of Middlesex. His first work appeared in the *Phytologist* in 1862. Soon he became acquainted with W. T. Thiselton-Dyer, the present Director of Kew Gardens, and the result was their admirable "Flora of Middlesex," published in 1869. This work still holds a position in the first rank among county "Floras." In 1886, Trimen discovered *Wolffia arrhiza* at Staines; the first locality recorded for it in England. It was in that year that writer became acquainted with Trimen and his associate, and made various excursions with them collecting materials for their "Flora." In 1870, Trimen joined Dr. B. Seemann in editing the *Journal of Botany*, and on the death of the latter he assumed the full responsibilities of editor, which he continued to exercise until he went to

Ceylon. Concurrently he was conducting his investigations in medical botany, and he associated himself with Robert Bentley in the publication of an illustrated work on "Medicinal Plants"—a work of much research, comprising four volumes containing upwards of 300 coloured plates. Passing over many minor events, we come to the period when he was appointed to succeed Dr. Thwaites in the important and onerous duties of Director of the Botanic Gardens of Ceylon—duties he discharged in a manner satisfactory to the home authorities and the colonists. His annual reports are models of what such reports should be. He at once took up the study of the native flora, and was soon actively engaged in the introduction of valuable economic plants of other countries for cultivation in Ceylon. The first volume of his "Handbook" appeared in 1893; the second in 1894; and the third in 1895; and from his last letters we learn that he was still working with a will, in spite of his afflictions.

As a botanist, Trimen was a man of great attainments. As a friend, he was sympathetic, sincere, and constant. His work was always thoroughly and conscientiously performed, and is consequently of an enduring nature. This was recognised in his being elected a Fellow of the Royal Society in 1884

—*Nature*

W. BOTTING HEMSLEY.

CHINAS' TEA TRADE.

Eight of the leading British tea merchants in northern China have addressed to the Shanghai Chamber of Commerce the following interesting letter:—

"As a Tariff question is now being re-opened, the occasion seems fitting that we, the undersigned, buyers of tea in North China, should ask your particular attention to the disastrous condition into which the Chinese tea trade has fallen; which is, in our opinion, largely due to the heavy taxation under which it has laboured for many years, a taxation far in excess of the Treaty tariff of 5 per cent. *ad valorem*.

"During last season, 1895-1896, the export of black tea from China to great Britain has amounted to only 37½ million pounds, as against 117 millions in season 1887-1888, and 169 millions in seasons 1880-1881, a decrease of 131½ million pounds in fifteen years. This enormous decrease in the volume of the trade, one of the main foundations of our commercial existence in China, has, needless to say, been attended in its course with terrible loss and distress to a large number of foreigners and to hundreds of thousands of Chinese.

"The taxation consists of the export duty, Haikuan Taels 2½ per picul, and the *likin* taxes which average about Taels 2½ per picul,—in all, say Tls. 5 per picul, which was the average cost of black tea in North China is about Tls. 20 per picul duty paid, means a tax of over 30 per cent. on the cost of tea purchased at the treaty Ports. On sound common tea, which costs about Tls. 11 per picul duty paid, the taxation thus amounts to over 80 per cent. on the cost. Now the Treaties of Nanking and Tientsin (1842 and 1858) fixed the duty on tea at Haikuan Taels at 2½ per picul, which was to represent an *ad valorem* rate of 5 per cent. At the present time, however, an *ad valorem* rate of 5 per cent. would be only about ¾ of the Tael per picul and foreigners were entitled every ten years to have the Tariff revised in this sense, under Article 27 of the Treaty of Tientsin, 26th June, 1858. As to the *likin* exactions, which go to make up the Taels 5 per picul, these were of course never contemplated by the Treaties.

"It is only natural that Chinese tea penalised as it is by this crushing taxation, has been quite unable to compete with the untaxed produce of India and Ceylon. Not only in England but also in the smaller markets of Australia and America, do we see the working of this inevitable law.

"To Australia, China will ship this season only about 7 million pounds of Black Tea, as against 21 millions in 1880 and 1881; there the untaxed

British grown teas have begun to be taken of late years with the usual result, so that the Australian is now almost on all fours with the English trade.

"To North America China ships bulk of her green teas, and there again the taxation tells, as in that market these teas have to face the competition of comparatively untaxed Japan teas (the duty in Japan being only \$1 per picul) with the usual result of a declining export from China."

"The decay of China Tea Trade is going on so persistently that it will soon become a lost trade, unless its burdens are removed. To restore it to a healthy state, we would recommend further steps being taken towards improved quality, and as the producers seem unable or unwilling to effect reforms in this direction, it would be well if the government were to appoint a board of enquiry, to carry out such reforms as might suggest themselves, from a study of what is done elsewhere."

The same subject occupies the attention of foreign merchants in Amoy, where the proximity of Formosa and consequent familiarity with Japanese rates of taxation, bring into marked salience the crippling weight of the Chinese impost. Tea grown in Formosa under Japanese rule pays no *likin* or other local tax the only impost levied being an export duty of \$1.10 per picul. On the other hand, tea exported from Amoy pays an export duty of \$3.85 per picul, together with about \$3 *likin*. Thus the difference of taxation is no less than \$5.75, or, in other words, tea exported from China is taxed more than five times as heavily as tea exported from Formosa. A great difficulty against which Formosa has to contend is the want of harbour facilities: there is no harbour within easy reach of the tea districts where large steamers can load safely throughout the year. Hence Formosan tea has hitherto been carried to Amoy for final shipment, and the merchants of Amoy are naturally apprehensive lest, under Japanese rule in Formosa, the course of trade may be altered. Mr. Consul Gardner, in his last trade report for Amoy, says:—"The loss of the Formosa tea business to Amoy would be a very serious blow to the prosperity of the port, would seriously effect the Customs revenue in the matter of tonnage dues, would throw out of employment many hundreds of labourers, and by reducing the circulation of money in the city by some millions of dollars, materially affect its already rapidly-declining prosperity. It is impossible to over-estimate the value in indirect ways which the Formosa tea trade is to Amoy, and all interested in the welfare of our port, officials and merchants alike, should do their utmost to retain it."

We do not, for our own part, believe that the want of harbour facilities will long be suffered to injure Formosa. Harbour improvement is among the projects seriously contemplated by the Japanese. Meanwhile, it is possible that the vivid object lesson furnished by Japan's methods in Formosa may help to teach wisdom to Chinese officialdom. Mr. Gardner says that, were it not for excessive taxation, the Amoy tea districts could compete with Formosa in growing Oolong. Twenty-five years ago, three million dollars was the annual income derived by Fokien from the business of growing tea for foreign markets; today, the income is little more than one-tenth of that sum.

This question of the duties levied by China upon tea has much interest for Japan, apart from the Formosan phase of the problem. There is no doubt that the cheaper grades of Japanese tea would find a considerable market in the north of China were not the duties prohibitive. In the early days of China's tea trade, the tea had to be carried to Canton for firing and packing, with the result that its original price was doubled, approximately. Moreover, the producer obtained a comparatively high price in those times, so that, on the whole, the specific export duty of 2½ Tls. per picul was not very onerous. But when the tea came to be shipped direct from Hankow and other producing centres,

the manufacturing charges were largely reduced, and at the same time, the producer's price fell in response to the European markets. The average cost of black tea in northern China being now 15 Tls. per picul, approximately, it is evident that an export duty of 2½ Tls. (S) and *likin* of 2½ Tls. (S) represent taxes aggregating 33 per cent. Now Japanese tea sent to China has to pay an import duty of 2½ Tls. (S) per picul, together with 1½ Tls. *likin* or 1½ Tls. in all, and as the average cost of the tea at the port of shipment is 7 Tls. it results that the taxes levied in China aggregate nearly 59 per cent. If, despite this crushing impost, nearly a hundred thousand *yen* worth of Japanese tea found its way to China last year, we may reasonably assume that were the import duty and other taxes reduced to 5 or 10 per cent; the Japanese leaf would find a considerable market in the neighbouring empire.—*Japan Weekly Mail*, Oct. 17.

THE YATIYANTOTA TEA COMPANY, LIMITED.

At a meeting of the shareholders of the above Company, held on Thursday, 19th November 1896, the following were present:—

Messrs. W. D. Gibbon, in the Chair, A. Thomson and E. S. Anderson (Directors) and Messrs. J. H. Starey and D. Edwards.

The following were represented by their attorneys:— Messrs. C. Young, W. H. G. Duncan, G. W. Carlyon, Mrs. L. T. Carlyon, J. MacLiesh and J. K. Morrison.

It was proposed:—"That the Yatiyantota Tea Company, Limited, be wound up voluntarily"—which was carried unanimously.

COFFEE IN GERMAN EAST AFRICA.

The German East African Company in its report on the proceedings of the last twelve months dwells with satisfaction on the coffee plantations at Agnolo and Derema (where girls' schools have been founded, of which the company is not a little proud), inasmuch as, according to some contemporaries, the *leit motive* of German colonisation is the spread of civilisation. *Revenous à nos moutons*, or rather to coffee. The inroads of *Hemileia vastatrix* have been victoriously overcome. There are between 500,000 to 600,000 coffee trees in excellent health. The yield of berries during the last year has been 700 cwt. The first quality of coffee fetched 1 mk. 10 pf. on the Hamburg market, and as about 100,000 young trees will come to maturity this year a larger yield is confidently anticipated in 1897. Mr. Rowehl, overseer, as yet has chiefly planted Arabian coffee. Liberia coffee trees are principally flourishing at Langula, where the high ground suits them.

Tea plantations are likewise prospering at Derema, but it is too soon to judge of the quantity of the leaf, though the trees look healthy. Should these tea plantations prove a success, the company consider that Chinese and Soudanese coolies will be indispensable for the delicate manipulation of the leaves, to which Europeans have not been trained. It is hoped in Berlin that the German Government will give its assistance to the procuring of coolies from the East. Meanwhile the Wanyamwezis and Wafykomas have proved excellent labourers, and are so pleased with the work they propose transporting the Smalaks (wives and children) to the vicinity of the tea plantations. Cocoa culture does not thrive at Derema because the ground lies too high, whereas it prospers over a surface of 3,600 hectares along the coast between Mnoa and Jastae. Sea breezes favour the health of the trees.—*Central African Planter*, Sept. 15.

THE RAMIE SYNDICATE.

The *Textile Industries and Journal of Fabrics* says:—

The treatment of the Rhea or Ramie fibre is at present receiving a great amount of attention, and many inventors are attempting to perfect systems by which they hope to gain the immense returns that are certain to be the reward of the one who brings forward the process which proves itself a perfect commercial success. This Journal has paid no small amount of attention to the question of Rhea, and, during the past few years, much interesting information on the subject has been given in its pages. One invention after another has been fully described, and, as recently as July, we gave particulars of two processes which are considered to have a favourable chance of being crowned with success. Another system has been brought prominently before the public, namely that of Mr. Taylor Burrows and Mr. D. Edwards-Radclyffe. This being worked by the Ramie Syndicate, who after exhaustive experiments, have commenced a factory at Hythe End Mill, Staines, near Windsor. This factory is furnished with a complete plant for the treatment of Rhea, from the decorticating of the stems to the spinning of the yarns. There are already between thirty and forty hands employed, and the Syndicate hopes before long to greatly increase this number. The factory premises can be extended as the success of the enterprise may call for additions, and, we understand, that, already, largely increased power has been rendered indispensable.

Prominence has been given to the Ramie question by a meeting of members of the press, which took place at the Syndicate's works a day or two ago when the whole process was seen in operation. We are informed that the company is executing orders for such quantities as have never before been attempted. The largest consignments are, however, being made for canvas manufacture, also for sail cloths, fishing-lines, and similar purposes, but many good orders have been given for the better classes of fabrics, such as for lace, dress materials, hosiery, cloths of various kinds, velvets, and similar fabrics, and also for tapes and boot laces. Some of the Bradford, Manchester, and Glasgow firms are already employing the Rhea manufactured by this Syndicate in their works. The great strength of the fibre appears to attract manufacturers, and, where a proper chemical treatment is afforded, time has no weakening effect upon the material. But this is a great point—it is a very easy matter to remove the gum and bleach the fibre, but whether or not its strength has been deteriorated, time alone can, in many cases, determine. Should this process possess all the advantages claimed for it, manufacturers will find other attractions in Rhea, apart from its strength, as its silky nature and its suitability for a variety of high-class fabrics is well-known. When once the proper method of utilizing Rhea has been clearly demonstrated, there will be no end to its uses, and so easily is it cultivated in all sub-tropical countries that, given the demand, the supply may be always ready.

The plant which the Ramie Syndicate has at work includes decorticating, boiling and softening, preparing, combing, and spinning machinery, so that the whole process is gone through at the works. We give an illustration of the decorticating machine in Fig. 1, which turns out as much work as fifty men can do by hand labour. It would therefore pay planters to have such machines in their fields, as the treatment on the spot would be of great advantage to them, whether compared with decorticating by hand labour or exporting the Rhea in stems. Very little need be said in reference to this machine. It is simple in construction and effective in its operation, the stems being fed in at one end and returned as fibre, whilst no skilled labour is required, two boys being able to attend to it. It is portable, and can be worked by steam, water, or animal power, so that it is very suitable for dealing with the stems where grown. The next process to the decorticating is the boiling,

which takes place in a large square tank, heated from underneath by an ordinary furnace. The tank contains perforated, rotating cylinders, into which the material is put, and kept continually on the move. The process takes about three hours to accomplish, and the fibre is then placed in the bleaching tank, where a secret chemical process adapts it for further mechanical treatment. The bleaching is described as having no deleterious effect upon the material, as is the case where high pressure steaming is adopted, or where caustic soda is employed, but the gum is thoroughly extracted.

The next machine, shown in Fig. 2, combines the purposes of a wringer, separator, and softener. This requires but little description as the illustration easily explains itself. Its main feature consists of a number of fluted rollers, between which the material is passed. The drawing machine, Fig. 3, is worthy of attention, as the fibres are evenly drawn, without waste, into a sliver, to be treated on the combing and spinning machinery. A travelling apron, A, is mounted on rollers, B and B1. On this the fibre is placed in parallel order. The apron rotates towards the machine. There is a roller, B, and another, C, placed over B, both of which are fluted. The latter acts as a pressure roller, so that a firm grip upon the fibre is secured. Next is another apron, mounted on rollers, F1 and F. The roller, F1, is placed in contact with, but a little lower than, that marked B. The other roller, F, has another one, G, and another, J, below it. These latter are also fluted, the former acting as a pressure roller. The speed of these is greater than that of the first pair of rollers, so that the proper drawing action may be afforded, in order to bring the fibres parallel. A feed sheet, I, passes round a roller, J, and carries the fibres to the last pair of roller, K and L, and, after passing between these, goes forward under a large lapping drum, M, and over other rollers, J1, and J2, and back to the roller, J, near the second apron. There are springs and levers to keep top and bottom rollers in contact. The fibre to be treated is wet and is kept in this condition during the operation of drawing, which, by this means, is more easily accomplished. The fibres therefore pass from the first pair of rollers, B C, to the second pair, F G, and the drawing is repeated through the third pair, K and L, when the fibres are thoroughly drawn out, and appeared in the form of an even sliver. This may be wound on a cylinder, M, or run into a sliver can, or disposed of in any suitable manner, as it leaves the machine.

Numerous modifications have been made in the combing, spinning, and other machines employed, and so effectively can Rhea filasse be treated that, if put into work one day, the yarn can be delivered the next. By the complete machinery which the Syndicate has at work, the fibre can be prepared for any branch of the textile trades—woollen, cotton, linen, or silk. The present price of Rhea is about £15 per ton, but, when a good demand is established, it is considered that the price will come as low as £6 per ton, but even at the higher rate, we understand that, by this process, filasse and prepared sliver can be produced at from 2½d. to 9d. per pound, which will realize from 1s. 6d. to 5s. per pound in the market, according to the purpose for which it is produced.

THERE IS NO REASON WHY RHEA FIBRE SHOULD COMPETE WITH COTTON.—If only planters will keep it up, the area for growing is enormous, and the price could be reduced lower than cotton, and still pay the planters enormous profits. The official report from Mexico, where it is being taken up by the Minister of Public Works, although there they are under the disadvantage of stripping the ribbons by hand labour, says the profit shows 145 per cent. on the working capital. Now with decorticators, this profit would be increased, and if the planters will go one step further, and ungum it whilst green, not only will a still superior quality of fibre be produced, but the filasse will command a higher price. The report adds "all scientific authorities

agree in declaring the Ramio fibre to be superior to any other fibre in length, strength, and beauty, as it is fine, silky, and brilliant." When Ramie is once planted, it lasts from 16 to 18 years before it requires replanting. It merely needs ordinary attention, such as keeping the land clean and similar attentions. It crops three to four times a year and pays for manuring. Particulars as to seed, cultivation, &c., can be had of Mr. D. Edwards-Radclyffe, 56, Gloucester Crescent, Regents Park, London, N.W.

We shall be glad to see this or some similar process prove a great commercial success, as the solution of the proper utilization of Rhea fibre must be accomplished sooner or later, and the inventors who succeed in this will not only have the approval of the whole textile community, but will also reap a large reward for their labours.

NEWS FROM BRITISH CENTRAL AFRICA.

Employers of labour, or persons recruiting labourers in the Central Angoniland District, are requested in all cases to pass any labourers whom they may recruit in such district before the Collector for Central Angoniland before leaving the district.

It has been found that the Central Angoniland natives, who have only comparatively recently come directly under European influence, have not in many cases understood thoroughly the terms which have been proposed to them for service in the Shire Highlands. When these men are passed before the Collector for their own district everything can be made distinct and clear to them by him, and all future misunderstandings provided against.

Mr. R. E. Codrington, the Collector for the district, is willing to take steps for the forwarding of parties of men to employers who may require them.

If, however, labourers are taken out of the district and not passed until they arrive at their destination, so many misunderstandings have arisen that it may be found necessary to limit recruiting in this district.

H. M. Acting Commissioner therefore trusts that employers of labour will follow the course now laid down.

(Signed) ALFRED SHARPE, H. M. Acting Commissioner and Cml.-General.

Zomba, 9th September, 1896.

—*British Central Africa Gazette.*

TEA SEED OIL.

A Ceylon subscriber, Mr. O. Collett, has kindly sent us the following for publication, with a note however that he thinks it very unlikely, as we do, that it would pay anyone to grow tea-seed instead of tea-leaves. Nevertheless, as a bye-product, tea-seed oil may in the near future be no inconsiderable factor in estate profits:—

CITY ANALYST'S OFFICE, 56, KOLLUPITIYA ROAD,
COLOMBO, 20th April 1896.

Examination of a sample of tea-seed oil, received on the 16th instant, from M. O. Collett, Binoya Estate, Watawala.

The oil was clear, of a golden yellow colour, its specific gravity at 90° F. was 9.125, distilled water at the same temperature being taken as unity. At this temperature, olive oil, with which the sample was compared, had a specific gravity of 90.904. The comparison was made with olive oil, as it is considered the best lubricant amongst the vegetable oils. The oil had the reactions of a non-drying oil.

The viscosity of the oil at 90° F., the temperature of the air at the time at which the experiments were made, was slightly less than that of olive oil. A measured quantity of the oil took 1 minute 8 seconds to run through a small orifice, as compared with olive oil, which took 1 minute 10 seconds.

The oil gets gradually thicker as it is cooled, but retains its transparency at 34° F., at which temperature it can still be poured, although sluggishly.

With regard to the lubricating properties of the oil, I tested the same on a jinricksha wheel. When the axle was lubricated with this oil, and the wheel set in motion, it continued to revolve for 1 minute 23 seconds. When olive oil was used, and the impetus given was as nearly as I could judge the same, the wheel revolved for exactly the same length of time. When lard was used, the wheel revolved for 1 minute 42 seconds. Freedom from free acids is an important point in favour of a lubricating oil. In this respect the oil compared very favourably with the sample of olive oil with which I compared it; but it should be stated that by long keeping olive oil develops free fatty acids. The olive oil I used was from a newly-opened bottle of J. T. Morton's fine sublime olive oil, but of course, it might have been long in stock. The oil was also compared, with respect to free acids, with coconut oil; the latter was found to contain about one-third more. The oil is prized in Japan as a lubricant, and the result of my experiments goes to confirm this good opinion.

As regards its burning qualities, I made a rough test, which showed it to be quite equal to coconut oil at the temperature of Colombo as regards its illuminating effect.

I understand that the oil has been found quite suitable for the manufacture of soap, but I have made no experiments in this direction, as I fancy that in the matter of price, the oil could not compete with other soap-making materials.

(Signed) M. COCHRAN, F.C.S., City Analyst.

—*Planting Opinion*, Oct. 10.

AGRICULTURE IN THE AUSTRALIAN COLONIES.

—We have to hand an interesting and exhaustive report by Messrs. Halse and Viner who were commissioned by the Department of the Cape of Good Hope to report upon the agriculture of the Australian colonies, and specially on wheat growing. We were always ready to admit that the Agricultural Departments of the Australian colonies were admirably worked, and the report to hand only tends to confirm us in this belief. We cannot too highly commend the liberality of the Government in voting large sums for the encouragement of agriculture. The Agricultural Department of Victoria has been allowed the following votes:—

For the importation of new varieties of seeds and plants	£3,000
For supply instruction in connection with the introduction of new vegetable products and improvement of existing agricultural methods	£43,000
For the introduction of new machinery and appliances to perfect the treatment of new agricultural products and to improve present agricultural methods and for prizes for the new inventions in general agricultural appliances	£4,000
For publishing agriculture reports in connection with educational work	£11,000

These are only some instances of what the Government is doing for the agricultural advancement of the colony, for which we note that an aggregate annual vote of no less than £272,253 is supplied to the agriculture department. Our officials might well stare aghast at these figures after their experience of the parsimonious agricultural policy of the local Government. It is high time that some properly organized scheme for the agricultural advancement of this colony came to be seriously considered.

VEGETABLE GARDENING IN CEYLON.

The growing of vegetables of European *habitat* has long been successfully followed upon many of our upcountry estates, and at higher elevations, such as that of Nuwara Eliya, their cultivation has become quite a large and paying industry. Kandy and Colombo may both be said to be supplied with these luxuries in sufficient quantity to meet the demand, though this last would receive great extension were the prices somewhat reduced. But there are many localities wherein Europeans reside in this island where no supplies of the kind are available, and where no effort is made to meet the deficiency by local cultivation. We apprehend that the omission is largely due to want of knowledge as to what is practicable as to this, and many residents in lowcountry outstations would probably be glad to be able to vary their dietary did they know that the growth of many kinds of European vegetable may be accomplished by care, even under the drying heat of low elevations, by a plentiful supply of water, and judiciously applied artificial shading. The late Mr. P. A. Dyke, when Government Agent of the Northern Province, made persistent effort in this direction, securing a large amount of success. With that liberality that so distinguished him, he almost daily distributed the products of his vegetable garden among his European neighbours, and the arrival of his messengers with the baskets of varied supplies was always warmly welcomed and appreciated. What Mr. Dyke did on a large scale it would be perfectly possible to accomplish on a more restricted one, and many housekeepers, both male and female, would find themselves to be well repaid by the practice of an interesting occupation. Perhaps the vegetable with which Mr. Dyke was most successful was the delicious knolkohl, a species of German turnip little if at all known to residents in England. But with carrots, beans, and several other vegetables, Mr. Dyke was equally successful. What he succeeded in doing in the dry and arid climate of Jaffna we feel sure could be even more readily accomplished in a great number of lowcountry localities. Unfortunately we are not ourselves able to describe the *modus operandi* followed by the former able agent of the Northern Province. But there must, we should say, be still many residents of the northern capital who could supply the information with a sufficiency of detail. With some care exercised, and at but relatively trifling cost, an occupation could be secured by many otherwise unemployed wives who would feel a natural pride in adding the luxury of European vegetables to their daily *ménus*.

NOTES FROM THE METROPOLIS.

LONDON, Nov. 2.

Is

COFFEE

to be overproduced like everything else, may well now be the question? On the head of the news of what is doing in East Java, the Malayan Peninsula, East Africa, Costa Rica and in Brazil itself to make up for the deficiency caused by the collapse in Ceylon, Southern India and old Javá, there now comes the report from two or three quarters, that Brazil itself is giving this year the largest coffee crop it has ever produced. But this is not all: here is the paragraph which appears in this week's issue of the *Society of Arts Journal* and which (if further verified) may eventuate in a "rush" of capitalist-planters to the Congo region:—

Coffee in the Congo.—M. Laurent, Professor of the Agricultural Institute of Gembloux, entrusted by the independent State with a mission to the Congo, has just published a report upon the results of his travels, in which he says that the Congo will, in some years to come, be as important a coffee-growing country as Brazil is at the present time. The coffee tree will find in the great equatorial forest the conditions of soil and climate that are the best suited for it. It grows there in a wild state, and there are three descriptions known, two of which yield excellent results. According to the information M. Laurent has obtained at Bosoko and Caquilhatville, the preparations of the ground for coffee plantations would require native labour, which could be obtained at a cost of about £10 per hectare (2.47 acres).

I have applied to M. Laurent for a copy of his report referred to above, in order to review it in the *Tropical Agriculturist* for the information of planters and capitalists. It will be interesting to see what extent of "wild coffee" has been seen or explored by M. Laurent or his informants.

I see that Mr. T. C. Anderson's

GARTMORE GROUP OF ESTATES

to be offered by auction in Mincing Lane on 26th November by Messrs. Cow, Wilson & Stanton, comprise Gartmore, Larchfield and Bevys estates, most compactly situated in one block, 490 acres of tea and 143 of forest—truly a valuable property.

Port of Spain (Trinidad) papers have been specially sent to me with articles marked, reviewing

MR. ARTHUR SINCLAIR'S

chatty clever volume, "In Tropical Lands," issued in 1895. The book seems only to have reached Port of Spain and to have created a mild sensation, judging by the criticism, although I can discover no substantial grounds for the complaints hinted at, rather than openly formulated, against the author. For instance, one paper gives some columns of extracts prefaced by the following sentences; but nowhere can we find in it what the "palpable misrepresentations" may be:—

IN TROPICAL LANDS BY ARTHUR SINCLAIR, 1895.—The following extracts taken from one of the latest additions to the Public Library will arouse feelings of astonishment owing to the number of palpable misrepresentations with which the book teems. The sources from which such travellers obtain their information will require to be looked into, and we will probably have some remarks to offer in a future issue.

In another paper, however, we have a full editorial critique with some strong language, but calculated, I should say, to amuse rather than annoy the author who is placed in such company as J. A. Froude—"the worst offender of all" against Trinidad. Here is, however, the article in full, to prevent our Trinidad neighbours thinking it need be in any way burked:—

MR. SINCLAIR'S BOOK.

Mr. Arthur Sinclair is by no means the first and we fear will not be the last of the writers who, after paying a visit sometimes of a few weeks, but oftener of a few days, to Trinidad, do not hesitate to issue "for general information," their impressions of a country and a people of both of which they are absolutely ignorant. Without going back to the earlier writers who have sinned in this way, we will instance James Anthony Froude, the worst offender of all, who stated the principal crops the Island to be indigo and coffee, adding that there are still some larger sugar estates and that as the owners had not succeeded in making the negroes work for them they had introduced "a few thousand coolies under indenture for five years." With characteristic inaccuracy he also described the Island as having been "alternate y French and Spanish until captured by Picton in

1797," the fact being that it had never for a day been under any flag but that of Spain and that it was not captured by Picton, but by Abercromby on whose staff the former was serving at the time. Such mistakes as these were nothing to the most unscrupulous perverter of history of modern days. We will however leave Mr. Froude and turn to his most recent follower.

Mr. Sinclair does not seem to have been at all favourably impressed with our chief Town for he writes:

"Port-of-Spain will hold its own with any city in the world for the rankness of its smells and the viciousness of its mosquitoes."

With regard to the latter, as far as our own rather extended experience goes, the mosquito exhibits a wonderful similarity of viciousness wherever he exists. We have never yet met a tame one and although the poet tells us that education—"Emollit mores nec sinit esse feros." We do not think the experiment has ever been tried on these wretched little pests who are neither better nor worse in Port-of-Spain than elsewhere. With regard to smells, although we cannot deny that they are sometimes rather too pronounced, yet this is common enough in all sea port Towns standing on a low level, and those who have experienced the odours which assail the nostrils in Cologne, Constantinople, the Bazaars of any Indian Town, or even in the purlieus of the East London Docks, will scarcely think Mr. Sinclair's verdict a fair one. In his next paragraph our author gives the first instance of the very superficial knowledge he contrived to acquire of the country he has undertaken to describe. He alludes in it, and in other places also to the "Tamil Coolie" in a manner showing that he is under the impression that the greater portion if not the whole of our Asiatic population comes from Southern India whereas as a fact we are sure we are well within the mark in saying that not one per cent of it is Tamil. There has been no importation of Madrasses for over 20 years although a good many have arrived here of their own accord from Martinique. Although Mr. Sinclair grumbles at the smells and mosquitoes he is fair enough to admit that Port-of-Spain is one of the most beautiful cities in the West Indies. He has a word of praise for the two principal churches but does not think much of our other buildings. His description of "the best hotel—absurdly called the 'Ice House'—as nothing more or less than a huge drinking bar with a few bedrooms attached," is incorrect even applied to the time when he visited us which seems to have been about five years ago, and would be a gross misstatement now. We wonder if the Messrs Siegert will appreciate his statement delivered *ex cathedra*, that their world renowned Bitters are "made from the bark of small shrub (*Galipea trifoliata*) belonging to the Rue family"? We imagine that Mr. Sinclair obtained that information from the same person who told him that the old Governor's residence was burned down some years ago, for one is as correct as the other. After some complimentary remarks on Mr. Hart, and praise of the Botanic Gardens, followed by an extract from Charles Kingsley's "At Last," we come to one of the strangest parts of Mr. Sinclair's description of his experiences of Trinidad. He mentions no names but we can see that the valley alluded to is that of Maraval, although it is somewhat difficult to recognise.

"A lovely ride, past the reservoir" is clear enough, but "for some miles through abandoned sugar estates is puzzling. "A pretty little bungalow on a knoll," may be recognised, and we know of "good natured Irishmen," who would "provide a good dinner, but we are at a loss to locate any decent house where the following incident could have occurred.

"As the hot night advanced the smells increased till sleep was out of the question..... Daylight at length came to our relief, when a search revealed the fact that a dead hen lay beneath the bed and a dead dog on the doorstep—both supposed to have been bitten by snakes."

The description of the St. Antonio Cacao Estate and of the Sta Cruz Valley is accurate enough and

is pleasant reading, but the late Sir Joseph Needham would not have liked to be told, nor do we think it will please our living planters to hear, "that there is no attempt at cultivation." We think also that Mr. Sinclair should have abstained from quoting Mr. Hart's views on the planters of Trinidad. Mr. Sinclair ends by saying:—

"We left the Island of Trinidad—beautiful as it unquestionably is—without much regret. The climate is evidently perfect for the cacao tree, but for the average Briton so enervating that, as Froude found there is a constant 'Craving for cock-tails,' and the viciousness of the mosquitoes shows that there is something very far wrong with the sanitation. Moreover the Spanish element is still too strong to be pleasant for a free-born Briton. After all the best man in Trinidad, and the hope of the future, is the so-called Tamil 'coolie.' Why coolie? I cannot conceive."

We can only say that we close our remarks on Mr. Sinclair and his book with an equal absence of regret. If Trinidad has too much of the Spanish element to be agreeable to him as a freeborn (there is a strong flavour of music-hall patriotism about this phrase) his book is far too full of bigotry, prejudice and intolerance to be pleasant reading to those who believe that whilst to be a British subject is a great privilege, to be British born is not an essential for salvation, either in this world or the next. In the first portion of his work, which treats of his travels in Peru, the author spoils an otherwise most interesting narrative, by sneers in the worst possible taste, at the Roman Catholic Religion and its ministers, and in the part treating of Trinidad he endeavours to create a bad impression as to the value of the island and the intelligence of its planters. As to the third part, knowing nothing of Ceylon we cannot judge of its merits.

Mr. Sinclair is evidently a man of considerable powers of observation and we doubt not is an able botanist, but outside of his professional qualifications his chief attributes seem to be narrow-minded bigotry and intolerance.

Now, it is evident that the critic is hard up for complaint when in the forefront he places the extremely trivial slip—if slip it be—that to General Abercromby rather than to his lieutenant, the gallant Picton (who no doubt did the business) should be attributed the capture of Trinidad a hundred years ago! There is really nothing else to notice in the criticism calculated to provoke more than a smile over the touchiness of the editor who winds up by praising Mr. Sinclair's ability as botanist and observer, but condemns his "narrow-minded bigotry and intolerance"—a charge, which, of course, is made in ignorance of the fact that the gentleman referred to, a Scottish Episcopalian in his bringing-up and choice, is well-known as one of the broadest and most liberal of Churchmen, the friend of all schools and sects, not excluding even the Roman Catholic priests and dignitaries of twenty years ago in Ceylon. — One result of the writing at Port of Spain and its republication should be an increased demand both there and here for the volume with its well-written descriptions, lively though by no means ill-natured observations, and really valuable botanical and planting information.

THE INDIAN AND CEYLON EXHIBITION

at Earl's Court closed a few days ago, and the lent articles have been duly returned. For 1897 season, we read:—

At Earl's Court next year there will be the Victorian Era Exhibition, which will show the progress made during the past sixty years in commercial and industrial pursuits, economic and scientific interests, music and the drama, sports, pastimes and recreations; while an important section will be devoted to women's work. No industrial exhibits will be accepted which do not emanate from the United Kingdom.

MARKET FOR TEA SHARES.

[FROM OUR SPECIAL CORRESPONDENT.]

THURSDAY EVENING, November 5, 1896.

Business in Indian Tea Companies' shares, though interfered with a little by the sympathetic influence of the uncertainty pending the American Presidential election, has continued steady throughout the week, and strong investment buying still goes on. Some of the best-reputed stocks have, moreover, risen to quite record prices.

The *Bullionist* of last Saturday (October 31) published an interesting and intelligent article on the Preference Shares of Indian Tea Companies.

Their article confines its attention to those shares which still yield approximately 4½ per cent., that is among the officially quoted stocks.

It may be noted that Jokai Prefs., and Doors Company's Prefs., as well as those of the Ceylon T. P. Company, cannot now be purchased to pay more than about 3¼ per cent.

Mincing Lane seems to have now in a great measure recovered from the position of weakness chronicled during the past few weeks, and the tendency is now again rather upwards.

Reports from India indicate the prospect of the later teas showing better quality than characterises those now being sold under the hammer here.—*H. & C. Mail*.

THE FERTILITY OF THE SOIL.

In a recent article dealing with the formation of the soil, the various agencies at work in this highly important operation were enumerated and described. It was pointed out that while geology gave us a valuable indication of what the nature of the soil was likely to be, it could furnish little information on the subject of soil fertility. To study this subject, which is surrounded with much difficulty, we must have recourse to other sciences, more especially agricultural chemistry, and, as the latest researches have shown, to bacteriology. At first sight the subject seems much simpler than in reality it is. We are inclined to think that all that is required is a knowledge of the soil's composition. No doubt such knowledge is by itself of very great value, but it is insufficient to solve the problem. For one reason, there are properties in a soil which exert a very important influence on its fertility. These are known as its mechanical or physical properties, and include the state of division of its particles, its porosity, and its heats and water absorbing powers, &c. There are also factors, other than those mentioned, which have a most important influence on fertility, which, however, we need not concern ourselves with in this place. These are climate, altitude, exposure, and the nature of the season. The significance of these is undoubtedly enormous, the influence of the last named being probably more potent than that of any other. But valuable as the study of the nature of such influences is, it is not likely to lead to any practical results, since it is still out with the power of man to alter in any way the climate of a country or the nature of the season; whereas the study of the composition and properties of the soil is likely to furnish us with knowledge we may turn to a practical account.

When we come to study the composition of the soil we are met by unexpected difficulties. In the first place, it is not sufficient to know of what substances it is formed, but, further, what are the exact forms in which certain of these substances are present. This is a problem which chemistry is still unable to solve satisfactorily. The question is further complicated by the fact that the soil is not a substance of stable—i.e., unalterable—composition, but is constantly undergoing a process of change. Indeed, it may not inaptly be likened to a gigantic chemical laboratory, in which the most varied operations are constantly taking place, and in which chemical changes of a most involved and subtle character are being effected. Another reason of the difficulty of the problem is to be found in the unsuspected world of minute life with which the soil is teeming, which play a most important part in the promotion of vegetable growth, and which are ever busily engaged in preparing and elaborating for their use food materials which the crops of the field require. As we know but little of the nature of these chemical changes, and of the conditions under which the microbial denizens of the soil carry out their important functions, it will be at once seen how it is that such ignorance should hamper us in our study of the important problem of the fertility of the soil.

That the soil plays an important part in ministering to the growth of the plant has always been recognised, although many and erroneous have been the opinions in the past held with regard to what that part is. We need only notice the famous theory associated with the name of Jethro Tull—a theory which exercised such an important influence on the development of modern agriculture. Tull, who was a farmer in Berkshire, was led to conclude from his observation of the great benefit which followed the application of very thorough cultivation of the soil—such as is pursued in the case of the culture of the vine grape—that the food of the plant was derived exclusively from the soil. He consequently set himself to advocate what he termed "horse-hoe husbandry," a system of husbandry which he was of the opinion should facilitate to a very great extent the assimilation by the plant's roots of this food. The crops of the field, according to him, should be shown in rows or ridges, wide enough apart to admit of the thorough tillage of the intervals by ploughing and by hoeing. The custom of applying farmyard manure, so old and approved a practice, owed its success, he held, to the fact that in its fermentation it helped in the pulverisation of the soil. A thorough system of tillage consequently obviated the necessity of the application of manures.

With the great advance in our chemical knowledge which took place at the close of last century, truer ideas began to prevail on the subject of the part played by the soil in supporting plant growth. Owing to the researches of such men as Priestly, Bonnet, Ingenhousz, and others, the source of the largest organic constituent of the plant—viz., carbon—was traced to the atmosphere; while the source of hydrogen and oxygen gradually came to be recognised as water. Attention, therefore, came to be centred in the mineral or ash portion of the plant; and this was shown by the Swiss investigator, De Saussure, in an investigation published at the beginning of the century, to come from the soil. Sir Humphrey Davy devoted much attention to the relation of the soil to the plant, and generally the question of what constitutes fertility in a soil. He studied what we have already referred to as its physical or mechanical properties, and showed what an important bearing these had on the question of fertility. He may be said, however, to have rather overrated the influence of such properties. Moreover, he scarcely recognised at all that the plant drew a certain proportion of its food from the soil. In his view the chief function of the soil was simply to act as the mechanical support of the plant. For a considerable number of years little progress was made in elucidating the true relations between the soil and the plant, and it is not till nearly the middle of the present century that any important advance has to be chronicled. At that time widespread interest in the subject was aroused by the publication of Baron Liebig's works, the first of which appeared in 1840 in the form of an address to the British Association. By the promulgation of his famous "mineral theory" he drew the attention of the agricultural community for the first time to the really important functions discharged by the soil in plant growth. He restated the doctrine, taught by De Saussure, that the plant drew the mineral matter which it contained from the soil. He also recognised that the plant derived its nitrogen to a large extent also from this source, but this element he considered was derived from the air in the form of the ammonia which was washed down by the rain in sufficiently large quantities to supply the needs of plants. Liebig's teaching was of the highest value, as it drew attention to the need of restoring to the soil the mineral ingredients, phosphoric acid and potash, the two substances among mineral plant foods which are alone generally present in deficient amount, and which for this reason regulate to a large extent the rate of plant growth. In this way he may be said to have been instrumental in starting the practice of artificial manuring, a practice which has done so much to revolutionise modern

agriculture. He also discovered what has proved to be a fact of enormous importance for modern agriculture—viz., the action of sulphuric acid on phosphate of lime in rendering it more, speedily available to the plant as food.

Liebig's work has been carried on and developed by a large number of investigators, among whom may be specially mentioned Sir John B. Lawes and Sir J. Henry Gilbert, who for a period of more than fifty years have devoted their lives to the elucidation of many problems in agricultural chemistry, and chiefly to the investigation of the questions of the relation of the soil to the plant and the action of fertilisers.

During the last thirty years the amount of attention devoted to the subject of the fertility of soils has steadily increased. These years have seen the growth and development of large numbers of agricultural research stations, where the nature and functions of the soil has formed the chief subject of research. The earliest of such institutions was that at Bechelbronn, in Alsace, where the distinguished French agricultural chemist, Boussingault, devoted himself to the question of investigating problems connected with the growth of the commoner agricultural crops. But the most magnificent example of a research station of this kind is that furnished by Rothamsted. This research station was started more than fifty years ago, and has been maintained ever since, at his own private expense, by Sir John B. Lawes, Bart. The name of this famous research station is familiar to everyone who takes any interest in the scientific aspect of agriculture; and the example of scientific collaboration furnished by the work of Sir John Lawes and his colleague, Sir J. Henry Gilbert, is quite unique in respect of the length of time over which it has extended.

On the continent and in America there are a large number of those agricultural experiment stations, where the study of the soil is made the chief subject of investigation. The properties of a soil which influence the growth of vegetation upon it may be grouped under three classes. The most obvious function of the soil is to furnish the plant with mechanical support, and to maintain it in an upright position. It must, at the same time, be of such a nature that the plant's roots can draw from it the moisture, nourishment, and air which they require for their proper growth. If, therefore, it is to successfully perform this function, it must possess certain mechanical or physical properties, as they have been called, among the most important of which are a certain porosity, and a capacity for absorbing water and heat. Porosity is of importance for several reasons. It is only in a porous soil that the necessary supply of air reaches the plant's roots. On soils where this is not the case, as in water-logged soils, for example, vegetation cannot flourish—at any rate vegetation of a high type. Again, porosity is of importance as it enables the plant's roots to push their way downwards in the soil. Too great compactness in the soil prevents growth, since it limits the spread of the roots. The more deeply rooted and the wider the area over which the roots of a plant extend—the better able is such a plant to draw its nourishment from the soil, and withstand the action of drought by obtaining its water from the lower layers of the soil. A still further reason of the importance of porosity is connected with the micro-organic life of the soil, since for the proper development of these numerous microbes, many of which discharge important functions in preparing plant food, a supply of air is a necessary condition. Lastly the rate of decomposition of the material of the soil—inorganic as well as organic—depends largely on the access of the air to the soil pores. Not less important are the powers possessed by the soil of absorbing and retaining water and heat. These powers are necessary for fertility, since the fertile soil must be able to absorb and store up water and heat against periods of drought and cold. The conditions which influence these properties are the stat

of division of the soil particles and the nature of the soil itself. Everyone is aware how parched sandy soils become in dry weather, and how well clay soils are enabled to withstand long periods of drought. Among the influences which affect the heat absorbing power of a soil colour may be said to be one of the most important. A dark soil absorbs more heat than a light-coloured soil. What gives colour to a soil is chiefly the amount of organic matter it contains. Iron, again, is very often the cause of the colour of a soil. Even a small percentage is able to exert an important influence in this respect. Soils containing iron generally have a very red colour. Some idea of the influence the colour of a soil has on its power of absorbing the sun's rays will be obtained from the statement that a difference in temperature amounting to thirteen or fourteen degrees Fahr. has been found to be due to colour alone in soils adjoining one another. There are other sources, of course, from which the soil may derive its heat in addition to the sun's rays. Thus the decay of organic matter, when taking place at all rapidly, engenders much heat.

But, important as the physical properties of a soil are, they only partially explain its fertility. The soil not only acts as a support to the plant and as a medium through which its roots may drink in air and moisture, but it also furnishes the plant with certain necessary food ingredients. What, then, are these food ingredients, and to what extent are they present in most soils? The composition of the soil, as we should naturally expect, includes a large number of different substances, but the greater part of it is made up of only a few bodies. Silica is by far the largest constituent, and is present in an almost pure form as sand, or in combination with alumina, as clay. This latter substance is the constituent which, next to silica, is the most abundant constituent. Together they may be said, as a rule, to form at least four-fifths of the inorganic portion of soils. Very much less in amount is lime. Magnesia is also a constituent of some importance. It may be here pointed out that the physical properties of the soil are influenced almost entirely by the proportion in which organic matter and the above-mentioned ingredients are present. Very striking, more especially on the texture of the soil, is the effect of lime. By its addition the stiffest of clays may be made friable. A very strange fact with regard to the two largest constituents of the soil is that neither of them is a necessary plant-food. Silica, it is true, is found almost universally present in plants; but the most careful research has failed to show that it is absolutely necessary for plant growth; while, with regard to alumina, it is not even found in the plant. Lime, magnesia, and iron are, on the other hand, necessary foods; but the same economic importance does not attach to them as does to two other plant-foods—viz., phosphoric acid and potash, and this is for the reason that the three first-named substances are almost invariably present in amounts which, so far as the needs of growing plants are concerned, are abundant; whereas the last named are by no means so plentiful and hence, along with nitrogen, do much to limit the growth of the plant. It has been found that few soils contain phosphoric acid in quantities over two-tenths of a per cent; while the average amount in most fertile soils is probably not more than half this. There are a few soils, it is true, where it occurs more abundantly. Thus in certain very rich Russian soils it has been found to be present to the extent of more than one-half per cent.

But it must not be imagined that the whole of this amount, trifling though it may appear, is in a form in which the plant can at once make use of it. This is not the case. Only a very small trace is present in a condition available for the needs of the plants. How much this is it is very difficult to say, as we do not know any exact method for estimating it. It must be pointed out that it is not merely that which is soluble in water which is in a condition available for the plant. There is a certain amount of plant food in the soil which, although not soluble in water, is yet available for the plant's im-

mediate requirements, since it is capable of being dissolved by the acid sap of the plant; and lately an ingenious method has been devised which aims at estimating what this amount of available mineral food really is in the case of phosphoric acid and potash in soils. For this purpose a weak solution of citric acid, 1 per cent. strong, is used. The results as yet obtained by this method show that while the total amount of phosphoric acid in a fairly fertile soil may be as much as between three and four thousand pounds per acre in the surface foot of soil, the amount immediately available for the plant's needs may be considerably less than a tenth of this amount. Similarly with potash, which may be taken in most soils to run as high as 1 per cent, very few soils probably would contain anything like a hundredth of a per cent in the soluble condition. The constant removal, due to drainage and the growth of crops, of phosphoric acid and potash, as well as of that other important plant-food, nitrogen, which is being effected on our cultivated fields, calls for the application of fertilisers if the fertility of our soil is to be maintained. Hence it is that much of our cultivated land is constantly being reinforced in its fertilising constituents by the addition of costly manures. But with the advance of recent science we are beginning to recognise that what is probably the most important condition of fertility of the soil is the presence of countless myriads of microbic life, with which we know every ounce is teeming.—*Scotsman*.

COFFEE-PLANTING IN BRITISH CENTRAL AFRICA.

(From *Chambers's Journal* for October.)

BY MR. H. D. HERD.

Although by the latest arrangement between the British South Africa Company and the Foreign Office with regard to these territories in 1894 the area over which the British protectorate immediately extends has been considerably lessened, there still remains under the direct administration of Her Majesty's Commissioner a country equal in extent to the area of Great Britain.

This country extends from Lake Nyassa on the north to a point on the Shiré River near its confluence with the Zambesi on the south; but the district to which our attention is more particularly directed is that tableland lying between the Shiré on the west and the borders of the protectorate on the east, and perhaps best known as the Shiré Highlands.

Here is the latest home of coffee; and seeing that the country has now passed through its little fever of wars with the Arab slave-traders on its borders, and peace seems to have come to stay, we think that the present position of its staple industry and its future prospects merit a wider publicity in the interests of those to whose enterprise and hardihood the country owes what prosperity it has.

The history of coffee in Nyasaland dates back only to the year 1878, when three small coffee plants from the Edinburgh Botanical Gardens were taken out by Mr. Duncan, then gardener to the Church of Scotland Mission at Blantyre, and planted in the mission garden there. This was done at the energetic representations of Mr. John Buchanan. In the year 1880 the sole survivor of the three plants brought out by Mr. Duncan bore a crop of about one thousand beans. From the distribution of the seed, three years later, may be dated the beginning of coffee-planting on an extensive scale; but in 1881 the first serious attempt to put coffee on the home market, and to gauge its value as a commercial product in competition with other coffees, was made by the late Mr. John Buchanan, of the firm of Buchanan Brothers, whose name is so honourably connected not only with the commercial but the political development of the Shire Highlands.

A sample of the first crop was sent home for valuation, and was quoted in the London market at eighty-five shillings per hundredweight.

From this time onward the unsettled state of the country made the future of coffee very uncertain, till in 1889 the declaration of a protectorate restored confidence and gave a great impetus to the industry. Messrs Buchanan Brothers opened up large plantations at Zomba, Michiru, and elsewhere, while the African Lakes Company's coffee at Mandala continued to do well. Mr. Brown, of Ceylon experience, settled in the Mlanje district, which had been strongly represented by the late Rev. Robert Cleland as exceptionally well suited for coffee; and Mr. Duncan, having now left the mission, opened up a plantation near Blantyre.

From this point, so rapid has been the progress made, that the late Mr. John Buchanan wrote in *The Central African Planter* for October 1895 that no less than one hundred plantations had been opened up under the respective interests in the country, and that these plantations represented an area of six thousand acres under cultivation. The local revenue rose from nothing to £20,000 per annum in five years.

The services of Mr. Buchanan were recognised by the Government, and he received a C.M.G. in 1890. Much to the regret of every one, he died on his way home for a holiday on 9th March of this year.

Mr. E. C. A. Sharrer is now the largest owner of estates in the protectorate, amounting to about three hundred and sixty-five thousand acres, of which only about nine hundred acres are under coffee. It has been suggested that planters should also turn their attention to cotton-growing. Tobacco and tea have both been introduced.

So extraordinary has the development been during the last few years, that since 1889 the quantity of coffee exported has increased in an almost geometrical progression. The exact figures have been;

	Tons	
	parchment.	
1889 5
1890 —
1891 10
1892 —
1893 42½
1894 74
1895 146
1896 (estimated) 350

The year 1897 is looked forward to as likely to prove a record year, chiefly because a very large number of plantations come into bearing for the first time in that year; some planters being so sanguine as to put the yield at twelve hundred tons 'parchment'—as the raw coffee is called before the membrane covering the seeds is removed.

The varying degree of success attained have been due to many different causes, arising mostly from experience in trying to reconcile the approved methods of coffee cultivation in Ceylon and India with the conditions of the new country; and partly also from local difficulties, as for instance the labour question, which were unforeseen, and could only be resolved as they presented themselves.

In the early days there was an abundance of local Yao labour, but the supply was irregular and unreliable. Constitutionally indolent, the natives in the immediate neighbourhood of the plantations were soon satiated with calico and other barter goods; and in the wet season, just when labour in the plantations was most needed, there was none to be had, as the villagers had betaken themselves to the hoeing of their own gardens. The necessity for a reliable labour supply being evident, an attempt was made to bring down Atonga labour from the west of Lake Nyasa, which was entirely successful, the new-comers readily engaging to work on the plantations for several months at a time, and this at the most important period of the year, the wet season.

It is hoped that, acting in conjunction with the Portuguese government, the promoters of this scheme may be able very shortly to extend the line all the way to the coast at Chinde.

A further step in advance was made by inducing the Angoni, an offshoot of the Zulus, and long the scourge and terror of the Shire Highlands, to accept work in the dry season on the plantations; and now, instead of coming down in their thousands to devastate the country, they lay aside the shield and spear, and handle the hoe with equal skill. Only last year another large field of labour supply was opened by the subjugation of some disaffected chiefs on the north-eastern slopes of Mlanje. The Walolo, occupying a vast tract of hilly country to the east of Lake Shirwa, had for some little time been venturing down in small companies to work for the Europeans, but by the timely action of Sir Harry Johnston, Her Majesty's Commissioner, against these chiefs, the whole Walolo country has now become accessible to European influence. It is evident that there is every prospect of an abundant labour supply, and in this respect the outlook is very bright.

The chief drawbacks to coffee-planting have hitherto been the labour question mentioned above, and the inadequate and expensive means of transport. The Shire is navigable for the present flotilla of steamers plying upon it as far as Chiromo, three days distant overland from the coffee district. For a very few weeks during the rainy season it is possible to reach Katunga, a point about twenty-eight miles from Blantyre. From the plantations to either of these points the coffee crop is carried in bags on the shoulders of coolies. The risk, inconvenience, and expense attached to this mode of transport have been greatly felt, but even this difficulty is about to be met by the construction of a narrow gauge railway line which will run from Chiromo to Blantyre, passing through or near many of the largest plantations.

The reckless mode of agriculture followed by the natives, by which they clear large tracts of forest land on which to make their gardens, is becoming so serious a question that the expediency of legislation in the matter has been considered. It is well known that deforestation is followed by a decreased rainfall, which reacts not only the coffee crops, but on the health of the European. And where such wholesale clearing has taken place, land which might otherwise have been good for coffee is rendered temporarily useless for want of shade.

Efforts are being made to lessen the various circumstances disadvantageous to coffee by better systems of irrigation, planting of shade trees, and manuring. As showing the enterprise which is so prominent a characteristic of those Central Africa pioneers, it might be stated that during the past year a 'Chamber of Commerce and Agriculture' has been formed, which promises to do much good in securing authoritative and unanimous action on the part of the planters in questions affecting their interests. But perhaps, above all, the *Central African Planter*, started last year and so ably conducted by Mr. R. S. Hyde, F.R.S.G.S., in the planting interests, is an unequivocal sign of a very bright and prosperous future for coffee in Nyasaland.

By the foresight and discretion of Her Majesty's Commissioner, who has given the industry much encouragement and consideration, the danger of introducing the leaf disease so common in Ceylon and India has been averted. No seed is allowed to be introduced into the country, even though sterilised, and although some inconvenience has undoubtedly thereby arisen, the risk justified the stringent measure.

The eyes of Ceylon planters have been for some time turned to Nyasaland, and in 1895 was formed the 'Nyasaland Coffee Company, Ltd.,' with a capital of three hundred thousand rupees. The quality of the coffee has been highly spoken of by the London coffee brokers, and it holds its own with the best Ceylon and Mocha coffees.

The late Mr. John Buchanan estimated that to bring a plantation of say two hundred acres into bearing in the third year would require an expenditure of two thousand to two thousand five hundred pounds (sterling). And he cautioned

planters against allowing the trees to bear too heavily in the maiden crop, as there is a danger of the plant being thereby weakened,

Other estimates put the expenditure at *not more than* ten pounds per acre, or a little over three pounds per acre per annum for three years, and thereafter a large profit. The price of Nyassaland coffee as quoted in the London market for late years has averaged one hundred shillings per hundredweight, but it has reached as high as one hundred and twelve shillings.

Under varying conditions the average yield per acre is somewhat uncertain, but competent judges put it at from three to four hundredweight per acre. Some maiden crops have yielded eight hundredweights—but not without injury to the plants.

Taking four hundredweight as the average, on a plantation of two hundred acres this is equal to forty tons, with a selling price in London of four thousand pounds. From this, of course, must be deducted freights, which will not be less than eleven pounds per ton from the plantation to the market.

In the report on the protectorate by Commissioner Sir Harry Johnston, issued in August last, there is a valuable appendix devoted to the coffee industry, with a map of the southern Shire Highlands devoted to coffee-planting. We learn from it that a survey for the proposed railway connecting Blantyre with Chiromo has been made, that the native population in the Lower Shire district since the suppression of the slave-trade has increased from 1,000 in 1891 to 14,385 in 1896, and that if malarial fever could in some way be eliminated, British Central Africa would be an earthly paradise. The chief bane of British Central Africa according to the Commissioner is that 'accursed spirit whisky.' The exports have doubled during 1895-96, and not a little of this increase is due to ivory and coffee. Sir Harry Johnston entertains great hopes of the development of the negro of Central Africa. At Zomba there is one European headprinter; all the other printers are natives, who have been either locally trained at the missions or by the head-printer. The Commissioner has also an encouraging report regarding mission work in British Central Africa, and special mention is made of the work of Dr. Laws and others at Bandawe, concluding 'that it has only to tell the plain truth and nothing but the truth to secure sympathy and support.'

Three species of liliaceous plants, of easy propagation, promise to yield fibre worth nearly £10 a ton. India-rubber is another product which it is hoped may be largely developed, as the demand for it at present almost exceeds the supply. We are told that 'given abundance of cheap native labour, and the financial security of the protectorate is established. The European comes here with his capital, which he is ready to employ to almost an unlimited extent if he can get in return black men who will, for a wage, work with their hands, as he cannot do himself in a tropical sun. It only needs a sufficiency of native labour to make this country relatively healthy and amazingly rich. The cultivation of coffee would be a hundred times more extensive than it is if there were an adequate labour supply.' For unskilled labour three shillings a month, with or without food, is paid, and proportionately less for women and children. Skilled native labourers—carpenters, masons, brick-makers, &c.—receive wages of from four shillings a month to £10 a year. There seems to be every reason to believe, in accordance with the opinion of the oldest and most experienced planters, that the prospects of success in this industry are very hopeful. Considerable areas of land suitable for coffee are yet to be had, the price varying from five shillings to twenty shillings per acre, and no doubt as the country is better known, and more capital is introduced, the difficulties which have kept back and hampered its development will rapidly disappear, and British Central Africa will yet become, if not the most extensive, perhaps the most successful coffee-growing country in the world.

TALK WITH A TEA PLANTER.

(From *Natal Mercury*, Oct. 30th.)

CEYLON AND NATAL COMPARED.

We have had a call from Mr. John Fraser, a tea planter, of Ceylon, who is on his return journey after a trip to Europe. He and the Messrs. Aitken, of the Lower Umzimkulu, parted as young men in Aberdeen 31 years ago, and unexpectedly met a week or two since at Ruthville. Mr. Fraser has utilised his stay in South Africa to see the tea gardens of Natal, and the results of his observations are of value. In Ceylon he grew coffee for 16 years, and when that failed he, in common with other islanders, planted tea. The herb began to be generally grown there in 1880, about the same time as its cultivation was started here, although a commencement had been made four years earlier. The progress of the industry in Ceylon, compared with the progress made in Natal, is a matter that deserves investigation—as to why Natal tea has advanced so slowly, comparatively, as regards the output and its general use. Within six years, in 1886, Ceylon was producing over 5,000,000lb. of tea and the output for 1898 will be over 100,000,000lb. The rapid strides of recent years as regards export to America were due to the efforts of Sir John Grindinton, a Member of the Council, who advertised the Ceylon beverage at Chicago, and Mr. William Mackenzie, himself an astute and successful planter. China, which used to supply England annually with 300,000,000lb. of tea, now exports no more than 40,000,000lb. and the shortfall is being made up by India with 150,000,000lb. and Ceylon with 100,000,000lb. What is Natal doing for the world's consumption? Ceylon looks upon South Africa as a country that grows its own tea, and Ceylon will not push itself into our market unless Natal fails to fill it herself. Mr. Fraser was himself asked to send from Ceylon a shipment to Johannesburg of 5,000lbs. of tea, to be followed by monthly shipments of 10,000lbs. If Natal, however, allows outsiders to come in, a taste will be created for foreign brews, and Natal will have admitted a competitor for which there should be no call. Ceylon tea, however, is beginning to find its way to this country. In Johannesburg, next to Heath's Hotel, is a cafe which makes a special feature of Ceylon tea at 6d. a cup; crowds of a night take advantage of the opportunity, and so a liking for Ceylon tea is created. If this taste gains a firm and general hold, Natal tea will be looked on with less favour—for the reason, it is stated, that merchants cannot rely on an even quality in Natal brands as they can in the case of Ceylon. A rapidly increasing output would be less desirable than a steady and reliable quality in the produced—a quality which has not been sacrificed to the desire to promote the output. Mr. Fraser thinks that tea would grow anywhere in Natal, but not at a profit. Maritzburg seems the extreme upper limit of profitable industry. Beyond the vicissitudes of climate would probably prove fatal. Ceylon has no winter as in Natal, and there is no cessation in the plucking season; and another advantage the island possesses is a more frequent flush. With advantages of this nature to compete with, it behoves Natal to see if there are any means within her reach to improve the quality of her product, as she cannot change the weather or force the leaf. To begin with, Mr. Fraser is able to assure us that we have in the Colony a good *jat* of tea—in fact, the average quality is equal to that of Ceylon, at all events, so far as the early fields are concerned. Ceylon is now, however, paying as much as £20 for a maund (80lb) of indigenous seed, and this is only sufficient for four or five acres. Our informant has no word to say in regard to the quality of the plants he has seen in Natal, or the manner of their planting. From this point, however, is to be traced our weakness. The bushes are not cleaned enough—more old wood should be cut down; and whilst pruning would reduce the quantity of the crop the quality would assuredly be superior. The Natal tea planter has every appliance, proper machinery, adequate premises—all equal to anything in Ceylon—but the system of manufacture is

generally at fault. The withering, in the opinion of the Ceylon planter, is very uneven. The reason of this lies in the inequality of the leaf, the larger leaves, of course, taking longer to wither than the smaller leaves. In Ceylon there is required one coolie for $1\frac{1}{2}$ acre, whereas in Natal one coolie is supposed to be ample for four acres; hence the advantage in point of labour is shown in favour of Natal. The result, however, is to some extent an indiscriminate plucking. With so large an area to cover, the coolie has to exercise a haste which does not allow of carefulness in selection, and in consequence a larger leaf is plucked than should be admitted, and the uneven withering that follows is fatal to a first-class tea. It is admitted that Natal makes as good tea as Ceylon did 10 years ago, but if Natal wants to compete on even terms with Ceylon and India in the world's market, or even to keep foreign teas out of South Africa, she must improve her manufacture. What would doubtless tend to this in the first place would be a visit by Natal planters to the home of successful tea-growing elsewhere. A few weeks' residence in Ceylon would be of infinite value; but, even in Natal, an advance in the standard of manufacture would be possible if planters worked together for mutual good, as is the case in Ceylon. There the neighbouring planters pay neighbourly calls, and enter each other's factories, and question and criticise, advise and compare notes, and so the experience of all is gained and given for the benefit of each. In Natal there appears to be no community of ideas, no common interest, and one planter rarely enters the factory of his fellow. What Ceylon did with its coarse teas was to send them to town in sacks and sell to the natives at 1d. or 2d. per lb. The natives were glad to pay that amount for the leaf, and while the grower in this way received some return for an article that could find no other market, he was careful to ensure that no tea which left his factory for ordinary consumption under his own brand was other than excellent and even in quality. By strict attention to this detail a reputation has been built up, and the world is now willing to take all the tea that Ceylon can produce. The coolies in Ceylon are drawn from and around Madura and south of Madras, whereas Natal gets her labour from Madras and from Calcutta. The Indian coolie is paid in the rupee, the value of which is now 1s. 2d., and the wages for children, women, and men run from 16 cents. to 40 cents. per day—an average check-roll showing perhaps 35 cents. per head, or about 5d., and the coolies feed themselves. If cost of labour in this Colony is higher than in Ceylon, that Colony has to pay a duty wherever its tea enters, whereas Natal has the whole of South Africa to exploit for a market. Mr. Fraser, however, is not too favourably impressed with the energy of the Natal farmer and planter with the exception of two, viz.—Mr. Hudett of Kearsney estate and Mr. Hindson, Clifton, both shrewd and intelligent men and have done as much for Natal tea as any two men in Ceylon have done for Ceylon tea. The coffee disease in Ceylon, which swept the island clean and practically abolished coffee-growing there, was worse than locusts and rinderpest combined. Men everywhere were ruined, and yet they at once set to work to build up a tea industry on the ruins of coffee, and with what success all the world knows. Yet there are not 4,000 Europeans in the whole country and scarcely any European labour is employed. For instance, an estate of 700 acres would be managed by the manager and one European assistant, with the aid of native conductors. Our Scottish visitor cannot believe that Natal planters are planting at a profit under their present system. It is not quite clear, however, what that system is, as planters are reticent in giving figures. Mr. Fraser has great doubt as to what this may mean. It may be that they are dissatisfied with their figures, or that they do not wish to make known the profits they are making. At all events, they appear to be so bound up in their own ideas that to give a friendly hint is to be looked on with suspicion. "But with all the drawbacks," concluded Mr. Fraser, "I think there is still a good opening for outsiders to come in and plant tea in Natal."

PLANTING AND PRODUCE.

(From *H. and C. Mail*, Nov. 6.)

TEA FREIGHT IN CHINA.—A resident in Shanghai calls attention to the question of steamship discrimination in favour of foreign, including American, ports. He says: "Last year I called attention to the fact that lying off the bund at Hankow were two steamers belonging to the same company, one loading teas for London at 70s per ton, the other teas for Odessa at 40s. History repeats itself; steamers are now loading here for New York at 30s, while the rate to London is 40s, and the London steamers fill up at Colombo with tea at 6s 3d. Owing to excessive taxation the tea trade from China to London has practically been killed, and it would be satisfactory if steamer agents would explain why they imposed this additional burthen. The inevitable result must be to prevent London from being, as she has been hitherto the distributing centre. Until this season many shippers sent their teas 'optional'; that is, they could be landed in London or forwarded to New York as the markets permitted. Now it is cheaper to ship New York and thence to London than to London direct; yet steamer agents profess to wonder why their London steamers do not fill."

THE TRANSIT PASS SYSTEM IN CHINA.—Mr. Herbert Brady, the British Consul at Kiu-kiang, in his last report refers to the system of transit passes in China, by which, on payment at the port of entry of half the import duty in lieu of transit dues, goods are allowed to go free of transit duty to a declared destination. This means, after the half-duty is paid, the goods are still liable to the exactions of corrupt officials at the transit barriers—in other words, that the pass is not respected by those to whom it is really addressed. Mr. Brady says: "Last year imports to the value of about £300,000 were sent from Kiu-kiang into the interior under transit passes, being about £75,000 more than the previous year. This is done by native merchants, who monopolise the whole of the import trade of the place. During the year only one complaint, and that of a most trivial nature, was received at the Consulate in regard to breaches of the protection afforded the passes." Mr. Brady says "there is no doubt that the latter are respected at the inland barriers, for inquiries which have been widely made amongst the Chinese merchants show no complaints. They say that no additional or differential taxation of any kind is imposed at their destination on goods which have been covered by a pass. If they are carried beyond the place mentioned in the pass they pay exactly the same charges at the further barriers as ordinary goods in transit. As to the saving caused by passes, this is variously estimated; it is difficult to fix a proportion, because the pass covers goods to any distance, while uncertificated goods pay at every barrier, and the advantage of the pass therefore grows with the distance traversed. Kerosine oil is largely carried inland under transit passes, and there is said to be a saving in this instead of paying the transit dues at the barriers: and the same may be said of piece goods, lead, and iron. No transit passes for exports have been taken out, although rules for granting them were made six years ago. The reason is that the foreign merchants at Kiu-kiang have no direct interest in exports, save that of tea and the conditions of the tea market have so greatly changed in recent years that foreign merchants are content to buy in the local market and not go into the interior to buy, as in former days. Hence the mode and circumstances under which the tea arrives in the market are of no concern to them. Mr. Brady thinks that no difficulty would be made in the issue of transit passes for exports, nor does he believe that the same obstruction would occur at the inland barriers as twenty-five years ago, when a British merchant brought down tea from the interior under a transit pass for the last time."

THE POSITION OF THE WEST INDIAN SUGAR INDUSTRY.—The present position of West Indian sugar planters is one of despair. Having thoroughly made up their

minds that the Continental bounty system has practically ruined them, they decline to accept any other theory for a moment. The planters of British Guiana are deeply concerned, and the Georgetown Planters' Association has applied to the Imperial Government for relief, and has suggested that one of the following three measures should be adopted:—(a) The immediate payment from the Imperial Treasury of a sum per ton of sugar exported from the colony equal to the bounty on export sugar given by Germany, so as to place the industry in the colony on an equal footing and in as favourable a position as that of foreign countries now exporting beet sugar to Great Britain. (b) The arrangement of a conference of the European countries giving export bounties on beet sugar, with a view to settling a joint agreement for the immediate abolition of such bounties. This matter of relief to be of any assistance to British Guiana must be very promptly carried out. (c) The imposition of a countervailing duty on all foreign sugar imported into Great Britain equal to the bounty given at the port of export." Unfortunately the planters of Demerara and Essequibo are not the only persons who have had to face an enormous fall of prices. Other agriculturists have suffered in the same way, and might ask for a subsidy also, and the question is, when should such subsidies stop? Supposing that China and Japan, owing to Government subsidies, were to become formidable rivals of Indian and Ceylon tea planters in the tea markets of the world, the latter would be entitled to ask for subsidy from the British Government, in the same way as that suggested by the sugar planters of Guiana. Our sympathy is with the sugar planters of British Guiana and the sugar-producing colonies, but we fear that protection will not help them. Cane sugar is grown in the United States, and it is protected, except as regards Hawaiian sugar, by a very heavy duty; but, in spite of this duty, German beet-sugar is being imported into the United States in quantities which are increasing enormously, the total for the first eight months of this year being estimated at nearly 600,000,000 lb. as against only about 135,000,000 lb. for the corresponding period in 1894 and about 167,000,000 lb. for the first eight months last year.²

SCIENCE AND IMPROVED MACHINERY.—Sir Charles Bruce has just reported on the decline of the sugar industry in the Windward Islands. He opines strongly to the view that the main cause of this decline is the system of subsidies adopted by foreign governments which guarantee the producers a margin of profit even when the price is below the cost of production. Whatever the reason, the decline during the last fifteen years is very striking. In St. Vincent, for instance, the value of the export in 1880 was £123,603; in 1895 it was £21,581. In view of these figures, it is satisfactory to learn that Professor Harrison, who has reported on the agricultural prospects of the islands, holds out great hopes of renewed prosperity from scientific treatment of the soil and improved machinery. Sir Charles Bruce in his report on St. Lucia shows how much headway may be made even against the worst of agricultural depression. The mortgagees in possession of the estates of the Central Sugar Factory Company gave notice of withdrawal from the property. As the company itself was entirely without funds, it seemed certain that the estate would revert to its natural condition of jungle, and that a large body of labourers would be thrown out of work. A local syndicate then came forward and took over the estates for a year. "I understand," says Sir Charles Bruce, "that the estates have been worked with such superior energy, skill, and economy as to realise an immediate profit, and to justify the belief that the cultivation of the property will be permanently maintained and extended, with profit to the undertakers and every advantage to the colony."

COOLIE LABOUR IN THE WEST INDIES.—There is one point in connection with the crisis in the sugar planting industry of British Guiana which must not be overlooked, and that is the difficulty between maintaining the validity of the posi-

tion of the indentured coolies on the one hand and the employment of coolies whose contracts had run out at less wages on the other; the alternative being the closing of the estates, which means ruin to practically the entire population. There is also a far more serious question to be faced by the Imperial Government, as the insolvency of the whole sugar industry will also mean the insolvency of the colony for the heavy loans to the estates guaranteed by the colony, while the revenue will suffer in proportionate ratio. The obliteration of the sugar industry in British Guiana will mean the disappearance of at least 75 per cent. of the whole trade of the colony.

CUBAN PLANTERS AND THEIR TROUBLES.—It is an ill wind, &c., and the losses of the Cuban sugar planters from the insurrection in the "Pearl of the Antilles" has been some gain to sugar planters elsewhere. The exportation from Cuba to the United States had fallen off by two-thirds up to August, and has now ceased, to the advantage of sugar cane growers in the West Indies, and in the East too. As to tobacco, owing to exceptionally large stocks being in hand, the market for Havannah cigars has not yet risen to the extent expected. But experts in the trade predict that in another two years there will be such dearth as will place prime Havannahs beyond the reach of all except the very wealthy.

COFFEE IN THE CONGO.—M. Laurent, Professor of the Agricultural Institute of Gembloux, entrusted, by the independent State with a mission to the Congo, has just published a report upon the results of his travels, in which he says that the Congo will, in some years to come, be as important a coffee-growing country as Brazil is at the present time. The coffee tree will find in the great equatorial forest the conditions of soil and climate that are the best suited for it. It grows there in a wild state, and there are three descriptions known, two of which yield excellent results. According to the information M. Laurent has obtained at Bosoko and Coquillhatville, the preparation of the ground for coffee plantations would require native labour, which could be obtained at a cost of about £10 per hectare (2.47 acres).

COFFEE IN THE CONGO STATE. WEST AND CENTRAL AFRICA.

We have received from the author, M. Emile Laurent, Professor in the Government Agricultural Institute at Gembloux, Belgium, a copy of his Report in French, addressed to the Belgian Secretary of State, on the Agricultural Prospects revealed by his journey in the Congo Free State appertaining to King Leopold. This journey, specially subsidised by the Government, extended from the 8th September 1895 to the 14th of May 1896, and included a great portion of the vast extent of territory comprised in the State for over ten degrees south and five degrees north of the equator with some twelve degrees of latitude. Pending a full translation of this important Report, which we may publish *in extenso* in our *Tropical Agriculturist*, we may forthwith give a general idea of its contents. This must be very brief; for the Report covers over forty pages of a large size printed pamphlet. It has passed into a third edition, so it is evidently attracting a good deal of attention in Belgium and on the Continent generally; and as a result we may expect a considerable introduction of both planting pioneers and merchants as well as capital into the Congo. But it will be surprising if British traders and money do not take priority when it is found that there are new products available, much in demand in Europe and America. Already, the Congo State is the scene of some very successful English Mission Settlements.

M. Laurent voyaged up the Congo and begins by describing the "District of the Cataracts," its narrow fertile valleys, its wooded ravines and sandy plains. Here he considers there may be scope for the planting of Liberian coffee, in spite of the disadvantage of the long dry season; a small area already contains plants two years old. The district of Stanley-Port and of the eastern Kwango contains several varieties of India-rubber of the *Landolphia* genus growing in great abundance, and experiments of coffee growing and two cacao trees are referred to; but they show so far no great promise, the soil being too sandy and dry. The district of Lake Leopold II promises most for India-rubber, plantains are abundant and probably tobacco would do well.

In the district of Kassai and the Lualaba, the upper streams near the source of the Congo, M. Laurent found what seemed to him a new variety of coffee growing wild. It is a small tree from 3 to 5 yards high with spreading branches often growing over streams of water. The leaves are larger than those of Liberian coffee and the flowers small like Arabian coffee.

In one plantation he was able to compare the growth of this variety with the Liberian. In the Arab zone, or district of the Stanley-Falls, he noticed in the forest region very fine potatoes, the fourth crop within fifteen months. He thinks cotton and indigo may possibly grow well. Then follows "The forest region." In the district of the Aruwini were some coffee and cacao plantations of which more detailed statistics are given as also of others in the district of the Bangalas and that of the equator. The second part of the paper is on the cultivation of coffee, and on minor cultivations. The third part is on the objects to be pursued in the Congo, by the Belgian state and cultivators. The information altogether is of much practical value and we shall refer to it when the details are all before us.

CEYLON TEA IN AMERICA AND RUSSIA.

We think the time has come when the Committee of the Ceylon Tea Fund should consider the desirableness of discontinuing any and every subsidy to private individual or firm in both Russia and North America. If our information be correct in respect of both countries—and it is derived from well-informed quarters—Ceylon tea has got a good hold in both countries and is now handled by far more firms and individuals than those who have received, or are receiving, aid from the planters' funds. One consequence is that jealousy and other ill-feeling are being engendered in connection with the action of the local Committee and their agents, and the result of certain favored dealers being subsidised any longer will be to increase these antagonistic feelings. In this way, not only are the majority outside the subsidised list who have to touch Ceylon tea, hindered by a very natural jealousy, from going into the trade as freely and fully as they would otherwise desire; but many more dealers who would probably follow suit if they saw a clear field and no favour, are holding off as long as ever they can, under present circumstances. On the other side, it will no doubt be pleaded that the best way to force the hands of the big and little tea houses in the United States and Canada is to work through a very few leading firms who are ready to expend any money from Ceylon in advertising its tea, hold-

ing and distributing a supply on their own account. But surely, it is not impossible, now that a considerable acquaintance with the tea business in the United States and Canada has been acquired, to expend all local funds in advertising direct—each advertising for the benefit of all, equally, who are ready to hold and distribute Ceylon tea? Our readers are aware that from the outset, we discouraged the plan of private subsidies in the case of the American market as being unsonnd in principle, and calculated, sooner or later, to engender prejudice and jealousy. We are free to admit, however, that to get a start in the face of considerable opposition, a temporary subsidy in a few well-selected quarters may have been advantageous. But, if so, we think there is evidence that a change of policy to direct and impartial advertising in the United States and Canada, would now be still more advantageous, as well as a wise and politic course to pursue in the interests of all concerned. We know that the expense of advertising in the best papers and periodicals in America is described as very high—much higher it is said than any rates quoted in the British Empire—but if the right course is adopted, it must be nearly, if not quite, as economical to advertise direct, as through the agency of subsidised firms. What is wanted is, we suppose, a very concise notice setting forth the merits of Ceylon Tea and appended to it a list of the houses who keep a supply for distribution in the State or City in which the advertisement appears? Giving the names of all who keep our teas, in this way, should be a very acceptable, as well as fair, mode of extending aid from the Ceylon producers. We leave the subject, as regards the United States and Canada, in the hands of the Committee. Very probably, our shrewd Ceylon Commissioner may, in his present visit to America, arrive at the conclusion that the time has come for general and impartial advertising, in which case a speedy termination would, no doubt, be put to special or individual subsidising; and advertising in the interests of all become the rule. In addition to the mention of the names of dealers in the Planters' Ceylon Tea Advertisement for America, a supply of literature in pamphlets, leaflets, wrappers, &c., should be furnished to each house taking up our teas. Many of the larger firms would, perhaps, prefer to prepare such for themselves; but smaller dealers might be very willing to utilise such literature, stamping their own names on all they distributed. In any case, we plead that the time has come for the removal of any cause of bickering or jealousy, or for the preferring of a charge of favouritism on the part of Ceylon planters, among the tea dealers in the United States and Canada.

In the case of Russia, we believe the time is also fast approaching, if it has not already come, for ceasing individual aid. We do not suppose such aid is given in more than two or three cases. But the number of people exporting Ceylon tea to Russia either direct or from London, or dealing in it, in that country is considerable. The latest illustration is afforded in our "Metropolitan Notes" where reference is made to the great success of Lipton's new establishment in St. Petersburg. A single order for 3,000 chests of tea, mainly Ceylon, from that one distributing store, which was being executed in London in early November, indicates great progress; and Lipton is not alone, we believe, among new houses exploiting Ceylon tea in the Russian Empire.

Correspondence.

To the Editor.

COFFEE IN SOUTH SYLHET.

Daurachura, Munshi Bazaar, South Sylhet,

Oct. 3.

DEAR SIR,—I have been experimenting for the last three years with different varieties of coffee in this district. I have been advised to send you a sample for your opinion. If you would kindly let me have your opinion on the sample, which I am sending per parcel post, as to its quality and approximate price in the market, I would be obliged. The sample is taken from a maiden crop, three years of age. The seed was got from Coorg, and was grown at a low elevation—50 ft. above sea-level only.—I am, dear sir, yours faithfully,

JAMES LAURIE.

[An expert to whom we submitted the sample reports:—"It is very small, and the silver skin has been allowed to settle on the bean—a bad fault in curing. I am unable to give its present value."—ED. C.O.]

GOOERA (CEYLON) TEA ESTATES,
LIMITED.

Oct. 21.

DEAR SIR,—We have received advice from London that this Company has declared a final dividend of 10 per cent. making, with the *interim* dividend paid in March, a total of 17 per cent for the year, and the balance carried forward is equivalent to 7 per cent. on the capital of the Company.—Yours faithfully,

BAKER & HALL, Agents.

THE MANUFACTURE OF TEA IN CHINA :

COMPETITION BETWEEN INDIA AND CEYLON.

Colombo, Nov. 7.

DEAR SIR,—We have much pleasure in enclosing a letter received by us from a gentleman in China (also an owner of estates in Ceylon) in regard to the awakening of China merchants to the fact that unless something is done, the total extinction of their foreign and colonial trade is within measurable distance. The means adopted to counteract this are the importation of an economic roller and the adaptation of Ceylon methods for withering, drying and rolling the leaf. Samples of the first teas made under the new process have reached us from both China and Australia, and after a careful examination we find there has been an improvement made in the appearance, but the lignors still remain those of China teas, with all their characteristics. It would be unwise to under-estimate the opposition of China, whose hold upon several markets of the world is still a strong one. At the same time no good can come of over-estimating it, and we feel assured that China's real obstacle to regaining her old position in the trade is owing to the fact that her soil cannot produce tea of sufficient body and strength to the possession of which the popularity of Ceylon and Indian tea is due. Improved methods of manufacture may and will no doubt result in the production of tea resembling somewhat in appearance that of India and Ceylon, but there is no possible method of manufacturing by which the evil of the soil producing the tea can be over-

come. Were fresh land in China opened and planted with good Indian seed, it is possible an improved article might be produced, but if the attempt at the resuscitation of the trade begins and ends with manufacturing the present leaf by Ceylon and Indian methods, the interests of Ceylon are not threatened.—Yours faithfully,

CROSFIELD, LAMPARD & CO.

(Copy of letter received.)

Oct. 9.

My dear L,—Thanks for your last letter. I see that you agree with what I previously wrote on the subject of encouraging the sale of your teas in Russia, and as you are much interested in that, you may like to have a few more notes from me on it.

That a start has been made in increasing the use of Ceylon teas in Russia is evident to all, and the course of the Northern markets in China this season go to prove this for the direct export to that country has fallen off 4 million pounds. Nor has this so far been made up by purchases on the London market, one of the best informed houses there writing that the expected demand for black leafs for export has not yet shewn itself. The start having been made it behoves all interested to help it along, and the need for this to be done *immediately* is becoming more urgent and for the following reasons. The merchant in China has awakened to the fact that the critical period has arrived and he is taking steps to ward off the total extinction of the trade. From Shanghai very strong representations are being made by the Chamber of Commerce to the Chinese authorities through the medium of foreign ministers at Peking, pointing out the evils which press so heavily on the trade, especially such as the "lekin" tax and the export duty. When many years ago, the latter was fixed at R2.5 per picul, it was regarded as the equivalent of 5 per cent on the value of the tea exported, but by reason of the great fall in the value of the article on the home markets, the same duty now represents from 25 to 30 per cent of such value. The Chinese are anxious to *increase* the duties on imports, and to obtain this, they *may* consent to a reduction of the duties on the export of tea. But the most important movement to be considered is that which is now taking place at *this* port having for its object the improvement of the teas produced here.

An "Economic" roller has been imported and a Company formed with the view of obtaining other machines for distribution amongst the various tea districts, so as to try where the Ceylon method of withering and rolling can be successfully applied. The machine arrived too late in the season to be tried upon first-crop leaf, and the several parcels of tea which it has turned out from "*second* and *third*" crop leaf have been disappointing—the teas rapidly "changing" and, though shewing more strength than the same leaf produced under Chinese methods, giving no flavour in the cup. But it must be remembered that so far only the second and third crop leaf from one of our poorest districts has been experimented upon, and the promoters of the Company are sanguine of better things resulting from the treatment of first crop. The Chinese teamen generally are averse to the use of machinery, but many are willing to try the Ceylon method of withering and the more careful manufacture of the leaf by "*hand*."

I naturally take great interest in the subject and I have sent to you today a sample of both machine and hand made teas under the new system of fermentation, and I am sure that any one sufficiently interested to take the trouble to obtain from you a glimpse of these samples, would be shewn them with pleasure. It will be seen from an examination of these samples that in "appearance" the new makes compare favourably with many of your broken pekoes, and this being so as regards the leaf it may well be that with first crop leaf and in time better cultivation of the plant, competition from this country may again be felt.

Further it is already being mooted as to foreigners leasing lands in the tea-districts and through their own Chinese employees, "*growing and manipulating the teas from start to finish*," which would certainly lead to improvement. Of course it will take some time to show any result from these attempts, and they may be unsuccessful. My aim is to shew you what is being done with a view to meet your competition and as it is a question of "success," or "extinction," you may sure the matter will be thoroughly thrashed out here. It seems to me therefore that the moral to be drawn from what I have written is the rigorous and *prompt* pushing of the campaign in Russia, one of the largest consumers of tea in the world and the careful upkeep of a good standard of quality, for in common teas China can beat the world in giving a well made article at a low price, and should the vexatious "lekin" and the heavy export duties be removed or lightened, she may yet endeavour to stem the tide of competition which is now threatening to drown her.

I would take this opportunity of again urging the application to the Russian Campaign of a *large portion* of the funds now being spent in Canada, where I am certain from my own observation, that all the good that your Delegate was expected to do, has already been accomplished and the further exploitation of that country may be safely left to those engaged in the trade.—Yours sincerely,—

P. S.—I have sent you to-day a third sample marked XX, which is the best specimen of the new style which has yet appeared, and which really *does* possess strength and flavour together with a tippy leaf.

THE RHEA FIBRE SYNDICATE AND GRANTS.

SIR,—I notice in Monday's "Times of Ceylon" a letter from the well-worn pen of "Vril" on the subject of grants in general and Rhea in particular. If "Vril" serves as *nom de plume* to veil the powerful entity I think it does, he has been out long enough to have been a keen observer of, and cynical though not unkindly commentator on many jobs of sorts. But this last impudent attempt to get the pick of a province for nothing seems to have goaded "Vril" into really serious remonstrance. But as he says—we have no safeguard against this sort of thing going on for ever. Nor shall we have, until it is laid down that no grants of land shall be made except by the Legislative Council, and that would mean that none would ever be made. And so mote it be.—Yours truly,

OVER PRODUCTION.

CASTILLOA RUBBER.

Wiharagama, Matale.

DEAR SIR,—You have shown such special interest in the matter of rubber cultivation and upon one occasion getting a highly favorable report from home on a sample of this particular variety from Matale, that I am sure you will excuse my calling your attention to an article in the last *Chambers Journal* to hand viz. for the month of October. It is far too lengthy an article for me to quote, but it contains so much regarding the practical cultivation of *castilloa elastica*, and with such splendid prospects of success at Nicaragua that to give the crude outline without details would make one's hair stand on end. The writer says that estimating the "9 years' yield value of £50,000 and deducting cost, interest and expenses the nett profit will be £47,620," which is a pretty good return for a nett capital outlay of £3,625!

He states that trees tapped in the wet season are estimated to yield five times as much milk as in the dry. Is this the explanation of the lamented Dr. Trimen reporting on the poor yield of this variety? I believe this is the secret of our disappointment in quantity. As regards quality of that sent from Wiharagama, Matale, your senior had the report from experts that it was the best rubber they had seen from Ceylon.

The opening suggested by this article deserves your bringing it into notice of your planting friends.

J. M. KANDY.

THE DUMONT COFFEE COMPANY LIMITED.

45, Leadenhall Street, London, Nov. 6th.

DEAR SIR,—We beg to inform you that on the 2nd inst., we received the following cablegram from Mr. G. A. Talbot, one of the Directors of this Company, who proceeded to Brazil on the 2nd ult., to inspect this Company's properties.

"I consider property a magnificent one, and exceeds in luxuriance anything I have seen in Ceylon, the Straits, or Java.

"Favourable crop prospects for next year.

"I am confident we can raise the value of our coffee by introducing improved methods of preparation.

"Steps will be taken to ensure a proportion of next season's crop being cured by Ceylon methods.

"Have decided our railway be exented at once, as it is likely to prove a source of increased income."—We are, dear sir, Yours faithfully,

P. R. BUCHANAN & Co.

Secretaries.

INDIARUBBER.—There is a greater demand now for the product of the indiarubber tree than has ever been known, the tires of the ubiquitous bicycle and other vehicles alone consuming an immense quantity. Everything regarding the substance is therefore of real interest to many, and Sir Henry Derrings' recent report on the rubber industry as carried on in Mexico will find many readers. The methods of its collection in Nicaragua, and the profitable nature of the industry are fully discussed in the article, "Out with the Indiarubber Gatherers," on a previous page.—*Chambers' Journal*.

NOTES FROM THE METROPOLIS.

Nov. 6.

I have been favoured with the following official Report of the proceedings at the recent statutory meeting of

THE GALLAHUA CEYLON TEA ESTATES AND AGENCY CO., LD.,

held at 29, Lime-st. on 29th ult:—

After the notice had been read by the Secretary, the Chairman (Mr. C. E. Strachan) addressed the Shareholders, and reminded them that this was the Statutory Meeting which had to be held within a certain time of the registration of the Company. It was quite of a formal character, and there was no resolution to bring forward.

Mr. Strachan, however, took the opportunity of speaking about the formation of the Company and the working of the estates. He mentioned that the Prospectus stated the subscription list would open on Tuesday, the 30th June, and would be closed before or at 4 p.m. on the following day, but in order to avoid disappointment it was found advisable to close it at 2 o'clock on the Tuesday, as by that time applications had been received for no less than 12,184 Shares, or more than twice the amount offered, and he felt sure that if the list had been kept open longer it would have been covered several times over. This he considered very satisfactory, as it showed the confidence of the public in the undertaking. The allotment of the Preference Shares was made with great care, and as no complaint had been made it was presumed it had given satisfaction. In accordance with the Prospectus an application for quotation was made to the Committee of the Stock Exchange, and this has been granted under the usual conditions. The price in the official list was 10s. to 15s. premium, and the Chairman thought his quotation would advance, as it was not easy to obtain Shares so amply sought as these were to yield such good interest at so cheap a price.

With regard to the prospects of the Company it was of course too early to make any definite statement, but there was no reason at the moment to alter the estimates. Up to the 30th September, 19 per cent. of the estimated Tea crop had been harvested, which is considered by the Colombo Manager in a recent letter as very satisfactory, and on some of the estate covering a large acreage it is expected that 60 per cent. of the estimate will be secured by 31st December. This would be very good indeed, as it was usual to expect two-fifths of the crop during the first six months, and three-fifths during the last six months of the season, April May and June being the best months in Ceylon for yield.

The quantity of Tea crop sold in London to date was 79,748 lbs., which had averaged 789d per lb. net, or upwards of 3d per lb. above the estimate of price stated in the Prospectus, and as the quality is uniform, there is no reason why prices should not keep fairly steady.

Mr. Strachan also said that when the additions now being made to the Factory were completed, the Company would be able to take in all the leaf for several years, and if further extensions should then be necessary, the Company would be able to afford the cost, as more space would mean more leaf and more profit. The cost of the permanent works would be met out of the sum of £10,000 set aside for capital outlay. About 300 to 400 acres of new land are being opened up, this meaning virtually the addition of a new estate to the group, as estates in Ceylon average about 250 to 300 acres, and each year further clearings will be opened up until all the available land is planted. Such buildings as coolie lines, are being made permanent, and this is being done at a small cost, as the Company owns a brick and tile manufactory, a property which adds a good deal to the value of the estates. All these additions add very materially to the security of the Preference Shareholders.

The supply of labour on the Company's properties is ample, and full numbers of coolies are always ob-

tainable, as this is a favourite part of the country with them, and their comfort has always careful attention.

Mr. Sinclair said he had only to complain of one thing, and that was that he had not been allotted the full number of Shares he had applied for. Being an old Ceylon Planter, and knowing these estates well, he would have liked to have had more of the Shares.

The proceedings closed with a vote of thanks to the Chairman, proposed by Mr. Sinclair, and seconded by Mr. Low. C. E. STRACHAN, Chairman.

The Mr. Sinclair is, of course, Mr. James Sinclair, Chairman of the Dimbula Valley Company. The latest rumour is that Mr. Strachan has been offering a large sum (£50,000 is the report) for two well-known Maskeliya estates; but that may be for a separate Company—that is if the sale takes place.

Of another

CEYLON TEA COMPANY,

the *Financial Times* has the following:—

CENTRAL TEA OF CEYLON.

The report of the directors of the Central Tea Company of Ceylon for the year ending 30th June last shows that the net profit was £3,091. A dividend of 10 per cent. on the ordinary shares is proposed, leaving £281 to be carried forward. To meet the purchase of two estates acquired since the company was formed a temporary loan of £3,584 was arranged, and it is now proposed to issue 593 ordinary shares at a premium in order to deal with this.

THE EASTERN PRODUCE AND ESTATES COMPANY, is evidently doing well this year: an *ad interim* dividend of 2s 6d per share having just been paid.

I quote the following

COMPANY REPORTS,

because first the exports of coffee from Brazil this season are said chiefly to depend on the capacity of the San Paulo Railway as a traffic carrier, and secondly Natalians are ambitious of developing an appreciable tea industry:—

PUBLIC COMPANIES.

San Paulo Railway.—Yesterday, at the Cannon-street Hotel, Mr. Martin R. Smith presided over the seventy-fourth general meeting of the shareholders of the San Paulo (Brazilian) Railway Company. In moving the adoption of the report, he said it was true that the net receipts for the half-year were some £27,000 less than in the corresponding six months of 1895; but last year £30,000 was absorbed in making provision for depreciation of assets. Therefore the net profits showed an increase of about £3,500 available for distribution. The falling off in receipts was due principally to a decrease of no less than 32,000 tons of coffee carried, and the increase of working expenses. They were employing more men, and until the duplication of the line was completed they had to meet heavy expenses in the maintenance of the permanent way. The further traffic expected would be provided for by an increase of rolling stock and already they had shipped 15 locomotives and 25 wagons. The total cost of the additions to the rolling stock would be £150,000. This expenditure would come out of the creation of new capital. One adverse circumstance was the downward tendency in the rate of exchange, but on the other hand it was valuable to them in Brazil. They had been unfortunate in the collapse of the premium at first quoted for the new issue of shares, but it resulted from a variety of causes. He was confident however that a recovery would soon take place. In conclusion, he mentioned that the receipts from June 30 up to date were approximately £40,000 in excess of the corresponding period last year. The report, which recommended the payment of a dividend of 6 per cent for the half-year, together with a bonus of 8s. per share, was adopted.

Natal Estates.—The first annual general meeting was held yesterday at the offices, 3 Fenchurch-street, E.C., Mr. Thomas Bell presiding. The Chairman, in moving the adoption of the report, said the transfer of the property had been completed, and that the trust deed securing the debenture holders had been duly registered in Natal. The profit on the operations of the company amounted to £10,482 16s. 6d. From this amount £1,000 had been written off for depreciation, as well as £1,538 the whole cost of the transfer of the property, &c., and after allowing for the payment of debenture interest &c., there was an available balance of £4,536 16s. 6d. Out of this the directors proposed to pay a dividend of 5 per cent. for the past year which would absorb £3,750, leaving a balance of £1,086 16s. 6d. to be carried forward. In conclusion the Chairman said that good progress was being made with the erection of the building for the sugar machinery. Captain G. A. K. Wisely seconded the motion, which was carried.—*Daily Chronicle*.

COFFEE IN NYASSALAND.

Chambers' Journal for November has an article on coffee planting in Nyassaland worth giving in the *Tropical Agriculturist*; also a good deal of information about India-rubber which must, undoubtedly, be cultivated in Ceylon much more widely than it is so far. Orange-growing in Jaffa, Syria, is the subject of another paper.

AT THE NATAL TEA GARDENS.

HOW A BIG INDUSTRY HAS GROWN—A VISIT TO KEARSNEY—RE-OPENING OF THE NEW FACTORY.

"Mr. and Mrs. J. Liege Hulett at Home, October 14th, 1896, at 2.30 p.m., on the occasion of the opening of the restored Kearsney Tea Factory, by his Excellency the Governor." Thus ran the invitation received, and which was readily accepted, for several reasons. To begin with, I—the first person is adopted for the sake of convenience—had never, despite a long residence in the Colony, seen a Natal tea estate, and, in addition, I had so often had to decline Mr. and Mrs. Hulett's kindly invitations, that I could not allow such a special opportunity to pass. Well, then, after much preparation, such are the exigencies of the journalist's daily round, Tuesday saw me rushing madly along, so far as N.G.R. conditions (with allowances for long rests at the various stations, almost as marked as the long waits at theatrical performances) and post-cart arrangements would permit. The roads were in excellent condition; indeed, as one of the members for Maritzburg remarked (little thinking of the compliment he was paying to the Government), you could get along well on them by bicycle. I hasten to say that the member in question was Mr. Tatham, who was in a most complimentary mood, and was not heard to hurl a single epithet at the "terrible" Ministry by which Natal is at present governed. This, by the way. There was a race, *en route*, between the post-cart and a Government official—but that is another story, which shall be duly related and embellished at another time. On we bowled, arriving at Stanger just as a riderpest meeting was over. Twelve to fourteen years have rolled by since last I was at this village, and, while it did not seem much altered, there were notable surrounding additions. Our host's stalwart sons and his son-in-law (Mr. Clayton, met us, and drove us at an enjoyable and inspiring pace the five miles to Kearsney, which estate soon burst into view, with the palatial residence of the founder of the tea industry, commanding an extensive and charming view from the eminence on which it is situated. I should say it is one of the finest residences in the Colony, and its respected occupants are more than proportionately hospitable. Some of the guests invited for the occasion had arrived in the morning, and the remainder arrived during the evening. His Excellency the Governor, the Hon. Mr. Murray,

C.M.G., and Capt. Marshall travelled leisurely in the Government mule-wagon, breaking the journey at the large new Tongaat Sugar Mill, which they spent some time in inspecting, and also lunched with Mr. Saunders. Amongst others were Colonel Gough, Mr. G. Payus (Mayor of Durban), Mr. F. S. Tatham, M.P., Mr. F. G. von, M.P., Mr. Marshall Campbell (of Mount Edgecumbe), and Mr. Humby, engineer of the North Coast Line, the embarkment for which, by the way, is being very smartly put on, work being done all the way to Stanger. It was a grand and pleasant party that assembled, and afterwards the majority slept so soundly that they were up by 5 o'clock next morning—at least some of them—enjoying the fresh air and exploring the estate. The scope there is for this may be gathered when it is stated that you can walk for 10 miles and yet keep within the bounds of Messrs. Hulett & Sons' estate. And such an estate! Row upon row, almost as far as the eye can reach, are to be seen the verdant-looking tea plants, all well tended and in order. It is, in fact, a huge, well-kept garden, and gazing upon it one can realise the immense amount of labour necessary to keep it in order and carry out the work, and also why planters and farmers are such consistent advocates for the employment of Indian labour. Mr. Hulett will tell you, for instance, that there are not kafirs enough in the Colony able to work to supply its needs; that if there were they are not comparable with the coolie, who gives twice as much work; that although in the old days native labourers, to a limited extent, were employed at an average wage of 10s, the coolie is much more satisfactory at the increased cost. But this is a question about which, amongst others, a great deal was said, and much that is useful during discussion at Kearsney, and which scarcely come within the scope of this article, which is to describe an industry and a pleasant function in connection with it.

On Dec. 27th last, during the hours of the night, the industrious family at Kearsney were roused by the dreaded cry of "fire," and hastily running to their windows they beheld the factory on fire. It was completely within the power of the flames, and practically everything, except the engines and boiler, was lost. It was about 4 o'clock in the morning before Mr. Hulett, senr, was made acquainted with the calamity, and in his practical way he set about considering the position. Before 6 o'clock he had written out telegrams to Durban, and cables to England, ordering new machinery. Next day clearing the *debris*, was commenced, and soon Mr. Hulett and his sons along with all labour that could be commended, were busily engaged in brick-making and other work, and a plan having been decided upon, the small sections—*i.e.*, small in comparison with the main building, though large in themselves—were commenced, and were ready to receive the new machinery, which arrived from England within two months of the fire, and within two and a-half months were in position and work commenced. As a specimen of colonial enterprise and determination after disaster it is surely worthy of the highest admiration. The main factory, built on the foundations of the old, but a story higher, was quick to follow, and it was the opening of the completed factory that prompted the visit to Kearsney. The main building is 150 ft. long by 70 ft. wide, and contains, in addition to the ground floor, four large upper floors. The fall size of the building, and two, 150 ft. by 23 ft., in the lantern which surmounts it. With the large box-room, lead-room, workshop, the large rooms containing the machinery, &c., the whole length of the building is about 450 ft., and is built of brick, with substantial wood and concrete floor.

A brief description of the processes within these premises may be interesting and instructive. As the coolies come in from the gardens with their baskets, the pickled leaves from the tea plants are spread on the floors in a thin layer, to wither, the idea being that the leaf should then be to the touch something like a soft silk handkerchief. Because

of the even and thin laying so much withering space is required. The process is a quick one, as indeed the whole of the tea gathered in one day, should within 24 hours be withered, dried, rolled, and manufactured into tea ready for disposal and distribution anywhere and everywhere. This is the rule which obtains. On the seven floors in the new mill, if all were laid, there would be sufficient leaf for 5,000 lb. of tea and this process continues from the middle of September to the middle of June. Then commences the pruning and general attention to the cultivation of the plants. Through all the floors in the mills is communication with the ground room, where shutes, conveying the duly withered leaf, pour it into the rolling machines, whose work it is to break the juice-cells. Five hundred men a day would not roll out, as much tea as can the four machines (Jackson's rapid rollers) in the corner of the room referred to. These were the machines that were cabled for at once on the night of the fire. The length of time occupied in rolling depends upon the condition of the leaf; it may be 20 or 90 minutes. The next machine to which the tea is taken is the breaker and cooler, for the purpose of separating the fine leaf from the coarse. This machine divides the leaf into "fine" and "medium," and the latter is put back into the roller. The fine finished leaf is removed and laid on the floor to ferment. Fermentation actually begins when the rolling commences, but the leaf is left on the floor till such time as it changes colour sufficiently to pass through the driers. Thus we pass into the drying room, a large and lofty room, with concrete floor whereby all chance of fire outbreak again is, it is hoped, obviated. Here are four of Davidson's down draughts, one of Davidson's uprights, and one of Gibb's latest patent, a cylindrical machine. The furnaces are of a patent character, consuming their own smoke, and during the afternoon an experiment was made in the use of St. Lucia coal, of which so much has been heard in connection with the Natal-Zululand Railway. St. Lucia coal is considered to be of special value for furnace purposes, being almost smokeless. Indeed, says Mr. Hulett, in this respect there is no comparison with it and Natal coal, which has been tried. Continuing our survey of the works, the next department encountered was the carpenters' and engineers' shop (all repairs having to be executed on the premises), the engine rooms (containing between them 20 horse power) boiler shed, a room in which the tea boxes are lead-lined and soldered. In connection with the latter, it is interesting to note that it is expected 60 tons of sheet lead will be required this year, and which, like the timber for the boxes, has to be imported. In the latter respect supplies are also largely drawn from Durban firms. Again we have to hark back to the machinery. When the tea comes out of the drier it has still more processes to undergo, and is next passed through the sorter, which returns it in various grades. Still another sorting machine deals with a certain proportion of the tea, which is now in condition to be placed in the large bins made for its storage, to be drawn therefrom as required. Anent complaints of variation in quality of the same brand of tea, it may be mentioned that, in order to maintain as even a quality as possible, as the tea is drawn from the bins, it is taken from the bottom, and then, when extracted, is thoroughly mixed, so that one day's manufacture is not sent out by itself, but several days' teas are mingled. The bins are capable of holding from 80,000 lb. to 90,000 lb. Next comes the packing, and exceedingly interesting it was to watch the Indian children making up pound packets. It was very quickly done, and by a simple contrivance hit upon by Messrs. Hulett, which they find far more satisfactory and expeditious than many patent methods they have tried, lead-paper is wrapped round an oblong box into a capacious saucer, on which the weighed-off tea is poured. The wooden box fits into a receptacle in the table, a wooden hand lever forces and packs the tea through the box, which is then withdrawn from the lead-paper, the package is sealed and relieved from under the table, coming out neatly

made-up. The process is very rapidly executed, some 16 or 17 children being able to pack 4,000 lb. in the course of a day, and up to 6,000 lb. of fine tea. The weakest feature at present is the weighing, the scales employed not being satisfactory in the interests of the firm, though the public will not groan. An instance will explain why. At Port Elizabeth recently, the Customs authorities weighed a pound packet and found it half an ounce too heavy, and a 14 lb. box was found a little too heavy, with the result that duty had to be paid on more than was actually sold to the importer. Of course the consumer gets the benefit.

Conversation with Mr. Hulett elicited further interesting information. An experienced tea planter from Ceylon, who last week went over the factory, assured Mr. Hulett that there was not a factory in the whole of Ceylon capable of turning out as much tea as Kearsney, whose output this season will be 750,000 to 800,000 lb. Towards this Kearsney and its sister estates will contribute 450,000 lb., while other estates from which tea is purchased will provide the balance. The factory, as a fact, is capable, by arrangement and with appliances on Messrs. Hulett & Sons' other estates, of manufacturing a million and a half pounds of tea; yet the drying room will probably have to be enlarged next year. The other estates are Kirkly Vale and Sprowston, the latter having been purchased from the late Mr. T. Peachey, and the three are contiguous, and altogether about 1,000 acres are now planted with tea. Leaf is also purchased from 10 other growers. Messrs. T. Hindson & Co., likewise large growers and manufacturers, whose tea is also well known are neighbours of Mr. Hulett's. There are five kinds of tea placed on the market, viz.: Souchong, Pekoe Souchong, Pekoe, Flowery Pekoe, and Golden or Orange Pekoe. The Souchong has to be made to undersell the lowest and cheapest tea that can be imported into Durban in bond, but all Natal teas are cheaper relatively than bond teas imported. It will probably be asked as a question of curiosity how tea growing commenced in Natal. The failure of coffee was the cause, compelling people to look for other means of living. Tea had been growing after a manner in the Colony for years. The first curator of the Durban Botanical Gardens planted it at Tongaat, and a few others also planted it. It was known to grow well, but they did not know how to manufacture it. Messrs. Hulett and Sons were the first to start it on a commercial basis, and Lyle and Reynolds at Kirkly Vale also entered upon the business. The first plants of the tea now grown were obtained from India in 1877, and from the seed Mr. Hulett planted his first five acres in 1880. seed was also obtained from Assam, and from the plants at Kearsney the seed has gone to almost all other estates in the Colony. Fortunately, so far, locusts have not seriously attacked tea, though they have nibbled at it. They attack the old leaf which is not used in tea manufacture, but the trees are thereby spoiled though not materially injured. The effects of locusts round and about Kearsney are most marked, trees that were an ornament to the grounds and to the landscape being stripped of their foliage.

OPENING CEREMONY: SPEECH BY THE GOVERNOR.

Wednesday was like a holiday for Stanger. Mr. and Mrs. Hulett had invited their neighbours and friends to be present at the opening of the factory, and to rejoice with them in the achievement. In the afternoon, therefore, a goodly number of ladies and gentlemen arrived at Kearsney, where they were warmly welcomed, and afterwards adjourned to the factory, where excellent provision was made. The large office was turned into a refreshment room, and a portion of the main room was curtained off and a platform erected. Here His Excellency Sir Walter Hely-Hutchinson performed the opening ceremony, being supported by the gentlemen whose names are mentioned above, while among those present were:—Messrs. Geo. H. James, A. S. L., Esq., and W. A. Hulett,

Mr. W. F. Clayton, Mr. F. Sinter (acting magistrate of Stranger), Rev. A. E. Howes, Dr. Jones, Messrs. H. A. Clark, W. F. Addison, A. F. Foss (clerk of the peace), Geo. Stewart, A. E. Jackson, T. G. Colenbrander, E. Essery, B. Balcomb, W. R. Hindson, Geo. Nicholson, Geo. A. Clayton, L. Moe, Arthur Bull, Carl Weber, &c.

Sir Walter Hely-Hutchinson, in opening the factory, said:—Ladies and Gentlemen—I dare say some of you will remember that in addressing the members of the Durban and Coast Agricultural Society, at the society's dinner at Durban last July, I dwelt at some length on the duty which rested on the colonists of Natal of continually seeking after the adequate development of the resources of the country. Taking, as I do, such a lively interest in this matter, it has been a source of peculiar pleasure to me to be able to accept Mr. Hulett's kind invitation to be here to-day, and to lend him what countenance and encouragement I can in the enterprise in which to-day's ceremony marks a new departure (applause). The tea industry in Natal, of which Kearsney is the leading exponent, owes its inception and its promising state of development mainly to Mr. Hulett's enterprise, energy, and steadfastness of purpose; and he has shown that he possesses in an eminent degree those qualities which are the necessary attributes of the pioneer colonist, and have given to our nation in these later years the practical monopoly of successful colonisation. You will, I am sure, gladly join with me in wishing well to Mr. Hulett's enterprise, and in anticipating for him and for his firm that full measure of success which his persistent efforts for the development of the country's resources deserve. This fine building in which we stand to-day is in itself a monument to our host's tenacity of purpose. Its predecessor, which was on the point of completion when I was here three years ago, was, as you know, burnt down last December with all that it contained, but its ashes were scarcely cool before a cable was no its way home ordering new materials and machinery, and a new structure has arisen within ten months on the ruins of the old one, larger I believe than its predecessor, and containing all the most recent improvements in machinery for the manufacture of tea, and fitted to deal with a crop twice as large as that which is now afforded by the present plantations. The year 1896 has been a trying one for Natal—drought and locusts last summer; political trouble in the Transvaal, which at one time threatened the peace of the whole of South Africa, and has arrested its development in many ways; terrible accidents by land and sea, which have brought mourning into many a Natal household; rinderpest threatening our borders, and even now a dearth of rain which promises, if long continued, to do serious injury to the growing crops. But the colonists of Natal have faced difficulties and have overcome them in the past, and they will meet the present difficulties in the same spirit. 'Tis not in mortals to command success: but we'll do more, Sempronius, we'll deserve it." These words, put into the mouth of a heathen, might well be in the mouth of a God-fearing, Christian man (applause). Providence helps those who help themselves, and I have that faith in the qualities of the colonists of Natal, amongst whom our host is to be reckoned as one of the pioneers, that I believe their conduct, under existing difficulties and drawbacks, will be such as to deserve the success in the development of this country which, under Providence, they will in the end undoubtedly achieve (applause). I ask you, ladies and gentlemen, to join in wishing all success to our host (Mr. Hulett) and his great enterprise (applause).

Mr. Hulett expressed the pleasure it gave him to welcome the representative of the Queen on an occasion of that kind. They were all in Natal loyal subjects of the British Crown (applause), and whatever their position, it was for them to do their part in connection with the building up of the mightiest Empire in the world (applause). There were some amongst

them who came from other portions of Europe, but they were all there as British subjects, endeavouring to assimilate into, he trusted, a large and mighty South African Empire (applause). However that might be, it gave him a great pleasure to welcome them. He was an old colonist now. He came there nearly 40 years ago, and in spite of difficulties all round them, they had had but one motto, and that was, under any circumstances, always endeavor, if anything happen adversely, to take a step forward instead of backward (applause). He had to thank his friends and neighbours, and colonists generally, for the large amount of earnest sympathy in their serious loss 10 months ago. He hoped that, despite the difficulties surrounding them at the present time—there were difficulties arising from drought and locusts which gave them pause, and to ask whether after all they could overcome them—they would look back on what had been overcome, and remember that every cloud had its silver lining (applause). In conclusion, he thanked Mr. Murray, as representing the Government, for being present to countenance their enterprise, he thanked His Excellency for opening the new factory, and his many old friends for their presence.

The Hon. Mr. Murray, in reference to the remarks of Mr. Hulett in regard to Mr. Campbell, said they must realise that tea was no use without sugar. It afforded him great pleasure, on behalf of Government, to be present, and he endorsed every word his Excellency the Governor had said in regard to the industries of the Colony. He had done his little best in that direction, and the Government would do all it would to encourage Colonial industries. With regard to the many difficulties they had to encounter, to the Government those difficulties were far greater, for the burden was upon them, and they were looked to to help them. They did try all they possibly could to lessen those burdens and prevent further burdens falling upon them. With regard to the serious affliction—the terrible plague of rinderpest—threatening the Colony, he assured them that Government was doing all it could to prevent it. Should it come, they would do everything possible to prevent it spreading, and to alleviate and assist in any way those who suffered from the plague. They trusted to everyone doing his best, for it rested with every individual in the Colony to assist Government in carrying out the duties it had to perform. It would be useless to complain afterwards unless they tried to help in averting the trouble (applause). He endorsed all his Excellency had said in reference to Mr. Hulett's perseverance and energy. As a politician in the Colony once said, he was like an Indian rubber ball; the more he was kicked the more he jumped. The more he had to contend with the more he rose to the occasion, to contend with it in that spirit they all admired. Not only was he assisted by Mrs. Hulett, but by a family of sons and daughters who took as lively an interest in the tea industry as Mr. Hulett himself. It was a source of gratification to him to see them assisting their father to develop so fine an industry (applause).

Mr. G. Payne, called upon as mayor of Durban, pointed out that Durban was essentially interested in this industry, for what proved successful in that district would benefit Durban. Therefore, the people of the Port were interested in Mr. Hulett's enterprise, and he wished to convey to Mr. Hulett his personal congratulations on the evidence before them of the enterprise he had shown. This was his first visit to the locality. He had often heard of the attractions of Kearsney, and he could truly say that "not one-half had ever been told." He was certainly much impressed with the bounties of the district. Mr. Hulett had resided and worked there for a good many years, and his efforts were worthy of the fullest admiration. Seconded by his sons, he had succeeded in taking the industry beyond the experimental stage. He had dealt with difficulties, and in a manly and courageous manner had erected a mill, for which he hoped Hulett and Sons would be amply rewarded. —*Natal Mercury*.

NOTES FROM THE METROPOLIS.

LONDON, Nov. 6.

An ex-Ceylon Colonist wrote to me some weeks ago that I must not leave London without paying a visit to the new offices in City Road of the farfamed

MR. LIPTON.

Such was my full attention, apart from this reminder; for, whatever feeling may have been aroused in the minds of Ceylon planters and other residents—ourselves among the number—in the early days of Mr. Lipton's connection with Ceylon tea, through his advertisements—tea direct from his estates, his use of "Ceylon" although his sales were chiefly if not entirely "blends" rather than the pure article and his picture placards of the island and Lipton's estates as if he said "I own or personify Ceylon tea"—yet, allowance being made for the ingenuity, imagination and enterprise of advertising hieutenants—there can be no shadow of doubt now about the enormous benefit conferred by this big capitalist and far-reaching distributor on our staple and local planting industry. In the first place, there is the capital he introduced (at a time when faith in Ceylon tea was not too strong in the City of London and Companies were few and far between) to purchase the Dambattenne and Pooprassie groups of plantations, and the first-class way in which he has since developed these properties, and litted up model factories. No one can say that "Lipton" is behind any Ceylon estate proprietor in this respect. Then it is undoubted that few, if any, buyers of tea in "the Lane" (not to speak of Colombo or Calcutta) handle so much of Ceylon as well as Indian tea in the present day as does Mr. Lipton. The trade in Ceylon tea for his London open and bonded stores has grown to an enormous extent: we are now speaking of what *we have seen* during our visit. But even before then, we were aware that the great food distributor could not be honestly regarded as otherwise than a benefactor to the colony. Two stories we have been fond of repeating in and out of Ceylon of late years, as compensation for some sharp criticism in earlier times of "Lipton's" system of working:—(1) An old planting friend, still in the island, brought out from Nottingham samples of "Lipton's teas" and coming to the *Observer* Office, arranged to breakfast with the editor at Mount Lavinia, in order to give a fair trial to the teas and to state the result—*condemnation*, as I fancy both mentally anticipated! The samples were of the 1s. 4d. and 1s. 7d. teas—the latter about the best sold of Lipton's blends and our cups from it were sufficient to convince both the critical planters and myself that there was no room for condemnation—the tea was simply about the most palatable and refreshing we had ever drunk. I then learned and admired Mr. Lipton's enterprise in getting water from all the large British cities and preparing his blends (as experts only can) to suit the different waters. [N. B.—There must be something in common between the water of Mount Lavinia and that of Nottingham!] Such enterprise deserves, as well as commands, success. Story No. 2.—Another old Ceylon planter and friend, set up in business as Agent for a Ceylon-London tea distributing house in Dublin: Lipton had not been long at work before he had to stop, because, to use his own words:—"Lipton had started next door and sold a *better* tea for a *less* price than he had to offer,"

"Such testimonies were from men who desired to be critics rather than admirers of the great dealer. Here again of his enterprise in Ceylon as capitalist, we have been hearing lately that during the present year he will have added five or six additional plantations to his purchases of properties in Ceylon.

With some such mingling of thoughts in our mind, we made our way the other evening to City Road expecting to spend half-an-hour or an hour in running over the new offices. But we little anticipated their extent or what we had to see; for, although every facility was shown to us, first, by Mr. Lipton himself, his Secretary, and the separate managers of half-a-dozen Departments, and although we literally walked through with very little standing about—indeed merely glanced in at the doors of certain working rooms or stores, it took us from 3:30 to well-nigh 6:30 p.m. (the establishment cleared at 7) to complete our round, with only one break for a cup of tea and refreshment with Mr. Lipton and his tea manager. First of all, the conspicuously handsome block of buildings, with its huge flag, and huge stone-cut letters "Lipton" beneath the central front turret as well as on the doorway, arrested attention. The site, though a little out of the best of the ordinary city-goer (at least among the colonists at home) is for the business no doubt a highly convenient one. It is most advantageous in occupying the corner between two roads, so that the extensive accounting offices below, and the many Departments above in the main block are most admirably lighted from two sides. No doubt engravings of these offices are familiar to many Ceylon readers; for, already such have appeared in *Black and White*, where the offices were described as "an important addition to the architecture of the district—designed by the late Mr. Mark W. King of Fenchurch Avenue, the buildings have been constructed of white stone and red brick and they present an imposing aspect. The *Illustrated London News* pays a higher compliment; for it not only offers a first-class engraving, but the following liberal amount of letterpress:—

A GREAT INDUSTRIAL ENTERPRISE.—An imposing addition to the architecture of the great thoroughfare known as the City Road has been made by the completion of the new Central Offices of Mr. T. J. Lipton, "the Tea-King," as he has been dubbed by his friends. The new buildings, which have been erected by Messrs. Grover and Son, under the guidance of Messrs. King, the well-known architectural firm of Fenchurch Avenue, are of red brick and white stone, with a spacious doorway flanked on either side by grey marble pillars. The staff of more than three hundred men and women engaged as clerks is accommodated in a fine saloon with a floor area of some six thousand feet and a handsomely panelled ceiling. Smaller offices conveniently arranged flank this saloon, the most notable being Mr. Lipton's own private room, which is panelled with no less than ten different kinds of wood and tastefully fitted in every respect. The most striking feature of the first floor is the advertising department, wherein are filed twelve hundred newspapers containing advertisements of Mr. Lipton's wares. Other offices on this floor are allotted to Mr. Lipton's own staff of architects and solicitors, whose services are retained for the building, leasing and other operations constantly required by Mr. Lipton's great provincial organisation. On the second floor are printing works, in which some two hundred hands are engaged in the printing of posters, circulars, and other "copy," and not in one language only. On a still higher floor all the tin and wooden boxes necessary for the proprietor's many wares are manufactured by a staff of skilled workmen. Truly, to explore such a building, to see its ample accommodation for a thousand employes of one kind or

another, is to endorse to the full Mr. Lipton's motto 'Labor omnia vincit.' As a pleasant illustration of the cordial relations which prevail between Mr. Lipton and the great army of workers engaged in his service, it is worthy of note that the enterprising proprietor has been presented with a portrait of himself, painted by Professor Herkomer, for which his employes in all parts of the world have subscribed.

Next, the *Illustrated Sporting and Dramatic News* goes one better still both in engraving this several "Lipton" blocks in the rear of the main new offices, and in letterpress which is still fuller in description. This, however, we need not repeat; for our one quotation already saves the needs of elaborate description at our hand. We may premise by saying that in many respects Mr. Lipton himself as the centre and head of the vast establishment—and a business literally world-wide—commanded most interest. He is still a young man*, tall, lithe and alert; but without any over-powering sense of force of character or intellect visible; and yet few men, to judge by results, can excel him in keen business perceptions, power of organisation and ability to select suitable deputies in the different departments and agencies of his widely spread enterprise, and to attach them to himself. In this last faculty of selection, must rest the secret of a great deal of his success. Manager after manager was introduced as being with him "from the beginning" or for a long number of years and the feeling on both sides appeared most cordial; while all we said indicated that better accommodated employes from the Managers and Accountants down through many rooms of men, women, girls and lads, to the ham enners in the last block, are scarcely to be found in the City of London. Surrounded by every modern appliance in telephones, electric bells, clerical aids, &c., in his own room, Mr. Lipton is now enabled, to devolve his duties at every turn, so as, if he so cares, to be a man of comparative leisure; but this, I gather, he does not desire; for, though he takes an interest in horses (and has full stables)—in his gardens and conservatory, he is likely to be able to show tea, coffee and cacao plants in all varieties there ere long—his devotion to business continues unabated: and in referring to a private offer (of a large amount) made to him by a well-known London promoter of Companies, Mr. Lipton indicated his answer to be a question as to what he would do with the money—a man of the simplest tastes, delighting too in work and in being the active head of a concern giving useful employment to thousands. Then again to his credit be it mentioned that though frequently pressed, and tempted by assurances of large returns and promotion money, Mr. Lipton has never become director or shareholder in any Company or concern beyond his own—quite enough for one man in all conscience. Since writing so far, I have seen a London *Evening News* with its No. XXXI of "Men who have earned success"—"Mr. Lipton, Purveyor of Tea to H. M. the Queen." I don't know if this has been laid before your readers; but two passages will bear repetition even now:—

Twenty-six years ago there were tears and handshakings abundant in a little house in "auld Glasgow." Young Tom Lipton was going away—so the rumour ran down the street—to make his fortune in America. Tom's parents were in a small way, and it behoved their son to make a push and exert himself for them,

So he bade them "guid-bye" tore himself away, and took a steerage passage in an American liner. He soon settled down in the States, and regularly as clockwork came remittances for the old folk at home. Several years passed away, and at length young Lipton, finding himself in possession of a hundred pounds or so, returned to Glasgow, and opened a small provision shop there.

But how many people start small provision shops and never get any "forrarder"! Tom got "forrarder," though. He used to make his customers "larf" did Tom. Funny cartoons, funny placards, funny advertisements made the canny buyers smile and say that young Lipton "gaed at it wi' a vir." For instance, one of his best cartoons represented the members of a defeated Ministry entering Lipton's shop by one door in a sadly dejected condition, all limp and wobegone, miserable sinners indeed. But cheek by jowl came another cartoon depicting the exit of those politicians in a highly mirthful condition, smiling a'lover their faces, and

CLUTCHING PACKETS OF LIPTON'S TEA with the result that that small shop proved to be the nucleus of the biggest provision-dealing establishment in the world!

Mr. Lipton is a little over 40, strongly built, and 6 ft high, though his erect carriage, which would do credit to a Lifeguardsman, makes him look taller. His hair and heavy dark moustache are tinged with grey, and he has keen blue eyes which gaze in a penetrating way from beneath his arched eyebrows. His face is one of great power, the expression firm, yet most kindly. In short, he strikes one as being a man who was born to control large forces, and carry on a bewilderingly huge business.

MR. LIPTON IS A BACHELOR, for his business takes the place of wife and family. Every morning he is at his office early, and rarely leaves it until late at night.

As to the Departments in the City Road Offices, I will only very briefly refer to a few items that made an impression, leaving out the offices *par excellence* for managers, solicitors, architects, accountants, &c. The printing department was specially interesting with its 200 Scotch workmen and great variety of machines, some very unusual for the printing of coloured labels on tin as well as paper. The machines for forming cardboard, as well as tin, packages of all sizes, were most ingenious, mainly worked by girls who, paid by "piece work," in some cases did 15,000 a day—that is of one particular operation. We ask "What is done with the strips of tin left of the sheets blocked out?" "Sent to Germany for a chemical process which takes off the tin for solder, while the iron strips are utilised for mattresses." The army of coopers making ready the chests—for tea export for America (North and South), Africa, all parts of Europe, &c.—need only be mentioned, to say that the lead saved in chests from Ceylon, India, &c., brings in £100 a week. "What stock of tea do you usually store here?" we asked the experienced snave Tea Manager and chief buyer, Mr Smith. "Not fewer than 50,000 to 60,000 chests of all kinds"—and as we passed through long rows and lofty piles of Ceylon tea chests, it seemed to our "Directory"-trained eyes, as if nearly every estate in the island was represented! The 500 to 600 young women busy at long tables in a comfortable room, weighing and filling tea-packets, each "table" paid by its work with a bonus to the "tables" that turned out most (so requiring little or no supervision) was an interesting sight. The tea-tasting room, with its stall of experts, was more extensive than any we have seen "in the Lane,"—no doubt here the "blends" for different cities and markets have to be tested and decided on.

But in respect of TEA, what surprised me was the

* Over 40 years, I see it stated, but I should have said not more than 35 by his fresh looks.

BONDED STORE,

with officers of H.M. Customs in uniform in charge, Mr. Lipton's employes working inside. I am not sure if any other London Tea dealer has a private Bonded Store on his premises? Here, of course, only tea for re-export for foreign countries or colonies—and therefore duty free—is allowed in or out. And here I may beg special attention on the part of Ceylon planters to the business which Mr. Lipton has developed. We saw a huge array of chests marked for *New York*, *Chicago* and *Toronto* and learned that his American tea-trade in charge of his former Calcutta manager is developing rapidly and entirely to Mr. Lipton's satisfaction. The process of educating the American palate to understand the difference between good and bad (and even artificially treated) teas is going on steadily. For St. Petersburg, where Mr. Lipton has now a highly successful branch, a single order for 3,000 chests of tea was being executed. Besides these we saw considerable consignments of tea chests in this warehouse marked for Durban and Port Elizabeth in South Africa; Buenos Ayres, Rio de Janeiro and Valparaiso in South America; Barcelona and Hamburg and Alexandria. Here is enough of indubitable evidence to show how wide a tea distributor Lipton is. It is specially interesting to learn the principle on which he began and continued business: *all profits to go in advertising*—the secret of so enormous a business being built up. [It reminds one of the American storekeeper who, coming into a big legacy, thought he would throw away £40,000 in advertisements to make his name known as his "pile" was made—the result being that he had to arrange forthwith to double his stores and employes!] In advertising, Mr. Lipton told me he never now spends less than £1,000 a week: sometimes £1,500.

THE COCOA AND CHOCOLATE DEPARTMENT, a separate block, was extremely interesting, had I had time to watch the various curious machines and modes of manufacture designed by the Manager, Mr. Rozairo (a Frenchman), more closely. In all branches of

CONFECTIONERY

as well as in so many staple articles of FOOD

of baking—pies, etc., as well as sausage-making, ham-making—Lipton excels: in fact, he only added tea, coffee, cocoa, and chocolate, to these of late years. The sample-room, made up with French taste for confectionery and tinned goods, is an attractive sight. A separate packing-room was devoted to orders from the Army and Navy. Another to butter and cheese.

I omitted to mention the huge revolving cylinders in one room for

BLENDING

the teas with the hoppers in a floor above, into which chests are literally emptied by the dozen. The weekly sales are said to equal 200 tons from Lipton's stores.—I must, however, close this hasty and discursive notice of the result of my three hours' wandering and observation: let anyone who thinks I have said too much go and see for himself and he will conclude the half was not told me. Again in South London there is a separate establishment, I was told, where 700 women—in all, perhaps, 1,000 employes—are engaged in the preparation, packing, etc., of jams and jellies; and yet there appeared to be no one so cool and unconcerned in the City Road offices as the responsible and sole head of this most world-wide business—Mr. Lipton himself.

THE CALEDONIAN (CEYLON) TEA PLANTATIONS, LIMITED.

Report of the Directors to be submitted to the Third Annual Ordinary General Meeting of Shareholders, to be held at 11, Old Broad Street, in the City of London, on Wednesday, the 11th day of November 1896, at 3 o'clock p.m.

The Directors beg to submit the accounts for the year ended 30th June, 1896, duly audited.

The profit and loss accounts, after payment of interest, London charges and income tax, and writing off £250 for depreciation, and £200 the balance of debenture issue and transfer of estates expenses, shows a credit balance of £2,014 8s 4d for the year, to which has to be added £334 18s 2d, the balance brought forward from 1894-5, making a total of £2,349 6s 6d.

The directors recommend the payment out of this amount of a dividend for the year of 12 per cent, free of income tax, which will absorb £1,800, and leave a balance of £549 6s 6d to be carried forward.

The yield of tea from the estates has been as follows:—

Venture	193,676 lb.
Selegama	77,140 lb.
Total	270,816 lb.

Against an estimate of	..	270,000 lb.
and a total crop in 1894-5 of	..	240,900 lb.
and 1893-4 of	..	235,237 lb.

The yield of coffee from Venture is now reduced to a very small quantity.

The total acreage and the area planted in tea are as follows:—

	Total.	Tea in full bearing.	Tea 1 year and under.
Venture	.. 406 acres	389 acres	—
Selegama	.. 934 "	198 "	225 acres

On Selegama 77 acres more have been cleared and will be planted this year, which will make the total area of this estate planted in tea 500 acres.

At the same time that the yield of tea has increased, there has also been a rise in the net average prices year by year, although the average price of the total market sales has been declining.

The crop estimates for 1896-7 are:—

Venture	200,000 lb. tea.
Selegama	82,000 "

The last advices report both estates in good condition, and the yield of tea leaf fully up to that of last season at the same time.

In accordance with No. 96 of the Articles of Association, two of the Directors, Mr. William Gow and Mr. H. P. Hanssen, retire from the Board, but, being eligible, offer themselves for re-election.

An auditor has to be elected in the place of Mr. A. N. Frewer, A.C.A., who has accepted an appointment requiring his entire attention, and therefore does not offer himself for re-election.—By order of the Board,
H. F. STANLEY, Secretary.
11, Old Broad Street, London, E.C., 31st, Oct., 1896.

A CEYLON PLANTER ON HIS JOURNEYS IN EUROPE AND SOUTH AFRICA.

We have been favoured with the following interesting communication from Mr. John Fraser of Brae who has just returned from a trip to Europe and South Africa:—

Nearing Galle, Nov. 20th, 1896.

Impressions formed on a run from Ceylon via England and Scotland, the Continent of Europe and South Africa—by a Ceylon planter:—

The "Himalaya" steamed into dock in London on 1st June after a most pleasant and agreeable passage from Ceylon—and there we parted from those we knew there would be little chance of

ever meeting again. But such is life. After a few days in London I took train for Aberdeen, where I had the pleasure of meeting a number of old and young Ceylon folks:—Dr. Craib and family, Mrs. Anderson, Bandarapolla, and family, Mrs. Joseph Fraser, Damboolugalla, and family, Geo. Maitland and Angus, both late Kelani Valley men; Mrs. Fraser, Abbotsford, and family, Charles Forbes, W. Jackson, of Roller Fame, Mrs. Davidson and daughter, late of Madulkele, all living in the West End and looking well, and all apparently enjoying the bright side of life! Taking a run further north I met more Ceylon folks. At Turriff I met James Beaten and family, who had purchased a farm and settled down, but had not given up all hope of visiting Ceylon at some future time. I next visited Redhythe, Portsoy, the home of the late Geo. Wighton, but whose remains now lie in the Churchyard there. Peace to his memory. Not a better hearted or more honest fellow ever came to Ceylon. A run through Craigellachie to Coulnakyle brought me to the present home of the Shireffs of Aldie, Bogawantalawa, who are spending the summer there. Mrs. Shireff had not been well, but was better, and all hoped to be back in Ceylon early in December. My next run was to Stonehaven to call on the Ross's of Venture. Mr. Ross, senior, had not been well but was better and had come from London to spend the summer with his family, who were all living there. Mr. Ross, junior, hoped to be in Ceylon in November.

The weather during the early summer was most favourable for crops, but rather too much rain for the holiday seeker. However, on the whole it was considered a fairly good season for all. After a couple of months in Aberdeenshire sight-seeing with some golf and shooting added, I left Aberdeen for Glasgow (but not on my bicycle as I found the roads *too narrow*!) I met there Mr. Polson of tea box fame, also Mr. Davidson, late of Rajawella, Ceylon. Both told me tea was making great strides in Glasgow, and that the metal chest was to be the chest of the future. I went to look for some friends who left Ceylon for Carlsbad some time before the "Himalaya" left Ceylon, but they had not then returned. In Edinburgh I had the pleasure of meeting Mr. D. Kerr, of Abergeldie, and James Brown of Hatton, both looking well. The former when I met him seemed rather in a *scrath*, but would no doubt get himself up to the scratch before he returned to Ceylon! The weather in the north of England appeared to have been much the same as in Scotland, but as you get nearer London there had evidently been a great want of rain. The crops were poor, and a very little pasture for cattle anywhere near London—Guildford and Cheltenham ways being specially dry. At the former I had the pleasure of meeting Mr. H. L. Forbes at his bungalow, one of the loveliest spots in England. They were just preparing to leave next day for their holidays, and were busy packing up. Mr. Forbes was expected to join his friends—Messrs. Cross, Kerr and Porter at some fishing in the highlands, while Mrs. Forbes and family were going to the sea-side for their holidays to be joined by Mr. Forbes later on. At Cheltenham—the great seat of learning, where I understand more young men pass into the Army and Civil Service than from any other College in England—I found Mrs. Mackie, of Great Western, and family settled down there for their education. All the schools and colleges were then closed being the holiday season, but judging from what I saw and had explained to me of the methods for

exercise, the training of the pupils must be excellent. We had a splendid drive out as far as the source of the Thames, returning through a very pretty part of the country. I was unfortunate in missing some of my "Himalaya" friends, who had gone north some days before my arrival in Cheltenham. During my week's stay at London I came across several Ceylon men:—Sir John Grinton, Messrs. J. L. Shand, and Thomas Dickson, senior, Mr. and Mrs. Hugh Parry, Messrs. W. Taylor, W. Jenkins, C. and W. Strachan, Colombo I met, Messrs. E. S. Grigson, A. Orchard, J. Forbes, J. Sinclair, W. Forsythe, Millingtons, F. D. Mitchell, Capper and others, at the Jameson-Aspland marriage, where we did our best to cool the air by drinking the health of the bride and bridegroom in iced champagne! All these old friends looked well, and appeared in the best of spirits.

The weather in London was very hot during the summer, and very dry. I took a run through Belgium, Holland, and Germany to Frankfort and Homburg *via* Cologne and the Rhine, returning to London *via* Paris. Notwithstanding Homburg being the watering-place of Royalty, I consider it in many respects a long way behind Carlsbad. For one cure effected at Homburg, I should think there were ten at Carlsbad. But fancy not being able to get a decent cup of Ceylon tea on the Continent of Europe!!! There is evidently a lack of room to exploit Ceylon tea there as well as in America. Leaving London by the 11.40 train for Southampton on the 15th of August, we were all aboard the ss. "Norman," and on our way to South Africa by 5 p.m. The leaving docks of a Union steamer from Southampton is a scene not likely to be soon forgotten, many last looks of friends of one another that day. When once on board, all farewells and wavings of handkerchiefs were soon over, but by many not forgotten. Three days' run brought us into Madeira harbour and during the few hours' stay a good many had a run up by train, which is on the Swiss principle on the Rigi mountain, and down by the Sleigh, which appeared to come down much faster than the train went up. After a look into the King's Palace and the principal street all went on board. The houses on the hillsides appeared covered with vines and grapes. Madeira is evidently the home of the vine. We had now to make up our minds to see no more land till we reached Cape Town, twelve to thirteen days hence. We had the usual sports on board in which most joined and made things pretty lively during the rest of the voyage. Captain Molony and the officers did all they could to make things pleasant for the passengers during what may be termed a short but pleasant run to Cape Town. On arrival there we were delayed a short time till the Governor, Lord Rosmead, had landed, there being a large escort of military drawn up to receive him on landing. Lady Rosmead was there to meet her husband. After their departure it did not take long to clear the ship of passengers. Both Governor and Lady Rosmead look very old and very different from the fine handsome couple they were when they landed in Ceylon over thirty years ago. The Governor appeared to be in weak health, and never entered into the spirit of the sports. He told me he had very pleasant recollections of his Governorship in Ceylon.

After a few days in Cape Town, driving and sight-seeing, I left for Kimberley in company with a namesake, and broker from Glasgow who had come out on a health trip, and like myself to see the great mines of S. A. We left Cape

Town on the 4th of September, and after two days and nights' travelling reached Kimberley. We rose some 4,000 ft., but through a very bare although rugged country—no forests of any sort to be seen along the line. Farmhouses were to be seen, but generally at long distances apart, showing very little cultivation. Of course the whole country I presume is suitable for grazing, and the only cultivation necessary would be for foodstuffs—food for the people which is principally mealies—Indiandcorn—and forage for cattle on transport, and it may be exported to neighbouring states. We spent a most interesting two days at Kimberley after a journey of about 750 miles from Cape Town. We spent an afternoon below inspecting all the mines, and next morning went through the diamond stores and sorting room, where we saw the previous week's diamonds being sorted, valued and packed for England and other countries—valued at about £90,000 sterling. In the afternoon we went to see the crushing, washing and the rough sorting, before sending to the valuing and assorting rooms for export. Since the de Beers Company was formed there is little business doing in the town; the small Companies are now rolled into one large Company, which rules the diamond market very much as it likes! Our next stage was Bloemfontein, in the Orange Free State, perhaps 300 miles from Kimberley, and at an elevation of about 6,000 feet. The town is small, but quite English in appearance, Aberdeen being well represented by a Doctor, a Lady Principal of College, as well as teachers and other business men. I understand Dr. Polson, a brother of Mr. Polson, of Alnwick, Kandapola, lives at Riddesburg, some distance out of town. I there met Mr. Smith, dairy expert, and Mr. Murray, Minister of Lands and Works in Natal. Both gave me introductions to their friends in Natal, for the better enabling me to see the country. We then left for Johannesburg, in the Transvaal, the young London of South Africa, and the centre of the great gold-mining districts. I am told that nine years ago there was not a house on the plain, where to-day you find a town of 150,000 inhabitants, and thousands pouring in monthly from all parts of the world. Judging from the shops in some of the principal streets you might fancy yourself in Regent Street, London. We visited several mines in the different districts. Robinson, New Clunes, Vogelstrauss, Durban, Roodepoort, Cyanide Works, Clydesdale Coal Mine, Heidelberg, and other districts, as well as the Town of Johannesburg, which is now of considerable dimensions. The rock from which the gold is taken in the Rand district is what is called *Banket*, more resembling porphyry than granite or quartz, and is very rich in gold and extracted by the Cyanide process after crushing. There is no doubt a great future for the Transvaal, Matabele, and Mashonaland (Rhodesia). We visited Pretoria and the historic jail of Jameson fame. Saw the President and was promised an interview, having got letters of introduction, but he was called suddenly away to the country that afternoon by telegraph. We then left Johannesburg, my friend, to return home by the "Norman," and I to make my way to Durban, leaving Park Station, Johannesburg, at 7 p. m. We reach the boundary of Natal next morning about daylight. Charleston station is not far from the two historic spots—Boer and English—*Majuba Hill* and *Langs Neck* of 1880-81. The elevation at this point in Natal must be over 6,000 feet, and the country from here down to Pieter-Maritzburg appears most suitable for pasture. Large droves of cattle, horses, sheep and goats are

to be seen grazing, and all look remarkably healthy compared to the half-starved appearance of the cattle on the Transvaal side of the border. Lower down in Weenen and Maritzburg counties there is more cultivation, farming being carried on to a very large extent in these two counties, and most farms are said to be paying well. There is also a portion of this land rich in coal. Several mines already opened are paying well, but for want of labour and rolling stock on the railway, the owners are unable to send it down fast enough to meet requirements of steamers calling at Durban. Steamers at present are lying for a week at a time waiting for coals, while one mine, I was told, was capable of putting out 800 tons a day. I called to see an old Skene man, Mr. Masson, who is now Surveyor-General in Natal, and lives with his family in Maritzburg. We called in the afternoon to have tea with Sir Walter and Lady Wragg (late of Ceylon). Sir Walter has very keen recollections of his Ceylon days. He told us his knowledge of Tamil and Sinhalese had been, and was still, very useful to him. Only the other day a Sinhalese man came to him in trouble and was so pleased when he was able to explain his troubles in his own language. Sir Walter takes a great interest in gardening; he has a very large collection of roses and in great variety, as well as many rare flowers. He is looked upon as a first-class judge and specially in native cases.

The journey to Durban shews some good scenery as you get near the Coast. Durban is a very pretty town, but especially the Berea where most of the towns-people live. On the face of a small hill which overlooks the town and the sea beyond, tramcars run all day to and from the point where the ships discharge and load, about 2 miles from the Town-house, and to the Berea other 2 miles but in the opposite direction. The ports along the East Coast of Africa are so often blocked by the accumulation of sand on the bars that it is impossible to keep regular dates of sailing. From Durban we went to Delagoa Bay to discharge cargo. This is the terminus of the Netherlands railway from the Transvaal, between the Portuguese and Netherlands. I have never seen such mismanagement and such careless treatment of goods. Judging from appearances some of the goods must have been lying there for years and exposed to the weather all the time. The Dutch and Portuguese ought to be ashamed of themselves.

Beira was our next and last port of call, and will eventually become the terminus of the Cape Town, Kimberley, Mafeking, Matabele, Mashonaland, Salisbury Railways and through the Portuguese territory to Beira, a distance, I should think, of over 2,000 miles. It is to be worked I understand by the British Government. And now in bidding good-bye to the "Clan Menzies," I have to thank the Captain and his officers for making what might have been a very tedious and tiresome voyage a most pleasant and agreeable one.

J. F.

CHAFED SKIN, PILES, SCALDS, BRUISES, CUTS, STINGS, NEURALGIC and RHEUMATIC PAINS, SORE EYES, EAR-ACHE, THROAT COLDS, and SKIN AILMENTS, quickly relieved by
use of CALVERT'S CARBOLIC OINTMENT.
Large Pots 13½d. each (English rate). Sold at Chemists, Stores, &c.

F. C. CALVERT & CO., Manchester.

DATE PALM GROWING IN CEYLON.

In "The Ceylon Forester" for this month there is quoted an article from an Indian paper in which it is suggested that numerous sites on tea plantations, such as in and around the coolie lines and factory buildings, sides of roads, tanks, &c., might be utilised by cultivating the *Phoenix dactylifera* or date palm. The editor of "The Ceylon Forester" adds:—

Surely it would be well worth while Government trying a small experiment of an acre or so, in the dry low country of the Northern or Eastern Provinces. The trial would not cost much and if successful, it would open up a grand new industry for the natives as thousands of Rupees worth of dates must be imported annually.

THE SPRING VALLEY COFFEE COMPANY, LIMITED.

5, Dowgate Hill, London, E.C., 7th Nov. 1896.

Sir,—I am instructed to inform you that the Board have decided not to pay an interim dividend for the past half-year.

The coffee crop for 1895-96 has been almost an entire failure, and the outlook as regards coffee for 1896-97 is, at the present time, little, if any, better than last year.

Tea prospects continue good, but the profits from the comparatively small acreage at present in bearing are severely taxed by the necessary expenditure on the upkeep of young tea and the extension of the tea area.

Under these circumstances the directors have decided to postpone the payment of a Dividend until the end of the financial year.

The area under tea is as follows:—

Over 5 years old ..	741 acres in bearing.	
Planted November—Dec-		} 770 acres not in bearing.
ember 1892..	53	
Ditto 1893..	243	
Ditto 1894..	179	
Ditto 1895..	145	
Now being planted		
1896..	150	

From the above statement it will be seen that the extension of tea is being rapidly pushed on. The directors regard this as of the first importance, as until we have a large area of tea in bearing, steady profits cannot be relied upon, and although the cost of extension and upkeep of young tea is a heavy burden on the revenue, the intrinsic value of the property is much increased, and future profits assured so far as is possible.—I am, sir, your obedient servant,

J. ALEC. ROBERTS,
Secretary.

MARKET FOR TEA SHARES.

Nov. 12.

A large and increasing business continues in progress in the shares of most of the Indian Tea Companies, and the official list shows a considerable number of advances in quotations.

Mincing Lane, after the rest of Lord Mayor's day, has firmed up, and notwithstanding the largest day's sale on record of yesterday, prices have strengthened rather than weakened. This rise in price, however, is required in order to compensate planters both for the fractional rise in the cost of few production resulting from the higher cost of the rupee and the increased cost of wages incurred by the rise in the price of rice owing to the unpropitious weather in some of the rice-growing districts.

Meetings.—The Associated Tea Estates of Ceylon, Limited, and the Lanka Plantations Company, Ltd., held their meetings this week. Reports of the same appear elsewhere. The Empire Company calls its first statutory meeting for November 20th, at 2 p.m. (Winchester House.)—*H. and C. Mail*, Nov. 13.

PLANTING AND PRODUCE.

(From the *H. & C. Mail*, Nov. 13.)

THE SUPPLY OF TEA.—A correspondent of the *Grocer* who has great faith in his own capacity to see round a corner, forecasts the tea market as follows: "At this period of the year, when the Mincing Lane market is supplied to overflowing with Indian growths of tea, it is customary for many wholesale and provincial buyers to 'rush in' and purchase abnormally large stocks under the impression, no doubt, that prices are about bottom. We are in the 'period of glut,' and at any moment may have a sick market when supposed cheap purchases may suddenly look dear. Allowing for the increased home consumption, there is every indication that supplies from our colonies of India and Ceylon will fully keep pace therewith. Taking as examples the production of several large Indian companies as 'cabled' up to end of October against output in previous season, there are indications of a largely increased crop. The figures furnished herewith relate to two Assam tea companies and one Sylhet company:—

	1895.	1896.
Doom Dooma Tea Company (Limited)	1,595,600	1,752,960
Jokai (Assam) Tea Company (Limited)	2,911,520	3,233,440
Lungla (Sylhet) Company ..	1,403,120	1,630,800
	5,910,240	6,617,200

Showing an increase of nearly 12 per cent. The usual telegrams respecting cold and unfavourable weather, early closing down of some gardens, &c., are to hand; still, as Indian tea's growing over such an enormous area, many districts will doubtless be plucking greatly increased quantities, to more than compensate for any slight falling off in other parts. Ceylon is an important factor, and the ever-increasing supplies from that sunny spot should not be lost sight of. Within two or three months we may expect supplies gradually increasing from nine to twelve millions per month, and of tea that will not keep but must be sold quickly after his arrival. Your readers who work out the figures for themselves will probably come to the conclusion that there is plenty of tea before us, and that buying for requirements means keeping prices on as favourable a basis as at present for a long time to come."

TEA AND BROKERS.—In an article under this title which appears in our Calcutta contemporary, *Capital*, the writer advocates the selling of a larger quantity of tea in Calcutta. He says in the course of his comments, which we confess we do not agree with, that—"It will have been noticed that a very great number of companies' teas have been withdrawn from sale and shipped from London to deal with, and the reason is not very far to seek. We are aware that the greater number of planters prefer having their teas sold in Calcutta, as they know what they are doing in a very short time instead of living in uncertainty as regards the quality of their teas, till one might say half their crop was made, but here comes in the handicap. The London agent likes the teas sold in London, as no doubt there is a 'picking,' and when the local management ventures to protest mildly that it would be preferable to sell in Calcutta, the reply comes back; how can your teas get justice done them when your broker is both buyer and seller? And, surely, the trade is large enough now to admit of the business being divided? To the beginning of October altogether 343,100 packages had passed the hammer this year, and this number, we feel sure, would be considerably increased had we a distinct division of the business into buying and selling departments. We feel certain that it must come sooner or later, and the sooner the change is effected the better it will be for all those concerned. Of the 343,100 packages that changed hands, taking a package as equal roughly to 80 lb, about 29 million lb. out of a total export of nearly 70 millions, about 40 per cent., were handled. Dividing

this evenly amongst the six firms of brokers it gives an average of nearly five millions to each, which meant handling, lotting, sampling, &c., of about 62,500 packages. We feel certain that were business divided as we suggest this quantity would be considerably increased, and we commend the matter to the Indian Tea Association and Chamber of Commerce, feeling sure that it will receive the attention it deserves."

PARAGUAYAN TEA.—Apropos the fact that as we announced some months since, mate or Paraguayan tea is advertised in London, the *Pall Mall Gazette* is quite fervent. It says: "Shall we import our tea from South America instead of India and China? Shall we grow it ourselves? Shall we suck it up like a straw drink through a bombilla? If mate tea is introduced to this country we may do any or all of these, and there are those who are trying to introduce it. It is the drink of the Paraguayans and the Brazilians, and of the Europeans who dwell in their midst, and there is not wanting evidence in its favour—the evidence of medical science, the evidence of travellers, the evidence of those at home who have had the good fortune to try it. Those who speak with authority on such subjects declare that it contains a nitrogenous principle which is both nourishing and sustaining; that it does not tax the digestive powers; that it contains more theine than tea itself and less tannin; that, for many other reasons, it should fight tea and coffee on their own ground and win easily. Let the capitalist scent a new industry, the tea-growing East look to its laurels, and the Chancellor of the Exchequer think of transferring the Customs duty." The increasing favour of tea with the consumer and the importance of the Indian and Ceylon tea industry have developed some fanciful views as to the possibility of a rival product, but we do not think this competition will come in the form of Paraguayan tea. Up till now the shares of Indian and Ceylon tea companies have not shown signs of weakness, nor are the public, so far as we can gather, showing any keen desire to be nourished and sustained by mate, either with or without the bombilla.

ONLY A MODEST SUGGESTION.—We sympathise with the editor of our Calcutta contemporary *Capital*, who mentions that a Calcutta journal has published a list of Calcutta tea companies taken from *Capital* without acknowledgment. We know something of the feeling called into play by that kind of thing, and have borne with fortitude a long series of offences with but an occasional remonstrance. Articles, tables of statistics, and paragraphs appearing in these columns are not only sometimes inserted in other journals without acknowledgment, but they come back from the East to the West and quoted from the journals which, shall we say, purloined them, they again appear in this country with all the coy graces of a first appearance. That accidents will happen in well regulated Press circles we have a proof only this week. In our issue of September 18 we gave an extract from a magazine called *Colonia*, in which Mr. Elphinstone had written on tea planting in Ceylon. We prefaced this with some remarks of our own on the attraction of tea planting. Our contemporary the *Indian Planters' Gazette* reproduces the entire article and quotes our comments, we feel sure, in absolute good faith, from the *Ceylon Independent*. We make no complaint against either of the journals named, who are, no doubt, not intentional sinners, and usually give credit where it is due. We merely take this opportunity of suggesting that in cases where extracts from our columns are made the source should, when the printer has the necessary type, be quoted. If this is not acceptable the name of this journal being long, there is a really admirable way of meeting the occasion by adding the letters H. and C. M., which is mysterious to the uninitiated and does not necessarily mean anything at all. We would not mention this trifling matter if it were not for the short and simple fact that we write mainly for our own readers, and although it is kind and attentive on the part of other journals in Timbuctoo and elsewhere to honour us by reproducing the gems we set, it occurs to our mind

in moments of depression that it is not so conducive to our welfare as they fondly imagine. It is an age of self-denial and hair shirts. Reluctantly, therefore, we surrender the pleasure of seeing our pet paragraphs reproduced without acknowledgment, and say to those who do not quote us: if you find it necessary to the happiness of yourself and your readers to use any extracts from this journal print the name somehow, if only in initials and comparative happiness will be our portion.

NOT TOO MUCH ADULTERATION, BUT QUITE ENOUGH.—The report of the Local Government Board on the adulteration of produce is always pleasant reading in the far-away home of the grower of produce. It proves that the watchful eye of authority is guarding his interests and that if the guardian dozes sometimes he wakes up at times and convicts the offenders. There were for the year 4,093 cases of adulterated samples and 2,313 convictions. Of tea the Commissioners of Customs reported to the Board that the analyst to the Commissioners had analysed 646 samples, and 573 of those samples were considered satisfactory. The remaining 73 samples were reported to the Board, and were disposed of as under: 10 samples (425 packages) were admitted to home consumption; 59 samples (1,524 packages) were restricted to exportation owing to the presence of exhausted leaves and admixture with other substances; and 4 sample (4 packages) were destroyed as being decomposed and unfit for human food. These, we take it for granted, all came from China. Of the 2,046 samples of coffee examined, 204 or 10 per cent were condemned. In 141 of these cases the proportion of added chicory was at least 40 per cent, a few of the samples being almost entirely chicory, though one was sold at the rate of 1s 6d per pound. There were 135 prosecutions, and in 119 cases penalties were imposed amounting in all to £157 17s, only 8 of them being of £5 and upwards. Out of 855 samples of ginger 61 were adulterated; of 182 samples of cocoa 36 were condemned; 353 samples of sugar were examined, and only 6 were found to be adulterated. There were 1,599 samples of pepper analysed, but only 8 were adulterated. This contrasts favourably with the report of a few years ago, when pepper was found to be extensively adulterated. Fines were inflicted in two cases of pepper.

THE LATEST FIBRE.—Sir H. Johnston, Her Majesty's Commissioner in the British Central Africa Protectorate, mentions a plant indigenous to that part of the globe which may have a future of great utility before it. An English firm recently gave their attention to the valuable fibres produced by three species of liliaceous plants of the genus *Sansevieria*. The *Sansevieria* grows in great quantities on all the barren, stony ground of the Protectorate, at low levels, especially on the rocky islands in Lake Nyassa. A machine has been invented which is able to turn out enormous quantities of fibres from this plant in a very short space of time, and it would seem as if the barren ground of the Protectorate would prove to be of almost equal value to the rich coffee producing tracts, since this fibre is worth nearly £40 per ton. Moreover, the *Sansevieria* is of most easy propagation, requires little or no attention, and in three years from the time of planting is ready to reduce to fibre. The fibre has long been used by the natives of Africa and India for making bowstrings, and has been called bowstring hemp,

THE TEA MARKET.

In the Tea market business is active at steady prices. The record deliveries for October should strengthen importers' position, especially as the strain of large imports (Indian) begins to abate. It is evident increased production, at any rate for season 1896-7, will not be more than to meet the universal increasing consumption. Of China Tea a further, though slight, easing in prices has not altered the general position. Ceylon Tea is firm with moderate imports.—*L. and C. Express*, Nov. 13.

WYNAAD PLANTERS' ASSOCIATION.

Proceedings of a general meeting held at the Club, Meppadi, 4th Nov., 1896:—

IMPORT DUTIES.—Read letter from the Secretary, U.P.A., enclosing copies of correspondence between the Secretary U.P.A., the Madras Chamber of Commerce and Messrs. Binny & Co. on the subject of Import duties on Artificial Manures and Tea Seed.

This Association is of opinion that the matter of Import duty on Tea Seed from Ceylon is not of sufficient importance to enter into.

Read letter from the Secretary, U.P.A., asking for the views of this Association on the resolution passed by the Nilgiri Planters' Association with reference to the appointment of a Specialist to enquire into fever. This Association is of opinion that this is a matter that may safely be left in the hands of Government.

CUTCHERRY AT MEPPADI.—Resolved that the Honorary Secretary be instructed to write to the Collector of Malabar, asking, if it could not be arranged that the 2nd class Magistrate of Vayitri should hold Court for 2 days once a month, regularly, at Meppadi; and if so, that due notice of his visit should be sent to the Honorary Secretary and be posted up at the Police Station and Post Office at Meppadi and the Post Office at Vellera Mulla. Also that beat constables be instructed to leave such information at the estates on their several beats.

COFFEE ROBBERY.—Resolved that the Honorary Secretary be instructed to write to the Superintendent of Police, Malabar, with reference to police arrangements during this crop season.

THE TEA MARKET.

In the Tea market another series of auctions (55,000 packages Indian), taxing the buying powers of the trade, have passed off satisfactorily. Prices rule at so moderate a range as to impart confidence, but a big margin exists between the middleman and those paid by the consumer. The gradual extinction of our trade with China is at last attracting serious attention, and some effort, it seems, is likely to be made to resuscitate it. At the prices ruling this season there has undoubtedly been more of it taken for home consumption. The change must proceed from Chinese sources, who have the foundation to favourably compete against all comers. Ceylon tea, its nearest competitor, is not now relatively above China values, as supplies are frequently of a disappointing nature.—*L. and C. Express*, Nov. 6.

TEA IN AMERICA.

New York, Oct. 28.

There is considerable speculative activity in the market, particularly in low-grade tea. Blacks, Japans and Country Greens are all doing better, and in an invoice way are up over 1½ to 2c per pound. Fancy grades of Formosa are in light supply and firmly held. The better grades of Japan are steady.—*American Grocer*.

New York, Oct. 30.

While prices have not advanced notably, there is a very firm tone to the market, holders ignoring all offers below their views and resisting sales at old quotations. There has been some improvement in the demand, which covers all grades and sorts. India and Ceylon teas are steady.

Today at noon the Montgomery Auction and Commission Company will sell 3,158 packages, viz.: 649 half chests Moyume—new season's attractive chops; 511 boxes Pingsuey—new season's; 598 half chests Congou, including fancy Pekoes; 29 boxes Capers; 77 packages India, Java and Ceylon; 1,304 half chests and boxes Formosa, including new season's.—*American Grocer*.

INDIAN TEA SALES.

(From *Watson, Sibthorp & Co.'s Tea Report*.)

CALCUTTA, Nov. 25th, 1896.

15,394 packages changed hands in the sales held on the 19th instant. The quality was above the average, but the demand was hardly so active as before and prices for all grades, although rather irregular, generally favored buyers. There was a fair amount of business done for the Colonies and other places, but the demand from the Bombay side was again very slack.

The average price of the 15,394 packages sold is As. 7-1 or about 8½d per lb. as compared with 17,550 packages sold on the 21st November 1895 at As. 7-1 or about 7¾d per lb. and 19,767 packages sold on the 22nd November 1894 at As. 9-8 or nearly 10d per lb.

The exports from 1st April to 23rd November from here to Great Britain are 102,334,515 lb. as compared with 96,529,065 lb. at the corresponding period last season and 90,912,724 lb. in 1894.

NOTE.—Last sale's average was As. 6-8 or about 8¼d.

TELEGRAMS.—Reuter telegraphed from London on the 19th instant.—Offered 51,000, sold 43,000 packages. Common qualities irregular. Finest very firm. Average 8¾d. "Type" 6-9-16d.

EXCHANGE.—Document bills, 6 months' sight 1s 3¾d.

FREIGHT.—Steamer—£1-10-0 per ton of 50 c. ft.

(From *William Moran & Co.'s Market Report*.)

CALCUTTA, Nov. 25th, 1896.

TEA.

The sales on Thursday last were again rather small for this time of year, 15,791 chests only being offered; nearly all of which were sold. Common sorts were a shade easier, while all other descriptions were freely taken at steady prices.

Tomorrow 21,000 chests will be brought to auction

Total quantity of Tea passed through Calcutta from 1st April to 23rd November.

[ALL RIGHTS RESERVED.]

Agricultural Pests:

WITH METHODS OF PREVENTION,

BY

MISS E. A. ORMEROD,

(Late Consulting Entomologist to the Royal Agricultural Society of England)

I.

INSECTS INJURIOUS TO GENERAL CROPS.

THE order *Diptera* includes the Gnats and Corn Midges, also the Daddy Longlegs, of which the grubs are so hurtful to many kinds of crops; the Blowflies, which cause great waste to meat in summer; the Gadflies, and a very large

number of other kinds, which, by means of their maggots, do boundless damage year by year to the roots of cabbage, onions, and other garden-crops, and likewise to the heart or stem of the growing corn, &c. All flies of this order have only one pair of wings; occasionally they are wingless. The hinder pair of wings is represented by a pair of appendages, often like a slender pin with a small head; these are known as "poisers" (scientifically, *halteres*), because they help, or appear to help, to poise or balance the insect. Some of these insects feed by suction, as in the case of the gnats, to our great annoyance. The maggots, or larvae, are fleshy and (with few exceptions) footless; sometimes, like the Daddy Longlegs grub, they have a hard head, furnished with nippers, or jaws; sometimes they have a soft mass which answers for a head, commonly bearing a pair of hooks instead of jaws, with which they clear out the substance between the two sides of a turnip-leaf, or from the inside of an onion-bulb, or

other soft material in which they may be feeding. The pupa-case, or chrysalis, varies in shape; in some kinds, as of the Gnat and Daddy Longlegs, for instance, it is in shape much like the creature within, with its limbs folded; in many other kinds, as the Onion Fly, Carrot Fly and others, the pupa-case consists of the hardened maggot-skin, which shelters the forming fly within.

The Daddy Longlegs, or Cranefly, likes damp surroundings, and thus we get an idea of how to keep its numbers in check. The flies frequent damp overshadowed herbage, or marsh-land, or wet, neglected weed-growths, and in such places, they lay their eggs. The grubs thrive in such positions or at the roots of crops so long as the ground is not too dry for them, and when they have fed for some months they turn into a pupa, which, by means of the spikes at its side, sets itself up in the ground conveniently for the fly to come out from.

The best way to forestall attack is to make the land unsuitable for egg-laying. Draining marsh-land, and rough mowing long grass or neglected herbage in shady parts of pasture-fields hedge-sides, and other like places, drives off a great deal of attack; but the chief difficulty is on land broken up from pasture or clover-ley. The eggs are mostly laid, towards autumn, in such localities (that is, pasture fields or clover-ley); therefore, if these are merely broken up, without any measures having been previously taken to prevent egg-laying, or to kill the "leather-jacket" grubs in them, it is no wonder that the next crop should often be totally devoured. Any measures that will serve either of these purposes are highly desirable. Where pastures are to be broken up, it is a good plan to fold sheep on the ground and hand-feed them, thus making the ground obnoxious to the Cranefly for egg-laying, and also by the trampling and by soddening the ground with the droppings of the animals, destroying most of the eggs or young grubs that may chance to be on the surface. Heavy dressings of hot lime are useful, and dressings of fresh gas-lime, or alkali waste, which kill everything they touch whilst in their caustic state, are an excellent preservative from attack. These two chemical dressings cost little (where they are procurable at all), and gradually

turn to a manure of the same nature as gypsum. Salt also has been found useful for dressing leys with in autumn. Laid on at the rate of 10 cwt. the acre, and ploughed in, it has been found to kill the couch-grass (a very serviceable means of prevention of insect-ravage), and there was no further trouble from either grub or wireworm. Bush-harrowing does good, and paring and burning the surface is also an excellent remedy; but this has drawbacks, on account of the expense of labour, also wasting so much of what, in rotting, would have been fertilizing material.

Where eggs and maggots are in the ground, the most hopeful method of meeting coming attack is to make all possible arrangements to push on a good growth, and, firstly, to secure a good start. This is one reason why deep ploughing is advised in breaking up leys. Some of the eggs and young grubs will thus be turned down too deep to hatch, or to make their way up again. Also judging by what has been observed in other instances, those eggs which are well turned down, out of reach of the amount of air natural to them, will either not hatch or be so much retarded in date of hatching that the date of attack will also be retarded, and the young crop has a good chance to get well established before the grubs are ready. This first start is a very important matter; if the young plant is stunted in its first growth, it most likely will never do as well as if it had begun heartily; and this point should be borne in mind as one great method of counteracting injury from insect attacks to roots or leaves. Get a good start, by using good, fresh seed, by proper treatment of the land beforehand, and, if you can, by burying the enemy so deep down that it will neither make its own way up at the natural time, nor be turned up again by afterploughing or cultivating; and thus we get our plants so ahead in the race that we may hope to win. This is a general principle, suited to all crops.

But to return to special treatment of Daddy Long-legs grubs. If attack is found to be bad in growing corn, some fertilizer, such as guano and salt mixed, applied, say, at the rate of 4 cwt. the acre, has been found to do much good. Nitrate of soda also acts well, both by benefiting the plant and injuring the grub. In experiments tried by placing Daddy Long-legs grubs at a depth of one inch below the surface, it was found that where nitrate of soda at the rate of 2 cwt. the acre was well watered in, the grubs so treated were very relaxed, soft and helpless, and so continued whilst observed and reported. This helplessness is a very important point, for thus the grub, instead of creeping away, is kept under the action of the solution good for the plant but bad for itself, and ultimately dies.

Special chemical applications, only intended to kill the grub, have (in the instances noted) been found not to do good, because they are so much weakened in passing through the ground that they are quite harmless by the time they reach the creature they were meant to kill. This has been the case with chemical acids—carbolic acid, for instance; but whether we might not do good by vegetable applications, such as that of mustard-cake, is a matter for further consideration. The treatment may shortly be described thus:—prevent egg-laying, if you can; bury eggs and grubs deep down out of the way; give your plant a good start, and keep it well up under attack, if attack comes. But, further, we should in this, and in all cases, look at the special habit of the pest. The Daddy Long-legs grubs cannot bear heat, light, and drought; therefore two kinds of treatment, apparently quite opposed to each other, have been found useful, for they both bear on the above habits. Hoing has been found useful, because thus, in dry sunny weather, the powdery, dry ground is just what the "Leather-jacket" grub dislikes. Also rolling at night, or at early dawn, does good; for then, during the cool dusk hours, we may catch many of the grubs on the surface, and they may be crushed by the Cambridge roller or Croskill's clod-crusher; and rolling the ground firmly in this way

likewise prevents some of the grubs "travelling." There is one more point which has not been brought forward, but which, by watching the habits of the creature, I think might be very usefully worked in garden ground. I find the grubs like to lie under a thin damp turf; they will collect in large numbers in such a spot. Probably it would answer well, in garden-ground, to lay slates, or tiles, and send a boy round every morning to clear what lay below. I have only worked this plan out myself on a small scale, but it is worth considering. The above is one of our regular yearly attacks, especially to be looked for after a damp autumn and winter, because as we have seen, dampness and moisture suit the Daddy Long-legs in all their stages.

The next of this gnat-like division of flies that may be considered is the Wheat Midge (*Cecidomyia tritici*), the eggs of which produce the little orange or red footless grub known as the "Red Maggot," often found in wheat-ears. These little gnats are hardly more than an eighth of an inch long in the body, but have long legs and horns, and the female has a long ovipositor, as thin as a hair, with which she inserts her eggs in the wheat-florets, or those of such other kinds of corn or grass as she may infest. This operation is mostly performed in the evening, and we are indebted to the observations of Mr. Swanwick, of the Royal Agricultural College Farm, Cirencester, for the information that, just at the time of development, the flies were not only attacking the wheat, but were to be found in great numbers in clover-land which was in wheat the previous year, and also amongst rough grass at hedge-sides. The Maggots soon hatch, and feed on the germ or some part of the soft grain; they are very little grubs, hardly more than the twelfth of an inch long, yellow, orange, or scarlet in colour, and slightly pointed at the head. The loss they cause by feeding on the corn-grains sometimes amounts to as much as from one to about three sacks (that is, about half a crop) per acre. After they have left off feeding, some remain in the corn, and are carried with it; others remain in the stubble, or fall, or go down into the earth, where in time they change to chrysalids, from which the Midge-flies come out about corn-flowering time in the next year.

Our best method of prevention is to destroy the Red Maggot (for the chrysalis, if it has turned to it) in its winter shelter. Deep ploughing, such as will turn infested stubble thoroughly down, will act well, for once deeply buried the Gnat-fly either will not develop or cannot come up again. It is not enough considered in these matters that we may by our own common knowledge often guide ourselves. If a weak small grub (so small that we can scarcely see it) has a weight of earth put on it, somewhere about as much as if at least thirty or forty yards deep of earth were placed on one of ourselves, it is very unlikely that, where it is not specially supplied with powers for piercing the ground, it will come up again as a grub; and the Gnat-Midge, if it does develop, certainly cannot make its way through. This is one of the points that show us how to keep insects in check; we need often merely to consider just what is before our eyes and act on it. Once down, and left down (for, of course, if we bring the grubs up again by a second equally deep ploughing we lose our labour), we have in all probability buried the coming attack safely away. All measures which will lessen the amount of couch-grass, or other wild grass, (it is either known or believed, to lie in the heads, or shelter at the roots during winter), would help to keep the amount of this midge in check. Clearing and burning rough grass by hedge-sides is one method; gathering up the corn-stubble and burning it, directly the corn is harvested, gets rid of whatever is at the roots; and also (and this is very important) all the dust from the threshing-machine should be burnt where wheat is known to be at all infested. The Red Maggot may often be seen in millions in this, and absence of attack has been found to follow the plan of carefully burning the infested dust.

The Hessian Fly (*Cecidomyia destructor*) is another of the *Cecidomyia* which is very hurtful to various kinds of corn in America, and in various places on the Continent of Europe, and which was first observed in this country in the year 1886. With us the attack is in some degree to wheat, but chiefly to barley; and it does not appear likely to be a serious crop-pest. The perfect fly much resembles a stout-made little brown gnat, about one-eighth of an inch in length, with one pair of smoky-grey wings, and with long horns.

The attack may be to the young plant, but with us it mostly occurs only as a summer infestation to the growing stalk, where the small white legless maggot feeds *outside* the stalk, but *inside* the leaf-sheath just a little above one of the knots. Commonly it is just above the second knot, but the attack may occur lower down at the first knot, or close to the root, or higher up above the third or fourth knot. The mark of attack being present is the stem elbowing sharply down just above where the maggot lies. It does not commonly break, but unless the straw is very firm, it bends at the weakened spot, and thus damage is caused to the fallen head, besides difficulty in reaping from the confused state of the straw. The maggot may live for about four weeks in this position, and then it changes at the spot at which it fed, to a flat brown chrysalis, in the size and shape and colour minutely resembling a rather small and narrow flax-seed, whence the name of "flax-seeds" is commonly given to these chrysalis-cases or *puparia*. Within this hard outer husk the maggot changes to chrysalis, and the chrysalis to the perfect fly, but how long this may take depends very much on circumstances. It may occur, under natural and favourable circumstances, so soon that the whole time occupied in the life of the fly from egg to development is only about forty-eight days: or under favourable circumstances it may be retarded. Thus some of the Hessian flies may come out in autumn on the fields; whilst some of the "flax-seeds" threshed out, or stacked in the straw, or kept artificially for investigation, may very likely not hatch until May, or much later in the following year.

With this attack, more than, perhaps, almost any other, we rest on the application of common agricultural measures, and dates of sowing, for the treatment which, joined to effects of the climate, has hitherto kept this infestation in check. A great part of the damage caused by the maggot's presence, arises from the stem being so weakened that it elbows down; therefore, all selection of kinds of seed, and all treatment calculated to give a healthy strong straw which will not give way under a moderate amount of maggot infestation, are direct means of preventing loss. So far as wheat is concerned, our usual time of autumn wheat-sowing places the spring of the young plant well after the time when the summer Hessian flies are about. In the process of threshing, the so-called "flax-seeds" are thrown down with the light screenings, and can readily be gathered up with them and destroyed, thus putting an end to all chance of recurrence of attack from this cause; and as hitherto we have only been troubled by the summer attack on the corn stems, and had no difficulties from the additional multiplication caused by a winter infestation on the young plants, it may be well hoped that this corn attack will not take the serious place in this country which it does in many other parts of the world.

CAPSICUM, POTATOES, AND SOME OTHER ECONOMIC SOLANACEÆ OF INDIA.

[BY YOGENDRACRI GHOSA, OF THE AGRICULTURAL SOCIETY OF INDIA.]

(Continued from page 376.)

The uses and the habits of the potatoes are so well known that it is quite unnecessary to say anything about them here. Suffice it to say that although the cultivation of this wholesome tuber has become quite general in almost all parts of India, there are still to be found several orthodox enough so as not to use it in their food, rejecting it as a foreign article, and the number of such individuals in a town or village may be counted on the fingers. But there are numerous scrupulously pious Hindoos who still abstain from the use of potatoes on ceremonial observances, *e. g.*, on the death of parents or husbands. On such occasions no Hindu, properly

so called, should touch anything that does not belong to the category of "Aksaralarana" a technical phrase, literally meaning 'non-alkaline salt,' but including in that term the following articles of food:—(1) cow's milk; (2) clarified butter from cow's milk; (3) paddy (rice); (4) munga, a pulse (Phaseolus Mungo); (5) til seeds (Sesamum orientale); (6) barley; (7) sea-salt and salt from the Sindh. A longer list, however, technically called *Habisyama*, contains the following:—

1. Paddy (Rice) which has ripened in the cold season and which has grey husk, rice made from such paddy without boiling it for unhusking.

2. Munga (Phaseolus Mungo).

3. Til seed (Sesamum orientale).

4. Barley.

5. Kalai, pulses of the Phaeolus order.

6. Kangu, Panicum italicum, the Kank of the N. W. P., Kankuidana of Bengal.

7. Vastuka, the Betuasag of the Bengalis (Chenopodium album).

8. Hilamocika, an aquatic weed (Enhydra Binghamia, D.C.).

9. Kala. The karim or karm sag of the Thibetans and the Punjabis. A wild form of Cabbage or Colewort, much cultivated all the year round as a pot herb. (*Brassica sylvestris*?) In Bengal, however, the *kulekada*, a variety of *Capparis brevispina* is considered the same as the *kala saka* of the Castras. This latter weed grows, after the rains, in dried paddy fields, and is much sought after as a tonic and health-giving pot-herb.

|----------------|--|
| 10. Mulaka. | The radish. |
| 11. Panasa. | The Jakfruit. |
| 12. Amra. | The mango. |
| 13. Haritaki. | The Terminalia Chebula. |
| 14. Tintidi. | Tamarind. |
| 15. Jiraka. | Cumin seed. |
| 16. Nagaranga. | The orange. |
| 17. Pippali. | Piper longum. |
| 18. Kadali. | The plantain. |
| 19. Labani. | The nona of Bengal. Anona reticulata. |
| 20. Dhatri. | Emblica officinalis, Gaert. |
| 21. Kemuka. | The Kann of the Bengali Kavi-
[rajas] |

With potato ends the unarmed section of Roxburgh Solanums. The foremost amongst the armed Solanums of Roxburgh is his

7. *S. Melongena* Wild. in which may be included his—

8. *S. longum* Roxb. This is the well-known *Begun* of the Bengalis, the egg-plant. It has been diversely named and variously divided into subspecies and varieties.

- | | |
|----|----------------------------------|
| A. | <i>Solanum ovigerum</i> , Dun. |
| | <i>S. pseudo-undatum</i> , Be. |
| | <i>S. esculentum</i> , Dun. |
| | <i>S. insanum</i> , L. |
| B. | <i>S. Melongena spontaneum</i> . |
| | <i>S. incanum</i> , L. |
| | <i>S. undatum</i> , Lam. |
| | <i>S. zeylanicum</i> , Scop. |

Dr. Watt, in this Dictionary of Economic Products of India, gives the following synonyms in addition to those mentioned before:—

- | |
|---|
| <i>S. trongum</i> , Lam. |
| <i>S. ferox</i> , Var. B. Kurz., |
| <i>S. torvum</i> , var. <i>Inerme</i> , Dalz and Gibs., |

which brings 7, 8, and 9 under one general species. The uses of Brinjal as a vegetable is too well-known to be repeated here. One thing, however, should be noticed that almost all the species of the Solanaceae are considered by the Indian Kavirajas as increasing the wind-temperament. But the fruit of the Brinjal, if cooked when tender, *i.e.*, when the seeds are not sufficiently developed, is considered the best food for one with disordered liver. It regulates the action of the liver, which influence is perceptible within twenty-four hours.

10. *Solanum æthiopicum*, Wild. same as *Lycopersicon tuberosum*, Mill. This is not of much economic value.

11. and 12. *Solanum diffusum* is perhaps the same as *S. incanum*, Chienense of Pluck. This is, no doubt, the same as *S. Jacquini*, Willd., and the two varieties *a* with larger fruit and *B* with smaller fruit are the two varieties noticed by Roxburgh. He says under *S. diffusum* "there is another sort so exceedingly like this in every respect, that it was long before I discovered they were distinct. The chief distinguishing marks are the leaves in this are longer and more or less deeply lobated and the prickles much more numerous, longer and sharper, all perfectly straight."

This is the Kantikari of the Bengalis and the Sarpatanoo of the Sanskrit authors, otherwise known as Gadhini.

The fruits are much esteemed by the people, and are eaten freely in their curries, for which the plant is cultivated in some parts of India. As to its officinal properties, there is no place for them.

The *S. diffusum*, Roxb. (11) and *S. Jacquini* (12) therefore may be made into one species, *S. diffusum*.

13. *Solanum indicum*, L. This is the *Vyakuda*, of the native physicians, the *Vhati* of the Castras. It is the same as:—

- | |
|---|
| <i>S. violaceum</i> , Jacq. |
| <i>S. canescens</i> , Bl. |
| <i>S. cuneatum</i> , Moench. |
| <i>S. Heynii</i> , Roem. |
| <i>S. pinnatifidum</i> and <i>agreste</i> , Roth. |

It has been wrongly identified by some authors with the *Gudakamai* of the Bengalis. The *Gudakamai*, however, is *S. nigrum*, as stated under that species.

The fruits are used in curries, and it must have been known to the Sanskrit authors as early as the Brinjal, for under the list of foods prohibited of particular lunations both this and the Brinjal occur.—*Journal of the Agri-Horticultural Society of India.*

(To be concluded.)

TEA PLANTING THIRTY-FIVE YEARS AGO.

[By an Old Planter.]

Much has been written about the first efforts to establish the tea industry in India, but chiefly in official papers and in language too technical to excite more than a passing interest, and as most of the earlier pioneers have died out or retired, upon what not a few dividendless shareholders are wont to stigmatise as their ill-gotten gains, few have the slightest idea of how many of the older plantations were formed, the *shokes* and vagaries of those who opened them, what led first to the rush up Assam way, the crash of 1866. and the many ups and downs that have attended on the industry since. Of course, the old Government garden in Sibsaugor, as every one knows (or ought to) formed the pioneer or Assam Company, though the Saharunpore plantation in the N. W., stocked with seed from China by Mr. Fortune, was looked upon as the guide for all matters pertaining to planting and manufacture; we may remark, parenthetically, it would perhaps have been better if Dr. Jamieson, the Superintendent, had not compiled that almost forgotten record No. XXV., which, like most amateur essays, put us all wrong from the commencement. However, the above preliminary gallop must be curtailed.

Those who journey to what was considered, six and thirty years ago, the Eastern Eldorado, have but a faint idea of how the land of promise was reached. True, some ancient Government Steamers ran at odd times up the Brahmaputra, but the journey was chiefly performed by boat, the emigrant embarking from the Chitpore canal, then the main drain of Calcutta. Towards the close of 1858 I began my pilgrimage thither and for three weary weeks threaded the intricate water ways. It was necessary to re-provision at Khoodma; at least so said my Calcutta servant, and again at Barrisal, where I was most sumptuously entertained by the then Judge. The "dumpy levels" and yeomanry cavalry had

not then been disbanded so the *genus* loafer was unknown; hence the wayfarer throughout the country was received with the old unbounded hospitality which the now defunct Indians of the old school delighted to exercise. I tarried at Dacca, then garrisoned by H. M. 54th whose worthy Commandant I had become acquainted with a year previously. On resuming the journey I found the Moss President had restocked both my larder and cellar in the most bountiful manner and I was conducted to my boat in the witching hour, by a band of well-wishers, after one of those dinners the regiment was famous for. To cut a long story short it was on the evening of the twenty-first day I reached Chattue, having to proceed to Cherrapoonji first of all. All notice of that damp but, on the whole, delightful sanitarium—oh why was it ever abolished?—I reserve for a future paper. After a short sojourn of two days, during which I learnt my temporary destination was to be Cachar, I rode down to Sylhet for the X'mas week. That pretty little station, nestling in its embayment of wooded teelaha, was then a far different place of residence than now; there was a full staff of civilians; a wing of the gallant S. L. I., who had earned for themselves the distinction of holding the frontier tribes in check for three decades, capping their exploits, the previous year, by scattering the misguided mutineers of the 31th B. I. on the field of Latoo, but with the loss of their genial C. O. whose tomb in the cemetery, on the anniversary of his death for some years afterwards, was regularly illumined with chirags by the men of the regiment, till theirs and his fame faded gradually away into matters of frontier history. Shot through the groin, poor Byng bled to death, declining all surgical aid until his wounded men had been attended to. 1858 was the last great X'mas held in Sylhet, for there were 150 men of the Naval Brigade there, and a capital little theatre. It being before the advent of competition wallahs, at least to the penal settlement as Sylhet was then designated, all, from the Judge down, were true to the old Hailo-bury traditions, good horsemen and tolerably decent shots. Perhaps the perfunctory method of conducting public business at that time would not suit the present idea of the presiding powers, but that's a detail. More of Sylhet anon. Five days in a sumptuous pinnace took my guide, philosopher and friend, together with myself, to the highest point on the river that could be reached in our heavy, cumbersome, albeit comfortable boat, and here we expected to find our horses but, as not unfrequently happened in those days, the animals had gone to the wrong place, so a trudge of eight miles over a roadless country awaited us and, as the troubles of the past year, when my friend's regiment had saved the bustees from being looted, were still fresh in the people's memory, milk and what fruit was to be had at that season were freely tendered, payment being declined, though sundry *siccies* distributed among the children were duly appreciated. At length we reached the station and were soon comfortably housed in the hospitable bungalow of Bob Stewart, the Superintendent, as he was then called. An effort had been made to induce the hill men to come in and enter into friendly relations—an invitation not over freely responded to as the most urbulent failed to put in an appearance having sundry qualms of conscience mayhap, relating to past misdeeds. However, there was a goodly sprinkling of Munipoories, a few Burmese, with a mixed community of Kukis and representatives of sundry clans of Nagas: a few of the latter, by the way, caused the two ladies present to beat a hasty retreat, by their novel costume—or rather the want of it—for with the exception of an ivory or jade ring they were in *naturalibus puribus*. However, all went merry as the marriage bell, for the four days devoted to the mela. It may interest painters of the present day to learn that some first class ponies were brought down, the highest price then given being £60, for which I became the lucky possessor of a mouse-colored beast afterward well-known in the district as the *Muggra*, but who carried me for eight years without being a day sick or sorry.

The European patriarch of the district was an elderly Frenchman who some four years previously had come up from the Mauritius, wandering all the way to this *ultima thule* of British India to plant coffee. Failing in that he had invested the remains of his capital in rice land, becoming a zemindar in a small way, taking unto himself a Munipoorie wife, and eventually subsiding into a veritable bustee-wallah. His only outing was these annual gatherings, but as years passed on he kept to his solitary bari, communicating with no one but two of the pioneer planters, till his death in 1862. Poor old De Fonchê, I visited him once, finding that though fallen as he was, the innate politeness of his nation still shone out in vivid contrast to his meagre surrounding.

The gathering over we scattered. We planters (save the mark) hieing us off to the five factories (?) then existing. There were but six of us all told, and our qualifications for performing in an efficient manner the duties required of us may be gauged from the fact that our senior was a wild Irishman caught in a lawyer's office in Belfast, next came one from a London broker's establishment who astonished the natives by appearing for some months in full fig as if he were about to attend church; two brothers, one of whom had been quarrying limestone, the other fresh from the Australian diggings, an *ex* Bengal pilot and myself (almost direct from three years at sea). All were actuated by the best intentions but somewhat deficient in the agricultural line. The place to which I was bound necessitated our passing the night at the nearest plantation (?) and as we neared our goal my curiosity was rather excited as to what a tea garden for growing the plant was like; my previous notions being derived from such London suburban retreats as Greenwich and Kow, where you regaled on shrimps and bread and butter, in the back premises, and brought your own tea and sugar, the hostess supplying boiling water at 2d. a head. "There's the garden" said my friend who was to initiate me into the mysteries of planting; I certainly failed to detect anything in the shape of a garden, though among a sea of luxuriant waving thatching-grass the dilapidated roof of a tolerably large building towered; further progress on pony back was interrupted by a deep and exceeding muddy khal, spanned by what was known as a Kuki bridge, a delightful contrivance of two bamboos laid lengthways on others driven into the mud in the form of the letter X, there was a hand rail, deficient in parts, to keep one steady on the six-inch foot-way, but we all got over without mishap, each carrying his saddle, the ponies floundering through the slush as best they might, and on emerging from which, their heads alone shewing the real color of their hides, the rest of the body being of a dingy bluish grey. A rather sinuous path led through the grass, before mentioned, to the house, which stood on piles about three feet from the ground; there were sundry gaps in the creaking, bamboo floor which our host cautioned us against intimating he intending building a new bungalow immediately. I mentally thought it about time, for the present walls were propped up *secundum artem* by cross bamboos that endangered one's head and shins. The furniture having been derived at odd times and from various sources, had the recommendation of variety, chiefly consisting of a table formed of planks, ultimately destined to be turned into tea boxes, bedsteads of bamboo, and a few cane chairs that needed cautious sitting upon first of all, to avoid sundry obtrusive spikes that came through the seats, and needed careful balancing lest the occupant should topple suddenly over: I must not omit to mention a "Sam Slick" clock whose outward shell having succumbed to the dampness of the previous rains was neatly kept together by strips of split cane. I essayed a bath, but beyond the coolness of the water can't say I benefited much, as when emptying the garrabs over my head I became aware of little tricklets of mud coursing down my body. As I rejoined the party after my ablutions, the host remarked that the water was clearer in the rains,

and he was digging a well: I subsequently learnt he had a habit of commencing many things but seldom finished one. Tiffin over, we strolled out, and being anxious to see a veritable tea plant I asked where they were: "Oh" said the Manager, "here you are," and forthwith plunged into the grass, where after diving about for some little time I was invited to inspect a small single stemmed-shrub about a foot in height. "Oh then," said I, "tea needs shade?" "No" was the answer, "but the new buildings will require a lot of grass, so I'm letting it come on." It certainly was coming on, but the tea did not appear to be doing much in that line. I was shewn, however, several trees of the then despised wild or indigeuous tea, some twenty feet high, which the Manager, with a view to making as much out of it as possible, had rung near the ground to get the leaf from the shoots, reserving the upper branches for seed. It did not seem to strike us professional planters, that by diverting the sap the fruit would suffer. A plentiful dinner, washed down with clean water brought from a mile away, closed my first day on a tea plantation, and we were up betimes next morning to the shrill crowing of the jungle cock and sundry other novel sounds. We were soon mounted, riding through first heavy forest, then grass, an occasional clearing where tea plants in better condition, as they had plenty of room for development, being some twenty feet or thereabout apart, shewed up; then through a large Kuki poonji (ruled by a most grimy unwashed potentate called Manji How) who came out to greet us, and on hospitable thoughts intent tendered a bamboo flagon of *mood*, tippie, when fresh, by no means to be despised, though being somewhat squeamish at the time I should have preferred a cleaner drinking cup, more specially as, to shew his good will, the tenderer took first pull, previously removing a ball of some masticated delicacy from his mouth, in which by the way he only partially succeeded, ere imbibing. However, it was the custom of the country, so I explored. The worthy old fellow had evidently taken several stoups ere our arrival, for his heart was so much opened that he presented me—under the impression, from my youthful appearance and dearth of hirsute adornments, that I was one of the softer sex—with a very handsome piece of amber, much to the mirth of my companions. Settling some matters as to contracts with His Highness, we hurried on, shortly emerging on the Chuttahheel with its then enormous stretches of swamp, pool and seas of eka; the path was not over well defued and as we came on damp plaees we had to proceed rather gingerly, for, as my companion said, there was a "nag tel" somewhere about but they didn't know the exact place. "What is a *nag's tail*?" said I, imagining it to be some animal or other; I was soon to be enlightened, for suddenly my pony plunged his forequarters into the earth, up to the girths; "Jump off, jump off," cried the other fellows: I was saved the trouble, being precipitated over the struggling creature's head, where, falling sideways, I formed a stepping stone, of which he at once availed himself, as planting his forelegs on my stomach, with one desperate plunge he extricated himself from the abominable quagmire. Directing me to lie flat, my chums hauled me out on to *terra firma* by my legs; having thus had my curiosity gratified as to nag tels, we resumed our journey till we came to the crossing of the Gogra, the passage of which then lay in the open bheel. Bridges, above the water, in Cachar were then rarities, but an elephant bridge had been put down here; that is to say, the bed of the dirty stream being uncommonly boggy, sundr logs of wood had been from time to time thrown in, to form a foundation; however, suitable the dodge was to keep the ponderous beasts for which it was intended, from getting bogged, it certainly proved trying to the legs of other animals, either bipod or quadruped; however, it had to be negotiated: the heaviest of our number went first; now his beast almost disappeared under water; then scrambled on to a tolerably sound log, then got stuck between two, finally scrambling out on the off

side pretty well blown; performing much the same evolutions, we followed, I again distinguishing myself by coming over the tail this time, as my steed mounted the final log. Nothing of any consequence occurred for the rest of the ride and we were soon in the bungalow, a far superior structure than that in which the previous night had been passed. The garden? stretched away at the back while in front lay the open bheel and hard by ran the Jalingacherra, a small stream of what I did not till then believe existed in Cachar, *viz.*, clean water. Present planters might have objected to the want of such people as dhobies, sweepers, etc., as also living on their guns, the absence of bread, butter and modern adjuncts to the table—for, even did the salaries then paid admit of indulgence in such luxuries, our only means of obtaining the latter were by the monthly boat from Calcutta. The boat-club—there was then one for each station—was a great institution, and the secretary's honorary appointment by no means a sinecure. The *dak* took thirteen days from town; so by the time the invoice came in the boat should have passed all danger and when she was due expectation was on tip-toe. During the cold weather but little anxiety was manifested, but from March till October there was gloom on many faces did she not turn up, and earnest confabs as to the ark's safety. One would contemplate his dilapidated boots, pondering as to whether the expected new ones had been despatched, or whether they'd fit when they did come to hand; as for clothing, that troubled us but little, Munipoorie cloth being cheap, suitable, and uncommonly good wear. But space is limited and having brought this opening chapter down to arrival in the district, we purpose setting forth our efforts in actual tea planting and manufacture—according to our then lights—in future papers.—*The Indian Planters' Gazette.*

PLANTING IN LAGOS, WEST AFRICA.

FR M T E 31ST REPORT FOR THE QUARTER
ENDED 30TH SEPTEMBER, 1895,
ON THE BOTANIC STATION, COLONY OF LAGOS,
WE QUOTE THE FOLLOWING PASSAGE:—
ECONOMIC PLANTS.

Many new and valuable plants have been introduced during the quarter, my thanks are due to the Kew authorities, who have helped us considerably, also to other establishments who have assisted to increase our collection.

Before leaving England the Kew authorities placed in my care a Wardian case of Plants that I selected. Since then two cases of Para rubber plants. *Hevea brasiliensis* have been received these plants are no doubt among the most valuable plants introduced during the quarter.

Rubber Plants:—Most of these that have been introduced thrive exceedingly well, especially the *Manihot Glaziovii* which yields Cearar rubber, any soil appears to suit it light or heavy. The *Castilloa elastica*, West Indian, Guatemala, and Honduras rubber trees have done remarkably well, and promise to be well adapted for cultivation in this Colony, some of these have been attacked by a borer, which if not destroyed kills the tree.

Hevea Spruceana, although it has not made such robust growth as some of those previously named, yet it has done fairly well. *Ficus elastica*, splendid trees of these exist, and it should do well, as numerous species of this genus *Ficus*, are represented here.

Coffee, *Coffea liberica*. As Coffee is being largely planted in this Colony, it may prove interesting to record the following report on samples prepared at this Station, it will be seen that they are not everything that could be desired, this was duo to my departure, and being anxious to take the samples with me, before sufficient time was given for the beans to be properly dried.

MESSRS LEWIS AND PEAT TO ROYAL GARDEN, KEW.
Mining Lane, London
11th February, 1895.

Dear Sir,—We duly received your favour of the 8th instant, with two samples of Coffee which we have carefully examined, and beg to report upon the same as follows.

The sample of *Liberian* is good, both in size and appearance, but it has not been dried sufficiently the berries turning out very soft and green.

The sample marked *Abeokuta* is however smaller, in size, hard and very coated, and has the usual growth of African Coffee.

Most of the berries are shaped like *Liberian*, and only a very few are of the *Arabie* kind.

From its appearance we should think this lot must have been affected by drought or probably the soil is not moist enough which would account for its poor appearance.

Liberian Coffee can be cleaned and sized here in London, but please urge thorough drying before shipment.

For low lying districts the *Maragogipe* (Brazil) kinds promise well, and where it has been tried it has given better results than *liberian*, but both samples that you sent would find a market, especially if better cured.

We are, Dear Sir, Yours faithfully,
LEWIS & PEAT

D. Morris, Esqr., Royal Gardens, Kew.

It is a most important thing to have the beans thoroughly dried as will be seen in the report; this can easily be carried out.

Abeokuta Coffee is evidently different to the *Liberian* Coffee, when at *Abeokuta* I had an opportunity of seeing a small plot of these two varieties of Coffee growing together, and one could at once see that *Abeokuta* was very different to *Liberian* in growth and appearance.

In appendix I. I give a report on two Coffee plantations which I visited on my return from *Abeokuta*.

COFFEE PLANTATIONS IN THE COLONY OF LAGOS.

It will probably be interesting to record the advancement made in Coffee plantations in this Colony, which have originated through the establishment of this Botanical Station.

When returning from *Abeokuta* His Excellency the Acting Governor gave me permission to visit two plantations situated near the *Ado* river.

The first one I visited was at *Soto*, and is owned by the *Iaro Estates Plantations Co. Ltd.*, it was commenced in 1892, and is under the management of a European. The manager *Mr. Punch* took me round and kindly gave me quarters for the night.

Mr. Punch calculates that he has 150 acres under cultivation which includes 50,000 plants of *Coffea liberica*, these plants are in different stages of growth, 1,200 plants are three years old and are producing a fine crop of large bold berries. 5,000 trees are two years old and are in a very healthy and flourishing condition, these also are producing berries, these are doing remarkably well when taking into consideration that a crop is expected much before three years, 9,000 plants were planted out last year and 36,000 during the present year.

About 1,000 *Coffea Arabica* are planted out, these have produced good crops of berries which are of good size.

Cocoa is also being grown 4500 plants have been planted out and their appearance is everything that could be desired for young plants.

Rubber trees:—*Ceara* rubber, *Manihot Glaziovii* are also being cultivated, 700 trees have been planted out and are doing exceedingly well, a few plants of *Ficus elastica* have made considerable growth.

Fruits.—*Pine apples*, the cultivated varieties of this fruit, are grown to a small extent, and produce fruit of good size and flavour.

The work is being carried out systematically, good roads cut, shelter belts left, and planting and hoeing being attended to, and carried out properly.

The ground is kept free from weeds as much as possible.

Nurseries:—Seedling plants of Coffee in beds number about 10,000 large nurseries are being made for the reception of seeds for supplying plants to further extend the plantations, *Mr. Punch* hopes to raise 50,000 plants.

The plantations are worked at the present time by about 70 *Kroo* and *Native* labourers.

Judging from the healthy appearance of the plants, and their development since they have been planted out, the soil must be everything that could be desired, and well suited to the cultivation of Coffee and other plants.

The work is very creditable to *Mr. Punch* who takes great interest in his work, and who was pleased to see me to obtain information on many points.

I next visited the plantations the property of *A. C. Campbell & Co.*, situated on the other side of the river and about 1 hour distant from the town of *Ajilete*. I visited this plantation in the early part of 1893, and reported on it, then preparations were being made for planting out during the rains, I could see a marked improvement since my first visit, and considerable work had been done.

Mr. Campbell offered me every facility and was pleased to see me visiting the plantation. *Mr. Campbell* states that he has 160 acres under cultivation most of these being planted with *liberian* Coffee, which number about 67,000 plants, and are represented in three stages of growth, 13,000 of these plants were planted out in 1893 and are in a most flourishing condition the berries are well matured and of good size. In 1894, 22,000 *Coffea liberica* were planted out and are doing well, 32,000 have been planted in their permanent place during the present year, the plants are looking very satisfactory for the time of year.

Here also are a few plants of *Coffea Arabica*, they have done so well that *Mr. Campbell* intends to extend the plantation and plant more of this kind.

Nurseries:—About 25,000 plants of *Coffea liberica* are in beds large enough to transplant.

Vanilla:—*Vanilla planifolia*, these were obtained from the *Batanic Station* and put in a shady and cool place in the plantation, here they have made enormous growth, and have been doing so well that *Mr. Campbell* anticipates planting out an acre with this valuable plant.

Kola:—*Kola acuminata* about 600 of these have been planted under the shade of forest trees.

300 plants of *Cocoa* have also been planted out to ascertain their suitability of further cultivation.

The plantation is kept in a clean condition free from weeds, the soil here too is rich in vegetable matter, it is pure forest land, and several streams pass through the plantation, which are very useful in watering the nurseries.

The work has progressed considerably since my previous visit; and the work carried out by *Mr. Campbell* is very creditable indeed. This plantation is worked by 45 labourers.

Insects:—To a small extent these exist in both plantations' the borer is the most destructive, but there are very few plants attacked by it, on its first appearance it should be at once got rid of. *Mealy bug* and *scale* attacks some of the trees' also a peculiar caterpillar at certain season of the year devour the leaves.

H. MILLEN,

Curator, Botanic Station

Botanical Station, Ebuto Metta, 23rd October, 1895.

(To be continued.)

ADULTERATED MANURES.

A matter which has for sometime been engaging the attention of prominent members of the Planting Community in Ceylon is that of adulterated manures, and from what we hear, we should not be surprised if the Hon. Mr. Christie brought it before the Legislative Council on an early occasion. We have not before us at the moment a copy of the Agricultural Fertilizers' Act which is in force in England, but we are informed that its operations have had a very beneficial effect. Of course there is much more occasion for such a law in the old country than here on account of the extent to which artificial manures are used, there; but this is a distinctly Agricultural, community, and if it can be shown that our planters suffer in any way on account of the quality of the manures with which they are supplied, we think the Legislative Council might very well consider how far the provisions of the Home Act may be utilized here. It may be pleaded that the business in manures here at present is very small. Granted that it is, is that any reason why the business may not develop?; and is it not wiser to take protective measures in time than wait until the evils have arisen? By some we know it is felt that there will be a difficulty about securing a sufficiently independent man to act as chief analyst under such an Ordinance as the Act that has been passed in England. Difficulties exist in order to be surmounted, and we cannot think that the one mentioned is an insuperable one. In this connection the name of Mr. Cochran naturally occurs to us. Of large experience in analytical work and proved ability, he is, we believe, sufficiently independent in character and position to perform with satisfaction what may be required of him under the provisions of such an Ordinance as we are referring to; and we are certain that if he were sounded on the subject it would be found that the expense of carrying out the law so far as his work is concerned, would be comparatively trifling. A well-known planting colonist of considerable standing in discussing this matter was most emphatic in expressing the opinion that manure was as essential to the success of the planting industry here as it was to agriculture at home and that manure dealers should be bound to sell on analysis,—adding “the way we are practically swindled at present is monstrous.” The case of a planter whose experience in purchasing manure has left him “a sadder and wiser” man has been mentioned to us. According to our information a certain firm handed to him an analysis showing 2.30 per cent sand in the manure and said that what they would supply would approximate to this, though not prepared to guarantee the analysis. Out of a large parcel purchased on the strength of this, four analyses were made which showed the per centage of sand to range from 28 per cent to 35 per cent. Legal advice was taken on the matter, and we understand that it was stated that no guarantee having been given no rebate could be allowed. We merely give the alleged facts as they have been brought to our notice, and we shall look forward with much interest to the decision in the case which we understand will come before the Kandy Court at an early date. The case will no doubt be regarded as a test one, and show whether the ordinary law can be relied upon to protect planters in transactions of this nature. In the meantime it is well, we think, that public attention should be directed to the advisability

of provisions like those in the Fertilizers' Act being applied to Ceylon, and we shall be glad to hear what our planting correspondents have to say on the subject.

LADY BIRDS.

We are glad to be able to publish the following extremely interesting notes by Mr. H. O. Newport, Honorary Secretary of the Lower Pulneys Association. The thorough manner in which he is pursuing his investigations is worthy of all praise, and in view of the possible enormous value of such research, the need of an entomological expert must be patent to all:—

NOTES ON LADY BIRDS AND COFFEE BUG ON THE LOWER PULNEYS.

The following letters that I have lately received from Mr. Waterhouse and Professor Tryon are of sufficient interest to publish, I think.

Mr. Charles O. Waterhouse, of the British Natural History, Museum, does little more than corroborate Mr. Alcock's identification of the Lady bird, *Chilocorus nigritus*, but Professor Tryon, of the Department of Agriculture of Brisbane, gives a lot of very interesting information.

The reason why the specimens of *Cryptolæmus Montrouzeri* and *Rhizobius Ventralis* have not come is here explained.

With regard to *Chilocorus nigritus*, so far as experiments have gone up to date, they have been absolutely unsuccessfully tried upon both the Brown bug (*Lecanium coffee*) and the White or Mealy bug (*Pseudococcus adonidum*). The Lady birds have in the case of the former refused to touch the scales. This is only natural, as it is only the larger and stronger Lady birds that do prey upon the hard shelled scales, to which class *Lecanium coffee* belongs, and there are not many Lady birds that will do so at all. There are other flies that do so, but these are more of the nature of *Ichneumonidon* and do but little good I am afraid.

In the case of the Mealy bug, *Pseudococcus adonidum*, some of these scales were put into the bottle containing the *Chilocorus nigritus*. The Lady birds had for two or three days previously not had any food, and on this scale being put with them attacked it at once, but only devoured a very few and shortly afterwards died. Some were let free upon some Atti trees that were covered with this scale, but these flew up to the tops of the trees and were lost sight of. Experiments are being carried on, but from what I have seen, I doubt if *Chilocorus nigritus* will prey upon any of our coffee scales but the one I first observed it upon.

The *Pseudococcus adonidum*, however, does not do one tithe of the damage to coffee that any of the other scales do, and of these especially *Lecanium viridi* which has so rapidly increased in S India during the past year.

One Lady bird and several species of small yellow or parti-coloured flies have been reported to prey upon the Brown bug *Lecanium coffee* and one Lady bird and several more flies upon the White bug *Pseudococcus adonidum*. One or two other predaceous insects have also been reported to prey upon the coffee louse (*aphis coffee*) and tea scale bug (*Chinaspis theae*), but so far as I can gather none have been reported as destroying either *Lecanium nigritum*, *Dactylopius adonidum*; or the Green bug *Lecanium viridi*, except the Black Lady bird *Chilocorus nigritus*.

This Lady bird has, I am glad to say, increased rapidly on this Estate during the past month. I have observed it in all three stages of eggs, larvæ and mature insects upon the coffee. These are doing good work, but are not increasing as rapidly as I should like to see them, and certainly not as rapidly as either of the two Australian Lady birds did in Hawaii.

When the *Cryptolæmus Montrouzeri* was introduced into Hawaii first, some pains had to be taken to pro-

fect. them and careful notice taken of their habits and movements to assist and make sure of their rapid propagation and increase. So far nothing has been done with *Chilocorus nigritus*. Whether the slow increase is due to the presence of a parasite or to other natural causes, I cannot say. I have never, in my observations, seen more than five or six eggs together that have been laid by the Lady birds, and this may be a reason, but until an expert entomologist looks into the matter, this point will not be satisfactorily settled.

It appears from Professor Tryon's letter that this is a bad year for Lady birds in Australia, and until we have the opinion of an expert to the contrary, may conclude that the 'exceptional meteorological conditions' Professor Tryon speaks of may have been present in India also. *Chilocorus nigritus* on the Lower Pulneys have increased to a great extent since first noticed, and so far as I can tell as fast as could be expected, without any protection of any sort, and if they continue to increase a little while longer will do all that is expected, and hoped of them.

With regard to the Ceylon Green bug (*Lecanium viridi*), it appears, from notes on the subject I have obtained from the India Museum, that hitherto no male has been observed. Mr. E. E. Green in his Life-History of this scale (*Lecanium viridi*) says:—

"The male insect is at present unknown. It is probable that the insects now existing, though externally resembling the female form, are asexual, and that their broods are produced by the phenomenon known as "Parthenogenesis, by which several successive generations are fertile without the aid of the male element (as is known to occur in the development of Aphis and a few allied insects)." It may, therefore, be presumed that this pest will appear and disappear again at regular intervals probably of some years' duration, and that when the male element becomes necessary again, the scale will die off, or disappear, leaving only a very few living to perpetuate the species which will again after due season becomes asexual and propagate in very large numbers. It is 10 to 15 years since greenscale bug did much damage in Ceylon, and so far as is known was reported in S. India for the first time last year. How long the bug remained in Ceylon is difficult to say, as its natural food, coffee, was probably removed before it had naturally disappeared, but we may reasonably hope, I think, that in a year or within a few years time, this pest will disappear as rapidly as it appeared, and that we shall then be free of it for another long term of years.

With the many insects that are reported as preying upon various of our scale pests—a list of which I give below—as far as I can ascertain no experiments have been carried out or endeavours made to propagate any one with the object of exterminating coccids.

The following list will show that we have several indigenous Lady birds and many flies that will and do prey upon plant lice and scale, the examination of which, together with the introduction of well-known foreign insects, would surely give an entomologist plenty to do and sufficient material to work upon to ensure a satisfactory result. If our indigenous Lady birds with ordinary care are not found to propagate sufficiently fast, the imported Lady birds can, as has been shown, be propagated with due care.

List of coffee scales, &c., and predaceous insects.

Brown Bug— <i>Lecanium coffee</i>	=	<i>Chilocorus circum-</i>
		<i>datus</i> , Lady bird.

	<i>theoe</i> . Fly.

Coffee Bug—*Dac'yllopius adonidum*.

Black Bug—*Lecanium nigrum*.

India Museum Notes, Vol. II., No. 6. Howard O. Newport, Honorary Secretary, Lower Pulney Planters' Association, 15th October 1896.

Letter from Cash O. Waterhouse to H. O. Newport, dated British Museum (Natural History), Cromwell Road, London, S.W., September 7th, 1896.

Dear Sir,—In reply to your letter of 11th August, I beg to inform you that the Lady birds sent are to the best of my judgment *Chilocorus Nigritus*, Fabr. *Cryptolacmus Montrouzeri* and *Rhizobius Ventralis* belong to the same family, but are both quite distinct from your beetle. I can give you no information respecting the scale insect at present. I am, dear Sir, Yours truly, (Signed) CHAS O. WATERHOUSE.

Letter from Professor Henry Tryon, Queensland, Department of Agriculture, Brisbane, to Howard O. Newport, Esq., Honorary Secretary, Lower Pulneys Planters' Association, Dindigul, S. India, dated 7th September 1896.

Dear Sir,—I have delayed replying to your letter of 15th June until now, having hoped in the meantime to have received additional specimens of the coffee-tree scale insects, concerning which you have consulted me; those you have sent not being in a condition suitable for accurate investigation owing to their having been badly molded. However, as you write to me again on the subject, under date of 11th August, I will no longer delay communicating what I have to say in the matter.

The "smaller almost transparent light green scale" that appeared upon the trees during the "hot months of March, April and May, but disappeared again when the rains came on in June and July" is, I presume, the insect that I have met with upon the coffee leaves you have sent. If so, I may state that this is with little doubt the coccus that Mr. E. E. Green has described under the name *Lecanium viridi*. This species is recognisable owing to the presence of a series of branched appendages of microscopic dimensions that occur along the margin and which are not difficult of demonstration.

The second variety of scale that you mention, but neither describe nor designate, I have however failed to meet with in your consignment and therefore cannot now treat of. But I may remark that I have detected, upon some leafless branchlets, from which I presume the *Girillea* leaves—that you also send—have become detached and which therefore may too belong to this shade tree, numerous elevated rounded black bodies. These may have formerly been scale insects, but at the time of their receipt were merely masses of fungus having blackish-brown spawn-threads and bipartite spores.

I have little doubt but that the green bug (*Lecanium viridi*), as are other members of the genus to which it belongs, would be held in check by either of two of our scymnid beetles—*Cryptolacmus Montrouzeri* or *Rhizobius Ventralis*—a consignment of both of these predaceous insects I had expected to have placed at your disposal ere this; but it has unfortunately happened that owing to exceptional meteorological conditions that have been experienced during our winter months, these two

insects—that are usually plentiful—are comparatively scarce, so that the obtainment of an adequate experimental shipment would now involve three or four days continuous labour, *i.e.*, the expenditure of more time than I can at present devote to this business.

Past experience however leads me to conclude that this scarcity is only a temporary one. Meanwhile it is gratifying to learn (though I still consider myself pledged to assist you) that you have in your midst an Indian insect that you have found to be destructive to the green bug in a manner similar to that which it was hoped the Queensland Lady birds would display.

I may inform you then, in conclusion, that these Lady birds that you send, and that you have observed "feeding on the green bug on the Coffee Bushes" have been examined by me with much interest, and I must congratulate you on the discovery of an insect of such great economic importance. At first I thought they were examples of a variety of the European and Asiatic *Exochomus nigromaculatus* Goeze named by Erichson *nigripennis*; but the structural features that they manifest clearly locate them in the genus *Orcus*. This being so, I am inclined to think that the species is undescribed: but I have not access to the most recent literature relating to Indian Coleoptera, and, therefore, cannot pronounce on this point with certainty. Doubtless, however, its habit of consuming *Lecanium viridi* has not hitherto been observed or if so recorded.

We have a related though a quite distinct species of *Orcus* inhabiting Queensland from Keppel Bay northwards that is a formidable enemy of scale insects—especially feeding upon the species of *Mytilaspis* and *Aspidiotus* that injuriously affect citraceous trees. And other congeners, that however present marked dissimilarity both in livery and pattern, but that are also most useful in destroying coccus insects, occur in the latitude of Brisbane and elsewhere in the colony.

From the foregoing statement you will have also inferred that your Lady bird is neither of those you mention, *i.e.*, *Rhizobius* or *Ventralis Cryptolæmus Montrouzeri*. Indeed from both of them it may be once distinguished at a glance in being glossy and hairless, instead of being dull and copiously clothed with a short pubescence.

Apologising for the length of this communication, I am, dear Sir, Your faithfully, (Signed) HENRY TRYON, *Entomologist*.

P.S.—Your last consignment arrived in excellent order. I hope you will continue to send me examples of injurious insects. When it is necessary to send me them occurring upon their food plants, as in the case of scale insects, the specimens should be dried (not desiccated) prior to being packed. All specimens (except butterflies and moths) should preferably be first dipped in a weak solution of corrosive sublimate in alcohol.

Letter from H. O. Newport to Professor Henry Tryon, Department of Agriculture Brisbane Queensland, Pillavaly Estate, Ahtoor P. O. Madura District, dated 13th October 1896.

Dear Sir,—I am in receipt of your letter of the 7th September 1896, for which, and all the information it contains, I am much indebted to you.

The green bug or coffee scale that I forwarded to you I have little doubt is as you say *Lecanium viridi*. The black scale that I sent upon some cuttings of the *Grevillea robusta*, I am inclined to think may be *Lecanium nigrum*, but am not at all sure of this. I will however take the liberty of sending you some more specimens of that, and any other coffee scale I can find, packed in testitubes with weak spirit as I am doing at the request of the Superintendent of the Indian Museum, Calcutta, and trust that thus preserved they will reach you safely and in good condition.

The black Lady bird, specimens of which I sent you, I have obtained an identification of from Mr. A. Alcock, of the India Museum, Calcutta, as *Chilocorus nigritus*, and have had this subsequently confirmed by Mr. Waterhouse, of the British Natural History Museum, London. Mr. Waterhouse says that *Cryptolæmus Montrouzeri* and *Rhizobius Ventralis* belong to the same family, but are both quite distinct from my beetle. He gives no further particulars however,

It appears that this black Lady bird is known therefore; but is peculiar to India I believe. Another Lady bird *Chilocorus circumdatus* has been reported to feed upon the *Lecanium coffeæ*: but the fact of *Chilocorus nigritus* preying upon any of these scales does not appear to have been noticed or reported upon before this.

I thank you for your congratulations, and hope this discovery may be of use to the planting community here. I brought the matter to notice in a paper I read before the United Planters' Association of Southern India at the Annual General Meeting in August last, and hope they will now take the matter up and engage the services of some entomological expert to carry on further experiments.

As I am not a Naturalist, I feel the subject is getting beyond me. Since last writing to you the green scale *Lecanium viridi* has, I am sorry to say, very much increased in this district. The Lady birds have also increased and are doing good work in a small way but are not increasing as I should like to see them, nor are they increasing in anything like the proportions *Rhizobius Ventralis* or *Cryptolæmus Montrouzeri* must have done in Hawaii.

Whether this slow increase points to the presence of a parasite or is due to other causes I cannot yet say. I am still carrying on experiments, but find myself very much handicapped by want of knowledge of the subjects and experience.

I hope soon to receive the consignments of *Rhizobius Ventralis* and *Cryptolæmus Montrouzeri* you speak of and to experiment with them.

I am confident that these insects will do all we require in eradicating, or at any rate keeping the pernicious scales in check, if we can only propagate them in sufficient numbers.

If the slow rate of increase of the *Chilocorus nigritus* is due to the presence of an *ichneumonid* or parasite, do you think it likely that that same parasite would give us any trouble by attacking and reducing in numbers either *Rhizobius Ventralis* or *Cryptolæmus Montrouzeri* if we imported them?

The presence of a parasite very much complicates matters, and for this reason particularly I am urging the engagement of an entomological specialist. I did what I could at the U. P. A. S. I. Meeting, but for want of funds the matter had to be temporarily dropped.

I am now in correspondence with the Honorary Secretaries of other Planters' Associations endeavouring to start a fund in conjunction with the Ceylon and Singapore Coffee Planters to engage the services of Professor Koebele or some other expert for this work.

Apologising for the length of this letter, I am sir, yours faithfully, (Signed) HOWARD O. NEWPORT, Honorary Secretary, the Lower Pulneys Planters' Association, Dindigul.—*Planting Opinion*, Nov. 21.

AFRICANA.

ROADS AND RAILWAYS.

Every year, when crop comes round, the transport difficulty becomes more acute. Want of good roads still prevents the general use of ox-waggons. The planter has to compete with the trading companies and the Administration for human carriage. Often he has to take the sorely needed labour from estate-work and send them *tenga-tenga* and still nothing seems to be done to mend this deplorable state of matters. If our Chinde correspondent is right and some of the three millions voted for the Uganda railway is to be applied in B. C. A. for railway purposes then we will have much cause for thankfulness. Most of us are wondering why our railway schemes are still so much in the air. If a serious block is not to occur soon then a railway must be put in hand early next year. According to all reports the Quilimane-Ruo line is being started in earnest and it is not consonant with our boasted energy that our line should still be in abeyance. There is no question but that it will

pay; the route presents no insuperable difficulties; and the time is ripe for it. Meanwhile the need for roads is as urgent as ever. Why can Government not get out a military engineer either from home or from India instead of frittering away money in amateur attempts by men who know nothing whatever about roadmaking. One of our Indian Officers might easily be picked from the engineers and then we would be able to get roads and not useless tracks. Money is, in many cases, simply being wasted on so-called roads which will never be fit for vehicular traffic. Once a road is surveyed it would be better, too, to get it made by contract and let the Government cease to compete with merchants and planters for labour.

THE PRESERVATION OF GAME.

We have, of late, had more to criticise than to praise in the action of the Administration so that it is a pleasure to be able to commend the proclamation in the last *Gazette* as to the preservation of the game in what used to be known as the elephant marsh. The elephant marsh being so easily reached from Chinde is a favourite hunting-ground, but unfortunately the hunting has not always been carried on in a sportsmanlike manner. Game is sometimes shot irrespective of size, sex, or condition; and often the carcasses are left to the vultures and the hyenas. The declaring of this area a preserve will therefore commend itself to all right thinking persons. There is, moreover, another aspect of the matter. It may yet be found possible to utilise the zebra, if not the buffalo, as draft animals and this preserve will afford the material to experiment upon. Both the African elephant and the zebra have been tamed and used and it is a pity we here in this protectorate cannot make use of their services. The African elephant, for example, would very quickly solve the transport difficulty if only someone with capital sufficient would seriously attempt to utilise it.

COMMENDABLE ENTERPRISE.

Mr. Morkel, who has started a transport service on the Blantyre-Zomba road, is now busy making drifts at all the streams and doing his best to improve the road for transport work. This is work the Administration have been urged to do again and again but as usual it has been left to private enterprise to see the improvement effected. We hope, however, for the sake of their own good name that the Administration will see that Mr. Morkel is suitably recompensed for his work, undertaken in the public behoof as much as his own. It will be remembered that Mr. Morkel successfully carried through his contract with the Transcontinental Telegraph Company when they were laying the line between Blantyre and Zomba and lately he has taken a large quantity of the Messrs. Buchanans' coffee from Zomba to Michiru. Such work as Mr. Morkel's deserves every encouragement as it sets free much needed labour for plantation and other work.

A COFFEE EXPERT.

The African Lakes' Corporation deserve the thanks of the planting community for the latest fruit of their enterprise—Mr. J. B. Ferguson of Coorg, S. India. Mr. Ferguson has been appointed to visit the various coffee plantations and to report on the prospects of the coffee-planting industry. We are sure planters all over the country will give Mr. Ferguson a warm welcome and we trust they will not be backward in stating their difficulties as only thus can we hope for much good from Mr. Ferguson's visit. We are glad to see that the "Chamber" accorded him a warm welcome and we are sure that in his journeys he will find the B.C.A. Planters as hospitable as those of any other country. So far, we understand, Mr. Ferguson's opinion of our industry here is a very favourable one. He advocates shade and manure, the former, native fig trees or the Indian Banyan tree; and the latter, bonedust and poonae. We understand his opinion of Pride of India as a shade-tree is very low.—*Central African Planter* for October.

SUGAR AND TEA.

VIEWS OF NATAL GROWERS: ON VARIOUS POINTS.

"We don't rub shoulders enough with each other" was the observation of a planter, after a long and discursive chat, the remark being prompted by the interchange of views on various topics, during which each taking part in the discussions saw matters more clearly from his neighbour's standpoint. During my visit to the North Coast I had talks on many matters, and afterwards I regretted that I had not taken note of many of the points advanced. It is impossible to remember all just now, but I purpose to give off various "ideas" as they will submit themselves to my pen. Of course, the Indian question served as a fertile topic, and the views of planters thereon cannot fail to be of value. They warmly assert that the coolie has been the greatest blessing this country ever had, for without him Natal would have stagnated. As may be expected, they resent as unjustifiable the bitter opposition manifested in Durban to the coolie, not, as it remarked—for I did not hear a single word in that respect—the opposition to the introduction of the artisan. It was pointed out that until we got railways, Durban largely depended upon the coast sugar industries, and the merchants and tradesmen were then only too pleased to compete for and get the business resulting from them. And even now, it is asserted, Durban and adjoining towns and villages profit hugely. As the result of the labours of the Indians on the estates, about £89,000 per annum is obtained from the soil. This is distributed in various ways. Supplies are drawn for the feeding of the Indians, there is transport requiring wagons to be made, machinery and appliances have to be purchased and repaired, building and other materials are necessary, ironmongery is an important item, managers and assistants have special needs, their houses have to be furnished, they and their families have to be fed and clothed, their horses require harness, their carriages need repairing from time to time, and so on. Over and above this, a large amount of freight is provided for the railway, and customs also benefit from imports. Then, as to the wages paid to the coolie labourers. I was informed that a very small amount comparatively went out of the country or was hoarded; but on the contrary, the money was spent in the Colony. This, I was assured, was corrected by one planter, who informed me that he was banker for his Indian employes, and therefore knew it to be a fact. Of course, it is also argued, that the employer spends largely of his profits in successful seasons, and that the Colony reaps the benefit. In short, it is contended that as the result of sugar, tea, and other industries, a very large sum is annually put into circulation, and, directly or indirectly, benefits everybody, it being maintained that so long as the coolie (and the white man could not possibly do his work) brings something out of the soil he is doing the Colony good, and gives scope to the merchant and tradesman to meet requirements thereby created. Now this is an assertion which is, certainly deserving of study in connection with the arguments for and against Indian immigration. While the planter strongly maintains that Indian labour immensely benefits the Colony, he is equally at one with those who object to the importation of the free Indian. This, says the planter, is the man doing the mischief, and from whom no real benefit is derivable, and agrees that, if possible, means should be adopted to check him. He not only competes, but fails to distribute his profits in the Colony. In connection with the free Indian imports, I may mention an important feature which came to my knowledge. Those agents who are importing these men are actually offering them as labourers to the planters, at a less rate and at lower wages than have to be paid for those obtained through the Indian Immigration Department. Thus it will be seen that by private enterprise Indian labourers are being brought to this Colony in competition with the official department. They are offered to the planters on an agreement for a certain number of years, such agreement to be ratified before a magistrate,

Of course, there is no authority over such men, the Protector would have nothing to do with them, and only the common law of the Colony would affect them or their employers. It is only fair to say that, despite lower wages, the planters are looking askance at these men, but they may be secured by the inexperienced. A question suggests itself in connection with these men. How will they be affected, if at all, by the new Indian Immigration Law? That law provides for re-indenture, return to India, or a penalty. How are those conditions to be applied to men introduced independently, and who, as we know, are coming in boat-loads of 300 to 500? If there is no application, it is probable there will be demand for amendment of the law to cover all Indian labourers employed on estates, farms, &c. In that way the difficulty may, perhaps, be met, but the alternative may be to drive these men to enter the competing ranks of Shopkeepers and small farmers. Anyway, this phase of the question is a new and interesting one. Amongst demands in connection with the agitation is that the duty of 3s. 6d. on sugar should be abolished. Seeing that sugar has done so well lately, this seems a fair and equitable demand, but the planter maintains that its removal would be a great mistake. The amount added to the price of their sugar is nothing but it is just sufficient to enable them to manufacture profitably. The amount of the duty does not go into their pockets, but the exchequer of the Colony gets the benefit. Its removal would have the effect of introducing an inferior sugar into the market, whereas at present the consumer gets a good article at a reasonable rate. Abolish it and harm is done to a big industry, which may be crippled by competition, with the result that up would go the price of the imported and inferior and foreign-made article. Where, then, the benefit? The same contention is made in regard to tea. Remove the 6d. duty, and you admit all sorts of rubbish (some of it now is bad enough in all conscience!), and at no cheaper price than that now required for the pure and unadulterated colonial article. Further, the tea industry would be crippled, the Colony at the same time losing trade benefits and the revenue the exchequer now derives from the duty. It is thought by some people that the planter pockets the equivalent of the duty on tea, but he does nothing of the kind. He charges the lowest level price for his tea, the consumer gets it cheaply, and the colonial revenue benefits by the duty on the imported article. On this point, and on the great benefit the Colony has derived from the introduction of the Indian, the planter is unswervingly strong, and asserts that those who are so warm in the Indian agitation do not look all round the question, being rather led away by fancied or at best minor grievances, instead of weighing the undeniably great advantages, as against the minor drawbacks. In comparison, the Colony (whatever the planter may have done) has, it is held, been enormously benefited, and that the introduction of the Indian labourer was the best thing that Colony ever did. In proof of the folly of prohibition, Queensland is pointed to, where Indian labour was stopped and Kanaka labour tried instead. What was the result? So serious were the effects of the banishment, so rapidly did the industry decline, so disastrous were the effects on trade generally, that the very man who introduced the expulsion measure moved for its repeal, for reversal of his policy, and for a return to former conditions. Leaving that branch of the question, and going to another as affecting colonial industry; the question was asked why Natal tea was not pushed in the English market, where Indian and Ceylon teas have done so well. That at once brought out another reason why the Natal growers should be encouraged as far as can legitimately be done. "Give us the same conditions as our competitors in other parts of the world," said one, "and we will compete." Enquiry as to the disadvantage led to the information that currency affected the question to a very important extent. In Ceylon the Indian labourer

is paid in rupees, and the difference between that currency and English coin is often considerable. This enables the grower to send his tea to the English market, for which, of course, he is paid in English money. Were it not for this margin in the cost of labour it is very doubtful whether tea-growing would pay in Ceylon and India, and it is this advantage which tells against the Natal grower, who has to pay for his labour in British coin. Where hundreds of Indian labourers are concerned, it will be seen that the difference in the aggregate is considerable, and that it precludes the Natal grower from sending his tea to the English market with any prospect of profit. As a fact, the competition in that market is exceedingly severe, and when, in addition, the comparative high cost of shipping, and the effects of drought and locusts on food crops are considered, it is evident the disabilities are not of a light character. There is no question as to the suitability of the soil to grow good tea. That has been abundantly proved, and no one can doubt it after gazing upon the hundreds and thousands of acres in Victoria County covered with the pretty and luxuriant tea plant, and seeing the leaf turned into the article of commerce. The Cape and the Transvaal have, therefore, to be looked to as the markets of the future. These again are affected by Customs duties, but, had the Natal Government's proposals at the last Customs Conference been accepted, the barrier would by free trade in South African products have been removed, each Colony and State would have been benefited, and at least two important industries in Natal would have been immensely encouraged. It is hoped that the time is not far distant when an understanding will be arrived at by which South African neighbours will be enabled to supply each other freely with articles of commerce that each requires. The foregoing is given—without implying occurrence with the views expressed—as an exposition of some of the arguments of colonists prominently connected with industrial enterprise in Natal.—C.W.—*Natal Mercury*, Oct. 23.

TEA COMPANY MEETINGS.

THE LANKA PLANTATIONS COMPANY, LIMITED.

The ordinary general meeting of the shareholders of this company was held at the offices, 12, Fenchurch Street, on Wednesday last.

The Chair was occupied by Mr. George Allen, chairman of the directors, and amongst those present were Messrs. William Austin, Henry Bois, and Edward Pettit, directors.

The Secretary (Mr. Robertson) read the notice convening the meeting, and the minutes of the previous meeting having been read and confirmed, the Chairman said,

Gentlemen,—I presume you will take the report, which I hope you will take fairly satisfactory, as read. Referring to the paragraphs given therein in their order you will observe first that the coffee crop shipped to London was 605 cwt., against 1,371 cwt. last year, a deficiency of 766 cwt., and a deficiency in cash of £3,807. In 1894 we received about the same as now, and I hope that next year the figures will be equal to those of 1895, although I doubt it. The coffee grown on the estates is certainly as fine as any grown in Ceylon. With regard to cocoa, we now have 150 acres more than in 1895, the cost of the land and the new planting having been charged to capital account. Prices have been somewhat lower. We have always produced an extremely good crop from the estate, and continue to add to the acreage by buying small bits of land from the natives as opportunity occurs. Referring to tea, the next item in the report, I may mention that the increase in the quantity received from the estates during the year as compared with last year was 118 113 lb., representing an increase in cash of £4,460. Our teas always maintain good prices, and I think that great credit is due to our Superintendents for having so well maintained the quality of the teas. With regard to the statement showing the acreage of

the Company's estates you will observe they are as follows:—Coffee, 210 acres; tea, 2,166 acres; cocoa, 671 acres; grass, 163 acres; chena, 579 acres; forest and timber trees, 511 acres; making a total of 4,303½ acres. I will now deal with the profits for the past year. These, as you will see by the report, have been £10,708 1s 1d, to which must be added the sum of £1,270 18s 10d. the balance brought forward from the year 1894-5, making together £11,978 19s 11d. In my remarks last year I referred somewhat fully to the suspense account. As I at the time explained, this account was brought about by the substitution of Cinchona for Coffee and Tea for Cinchona. This has been done at a cost of £21,704 14s 7d, of which £14,056 8s 8d has been paid. The account is being reduced every year, and I hope you will consider the result satisfactory. In dealing with it I think we have been a little too virtuous. This year, for instance, in my opinion, £150 of the amount charged to this account might have been charged to capital, instead of to the suspense account. To those who have bought shares in the Company at a low rate, it does not much matter whether items are charged to the suspense or capital account, but it is only right that Shareholders who have been through the brunt of the battle should share in dividends fairly earned. I may state that during the past six years our dividends have been as follows:—1891, 2½ per cent; 1892, 1½ per cent; 1893, 3 per cent; 1894, 2 per cent; 1895, 4 per cent; and this year 5 per cent. With regard to the future prospects of tea, our principal customers abroad have been Russia, Canada, and America, and in all those countries the popularity of Indian and Ceylon tea is growing fast. I read in the report of Messrs. George White and Company that in the year ending 31st July last there were 81½ million pounds against 75 millions in 1894, the exports being 7¼ millions in 1896. It is gratifying to find that the exports of Ceylon Tea in 1896 was 7¼ million pounds of Indian Tea. I will read you an extract from a letter by Mr. Mackenzie which appeared in the *Home and Colonial Mail* of June 5. With regard to Indian and Ceylon tea in America Mr. Mackenzie says:—"The increase in the imports of British-grown teas into North America from 5,379,542 lb. in 1894 to 9,283,144 lb. in 1895, an increase of 72 per cent, is a striking fact, and, while demonstrating the value of past efforts, gives the greatest encouragement for the future. It may be confidently anticipated that, as in the United Kingdom, so in America, Ceylon and Indian teas will now rapidly come into general use and establish for themselves a wide demand. . . . Besides general advertising, we assist by subsidies many firms who advertise in many ways—in papers and magazines, by circulars and samples, by posters and signs, and by 'demonstrations,' where girls give away tea, and advise as to method of making it, in leading shops in many towns. We have also done much at theatres, giving tea to such as care to have it between the acts; and we have a lady who attends all church and social gatherings in New York and Brooklyn, to which she can gain admittance, with a complete apparatus of urn, teapot, several dozen cups and saucers, &c. She lectures on the merits of pure machine-made tea as contrasted with the weak, washy, hand-rolled article." This, I think you will agree with me, shows the great effort which is being made to supersede Japan by better class tea. At home there is still considerable difficulty in procuring pure Ceylon tea at the stores and elsewhere. This I can only account for by the fact that, in order to keep up a certain retail price, the Ceylon tea is mixed with inferior kinds by the retailers. I shall now be pleased to answer any questions Shareholders may wish to ask, and move that the report and accounts be received and adopted.

In reply to Mr. Tye, the Chairman stated that the variety of the coffee on the estates was what remained of the old Ceylon coffee. The Liberian coffee was interlined in the cocoa.

Mr. Ford North expressed his entire satisfaction with the report, which he maintained did great

credit to the directors and managers. He was pleased to see that there had been no tendency to do away with coffee, which he believed would pay in the long run. He deprecated the existence of the suspense account. As a man of twenty years' experience in large tea concerns he had long been accustomed to see suspense accounts extinguished. In the present case he would be quite satisfied if the account was not increased.

The Chairman explained that when the suspense account was opened they issued 6 per cent. stock, which now stood at 12, and they (the directors) did not want to issue more. If they were their own masters they could charge everything against revenue, but when others had to be considered this would be decidedly unfair. This year they had to face a factory, and two or three years hence perhaps another. He considered that the expense should be charged to capital account, but circumstances might make it desirable to charge it to suspense account. Subject to this there need be no more additions to the suspense account. This year the additions had been made by the cost of fresh plant, a withering shed and timber for the new factory. He might add that if the profits had been taken from the suspense account there would have been sufficient to have paid 7½ per cent.

The following resolutions were then unanimously adopted:—

1. Proposed by the Chairman and seconded by Mr. Pettit: "That the report and accounts be received and adopted."

2. Proposed by the Chairman and seconded by Mr. Bois: "That the payment of a dividend on the 6 per cent preference shares for the six months ending December 31, 1895, be confirmed, and that for the six months ending June 30, 1896, be paid forthwith."

3. Proposed by the Chairman and seconded by Mr. Austin: "That a dividend on the ordinary shares for the year ending June 30, 1896, at the rate of 5 per cent, equal to 10s per share (free of income tax), be paid forthwith."

4. Proposed by Mr. George White and seconded by Mr. Ford North, "That Mr. Henry Bois, a director who retires on this occasion, be re-elected."

5. Proposed by Mr. Collinge and seconded by Mr. Ford North: "That Mr. William Austin, a director, who retires on this occasion, be re-elected."

6. Proposed by Mr. Collinge and seconded by Mr. Tye, "That Mr. John Smith be re-elected auditor for the year 1896-7 at the remuneration of £21."

A vote of thanks to the Chairman, Directors, and Managers of the estates in Ceylon was proposed by Mr. Ford North and seconded by Mr. Collinge.

Mr. Giles Walker expressed his pleasure at the inclusion of the Managers in the vote of thanks. He knew how hard they worked, and a recognition of this kind was sure to give a fillip to their efforts.

The Chairman having briefly responded, the proceedings terminated.

THE ASSOCIATED TEA ESTATES OF CEYLON, LIMITED.

The statutory meeting of the shareholders of this company was held at the offices of the company, 31, Billiter Buildings, on Monday last.

The chair was occupied by Sir Alexander Wilson, chairman of the directors.

The secretary having read the notice convening the meeting, the chairman said:—

Gentlemen, this is merely a formal meeting which is held within four months of the formation of the company, in accordance with the Act of Parliament. I have very little to say except that all the estates purchased by the company were transferred about the 10th of September, with the exception of Doragalla, the transfer of which was delayed on account of a marriage trust settlement on a portion of the estate, the existence of which had been overlooked by the vendor, having been originally made by him over fifty years ago. The matter has now been put right, and the necessary documents are at present

sent en route to Ceylon to enable the transfer to be completed. Our agents in Ceylon, Messrs Finlay, Muir, and Co., have now obtained control of the other four estates, and the tea of recent growth has been shipped home to the company, the first of it being printed in public auction for tomorrow. The delay with regard to the transfer of Doragalla estate has caused delay in making application to the Stock Exchange committee for a special settlement and quotation, but all the papers have now been lodged, and it is probable that the Stock Exchange committee and its meeting today will arrange the matter. The aggregate yield of all the properties up to latest advices received is satisfactory in comparison with the corresponding period of 1895, and the teas sold by the vendors, the proceeds of which, for all manufactured after the 1st of July, belong to, and will be accounted for to this company, show an advance in prices over those obtained at the time of the formation of the company. The outturn is also better, and in fact everything bids fair for smooth working. I hope to visit the estates within the next three months, having other business in the East, and to be able to give my personal views at our first ordinary general meeting. With regard to the making up of accounts and the payment of dividends, the directors have decided that the preference dividends shall be paid in two equal instalments on the 31st of March and 30th of September, which dividends will relate to the periods ending 31st of December and 30th of June, the interval of three months being necessary to get the produce home and sold and the accounts made up. I shall be pleased to answer any questions, and hope at the next meeting to have a much more interesting account to give.

In reply to a shareholder, the chairman stated that the tea which had been sold belonging to the vendor had been of good quality, and had reached higher price than was anticipated.

A vote of thanks to the chairman for presiding at the meeting, proposed by Mr. E. Loewenstein and seconded by Mr. G. W. Bake, was unanimously adopted.

The Chairman, in briefly responding, expressed the hope that, being an old tea planter, his forthcoming visit to the estates would be beneficial.

The proceedings then terminated.

[The quotation referred to above has been granted by the Stock Exchange committee, and the special settlement fixed for Nov. 18th.]—*H. and C. Mail*, November 13.

THE CEYLON HILLS TEA ESTATES COMPANY, LD.

The first general or statutory meeting of the Ceylon Hills Tea Estates Company, Ltd., was held at the offices of Messrs. Bosanquet & Co., Chatham Street, in the afternoon of Tuesday 1st Dec. Mr. J. H. Renton presided. The Directors present were Messrs. F. Liesching and W. W. Kenny, and the following shareholders were present or represented by returns:—Messrs. Delmege, Reid & Co., Mr. Harry Creasy, Mr. A. M. Caldecott-Smith, Mrs. Caldecott-Smith, Mr. R. A. Bosanquet, Mr. G. F. Traill, Mr. W. R. Alexander, Mr. James Alexander, Miss C. M. E. Alexander, Miss R. A. Alexander, Mr. W. Dougall Stuart, Rev. C. Bosanquet, Mr. F. A. Bosanquet, Q.C., Mr. E. F. Bosanquet, Mrs. R. A. Bosanquet, Mr. R. W. Wickham, Mr. N. C. Davidson,

Mr. H. CREASY proposed that the retiring Directors (Messrs. J. H. Renton, F. Liesching, and W. W. Kenny) be re-elected.

Mr. CALDECOTT-SMITH seconded.—Carried.

The CHAIRMAN laid a short account of the position and prospects of the company before the meeting; and re-election of Directors being the only business the proceedings ended.

THE FERNLANDS TEA COMPANY, LIMITED.

This Company is being registered by Messrs de Saram with a capital of R275,000 with the object primarily of acquiring the Fernlands and Eton Estates at Pundaluoya for £16,000 sterling. The signatories to the memorandum published in tonight's *Gazette* are:—Isabella Frances Green, Edward Ernest Green, Helen Mary Green, Geo. H. Green, Arthur P. Green, Staniforth Green, H. L. Egan.

INDIA-RUBBER.

India-Rubber is in a fair way to become one of the prime necessities of civilisation. Numberless human beings, in the class which could not afford wet-nurses, owe their lives to the feeding-bottle. Everybody knows that in the last five years the use of pneumatic tyres for cycles and solid rubber tyres for horse-vehicles has enormously increased our consumption of this article; but, quite apart from that more obvious fact, india-rubber is daily being introduced more and more into all sorts of machinery. Highly competent judges say that if the output could be doubled within a year, so many new applications of the material would instantly arise, that the price would not fall appreciably. As a matter of fact, the export of Para rubber has increased within the last twenty-five years from 5,600 tons to 20,000 tons; and the price fetched by the best quality has risen from 2s. to 3s. a pound. It is the one jungle product which society finds indispensable. Hundreds of men have racked their brains to produce a substitute, but none has in the least degree succeeded; and such attempts must be permanently discouraged by the knowledge that india-rubber exists in limitless profusion upon known spots of the world's surface which may at any time be made accessible. In any of the swampy equatorial regions, where vegetation grows rank and sappy, so that a knife will slash through branches as if they were made of cheese, there is pretty certain to occur some one or two of the score of trees which produce rubber. While forests of them are known to exist in Central Africa, only waiting to be tapped. But the regions which produce them are precisely the regions most deadly to the white man; and when the rubber is made it has to come to the coast on the heads of negroes, and will not pay the cost of transport. When an accessible forest is discovered it pays like a goldmine. A tree was discovered near Lagos which was believed to produce rubber; specimens of bark and foliage went home to Kew and the authorities pronounced it the right thing. In 1895 the export began, and amounted in the year to 2,263 tons, with a value of £270,000 in round figures.

India-rubber would seem to be the one certain source of wealth now locked up in Central Africa, and perhaps the most valuable thing that the region produces or can produce. Ivory is only a fancy article, and palm-oil has many substitutes. Gold no doubt exists there, but in the first place, it is doubtful whether the pure negro can be made into a miner; and in the second, gold is to be got in regions where white men can live. It seems, therefore, as if the special function of the tropics just now was to produce India-rubber, which is wanted everywhere and cannot be grown elsewhere. No cultivation is needed; Nature requires of man very little skill, scarcely any exertion, and only a reasonable avoidance of waste. Yet this is asking more than the African negro is at present able to give. The great rubber-producing region of the world is the basin of the Amazon, which yields about two-thirds of the entire annual output. The quality of this rubber is immensely superior to all others; the best Para will fetch in England as much as 3s. 6d. a pound; the worst African goes for under a shilling. Brazil has, of course, an immense advantage in its great water-

way; ocean-going steamers run twelve hundred miles up the Amazon, whereas every African river except the Congo has a bar at its mouth, and cataracts not far distant from the coast-line. On the other hand, the forests in Brazil seem even more impenetrable than in Africa. Not even such roadways as the African man-paths can be maintained against the encroachment of the jungle. But the native Brazilian race is incomparably more intelligent than the negro. Their caoutchouc is better prepared, and what is far more important, they farm the trees as carefully as the Red Indians used to farm the beaver. In Africa the rubber is generally produced not from a forest tree, as in Brazil, but from the *Landolphia*, which is a climbing shrub. The negroes deal drastically with this, and simply cut it down, and then get what milk they can out of it. So year by year the rubber-trees are destroyed, and year by year the negroes have to go further afield to seek them. If they are left to themselves they simply cease to produce india-rubber, and there is an end of it. If they have the fortune to live in the happy Congo State a certain amount of the stuff is exacted annually from each village; when the trees within each are exhausted, the collector comes round, finds no rubber, and goes home with a string of ears and noses instead. No doubt the West Coast negro is a trying person to deal with, but these in thods have been so long employed unsuccessfully that civilisation, we hope, may discover a better way, and educate the black man instead of torturing him. One is sorry, therefore, to hear that at Lagos, where the rubber is being produced from a forest tree, the *Kicksia*, the natives have been allowed to over-drain the trees of their milky sap and stop its production. The supply of rubber-producing plants in Central Africa is practically inexhaustible; but the number of places where they exist within easy distance of some export station is small, so far as our present knowledge goes. Yet for the present, speculators will probably hasten to be rich and if they hit upon a forest will treat it like a mine, anxious simply to take out the maximum at the minimum of cost.

Whether our State, or any other, will, ever make this a great branch of its tropical forestry remains to be seen. The Germans, with their usual thoroughness, have a strong scientific staff at the Cameroons. The English, in their usual makeshift way, content themselves with sending home to Kew for suggestions. But the Government of India have at least tried an experiment upon the great scale. No private firm, however wealthy, would embark upon the cultivation of indiarubber; the trees take a matter of twenty years before they can produce a penny-worth. In addition to that, cultivation must occupy a huge extent of ground of such a nature that no European can enter it during the rainy season, and where the growth is so thick that twenty men might be tapping trees within a mile of the ranger, and he none the wiser. Nevertheless, the Indian Government have a nursery of Para rubber-trees in Assam, extending over two hundred square miles, which will in time begin to yield; and if any department can control such a farm the Indian Woods and Forests will. Yet it seems, perhaps, a likelier scheme to carry out Sir Henry Johnson's general policy in this particular, and organise under Indian surveyors a forestry department in East Africa, where the trees exist in plenty. The industry is of course not confined to Africa and South America; rubber comes from Assam, Rangoon, Borneo, Penang, and Madagascar, amongst other places, but last year's export from Lagos more than doubled the united output of all those that have been named. If we are to stay in equatorial Africa, it will be a satisfaction to think that we can make some advantage out of it. What it costs to keep slavery in check from Uganda to Coomassie only mothers know who have sons in those happy regions. Civilisation is spending a great deal of energy on Africa, and one will be glad to find that Africa makes some return, if it be only to lower the price of pneumatic tyres.—*Spectator*.

WE-OYA TEA COMPANY, LIMITED.

At a meeting of the Shareholders of the above-named Company, held on Monday 7th December 1896, the following were present:—Directors; Mr. E. J. Young in the Chair, Messrs. W. J. Smith & E. S. Anderson.

Messrs. J. D. Balfour, A. Thomson, E. H. A. Vanderspar, G. Vanderspar. Mr. C. J. Donald acted as Secretary.

The following were represented by their Attorneys:—Messrs. C. Young, A. Morrison, W. Cooke, Major G. L. Gwatkin, Mrs. E. C. Baillie.

The following were represented by proxies:—Messrs. W. R. Tatham, J. Polson, Sir J. W. Bonser, D. Edwards, F. G. A. Lane, G. Pyper, W. H. P. Spurway, A. L. Hine Haycock, H. S. Rix, Mrs. E. C. Baillie, Mrs. A. S. Donald.

The following resolutions were carried:—

1. "That the following resolution passed at the Extraordinary General Meeting of the Company held on the 19th day of November 1896, viz: That the We-Oya Tea Company Limited be wound up voluntarily be, and the same is hereby confirmed as a Special Resolution."

2. (a) "That George Hay Alston of Colombo, Merchant, be and he is hereby appointed Liquidator of the We-Oya Tea Company, Limited."

(b) That the said Liquidator be paid a remuneration of one-half per cent on the price realised by sale of the Company's estates, in addition to all general Agency charges and commission similar to those at present paid by the Company."

THE YATIYANTOTA TEA COMPANY LIMITED.

At a meeting of the Shareholders of the above-named Company, held on Monday, 7th December 1896, the following were present:—Directors; Mr. W. D. Gibbon in the Chair, and Messrs. A. Thomson, E. S. Anderson, Mr. E. H. A. Vanderspar.

The following Shareholders were represented by the holders of their Powers of Attorney:—Mr. Chas. Young, by Mr. E. J. Young, Mr. W. H. G. Duncan by Mr. A. Thomson, Mr. G. W. Carlyon by Mr. A. Thomson, Mrs. L. T. Carlyon by Mr. A. Thomson, Mr. Jno. McLiesh by Mr. J. D. W. Wilson, Mr. J. K. Morrison by Mr. J. D. W. Wilson.

The following shareholder was represented by proxy—Sir J. W. Bonser.

The following resolutions were carried:—1. "That the following resolution passed at the extraordinary general meeting of the Company held on the 19th day of November 1896, viz:—That the Yatiyantota Tea Company Limited be wound up voluntarily be and the same is hereby confirmed as a special resolution."

2. (a) "That George Hay Alston of Colombo Merchant be and he is hereby appointed Liquidator of the Yatiyantota Tea Company Ltd."

(b) "That the said Liquidator be paid a remuneration of one half per cent on the price realised by sale of the Company's Estates in addition to all general Agency Charges and commissions similar to those at present paid by the Company."

SELANGOR PLANTERS' ASSOCIATION.

The following are extracts from the minutes of a General Meeting held at the Selangor Club on Saturday, 21st November.

Read letter from the Colonial Secretary in reply to the Hon. Sec., S.P.A., *re* "An Ordinance, for the Protection of Indian Immigrants." Resolved that the Hon. Sec. should, as suggested by the Colonial Secretary, apply to the Resident-General for information as to whether fresh legislation on colonial lines is meditated for each or all of the Confederate States.

The Draft Federal Produce Protection Enactment, 1897, was discussed and it was resolved that the following additions be recommended to Government—*viz.*, that "plantation" shall include in addition, pepper, nutmegs, ramie and rubber; That "produce" shall also include "sap;" That in para 4, the words "nutmeg tree" and "sap of the rubber tree" be added.

The following resolution, proposed by Mr. Carey and seconded by Mr. Walker was carried unanimously—*viz.*, "That Government be urged to throw open the Magistrates' Courts of the Federated States to legal practitioners of status and position, the large vested interests of capitalists deserving in the opinion of this Association more adequate protection than that afforded at present."

Read letter from Mr. Gunn *re* closing market prices and it was decided that all the planting members of the Association be invited to support the project on the basis of a *pro rata* payment for each estate, or group of estates owned by the same proprietors. A sufficient number of the members present having signified their wish to join in the scheme, it was agreed that the offer of the Secretary of the Singapore Exchange should be closed with.

Mr. Dalrymple was elected a member of the Association.

NOTES FROM THE METROPOLIS.

Via Genoa, Nov. 16.

THE DUMONT COFFEE COMPANY.

Possibly you may have heard by telegraph of Mr. G. A. Talbot's very reassuring report on the property of this Company. It was, indeed, a very wise move to send Mr. Talbot across to Brazil; for he has not only had a long and varied experience; but is noted for his caution and has a special Ceylon reputation at stake. When, therefore, Mr. Talbot reports so favourably, as he does in his "cablegram" to Mr. Rutherford, of the Dumont property, it is quite evident to all who know them both that the position of the Company ought to be greatly strengthened.

THE LANKA PLANTATIONS COMPANY

has had a successful annual meeting, at which a favourable report has been adopted and a satisfactory dividend declared.

The affairs of the

ORIENTAL BANK ESTATES CO.

are, however, not yet settled, although the Committee of investigation or arrangement, has had several meetings and gone to a good deal of trouble. There can be no doubt of the valuable assets owned by the Company if only a fair start could be got. The Mauritius management of the Company's affairs, I see, is blamed in a letter to a Financial paper and a change called for. If only there could be a separation of Ceylon and Mauritius interests with a different Board for each, it might be a case of plain sailing; and there could scarcely be a more favourable time than this, for, with the troubles in Cuba and the Philippines, it looks as if Mauritius

might have "a good time." Let those who know, and believe in, the Sugar Island get their own Company for the estates and business there; while putting the Ceylon business and estates under a Company supported by those who know about our island, its products and prospects.

A lecturer on Hygiene of high standing in London has recently been recommending the drinking of a decoction not of "Cocoa or "Cacao" nibs, but one made from the husk, or what is known in the trade as

"COCOA SHELLS"!

He mentioned that these could be bought at 4d. a lb. and that the preparation was specially valuable to brain-workers because of the large proportion of phosphorus—he was lecturing mainly to an assembly of clergy. Some years ago, I announced in the *Observer*, the use of these cocoa husks for a palatable drink and how one West End clergyman regularly used it in his family (along with their servants)—gave it the preference over tea or coffee—and who, moreover, bought their supply by the bagful from the Cocoa-preparing Factory at the low rate of 1½d per lb. I have verified this account and find that the experience continues and the price has not risen.

The question now arises, whether the

COFFEE HUSKS, OR CHAFF

from Colombo mills—alas! a greatly diminished quantity—might not be utilised in the same way. Probably they are not so rich as cocoa husks; but the experiment may be worth trying.

I have just heard from the editor of *The Friend* that the Society of Friends has now definitely taken up the Industrial Mission to Pemba (Zanzibar) in the interests of the Freedmen with a view to employing them in the

CLOVE AND COCONUT

"Shambas"; and that Mr. Theodore Burtt, sails in the P. & O. ss. "Caledonia" from Marseilles on 2nd January, to take up the superintendence of the Mission. I have been applied to for copies of our Planting Manuals,—“All about Spices,” copies of which I have much pleasure in placing at the disposal of so deserving a Mission.

VOGAN TEA COMPANY OF CEYLON, LD

An extraordinary general meeting of this Company was held on the 12th ultimo., for the purpose of authorizing the directors to accept the purchase of land, aggregating about 210 acres, made by their authority on the 30th November and 1st December last, and to issue debentures from time to time as required for the purposes of the Company, the aggregate not to exceed R100,000 at 7 per cent interest or less.

THE KANAPEDIWATTE TEA CO., LD.

The latest of the new Tea Companies registered is the Kanapediwatte Tea Co., Ltd., for the purpose of acquiring and working the Kanapediwatte, Blackford, and St. Cuthbert's estates, situated in the Pussellawa and Ulapane districts. The signatories to the Memorandum of Association are Messrs. W. Kingsbury, E. M. Shattock by his attorney W. Kingsbury, A. J. Gordon Field, Reginald John, A. M. Caldicott Smith, E. H. A. Vanderspar and A. Alex. Hankey.

THE OTTERY TEA COMPANY OF CEYLON, LIMITED.

An ordinary general meeting of the Ottery Tea Co. of Ceylon, Ltd., was held at 12 noon on Tuesday the 8th Dec. at No. 1, Baillie Street, the offices of Messrs. Lee Hedges & Co. Those present were Mr. R. H. S. Scott (in the Chair), Mr. W. Kingsbury, Mrs. R. H. S. Scott (represented by her proxy,) Mr. R. H. S. Scott, Mr. V. A. Julius, Mr. E. M. Shattock (represented by his proxy), Mr. W. Kingsbury.

The CHAIRMAN proposed that the Report of the Directors and the accounts as presented be adopted.

Mr. SHATTOCK seconded:—Carried.

THE REPORT

The Report was as follows:—

The Directors beg to submit their Report and Accounts for the season ended 30th September last, which they trust will be considered satisfactory.

The total quantity of Tea secured was 147,613 lbs., or a yield of 404 lb. per acre off 365 acres, which realised a nett average price of cts. 53 51 per lb.

After providing for the payment of R1,793·57, interest on Mortgage, R8,328·59 in reducing the Mortgage debt by £500, and R1,507·32, the total amount of Preliminary expenses, the balance available for distribution amounts to R30,040·45. Of this sum, R14,900 were absorbed by the payment of an interim dividend of 5 per cent. for the 6 months ended 31st March last, and the Directors now recommend a further dividend of 5 per cent. for the last 6 months, making 10 per cent. for the year, and the carrying forward of the balance R240·45 to the new year.

A sum of R1,988·18 was spent on manuring during the 12 months under review, and was charged to Estate Expenditure.

The Estate was visited by Mr. Keith Rollo on the 8th October, and his Report on the condition and prospects of the property is highly satisfactory.

The meeting will have to elect an Auditor for season 1896-1897.

A DIVIDEND.

Mr. SHATTOCK proposed that a final dividend of 5 per cent. be paid forthwith.

Mr. JULIUS seconded:—Carried.

ELECTION OF AUDITOR.

Mr. R. H. S. SCOTT proposed that Mr. H. S. Scott be elected auditor for the season 1896-7.

Mr. E. M. SHATTOCK seconded:—Carried.

This was all the business done.

AN AUXILIARY TO TEA.

Those possessing suitable land at the proper elevation, might well go in for the cultivation of the *Jalap* plant, *Ipomœa Purga*. This is a beautiful climber, with rose-coloured flowers and belongs to the natural order *convolvulaceae*. It grows wild on the mountains of Mexico, and derives its name from the city of Xalapa, the capital of the state of Vera Cruz, which has long been the emporium of the jalap trade. It is successfully cultivated on the North-West Himalaya, at Mussorie, and the Nilgiris near Ootacamund. The dried roots or tubercules of well-matured plants, give an equal yield of the active resinous principles with the best jalap imported from Mexico and South America. So it is well worth the while of planters, favourably situated, to study its culture and extend its cultivation to other parts of India, where it has not as yet found its way. As a secondary crop and as an auxiliary to tea, it will well repay attention. It has also been established on the Cinchona plantations of Jamaica, where it thrives remarkably well. Jalap occurs in commerce, in dry pear-shaped masses, usually called *tubers*, and vary in size, from that of a small nut, to that of an orange. The so-called tubers are however, simply

enlarged divisions of the root known botanically as *tubercules*. A tuber is an enlarged underground stem, and the term is therefore, incorrect by applied to the transformed roots of the jalap plant. Jalap is used medicinally as a hydragogue purgative. This *true* jalap must not be confounded with *Ipomœa Turpethum*—the Indian Jalap (Turpeth Root), which the Bengalis call *Teori* or *Dhud*, and the Hindustanis *Pitohri* or *Tarbud*. This is a perennial plant growing wild almost all over India. The root-bark is obtainable in the bazaar, and is cathartic and laxative, resembling the true jalap in its action. Jalap requires a rich soil, for the crop is an exhausting one. It cannot be grown amongst tea bushes, for it will thrive at the expenso of the tea. A rich, deep vegetable sandy loam is best suited to the cultivation, and although moisture is necessary, undrained soils are fatal. In its natural condition, the jalap plant is found in shady woods, at an elevation of 3,000 to 5,000 feet above the sea: in regions where there is an abundance of rain, and where the temperature during the day ranges between 60° and 70° Fahr. Plants may be obtained from cuttings of the side shoots, set in a sandy soil in a shady place, and kept constantly moist. But for cultivation on a large scale the smaller tubercules should be planted, or cuttings of underground stems may be buried a few inches below the surface. The tubercules should on no account be exposed to the sun, or they will lose their vitality, and they should be planted out as soon as possible after they have been dug out of the ground. The land should be well tilled, and trenched to the depth of two feet. The trenches may then, with advantage, be partially filled with surface soil. The tubercules are planted in the trenches one foot apart, and to the depth of about six inches. When the vines grow, stakes must be firmly fixed on the ground for them to run on. After the plants have made some growth, they should be moulded up with earth, taken out of the trench. Weeding should be done at intervals to keep the land free from weeds. At the third year a return may be expected. Out in this country 1,000 lb. of dry tubercules can be gathered from an acre, and crops may be reaped every third year thereafter. This best plan is to lift two or three plots one year, leaving others undisturbed until the following year, and so on. By so doing crops will be got every year. The drying process is a difficult and trying one, for 70 per cent. of the weight has to be evaporated. It frequently happens that when the tubercules are in the sun, there is a considerable loss on account of some becoming mouldy, and others becoming subject to fermentation. This loss may be prevented to a great extent by gashing the tubercules, or cutting them into slices. But jalap prepared in this way fetches a lower price in the English and American markets. The tubercules might be dried in an evaporator or drier, but great care would be necessary, as too much heat spoils the product. The Indians of Mexico prepare jalap in the following way. The tubercules, when gathered, are freed from earth and foreign matter, and then hung up in a net over a wood fire. The fire is kept constantly burning in the hut, and in consequence the jalap acquires a smoky flavour, which is considered by buyers to be one of the tests of "the good tubers." This method might be adopted. Rough inexpensive sheds or bashas might be easily erected, and the tubercules dried slowly in them, over a wood fire. The fires could be damped, or put out, at night; the heat and the smoke would prevent fermentation and mouldiness. As jalap is used in medicine alone, in order to obtain the highest price, it is best to place the product on the market in the form best known to wholesale druggists. *Resina Jalapæ* of the Pharmacopœias is a pale brown powder. It contains two glucosidal resins, which have been named *Convulvulin* and *Jalapin*. Jalapin of pharmacy is the purified, decolorized resin of jalap, in whitish amorphous powder. Jalapin sells at about 2s 3d per oz. or 1 lb. 30s Radix Jalapæ 1s per lb., or 100 lb. 10d per lb.—*Indian Planters' Gazette*, Nov. 21.

THE COFFEE SITUATION.

The crop of 1896-97 is a demonstration of the extent to which a period of high prices has stimulated production. The area devoted to coffee has been rapidly extended in Brazil, in Central America, United States of Columbia, Venezuela and Mexico. Coffee-growing is a profitable industry when coffee sells in New York at prices considerably below a basis of 100 cents for No. 7 Rio. At the prices of the past five years planters have been receiving enormous profits.

It is apparent that we have entered a period of low cost. A decline has taken place of over 5 cents per pound in the cost of Brazil sorts, and the question is whether this fall in the price has fully discounted a supply largely in excess of the world's requirements. The answer will be found in the estimated outturn of the 1897-98 crop. If that is up to or above the average supply, then there is a chance for lower prices. If the next crop is to be light in Brazil, it would seem as if the present basis was near bottom.

Messrs. W. H. Crossman & Brother are very close students of the coffee markets of the world, and show their faith by their works, and generally take the public into their confidence by issuing a circular giving their views. This they have again done under date of October 23, estimating an enormous crop in Brazil for 1896-97, viz., a total export of not less than 8,000,000 bags. This is a total far beyond the yearly average for seven years, ending June 30, 1896, of 5,657,236 bags (332,781 tons). In 1891-92 Brazil exported 7,267,000 bags, and it is certainly not unreasonable to estimate that the exports from the largest yield on record should exceed the shipments of 1891-92 to the extent of 733,000 bags. Brazil has furnished 54 per cent. of the world's supply. On that basis the crops of 1896-97 will aggregate 14,814,800 bags. Crossman & Co. estimate the total crops at 14,000,000 bags, based on a minimum Brazil yield of 8,000,000 and 6,000,000 for other countries, or about 500,000 bags above the average crops of the past three years.

The total deliveries in Europe and the United States for five crop years ending June 30, 1896, were 54,677,976 bags, or a yearly average of 10,935,595 bags.

Hard times curtail the use of coffee, especially if prices rule high. There has been no increase in the deliveries of coffee worthy of note since the advent of high prices, as the following table of deliveries in Europe and the United States shows:

Year.	Bags.
1895-96	11,142,813
1894-95	11,212,851
1893-94	10,571,533
1892-93	10,946,228
1891-92	10,804,551
<hr/>	
Total five years ..	54,677,976
Yearly average (643,270 tons) ..	10,935,595

The above shows the steady nature of the world's requirements, which is subject to other than crop influences. Hard times and high cost cut down the demand. With a return to prosperity, the United States should increase its consumption of coffee at least 400,000 bags. Last year the deliveries fell below 1894-95 here and in Europe, but to slight extent. This shows the fairness of Crossman & Co.'s estimate of requirements, viz., 11,500,000 bags, to meet which there is an estimated supply of 14,000,000 bags. Has a 5 cent drop discounted this big yield? Crossman & Co. claim not, and evidently look forward to coffee on a basis of 7 cents for No. 7 Rio in New York, based on former experience with a visible supply of 5,000,000 bags. The outlook for the 1897-98 crop is favorable for a full average yield. If it should duplicate the supply of 1896-97, we cannot see how it can fail to foster and maintain an era of cheap coffee. There is certainly no basis in sight upon which to carry forward a bull campaign. We have arrived at a time when it is fairly

safe to carry liberal stocks, and the lower prices go the safer the operation of buying freely. Based on the actual movement of coffee, the Crossman & Co. circular is a conservative presentation of its situation.—*American Grocer*, Oct. 28.

PLANTING AND PRODUCE.

(From *H. & C. Mail*, No. 20.)

RUSSIA AND TEA CULTIVATION.—In an address recently delivered by M. Alexis Yermoloff, who since 1893 has been Minister of Agriculture and State Domains in Russia, before the Societe Nationale d'Agriculture, in Paris, reference was made to tea cultivation. In his address M. Yermoloff said that in any attempt to obtain a complete view of the practical agriculture of the Russian Empire it is necessary to remember that the country extends from the Polar regions of the north to the semi-tropical regions of the south, from the Baltic Sea in the west to the Pacific Ocean in the east; that Germany and China alike approach its borders. Throughout this vast area agriculture forms the chief occupation of the people and is the main source of their wealth. From the lichen (Iceland moss) which serves to nourish the reindeer in Lapland to the olives and bays and tea-shrubs of the Caucasus, all species of plants, cultivated or wild, of the temperate region of the northern hemisphere have their representatives in Russia. But it is the cultivation of cereals that forms the basis of Russian agriculture. With regard to the cultivation of tea in the Caucasus this work has been undertaken not only on the Imperial domains, but by private growers, who have studied the industry in China, India and Ceylon. Russia claims to be the largest tea-drinking country in the world, and till recently has been entirely dependent upon China for supplies.

STILL ON THE DOWN GRADE.—The Chinese have not now much tea trade to boast of except with Russia, but up to a year or two ago there was something doing as regards the export of scented teas. Now, however, this trade is on the down grade, as is evidenced by a recent consular report from Canton. The export of scented tea to Great Britain during the season 1895-96 was 5,750,000 lb, against 5,500,000 lb. the previous year, and 6,000,000 lb. for 1893-94. The quality of the early shipments was fully up to the average, though not so good as that of the previous year, and it deteriorated towards the end. The result was again disastrous to shippers, in spite of the fact that teas were laid down cheaper than ever known before. The unprecedentedly low prices ruling in London are attributed to shipments being more than the trade required and to the absence of competition consequent on the fact that, whereas these teas—scented capers—were formerly taken by a number of retailers in various parts of the country, they are now only used by a few large blenders, preference being given to low price Indian and Ceylon teas. This latter reason also accounts for the deliveries falling short of those of 1893-94. The demand for scented capers has steadily declined for several years past, and it is not unreasonable to suppose that at no very distant date it will become altogether extinct, Great Britain being the only country where such teas are used. It is thought by some that, but for the low prices, there would be no demand at all. Others, however, do not share this opinion. Congou, a peculiar kind of black tea known as Hoyune Congou, was several years back shipped in considerable quantities. It is now hardly worthy of notice, the export barely touching 200,000 lb. Kooloo, a high-class tea for Chinese consumption in Australia, and low-priced teas of similar kind for the River Plate, continue to be taken to a moderate extent, but do not hold a prominent place in the tea trade as carried on by foreigners. The trade in long leaf scented orange pekoes is now reduced to practically nil, the shipments being most insignificant.

JAPANESE TEA.—Owing, as they say, to the late war the Japanese have been doing little of late as exporters of tea.

This season's exportations have been only about half those of last year. We inclined to the belief that it is the competition of India and Ceylon that is the real cause.

COFFEE PROSPECTS.—Although coffee drinking is on the decline in the United Kingdom owing to the wonderful increase in the popularity of tea, coffee still holds its own on the Continent if we except Russia; the demand for France, Germany, the United States, and South America being sufficient to stimulate a constant increase of production. The coffee planters of South America have found coffee growing so remunerative that they have extended the area devoted to the crop with some recklessness, and the result is that the supply is in excess of apparent requirements. Authorities estimate "an enormous crop in Brazil for 1896-97—viz., a total export of not less than 8,000,000 bags. This is a total far beyond the yearly average for seven years ending June 30, 1896, of 5,657,286 bags (332,781 tons). Brazil has furnished 54 per cent. of the world's supply. On that basis the crops of 1896-97 will aggregate 14,814,800 bags." The estimate for the total crops is 14,000,000 bags, based on a minimum Brazil yield of 8,000,000 and 6,000,000 for other countries, or about 500,000 bags above the average crops of the past three years. It is anticipated that the improvement of trade in the United States will bring the demand for coffee, which the working classes use sparingly in hard times, into line with the enormous supply.

TO DETECT CHICORY IN COFFEE.—The following method of detecting chicory in a sample of powdered or ground coffee is suggested by a French paper: Take a sample of the suspected powder, and add to it about ten times its weight of water, and add a few drops of hydrochloric acid to acidulate the water, and then shake up the whole mixture. The coffee powder will float, and will impart a yellow straw tinge to the water. Chicory, on the other hand, will form a deposit, and will give the water a brown colour.

TEA AND COFFEE IN THE UNITED STATES.—Mr. McKinley, the President-elect, is moderating his zeal on behalf of protection. It is said that he is not in favour of a tax on tea and coffee.

JEDDAH COFFEE.—A curious fact about the Jeddah coffee trade is mentioned in a report to the Foreign Office for the year 1895 from that consular district. In the beginning of the year the price of coffee remained high. But after a time the arrival of an enormous quantity of coffee from the interior of the Yemen, where there is no sale for this article, the people themselves using coffee-husks called "Keshar," brought the price of coffee down. This led to a large quantity of coffee being shipped at the end of 1895.

VERY SOOTHING TO THEIR FEELINGS.—While the sugar planters of British Guiana are bemoaning the decay of the sugar industry their Governor, Sir Augustus Hemming, has returned to them full of hope on one point. He is bent on soothing their feelings with good cricket. He has arranged with Lord Hawke, who will take out an English cricket team early next year to Georgetown. Sir Augustus Hemming remarked in conversation before his departure a few days since that at Georgetown they had a very good cricket ground and a very good team; and one could play cricket in British Guiana all the year round. Planters who do not play cricket to any great extent are more interested in the staying off the crisis which must inevitably come unless something is done about sugar. In answer to the suggestion that they should improve their methods of manufacture, they say: "What is the good of laying out our dwindling capital on new sugar machinery in order to produce a better article at a lower price, when we know that Germany will respond by increasing her bounties?" They

maintain that they have been sacrificed in the interests of cheap jam and the expansion of the confectionery trades, forgetful of the fact, perhaps, that this is a free trade country, and that the home consumer who has a vote would kick if his sugar were taxed. The decay of a West Indian industry counts for little, as against the great principle or fetish, as some prefer to call it, of free trade. Anyway it looks like it.

LATENT LIFE IN SEEDS.—Professor Casimir de Candolle, of Geneva, recently contributed, according to *Nature*, some exceedingly interesting notes to the Botanical Section of the British Association on latent life in seeds. The author gave an account of some experiments recently carried out on the power of germination of seeds exposed for different periods to a low temperature. He also recorded striking instances of the development of normal seedlings from seeds which had been kept for a great number of years. Robert Brown obtained perfect seedlings from seeds of *Nelumbium speciosum* more than a century old. Plants buried under rubbish heaps collected by the Greeks have been found to develop and bear flowers from seeds which must have been at least 1,500 years old. To test the condition of a dormant seed, M. de Candolle exposed the seeds of several plants to a temperature too low to permit of the continuance of the process of respiration. Seeds of corn, oats, fennel, &c., were exposed for 118 days to a temperature of 40 deg. F. below zero. The experiments were carried on at Liverpool in refrigerating machines, in which during eight hours each day the average temperature recorded was 40 deg. F., and occasionally far lower. Nearly all the seeds of corn, oats, fennel, and many of the others germinated. The conclusion to be drawn from the experiments seems to be that in resting seeds the protoplasm is not actually living, but has reached a stage of inaction in which, although not dead, it is endowed with potential life. In other words protoplasm in resting seeds is not analogous to a smouldering fire, but rather to those chemical mixtures made up of bodies capable of combining under certain conditions of temperature and illumination.

MARKET FOR TEA SHARES.

THURSDAY EVENING, Nov. 19, 1896.

Business in Tea Shares of the Indian companies has been "a shade" quieter during the past week. A steady investment business, however, still continues in progress, more especially in the Ordinary shares, the high yield of interest obtainable on which, compared with what can be got on their securities of equal soundness, seeming to tempt investors even more than the greater security offered by the Preference issues, few of which latter can now be got to yield 5 per cent.

Mincing Lane, though still steady, has shown a slight weakness in the face of the large supplies brought to auction. News from India, moreover, by wire gives rise to the belief that the shortness of the late "fall" crop, recently forecasted in the public press, will not be so marked as was at one time expected, though the total available for shipment to the United Kingdom is still expected not to be in excess of actual requirements.

MEETINGS.

The Empire of India and Ceylon holds its first statutory meeting to-morrow (Friday), 2 p.m., at Winchester House.

Our readers will learn with regret of the sudden demise, while presiding at a business meeting at Winchester House to-day (Thursday), of Mr. John Berry White, whose cheery face and stolid form were well known to all Tea shareholders owing to his close connection with the Tokai and other companies, as well as his stalwart championship of Indian Tea interests for many years past.—*H. and C. Mail*, Nov. 20.

THE BORNEO COFFEE COMPANY, LTD.

The Annual General Meeting of the Shareholders of this Company was held at the Office of the Company 24, Rood Lane, on Wednesday, 23rd Sept. at 3 p.m., Mr. C. A. Whitehead presided. After the business of the meeting was over the Chairman called upon Mr. Henry Walker, who had recently returned from Borneo, to address the Meeting which he did, as follows:—

Having lately returned from North Borneo, the Shareholders will probably be glad to hear some details concerning our Estate, which I visited a few days before my departure—

The present planted acreage is 185 acres planted with Liberian Coffee, and 25 acres planted with coconuts, and from about 100 acres of the older coffee I expect we shall this year get a crop of about 300 piculs or say 350 cwts. A large area will be in bearing next year, and I believe we shall get nearly 600 piculs of coffee, or about double what we expect to pick this year. When sending in my estimate of crops for the current year I noted what amount of crops we might expect each month of this year, and I see from the Manager's returns, which we have received for the first four months, that the crop already gathered is in excess of the amount I estimated for the four months.

Estimated gatherings, four months ending 31st July 326 piculs cherry.

Crops gathered 386 " "

ten piculs of cherry turn out one of clean coffee. The appearance of the estate generally is very promising.

We have hitherto had great difficulty in keeping the estate clean, and a very serious expenditure has annually been incurred on weeding, but now that we have a large supply of coolies we have been able to cope with this difficulty, the estate is being gradually cleaned up and the Manager's later reports shew a saving on the estimate. When I last visited the estate, in April and May, I was able to compliment the Manager and assistant on the great improvement under the item of weeding, and I anticipate that we shall be able to get and to keep the land thoroughly clear of weeds, and in this we shall be assisted by the growth of the coffee, which will shade the ground as it ages. Our oldest field, 27 acres, is a proof of this, as it is perfectly clean, and the cost is only fifteen dollars a month or about 55 cents per acre.

To enable us to cope with the weeding during the wet season, a strong force of coolies is requisite, and this we have now got. We had to go to considerable expense in providing accommodation for our coolies, and in putting up a bungalow for the assistant, and I am glad to be able to tell you that our people are well and comfortably housed. We have never had to contend much with sickness, and I am glad to say that the coolies are in a very healthy state. The food supplied by the estate shop is of good quality and the prices of the principal articles, viz., rice, fish, salt, sugar, etc., etc., are on a fixed scale of prices, a list of which, in Malay and Chinese, is hung up in the shop. In addition to the estate shop there are several shops at the new Government Station on the Bay, which is about two miles from the estate, where our coolies can also buy their supplies, and in addition to the shops the Malay and Chinese fishermen bring fresh fish to the estate several times a week; besides this a supply of beef and pork is frequently obtainable at about ten and twenty cents the catty of 1½ lb., or say about twopence and fourpence a pound, and fish at one penny a pound.

Of course, when we first commenced operations, we had not the same facilities we now have. Communication with Kudat and with the East and West Coasts, is now possible four times a month by means of the Sabah Steamship Co., whose steamers call at Taritipan or as the new station is named, Tanjong Batu, where there is a wooden wharf; and later on, I think it is likely that Holt's steamers may eventually

call for the tobacco crops from the five tobacco estates adjoining our estate. From Tanjong Batu to our coffee estate, the Government has lately made a riding path, which continues through our land up to the cart road on the adjoining tobacco estates, and I hope the day is not far distant when this riding path will be converted into a cart road. At present our transport is done by the shop boat, brings the shop supply from Kudat up a creek to the estate landing place, from whence the goods are carried by bullock cart along our private cart road, not quite half a mile to the shop, which is close to our coffee store. The expense of the boat and boatmen is borne by the shops, and the estate finds the bullock cart and driver. In return for this our coffee, our coolies, and our estate requirements generally are carried to or from Kudat in the boat free of charge. The estimate of expenditure on transport for the current year is not large, but I see that the expenditure for the first four months is less than the estimate.

On my way home I visited Selangor and Ceylon, and after comparing our coffee with that of our competitors in the native states and Ceylon, I came to England more convinced that it was my duty to impress on your Directors the desirability of increasing our acreage. We have the labour supply, and we have the management necessary to carry out the work. In Mr. Shuck and his brother we have the assistance of two gentlemen whose hearts are in their work, and on whose energy and integrity of character I have the greatest reliance, but the acreage the Manager has in hand is too small for the cost of superintendence. With the same superintendence we ought to have, at least, double the area, and the Manager and the assistant will reap a benefit by the system we have adopted of paying a bonus on each picul of crop picked, the larger the area and the larger the crop so the bonus will increase.

I think we ought to lose no time in planting an additional 100 acres with coffee, and 100 acres with coconuts. I have supplied your Directors with estimates of cost, and I have shewn that the additional cost of adding to our present acreage is really very small. We require no new buildings, many of the expenses are the same for a small estate as for a large one, and we shall be able to keep up a good sized labour force, which the Malay coffee likes to see. He likes society, and he likes the good things obtainable by a large number of people; for instance, more frequent killing of cattle, a large and more constant supply of fish and other things. I mention these details so that you will realise more vividly the advantages to be obtained by a further outlay. I believe our position warrants our increasing our estate, and I believe we shall reap a very handsome return on the capital we have expended, and in return for the long delay in seeing a dividend. I think we shall be in a very strong position next year, our crops of this year will probably be doubled or nearly doubled next year, and when the different clearings come into bearing we shall get a crop quite equal to the estates in Selangor, which I understand bear an average of 7 cwts. per acre.

The expense of gathering, curing, and bagging coffee on the estate is now about 15s per cwt. which, with the introduction of machinery now proposed, will be reduced to about 11s 6d and the freight and docksale charges amount to about 9s, say a total cost under these headings of 20/6, to which must be added the expenses of management, weeding, etc., etc., which will probably total 35/- per cwt., on a crop of six to seven cwts. per acre, which, would yield a profit of say 25/- per cwt., at the present London market price of about 60/- per cwt.

I may say that the appearance of our coffee warrants very sanguine hopes of what it will do in the future. I took measurements of our different products, which I published in the "North Borneo Herald," of 16th May, 1896, and when I visited Selangor and Ceylon on my way home, I compared their growth with ours, and found that age for age, we could shew a superior size of stem and spread of branch, and from the appearance of the coffee

crop on our trees, I have little doubt that we shall eventually shew larger crops per acre than those countries have done. Our soil is decidedly richer. I brought home a sample of soil which it may interest you to examine.

I have asked your Directors to send out a turbine, and to put up a drying chamber which will enable us to work with greater economy, and to place our coffee on the market in greater perfection, and so command a higher price.

I would finally urge upon the shareholders the desirability of taking up their *quota* of the new issue, which will be at the same figure as the old shares, viz., £8 paid up, and £2 liability. I have applied for more than my *quota*, as I believe it is to my advantage to increase my holding as much as I can. The area planted will be larger, and proper machinery will be put up which will enable the Manager to economise on the annual expenditure.

I have drawn up an estimate of the probable expenditure of this year and of next year, based upon the actual expenditure up to date, which shews that with the assistance of the cash obtained by the issue of 200 new shares, which will be expended on new clearings and on machinery, we may expect to have, a balance in hand of about four hundred pounds after paying our very moderate London management expenses, which only amount to about fifty pounds a year. I would take the present opportunity to remind our shareholders that we pay nothing to our Directors, and before I sit down I should like to propose a very cordial vote of thanks to our Directors for the time and care they give to our interests.

With a vote of thanks to Mr. Henry Walker, and to the Directors, the meeting terminated.

THE OXIDATION OF TEA.

Messrs. Richard Moreland and Son, the makers of Mr. Nathan Sharpe's tea machinery, have just constructed a machine which they call the "Simplex Cool Oxidizer" (Nathan Sharpe's Patent). It is designed for keeping rolled leaf perfectly cool during the important process of oxidation or fermentation, and it is claimed for it that it thus improves the quality and market value of the manufactured tea.

At present oxidation occupies various periods of time according to atmospheric and other conditions. These various periods of time, it is stated by the manufacturers of the machine, may now, by the use of the "Simplex" Cool Oxidizer, be turned into regular periods of given time, at the termination of which the tea maker can rely on the proper colour being attained. It is also claimed that besides improving quality by cool oxidation and ensuring regular time, this machine dispenses with the present necessity for the erection of separate fermenting rooms or houses, as well as the attendant labour for syringing the walls and surroundings with water. Great economy in room is also effected, as the machine only occupies a ground space of 12 feet by 6 feet, 864 square feet of leaf surface being attained. Thus a machine of this size will approximately take 36 rolls, or 11,000 lb. of rolled leaf at a fill.

The "Simplex" Cool Oxidizer is made in two sizes, although any special size can be made to suit garden requirements.

The machine consists of a series of racks, upon which the trays filled with rolled tea leaf are placed. A tank at the top of the machine is kept full of water and this water is fed by means of perforated pipes in small sprays down inclined boards on to the (fermenting) cloth ends and sides of the machine, which are thereby automatically saturated, thus forming a saturated cloth chamber in which the leaf is placed. For the effectual cooling of the air, and consequent reduction of temperature, two air propellers play on to and force air through the saturated cloth ends of the machine. The air thus forced around the leaf is effectually cooled by its displacement and contact with the saturated cloth. When the desired colour of leaf is attained the water is turned off (by the regu-

lator taps), the air propellers stopped, and the saturated curtains at the sides of the machine pulled on one side. The trays being withdrawn, emptied, and recharged with freshly rolled leaf, the curtains are again closed up at the sides, the water turned on and the air propellers started. Some idea of the cooling capacity of the "Simplex" Cool Oxidizer can be imagined by the fact that the two 42 in. air propellers pass 26,000 to 30,000 cubic feet of thoroughly cooled air through the machine per minute, and without, it is said, in any way disturbing the leaf.—*Planting Opinion*, Dec. 5.

DIGESTED TEA NOTES.

In studying Bamber's ever-useful pages, it has often struck me how little the scientific portions of it are appreciated by the ordinary reader. Nay, even the practical parts are only half-digested, if one can judge from casual conversation with those who profess to highly appreciate the book. I have an idea the fault is as much due to the author as to the reader; to the former because he introduces a vast deal that might very well have been left out (he was told to write out a book and he had to smell it out somehow!), and to the latter for carelessness in seizing upon the main points. So that now the book has been in print so long that even a bare-faced reprint would hardly effect its sale, I venture to give your readers what I have called a "Planting Digest" of sorts. Inasmuch as most eminent scientists, Huxley and a few others excepted, have their humbler public exponents of their high mysteries, M. Keiway Bamber will not quarrel with me for rendering him a similar service.

GENERAL.—In his opening chapter on the history of tea, the first practical fact we have is that tea grows over the vast space of 23 degrees latitude and 30 degrees of longitude, consequently can stand almost any climate; from the snow-covered hills of Darjeeling to the moist burning plains of Assam. The chief differences in climate between China and India are that in China the rains are much better distributed, and the range of temperature is far greater. The tea shrub gets a far longer period of rest, and the picking season is a great deal shorter. In Java, as everywhere else, it has been found that the higher the elevation the better the flavour; the best altitude for all-round profits is from 3,500 to 4,000. Tea plants from China were first introduced into India in 1780, but there is strong evidence to show that the tea plant is indigenous to India, from whence it was probably introduced into China hundreds of years ago. After various abortive attempts to introduce the culture of the plant, some Bohca seed was obtained in 1835 and distributed in various parts of India: the Nilgiris were one of the only two districts in which they grew at all. Captain Minchin planted a few of them at Manantoddy, Wynnad, where their growth was excellent. It was in 1823 that indigenous varieties were found to be growing in Assam, but the value was held to be but small. Finally in 1818 Mr. Fortune made his famous trip to China, but by that time about 500 acres had been planted in various parts of Upper India. These plantations were all Government or rather "John Company" ones. Hence in our frequent railings against the Government, we should not forget that the very industry on which we (some of us) thrive is due to their initiation.

PLANT LIFE: THE BARK.—The usual scientific platitudes that the roots go down and the shoots grow up, I will pass over. But the almost equally trite remarks on the bark are worth dwelling upon, for the most astonishing ignorance prevails on this point. The bark consists of a layer of vitally active cells, which in a mature plant are the only channels by which the food saps pass up from the roots. In cold weather the cells are inert, but in spring they are in full activity. Yet how often one sees a man puzzle his brains over a sulky tree, with a flagrantly dilapidated bark. What can be the matter with the tree? He finds a few spots on the leaves. Now he has got it! It's a fungus, that's what it is. And though he doesn't

dream of trying to cure it, yet the supposed discovery of the cause of the sickness relieves his mind of a certain responsibility.

Roots.—Another fact that bears dwelling upon. The feeding rootlets convey the nutriment they have absorbed into the bark cells of the large main roots. If these food-channels (*i.e.*, bark cells) are exposed to the air and bruised, the flow of food stuffs is hindered and the growth of the tree is retarded. Yet how often does one see exposed, bruised and torn roots starting from the ground, as if mutely protesting against the brutal treatment they have received. Dumb yet eloquent victims of gross neglect; one would think your story was plain enough without these words of explanation! A clean cut, on the other hand, is only a temporary check, as new rootlets soon form, and the absorption of food proceeds as fast as before. Thus in young plants, as every planter knows, or it is high time he did know, the main thing to be observed in transplanting is to preserve the delicate feeding rootlets uninjured. At the same time the food-channels of the tap-root should be kept in working order, by keeping it from being bent. The freest use of a (sharp) knife in trimming tap-roots is to be preferred to running any dangers from the coils twisting or bending them.

TRANSPLANTING.—If plants are transplanted in the growing season, a warm soil and moist atmosphere are indispensable for success, as though many of the young rootlets will be destroyed, yet a fresh lot will soon start. But it is best to transplant when the growing season is almost or quite over, when the needs of the young plant are fewest. This most important point needs to be made very clear. If a young plant is in active growth, there is a constant flow of food up from the roots. Now this food can only be taken up by the tips of the young and freshly formed rootlets. If the plant is removed at this stage in the usual way, the majority of these tips are broken. The plant thus has its food supply suddenly stopped, and until fresh rootlets are formed, has to starve. On the other hand, if the plant is dormant, the sap stagnates so to speak, and removed at this stage can only affect the plant in a very slight degree, and the fresh rootlets have ample time to form by the time their services are again required.

Roots.—As a snake swallows its prey by in reality crawling over it, so does a root travel through the soil solely by the absorption of the plant food it (the soil) contains. Roots grow in length by the formation of cells at the extremities, and as they almost wholly feed with these extremities, they are always in the most favourable position for a good supply of food, as they are continually getting into new soil. Roots have a marked power of selecting certain foods they require, hence the great difference in the constituents of different species of plants. But his power is strictly limited and does not prevent their absorbing poisonous juices should such be present, often in this way causing the illness or even death of the plant. Another peculiar property, and one very little known, lies in their power of excreting substances injurious or unnecessary to the plant. This is distinct from their solvent root action, *i.e.*, power of exuding acids that decompose and render soluble otherwise useless, because inert, minerals. As may be imagined, one of the chief reasons of the failure of great numbers of any particular species of plant to grow continuously in the same soil is due to the accumulation of these excreta. This, as Mr. Bamber says, would partially account for the gradual decay and dying out of old tea plants.

As I mentioned before, anything that tends to obstruct the free passage of sap along the sap-channels, *i.e.*, the bark, must result in weakening the growth. Knots are one of the commonest forms of obstruction, and should be sedulously removed.

SAP.—The uses of leaves are principally the conversion of the crude sap taken up by the roots into forms available for the production of new wood and other growth; the evaporation of excess of moisture from the sap; and lastly the absorption of gases.

Evaporation proceeds in the case of tea principally through the openings on the under side of the leaf. The result is concentration of sap, which by the law of endomosis (the power of fluids of different densities to mix and become of the same density) results in a farther supply of sap coming up from the roots. The moister the atmosphere the weaker or more diluted is the sap, especially in the growing shoots.

Now, the thorough transformation of the crude sap in the leaves into those products suitable for the formation of fresh cells, requires certain conditions of climate, season and time. The special "tea-moral" of this is, as Mr. Bamber points out, very obvious. What we call flavour, body, pungency and strength are entirely due to certain sap compounds formed in leaf under favourable conditions. Very quick flushing means a loss of some of these compounds, especially when this quick growth is from a freshly pruned bush, which has not sufficient leaves to carry on the necessary chemical changes.—TEA PLANTER.

—*Planting Opinion*, Dec. 5.

EMPIRE OF INDIA AND CEYLON TEA COMPANY.

The first ordinary general (statutory) meeting of the Empire of India and Ceylon Tea Company, Limited, was held on Friday at Winchester House, Old Broad Street under the presidency of Mr. W. H. Verner the chairman of the company.

The Secretary (Mr. H. F. Turner) having read the notice convening the meeting,

The Chairman said:—Gentlemen, this being the statutory general meeting it will not be necessary for me to deal at any length with the position of the company. In fact, I could not do so, for we have not got the necessary figures. There are, however, a few remarks that it would, perhaps be well for me to make. There is one matter about which we have heard certain people complaining, *viz.*, the delay in obtaining a Stock Exchange quotation. The solicitors I think are in some measure responsible for this, for they have required a great deal of information, and although we are inclined to think there is generally some useful excuse in all such cases, there is, in the present instance, a reasonable explanation to be given, because in the matter of these properties I find that the solicitors have had to satisfy themselves as to the good title in the case of some fifty-seven tenures, and that means a good deal of investigation which cannot all be done in a day. If any shareholder wishes for an explanation of the matter our solicitor is in the room, and will reply to any question which may be put with reference to the property about which there has been some difficulty in closing the transaction, *viz.*, the Kamlai property. It is comparatively small and unimportant property, but owing to a difficulty that has arisen it is not quite certain that it will really become the property of this company, although it is believed it will. At all events there has been some delay about it. Some of you gentlemen will perhaps be saying, "Well, now, we are getting on in the year, and perhaps you can tell us something about what the results are going to be." Well, gentlemen, I am very sorry to say I cannot tell you that with any assurance; but what I can say is this, that the company's gardens generally have been making good teas, some of them very high-class teas, those of the principal garden having averaged up to date close upon 13d; and tea experts, of whom I see several in this room, will tell you that is a very good figure. On the other hand, these same tea experts might turn upon me and say, "What about the prices you are getting for your Haiha Patha teas?" These are low, I quite admit, but I would point out that this garden is giving a yield of about eleven maunds to the acre, so that I hope this large and very uncommon yield of tea will make up for the lowness of its price. The greater number of the gardens of the company are turning out teas far above the

average, and some of them are realising very high prices. Of course we have only sold a certain portion of our tea, and it would be quite premature on my part to predict what is likely to be the result of the current year. Everything, however points to favourable results. Some few weeks later—about the end of the year—when the time comes to pay you an interim dividend, I hope I shall be in a position to tell you what the teas have realised and what is the approximate value that they are likely to realise through the whole year. I can only say that the portion which has been sold has been sold satisfactorily.

As regards the future of the company I will not say very much, but I may tell you that the directors entertain a very strong expectation of success. There are, of course, certain matters which must always be guarded against, and possibly even be feared, but those are attendant on any commercial undertaking, and in the case of this company, as in most other tea undertakings, they are of quite a minor character. There may be difficulties about exchange and similar matters, but there are two things particularly upon which our success must greatly depend, and to these I will draw your attention. One is the question of obtaining new markets, and I am glad to be able to tell you—for I know something about the matter, as I happen to be on the special committee appointed by the Indian Tea Association, which deals with the question of new markets—every day seems to show that Indian teas are spreading more and more abroad through America, Canada, Australia, Persia, and many other countries; and—we hope we shall be able to make a very considerable advance in the consumption of Indian teas on some parts of the continent of Europe. There is one other thing which is of very great importance, and that is that, so far, matters connected with the tea industry have met with very little of what I might call scientific attention, but now I am glad to say a number of people who are most active in the tea business are trying to look at the thing from a more scientific point of view, and the question has been raised about the appointment of a scientific investigator or analyst in connection with the Indian tea industry. Now, I would remind you of the words that fell from Mr. Balfour yesterday. What he pointed out was that the manufacturers of Germany were maintaining at their own cost special scientific investigators to consider how far their business could be advanced by recent discoveries, and also to make discoveries so far as they could themselves. Now, we are just in the position of manufacturers. We grow tea, but we are also manufacturers of it, and if there is one thing that the tea industry requires more than anything else—one great safeguard—it is that this matter should be dealt with: I refer to the growth and production of tea by real experts, fully versed in the latest scientific discoveries. You can well understand why this matter has been raised, and I am glad to say we are told that the Government of India will give the tea industry some support in this direction. I hope we shall be able to make some arrangement whereby we shall get some really good men who will not merely help us to guard against blights and other dangers to which tea-growers are subject, but who will go into the whole question of the manufacture of tea—the drying, withering, and fermenting from scientific point of view—showing where we can hope to make advances in quality and where we can hope to guard against the blights which have already appeared, but which I am glad to say have made no further progress. I refer to the mosquito fly, red spider, and so on. I trust we shall then be able to guard against all future evils of the same sort. I have no doubt that a large number of companies, including the company which I here represent, and also other companies of the directorate of which I am a member, will join together and arrange matters so that we may not be surpassed in the business by Germans, but may bring to our assistance all the resources that science can produce. Such a step would, I think,

greatly contribute to the success of not only this company, but of all other Indian tea companies, and enable them to obtain large profits and distribute large dividends in the future. It is hardly necessary, perhaps, for me to address you about these things, but you can understand that it is just as well that such an important question as I have referred to should be ventilated as far as possible. I see before me a large number of gentlemen well acquainted with the business and well versed in such matters, and it is for that reason that I have made these few remarks upon the question of scientific help.

A Shareholder inquired when a settlement in the shares would take place.

The Chairman:—I am very hopeful that it will take place almost immediately. It is a matter that is before the Stock Exchange to-day. We have applied, but there was a little legal difficulty in one point which, I think, kept us back a little. That, however, has now been got over, and I hope the Stock Exchange will fix a day for a special settlement and will grant us a quotation.

There was no motion to submit, and, there being no further questions, the meeting closed.

[The quotation, referred to above, has been granted by the Stock Exchange Committee, and the special settlement fixed for December 2.]

TEA MACHINERY.

There are many planters still on the active list, who will remember the old days, when every process connected with the manufacture of tea was done by manual labour, and when tea was fired over charcoal fires. When driers were first introduced, a great controversy arose as to whether tea could as effectually be dried by pure hot air, as the heated air which arose from burning charcoal. It was alleged by some, that the fumes arising from live charcoal fires, acted in some way chemically on the leaf, and that this action was essential to good tea being manufactured. So also with rollers: the conservatism of that time, declared that leaf could never be so well rolled, and such exquisite twist obtained, by machinery as by hand. Many thought that although machinery would be a great saving of labour, it would practically mean the deterioration of tea. As for packing by machinery, such a thing was never dreamt of, even in the wildest flights of imagination. It was as far from the thoughts of the old generation as plucking by machinery is from ours. Yet, when we look back, even the past ten years, what wonderful improvements have taken place; and if we progress in the same ratio, we see no reason why there should not be plying an automatic plucker, ere another decenary passes over our heads. When we look back, down the vista of the past, and survey all the machines which have been invented, and which have had their day and passed out of use, we are simply amazed at the rapid progress which mechanical skill is making, in turning out new and improved machinery for the tea industry. In fact, so rapid is the pace, that before some of the late inventions have had time to be classed as old, they are superseded by latter improvements, which place the former in the category of those defunct, and merely to be added to those already gone before. Thus, early in their infancy, having finished their course, they serve only to stand as memorial stones along the path of progress. There are now so many machines that purchasers find it very difficult to decide which to choose. The two best known inventors are Messrs W. and J. Jackson, whose tea machinery are manufactured by Messrs. Marshall, Sons and Co., Ltd., Gainsborough, England, and the Messrs. Davidson and Co., of Belfast, Ireland. The brains of these gentlemen never seem to tire, and the rivalry is so keen between them, that we are not allowed breathing time to decide the merits of any one machine, before it is "capped" by another. In these days of competition, it is impossible for such machinists to rest on their oars. Go ahead they must, for if they

do not, the only alternative for the one which fails to keep pace with the times, is to go to the wall. It is a death struggle, and one which of sheer necessity must be maintained. The question is what is it leading to? Have their machines by any means reached the point of perfection, or will they yet produce machinery, which it has not yet even entered into our minds to conceive of in our flights of fancy? Is tea machinery yet in its infancy? We are inclined to think, judging from the past, that the day is not far distant, when we shall look upon our present machines as antediluvian—so many more milestones marking the march of progress. It is impossible to forecast what evolutions will take place, but the finger of history points very clearly to vast improvements, even on our present machines. We consider them well nigh perfect, and can scarcely conceive of more perfect machines, but time alone can show us what the ingenuity of engineers and machinists can devise. When we come to think of it, even the best of our tea factories are far from what they should be. This, of course, is owing more to economical reasons, than aught else. Estates cannot afford to cast aside their old machines and be constantly investing in new ones. But, little by little, the old and antiquated machines will have to be discarded, and replaced by those of the latest type. The change will be gradual, but certain. And so with our present tea-house, they will also give place to vastly improved factories. As new and improved machinery is evolved, so the edifices to contain them will likewise have to be built to new patterns. In another ten or fifteen years' time, we shall look upon our present buildings as so many veritable Noah's Arks. These remarks have been called forth by our attention having been drawn to some new automatic machinery advertised (in our advertisement pages) by Messrs. Davidson & Co.,—Mr. Davidson's patent new Automatic Sirocco Tea Drier, and the Davidson-Magniro Patent Tea Packer. It is necessary for us to introduce "Sirocco" machinery to our readers, as its merits are so widely known amongst all planters, but as Messrs. Davidson & Co. have recently introduced so many improvements in their old machinery, and have also put on the market some entirely novel machines, we feel justified in giving a few particulars. With reference to the "Automatic Continuous Web Sirocco Tea Drier," the machine has worked the whole of this season, and yielded results beyond expectation. It has turned out an average four mannds an hour of *pucca* dried tea, which shows what an advance it is on other similar machines. The chief feature about it is that the damp leaf is introduced into the *hottest* blast of air, which effectually and instantaneously checks the fermentation. The tea is then finished off at a lower temperature, as it automatically traverses through the machine, finally coming out cool to the hand, with a delicious aroma. This method of drying allows for the extraordinarily high temperature of 300° to be used without risk of overfiring, as, for as long as the tea contains any moisture, its temperature cannot be raised above about 200°. It may appear strange to our readers such a high temperature being permitted, but when we can state as a fact, that the teas dried in this machine this season, have fetched $\frac{3}{4}$ d. a pound more than last season's teas, they will see for themselves the advantages to be derived from this method of drying; one which is sure to be followed in future machines. The stove is of the multitubular pattern, the smoke and flame passing *through* the tubes, enabling any accumulation of soot to be removed by means of a wire brush, a very much simpler operation than cleaning the outside of a nest of tubes. The whole of the furnace is of iron, no brick entering into the arrangement.

All types of *Updraft Siroccos* are built with combined air and smoke chimneys, on the principle of the original No. 1 Sirocco, which has always been considered by planters as the best machine for drying tea. These machines have been giving very good results as regards the quality of tea made, and Managers report increased outturn.

The tea Packer has been affording satisfaction, and its advantages duly appreciated, especially by the brokers in London, who have been issuing very valuable reports on the condition of the teas packed by this machine. The latest improvement to it is a self-feeding hopper, which considerably facilitates the working of the machine.

In addition to these machines Messrs. Davidson & Co. have also Sorters; but their latest marvel is a new patent Tea Roller, which, if it fulfils all expectations, and accomplishes all that is claimed, for it, will indeed take the cake, and put the other makers on their mettle. This Roller has a capacity for holding 300 to 400 pounds of withered leaf, and is said to require the very small driving power (indicated by dynamometer test) of 1-20 H.P. only when empty and $\frac{3}{4}$ H.P. when working at its maximum load. The leaf is kept absolutely cold during the rolling process; lumps, etc., are automatically broken, and any tea that escapes from between the upper and lower rolling surfaces, is automatically swept round to a delivery spout on the table, where it can be collected in a basket or box. The machine is strongly and well made; all parts in contact with the leaf are made of brass, and the price f.o.b. steamer, Birkenhead, is £115 only.

No special machine, or apparatus, for *fermenting* has as yet been devised, but doubtless this process will also in time occupy the attention of some scientific mechanician, and so ne patent be produced, which will enable us to catch on to, and permanently hold, the exact colour required by the market. It is not by any means an impossibility; a man with his wits about him, and who will take the trouble to thoroughly study the subject *practically*, will, we feel sure, eventually succeed in inventing an apparatus, which will automatically ferment leaf to any colour required. Such a machine is certainly not out of the realm of practical possibility, and it is more than probable, that ere long, a fermenting apparatus will be found in every tea factory throughout India.—*Indian Planting Gazette*, Nov. 27.

PLANTING AND PRODUCE.

PERSIAN "WHITE TEA."—According to the *New Bulletin* a small quantity of the "white tea" of Persia, as it is called, has been forwarded by Her Majesty's Consul at Ispahan for the Museum of Economic Botany. The tea proved to be very similar to that described in the *Bulletin* under the name of P'u-erh tea in 1889. The finest of this tea is said to be reserved for the Court of Peking. The sample from Yezd was composed of the undeveloped leaf but buds, so thickly coated with fine hairs as to give them a silvery appearance. The liquor from the Persian white tea was of pale straw colour with the delicate flavour of good China tea. It is known, but now little appreciated, in the English market. The following particulars respecting it were communicated by Messrs. Gow, Wilson, and Stanton:—"This class of tea has been very scarce during the last few years upon the London market, the price which the English trade were prepared to pay being very unsatisfactory compared with that which could be obtained in Persia. In London this class of tea is called 'flower pekoe congou,' and the last lot that we remember having seen, which was some two or three years ago, we ourselves sold to a client in Constantinople, the tea evidently being destined for the Persian market. For home-consumption this tea is not worth much more than 1s per pound, but for export purposes good specimens command as much as 3s to 5s per pound."

THE COMPETITION IN THE TEA TRADE.—The energy and enterprise shown in the pushing of packet and other teas are remarkable, and there seems no limit to the devices employed to catch buyers. Nearly all the articles comprised in the furnishing trade, including pianos, have been offered at one time or another to the purchaser of a given quantity of tea, and now we notice the following advertisement: "Free.—One lesson (twenty minutes) on violin or

mandoline will be given to every one who buys one pound of advertiser's two shilling tea.' As a contrast to this kind of thing a supply stores in Essex woos customers with a notification which says: "We have no expensive advertising or crack-jaw names for our customers to pay for. When you buy tea don't pay for other people's boasting. For ready money we guarantee that you will get better tea from us than you can buy anywhere else at the price. Will you put us to the test? Our tea is justly celebrated for its marvellous strength and luscious fragrance. Will you try a quarter-pound sample packet to-day?" The ingenuity of the advertiser is profound. The latest development is so remarkable that it deserves special notice, although it has nothing to do with tea in this case. The proprietors of a certain article, which shall be nameless, are going to send up a billon at an early date from which a number of cheques, varying in value from £1 to £10, will be thrown out. They will, of course, subsequently be cashed at the offices of the firm in question.

LAST WEEK'S TEA MARKETS.—Referring to last week's tea sales the *Produce Markets Review* says: "With ample supplies to meet the increasing demand, the market for Indian tea continues steady, excepting for the common and undesirable kinds. The latter have formed a large proportion of the quantity brought forward, and as they have now receded to a low point they will, no doubt, go more freely into consumption. As the imports, however, will probably for some time largely consist of common grades, buyers will be able to replenish their stocks as the necessity arises; at the same time prices now appear to have reached a safe level. For the better sorts there has been good competition at quite former rates, and it is quite likely that there will be a firmer tendency rather than the reverse, as the consumption is keeping pace with the supplies. It is evident from the deliveries, which show a considerable increase over those of the preceding year, that even if the latest estimate of the crop is reached, it will not prove excessive to meet the considerably increased consumption. At the public sales there were 50,300 packages offered, including a good assortment of most growths, competition being very active in some cases. This was particularly noticeable for the finer Darjeelings, which were of exceptional quality, and fetched extreme rates, while the finer descriptions of other growths sold readily at rather firmer prices. Medium sorts were well bid for at late rates, while the common teas sold in favour of buyers. At the Calcutta sales on the 19th inst. the common grades generally passed at slightly lower rates, but there was a strong demand for the better teas. The market for Ceylon teas has been rather better supplied, although the quantity offered is still small. Competition for all good grades continues active, especially for medium Pekoes, and the market closes with a stronger tendency. The demand for the common descriptions is steady at prices showing no quotable change, and the values of the lower broken kinds remain unaltered. Good broken Pekoes are still difficult to obtain at about 10½d to 11d, while the finer descriptions have been well competed for at firm rates."

FREE TRADE IN TEA AND COFFEE FOR BELGIUM.—The *Belgian Times* states that it is the intention of the Belgian Government, in the course of the present session to introduce a Bill for entirely freeing both coffee and tea from import duties.

THE INDIAN MANGO.—Surprise has often been expressed that no effort has hitherto been made to introduce the Indian mango to the home fruit market. Except in the form of chutney it is unknown here, and we are, therefore, glad to learn that a determined attempt is to be made next year to bring the mango to London in sufficient quantities to be of commercial consideration. The possibility of conveying a fruit so delicate and quickly spoiled as this has on several occasions been demonstrated, and for some years past a dish of them has been a feature of the official dinner of the Secretary of State for India on the Queen's birthday. Several

gentlemen, who take an interest in the matter from a patriotic as well as an industrial point of view, want to give the experiment a large and conclusive trial. English taste has taken kindly to the banana and the pomegranate, and is grateful for the West Indian pine apple, and there seems every reason to think that the Indian fruit would be no less welcome.

THE CENTRAL AFRICAN PLANTERS DINNER.

(From the *Central African Planter*, Oct. 15.)

The First Annual Planters' Dinner was held on the evening of the 18th Sept., at the Zambesi Trading Company's new hall, kindly lent for the occasion by the Manager, Mr. Beyer. The hall was beautifully decorated with a coffee wreath going the round of the walls; also with four festoons of coffee leaves hung from the centre of the ceiling to the four corners. The tables had a nice display of flowers and evergreens and the general effect was very tasteful. Mr. C. M. Dunean of Michiru was in the chair.

After various sentiments had been pledged, our contemporary's report continues:—

The Chairman then rose to propose the toast of the evening—"Coffee and the Planters." In the course of his speech he said that whatever else might be said this country must stand or fall by coffee; things no doubt would finally come out all right; he had himself taken up large interests in the country, and he was not afraid of high money.

Mr. A. PAOLUCCI, who replied to the toast, said—Mr. Chairman, Gentlemen, Friends—Our chairman has done me the honour of calling upon me to respond to the toast of the evening "Coffee and the planters." I see here Scotchmen, Englishmen—I regret there is no representative of the Emerald Isle but we shall have later on—and foreigners of various nationalities: but all Britishers and foreigners either by reason of nationality, or old connections and associations, or deeply laid interests, are all extremely interested in this country, and our prosperity and welfare are bound up with the prosperity of the Shire Highlands and British Central Africa—and this prosperity depends mainly on coffee. Some of us have had a crop this year, and as for those that have not got one, why they are even better off, as the joys of an anticipation are far sweeter than the satisfaction of a perhaps indifferent reality. It is well befitting that after all our trouble, we should hold this social gathering as a relaxation. I remember when some years ago I used to go up and down the river about this time of the year in those boats and canoes, that were then the real tramps of the river, I started many times from Chikwawa with two little boys hoping to wake up my crew on the way. I stopped at the first village and made enquiries but was told the people were all on the other side. Doing what? At a beer-drinking! Everywhere almost the same answer and then it struck me that really the native after all his trouble in getting in his *chimanga*, shouting himself hoarse to frighten away the birds, after his tremendous exertions, which perhaps we cannot well realize, when he had gathered his crop he wanted to relieve his pent up feelings and went beer-drinking. We also have had our crops and want a relief. Do not think the comparison unjustified as it is all well within the iron ring of human nature, which encompasses all humanity, at whatever age, in whatever climate, under whatever colour of skin.

I do not pretend or say that this dinner constitutes in itself the relaxation; no, but it is a good start, and if any planter wants more relaxation, why, he knows where to go and get it (laughter). I said that we have had our crops, for some the second or third, for some their maiden crop. Here remark, please, how appropriate the word *maiden* is. The striving after those few hundred pounds, represented by the maiden crop, is certainly quite as exciting, and in its inner working quite as poetical and interesting, although not quite so pleasant, as the wooing of a fair maid. You remember when you had decided to turn planter, the looking first for the land, that was to be *the pick of the land*, the tramping up hill and down dale; but that was nothing. The troubles began when you began canvassing for friendly advice (laughter). You went to a friend and said, "Oh! I have my eye on a splendid piece of land, full of *masuku* trees." "My dear fellow, have nothing to do with *masuku* land—I know too well by experience. Then you started again and went to another friend—"found the finest bit of land out-deep loam-chocolate colour—the very thing to plant coffee on—"to be met with, "Well, old chap, of course the money is your own and you can do what you please with it, but if you care for my candid opinion, if you want to ruin yourself you could not start better than by buying that land" (laughter). However you finally take the plunge, buy the land, and there you are land-owner and planter—a country squire. Then begins the whistling for labour which does not turn up and for rain that won't fall, but at last after all your efforts and exertions you see then the flowers on your trees, the young spikes forming and finally the young berries formed. Oh, those berries! they are from that moment the children of our hearts and we give them all a father's care. We keep away from them the weeds and the vermin, and when they are ripe we leave them to be plucked by dark but comely Angoni maidens and children. Then we submit them to the short but severe trial of the pulper, out of which they come free of uncountness, and as "cleanliness is next to godliness" we wash them in the tank prepared for them. In this operation all the bad characters, all the refractory ones, are revealed—unlike the child in Pears' soap, instead of staying at the bottom of the tank, these bad ones insist on coming to the top, and with an aching heart we put them away. It is very sad but cannot be helped—as there are black sheep in every flock so there are empty berries in every crop (laughter). After the beans have been washed we expose them to the kisses of the African sun, which makes them ready for their journey home, to be admired by our fellowmen across the sea, and be snatched up as they are offered. And now see these beans, the children of our hearts, closely elbowing each other in a bag, a nice bag, we shall say a hundredweight bag, marked with our brand. They are lifted on the shoulders of stalwart Machingas, who start on their journey to the river. We bid them God-speed, and in that moment we forget all past troubles, and with a contempt for arithmetic, which does us credit, we never stop to think what a small part of our troubles and money those beans represent, and after all if we had only ten bags for the fifty we expected, what does it matter? A merciful Providence (or shall I say the other party?) looks after its own, and the next crop will be a bumper crop, and soon

re-establish the balance of accounts. Yes, there are good times coming, but we must wait. Do not take this as a commonplace platitude, usual to be said on such occasions no, sterling worth to be proved must stand the trial by fire and the fact is borne upon me that we are simply going through a necessary period of probation. Men die of black-water fever or other insidious disease, cattle are taken off by some mysterious pest we cannot cope with, collee is inflicted with bastard wood and other passing ills, but we shall go through them all and triumph. There has been a first period of pure and simple pioneering when people did their best with a rule of thumb, now we are in the second period in which we talk very learnedly, very learnedly indeed, about shade, manure, phosphates, potash, nitrogen, but still take care not to go in for them as we cannot afford it. Then there is the third period near at hand and this is when the man with the *oof* (excuse the vulgarity of the word but it is very expressive) be he the large capitalist, afflicted with a plethora of cash and seeking investment for his surplus, or the young scapegrace whom a noble family loves very dearly but likes to see far away for a while, or the thrifty son of a thrifty father looking for higher interest for himself or his papa, the man with the *oof* I say will come, plank down his money, apply all the latest teaching of chemistry and agricultural science—and succeed. When that time comes we shall know (within thirty per cent or thereabout) what we are worth. Two kinds of people will regret this new state of affairs—those gifted with a lively imagination who will no more be able to count their wealth by thousands and sent of thousands, and those hopelessly despondent people who affect to be in a perpetual fit of the blues. Gentlemen, we could offer to the home investor 25 per cent, 15 per cent if we want to make sure, but for a dead certainty we can offer 12 per cent. Nor for 10 per cent men will soar to the skies and go deep down to the bowels of the earth but after having found, proved and established a truth the next thing is to hammer it into the heads of the people and this is the task which lies before you. Bring home to the investor the soundness of the investment we offer and there will be no money left at the Bank of England in a short time (laughter). In the meantime go on working hard and be of good cheer—there is nothing more manly than a proper spirit of cheerfulness under adverse circumstances and let your watchword be patience. Patience is a domestic virtue that everybody thinks the easiest thing to practise, in fact a cheap virtue and is identified generally with that humble but very useful animal (which of all our importations and improvements is certainly *the* successful one) the jackass; but patience, friend, is at the same time the virtue of the strong, conscious of good and solid work done—sulking is not patience, grumbling is not patience. I would like to repeat the words that Oliver Cromwell told his soldiers on the eve of a great battle if they might not seem ludicrous in the mouth of a young man like myself—"Trust in the Lord and keep your powder dry"—that means in our case, go on extending and improving, especially improving your estates, work hard and cheerfully as you have done before, and success will follow—it cannot fail to come. At the end of my speech I cannot help expressing some disappointment at many of our fellow-planters not turning up. Many have

pleaded extra work and distance and we will absolve them this time from the sin of omission. This year we have only been a little over thirty, but we have done what was necessary, established the precedent. Next year we will be fifty, sixty, let us hope. Next year instead of the Committee or the honorary Secretary having to button-hole every fellow and coddle him to come to the dinner, we shall simply advertise in the local papers that "The Guild or Corporation of Planters will hold their annual dinner at Beyer's Hall on such and such a date" and I am sure everyone who possibly can will come. In this place where there is an excellently organised and highly successful Shooting Club, a Sports Club which promises to be equally successful, a Social sociable Club, open to everybody on the most liberal terms, surely there is enough public spirit left to support a Planter's Dinner, a social function which occurs only once a year and at which planters renew or cement friendships and discuss, I won't say their interests, but some choice viands irrigated by a not too abundant flow of light wines. Material interests must stand pre-eminent, but you cannot in things human abstract from the moral point of view. A dinner such as this will not put a penny in your pocket—in fact it will subtract from it the exact amount of one pound eight shillings and six pence (laughter)—but it cannot fail to promote harmony and good feelings and so, in however a small degree, it may help to promote material interests also. I cannot conclude without giving greeting to the oldest pioneer amongst us, and in doing so I am sure I express the feeling of all. I refer to Mr. J. Duncan—he is known and dear to us all; he brought the first coffee plant into the country; he has worked hard and is the portrait of health. He is an excellent specimen of the Planter of this country and so I will couple his name with the toast which I ask you to drink—the health of the Planters and the success on the coffee growing industry in B. C. A." (Applause).

Mr. Jonathan Duncan, the pioneer planter, then rose and gave a few words on coffee and his experience of it.

CEYLON TEA IN AMERICA AND RUSSIA.

WE were only able yesterday to direct attention to the minutes of the last meeting of the Passara Planters' Association. The business, however, is worthy of more than mere passing notice; and the subject to which we would now make special reference is the resolution proposed by Mr. Deaker to the effect that private enterprise might now be left to expand the Ceylon tea market in America, and more money should be spent in pushing our trade in Russia. Some weeks ago we ventured to express the opinion that the time had now come when those who were charged with the disbursement of the Tea Fund should consider the desirability of discontinuing private subsidies both in North America and Russia, that opinion being based upon information we had received from reliable sources that our tea had now got such a good hold in both countries that it was being handled by far more firms and individuals than those receiving aid from the Tea Fund. It will be seen that Mr. Deaker's resolution is not quite in line with what we then advocated; but we are pleased to think that the subject even in a partial form, has been ventilated in a meeting of planters with the

result that it is likely to be brought before the general body at its next meeting. We do not advise the abandoning of America in favour of Russia; we wish both countries to be treated with on equal terms, no particular trader or traders receiving special advantages in the way of subsidies, over others; and now that so many feel it necessary to handle our tea in consequence of the demand that has been created, we think the fairest plan is to let ordinary business competition take its place, and expend our funds in carrying out a general system of direct advertising from which all would benefit alike.

In connection with the American campaign a contemporary hears "that, by the recent Orient mail, a letter was received by the 'Thirty Committee' from the Ceylon Commissioner in America containing a further report on his work. Mr. Mackenzie wrote in a very hopeful strain as to the prospects before Ceylon planters in the States and Canada, and stated that, if we continued the campaign vigorously, victory would be ours. But to attain this end extensive advertising must be done, and for this purpose an appropriation of £12,000 from the Tea Fund was asked for. The 'Thirty Committee' at a recent meeting considered the request, and it was found that a balance of about £8,000 was in hand to meet next year's expenditure." But the question now is,—who are to have this money? or how is it to be spent? Let the planters carefully consider this matter.

TEA IN AMERICA.

New York Nov. 11.

The firm tone of the market continues. Low grades hold the advance of 2 to 3 cent per lb. Fine Formosa Olongs are steady at full figures. Greens are held with more confidence. Japan grades steady. To-day at noon the Montgomery Auction and Commission Company will sell 3,353 packages, viz: 509 packages Moyune, including the celebrated "Emperor Chop"—new season's; 210 boxes Hoochows, new season's 828 boxes Pingsney, new season's; 45 half-chests Japan Nibs; 575 half-chests Congou, including new season's fancy Monings and Keennuns, and handsome Leaf Pekoes; 136 packages India, Java and Ceylon—an attractive assortment; 573 half-chests and boxes Amoy; 40 half-chests Foochow; 417 half-chests and boxes Formosa new season's and comprising a Fancy Chop, grading fine to choicest Extra Sifted Teas.—*American Grocer.*

THE TEA TRADE IN RUSSIA.

Tea is the national drink *par excellence* in Russia; it is as indispensable in the food of the people as bread or meat, and is taken at all hours of the day. In every town tea-houses are found where a largo glass of tea, with plenty of sugar in it, is provided at a cost of from three halfpence to twopence halfpenny, according to the town and the position of the customers frequenting these establishments. In these circumstances it is only natural that the consumption of tea in Russia attains enormous proportions, and is yearly on the increase. According to the *Journal de la Chambre de Commerce de Constantinople*, Russia imported in 1894, through the port of Odessa, 15,692,000 kilogrammes (kilogramme—2,204 lbs.) of tea from China. Through the Custom-house of the Baltic large quantities of tea are entered, chiefly consigned to Moseow, or for local consumption, and by the land customs of Eastern Siberia, about 20,000,000 kilogrammes of tea, representing a value of about 50,000,000 roubles, were imported. All the tea imported by way of Odessa or other European frontiers is leaf tea, but that coming into the country *via* the Chinese frontier

is chiefly tea in bricks of different dimensions. These teas are consumed by the nomads and the northern peasants, by reason of their cheapness and the facilities of transport. The customs duties on this kind of tea are much lower than those on leaf tea. In the various retail shops leaf tea is sold in packets weighing $\frac{1}{2}$, $\frac{1}{4}$, $\frac{1}{2}$, or 1 Russian pound at prices, varying according to quality, from 80 copecks to 5 paper roubles the pound, but, as a rule sufficiently good tea may be purchased for 1 rouble 50 copecks to 2 roubles 50 copecks per pound. Russia exports annually a certain quantity of tea in packets, prepared by the large importing houses of Moscow, which are well-known throughout the whole of Europe. By way of Ojessa, 30,000 kilogrammes were shipped in 1894 to the destination of Roumania, Bulgaria, Turkey, and Austria-Hungary. About two years ago tea from Ceylon began to be imported, but the quantity so far has been inconsiderable.—*Journal of the Society of Arts*, Nov. 27.

ANOTHER CEYLON TEA COMPANY.
AN IMPORTANT AND EXTENSIVE
VENTURE.

We learn that it has been decided and the preliminary steps have been taken to float another large Company to work several very fine properties in the Upper Dikoya, Upper Dimbula, Ramboda and Nuwara Eliya districts. The estates which the projected Company have acquired are Kandapola, and Monkwood worked in connection with it, Frotoft and Tymawr, with Rushbrook estate and Poojagodde estate worked with these; Erroll estate, and Middleton and Tallankanda estates. The following is the acreage of estates:—

	Total acreage.	Cultivated in tea.
Kandapolla (Nuwara Eliya)	280	.. 249
Monkwood (Nuwara Eliya)	197	.. 197
Frotoft and Tymawr (Rambodde)	316	.. 306
Rushbrook (Rambodde)	306	.. 150
Poojagodde (Rambodde)	450	.. 50
Erroll (Dikoya)	239	.. 215
Middleton (Dimbulla)	250	.. 225
Tallankanda (Dimbulla)	265*	.. 121
	2,333	1,513

* Tallankanda 118a. cinchona, 10a. coffee.

The Ceylon agents for the above estates are Messrs. Bosanquet & Co., but the Company is being promoted in London. We understand that the estates will be worked for and on behalf of the Company as from the end of the current year.

CARDAMOMS.

It is a good many years ago since cardamoms have been so dear as they are today. In fact, there has been no such scarcity of the drug since Ceylon commenced to supplant Southern India as the principal source of supply. That was about twelve years ago. So recently as 1884 the bulk of the cardamoms seen in the London market were the produce of the native States of Travancore and Cochin, while smaller but regular consignments were also received from other portions of the Malabar coast. The Maharajah of Travancore used to draw a handsome revenue from his cardamom monopoly, which was mainly based on the simple plan that the growers must consign the whole of their crop to a specified port—Aleppey—and there sell it to the officials of his Highness. Cardamom culture by Europeans was discouraged at Travancore in those days. We believe that it is now permitted, and that a tax has been substituted for the old monopoly system. But the low market-rates of the

past few years have taken the gilt off the industry in Travancore, just as the former high prices stimulated by the monopoly system encouraged the spread of cardamom-culture in Ceylon.

Before 1884, Ceylon did not export any cardamoms worth mentioning, and those that she did send abroad consisted mainly of the long, greenish-brown, three-sided arched fruit which we know as wild cardamoms. This variety is but rarely seen now, and when a few cases appear on the market they are always well competed for by German exporters, for the seeds have a very distinct aroma, and are prized in Southern Germany for confectionery and, we believe, as ingredients in liqueurs.

In the early eighties, European planters in Ceylon commenced to turn their attention to cardamom growing. The cultivation of that product is rather easy, and was, at that time, very profitable. Moreover, the soil of Ceylon proved to be excellently adapted to the raising of the drug, especially at altitudes of between 3,000 and 4,000 feet. The process adopted in Ceylon for drying and bleaching the fruit was also much better than that generally used in India, and as a result of all these favourable circumstances Ceylon cardamoms quickly became popular in the London market. During the first years of prosperity of cardamom-growing in Ceylon, it was calculated that certain small plantations in good positions yielded a year's profit of from 200% to 300% per acre. Naturally, the thing was overdone. In 1880-81 there were about 1,200 acres under cardamoms in the island. The entire exports amounted to about 16,000 lb. The highest price paid for Ceylon cardamoms in London in that season was 9s. 1d. per lb. In 1881 the cardamom area had risen to 4,000 acres, and the exports to 236,056 lb.; but the average price had fallen to less than one-half that of 1881. The output of Ceylon cardamoms was then estimated at about 20 per cent of the world's production. Since then Ceylon has shipped from 300,000 to 400,000 lb. a year, and the present season appears to have been the first in which the demand has outrun the supply.

The present scarcity seems to be due rather to a failure of the Indian crops than to a serious falling-off in the Ceylon output. India is a very large consumer of cardamoms, and imports, even in ordinary times, a considerable proportion of the Ceylon crop. This season, owing to the failure of her own harvest, she has taken more than ever, and as London at first declined to believe in the possibility of a cardamom "famine," and would not pay the prices that could be obtained in India, it now finds itself with a depleted stock, a strong demand from America and the Continent—the consuming season being at its height—and uncertain prospects of sufficient shipments for two or three months to come. No wonder, then, that values have already more than doubled, and that there is thought to be no prospects of a serious decline. The new Ceylon crop, which generally begins to arrive in January, will no doubt, be hurried forward with unusual speed this year, and it seems likely, therefore, that the Ceylon cardamoms of 1897 will fall below the average in quality. It is somewhat strange, by the way, that the present scarcity of the ordinary commercial varieties of cardamoms has not led to an attempt to introduce upon our markets the Siamese cardamom, of which huge quantities (much larger than the produce of Ceylon) are shipped every year to Singapore and China. Though the fruit differs greatly in appearance, the seeds of this variety, the true *Amoma cardamomum*, greatly resemble those of the Malabar kind.—*Chemist and Druggist*, Nov. 23.

TEA IN MELBOURNE.

At the auction on 24th November 598 packages of Ceylon were offered, of which 558 packages sold up to the following prices: For pekoe, 9½d; orange pekoe, 10½d; pekoe souhong, 8d. broken pekoe, 10½d; broken orange pekoe, 1s 2d.—*Leader*.

SALE OF ASSAM TEA GARDENS.

NELLIE TEA GARDENS.

Messrs. Mackenzie, Lyall and Company, on behalf of Messrs. Cresswell and Co., offered for sale by public auction at the Tea Sales Room, No. 5, Fairlie Place, Calcutta, at 1 p.m. on Monday, in four separate lots, four valuable tea gardens. The first lot put up to the hammer was the garden known as the Nellie Tea Garden, situated in Zillah Nowgong in Assam. This garden comprises an acreage of about 664 acres, of which about 612 acres are held under fee-simple grant and about 52 acres under ten years pottage. The area under tea cultivation is about 225 acres. The tea is on the fee-simple land, with the exception of about three acres, which are comprised in the pottah land. The out-turn of this garden last season was 45,120 lb., and the estimated out-turn for the current season is 52,800 lb. The factory buildings consist of a wooden bungalow with thatched roof, a tea house with corrugated iron sides and roof and cemented floor, size 66 feet by 48 feet. Also two large eutcha withering houses and one fermenting house, and machinery. The bidding at the onset was brisk, starting with R2,000 and advancing up to R6,500, at which figure the property was knocked down to Mr. Bates.

HILLISUR TEA GARDENS.

The second lot that was auctioned was the Hillisur Tea Garden, situate at Tezpur in Zillah Durrung in Assam. This Garden comprises an area of about 466 acres, of which 173.41 acres are held under fee-simple grant and about 293 acres under a pottah or lease from Government for 99 years from 1st August, 1860. There are also about 73 biggals 11 cottahs to the south of the above 466 acres held in ryottee tenure. The area under tea cultivation is 17,850 acres. There are several buildings on the garden, and machinery. There were no bidders for the property, so it was withdrawn.

LIZZIEPUR TEA GARDEN.

The next lot was the Lizziepur Tea Garden, situate at Kurseong near Darjiling. This garden comprises an area of about 1,956 acres, of which about 306 acres are held under Government pottah for 30 years from 1st June 1870, about 80 acres under Government pottah for 30 years from 1st April 1869, and about 850 acres under the same Government pottah for a similar period from 1st April 1869. The area under tea cultivation is 374 acres. The outturn for the past season was 83,520 lb., and the estimated outturn for the current season is 84,000 lb. There are several buildings on the garden with machinery. The first bid made was R10,000 which rose to R40,000, after which there were no bidders, and the property was withdrawn.

THE MATTAGARRAH TEA GARDEN.

The valuable tea garden known as the Mattagarrah Tea Garden, situate at Siliguri, Darjiling, was the last to be put up to the hammer. The property comprises an area of about 750 acres, of which about 346 acres are under tea cultivation held under renewable Government pottahs. The outturn for the past season was 101,868 lb. and the estimated outturn for the current season is 104,000 lb. The buildings attached are spacious, with some excellent machinery. The bidding started with R5,000 and advanced up to R31,000, when on behalf of the vendors, a further advance of R35,000 was made by the auctioneers, but there being no more bidders, the property was withdrawn.—*Englishman*, Dec. 9.

THE AMSTERDAM DRUG-MARKET.

Our Amsterdam correspondent, writing on November 24th, states that about 27 tons of now-crop Java cassia fistula has arrived. Four tons were offered by auction, but only about 12s per cwt. was bid, and the owners will not sell for less than 13s 4d per cwt. The crop is of fair quality, but not fine. A small parcel of cassia-pulp has also arrived. Cabbos remain quite neglected and without business. About 138 boxes of fine second Sumatra Benzoin have changed

hands at about £8 7s 6d per cwt. Only common qualities are now left in stock, but for these there is no demand. Cananga oil: Fresh arrivals have filled the requirements, and for the present there is no demand.—*Chemist and Druggist*, Nov. 28.

HIGHLAND COFFEE OF SIERRA LEONE.

(*Coffea stenophylla*, G. Don.)

The Highland Coffee of Sierra Leone (*Coffea stenophylla*) is an interesting plant, as being, according to the *Botanical Magazine*, t. 7475, "one of the two indigenous West African species* which in point of Commercial value may prove a formidable rival of the Arabian coffee." It was discovered by Afzelius upwards a century ago; but was not published until 1834, when G. Don. described it from specimens collected by himself at Sierra Leone. Sir Joseph Hooker remarks:—"It was regarded by Bentham, perhaps rightly, in the 'Niger Flora,' as a variety of *C. arabica*."

The plant is an evergreen shrub or small tree up to 20 feet high; youngest leaf-shoots are pink. Leaves four to six inches long by one to one and a half broad, bright green and glossy above, paler beneath; nerves, six to ten pairs, with small glands at the axils, which are white, and perforated on the upper surface. Flowers large, white, one to one and a half inches across the corolla lobes. Berry half-an-inch in diameter, globose. Seeds hemispheric, with a narrow ventral furrow.

It owes its name, "The Highland Coffee of Sierra Leone," to Dr. Daniell.

Mr. G. F. Scott-Elliott, F.L.S., the botanist to the Anglo-French Boundary Commission, in 1892, also collected specimens, which are now in the Kew Herbarium. Sir Joseph Hooker remarks that these are of a very slender shape, with lanceolate leaves only two to two and a half inches long by one-third to two-thirds of an inch broad, very different from those represented in the accompanying plate, "and these together favour the opinion entertained by Bentham, that both are forms of *C. arabica*, Linn."

Mr. Scott-Elliott's account (*Kew Bulletin*, 1893, p. 167) is as follows:—

"*Coffea stenophylla*, the narrow-leaved 'wild,' 'bush,' or 'native coffee,' is sometimes found wild in the hills, and is more often cultivated than the Liberian. It grows very freely, and yields quite as much as the Liberian, but is somewhat longer in coming into bearing. Both the natives and French traders at Freetown say that it has a superior flavour, and prefer it to the Liberian. In fact, latterly a certain amount has been exported to a French dealer, who is said to sell it at 4 frs. 50 cents. a lb. as 'best mocha.' Considering that it is worth at Freetown 6d a lb., this should be a fairly profitable trade, and a trial shipment should be made by the English merchants to find out exactly what the market value in Liverpool would be. The plant appears to thrive best in the higher hills about Sierra Leone, on gneissose or granitic soil and can be grown at from 500 to 2,000 ft.

The plant, from which the accompanying plate was produced for the *Botanical Magazine*, was raised at Kew from seed sent in May 1894 by Sir William H. Quayle Jones, late Chief Justice of the West African Settlement and Deputy Governor of Sierra Leone.

The circumstances under which the seed was collected is given in the following despatch communicated to Kew by the Colonial Office:—

Deputy Governor, Sierra Leone, to Colonial Office.
Government House, Freetown, Sierra Leone,
April 10th 1894.

My Lord Marquess,—In reply to your Lordship's Despatch, No. 15, dated the 23rd January last, transmitting a copy of a letter from the Director of the Royal Gardens, Kew, asking that a few pounds of fresh and authentic seed of *Coffea stenophylla* may be obtained and transmitted to him for distribution to the botanic stations in the West Indies, which request your Lordship desired should

bo complied with if possible, I have the honour to report that on the arrival of Mr. Crowther, the curator of the Gold Coast, in the Colony, I inquired what was being done in the matter, and on learning that it was said to be too late to obtain seed, and as authentic seed was required, and we have no expert in the Colony, I asked Mr. Crowther to be so good as to endeavour to obtain some seed, and if it was not possible to do this now, to be good enough to ear-mark some of the coffee plants of the authentic kind, so as to enable us to supply authentic seed when obtainable.

I am glad to say that Mr. Crowther was able to obtain some of the seed required (nine pounds), which he certifies as true seed, having seen it growing before it was gathered, and also gave instructions for its being packed.

The coffee is being addressed to the Director, Royal Gardens, Kew, and will, if possible, be despatched by s.s. "Sherbro," which takes this despatch.—I have, &c.

(Signed) W. H. QUAYLE JONES, Deputy Governor.

The Most Honourable the Marquess of Ripon,
K.G. &c. &c.

Plants raised from the seed, above mentioned, flowered at Kew as early as September 1895, in one of the tropical houses. Supplies of seed and plants of this coffee have now been distributed to the Botanic Institutions in India and the colonies from whence, if the plant resists the coffee disease and proves to be as excellent a coffee as the French merchants declare it to be, good results may be expected.

The results of the introduction to the West Indies are so far of a promising character. The plants have not, however, thriven so well as could be wished at Dominica and Ceylon. In the *Report* of the Botanic Station at Dominica for 1895 it is stated:—"A few plants of *Coffea stenophylla* were planted at the station, and twenty plants distributed in couples to various planters who expressed a desire to try them. Some are reported as thriving well; others are not so satisfactory. The plants put out at the station are by no means a success as yet, one only being in a really healthy state."

From Trinidad the prospects are more encouraging. In Mr. Hart's *Annual Report* for 1895 we find:—"From seed of this new coffee, sent from Kew, a number of plants have been raised. Some of the larger plants have been planted in permanent positions, and are now over three feet in height, and it is expected will flower in a few weeks for the first time."

At the Castleton Gardens, Jamaica, Mr. Fawcett is able to report:—"Fifteen plants of *Coffea stenophylla* raised from seeds from Kew, have been planted in different places about the garden and are doing well." From the *Report* of the Director of the Royal Botanic Gardens, Ceylon, for the year 1896, we learn—

"A small plantation of 36 plants of Sierra Leone or 'upland coffee' (*Coffea stenophylla*) received from Kew in 1894 was made in April, and plants of *Lonchocarpus* sp. (the one used in Trinidad as a shade-tree for Cacao) planted among them for shade. The growth of the coffee plants has been very irregular, varying from a few inches to 3 feet, and cannot be said to be very promising. They have the appearance of plants out of their element, and look as if the climate here did not suit them. On the other hand, the *Lonchocarpus* is certainly at home, having grown very rapidly with a branching habit, and it promises to be a very useful shade-tree at low elevations. Some of the shoots have grown 8 feet in nine months."

The Director of the Botanic Gardens and Forest Department, Straits Settlements, refers to the African coffee in his *Report* for the year 1895, as follows:—

"Among these [economic plants] is a small lot of the new coffee (*Coffea stenophylla*), a plant spoken very highly of. It is growing steadily and well, and at present does not appear to be affected at all by

disease. Plants have been distributed to coffee planters in different parts of the Peninsula for experiment and observation."

THE FATHER OF COFFEE-PLANTING IN MALAYA.

The introduction of Liberian Coffee into the Malayan Peninsula is to be attributed to Mr. Leonard Wray, the father of the Curator of the Perak Museum.

Mr. Wray came out to the East early in life and was interested in the Assam tea fields, and eventually retired after having made a small fortune, which he invested in planting-industries Malaya. He was a large shareholder and a Director of the Penang Plantations Company, Limited, which owned the Alma Estate in the Province, and also some tobacco estates in Serdang, Sumatra. The interests of the Company in the East were left in the hands of Mr. Walter Knaggs, also another experienced planter. In 1877, Mr. Wray was sent out by the Board of Directors to replace Mr. Knaggs, and it was when he was on the Alma Estate that he gave his attention to Liberian coffee. He was a firm believer in the adaptability of the soil of the Peninsula to the culture of this berry. The first nurseries of Liberian coffee were made in the Province, and thence seeds were taken into Perak to the Waterloo Estate, which at one time was owned by the Company represented by Mr. Wray. Arabian coffee was also not forgotten by this gentleman, and he had a large nursery of of the smaller berry from which Perak raised its supply.

After a lapse of twenty years, coffee is booming in the Malay States; but the younger planters of the present day may not recognise in Mr. Wray the Father of this Industry, if indeed they know or have ever heard of him. Mr. Wray is now retired from active life, and lives in seclusion in Taiping, Perak, where he has two sons in the Government Service, one of whom is well-known in scientific circles, while the other is a capable administrator. —P. G.—*Singapore Free Press*, Dec. 8.

TEA IN SOUTH CAROLINA, UNITED STATES.—Mr. J. M. Maitland-Kirwan (who is a passenger on the incoming P. & O. steamer "China" on one of his periodical visits of inspection of properties in which he is interested, in the colony) sends us a letter in reference to Mr. Shepard's experiment in tea planting in South Carolina, which makes us curious to learn more. We passed through the Carolinas in 1884, staying some time in the towns, but, of course, Mr. Shepard had not begun tea growing then. We, however, saw the tea bush flourishing in the open in Washington under the care of the Secretary to the Agricultural Department—a great admirer of the then young *Tropical Agriculturist*—and a most enterprising promoter of new industries. But candid man as he was, Mr. Saunder quite agreed with us that paying a dollar a day for negro labour, tea cultivation in the Southern States of America could not be made to pay, even with a good market at the producer's door, unless a heavy protection duty was imposed on imports. We trust there is no likelihood of this even from President McKinley. At the same time, we should like to see Mr. Shepard's individual enterprise meet with a due reward, more especially as his produce ought to aid in educating the taste of his countrymen in appreciating wholesome, pure tea. It will be remembered that for some time, Mr. Shepard employed an old Ceylon planter who has rolled about everywhere, Mr. Henry Cottam; but he must have left before Mr. Maitland-Kirwan's visit.

INDIAN MANGOES FOR THE BRITISH MARKET.

The following article appears in the *Fruit Grower* of the 18th November:—If there were no other psychological reason for bringing before our readers the importance of introducing the famous mangoes grown on the island of Bombay to the British markets, the unquestioned success of the recent importation into this country of oranges from New South Wales would surely serve. But the celebration next year of our Queen's long reign leads us to seriously urge upon the merchants and salesmen of this country the advisability of taking advantage of the special occasion, and considering the most important question of popularising the fruits grown in our colonies and dependencies. We think an effort should be made to show next year in every possible way the facilities we possess of supplying the home markets with, not only the necessaries, but the luxuries of life produced within the red line of the Empire.

INDIAN FRUIT GENERALLY.

If the orange, which is a fruit to be handled with considerable care, can be safely and satisfactorily transported from the Antipodes to this country, and meet a ready demand, there can be no reason whatever why fruits grown in India should not be more than equally successful. India, the native home of the orange, of the lemon, and other citrous fruits, is within 15 days' steam of the markets of the mother country; and the merest tyro can estimate for himself what this means to the fruit growers of India. It may be urged by the thoughtless that, well suited as India most unquestionably is for the growing of almost every kind of fruit, it is a land where very little fruit is actually grown, and the varieties are singularly few. This, however, is only a matter of time, and we shall without doubt succeed in stimulating the native landowner and produce grower in India as soon as we show him clearly that a safe and sure market exists for all orchard produce that he can place in sound condition upon the markets here. It is not only in this country that fruit may prove the salvation of the owners and tillers of the soil. It is a far larger question with regard to India, but none the less worthy of the serious consideration of all concerned.

SIR GEORGE BIRDWOOD.

There is one fruit, however, which is grown in India as it is grown nowhere else—the succulent, toothsome, savoury mango; and it was only natural, when we had decided to introduce this matter to our readers, that we should endeavour to collect, for their edification and instruction, some particulars of what has been done in respect to the importation of this fruit into Great Britain; and this brought us into immediate communication with Sir George C. M. Birdwood, K.C.I.E., C.S.I., who may be said to be the pioneer importer of the mango into this country.

Sir George has, however, only attempted to deal with the matter on purely private lines. He has for twenty-five years past received from friends in India small consignments of mangoes; and his success up to within the past few years was only, to say the most, moderate. The fruits arrived in this country in a badly unsound condition, until that system of packing which we have for so long advocated in connection with nearly all fruits was adopted; and the moment this simple and effective method was tried it was successful. The beautiful mango fruits now arrive

in splendid condition, and they are a luxury with which only very few in this country are acquainted. Grown on the island of Bombay, where by far the best mangoes are cultivated, gathered at the right time, carefully wrapped in paper and packed in shallow boxes partitioned off in pigeon-holes, as it were, each to hold one fruit, with holes drilled to admit of perfect ventilation, the fruits now come over in absolutely perfect condition; and are received by Sir George Birdwood and those friends who are fortunate enough to share his consignments with the real pleasure which their merits as a fruit unquestionably deserve.

Sir George was led to import these fruits from the fact that being an old Anglo-Indian, and having eaten the fruit regularly for 24 years, as soon as he came back to this country the craving for the mango developed to a degree that was only to be satisfied by the actual article being brought within his reach; and the disappointment and vexation attendant upon the unsuccessful nature of the early importations can be best conceived by those who, under similar circumstances, have patiently awaited the arrival of a much cherished luxury.

The best consignments of mangoes received by Sir George Birdwood have invariably been from Mr. Jansetjee N. Tata, Justice of the Peace, Esplanade House, Bombay; and no one could better advise than this princely Parsee merchant in organising the coming great fruit trade between British India and this country.

TRANSPORT ARRANGEMENTS.

The acceleration in recent years of the service between Bombay and England has overcome the difficulty of transport. The judicious gathering and packing of the fruit has followed, and thus all hindrance to its introduction on commercial lines here are abolished. The P. and O. boats usually arrive at Bombay on the homeward journey with a fair amount of room for cargo, and there is, therefore, no doubt that special arrangements could be made between merchants on this side and consignors on the other to develop this very promising branch of the fruit trade. The credit of establishing this profitable Anglo-Indian business will, we believe, be eagerly sought by merchants and growers alike.

ABOUT THE MANGO.

A good mango is one of the most luscious fruits grown, and a mango grove is a sight to be remembered. Full of juice, fleshy, with a soft pulp like flesh of the consistency of hardened butter, about the size of a very large orange with a peculiar point at the end of the fruit, the mango grows three or four on a stalk at the end of a branch. It is in shape very like a large kidney potato. In the centre of the fruit is a large stone, flat like a bean, the kernel being of a most peculiar and delicate flavour, and considered a great luxury when roasted.

There are many peculiar virtues attributed by the native Indian to the mango to which we shall refer when dealing with the matter in a second article; but we feel that we have sufficiently urged the permanent title of the mango to be placed on the list of fruits for the home markets from over-sea dependencies. We trust that no time will be lost by those of our readers who are in a position to move in the matter of introducing this fruit on a sufficiently large scale to make it popular in this country.

We shall be pleased to place those willing to negotiate for consignments of mangoes in communication with growers in India.

CHINA AS A POSSIBLE COMPETITOR WITH MACHINE-MADE TEAS?

INDIAN PLANTERS MUST WAKE UP LIKE THEIR CEYLON BROTHERS.

Is the news true that a full-blown Chinaman is among the Ceylon "creepers" of the present day, busy learning "all about tea" as carried on in this progressive Colony, in order to carry his knowledge and experience for application in his mother-land? We believe our question has been answered in the affirmative and the fact, taken in connection with the proposal of a London Syndicate to send out machinery for a model factory to "the Middle Kingdom" and with the information recorded from China in our issue yesterday, is by no means to be despised. If "John Chinaman"—under the auspices and encouragement of British and Russian Tea merchants,—wakes up to the need of adapting himself to the existing conditions of the European market, it is quite possible that a revival to some extent of the China tea trade even with the United Kingdom, may be on the tapis. For, it is not alone what may be done with machinery, especially in assortment, that would tend to awake rivalry once again; but there is the great advantage at present existing between the use of silver on a natural and an artificial basis. It will be remembered how effectively Mr. Balfour in the House of Commons pried his colleague, the Chancellor of the Exchequer, as well as Sir Wm. Harcourt, when he inquired if the condition of our Empire with no fewer than three different currencies, could be considered satisfactory:—

- (1) A Gold Standard in the United Kingdom, Australasian Colonies, &c;
- (2) A Silver Dollar Currency in the Straits Settlements and Hongkong; and
- (3) An artificial Rupee Currency in India, Ceylon and Mauritius.

As between China and Ceylon [and India] both silver-using countries, the advantage to the former, in having a natural dollar against our inflated rupee, is very great. Here is an estimate handed to us by a London merchant interested in Ceylon, just before we left the metropolis:—

Exchange.	15th July.	18th November.	Difference.
Bombay T T	1/2½	1/3 19-32	} say 1/3½ = 1½ say 10½ per cent higher.
Calcutta "	"	1/3 21-32	
Shanghai 4 m's.	3/0½	2/11½	1½ " 3 per cent lower.

China, receiving silver for its tea, and having no concern in the artificial rise in the rupee consequent on the Indian Government closing the mints, has the difference of

This advantage of 13½ per cent on tea at 8d, equals 1½d per lb.—since July.

We may add that, since November 18th, the difference in favour of China is enhanced—so that there is serious reason to anticipate a revival of trade such as must adversely affect the tea planters of India and Ceylon. There is the greater reason, therefore, why both communities should set to work, shoulder to shoulder, with more earnestness than ever before, to endeavour to win for their pure produce the markets still so largely in the hands of China and Japan tea exporters. The Indian tea planters have never yet done their duty in this respect; but have allowed Ceylon to bear by far the larger share

of the responsibility and expense of campaigns in Australasia, the Continent of Europe and America. It is time, therefore, that our friends in Assam and other Indian tea districts should wake up to a due sense of their responsibilities. If Ceylon with an export of 104 million lb. tea collects so much for its campaign fund, it is a simple question in proportion to show how much more ought to be contributed by Indian proprietors. Moreover, if the total expenditure of Ceylon—official and otherwise—in this direction, say since the Melbourne Exhibition, and also that of India, were made up, it would serve the more strongly to accentuate the failure of duty on the part of our neighbours and ought to shame them into making an effort equal to their responsibilities on the present occasion.

THE COLOMBO TEA MARKET.

It should indeed be a matter for great and general satisfaction among our planters that the local tea market has assumed such considerable dimensions. Our detailed table of the weekly sales, when completed, will show that not less than 31 to 32 million lb. of tea have been offered during 1896 in the Colombo market, or over 30 per cent of the total exports which, we suppose, may now be taken for 1896, at from 103 to 104 million lb.—or very close on the official estimate. Of the offerings nearly 26 million lb. were sold and the progress made (in sales if not prices) for some years may be indicated as follows:—

Colombo Tea Market.

Tea offered.	Tea sold.	Average price
1891 .. 13,933,793	.. 9,578,611	.. 41 cents
1892 .. 15,060,681	.. 11,518,869	.. 41 "
1893 .. 19,250,940	.. 14,365,017	.. 43 "
1894 .. 20,810,539	.. 15,738,343	.. 43 "
1895 .. 26,192,586	.. 19,668,116	.. 48 "
1896 Ests. 32,000,000	.. 26,000,000	.. 42 "

We have here the record of a great and growing local business which deserves the utmost encouragement, because it means, to a great extent, a direct trade between this producing Colony and such large consuming markets as are found in the Australasian Colonies, South Africa, the Continent of Europe and America, without troubling the London market. For this cause, also, it has not unfrequently happened that, while the London market was depressed, our local tea sales have been both active and buoyant and have given better rates than the simultaneous London quotations. There can be no doubt that the distributors of tea on the Continent of Europe and America will be inclined more and more to deal direct in the Colombo market and without the intervention of London. In many respects too, Colombo has great natural advantages over Calcutta as a central tea mart; and if it were thrown open in the same way, there can be no doubt that all the big tea-buyers in the world would very soon be represented here. Meantime, we must be satisfied with the steady progress made under existing circumstances and trust that for the coming year we may experience an even fuller supply offered and sold locally with enhanced prices. To secure the latter, several clouds now hovering on the planters' horizon must roll away—leaving us with cheaper money, more moderate exchange and freights, and an ample labour supply to gather in the abundant flushes which, we trust, may be anticipated during 1897. Meantime, that the Colombo Tea Market may continue to flourish and increase in extent and importance, month by month, is our very sincere wish.

MACHINE-MADE CHINA TEAS IN THE LONDON MARKET.

The first of the machine-made China teas have been placed on the London market. We have been shown a catalogue issued by Messrs. Ferguson Odell of Great Power Street intimating that 187 packages of China tea "specially prepared by a new method" will be sold absolutely without reserve by order of the Foochow Tea Improvement Company. It will be interesting to note what price machine-made China teas will fetch in Mincing Lane.

"THE THIRTY COMMITTEE"

Minutes of proceedings of a meeting of the "Thirty Committee" held at Kandy on Saturday, the 12th day of December 1896, at half past seven o'clock in the morning.

Present:—Messrs. A. W. S. Sackville (Chairman), A. Philip (Secretary), J. N. Campbell, A. A. Bowie, James G. Macfarlane, J. A. Spence, H. J. Vollar, W. D. Gibbon, J. H. Renton, R. S. Duff Tytler, F. G. A. Lane, Gordon Pyper.

The notice calling the meeting was read.

The Minutes of proceedings of a meeting of the Committee held at Kandy on Saturday, the 10th October 1896, were submitted for confirmation.

Resolved:—"That they be and they hereby are confirmed."

Submitted letters from the Manager, National Bank of India, Limited.

Resolved:—"That copies of National Bank of India, Limited, Head Office letters be forwarded to the Manager, National Bank of India, Limited, Colombo, for his information and guidance, and that further particulars be asked regarding his request for cheques in support of certain debits under Letters of credit issued in favour of Mr. Wm. Mackenzie."

Submitted letters from the Treasurer of the Colony.

Read letter from Mr. Francis F. Street.

Read letter from Mr. Gordon Frazer.

Read letter from the Secretary, Ceylon Chamber of Commerce, intimating that Mr. J. H. Renton had accepted a seat on the "Thirty Committee" in the room of Mr. G. F. Traill, who has left the island.

Read letter from the General Manager, National Bank of India, Limited, London.

Read letter from Government acknowledging copy of Minutes of proceedings of a meeting of the "Thirty Committee" held at Colombo on the 15th August and confirmed at a meeting held at Kandy on the 10th October.

CEYLON TEA IN RUSSIA.

Read letter from Government notifying that the Governor has been pleased with the advice of the Executive Council to sanction the expenditure of a further sum of £2,000 in pushing Ceylon tea in Russia.

Read correspondence between Mr. M. Rogivue and the Chairman.

Read letter from the Manager, National Bank of India, Limited, Colombo, forwarding letter of credit in favour of Mr. Rogivue for £500.

REPRESENTATIVE IN AMERICA.

Read letters from Mr. Mackenzie to Mr. Sackville dated Scotland, 1st October; London, 12th and 16th October, 7th October; 23rd and 30th October; New York, 10th November.

Read letters (two) dated Scotland, 30th September to the Secretary, "Committee of Thirty."

Submitted Mr. Mackenzie's statement of expenditure for "Committee of Thirty," dated 26th October 1896.

Read letter from Mr. S. Elwood May.

Resolved:—"That a further sum of £12,000 sterling be granted to Mr. Mackenzie for the purpose of pushing and advertising Ceylon tea in America, during 1897, and that the approval of the Governor in Executive Council be at once applied for; the amount named being the probable requirements of the Committee for advertising purposes in America during that year under the scheme submitted by Mr. Mackenzie.

GREEN TEAS FOR THE UNITED STATES OF AMERICA.

Read letter from the Agents and Secretaries of the Upper Maskeliya Estates Co., Limited.

CEYLON TEA IN BELGIUM AND HOLLAND.

Read letters from Mr. E. R. Templer.

Read letter from the Agents, Ceylon Tea Co., Limited, enclosing invoice of 20 half-chests—1,000 lb. Ceylon tea shipped per ss. "Oldenberg," costing R611.07 and requesting payment. Resolved:—"That the account be paid."

Read letter from the Manager, National Bank of India, Limited, enclosing "D" draft on London "P." £25 sterling favouring Mr. E. R. Templer.

Submitted connected correspondence.

CEYLON TEA IN NORWAY.

Read letter from the Agents, Ceylon Tea Co., Limited, enclosing invoice of 4 half-chests—250 lb. tea costing R170.25 in execution of the grant to Mr. C. Palliser.

CEYLON TEA ON THE CONTINENT OF EUROPE.

Read letters from Mr. R. V. Webster. Resolved:—"That the sum of £500 be granted to Mr. R. V. Webster for expenditure in further pushing and advertising Ceylon tea on the Continent of Europe, and that the approval of the Governor in Executive Council to the appropriation be applied for."

CEYLON TEA ADVERTISING.

Read letter from Mr. Rowbotham. Resolved:—"That the Committee regrets being unable to entertain the application."

CEYLON TEA IN AUSTRIA AND HUNGARY.

Considered letters from Messrs. Cooper, Cooper & Co. on the subject of pushing Ceylon tea in Austro-Hungary. Resolved:—"That the Committee regrets no funds can be contributed at the moment for the purposes indicated in Messrs. Cooper, Cooper & Co.'s letter, but the Committee will view with interest any advertisements bringing Ceylon tea prominently before the public in the countries mentioned. Should such advertisements appear the Committee will at a future date reconsider the application, but at same time would draw Messrs. Cooper, Cooper & Co.'s attention to the fact that in their letter of 17th June pure Ceylon teas were to be pushed whereas in their letter of 9th October Ceylon only bears a small proportion to the teas sold."

Read letter from Mr. C. M. B. Wilkins applying on behalf of Mr. T. C. Anderson for a free grant of 1,000 lb. tea for a firm in Buda-Pesth. Resolved:—"That under existing arrangements the Committee regrets it does not see its way to giving a grant of tea for Buda-Pesth."

CEYLON TEA IN CANADA.

Read letter from Mr. James Lumbers. Resolved:—"That in reply it be pointed out to Mr. Lumbers that a mistake has been made in supposing that the Committee give bonuses, and that Mr. Lumbers be recommended to communicate with Mr. Mackenzie in the matter of advertisements."

The "Thirty Committee" then adjourned.

A. PHILIP,
Secretary to the "Thirty Committee."

THE GERM LIFE OF THE SOIL.

Formerly we were wont to regard the soil as composed of dead, inert matter; now, however, thanks to recent bacteriological research, we know better. Most of it, it is true, is composed of dead matter; but this is so inextricably and intimately permeated by microbic life that it can hardly be regarded as dead. What all the functions of these microbes are we do not as yet fully know, but many effect the decomposition of organic matter; which, indeed, they have been shown to be among the earliest agents in giving rise to. The fertility of a soil is directly due to their initiative, for they elaborate in various ways the food materials of the plant, and convert the latter into forms suitable for assimilation. As was pointed out in a recent article on this subject, soils may be said to be, in a very direct sense, the product of their work through the long past ages. Till recently, it was believed that these organisms required for the development organic matter; but one of the most important discoveries in this domain which has recently been made goes to prove that some of them, at least, are able to subsist on a purely mineral food. These latter microbes are of very wide occurrence, and are found even on bare rock surfaces. Although we know as yet but very little with regard to the methods in which the decomposition of the material of the soil is effected, it would seem as if the ultimate results obtained are due to a highly interesting system of co-operation. Thus to one class is due the initial stage in decomposition; while another class carry out the work started by the former bacteria to a further stage of development, and so on.

Few of us probably grasp the importance, from an economic point of view, of the process of the putrefaction of organic matter constantly going on in the soil. It is one of the great factors in maintaining the circulation of matter, a law on which the perpetuity of all life depends. There is in this universe only a certain definite amount of matter suitable for the formation of new animal and vegetable life; hence, to permit of the formation of new forms of such life, it is necessary that the dead matter should become broken up, and rendered available for this purpose. Were this law inoperative, the result would of course be that the earth's surface would become encumbered with the accumulation of dead organic matter to so great an extent that animal life would be impossible. Hence it is that, in this respect, bacteria perform services to humanity, as well as to all other forms of life, of incalculable value.

With regard to the occurrence and distribution of these organisms in the soil, investigations have shown that it is almost entirely in their surface portion they are to be found, and that the deeper we go the less numerous do they become. Among the factors determining their abundance, the season of the year is one of the most important. Since among the conditions under which bacteria live one of the most important is the existence of a certain temperature, we find that they are most abundant during the summer time. Indeed, from spring to autumn there is a steady increase in the number. They may be divided into different classes, according to the nature of their products. A large class oxidise the ingredients of the soil by assimilating the organic matter, converting it into carbonic acid and water, and sometimes actually giving off oxygen. We have another class whose action is of a completely opposite character. These organisms exercise a reducing influence that is not helpful to the processes of agriculture. To this class belong those which give rise to a loss of nitrogen from its valuable compounds, and which thus impair the fertility of the soil. But, happily, the work of this class of organism is largely neutralised by that of a recently discovered class which enrich the soil in this valuable fertilising ingredient by fixing the free nitrogen of the air, and thus bringing it within the scope of the plant. Of these three types of organisms examples may be cited; and in doing so we shall select such as have to do with either the fixation or elaboration of that most important plant-food, nitrogen.

In the first place we have what are called nitrifying organisms. These organisms effect the preparation of nitrogen in a form suitable for the plant to absorb, and furnish a very good example of the co-operative method in which these minute denizens of the soil carry on their work. In the process three stages may be distinguished, in which, it would seem, three different classes of organisms are implicated. The first stage consists of the conversion of nitrogen in its various organic forms into ammonia. Abundant in the air, in rain-water, and in the surface of the soil, the microbes, active in the process of ammonification, flourish best at temperatures between 30 degs. and 90 degs. Fahr. Temperatures near the freezing point, or above 110 degs. Fahr., check their development. The second stage in the process is effected by ferments of a globular form, and consists in the conversion of ammonia into nitrites; while the final stage, which is effected by ferments four times as small as those effecting the second stage, consists in the conversion of nitrites into nitrates. Reference has already been made to this process in an article contributed to the "Scotsman" about a year ago, so that we need not further refer to it, except to add that the conditions regulating this process of nitrification are well known, and throw considerable light on the question of the fertility of the soil. We may also add that they are chiefly limited in their occurrence to the superficial layers of the soil, and have not been met with at a depth below six feet; while probably active fermentation is not to be found much below eighteen inches. The reason of this is that one of the chief reasons of their abundant development is the presence of a plentiful supply of air. It is on this account that they are not found in water-logged soils. Their susceptibility to poisonous substances, such as certain compounds of iron, which are apt to be produced where the soil is not properly aerated, and to sulphur compounds, serve to explain more clear than was previously realised the reason of the inimical action of such a body as fresh gas-lime when applied as a manure. And here a very interesting practical question presents itself. Since the fertility of a soil may be said to depend to no small extent on the abundance of these nitrifying ferments, in the case of a soil which from some cause or another may have had these valuable ferments killed out, is it possible—it may be asked—to re-seed the soil? To this it may be answered that numerous experiments have demonstrated in a striking manner the value of inoculating a sterile soil with nitrifying ferments. This has been effected by strewing over the fields some soil rich in nitrifying bacteria, such as an old garden soil. There can be little doubt, indeed, that the value of farmyard manure, to a certain extent, may be ascribed to the fact that it supplies the soil with abundance of such organisms. The principle of soil inoculation, as we shall immediately point out, has been more systematically worked out in the case of another class of organisms—viz., those which fix free nitrogen from the air.

The discovery of these organisms in certain excrescences or nodules on the roots of certain leguminous plants, such as peas or beans, was made in the year 1836. It has since been discovered that it is highly probable that quite a number of different kinds are implicated in the process; indeed that each different kind of plant has its own special kind of organism. These invade the roots from the soil, and give rise to the formation of nodules, where they multiply with great rapidity, and stimulate the growth of the plant cell. Three stages in the process may be defined. The first is that during which the bacteria live as parasites at the expense of the plant cell. Gradually, however, the struggle for existence becoming very intense, the bacteria become passive, and the cells become filled with bacterioids or bacterium-like bodies. It is when this period is reached that the plant absorbs the contents of the nodules, and leaves the cells, out of which they are formed, in a limp condition. How exactly the nitrogen

is fixed we do not know. All that is known is that the nodules are necessary for the process, since the more abundant they are on the roots of the plants the more abundant is the quantity of nitrogen fixed. It would seem that the soil is by no means an important factor, since from it must come the fixing bacteria; and experiments have shown that in this respect soils differ very considerably, some being more plentifully provided with nitrogen-fixing bacteria than others.

The discovery of the nitrogen-fixing bacteria was not long in being put to a practical use. Pot experiments were very soon started, in which soil extracts were used and experimented with. The result of these experiments showed that all soils are not equally suitable for growing leguminous crops; that many, indeed, are poorly supplied with nitrogen-fixing bacteria; but that such soils when inoculated with a soil extract from a portion of the soil taken from other fields rich in such bacteria yield a luxuriant growth. These experiments have led Professor Nobbe, a well-known plant physiologist, to prepare pure cultures of the nitrogen-fixing bacteria for general use. This very practical application of bacteriology to agriculture was patented in February of this year. The cultures are made on a wholesale scale by a well-known German firm; the same, indeed, as has already undertaken the manufacture of diphtheric anti-toxic serum. Of nitragin, as the culture is called, some seventeen different kinds are prepared. The pure cultures are grown in agar-gelatine—a common medium for the growth of bacteria. Sufficient for the inoculation of an acre of soil can be purchased for the small sum of five shillings. The culture may be applied in either of two ways—by making a watery extract of it and immersing the seed to be sown in this solution, or by mixing the culture with some pure sand.

We have referred to a class of organisms whose action is inimical. Among these the most important are those which effect denitrification, as it has been called. They undo the work of the nitrifying bacteria, often with the result that a portion of the nitrogen is set free, and, escaping in the gaseous form, is entirely lost to the soil. The conditions which favour the development of the denitrifying bacteria are the opposite of those which favour the development of the nitrifying bacteria. Hence, in order to prevent the development of the former, it is sufficient to aim at the development of the latter.

It may be well to add, in conclusion, that the soil may contain disease-producing germs. Thus, those giving rise to the deadly disease lock-jaw, or tetanus, are known to be often present in the soil. By the burial of animals which have died of germ-produced diseases, the propagation of that disease has been known to result. In one case, in France, it was found that sheep pasturing in a field where two years previous a single animal suffering from splenic fever had been buried were infected with the same disease, and died. Yellow fever, it may be added, is another disease the germ of which seems to be able to live in the soil. It need scarcely be pointed out that such facts furnish strong evidence in support of cremation as a mode of disposal of the dead. They also serve to indicate the risk attached to the indiscriminate use of sewage from our large towns as a manure for the fields.

—*Scotsman*. Nov. 23.

M.A.

THE BLACKSTONE TEA CO., LD.

A special meeting was held at the offices of Messrs. Carson & Co. on the 18th Dec in the afternoon to confirm the resolutions of a previous meeting, viz. :—

- (1) That the Company be voluntarily wound up.
- (2) That Mr. F. Maciudoe be appointed Liquidator for the purpose of winding up the affairs of the Company and distribute the property.
- (3) That the remuneration of the Liquidator be fixed at a fee of £750.

These were confirmed.

DR. MORRIS ON COMMERCIAL FIBRES.

Dr. D. Morris, C.M.G., Assistant Director of the Royal Gardens at Kew, delivered an interesting lecture at the London Institution, on November 30, on the subject of "Recent Researches in Commercial Fibres." The lecture was illustrated, and Dr. Morris, with his usual ability, set forth a large mass of valuable information in regard to the various classes of fibres.

After a brief review of the progress made in the production of fibres more or less familiar to European commerce, attention was directed to a floss yielded by the silk-cotton tree, known as Kapok. This has already formed an article of considerable export value in Java, and more recently it has been taken up in Ceylon and India. It is too short for textile purposes, but forms an excellent stuffing material, superior to everything except the best sorts of feathers, wool, and hair. The silk-cotton tree (*Eriodendron*) is one of the most striking features of the vegetation in some parts of the West Indies, especially in Jamaica. If the silk-cotton now wasted in the latter island were carefully collected, it is probable that it would yield annually 3,000 bales, of the value of several thousand pounds. In the other islands it might be worth while to plant waste places with this tree, which begins to bear in the fifth year, and without further trouble would yield yearly crops of an article evidently in increasing demand at fairly remunerative prices.

The recent developments in the singularly interesting fibres known as China grass and Ramie were then touched upon. These have hitherto been regarded as at once the most attractive and elusive of fibres, and as having not only raised the greatest expectation but also led to the most lamentable failures. The lecturer gave a sketch of their history, and stated that on the results of efforts extending over 50 years these fibres were at last being placed within reach of manufacturers in this country, and utilised for textile fabrics inferior only to silk. Considerable stress was laid on the fact that there were two plants concerned, viz., the China grass (*Boehmeria nivea*), a native of temperate China, and a plant known in Assam as Rhea, and in the Malay Islands as Ramie (*B. tenacissima*), a native of the tropics only. It was useless to attempt the cultivation of the former except in moderately warm countries, while the latter required especially hot conditions. Remunerative crops could only be grown from these plants in well-drained soils of exceptional quality and fertility. A plentiful rainfall well distributed over the year was also necessary, as well as a high and uniform temperature. Under favourable conditions it had been shown that two or three crops of stems, weighing, in the aggregate, 15 to 20 tons per acre, could be produced in one year, and as the plants were perennial, successive crops could be produced from ratoons, as in the case of the sugarcane. From the quantity of green stems above mentioned there would at least be yielded ribbons or raw fibre of the value (at present prices) of 8*l.*, and fibrine (the finished product) worth about 1*l.* According to returns from reliable sources the cost of the cultivation in favourable localities, on an average of years, would be at the rate of 4*l.* per acre.

Provided there was a careful selection of suitable sites for plantations, the cultivation was regarded as likely to prove advantageous in some parts of the West Indies, especially in the warm fertile valleys of Dominica, parts of the humid parish of Portland, in Jamaica, and similar localities in Trinidad, British Guiana, and the Southern districts of British Honduras. Dr. Morris spoke hopefully of the future prospects of the cultivation in the West Indies, but was careful to point out the conditions essential to success, and advised that only experienced and capable planters should attempt to start the industry, which, in their hands, might go a long way to relieve the people in the West Indies from their present difficulties.—*Colonies and India*, Dec. 5.

THE NAHAVILLA ESTATE CO., LTD.

The annual general meeting of this Co. was held at the offices of Messrs. George Steuart & Co., Queen Street, on the 19th Dec. in the afternoon were present, Mr. R. C. Wright (Chairman), Mr. Gordon Pyper, Mr. De Saram, Mr. J. Patterson, Mr. Chas. Gordon and Mr. E. S. Grigson were represented by their proxy, Mr. J. Patterson.

The Report of the Directors having been adopted, Mr. GORDON PYPER proposed that a final dividend of 7 per cent. be now paid, making altogether with the dividend of 6 per cent. already paid, 13 per cent.

Mr. DE SARAM seconded.—Carried.

Mr. DE SARAM proposed that the Directors' remuneration for the year ending 30th September, 1896, be fixed at R2,000.

Mr. PATTERSON seconded.—Carried.

ELECTION OF OFFICE-BEARERS.

Mr. GORDON PYPER proposed that Mr. William Anderson who retires by rotation from the Board of Directors, be re-elected.

Mr. DE SARAM seconded.—Carried.

Mr. R. C. WRIGHT proposed that Mr. John Guthrie be appointed auditor for the year ending September 30, 1897, on a remuneration of R100.

Mr. J. PATTERSON seconded.—Carried.

This was all the business.

MARKET FOR TEA SHARES.

THURSDAY EVENING, Dec. 3.

Although quiet at the beginning of the present week, business in tea shares has again recovered a little, with a fair number of transactions recorded. The general range of values, however, is slightly easier than it was.

Interim dividends are now the order of the day, either actually announced or in early contemplation, among them being:—

	January 1.	
Assam Company ..	5	per cent.
Cachar and Dooars (Pref.) ..	3	"
Chargola (Ordinary) ..	3½	"
Chubwa (Ordinary) ..	3½	"
Chubwa (Preference) ..	3½	"
Darjeeling Consol. (Pref.) (broken period), 3s 4d per share.		
East India and Ceylon (Ordinary)	3	"
East India and Ceylon (Pref.) ..	3	"
Jhanzie ..	4	"
Jokai ..	5	"

Mincing Lane keeps rather quiet, with some low prices ruling for the commoner sorts. Home consumption, however, as well as export, continue on a liberal and progressive scale.—*H. & C. Mail.*

WYNAAD PLANTERS' ASSOCIATION.

From official the minutes of a general meeting held at the Club, Meppadi on 2nd December we extract following:—

Read circular letter from Secretary U. P. A. having reference to the resolution of the Shevaroy Planters Association re the adulteration of coffee, and the formation of a Coffee Association for the prevention thereof. Also the Chairman U. P. A's letter on the subject. Recorded.

This Association agrees with the Chairman U. P. A. that the present is not the time to move in the matter.

Import Duties.—Read letter from the Secretary U. P. A. asking for statistics required by the Government of Madras regarding the quantity of artificial manures used in the district during the past 10 years. Resolved that the Coast Firms be requested to supply the information and that the Ag. Honorary Secretary be instructed to write to them on the matter.

Coffee Robbery.—Read Ag. Honorary Secretary's letter to the Superintendent Police regarding Police arrangements for this season. Recorded.

Roads.—Resolved that the Ag. Honorary Secretary be instructed to write to the Collector of Malabar to ascertain what steps have been taken with regard to H.E. the Governor's reply to the Deputation.

TEA IN AMERICA.

NEW YORK, Nov. 18.

The change which took place in the tea market early last month, and which led to largely increased business and an advance of from 1½ @ 3c per pound from the lowest, has been well sustained. There seems to be general confidence that the year's supply will fall from 12,000,000 to 14,000,000 pounds less of Greens and Japans alone. The Black tea crop is likely to be behind last season, except for Ceylon and India sorts. The present outlook is for a supply about 10,000,000 pounds less than requirements. A *resume* of the sales in first hands since September includes 18,000 packages Japan, 3,000 Country and 12,000 Pingsuey Greens, 15,000 Formosa, 7,000 Foochow, 10,000 Amoy Oolong, besides 6,000 Congou. This is the largest wholesale business in tea outside of the auction room in three years for the same period.—*American Grocer*, Nov. 18.

NEW TEA COMPANIES.

PALLIKELLE CEYLON ESTATES, LIMITED.—Registered November 11, by Hollams, Sons, Coward and Hawkesley, Mincing Lane, E.C., with a capital of £100,000 in 5,000 £5 preference and 75,000 ordinary shares of £1 each. Object, to adopt and carry into effect an agreement expressed to be made between G. A. H. Vandespar, E. H. Hancock, and W. Johnson of the one part and this company of the other part for the acquisition by purchase or otherwise of the Pallikelle and Rajawella Estates, in the Island of Ceylon; to carry on business as planters, agriculturist fruit growers and preservers, breeders of and dealers in livestock, and curers, packers, and shippers of all kinds of produce; as bankers, brokers, financiers, shipowners ship charterers, warehousemen, wharfingers, coal merchants, timber merchants, shippers, insurers, and carriers by land and water, engineers, ironfounders, contractors, builders, mill-owners, spinners and weavers, manufacturers of machinery, patent articles, &c.; to transact all kinds of agency and commission business; to turn to account such lands as may from time to time be acquired by the company by clearing, draining, fencing, planting, cultivating, mining, quarrying, building, farming, irrigating, and grazing. The signatories, who take one share each, are:—E. H. Hancock, 28, Mincing Lane, E.C.; W. Johnson, 25, Mincing Lane, E.C.; M. H. Paine, Stock Exchange, E.C.; H. A. Hancock, 28, Mincing Lane, E.C.; H. S. Hancock, 28, Mincing Lane, E.C.; C. A. Reiss, 51, Lime Street, E.C.; A. Zimmermann, 51, Lime Street, E.C. The number of directors is to be not more than ten nor less than five. The first are C. A. Reiss, W. H. Dodds, W. Johnson, E. H. and H. A. Hancock, G. A. Vandespar, and A. Zimmermann. Qualification, £250, Remuneration, £500 per annum, divisible. Registered office: 51, Lime Street, E.C.

AUGUSTA TEA ESTATE COMPANY, LIMITED.—Registered November 17, by Harwood and Stephenson, 31, Lombard Street, E.C., with a capital of £50,000, divided into 4,000 six per cent. preference shares of £5 each and 20,000 ordinary shares of £1 each. Object, to adopt and carry into effect certain agreements expressed to be made by this company with Messrs. Henry Wills, L. Reiss Brothers and Co., and Hancock and Co., to acquire by purchase or otherwise, lands, factories, and buildings, and any business in Ceylon or elsewhere, and in particular the estate known as the Augusta Estate, situate in the district of Hantane, in the island of Ceylon; and, generally, to carry on business as planters, farmers, graziers, cultivators and growers of tea, coffee, cardamons, and other crops; as miners, shipowners,

merchants, exporters and importers, carriers, agents, brokers, storekeepers, and contractors, &c.; to construct and maintain telegraph lines, telephones, electric light, heat, and power works, canals, reservoirs, waterworks, wells, aqueducts, watercourses, furnaces, gas works, piers, wharves, docks, saw, quartz, and other mills, hydraulic works, factories, warehouses, &c. The signatories, are:—C. A. Reiss, 51, Lime Street, E.C.; E. H. Hancock, 28, Mincing Lane, E.C.; H. A. Hancock, 28 Mincing Lane, E.C.; D. B. Crane, 28, Mincing Lane, E.C.; A. Zimmern, 51, Lime Street, E.C.; G. E. Elvish, 96, Embleton Road, Ladywell, S.E.; C. J. Haycock, 26, Birkbeck Road, Beckenham, S.E. The number of directors is to be not more than five nor less than three. The first are C. A. Reiss, E. H. Hancock, H. A. Hancock, T. J. Lawrence, and H. Wills. Qualification, £150. Remuneration, £300 per annum, divisible. Registered office, 50 and 51, Lime Street, E.C.

PUNDALOYA TEA COMPANY OF CEYLON, LIMITED.—Registered November 19 by Allen and Son, 17, Cullisle Street, Soho Square, with a capital of £150,000 in £10 shares. Object, to adopt and carry into effect an agreement expressed to be made between G. Christian, E. Christian, F. H. Christian, and C. M. Robertson of the one part, and this company of the other part, for the acquisition of the Sheen and South Pundaloya Estates, in the Pundaloya district, and the Wootton and Charing Cross Estates in the Kolagaloya Valley of the Dimbula district, and the Deeside Estate in the Maskeliya District, all in the Central Province of Ceylon, and to develop the resources of and turn to account the lands, buildings, timber, and rights for the time being of the company in such manner as the company may think fit, and in particular by clearing, planting cultivating, farming, grazing, mining, building, felling, manufacturing, and otherwise dealing with the same; as planters, farmers, and graziers, cultivators and growers of tea, coffee, cocoa, &c.; as shipowners, warehousemen, exporters and importers, carriers, agents; to construct and maintain rail and tram roads, telephones, telegraphs, reservoirs, waterworks, &c. The signatories, who take one share each, are: E. Christian, 1, Gloucester Mansions, S.W.; G. Christian, Bighton Wood, Alresford, Hants; C. M. Robertson, 12, Fenchurch Street, E.C.; A. Bethune, 44, Argyll Road, Kensington; C. H. Dendy, 8, Old Jewry, E.C.; H. Bois, 5, Astwood Road, South Kensington; F. H. Christian, Bighton Wood, Alresford. The number of directors is to be not more than five nor less than two. The first are E. Christian, F. H. Christian, and C. M. Robertson. Qualification, £1,000. Remuneration, £500 per annum and a share in the profits, divisible. Registered office: 12, Fenchurch Street, E.C.

TEA IN CAROLINA, U. S.—Since writing on this subject we have received a pamphlet from Mr. Shepard, proprietor of the Pinehurst Tea Plantation, in the Southern States, entitled "May Tea be profitably grown in the Southern States of America?" We shall reproduce it in our monthly *T. A.*, and meantime may notice that Mr. Shepard fully acknowledges the difference due to price of labour: to pluck the leaf alone per lb. with him costs as much as to supply the article packed from the East; but he aims at raising the quality and says he is succeeding! Assam Indigenous tea plants suffer because the temperature falls to 15° Fahr. in winter, and yet the average on Carolina is as high as 65° and the annual rainfall 56 inches. Mr. Shepard employs 20 negro children to pluck over 25 acres and they are kept steadily at work during the season. Evidently, too, the people of Charleston appreciate the quality of the tea prepared. For further particulars of Mr. Shepard's experiment we must refer to the *Tropical Agriculturist*.

THE TEA MARKET.

In the Tea market the low level of quotations is the feature; quality, too, is at a low level, and at the auctions (Indian) a large percentage of supplies does not realise more than about 6d. per lb. The past week shows an increased pressure of low grade Tea offering, whereas quality has not been fully represented, and Tea at 10d. to 1s. per lb. is dearer than that obtainable, say, in October, the cheapest period this season. The machine China Teas sold on 2nd inst. at 4½d. to 10¾d. per lb.—*L. & C. Express*, Dec. 4.

PUSSELLAWA PLANTERS' ASSOCIATION.

Minutes of proceedings of a Committee meeting held at Gampola Hotel on Thursday, December 10th at 9 a.m.

Present.—Messrs. J. Roberts, C. J. Jones, R. S. Duff Tyler (Chairman), and H. M. Picken, (Honorary Secretary).

Notice calling the meeting having been read, the minutes of last meeting held on Saturday, the 9th of May, 1896, were read and confirmed.

BUSINESS.—Resolved that the official crop for 1897 be stated as follows:—

Crop.		Total acreage under tea.	
1897	.. 6,534,600	1897	.. 17,845
1896	.. 5,849,000	1896	.. 16,648
Increase	.. 685,600	Increase	.. 1,197

or showing an average of 405 lbs. of tea per acre in bearing for the district.

MINOR ROADS.—Resolved that Government be asked to grant the sum of R450 towards the following minor roads in the district:—

	R.	c.
Pussellawa—Nawalapitiya	.. 100	00
Xussellawa—Nilambe	.. 150	00
Loolcondera—Karagastalawa	.. 100	00
Pussellawa—Deltotte	.. 100	00

Total .. 450 00

and the Secretary when applying for funds, do point out that no deductions should be made from monies collected for Resthouses, as none exists in the districts.

GAMPOLA-KADUGANNAWA ROAD.—Read letter from Mr. Shelton Agar, dated December 1st. Resolved:—"That Mr. Agar be thanked for kindly undertaking the supervision of above road, and that Government be asked to pay any unspent balance to Mr. Agar for 1896 and that a further sum of R3,000 be asked for, for 1897 *vide* Secretary's letter of July 29th, 1896."

PUSSELLAWA-NUWARA ELIYA ROAD.—Resolved:—"That correspondence be brought forward at next General Meeting."

DISTRICT HOSPITAL.—Read letter from Colonial Secretary, dated July 2nd.

Read letter from District Medical Officer *re* medical fees. Resolved:—"That the subject be brought before next General Meeting. Resolved:—"That Secretary write to the Principal Civil Medical Officer *re* the double allowance to D.M.O. whilst keeping two horses."

Blue Book returns for Assistant Government Agent, Nuwara Eliya.

Statistic forwarded by Chairman for the estates asked for.

H. M. PICKEN,
Honorary Secretary.

"THE GERM LIFE OF THE SOIL" is the title of an instructive article from the *Scotsman* sent us by an ex-Ceylon planter as of special interest, he thought, for his brethren out here in the present day.

DAVIDSON'S PATENT SIROCCO TEA MACHINERY.

Last week we quoted an article from the *Indian Planting Gazette* in which complimentary notice was taken of this well-known firm's tea machinery. The subject has again been brought to our attention by the receipt of a very useful and interesting pamphlet catalogue containing illustrations and descriptive matter of Messrs. Davidson & Co.'s various machines for the manufacture of tea and accompanied by a portrait of the head of the firm. Mr. S. C. Davidson, whose name, says the *Home and Colonial Mail*, has been so widely known throughout the tea districts for years that planters unacquainted with his personality might possibly have the idea that he is a grey-haired veteran. Although Mr. Davidson has been upwards of thirty years actively connected with tea, it must be remembered (continues our contemporary, that he started his planting career in his early teens, and we can state from our own personal knowledge that the portrait is a good likeness of him, time having dealt gently with him, and he not only is as vigorous, active, and enterprising as ever, but looks to be in the full possession of those important qualities, together with the secret of perpetual youth. The pamphlet opens with particulars of the various commercial changes lately made in India and elsewhere affecting the representation abroad of the Sirocco Engineering Works. Messrs. Davidson and Co. have now a branch establishment of their own at 4, 5, and 6, Lall Bazaar, Calcutta, under the experienced management of Mr. H. M. Harris, formerly of the Colombo branch, which is now under the management of Mr. George F. Shanks, from the Belfast office. Mr. C. W. U. Adamson is chief visiting engineer for Assam and Bengal, with Mr. Garratt as assistant, while estates in Ceylon, Southern India, and Java are looked after by Mr. F. G. Maguire, chief visiting engineer for the Colombo branch, with Mr. Farbridge as his assistant.

It is pointed out in the pamphlet:—"Our list of Tea machinery has lately been increased by a number of our Mr. S. C. Davidson's newly patented inventions, the addition of which now puts us in the pioneer position of being the first to supply Tea factories with an *entirely complete* outfit of mechanical appliances for each and every process in the manufacture of Tea, from the time the leaf is brought into the Factory up to its being sent off as finished Tea in packed chests.

This complete outfit comprises machinery for Withering and Fermenting, Rolling, Drying, Cutting, Sorting, and Packing; also our recently patented Steam Engines, Fans, and "Double-Clincher" Belt Fasteners.

We have been appointed Sole Selling Agents in Assam, Bengal, and Ceylon for Tangyes' Patent Oil Engines, The "Unbreakable" Pulley and Mill Gearing Co. Ltd.'s specialities for the economical transmission of power, and the "Titan" Edge Belting. Particulars as to prices, &c., can be had from our Calcutta and Colombo Depots."

The *H. and C. Mail* thus describes the pamphlet:—

The pamphlet, while partaking somewhat of the nature of a catalogue, is intended more particularly to refer only to improvements in existing and entirely new Sirocco tea machinery, and we notice that the order in which the machines are dealt with is according to the order of each process of manufacture, the first machine illustrated and described being for withering tea leaf, and as this is an entirely new machine we have no doubt planters will be very much interested in the particulars given. It is stated that for upwards of thirty years past the difficult problem of successfully accomplishing the withering of tea leaf by artificial means has received Mr. Davidson's unremitting study and attention, his investigations during the first half of this period having been carried out on his own estate, while his further experiments towards the development of a suitably practical form

of machine for the purpose were conducted at his works in Belfast, the outcome of which had been the machine now under reference. The first of these machines has been in practical operation during the current season at Rasetpur Tea Estate, South Sylhet, where it was shown to be capable of withering each charge of leaf, whether wet or dry, in an hour and a half. The leaf has merely to be thrown into the drum or cylinder, which is now being made capable of holding a leaf charge of about six maunds at a time, and when the engine is started the fan and drum are put in motion, and warm, moist air circulated through the leaf. All the heat necessary for warming the air and withering the leaf is supplied from the waste steam of the engine, and the air is kept continuously circulated through and through the multitubular heater, fan, and withering drum, so that it soon becomes charged with vapour from the moisture out of the leaf, and it is claimed that this hot moist vapour, in conjunction with the motion imparted to the leaf, accomplishes the withering of it efficiently and rapidly, and at the same time imparts to the leaf an agreeable perfume.

The trials that the machine has been subjected to at Rasetpur have shown that it fully withers the leaf in an hour and a half but as the leaf on being delivered from the machine is somewhat warm, it is obvious that modified methods of handling it in the subsequent stages of rolling, &c., will be necessary, as compared to the methods suitable for leaf withered in the ordinary way, and although Mr. Davidson is not as yet entirely satisfied with the quality of the tea produced by this machine the results already obtained are nevertheless sufficiently encouraging to convince him that, with a few further modifications in the methods of treating the leaf after it comes from the machine, as good, if not better, tea can be obtained from the machine-withered leaf as with that withered in the ordinary way. But as the machine Mr. Davidson has been experimenting with at Rasetpur would lie idle during the cold weather months, we understand he is at present arranging to have it transferred to Ceylon, where plenty of leaf is available at this time of year, in order that its further experimental trials may be continued there, and until these experimental trials are fully carried out he is not offering this machine for sale, but considers its preliminary working has been sufficiently successful to entitle him to include it in his present catalogue.

As the success of this machine would have such far-reaching effects, representing nothing less, in fact, than a complete revolution on present methods of tea manufacture, we, in common with every enterprising member of the tea community, will be much interested in watching its further trials and development, and shall willingly keep our readers posted with such information as we may be able to gain from time to time with reference to it, but we have no doubt it will take some little time yet before the correct lines of working the machine and effecting whatever necessary changes in the subsequent processes of manufacture are occasioned by its employment, can be definitely settled. However, from the results so far obtained, Mr. Davidson is thoroughly confident of its ultimate success in every respect, and we will now only express the hope that his most sanguine expectations may be realised to their fullest extent, and that this machine will eventually and soon take a high place among the many successful inventions with which his name is already associated in connection with the tea industry.

The next on the list is Davidson's Patent Tea Leaf Rolling Machine, which is a new departure in this line, and the leading features of which may be summarised as follows:—

1. The leaf receptacle above the rolling table is stationary, and the machine consequently has fewer moving parts.
2. The discharge of the leaf takes place through a side door in the stationary leaf receptacle, and not down through the centre of the rolling table, as in the machines hitherto in use.

3. The leaf receptacle in this machine being stationary, the power, which is absorbed in other machines for imparting motion, not only the movable receptacle, but also to its contained charge of leaf, is thus saved. The machine, when empty, can be easily driven at full working speed by one man, and when charged with about 350lb. of withered leaf it only requires two horse power to drive it.

4. The discharge of the rolled leaf is effected through a door in the side of the leaf receptacle over a stationary shelf or tray, so that the discharge is effected with great facility and cleanliness.

5. The leaf receptacle is entirely open over top, and all necessity for the application of any pressure on the leaf, by means of a weighted lid or cover, is entirely obviated, through the employment inside the leaf receptacle of what are termed in the catalogue "ploughs," and of a cone-shaped projection in the centre of the cavity or well in the rolling table, the combined operation of which, when the table is in motion, causes the leaf to so circulate that it has a continuous "boiling-up" movement in the centre of the mass from bottom to top of the leaf receptacle, where it falls outwardly all around to the sides, quickly finding its way down again to the bottom.

6. The outer surface of the leaf receptacle, and the outer edge of the rolling table are so constructed that any leaf and juice which escape through the clearance space between the lower edge of the leaf receptacle and the upper surface of the rolling table are automatically swept round to a delivery spout on the table, where they can be collected in a bucket and returned from time to time into the top of the leaf receptacle, whereby the danger of collecting such escaped leaf by hand from the upper surface of the rolling table, as hitherto necessary in other machines, is entirely obviated.

The many practical advantages which, as above mentioned, are claimed to be embodied in Mr. Davidson's new Rolling machine will be readily apparent to experienced planters, and as Mr. Davidson has spent about a couple of years in bringing the machine up to its present working efficiency, and is placing it on the market at a price lower than usual for Rolling machines of similar capacity, we would anticipate for it a very successful future.

Of the new Automatic Endless Web Sirocco Tea Drier, next referred to, it is claimed that the operations of this machine, which has been in use during the current season at Baraora Estate, Sylhet, where it gave an average output of 320lb. per hour of perfectly dried tea, accomplishes what has long been desired in the drying of tea—namely, in a continuous working machine to automatically subject the wet leaf at the start to a high temperature, so as to instantaneously arrest fermentation and then finish off the tea to perfect dryness at low temperature, which system of drying is claimed to enhance the quality of tea produced.

Then we come to the "Down-Draft" Sirocco, to which the special feature of the large automatic drier can now be applied in a modified form, so that the first tray of wet leaf can be brought under the influence of the fresh hot air from the store immediately on going into the machine. Then there is the "Up-Draft" Sirocco, with particulars of the latest improvements, in the way of fitting them with combination air and smoke chimneys, same as in the old original No. 1, which is still so popular. There is the well-known Tea Sorter as well as the Packer, to which a self-acting hopper for filling the tea is now applied. There is also an improved tea cutting mill, together with illustrations and descriptions of a special design of double cylinder steam engine suited for tea estates. So comparatively small a matter as a "Double Clincher" belt fastener, which has been a great success in various mills and factories in the United Kingdom, has not been omitted, and in looking through the pages of this pamphlet the reader will gather a good idea of the requirements of a tea garden and how efficiently Messrs. Davidson & Co. endeavour to cater for same.

PLANTING AND PRODUCE.

(From *H. & C. Mail*, Dec. 4.)

TEA IN THE CAUCASUS.—There have been so many contradictory reports about the tea-growing experiments of the Russian Government in the Caucasus that it is difficult to arrive at the truth. The latest account indicates that mystery attends the whole business. The Odessa correspondent of the *Times* on Tuesday stated that "another large body of Chinese have arrived at Odessa en route to the Caucasus, where they are going to superintend the cultivation of the tea plant. "Such success," he adds, "has attended the Government's efforts in tea-planting in the Caucasus that several large estates there have been acquired by private persons for this purpose, and it is expected that in the near future Russian tea from the Caucasus will prove a powerful rival in the tea markets of Europe." As it has been stated that the tea planting operations had resulted in failure, the Russian authorities must, if the last account be correct, have been "laying low" about them previously.

OTHER WORLDS TO CONQUER.—It is depressing to think that the tea drinking country of the world *par excellence*, Russia, is so faithfully attached to the China market, and that although bold efforts have been made on behalf of Indian and Ceylon tea garden proprietors to induce the Russians to change their ideas and alter their palates so little comparatively has come of it. The consumption of tea in Russia attains enormous proportions, and is yearly on the increase. According to the *Journal de la Chambre de Commerce de Constantinople*, Russia imported in 1894, through the port of Odessa, 15,692,000 kilogramme's (a kilogramme equals 2,204 lb.) of tea from China. Through the custom houses of the Baltic large quantities of tea are entered, chiefly consigned to Moscow, or for local consumption, and by the land customs of Eastern Siberia about 20,000,000 kilogrammes of tea, representing a value of about 50,000,000 roubles, were imported. All the tea imported by way of Odessa or other European frontiers is leaf tea, but that coming into the country via the Chinese frontier is chiefly tea in bricks of different dimensions. These teas are consumed by the nomads and the northern peasants by reason of their cheapness and the facilities of transport. The customs duties on this kind of tea are much lower than those on leaf tea. In the various retail shops leaf tea is sold in packets weighing $\frac{1}{8}$, $\frac{1}{4}$, $\frac{1}{2}$, or 1 Russian pound at prices varying according to quality, from 80 copecks to 5 paper roubles the pound, but as a rule sufficiently good tea may be purchased for 1 rouble 50 copecks to 2 roubles 50 copecks per pound. Russia exports annually a certain quantity of tea in packets, prepared by the large importing houses of Moscow, which are well known throughout the whole of Europe. By way of Odessa 30,000 kilogrammes were shipped in 1894 to the destination of Roumania, Bulgaria, Turkey, and Austria-Hungary. The import of Ceylon is so far inconsiderable, but it is hoped that it will improve.

CROP ESTIMATES, REVISED AND OTHERWISE.—A long continuance of cheap tea is the outlook the *Grocer* predicts. The speculative opinions indulged in with regard to the Indian tea crop for 1896-97 have been numerous and contradictory, but they have enabled the *Grocer* to safely come to the conclusion that the crop will be of much greater magnitude than that in the previous year, or even heavier than the one gathered in 1894-95. The actual outturn in that season, it will be remembered, was 127,127,000lb, followed by a largely increased yield of 135,479,000lb in 1895-96, and now there is another materially augmented crop raised for the present season. By favour of the Indian Tea Association in London, our contemporary is informed that the production for this year, based on the "first" revised estimate, was reckoned at 141,784,668lb., which was 2,518,852lb less than the original calculation in June, when it was expected the Indian tea produce would equal 144,303,520lb; but later advices received only a week ago state that,

according to the "second" revised estimate, the entire crop for 1896-97 will probably reach about 146,000,000lb, or 1,700,000lb over the first or original estimate that was formed six months ago. Details of the enlarged, or what may be regarded as the final estimate are not yet to hand, but are believed to be on the way, and will doubtless confirm the opinion that the total crop of Indian tea coming forward will embrace the outside quantity already named. If so the whole crop landed here since the middle of 1896, arriving, in course of shipment from Calcutta and to come on afterwards, will turn out to be the largest on record; and the London wholesale dealers may make up their minds for the handling of mammoth supplies of Indian tea during the remainder of the season.

LOOKING BACKWARD.—The early portions of the new gatherings that were offered by auction in July and August, when the market was bare, met with a good reception, and found free buyers, particularly for the finer grades with pungency and tippiness, which realised very firm prices to some advance. Subsequently, however, says the *Grocer*, the yield of many gardens turned out disappointingly as regards the quality, which showed a marked falling off from the character of the invoices imported at the opening sales, so that since then the demand at times has perceptibly flagged, and prices have been more or less weak. Autumn-flavoured kinds of the better class have mostly been taken at full rates, but "Calcutta bought" teas, as they are termed, together with low medium and commoner sorts whether leafy or broken below 1s per lb. have been disposable only at a repeated decline, till they were 1d to 2d cheaper than at the starting point. Though the results financially may not have been entirely satisfactory to importers, the cheapening of the article has had the salutary effect of greatly stimulating consumption, as is evidenced by the heavy quantities that pass out of the bonded warehouses every week; and the duty-paid entries on this description of tea in the United Kingdom for the first ten months of the year, as officially stated, amounted to 99,732,168 lb, against 93,844,535 lb in 1895, and 95,994,441 lb. in the corresponding period of 1894. Favourable as these facts may appear to the interests of consumers, there is still the possibility of the trade being overdone with an excessive glut of tea, and this too just when the heaviest importations from Ceylon are usually expected, which must swell the aggregate supply on offer, besides helping to establish an additional reduction in value all round. With this prospect before them, dealers and retailers generally may reckon upon having, as a benefit, a long continuance of cheap tea.

CHINESE IMITATION OF INDIAN TEA.—Some Chinese having got hold of some tea machinery, possibly of their own making, having been trying to imitate Indian tea, a few packages have been sent over for sale in "the Lane," but it is poor stuff, and certainly unlike Indian tea.

TEA IN CANADA.—A despatch from Montreal says that the Canadian Tariff Commission is disposed to favour a duty on tea. This report is much commented on in the Canadian press.

NATAL TEA CULTIVATION.—We have heard much at times about the possibilities of tea cultivation on an extended scale in Natal. The opinions expressed by the few planters from India and Ceylon who have visited the South African colony have differed, but the general view has not been very hopeful as to Natal producing a large crop of high grade tea. A few weeks ago Mr. John Fraser, a tea planter of Ceylon, touched at Durban after a trip to Europe recently, and after having seen something of the local tea gardens said tea would grow anywhere in Natal, but not at a profit. Maritzburg seems the extreme upper limit of profitable industry. Beyond, the vicissitudes of climate would probably prove fatal. Ceylon has no winter as in Natal, and there is no cessation in the plucking season. On the other hand, in Ceylon there is required one coolie for 1½ acres, whereas in Natal one coolie is supposed to be ample for four acres. The result in Natal however, is to some extent an indiscriminate plucking.

"NEW PROCESS" CHINA TEA.

We noted in our last issue that a new departure was announced in the sale of China tea, prepared more on the lines of Indian and Ceylon. Considerable interest is, indeed, being shown just now in the arrival of various parcels of Foochow tea, manufactured by a new process designed to produce something akin to Indian and Ceylon kinds. These parcels—five in all—are described as "machine" and "hand-made," and are, no doubt, produced with somewhat primitive appliances, and, therefore, capable of great improvement; but if we can judge of results from these experimental shipments, there is every promise of success when undertaken on a large scale. It is understood these teas—or some of them—were made in the Pakling district far on the season, when only third crop leaf of more or less undesirable quality was available, and if so, the result is all the more satisfactory. The quantity offered has been 119 half-chests and 156 boxes, the highest price being 10½d. for "Golden Pekoe" and 4½ for "Broken Pekoe." The prices realised are very good, and should give encouragement to the pioneers of this new departure which may be the beginning of a revolution in the whole tea trade, and prove to be a turning-point in the history and fortunes of China tea, which it is now seen can be produced more in accord with the English taste by a simple alteration in the form of manufacture. This being so, there are hopes of a new era of activity and prosperity being near at hand for those who take up the manufacture of China tea in an Indianised form. The only difference between China and Indian and Ceylon teas is one of manufacture—a question of retaining the tannin in the one case and extracting most of it in the other—and there is no reason why a rough, strong-flavoured tea should not be produced in China as elsewhere. With this in view, and given a continuation of the present exchange advantages to China owing to the artificial value of the rupee, and with prospect of reduced duties when the approaching revision of the tariff takes place, there is a hopeful prospect for Foochow—and, indeed the other tea ports. The machine made tea was catalogued as being sold by order of the "Foochow Tea Improvement Company." With such results as these, sales show there is every reason to expect a large import of similar teas over the next few years, and during the forthcoming season it is expected some 100,000 half-chests will be sent forward, "specially prepared by a new method," as the catalogue described those just sold.—*L. & C. Express.*

COFFEE PLANTING IN NYASSALAND BRITISH CENTRAL AFRICA.

LIST OF PROPRIETORS WHO HAVE TAKEN UP LANDS IN THE SHIRE HIGHLANDS &c. FOR COFFEE PLANTING.

We have compiled the following list from the Map accompanying the latest Report of Sir H. H. Johnston, K.C.B., on the British Central Africa Protectorate up to March 31st, 1896. The land taken up is spread over a large extent of territory in the Zomba, Blantyre, Mlanje and other districts. In some cases, enormous blocks of territory have been taken up; while in others, a few hundred acres comprise the allotment. We pick off the names of the proprietors from the Map, indicating the districts as well as we can,

with a very rough approximation to area taken up, based chiefly on the scale of the Map. The list runs as follows:—

Proprietor's Name.	District.	Approximate area. Acres.
Messrs. Buchanan Bros.*	Zomba or	15,000
Do. do	Upper Shire	12,000
Do. do	"	20,000
Messrs. Hinde & Starke	"	1,000
Do.	"	600
Mr. Burnet	"	400
" Purdy	"	1,000
" Smiley	"	1,000
" Baird	"	1,400
" Cameron	"	800
" Robertson	"	1,600
" Morkel	"	600
" Bruce	Namasi	70,000
Do.	Fort Lister	5,000
" E. C. A. Sharrer	Zomba & Blantyre	190,000
Church of Scotland Mission	Fort Roberts	1,000
Mr. Israel	Blantyre	1,000
" Waller	"	1,400
" Hastings	"	1,400
" Lindsay	"	1,400
" Duncan	"	600
Church of Scotland Mission	"	600
Pettitt Bros.	"	800
Messrs. Keiller & Nesbitt	"	1,000
" Buchanan Bros.	"	8,000
"	"	2,500
Zambezi Industrial Mission	"	8,000
B.S.A. Co.	"	14,000
African Lakes Corporation	"	18,000
Mr. V. Cox	"	1,200
" S. Steblecki	"	4,000

* The late John Buchanan, C.M.G. and brother—no connection of any Mr. Buchanan ever in Ceylon.—Ed. T.A.

† This is Mr. J. H. Carson of Haputale; no doubt the 3,500 acres belonging to the Ceylon Nyassaland Coffee Company is included in this block.—Ed. T.A.

‡ Ex-Ceylon residents.—Ep. C.O.

The acreage given by us is from the merest guess—based on applying the scale of the map to each block as coloured. We have probably, in many cases, under-estimated the blocks taken up. In regard to the districts, too, we have been at a loss, as the map does not indicate such districts or provinces as North Nyassa, South Nyassa, Mariмба, Nyassaland, &c. Perhaps, we may get a correspondent in Nyassaland to correct our list so far as area and districts are concerned; but it is of interest to put on record the names of the first proprietors. We are surprised that any one capitalist or pioneer should be allowed to take up 365,000 or even 50,000 acres. We should have thought that 10,000 acres ought to have been fixed as the maximum for any individual owner. Before many years elapse, there may be regret at the alienation of such large blocks.

In our Frontispiece, will be found a reduced copy (by Mr. Lawton of Jaffna) of the Map issued by Sir H. Johnston with his Report of the Shire Highlands, showing the estates or blocks of land taken up for coffee. It is roughly executed, but gives a sufficiently good idea of the relative situation and size of the properties when the numbers on the Map are compared with the following key:—

References to the Map.

Land which is left unshaded or the borders of which are shaded belongs to the Crown or to the natives under Crown control.

TEA AND COFFEE.

What a pleasant sight is the breakfast or tea table! However simple, there is something bright and attractive there. It seems to smile gladness and welcome to you as you sit down at it. The tea and coffee send out a subdued fragrance as they are being poured out, and the cups and saucers, however common, shine and sparkle. Tea and coffee!—what associations of comfort and refreshment and pleasure come with the words! What can our forefathers have done without them? They were, I suppose, much dependent on beer, as down in Suffolk and Norfolk and in north-eastern Essex to this day the farmer-folk, both at breakfast and tea, indulge first in a glass of beer, and put a cup of tea or coffee on the top of it. Well, that custom is gradually going out, too, as the older folks die off; and so, in this way, as in others, the demand for tea and coffee increases.

TEA.

For a long time we were dependent on China for tea; but now other countries are producing tea in large quantities, notably India, all along the sloping sides of the hills in Assam, and in many fertile districts in Ceylon, where the rich soil and the "spicy breezes" are greatly in its favour. The teas of Assam—most of them, if not all—are very strong; while some of those of Ceylon are more like the Chinese teas, and nowadays the bulk of the supply comes from these

regions, the Chinese teas still being used for "mixing" and "blending." This is still a large business, at which many experts are employed.

The successful "tea-taster" is a person who commands a good salary and a good position. He has to be very careful to keep his palate clear of contact with certain other things; taste and smell must go in nice association in his case. For hours before he begins his task of tea-tasting he must not try his palate with certain wines or with anything strong, but must keep it clean and ready for the flavour of the tea. He does not drink tea in the proper sense: generally speaking, he merely sips, gets the flavour, and then empties his mouth, and after the lapse of a certain number of minutes tries the next sample, or the next blending. He is always trying this mixture, that blend, so as to provide the best flavour for his patrons or constituents.

The tea plant, which is a very pretty evergreen shrub, grows to between five and eight feet high, and has a deep-green, smallish leaf. It needs, at certain seasons, a great deal of care and attention, trimming, dressing, &c. It is not a long-lived shrub. Nine years is about the longest it continues to yield the tender leaves fit for tea, as then they get hard, dry, and sapless. As the first crop is not yielded till the third year of the shrub's life, it is plain that on a tea plantation, after a certain period from the start, there must be a constant rooting out and replanting to keep up the continuous supply of tender, fresh green leaves, which are best the first year of yielding. When the leaf has reached a certain definite stage, then comes the very important work of picking. The shrubs are, as far as possible, planted in lines; and, just as in hop-picking in England, a certain length of so many lines is given to a picker or group of pickers. The tender young leaf is that which is picked. The first yearly crop is picked about the end of April, the second about the end of May, and the third about the end of June. Archdeacon Gray, in his great work on China—where he lived and worked for a lifetime—tells us that a clever labourer can pick from ten to thirteen pounds a day. But it should be remembered that the strict plantation rule is that he must pick only the young leaves, and never pick more than one from the branch at a time. So the work of picking is very monotonous and trying, as there is a considerable amount of stooping in dealing with the lower branches. The leaves of the first gathering of the season is considered to be the more delicate, and goes to make the finer teas mainly.

The teas having thus been gathered and sorted, which means the removal from the finer of any large and rougher leaf, what is called the "drying" or firing process begins. This is necessary to preserve the tea; so as to enable it to travel and not lose its fragrance. In great measure, the different teas, black, green, souchong, pekoe, &c., are produced by the variations of the process they are submitted to at this stage. It is often said that really to enjoy tea it must be drunk in China, or India, or in Ceylon, before it has been faced and packed, and gone long journeys or voyages over sea and land. All teas, however, are and must be, in greater or lesser degree, carefully dried either by exposure to the sun or by exposure to charcoal heat; and some of the more highly-coloured teas are in different degrees treated with powdered gypsum or turmeric, and some, again, where a certain tint is wanted, are actually treated to a rubbing with Prussian blue.

There is still a duty on tea which adds a few pence to the price of every pound; and there is a section of financial reformers who go strongly for what they call "a free breakfast-table," and demand that this duty should be altogether repealed, since tea has become a "necessary of life," which, at all events, hard workers will admit it to be, from its refreshing, stimulating qualities.

COFFEE.

Coffee in many minds, contests the high place with tea. If it does not have the delicacy of fragrance found, at all events, in the finer teas, it is refreshing, stimulating, and, especially

after meals, very salutary. Ceylon produced good coffee before it was famous for tea; but coffee originally came from certain parts of Arabia, where it is native. Now it is grown, and grown to profit, in several tropical countries. The finest coffee is still the Mocha, which comes to us from Yemen, in Arabia; but Java, the West Indies, Brazil, and stretches of Central America produce the greater quantity consumed. The coffee plant, left to itself, in favourable circumstances, would grow to a small tree some seventeen or eighteen feet high; but under culture the aim is to keep it low—a squat shrub—to save trouble and time in climbing up to pick the fruit; and for this reason it is seldom allowed to grow higher than eight or nine feet. The plant has longish leaves, placed exactly opposite each other on the stalk, and is not inelegant. Right above the point where the pairs of leaves join the stem, the berries grow in clusters. Each of these contains two coffee beans, which separate from each other when freed from the outside skiv. The gathering and drying of these, too, as in the case of tea, demand skill, care, and exact knowledge of the progress of the fruit, which cannot all be gathered at one time but the bushes have to be gone over again and again.

One of the most important processes in preparing the coffee is the roasting, preparatory to the grinding. This being underdone, the coffee does not grind clean; being overdone in the slightest, the fragrance is largely lost. On the Continent it is a common sight, in the morning more especially, to see the servants come out into the courtyards with a little circular, long-drum-looking machine over a box with heating apparatus. This they carefully turn, shaking the coffee beans about in it; and they say their care and expertness in this process just before the grinding is what gives the fine fragrance to Continental coffee. The practice of hotels and families roasting their own coffee in this style has not in the same way become common in England, but great improvements have recently been made in the larger machinery employed in the big establishments in England, and the fragrance of the coffee much improved on what it used to be—at which all those who do not roast their own coffee have surely the best reasons to be pleased.

—A. H. JAPP.—*Folks at Home.*

TEA IN NATAL.

As the tea industry is making such great strides in India and Ceylon, it will prove interesting to look abroad and learn what is being done in other lands. This journal, in its issue of the 31st October last, referred, in a note, to "Tea in Natal." Some samples of tea manufactured on the Natal estates, and which were entered for competition at the Pietermaritzburg Exhibition, were sent to London for adjudication. They have been reported on as superior in quality and value to those hitherto seen from Natal, as they resembled Indian tea of a good medium grade. Unfortunately they lacked the distinctive strength and flavour—the essential requisites in desirable teas. They came from estates situated close to the sea coast, at elevations ranging from 100 to 500 feet above sea level, with an annual rainfall of some 48 inches at the lower and some 40 inches at the higher level. It is not surprising that, considering the situation of these estates, a more favourable report was not forthcoming. The rider is added that these teas could not be exported with profit. Natal and Ceylon both started tea growing in earnest, and on a large scale, in 1880, although a small beginning was made in the former place in 1876. The progress made by the latter in comparison with the former is remarkable. In Natal, however, there are barely 3,000 acres of land under tea cultivation in the entire colony, and the number of large tea gardens is five. It is only since 1891 that tea cultivation may really be said to have made any perceptible progress in this part of the world. The tea district lies within six miles of a place called Stanger, amid beautiful

scenery, and a fine view of the sea can be obtained from some points in the gardens. In the burning of the large central factory at Kearnsey, 110,000lb. of tea was destroyed at the same time. It is estimated that the total crop of Natal tea this season will not be more than 700,000lb., but next year it is hoped that one million pounds will be made. The greater portion of the tea is consumed in Natal itself. The planting community are endeavouring to introduce their teas into the South African markets, specially into Johannesburg, but this town does not take kindly to it. Ceylon teas are getting firmly established there, and in many other parts of South Africa. It is a matter of surprise that no efforts are being made to push Indian teas in this quarter of the globe. Natal planters have many difficulties to contend with, their chief trouble being the cost of their labour supply, which is far too expensive. It is not probable that the tea industry in Natal, as conducted at present, will ever attain sufficient proportions to be included as an important factor in the tea trade of the world. The planters are very jealous of each other, and very reticent as to their affairs. They will not supply figures, so it is extremely difficult to know what progress is really being made. If they were not so bound up in their own ideas, and would accept of kindly advice, they would do well to engage the services of experienced planters and tea-makers from this country. Judging from accounts received, they lack knowledge and experience of both planting and manufacture. They are importing the latest and best types of machinery, but have no system. Without experienced men to lead and direct them, they cannot hope to make satisfactory progress, and their best efforts are bound to end in disappointment.—*Indian Planters Gazette*, Dec. 12.

ENEMIES OF THE COCONUT TREE IN MALABAR.

A Correspondent of the *Madras Mail* writing with regard to the ravages of the Rhinoceros Beetle on coconut estates in Cochin says:—Of coleopterous beetles that are destructive to coconut, palmyra and areca trees in Malabar, there are three varieties, one being already named. That one belongs to the genus *dynastide* and is easily distinguished by its geniculate horn which has given it its title of Rhinoceros Beetle. Another species is the *butocera rubus*, with two very long antennae and with great, long legs. It is commonly called the Coconut Beetle. The third variety is the *calandrum palmarum* or Coconut Weevil. The natives call all three varieties *chelle*, that is, fleas. Between these three robust little creatures thousands of coconut trees and coconuts are annually destroyed and human ingenuity has not yet been able to devise any very successful or practicable means of getting rid of the "herculean" pests—I say "herculean," because such is their strength, and such also is the title by which some entomologists have called them. The two latter kinds do not seem to be so much dreaded by the garden farmer and toddy tapper in Malabar as the other species, but all three are, I should think, equally destructive. The larva of the Coconut Weevil abides in the leaf bud and goes through its transformations there, the fibres surrounding the pith providing excellent material for the cocoon. However, before the cocoon has been formed, the larva which has been steadily at work has eaten pretty well through the heart of the tree, practically destroying it. The cocoon soon gives place to the chrysalis. Then in a little while, out comes the perfect beetle and escapes to bring more evil larvae into the world. The *butocera rubus* is still more wicked, for it instals itself at the very base of the trunk of the tree and there deposits its eggs. In due time comes the grub which eats its way up to the very summit, polishes off the leaf buds and at times accounts for the destruction of the whole head, spathe, leaf, stalks and all. Toddy tappers will tell you that this beetle in its perfect form cannot effect much injury, as its long

feelers prevent it from moving about freely among the tender leaves and flowers. But they do not seem to realise the vast amount of havoc that the larvae are capable of committing. The Rhinoceros Beetle works in quite a different method, for its larva enters the coconut tree at the top and works downward, gnawing up all the wood and fibrous tissue. It then builds its cocoon out of the very refuse it has created. The natives say that this beetle is most destructive after the new rains set in, and for good three months subsequently. It also proves very destructive to the "cabbage" in young plants, great numbers of which are thus irrecoverably damaged. When the spadix appears on mature plants, the beetle insinuates itself as at the base of the stalk, eats through the enveloping spathe and destroys the whole of the promised fruit. Spring leaves also are thus largely destroyed. The toddy tapper carries a long iron probe with him, and if ever he spies his foe imbedded anywhere in the trunk or frond, in goes the probe, transfixes and draws out the remorseless depredator. During the day time these beetles keep out of the way, but at night they emerge and start their destructive pursuits. The Rhinoceros Beetle in particular is very largely met with hidden in the soft but unwholesome soil of dunghills, and the tapper sometimes searches for his enemy in such places and destroys it. It is interesting to note that the refuse of the horse stable attracts the creature more readily than that of the cow pen. In some parts of Malabar the trees are afforded some relief by placing sea sand or salt in the midst of the leaves and flower sheaths. This appears to scare away the borer. I have not heard of any device in these parts for attracting the insects by lighting fires.

Insects, however, are not the only enemies that the coconut tree in these parts has to bear with. Bats, flying squirrels and flying foxes, tree dogs and toddy cats are also among the pests. In rural parts, monkeys also are very destructive, especially to toddy. As for the rats, they either build nests in the tree tops and remain on the scene to do damage, or they visit coconut gardens in large numbers by night, leaving before daylight, after having caused sad havoc all over the place. I have on more than one occasion observed at early morn the interesting sight of a colony of rats hurrying back home in procession after having had a night of it in my neighbour's coconut and cashew garden. Toddy tappers place bamboo sliding traps among the leaves to capture the rodents, or hang large tins with wooden sticks attached loosely to them. When the wind blows, the whole concern makes a noise, and the rat dreads strange noises which he cannot account for. Flying squirrels and flying foxes visit the trees at night for toddy and often get wofully intoxicated at these stolen orgies. The tree dog (*maru nai* of the natives) has a bushy tail and he will somehow dip the brush in and get it to absorb as much toddy as possible. Then he will pull his tail out and suck up the beverage. Toddy cats are less patient. They do the drinking awkwardly, often breaking the pot, get blind drunk and then gingerly drop down to the ground. The monkey on the other hand removes the pot, has his fill of toddy, and then throws the pot away.

CEYLON TEA CROP IN 1897.

MAY BE OVER 120 MILLION LB.:
SPECIAL NEED TO GET AT THE NEW
MARKETS.

"You have to face an increase of 15 million lb. in 1897 over the exports for 1896," writes a planter who wanders a good deal over the country and knows what he is saying. If he is right in his anticipation, our exports would run for five years:—

1893..	81,406,064
1894..	81,591,714
1895..	97,939,781
1896..	[Es.]	..	107,000,000
1897..	[Es.]	..	122,000,000

With anything like so great an advance—or even if we have to face 115 to 120 million lb.—it is quite clear there should be no relaxation in the efforts to win new markets. And most certainly we are not in favour of restricting the expenditure on advertising in either America or Russia. Quite the reverse. If it be true, too, that any dealer who can shew he holds and sells Ceylon tea in either country on making application to Commissioner or Committee, is almost certain to receive help towards advertising, the objection raised against partial subsidising should in a great measure fall to the ground. It is quite evident that no one can be more interested in the success of the mission he has taken up than the Planters' Agent for America, Mr. Wm. Mackenzie, and no doubt he will feel as all out here do, that a special effort is required to push our teas during the coming year in view of the expected large increase in crop. If we could only move the Indian tea planters to an adequate sense of their duty and responsibilities in America as also on the Continent of Europe, in Australasia and South Africa, success would be far greater. The want of stocks of Ceylon tea seem to be a drawback in America and to give Indian tea a pull over us. A common complaint seems to be:—“Very good teas, but they cannot be matched to standards”—consequently when Ceylon's are asked for and cannot be got, Indian's have to be supplied.

TROPICAL FRUITS IN MADEIRA.

Once upon a time there was an agreeable connection between India and Madeira, for it was to that little island in the North Atlantic that Anglo-Indians, in the latter part of the last, and the early part of the present century, were indebted for the strong-bodied wine, with the fine bouquet, that their souls loved. The insidious attractions of the blend that was called “brandy-pawnee” had been discovered, but this was not the beverage of what then passed as good society. Indian pale ale had not yet commenced to point the beery way to a peccage; and whisky was only found in the bungalows of the most Caledonian of Scots-Indians. Abstemious officials, like Warren Hastings, prided themselves on their Maderia, and gave standing orders to their wine-merchants in London to make to them periodical consignments of that wine. But times and tastes have changed, and hardly anybody in India nowadays drinks Maderia, or indeed, fancies it. For all that the tight little island remains where it stood in the dim and distant past, and it continues to attract to its rocky shores a number of people who are afflicted with weak lungs, and who have to flee from the severities of winter in Northern Europe. It is one of the oldest possessions, and it is now a province of Portugal, so that it has the right to send deputies to the Cortes at Lisbon. It is 350 miles from the north-west coast of Africa, 525 miles from Lisbon, and 430 miles from the Azores. It is linked with Europe at Lisbon, to the north-east, and with Brazil to the far West by submarine telegraph cables. It is about thirty miles long, and it has at the widest point a breadth of only thirteen miles, and its coast-line extends to about ninety miles. It is of volcanic origin, and it is remarkable for its ridges of lofty mountains, which attain an altitude of 6,100 feet above sea-level. The sea all around it is very deep, and the island is no more than the crown of a gigantic mountainous formation, that has its wide base in the depths of the ocean. At one period the islands was covered with primeval forest, in which no other reptile than a lizard could be found and it was owing to the wealth of materia, or “wood,” that the early Portuguese travellers conferred upon it, in their picturesque way, the euphonious name that it bears. The forests were not conserved, but were ruthlessly destroyed by the

strange mixture of Negro, Moor, and European that constitutes the local population. The Portuguese Government was far more skilful in making conquests than in turning its territorial acquisitions to good account, and as at Goa, so also at Madeira, the material and moral progress of the country was and is systematically neglected. The disafforestation of the highlands in the island has robbed it of the best means of storing the torrential rains that fall during the summer months, and the plains suffer acutely from the consequent wants of moisture in the winter. The Government has expended money grudgingly upon the construction and maintenance of irrigation works and tanks, but this expenditure has been far below the needs of the island, and the cultivation of all crops is seriously checked by the chronic dryness of the ground in the best season. So scanty is the water supply that in some localities water commands a higher price than land. But in the few favoured places where water is to be had without much difficulty, it is no unusual thing to see vines, sugar-cane, sweet-potatoes, and cabbages growing thickly on the same ground, regardless of the objections to over-cropping. And as the temperature never falls below 44 degrees in the winter, and stands at about 85 degrees in the summer, several tropical fruits, that have been introduced from time to time, have taken kindly to the soil. Some information about these fruits is embodied in a report that was submitted to the Marquis of Salisbury, as Foreign Secretary, by Mr. Vice-Consul Bell, at Funchal, last October, and we have gleaned some information from this record that may possibly interest those of our readers who cherish a regard for natural history.

The “Alligator pear” is the principal tropical fruit grown in the island. This fruit is not indigenous, for it was imported from Mexico or Central America, and acclimatised. It is called “Aguacate” by the Indians in Mexico; “Abacate” by the Portuguese; “Avocado” by the Spaniards; and “Avocado pear,” or “Alligator pear” by the English. Botanically it is known *Persea gratissima*. The tree is tall and slender. It grows to a height of about 70 feet, and has dome-shaped branches and smooth green leaves, resembling those of the laurel. The fruit grows in clusters of three to five, and is shaped like a pear, with a dark purple brown tint. It contains one large globular seed, around which—mango fashion—is the pulp or edible portion, which in some French colonies is called “vegetable butter,” as it has the consistency of butter. This pulp is stated to possess a delicate nutty flavour, which is greatly appreciated by those who have acquired a taste for it. The fruit is eaten either as a salad, being seasoned with pepper and salt, and a suspicion of vinegar to bring out the flavour, or as a dessert fruit, with a little sugar, like a melon. Next in importance to the alligator pear comes the banana, of which there are two varieties in the island, namely, the dwarf, and the silver bananas. The dwarf or Chinese banana, is known botanically as the *Musa Cavendishii*, and it is grown largely for both local consumption and for exportation. The wholesale price is about 3s 6d per bunch, and a good sized bunch contains, as we all know in India, a very large number of individual bananas. In London the retail price of bananas, as sold by costermongers from barrows in the streets, is a half penny each, at which there is an active demand. There would seem, therefore, to be a handsome margin of profit for the wholesale importer. The silver banana is much more delicate in flavour, and only about half the size of the dwarf banana, which is sold and largely consumed in the London streets, a coarse fruit that offers no attraction to an old tropical resident who remembers what well-bred and well-grown plantains in Madras are like. The banana in Madeira is found to grow best on fresh land sheltered from the wind, which is apt to uproot the trees, and seriously damage the fruit. Artificial manure is advantageously employed in the fertilisation of the trees, and the application of large quantities of offal from the slaughter-houses and the fish markets is found to be beneficial in increasing the weight of the branches and the size of the fruit.

As is the case in India, it is usual in Madeira to cut bananas while green, and to allow them to gradually ripen.

The so-called "Cape gooseberry" is largely grown in the island. This is the same fruit, we presume, as is grown so successfully on the Nilgiris, where it was introduced many years ago. The perfectly globular and highly polished, amber-coloured fruit is, as our readers will remember, enclosed within a loosely fitting and delicate green case, and this envelope protects it from insects, and from the impurity of dust. It lends itself most kindly to the manufacture of a toothsome preserve, which, however, has the demerit of not keeping well after the atmospheric air has been permitted to get at it. In Madeira also a preserve is made from the Cape gooseberry, and is in much local favour. Citrons used to be grown on a considerable scale in Madeira, and a pipe of citrons, containing about 500 fruit, would realise from £20 to £30; but the trade has been ruined by the active competition of Corsica, from which little Mediterranean islet Europe draws a large portion of the citrons that she consumes. It is usual in Madeira to pack citrons for export in pipes filled with strong brine, and a pipe usually holds from 350 to 500 fruit according to their size. Custard apples have also been imported and acclimatised in Madeira. The variety in most request is believed to have been obtained from Peru. In India the taste for custard apples is acquired with some difficulty, and only by a comparatively few persons. The fruit has a rather attractive look when it has upon it the bloom of ripeness; but when the gentle griff is solemnly told by an old inhabitant that, according to well-authenticated tradition, it was the custard apple that was the cause of the fall of man, he is led to the conclusion either that Eve must have had an extraordinary want of good taste, or that the Garden of Eden was poorly found in fruit. Yet in Madeira the custard apple is a favourite with all classes, and the doctors declare that it is a wholesome fruit for invalids when eaten in a thoroughly ripe condition. It grows there to a large size, and the choicer fruit sometimes reaches a length of 6 to 7 inches, and weighs 1½ to 2 lb. The hard, black, almond-shaped seeds that are so disagreeably prevalent in the variety that we are acquainted with in this country, seem to diminish in size and number in the largest and finest descriptions in Madeira; but, as in India, the smaller kinds are little sought after in consequence of the superabundance of seeds. The custard apple tree is not grown in plantations or orchards, but almost every garden contains it, and the largest trees attain a height of about 20 feet, and the branches spread from 15 to 25 feet. A well-grafted tree, when well cultivated, yields fully 200 custard apples a year, and sometimes gives the owner a profit of £5 in twelve months. But, as with other fruit-bearing trees in the island, little attention is given to the improvement of the cultivation, by pruning, manuring, etc., for the Portuguese authorities are far too proud to condescend to bestow attention on such a subject.

Guavas grow readily in the island. This fruit is rarely used in an unripe condition, but is usually stewed, or, as in India, made into the guava-jelly of commerce. Here also degeneration has resulted from individual and official neglect, and good people in London are far better acquainted with the guava-jelly manufactured by Venkatachellum of Popham's Broadway, Madras, than they are with its Madeira rival. Lemons, limes, and loquats are easily raised in the island. So also is the mango. The variety met with in Madeira was introduced from India, probably by the early Portuguese travellers to the East, and it is conjectured that the first plants, or seeds, were obtained from Goa. The tree grows well and Mr. Bell happily remarks that "when bearing fruit the appearance is very beautiful, the foliage being of smooth dark green leaves set very closely together, and the fruit as it approaches maturity being of a rich orange colour gradually changing to bright crimson which gives a very handsome and imposing appearance to the tree." The tree is found in most gardens, and the island-

ders eat the fruit while they live, and are enclosed doubtless in coffins made from its wood when they die. Unfortunately no attention is given to the production of fruit of a high quality, and none but small fruit are obtained, owing to the denial of fertilising agents. As in India so in Madeira it is found that the stone in the small-sized and low grade mango is out of all proportion to the pulp or edible portion. Mr. Bell regrets the degeneration of the mango, and considers with good reason that if the best varieties were imported from India and if proper attention were given to their cultivation, the local and foreign demand would soon increase, and high prices would be secured by the planters. It was hoped that oranges might be grown on a large and profitable scale in the island, and efforts were made to improve the local growth; but the results so far have been disappointing, and it is now supposed that the want of calcareous matter in the volcanic soil is the cause of the failure. Large quantities of Tangier oranges are now imported into the island for local consumption from Portugal and the Azores. At one time Madeira enjoyed a lucrative export trade in pineapples, for the fruit that is grown there is of large size and excellent flavour, but owing to the competition of the Azores the local market price of first class fruit has fallen from a maximum of 18s. each to one of 6s. In addition to the tropical fruits we have named, the following fruits of Europe are grown in Madeira:—almonds, apples, apricots, cherries, chestnuts, figs, grapes, passion fruit, plums, pears, pitaugas, pomegranates, quinces, rose-apples, strawberries, and walnuts; so, one way and another, there is a considerable show of fruits in the local markets all the year round.—*M. Mail*, Dec. 23.

TEA IN RUSSIA.

Two English Members of Parliament—Messrs Kearley and Lough—lately visited Russia on the invitation of General Annenkoff, a famous Russian General and Member of the Council of War. A very interesting account of the impressions formed—generally favourable to Russia—was given by Mr. Lough during an interview with a *Daily Chronicle* representative. Mr. Lough (known among his friends as "Tommy Luff") is connected with one of the large City Tea Companies—the Towers Tea Company if we remember rightly—and it is not improbable that he had an eye to business as well as to general observation, during his visit to Russia. A mutual friend was anxious we should meet to discuss the tea question; but time did not permit before we left England. Mr. Lough, however, in answer to inquiry, said he was scarcely in a position to give an opinion on the prospects of Indian and Ceylon teas in Russia:—"All trade with that country is carried on under great difficulties so far as I can find out." At the same time, it is indisputable that the big London dealers are more and more turning their attention to Russia, Mr. Lipton being a case in point with a house and manager of his own in St. Petersburg who has got a firm hold of the market and is likely to extend his tea business throughout European Russia.

TEA COMPANIES AMALGAMATION.

We give what may be "piper's news," but is worth repeating respecting the amalgamation of certain Kaimi Valley Companies:—

The new Company is to be called the Yatiyantota, Ceylon, Tea Co., Ltd. The authorized Capital being £250,000 in preference and ordinary shares. The first issue, to acquire and work the Yatiyantota and Weoya Companies' properties and the Walpola group is to be £100,000—£30,000 preference and £70,000 ordinary.

TEA CULTIVATION IN CEYLON,
INDIA AND CHINA.

MANURING AND RESULTS:
CRITICISM AND WARNINGS.

An up country correspondent sends us an extract from the letter of a friend in the North of Ireland which ought to amuse if not interest Ceylon tea planters. It runs as follows:—

"I hope your tea property is coming on well. I met a Mr. S——— a tea buyer of Shanghai when over in Scotland lately; he goes out every year for four months during the season and spends the end of the year at home, in Russia, and in America; he buys principally for Russians and Americans,—and he is greatly in favour of China Tea which he asserts is more wholesome than Indian Tea, as it is free of *tannin*,—and he says no other country can beat it. They have splendid soil and unlimited extent—and when one garden is exhausted, the Chinese abandon it and take in fresh soil. He told me he had heard of many Ceylon tea planters who were beginning to invest in coconut estates as they were afraid of tea dying out like coffee. I told him tea was quite different from coffee as the Ceylon climate favoured the production of leaf which was not so exhausting on the soil as the coffee *berry*, but he did not agree with me; he said tea was also very exhausting and that Ceylon tea plantations were yearly becoming poorer in the quality of the tea produced."

Our friend, with his local experience, criticizes this after the following pungent fashion:—

"There are S———'s and S———'s apparently; but the best comment on this bogey of dying trees and deteriorating quality of the leaf, is perhaps the presence in our midst of a keenly intelligent young Chinese creeper to whom nothing is a greater surprise than the expanse of young vigorous bushes, he sees in Dimbula. In the district from which he comes he says, the tea averages about 200 years old and without yearly doses of manure the leaf is absolutely flavourless. The most effective manure is *night soil*, which is very highly prized and diligently collected from all the nearest towns. To this the 'superior flavour' seems in a great measure due and if this is the only means of imparting it, I fear we cannot compete with the Chinaman; for, no money, no threats will induce our squeamish coolies to handle the stuff. A smart fellow is this Ling and will learn more in four weeks than some sporting creepers in as many years. He leaves Middleton, where he has been under the tuition of Mr. MacLachlan, at the end of this month. The *tannin* fad is rubbish, the result of over-infusing the leaf. Moreover *tannin* is not poison. Have we not seen Australians boiling the leaf for hours drinking the decoction and issuing out to cricket! And let the fellows have their due:—*such tea and such cricket!*"

Now it is a very old story this of Ceylon tea failing. Some ten years ago, two Indian tea planters passing through Colombo and who went up as far as Hatton, returned "perfectly satisfied" that the limit of production would be reached in *five* years and that thereafter the exports from Ceylon would be certain to recede. We have always pointed with satisfaction to the oldest field on Loocondura,

now in its 28th year, and which well maintains its vigour, and to Mariawatte with its wonderful crops showing little or no abatement, the oldest field on which of 104 acres was planted in 1879. Mariawatte is, of course, about the most liberally cultivated garden in Ceylon, and the advantage of continuous supplies of bulky manure is seen in the enormous crops reaching in one year to 1,347 lb. (16 maunds) of made tea per acre! Loolcondura has a very different soil and situation; but it has kept up its average well and the only manure applied, we believe, has been castor-cake. We are aware that a good deal has been done in other districts with bulky manure; but the records of our railway traffic alone show that there is also an increasing quantity of artificial manure finding its way into the tea districts, and on this head we have recently heard words of warning. "Nitrates and bone dust"—not so much uncrushed bones—"are likely to play the very mischief with the tea plant" is the summing-up of an experienced cultivator who says that very little "artificial" is used in Assam, because there, every cooly hut having a cow or cows attached, they have always a sufficiency of bulky manure available. Now the time has certainly come in the history of our tea enterprise for enquiry as to what is done in the way of manuring, and certain cautions may well be necessary to those who are inclined to force their bushes to the utmost possible yield on the principle of "making hay while the sun shines"—making tea while the price is fairly remunerative, regardless of what may happen to their fields (or those of their neighbours) some years hence. Possibly, the expectation may be "to sell to a Company" after the cream is taken off and before the trees lose their vigour, the extra return of profits through forcing manures telling all in favour of the price to be paid! If that has become the practice even in isolated cases, it is time that special mention was made in all estate reports and valuations as well as in Company prospectuses, of the extent to which manuring has been carried on, the manures used, and the periods of application.

In this connection we call attention to the letter Mr. James Westland sends to us with reference to a lesson taught in the manuring of turnips. He thinks it may have been applicable in our coffee experience; and certainly wherever there is *disease* in a plant or tree, it must be very foolish to use any of the diseased portions as manure. Dr. Thwaites advocated at one time the gathering and burning of the fungus-covered leaves of our coffee. But where there is no disease, we cannot see objection to the manuring of turnips, or coffee, cacao or tea, any more than coconuts and plantains, with the surplus refuse of the plant or tree itself. Still there is room for experiments after the fashion set by Mr. Sim, and we should also at this time like to hear from some of our leading planters on the subject of the manures used with most advantage at different elevations on our Ceylon tea. The occasion, too, is one on which our old adviser, Mr. John Hughes, may have something to say worth listening to; for, now that the mystery about "third-class" manures on the railway has been removed, the way is clear for considering how far the application to tea of imported or Colombo manures has extended during the past few years, and how far it is likely to be permanently beneficial or the reverse.

THE CEYLON CINCHONA ASSOCIATION LD.

At an extraordinary general meeting of the shareholders of the Ceylon Cinchona Association Ltd., presided over by the Hon. T. N. Christie, and at which there were present Messrs. James Anderson and W. H. Kingsbury, held in the office of the Agents, Messrs. Lee, Hedges & Co., at 11 a.m. today the following resolution, passed at an extraordinary general meeting on 8th inst. was confirmed:—

"That the Ceylon Cinchona Association, Limited, be wound up voluntarily."

To confirm the appointment of Mr. T. N. Christie as Liquidator, and to authorize the sale of Kanapediwatti estate to the Kanapediwatti Tea Company Limited for the sum of rupees one hundred and eighty thousand two hundred, payable in fully paid up shares in the said Kanapediwatti Tea Company Limited.—By order of the Board of Directors,
LEE, HEDGES & Co., Agents.

Colombo, December 16, 1896.

VOGAN TEA COMPANY OF CEYLON.

An extraordinary General meeting of the shareholders of this Company was held at noon today in the office of the Agents and Secretaries Messrs. Lee, Hedges & Co. Mr. F. W. Bois presided and present were Messrs. V. A. Julius, E. H. A. Vanderspaar, W. H. Kingsbury, Liesching and A. G. Field. The meeting confirmed the following resolutions adopted at an extraordinary general meeting on 12th instant:—

(1) That the Directors be authorized to accept the purchase of land, aggregating about 210 acres, made by their authority on the 30th November and 1st December last.

(2) That the Directors be authorized to issue debentures from time to time as required for the purposes of the Company, the aggregate not to exceed R100,000, at seven per cent. interest or less, on such terms of repayment and for such periods of as they may deem expedient.—By order of the Directors,
LEE HEDGES & Co.
Agents and Secretaries.

Colombo, December 15, 1896.

OUR COMING TEA CROP AND ESTIMATES.

We have no doubt that the responsible Visiting Agent, who wrote to us—"You have to face "an increase of 15 million lb. in 1897 over the "exports during 1896"—will be able to justify his position and statement. His object (equally with our own) in giving publicity to what he regarded as fact,—was entirely beneficial in the interests of the planters themselves, namely, to stir up all concerned in the industry, both here and in India to realize the necessity for an earnest and united effort during the coming year to win new markets in order to take off the increased quantity of tea. The earlier the Indian planters, especially, hear of an anticipated crop increase, the more likely they are to bestir themselves in the direction we are all anxious to see them take.—As to our evening contemporary's "highfalutin'" sentiments over exaggerated estimates emanating from this office, he ought to take warning by what happened in the first part of 1893 when he was specially loud on the subject—result shipments over 84 million against an estimate of 77. Our "Handbook and Directory" contains a record of the

annual estimates and results from the beginning of the local enterprise for which we and our informants have been responsible; and we have again and again verified the fact that while the London market for Ceylon teas is not in the very slightest affected by annual crop estimates, but only by anticipations of monthly shipments, the Indian tea planters—both as to planting and cropping—take very serious warning by such a piece of information as a planting authority sent us two days ago.

IMPERIAL DUTY FREE TEA, COFFEE, &c.—Mr. George Jager writes to the *Saturday Review* about the foreign bounties on beet-root sugar and the destruction thereby of the British sugar-refining industry and also of growing cane sugar in British Colonies. The remedy suggested is one that Mr. Jager says would not cost Government a farthing, but would increase the trade of the country by millions. Here is how Mr. Jager puts it:—

The measure that would bring about this wonderful and beneficent change is simplicity itself: make tea, coffee, cocoa, and dried fruit free of duty and place a differential duty on sugar that will bring in the same revenue. Thus tea, coffee, cocoa, chicory, and fruits together bringing in £4,333,305, and a duty of 3s. per cwt. on cane sugar, 4s. per cwt. on beet sugar, and 5s. 6d. per cwt. on refined sugar would produce about the same amount.

The result would be that we should pay a little more for our sugar, but that we should buy our tea, coffee, &c., at a corresponding cheaper price and no one would be the worse off or suffer in the least. For although jam and such like products would be increased in cost to the extent of a farthing in the lb., it would not affect the trade; for sugar would still be much cheaper in this country than in any other in the world, and the jam and confectionery trades would still retain the advantage they at present enjoy over other countries. Neither would it have any bad effect on our consumption of sugar; for since sugar has been retailed at 2s. per lb. we have arrived at what might be termed the saturation point of consumption, any further decline in price having had little or no effect in increasing the consumption per head of the population; and as the retail price of the people's sugar would, including the proposed duty, be still 2d. per lb., we have actual experience to prove that the importation of sugar would not decrease, and consequently there would be no national loss of trade.

Having now found that the proposed scheme of placing a duty on sugar and taking it off tea, coffee, &c. could be carried out without injury to any manufacturer's or consumer's interest, let us see what national and Imperial advantages we should gain. In the first place, an old industry now decaying would revive and require new capital to the extent of £2,000,000. Thousands of men now idle or pressing on the workmen of other trades would find constant employment, numerous trades which to some extent depend on the sugar industry would be stimulated. Shipowners would get an increasing amount of tonnage from cane-producing countries at rates varying from 20s. to 40s per ton, instead of freights from beet-sugar ports at 3s to 8s. per ton. Then, with the duty off tea, coffee, &c., the consumption of these articles would still increase, followed by an increasing trade with the countries of their origin—India and the East—where our most profitable trade exchanges are made.

We suspect, however, that Sir Michael Hicks-Beach as Chancellor of the Exchequer will have nothing to do with "differential" duties,—though the case is an extremely hard one for those dependent on sugar growing and refining, under British auspices.

Correspondence.

To the Editor.

TEA IN SOUTH CAROLINA, UNITED STATES.

Billiter Square Buildings, London, E C., Nov. 22.

DEAR SIR,—I notice reference to Mr. Charles N. Shepard's Tea in South Carolina in your *Overland Observer* of 27th October. When in South Carolina myself last March, I spent some days with Mr. Shepard who was most kind in allowing me to inspect his tea gardens. He also showed me some extremely fine samples of his productions. Mr. Shepard is one of the most interesting men I have met and what at first astonished me much, was his perfect knowledge of men and matters of our island. This however was explained by his informing me that he was a regular subscriber to the *Overland Observer*. He takes the keenest interest in Ceylon and I tried to persuade him to take a run over and pay it a visit and this I hope he will do when his domestic affair's permit. I shall long remember my visit to Pinelhurst and when I come out next month for a few weeks, I will be very pleased to tell you all about his tea trees.—Yours truly,

J. M. MAITLAND KIRWAN.

THE DUMONT COFFEE COMPANY.

Central Province, Nov. 25.

DEAR SIR,—Do Messrs. P. R. Buchanan & Co. really think that anyone here will take shares in the Dumont Coffee Company, Limited, because Mr. Talbot wires home that their coffee property excels in luxuriance anything he has seen in Ceylon, Straits and Java. How often were Ceylon coffee planters led on by the will-o'-the-wisp luxuriance of their fields one month, and the next month they had to howl over a virulent attack of bug, gout or leaf-disease? I fancy Messrs. P. R. Buchanan & Co. find the syndicating of this Dumont Coffee Company rather a trying business.—Yours truly, "ONCE BIT TWICESHY."

COFFEE IN THE CONGO STATE.

Greenwood, Nov. 26.

DEAR SIR,—I notice your leader of November 24th on "Coffee in the Congo State." I do not think that much reliance ought to be attached to the report of Mr. E. Laurent, Professor in the Agricultural Institute at Gembloux, Belgium, who, I surmise, has never seen coffee growing in the open before his trip to Africa and had a *special mission* as Government servant.

In 1892, I went to the Congo as Director of the State Plantations. Eight months' exploring brought me to the conclusion that no planting enterprise could be lucrative, because :—

1st.—There is no local labour available.

2nd.—The mortality of the imported labour is excessive, leaving alone the difficulty and cost of importation.

3rd.—The soil is generally of a poor nature, covered with rank high grasses. Only the very steep banks of the rivers are wooded in the Lower Congo.

4th.—The dry season lasts six months without a single shower.

5th.—The wet season is only a succession of "tornados," strong winds accompanied with heavy showers lasting a few hours, at intervals of from 4 to 15 days; but sunshine with 90° in the shade meanwhile.

6th.—The railway Co. had fixed the price of transport from Stanley Pool to Matadi (when the rail shall reach the former place!) at the franc per kilo of coffee (about 4½d per lb.).

7th.—Irrigation is not to be thought of. The streams running generally in deep clefts in undulating tablelands, would alone render the cost prohibitive.

Deeming these circumstances insuperable, I sent in my resignation and left a country which may well be called the "Strangers' Grave", for the mortality amongst the Chinese and Negro imported labour, as well as Europeans, was appalling during my sojourn.

In a garden, in the station of Leopoldville, on the banks of Stanley Pool, a couple of hundred Liberica coffee trees of five years had a fair crop ripening. They had to be regularly watered during the dry season. A large amount of them had *Hemileia vastatrix* on the berries as well as on the leaves, but few trees seemed to suffer much from it. The seed was imported from Monrovia, where I had made a stay and visited several gardens, but had noticed no signs of the presence of the fungus.

The coffee plants mentioned by Mr. Laurent to be in the district of the Cataracts are probably the result of the seeds distributed by me on my return to the coast.

Re Tobacco—two experienced Sumatra tobacco planters sent out for a Syndicate, during the time I was in the Congo, agreed entirely with the conclusions expressed above and left the country before me.—I am, sir, yours truly,
A. VAN DER POORTEN.

NUTMEG CULTIVATION IN THE WEST INDIES.

Edinburgh, Nov. 27th, 1896.

DEAR SIR,—I bought a copy of your valuable work "All about Spices" several years ago.

I am interested especially in nutmeg cultivation, having a plantation of nearly 400 acres in the Island of Grenada. The trees about 20,000 in number were planted in 1880, '81, '82, '83, and '84. and are coming steadily into bearing. I shall be glad to know if you have published any thing recently on nutmeg culture that would be of use to me.—I am, dear sir, yours faithfully,

PROPRIETOR. (Authenticated.)

[We can only refer our correspondent to the volumes of the *Tropical Agriculturist* for information gathered from all parts of the world of what is doing in "nutmegs" since our *Mannual* was published. The *T.A.* is filed in most of the West Indian Islands by order of the Colonial Governments.—Ed. *T.A.*]

MANURING TURNIPS AND COFFEE.

Gammadna Group, Gammadna, Dec 19.

DEAR SIR,—I enclose a cutting from the *Aberdeen Free Press*, which I think ought to be widely known and preserved in the *Tropical Agriculturist*. With this before me the idea has occurred to my mind that possibly manuring coffee in the old days with coffee pulp had something to do with bringing about destruction to our coffee,

I remember well that the fields I used to look after the manuring of in 1871 with coffee pulp, pig manure and bone-dust, were the first to go, when attacked by leaf-disease. Coffee proprietors might take a hint from Mr. Sim's experience and try the effects of coffee pulp on a few trees. The experience may be also useful to cocoa growers in their search for the cause of so many deaths amongst their cocoa trees within the past year.—Yours, &c.

JAMES WESTLAND

FINGER-AND-TOE IN TURNIPS :

A DISCOVERY.

(Aberdeen Free Press, 27th Nov.)

What seems to be rather an important fact for agriculturists has just been brought to light by Mr. William Sim, naturalist, Fyvie. It deals with finger-and-toe in turnips. About a year ago Mr. Sim's attention was drawn by a neighbouring farmer to a rather remarkable case of cankered roots. Across a field of perfectly healthy bulbs was a wide strip of very diseased turnips. On inquiry it was found that when the field had been in lea, three years previously, several cartloads of scrapings and refuse of the turnip shed had been spread over the lea as top dressing. At the same time, Mr. Sim discovered that a turnip drill which he had himself laid down under ordinary conditions for experimental purposes on land which had not grown turnips for 25 years, showed grave symptoms of finger-and-toe. He discovered that this experimental drill had been manured with a compost containing turnip refuse. Putting the two cases together, Mr. Sim came to the conclusion that the disease was caused by the presence in the soil of turnip refuse. Now, it has long been known to farmers that the refuse of cankered roots was highly dangerous to the new crop, but it had never been taught that the turnip remains of even sound roots were a source of grave danger as well. Mr. Sim determined to put the matter to a practical test. He laid down two drills 30 inches apart, in carefully prepared soil. The first drill got the usual allowance of farmyard dung and ordinary turnip manure as sold at manure stores. The second drill received the same quantity of artificial manure, and a rich compost of turnip scrapings. The results are astounding. In the first drill 94 per cent. are splendid roots and the remainder diseased, while in the other drill the results are simply reversed, there being only five sound but very small roots in the hundred. The diseased turnips, moreover, were almost entirely useless, and the remainder following fast. The presence of diseased bulbs in the first drill is evidently the result of their proximity to the noxious influence of the diseased root fibres, and had the distance between the two drills been increased, there is no doubt the first drill might have been entirely free from disease. To obviate the evils arising from the use of turnip refuse, Mr. Sim is of opinion that this refuse should be carried back to the turnip field and there laid down to be exposed to the frosts of winter and the heat of summer for five or six years (presuming, of course, a six or seven course rotation), until the dreaded germ has been destroyed.

THE DUMONT COFFEE COMPANY.

SIR,—No one in Ceylon is likely to question Mr. Talbot's assertion, that this property excels in luxuriance anything he has seen in Ceylon, Straits and Java. *It had need*, when it is proposed to convey shares in this property to intending investors at the rate of £130 sterling per acre for the coffee in bearing.

I don't know about Straits and Java, but I doubt very much if anyone has ever given half this rate per acre for Ceylon Coffee, and then made money by holding on to it. Can you give me an instance? Yours truly,

TWICE BIT SHY FOR EVER.

COFFEE PRICES, SERDANG, O. K. SUMATRA, A NEW PULPER FOR LIBERIAN.

SIR,—Some time ago I sent you a few figures relating to prices realised in Europe by Liberian Coffee from Serdang. I have today received figures from another proprietor, who shipped his coffee to Hamburg. The B. K. mark fetched 83 pfenings per $\frac{1}{2}$ kilo when at the same date 2,000 bags coffee, from Liberia direct, could not be sold for 62 pfenings and the highest price Santos was 54 pfenings per $\frac{1}{2}$ kilo.

My friend attributes his success in prices mainly to special care in curing. Many, perhas most men think. "It's all right if your pulper does not cut." But there is a deal more than that in curing Liberian coffee.

Massrs. J. M. Lyon & Co. of Singapore recently sent me a photo and description of their new patent pulper. I saw the machine some 18 months ago, since when, they write me, it has been much improved. I certainly saw little room for improvement when I tried the machine, so by now it ought to be perfection, there or thereabouts. The three points that struck me chiefly were simplicity of mechanism, economy of power, and remarkable saving of labour. The perfect separation of pulp from parchment is a notable feature, and saves much trouble in the cisterns while an ingenious arrangement of rubber washers makes the breast equally accommodating to large and small cherries, avoiding cutting the big beans, at the same time successfully pulping the smaller ones.—Yours &c.

W. TURING MACKENZIE.

THE TEA CROP OF 1897, AND THE NEED OF WINNING NEW MARKETS.

Central Province, Dec. 26.

DEAR SIR,—My reason for warning you that the Tea Market would probably, most probably, have to face an increased production of 15,000,000 lb. tea in 1897 was to prevent correspondents blowing cold on the exertions of the Committee of 39, and our able American commissioner to advertise Ceylon Tea through the channels they have found out to be the best suited for the purpose.

The Kelani Valley and the Pussellawa District Associations have already published in the newspapers their Estimates of Tea for 1897 and these show an increase of lb. 1,999,200 over 1896. These districts are fairly representative of Ceylon, as regards bearing, one being a very heavy cropping district, the other medium. These two districts comprise an area of 39,956 acres, and by your Directory the total area of cultivated tea land totals 304,843 acres,* so it does not take much calculation to discover that we may take 15,000,000 lb. as the increase on our output of tea in 1897.

We must not abate our efforts to push the sales of our tea everywhere they can be pushed, and my personal knowlege of our Commissioner in America convinces me that he is the last man to keep to himself the weakness of any scheme. He would have published it on the housetop long ago.

People who reside in Colombo seem to forget that manuring is very much increased, and those who travel in the Tea Districts know what that means!—Yours faithfully,

V. A.

* More than that considerably now Ed.—T.A.

MANGO (AS A MEDICINE):—CONFUNDED WITH MANGOSTEEN.

DEAR SIR,—One sometimes reads strange stuff in the columns of the press and the appended extract from the *Medical Press* is a notable example.

The medico who penned this paragraph might do worse than brush up his botany a bit, when he would find that there is no more affinity between a mango and a mangosteen than between a plum and a pumelo, or a strawberry and a pumpkin.

The mango is a not a *Garcinia*—the tree named after Dr. Garcia; nor the mangosteen a mango, though sounding something like it.

I shall endeavour to contribute to the export of these two fine fruits the finest which India produces—during the coming season, and while the doctors enjoy the luscious pulp of the mangosteen and inflict the rind upon their patients, may the large mango seed also be turned to some useful purpose and so introduce a new industry to us.

Yours truly,
PLANTER.

Extract.

"We are told that a determined effort is to be made in the wholesale fruit trade next year to bring the Indian mango to London in sufficient quantities to be of commercial consideration. Its introduction would undoubtedly be the signal for its use as a medicinal agent. The rind of the fruit (*Garcinia Mangostana*) contains a volatile principle, allied in action to pure terebene, and a better crystallisable substance to which the name of "Mangostin" has been applied. A decoction of the fruit is commonly employed in tropical climates as an astringent, and is found useful in sore throat, nasal catarrh, and other allied conditions. Mango chutney is used as a condiment, and is found efficacious in the treatment of many forms of dyspepsia. Dr. Murrell, who has obtained a small supply of the fresh fruit from India, finds that it may be given with advantage in the treatment of chronic bronchitis and winter cough.—*Medical Press.*"

TEA PLUCKING AND TEA MAKING.

Lower Ambegannwa, Dec. 27.

DEAR SIR,—The "Times" has sounded gong to the effect that superintendents ought to be teamakers, and teamakers field men. What a discovery! Does the "Times" people manufacture tea in their office? I should like much to see their samples. Rot, Mr. Editor: Tea-making begins in the field and plucking is the chief factor. Give me a fine plucking, say bud and 1½ leaf and I will stake my totum that I will put down a 9d tea in the London market. The burning question to be threshed out, is quality *vs.* quantity. Then comes in "will it pay" of Lanka's everlasting cry.
—Yours &c.,
C. T.

The Best Soaps for Warm Climates are CALVERT'S TOILET SOAP (6d. Tablets) and PRICKLY-HEAT SOAP (6d. and 1s. bars), pleasantly perfumed, for Bath or Toilet containing 10 per cent. of Pure Carbolic. Very serviceable as preventives of Prickly-heat and other skin irritation. Sold at Chemists, Stores, &c.

F. C. CALVERT & CO., Manchester.

INDIAN TEA SALES.

(From *Watson, Subthorp & Co.'s Report.*)

CALCUTTA, Dec 30.

15,390 packages changed hands in the sales held on the 22nd instant. The market was active and prices for all teas with good style and liquor show a slight advance, other sorts sold irregularly but without material change. The demand for the Bombay side was again very slack, but a very considerable proportion of the sale was taken for the Colonies and "other places."

The average price of the 15,390 packages sold is As. 6-10 or nearly 8½d per lb. as compared with 16,986 packages sold on the 20th December 1895 at As. 7-0 or nearly 7½d per lb. and 15,552 packages sold on the 20th December 1894 at As. 9-10 or nearly 10d per lb.

The exports from 1st April to 28th December from here to Great Britain are 116,275,383 lb. as compared with 108,494,990 lb. at the corresponding period last season and 104,743,429 lb. in 1894.

NOTE.—Last sale's average was As. 6-5 or nearly 8d. Telegrams.—Reuter telegraphed from London on the 21th instant.—Offered 7,000, sold 7,000 packages. Generally firm and prices fully maintained. Average 8½d. "Type" 6½d.

Exchange.—Document bills, 6 months' sight, 1s 32-32d.

Freight.—Steamer—£1-8-9 per ton of 50 c. ft.

(From *William Moran & Co.'s Market Report.*)

CALCUTTA, Dec. 23.

Yesterday's sale comprised about 16,000 chests nearly all of which were sold. There was a good demand and prices, though a little irregular, showed an upward tendency. Owing to the Christmas holidays, there will be no further sales until the 7th of January.

Total quantity of Tea passed through Calcutta from 1st April to 21st Dec.

	1896.	1895.	1894.

DRUG REPORT.

(From the *Chemist and Druggist.*)

London, Dec. 3.

CARDAMOMS.—The only arrival which we have to notice this week is one of 13 cases per "Cheshire" from Colombo. Privately the market remains extremely strong. A parcel of fine medium to bold Ceylon-Mysore for which 5s 4d was refused at the last auctions has since been sold privately, it is said, at 5s 6d per lb., and for fair small to medium Ceylon-Malabar, 4s 6d is asked. We also hear that several parcels have changed hands for shipment on the basis of 2s 10d per lb., c. i. f. November-December shipment for thin shelly Ceylon-Malabar. A parcel of good seed offers at the high figure of 4s 6d per lb., c. i. f.

CINCHONA.—At next Tuesday's cinchona auctions no fewer than 1,100 bags of Cuprea bark, imported about thirteen years ago will be offered.

DEAFNESS.

An essay describing a really Genuine Cure for Deafness, Ringing in Ears, &c., no matter how severe or long-standing, will be sent post free.—Artificial Eardrums and similar appliances entirely superseded. Address THOMAS KEMPE, VICTORIA CHAMBERS, 19, SOUTHAMPTON BUILDINGS, HOLBORN, LONDON.

COLOMBO PRICE CURRENT.

(Furnished by the Chamber of Commerce).

Colombo, Dec. 22nd, 1896.

EXCHANGE ON LONDON: CLOSING RATES, Bank Selling Rates:—On demand 1/3 8-16; 4 months' sight 1/3 7-32; 6 months' sight 1/3 1/2.

Bank Buying Rates:—Credits 3 months' sight 1/3 15-32; 6 months' sight 1/3 9-16; Docts 3 months' sight 1/3 1-32; 6 months' sight 1/3 19-32.

COFFEE.—Plantation Estate Parchment on the spot per bus., R15.50 to 17.12 1/2 Very scarce. Estate Crops in Parchment, delivery no quotations. Plantation Estate Coffee, f.o.b. on the spot per cwt. R83.00 to 85.00. Very scarce. Liberian parchment on the spot per bushel, R12.00. Garden and Chetty Coffee, f.o.b. per cwt. no quotations. Native Coffee f.o.b. per cwt. R63.00 Very scarce.

TEA.—Average Prices ruling during the week: Broken Pekoe, per lb 47c. Pekoe per lb 38c. Pekoe Sou-chong, per lb 29c. Broken mixed and Dust, per lb 24c.—Averages of Wednesday's sale.

CINCHONA BARK.—Per unit of Sulphate of Quinine per lb 03c.—Very scarce 1 to 5 %

CARDAMOMS.—per lb R1.50 to 2.50.

COCONUT OIL.—Mill oil per cwt. R14.37 1/2.

Dealers' oil per cwt. R13.75 to 14.00.—Coconut oil in ordinary packages f.o.b. per ton R315.00.—Sales.

COPRA.—Per candy of 560 lb R42.00 to 50.00.

COCONUT CAKE: (Poonac) f.o.b. per ton, R55 to 77.50. Cocoa.—Unpicked and undried, per cwt. R27 to 42.50.

COIR YARN.—Nos. 1 to 8 { Kogalla per cwt. R9 to 18
Colombo „ R7 to 14.

THE
AGRICULTURAL MAGAZINE,
 COLOMBO.

Added as a Supplement Monthly to the "TROPICAL AGRICULTURIST."

The following pages include the Contents of the *Agricultural Magazine* for January :—

Vol. VIII.]

JANUARY, 1897.

[Nos. 6 & 7.

SEASON REPORTS.
 OCTOBER.

EASTERN PROVINCE.—Yala crop harvested and threshed, Maha cultivation going on, some damage by rain to young paddy plants. Vegetables and fruits, especially latter, scarce. Crop prospects

fair. Rainfall plentiful.

Central Province.—Yala crop being harvested crop fair; Maha cultivation commenced. Dry grain crops are fair. Rainfall plentiful.

Northern Province.—Paddy and dry grain prospects good; a fair amount of rain.

Southern Province.—Yala harvest over and cultivation of Maha crop in progress. Some cattle disease in the Bentota—Welallawitti Korale.

Eastern Province.—Paddy, all harvests of present year over, next year's crop coming up; preparation of tobacco lands going on; cultivation of Indian corn and fine grains in progress; fisheries good.

N. Western Province.—Cultivation of next paddy crop going on; some damage to young plants in the Chilaw district by rain.

North Central Province—Paddy cultivation of Yala crop in progress; rain fall satisfactory except towards Kurunegalle; a good deal of cattle murrain prevalent.

Province of Uva.—Yala sowing going on; fruits and vegetables plentiful and cheap; cattle murrain in Buttala.

Sabaragamuwa Province.—Yala harvest over, outturn good; Maha cultivation going on; good Chena crops and prospects; health of cattle and

people satisfactory; rain at Ambanpitiya (up to 29th) 22.32, Ruanwella, 21.16.

NOVEMBER.

Western Province.—Paddy, a good deal of damage done to crops by heavy rains and floods; but a fairly good Maha harvest is expected.

Central Province.—Maha crop of paddy in various stages, some damage to crop in Matale prospects very promising in Newera Eliya.

Northern Province.—Rainfall general, and heavy in Jaffna; crop prospects good; some damage to crops in North by caterpillar (Arakkoddiyan). Murrain raged in Kilakumulai and spread south, 199 out of 208 reported to have proved fatal.

Southern Province.—Paddy prospects good, though some damage done by rain in the Galle District.

Eastern Province.—Paddy prospects satisfactory, though some damage done in Tamblegam pattu. Tobacco planting going on in Trincomalee!

North Western Province.—Crop prospects generally fair in spite of some damage owing to excessive rain.

North Central Province.—Rainfall general and satisfactory, tanks full, paddy crop in early stages of growth; cattle murrain prevailing in some parts and being treated according to the Asst. Veterinary Surgeon's instructions.

Uva Province.—Heavy rain; young paddy doing well; food supply good, fruits and vegetables being plentiful.

Subragamuwa Province.—Paddy crop prospects good, but lower fields damaged by rain. Rainfall at Ambanpitiya (up to 29th) 22.55. in Ruanwella 27.06.

Greatest amount of rainfall in any 24 hours —
on the 12th day of November, 4·80 inches.

Recorded by M. W. K. BANDARA.

OURSELVES.

The present issue will reach our readers during the first days of a new Year which we earnestly hope will be one of prosperity and plenty for all agriculturists in the Island, from the lordly tea planter to the humble paddy cultivator. Every year while it brings with it fresh knowledge of value to the cultivator of the soil also makes the problem of how to produce the best quality of crops, at the smallest expense and with the least deterioration of the land more difficult to solve. It has been our endeavour during the past seven and a half years to do what we could, albeit in a small way, to act as a medium for conveying to those who have chosen "the most healthful, most useful, and most noble employment of man" all such information as would better help them to meet the difficulties which they have to encounter in their attempt to render the soil subservient to their own and the general wants of the community, and we trust we have succeeded in doing some useful work in this direction. We take the opportunity of thanking our subscribers for their support, and the local press for its encouragement.

OCCASIONAL NOTES.

The students of the Forestry School returned from their tour on the 5th December, after having been away nearly six weeks. The route was from Colombo to Kurunegalle, across country to Dambool, from Dambool to Nalaude, Matale, on to Nawalapitiya and Galbolde, ending up with Nuwara Eliya where the class broke up and returned to Colombo. The Conservator of Forests himself accompanied the students who were put through a practical training in forest operations besides receiving lectures during the tour. The weather was not all that could have been desired, but the health of the students was on the whole

satisfactory. We understand that detailed diaries have been kept by the students and that the Conservator of Forests means to have the best of these published.

We regret to hear that the efforts of the Assistant Conservator of Forests of Trincomalee to conduct a Forestry Magazine have not met with success owing to a want of help in the way of contributions from the members of the Forest Department, and that the "Ceylon Forester" will probably cease to appear again on that account.

"Canary Guano" is the name of a new "compound manure" a sample of which has been kindly sent us by Messrs. Clark, Young & Co. The fertilising ingredients are in a very concentrated form and a very small quantity of the manure goes a long way. Canary Guano is specially intended for garden crops and should prove very useful in the cultivation of vegetables.

The Colonial Veterinary Surgeon, Mr. Sturges, left for Bombay and Karachi about the middle of December in order to select and purchase a fresh batch of Sind Cows for the Government Dairy. He is expected back early in January. Mr. Hoole, Assistant Veterinary Surgeon, whose station is Anuradhapura is attending to Mr. Sturges's duties in Colombo.

Cattle plague has been working great havoc in the Northern part of the Island as will be seen from the season reports for the months of October and November.

The rainfall in December may be said to have been unprecedented. In some parts of the Island much damage was done to crops and property and traffic was greatly impeded by washaways and earthfalls.

THE FOREST LAWS OF CEYLON.

THE PRESENT LAW AS ENACTED UNDER ORDINANCES NO. 10 OF 1885 AND NO. 1 OF 1892.

Chapter I, (Sections 1-3,) deals with the Short Title of the Ordinance, Repeal of certain enactments and Interpretation Section.

Section 4. Enacts that if in any prosecution or proceeding under the Ordinance a question of title should arise the Court or officer has jurisdiction for the purposes of the prosecution to try and determine the question of title, but that such decision shall not be pleaded in bar in any Civil Suit; and if in any subsequent action between the Crown and the claimant, judgment should be given against the Crown, the forest shall cease to be reserved from the date of such judgment.

Reserved Forests.

A preliminary declaration is made (Section 6) of which the object is to intimate to the public and to persons interested the intention of Government to proceed to the constitution of certain tracts as reserved forests.

This declaration, of course, must specify the limits of the proposed forest otherwise no one can tell whether he will be affected by it or not.

It is not necessary (but it is of course allowable) to have recourse to artificial marks, posts or pillars, to indicate, in the first instance, the proposed limits of the forest generally; it is enough to specify the limits by such general indications as practically meet the object in view. It is not wise to go to any expense in putting up marks at this stage; because it is obvious that they may be more or less altered during the process of settlement. The permanent demarcation, which is so necessary a part of the work of establishing forest estates, is the last stage of all, when everything is settled. The notification also takes the opportunity of appointing an officer, called the "Forest Settlement Officer," who will be the proper authority to whom claims and objections have to be addressed. Such an officer is not a forest officer, so that he may be perfectly unbiased by any professional interests.

Ad interim prohibition to fresh clearances.

When once this notification of proposals is out, it is obviously desirable to prevent fresh complications arising in the area by people continuing to occupy new land or to acquire rights. Section 8 therefore, prescribes that no one shall make fresh clearances for cultivation, or otherwise appropriate or occupy land, nor can any process of prescription for acquisitions of rights go on. A person may be within a year or two of completing his thirty years' exercise of some practice which would then become a right; but the issue of the notification would be a bar to his completing the acquisition. Only such rights as exist are saved, and such as government expressly desire to grant.

A person, who has a right already, may, of course, transfer it to another person, supposing it is the nature of the right to be transferable.

This provision is very necessary, since, if people were to go on developing new rights, and appropriating new clearings, the settlement would never come to an end. As fast as the first set of claims had been dealt with another would appear.

It is also absolutely necessary to draw the line and fix a date at which it may be ascertained that the existing conditions of rights were such and such; then it is easy to protect the estate in future from being burdened afresh with rights.

The Proclamation.

The next step is to explain to the neighbours what will be the consequence of making the land into a forest estate, and invite them to put forward all claims and objections within a certain reasonable fixed time.

The preliminary notification having been issued and the Forest Settlement Officer being in readiness, the "Settlement of rights" is the next important stage. All who desire to claim any plot of land as their own inside the proposed forest or to make known any right or user or other interest which may be adverse to the Government title have now the opportunity of getting their rights fully established.

The settlement, in fact, is a simple and speedy procedure whereby the rights of the state may be separated from those of individuals, and thus disputes may be set at rest, and injustice and hardship resulting from the assertion of the state rights in the forest be prevented and redressed.

Claims may be presented verbally and they are taken down by the Forest Settlement Officer in writing.

The claims made will be found to come under one or other of three distinct heads and a moment's consideration will enable any one to understand that they cannot all be dealt with in the same way:—

- (a) Claims to land (interest in or over land) in the area proposed to be constituted a reserved forest.
- (b) Claims to a right of way, to water-course.
- (c) Claims to rights of pasture or forest-produce.

When the Forest Settlement Officer has admitted any claim under (a) he may (section 13.)

(1.) *Come to an agreement with the claimant for the surrender of the right* Under this head an exchange is often possible. The owner may agree to give up the plot in exchange for another piece in another place. A suitable corner of the forest may in this way be cut off as a block of available land in which a number of little patches inside the proposed forest may be provided for; or

(2.) *Exclude the land from the limits of the proposed forest, i. e., the Forest Settlement Officer may either alter the proposed boundary so as to let it remain outside the forest or leave the land inside the forest as a privately owned plot not subject to the forest regulations.* Care must however be taken that the limits of the land are permanently demarcated so as to prevent future encroachment, and that a right of way through the forest to the land for the cultivator and his cattle is provided for and that regulations are made for the lighting of fires on the land which may spread to the forest &c.; or

(3.) *Acquire such land in the manner provided by "The Land Acquisition Ordinance, 1876," and Ordinance 6 of 1877.* In this case the Forest Settlement Officer is vested with the necessary powers under that Ordinance, and the process is compulsory. It would be followed on failure to come to terms under No. 1. It is always better to proceed under the Land Acquisition Ordinance where there is any doubt about the title to the land, for in that case Government gets the land with a clear title. If land is taken by agreement it is taken only with such a title as the owner really has. Where there is no doubt about the title, then agreement is a safe and much more economical and expeditious method; otherwise proceed under the Land Acquisition Ordinance because then the title acquired by Government cannot under express provision of the law, be questioned,

Claims to Right of Way and Water Pasture and Forest Produce.

In the case of claims to such rights the Forest Settlement Officer passes an order admitting or rejecting the same wholly or in part. When the right is admitted and if it is for the beneficial enjoyment of any land or buildings, the Forest Settlement Officer is bound to record the designation, position and area of such land and the designation and position of such buildings. When the right is a right to forest produce the Forest Settlement Officer is bound to record whether the forest produce obtained by the exercise of such right may be sold or bartered and such other particulars as may be necessary in order to define the nature incidents and extent of the right.

When the Forest Settlement Officer has admitted a claim to a right of pasture or to forest produce, he is bound (Section 15) to provide for the exercise of such right:—

(a.) By altering the limits of the proposed reserved forest so as to exclude land of sufficient extent, of a suitable kind, and in a locality reasonably convenient for the purposes of the claimant;

(b.) By recording an order continuing to the claimant a right of pasture or to forest produce (as the case may be) subject to such rules as may from time to time be prescribed on that behalf by the Government Agent. The order passed under this head shall record as far as practicable, the number and description of the cattle which the claimant is from time to time entitled to graze, the local limits within which and the seasons during which such pasture is permitted; or the quantity of timber or other forest produce which the claimant is authorized to take or receive, the local limits within which, the season during which, and the mode in which, the taking of such produce is permitted and such other particulars as may be required in order to define the extent of the right which is continued, and the mode in which it may be exercised.

The Forest Settlement officer has power, subject to such regulations as the Governor may from time to time prescribe, to commute such right, where such right has been admitted by paying a sum of money in lieu thereof, or with the consent of the claimant by the grant of land or in any other manner as the officer may think fit.

It will be observed that nothing is said of how the rights are to be valued, or on what principle either the grant of land is to be made or the grant of money awarded. All that is said is that the Forest Settlement Officer shall "commute" the rights.

Under this section it will be observed that it is the Forest Settlement Officer who determines, not the parties, whether it is a case for commutation. The Governor may make rules for the Forest Settlement Officer's guidance in such matters. Still the ultimate decision rests with the Forest Settlement Officer.

Extinction of unclaimed rights.

Having now dealt with admitted rights and either:—

- (a) provided for them *outside* the forest, or.
- (b) left them properly regulated *inside* the forest or

(c) having bought them out altogether, no other rights can by any possibility remain in existence so as to give rise to future question. The law gives the amplest opportunity to people to claim their rights without any formality or bar in the first instance. They may come and make any verbal representation they please. The F. S. O., himself will endeavour to find out if any rights not claimed, exists (section 9.); he will act as the next friend of ignorant or timid people and find out their rights for them. It is of course impossible that the wants of people and such claims as amount to rights and would be equitably recognized as such, should remain unknown. If they should, then such rights are declared to be extinguished. This is absolutely necessary; for no forest would be safe, and no repression of trespass or other offences in future would be possible, if unsettled rights remained for ever in the background. The only possible plan is to take every precaution that all rights are ascertained, and having done every

thing that is possible in this respect to declare that no rights not brought to light can be held to have any legal existence.

The law makes due provision for any accidental delay in presenting claims; as long as the final proclamation (Section 19) has not been actually issued, any delay, reasonably accounted for, is overlooked and the claim entertained and disposed of. And further, the power is given to the Government to enquire into any claim during three years succeeding the institution of the enquiry and if a person be absent from the Island when the inquiry of the F.S.O. was held the rights of such person may be inquired into during 10 years succeeding the institution of such enquiry. (Section 20. 10-85. as amended by Section 7 of 1 of 1892). With these ample provisions it will be observed that there can be no hardship.

Appeals from Settlement Orders.

It will be observed that the decision or order of the F. S. O., in respect of claims to a right in or over any land (Section 13) of and in respect of claims to rights of way, water course, pasture and to forest produce (Section 14) only are open to appeal.

The appeal may be by any party—either the right-holder or claimant or the Government—the forest owner. Three weeks is the limit for appealing. The appeal must be in writing and must be lodged with the F. S. O., who must transmit the same together with the proceedings taken by him to the Supreme Court.

Besides the power of appeal, Government may within 5 years from the publication of the final proclamation constituting the Forest a Reserved Forest (Section 19.), revise any arrangement made by the F. S. O., under Section 12 as to the practice of chena cultivation, or under Section 14 as to claims to rights of way, watercourse pasture and forest-produce, or under Section 15 as to the exercise of rights of pasture or forest-produce, and may rescind or modify any order made therein and may direct that any one of the proceedings in Section 15 be taken in lieu of any other of such proceedings, or that permission under Section 12 or rights under Section 14 be commuted under Section 16. (Section 22.)

New Rights cannot grow up in a Reserved Forest.

Under Section 23 no right of any description shall be acquired in or over a reserved forest, except by inheritance or succession or under a grant or contract in writing made by or on behalf of the Crown or some person in whom such right or the power to create such right existed when the final proclamation under Section 19 was published.

This provision cannot take effect until it is definitely known by the operations of Settlements what are the respective rights of the state and of private persons and how they have been adjusted from a given date. That being ascertained the forest is declared "reserved" from the fixed date and no right which on that date has not been admitted and recorded is held to have any existence. Hence this Section only applies to cases where the final proclamation under Section 19 has been published, and no new right can grow up nor any process of prescriptive growth go on.

This provision applies only to the definite area indicated by demarcation as the reserved estate.

The rightholder of a right under Section 15 cannot alienate the same without notice to the Government Agent; but if such right is appurtenant to any house or land and this is sold, then the right goes with the land and the sanction of the G. A. is not required. (Section 24.)

Power is also given to the Forest Officer to stop any public or private way or watercourse in a reserved forest, provided that another way or watercourse has been provided.

Persons who are in any way injured by such alteration may be compensated. (Section 24.)

Final Notification of Forest.

The close of the proceedings is marked by the issue of a final proclamation under section 19.

When all claims have been heard, appeals decided, or when the periods allowed in each case have elapsed, then nothing remains but to notify definitely the exact limits of the forest as in future they will remain (for the limits originally entered in the preliminary notification under Section 6 may have been altered in the process of Settlement) and to declare that from a specified date the estate so demarcated is a "Reserved Forest" and therefore subject to the provisions of the Ordinance. But power is given to the Governor by Proclamation to direct that from a date fixed by such proclamation any such forest or portion thereof shall cease to be reserved; rights extinguished do not however revive in consequence (Section 30.)

Demarcation.

It is essential for the all the objects of a forest estate that the boundaries should be known. It is not possible to punish people for trespass and mischief unless they can certainly know whether they are inside the reserved forest or not. The special provisions of the law as far as they relate to the protection of estates must necessarily operate within certain definite limits.

So with the Settlement of rights and the prohibition to their acquisition; it must be over definite areas that the rights have been settled and within which new rights cannot be acquired.

There is nothing in the Ordinance which requires that any particular form or method of demarcation should be adopted; but the boundaries must be easy to ascertain.

Forest leased by Government.

Forests leased by the Government can also be brought within the provisions of the Ordinance, and the Governor is empowered by Proclamation to do so and to alter amend or revoke such Proclamation.

JADOO FIBRE.

In a communication received from Colonel Halford Thompson, of "Jadoo" fame, the writer says "I am forwarding you a pamphlet which is perhaps somewhat out of date, but which will show you the theory, so to speak, on which Jadoo was founded and the original purpose which it was intended for. It was quite a chance which shewed that the root action it established was so valuable for planting purposes.....I have recently had Mr. Pilkington here on behalf of the Mysore coffee planters, who writes me, "I have great confidence in Jadoo from what I saw." He has had a ton sent out to him, and says he is going to give it a thorough trial, at both his

places in South India. It certainly seems to me that wherever either coffee or tea is grown on the "supplies" system, more especially when baskets are used, that Jadoo is just what is wanted for it undoubtedly will encourage the young plants to throw out roots, and make a certainty that they will get thoroughly established when planted out. We are getting most satisfactory reports from the West Indies especially as to the use of Jadoo for planting young orange trees which is now being done on a large scale in Jamaica."

We are glad to be able to state that we expect to receive shortly half a ton of Jadoo fibre, which it will give us great pleasure to distribute, as we have been requested to do, among those interested in the new growing medium, for Jadoo fibre must not be looked upon as a manure but a material in which roots grow and which encourages the production and development of roots. In another issue we hope to give further particulars regarding Jadoo—by which time the expected sample will no doubt have arrived—and also make reference to the pamphlet made mention of, which is a reprint of a lecture delivered at the People's Palace, East London, on Jadoo Fibre.

THE FRUIT TREE.

The Nursery is that portion of land in which we propagate and bring up our fruit plants. The Nursery required to start an orchard should be divided, so that one separate portion may be allotted to the sowing of seeds, another set apart for those subjects which are to be transplanted hereafter in order to undergo grafting. Plants propagated by cuttings, and which do not require any grafting, should also have a separate area, and lastly a plot will be also required into which to transplant and nurse the plants after having been grafted and before planting out.

The orchardist will always obtain better and more satisfactory results, by establishing a nursery of his own at the spot, instead of securing his plants from different sources and localities. By this means he will be perfectly sure of the varieties he wishes to grow, a more successful planting out would follow, and there will be an opportunity of promptly supplying those plants which accidentally should perish.—

The nursery should be started in a healthy and airy spot within easy reach; the soil should be easily worked, and as regards fertility we have seen that plants from a rich soil are to be preferred to those from a poor one, but are inferior to those started in an ordinary soil. The best fertiliser to be applied to nurseries is a compost of decayed vegetable matter, sweepings, and well seasoned cattle manure. Raw cattle manure should never be used as it would cause rotting of the roots. The soil of the nursery should always be kept cool, hence it requires to be permeable and deep; under these conditions moisture is easily maintained. In allotting the portion for the sowing of seeds, we should choose the one easiest for irrigation or watering, with very loose soil, it does not matter if not very deep, but the most fertile and free of stones. For cuttings and grafting subjects we should give the second choice, and to grafted plants the portion of the nursery which we find least exposed to the winds.

The preparing of the nursery consists in a general tillage to the depth of 3 feet; while doing this all weeds, roots, stones or pebbles should be removed and the different layers of soil generally met with thoroughly mixed, thus forming a uniform growing medium as regards fertility, texture &c., Virgin soil should never be turned over as excepting the vine it has been proved dangerous to all fruit plants.

To avoid confusion it is best to divide each plot of the nursery into beds. Good nurserymen have their beds 24 ft. by 4 ft. A space of about 9 in. divides one bed from the other and every six beds have a path about 3 ft. broad. Cuttings and grafting subjects are generally nursed in larger beds. It is strictly necessary that the nursery should be provided with broad and commodious paths to freely carry out all the work connected with it.

Seeds intended for the nursery should be heavy, well formed, procured from good, middle-aged trees and cultivated in perfectly opened and sunny places; they should be, if possible, obtained from warmer climates and it is essential they should have been raised from well matured fruits only. The germinating power of seeds and their durability differs according to the species; as a rule those with a soft covering last longer than those with hard shells. Seeds should be kept while being collected in dried sand. It is common, in order to obtain quick germination to wet the sand occasionally, a few days before sowing, and to expose it to the sun for about half an hour daily. The harder the shell of the seed, the longer it will take to germinate.

Before sowing the seeds it is advisable to spread over the beds some pulverized soil, this done, a light hoeing should follow.

The sowing of fruit seeds is done either in furrows or in holes, in both cases in straight lines and never at random, as symmetrical sowing will render easy all the work connected with the nursery. The depth at which the seeds are to be put in, varies according to the mechanical texture &c., of the soil and the size of the seeds. Small seeds, such as orange, lemon and similar fruits should be sown to $1\frac{1}{2}$ in. deep.

The practice here of sowing seeds in bamboos is good, provided the plants produced are not allowed to remain in them longer than one month and transplanted to larger receptacles afterwards.

Small seeds are sown in lines, by cutting with a hoe, which is kept straight by a stretched string, making furrows about 4 in. distant from each other, and of the depth required by the species of seeds to be sown. The seeds are laid at the bottom of it if possible at regular distances of about 3 in. With the back of the rake, the furrows are covered and a finishing touch is given all over the bed with the other side of the same tool, rendering it as level as possible and free of any roots or stones. For larger seeds and for those producing plants of rapid growth the lines should be more distant from each other and the seeds also sown at larger intervals. Sowing by holes is also done in lines and with the guidance of a string.

The work to be done after sowing consists of weeding, hoeing, thinning and watering. Weeding is indispensable as the nursery must be kept per-

fectly free of weeds. Hoeing must take place frequently, the oftener the better; this operation will aerate the soil, will bring to the surface the roots of weeds, and also remove the objectionable superficial crust which tends to form as the result of watering. Hoeing should not take place before the plants are one month old as too tender plants are extremely sensitive.

By thinning, we will remove all the fruit plants which have sprung up between the rows, and these could be transplanted to where the seed has not germinated by taking them up with a ball of earth adhering. This transplanting is not always successful and even if so the plants will not turn out strong specimens.

Watering must begin only when thought strictly necessary, as it must be remembered that once watering has begun it must be done daily and at regular hours; a stoppage would cause more serious harm, than if the seeds have been left in the soil without watering at all. Coir dust spread about $\frac{1}{2}$ in. thick over damped beds should keep moisture in this climate, enough for the requirements of the seeds.

About six months after sowing and with favourable weather plants intended to be a grafted should be transplanted to that portion prepared for them; those only should be picked out for this purpose which are at least about the thickness of a pencil. All others of inferior growth and vigour, should remain in their places for another season: with a sharp pruning knife these plants are cut down to the base in order to provoke the sprouting of a new and healthier stem; during their second start they should be watched and not allowed to grow more than one shoot, by suppressing all others as fast as they appear.

The transplanting is done more successfully in cloudy but not wet weather. In up rooting, great care should be taken not to injure the roots and if any bruises should occur it is better to treat such injured parts of the roots by a clean cut. Tap roots of all fruit plants should not be left longer than 5 in., and the cut should take place where there is most ramification of lateral roots.

Grafting is best done on a board, before transplanting and immediately after uprooting.

C. ZANETTI

◆

"NITRAGIN" OR THE USE OF PURE
CULTIVATION BACTERIA FOR
LEGUMINOUS CROPS.

(Continued.)

Up to the present time there have been prepared and put on the market pure cultivations of the organisms derived from the nodules found on the roots, and suitable for application to the growth, of 17 leguminous field crops.

Each bottle as sold bears a differently coloured label according to the kind of crop it is intended for, and also the German and the botanical name of the plant. The contents of a single bottle are sufficient for securing the inoculation of about half an acre of the land on which the crop is to be sown, and the present cost of a single bottle is M. 2.50, or about 2s 6d in English money. Thus the additional cost of inoculating a crop would come to about 5s an acre. To look at, a bottle appears to contain at the bottom of it

about an inch and a half depth of a light brown jelly, ramifying throughout which may be noticed a white growth or mould. The two principal precautions that must be taken with the material are (1) not to let it experience a heat greater than the body temperature (about 98° F.); and (2) not to let it be exposed to a strong light. Either of these would destroy the vitality of the bacteria, but if they be guarded against, the efficacy of the contents may be prolonged for an indefinite time.

The German name for the material is Impfdünger für Leguminosen, "nitragin" (inoculating manure for leguminous plants.)

The method of using the "nitragin" in practical agriculture is twofold. It consists either in inoculating the seed direct by bringing it by means of water, into contact with the "Nitragin," or in inoculating with the "Nitragin" some of the soil of the field on which the crop is to be sown and then spreading this soil over the plot and working it into a depth of of about three inches. The first thing to be done is to render the contents of the bottle liquid; this is effected either by putting the bottle for a short time into lukewarm water, or by bringing it into a warm room until the contents become liquid, or by other obvious means. Care must be taken, as already pointed out, not to exceed a temperature of 98° F. and not to expose the bottle to strong light. The following is, practically, a translation of the

DIRECTIONS FOR USE.

1. For inoculating the seed direct.

For every $\frac{1}{2}$ acre of land to be sown with the crop, take $1\frac{1}{2}$ pint of water in a vessel, and pour into it the liquid contents of one bottle. In order to completely empty the bottle, shake up some of the water with the liquid contents of the bottle, so that the whole gets well mixed, and then pour it into the vessel containing the water.

With the water thus prepared, sprinkle the seed thoroughly, and work the heap with the hand (in the case of larger quantities with a shovel) so that every seed is moistened.

If there be not water sufficient add more, but, speaking generally, $1\frac{1}{2}$ pint is enough for small clover-like seeds.

Dry the seed by mixing it with some dry sand or fine earth taken from the field that is to be sown.

Avoid excessive dryness or dustiness, and do not expose to bright sunshine.

Sow in the usual way.

II. For inoculating the soil.

Instead of inoculating the seed direct, it is rather better to effect this purpose by inoculation of the earth of the field that is to be sown. To do this, for every $\frac{1}{2}$ acre of land that is to be sown, take 56 lb of earth from the field, and pour the contents of the bottle over it as directed before, but using very much more water. In this way the earth will be inoculated. Let the earth dry in the air, or, if necessary, add more dry earth.

Then spread the whole evenly over the surface to be sown with seed, and work it into the soil to a depth of about 3 inches.

Sow the seed as usual.

Dr. Nobbe is of opinion that the inoculation of the soil is to be preferred to the treatment of the seed, inasmuch as it would seem more certain that the organisms come in contact with the roots during their search for food.

The production of "Nitragin" on a commercial scale being of such recent date, there has been little time as yet, even in Germany, to make extensive field experiments with it under ordinary agricultural conditions. Nevertheless experiments are being made at several experimental stations and on private farms, and so far as can be judged at an early stage, the treated plots are reported as showing some advantage over the untreated ones, while the roots of plants grown on the former appeared to have more nodules than the roots of plants in the latter.

The question now remains of what practical utility to the cultivators of the soil in general is the discovery likely to be? Is it likely to enter into ordinary agricultural practice? And will it pay to carry out!

VETERINARY NOTES.

A curious form of disease about which practically nothing is known occurs among stock in Ceylon. Among the symptoms are increased respiration, a darkening of the colour of the coat either completely or in patches, (while the hair of the coat at the same time tends to become long,) and, in milch cattle, loss of milk. On consulting Veterinary Captain Pease of the Indian Veterinary Department, that well-known authority replied that he had never heard or seen cases such as we have described. Professor Wallace of Edinburgh, who saw some cases in the Government Dairy, gave it as his opinion that the disorder was due to an affection of the liver and recommended treatment with calomel. The natives have their own treatment for the disease, which, according to them, would appear to be due to impurity of the blood, and the drugs prescribed by them are believed to be effectual.

Who knows but that this may not be a "new disease," just as albuminaria (known as Bright's disease in the human subject) is now recognised by veterinary pathologists as a distinct disease in cattle. We quote as follows with reference to albuminaria among stock:—

It is a difficult subject to treat at all times, but endeavour shall be made to explain it as simply as possible, compatible with facts. Albumen may arise in the urine from various causes—lesions of the nerve centres, indigestion, from injuries or cold, and from diseases of the kidneys. Also, physiological albuminuria may arise from the nature of the feeding, without any actual disease being present, the albumen in none of these cases being permanent. But, in the form under consideration we have disquamation or ulceration of the lining membrane of the uriferous tubes or ducts of the kidney, thereby permitting of the exudation of the albumen, one of the principal constituents and most nutritious substances contained in the blood for the nourishment of the tissues. The colour of the urine is smoky-brown, and it easily froths from the presence of albumen. The Specific gravity is low,—1.014—by abstraction of urea; quantity of urine much diminished owing to the reduced proportion of water; subsequently the urine becomes pale and opalescent, and is less apt to froth from there being much less albumen; the specific gravity declines yet much lower down, perhaps to 1.004, while the quantity of urine is increased, approaching almost to diuresis. To ascertain whether pathological urine is present or not, two samples should be sent to an organic analytical chemist for qualitative analysis, as the urine of domestic

animals is at all times difficult to test, that of bovines differing in its normal constituents from that of the equine species, the latter containing an acid peculiar to itself—hippuric.

In the early stages of the disease the animal has a stiff, straddling gait behind, cringes and stretches itself out, but in a very cautious manner, almost indicative of the seat of the affection. In the first stage the pulse and respiration are but slightly affected, but as the disease proceeds evidences of pain are evinced, the urine becomes darker and mucilaginous, the pulse more frequent, and respiration is increased; the animal continues to exhibit pain and restlessness, and unless a speedy turn for the better takes place paralysis ensues, death following from the poisonous effects of the effete products of the system not being eliminated by the diseased kidneys but retained in the system, causing uræmic or other blood poisoning. There is no cure; the treatment can only be palliative, such as good food, mineral tonics, mucilaginous drinks, &c. Were the disease detected in its incipient stage, before effete products had accumulated in the system, and the animal slaughtered, there could be but slight objections to the carcase being utilised.

Dr. Cowan Lees in concluding his able address at the opening of the Glasgow Veterinary College offers the following piece of advice to the younger generation of "Vets," which they might well take to heart: "To those who are now leaving College and about to enter upon the practice of veterinary medicine, I would remind them that it is a profession in which they cannot stand still; they must either progress or retrogress—and the only way by which they can prevent themselves from falling behind is by reading, by studying, and by observation. Allow nothing too small to escape your mind's eye; take up every detail and satisfy yourself regarding it before you pass on, remembering always that the beginning of disease is very small."

The benefit of judicious crossing is well illustrated by the facts recorded in a note by the Assistant Director of Agriculture for Bengal with reference to the cross-bred cattle of Bankipore. The reference is of particular interest because it has to do with an experiment initiated some 40 years ago. In 1856 a Mr. Taylor started a small breeding establishment at Bankipore where he kept English bulls. A few months later the Indian Mutiny broke out and put an end to his experiment. Some years later, however, Mr. Taylor resumed his breeding operations. In the result after nearly twenty generations the present stock of cross breeds still maintain manifest traces of their superior origin in make, colour, and size. The cows, which the Assistant Director saw in Bankipore, he regards as the finest that have come to his notice anywhere in Bengal—the best being capable of giving 20 seers of milk a day, and the worst 8 seers—a great yield when compared with that of the ordinary cattle of the Province.

The following remedy is given in the *Scientific American* for flies on cattle: Coal tar one part, oil and grease one part each; mix with a small amount of carbolic acid. Apply with a cloth, and it will drive off every fly, and last ten days or more in dry weather. Any kind of old lard or grease can be used. This remedy is equally effective as a lice exterminator on poultry, and is used for painting the sides and roosts of the

fowl-house. For a hen and young chickens saturate a cloth and place it in the bottom of a box, and put the hen and chickens in the box for an hour or so.

NATIVE LANDS.

There are large areas of land in different districts of the Islands owned by the inhabitants of the villages in the vicinity for ages. These lands are generally grants which their fore fathers had received for services rendered to the State, or by way of compensation for services expected of them. The Government under the Sinhalese Kings was more or less a patriarchal one; every man received justice whether he was rich enough to engage lawyers or not. Crime was punished there and then without the interference of busy bodies and in the absence of technicalities. No man was left without the means of employment; and whatever work a man was fit for he got enough of it to do. The Agricultural population was given as much land as they could cultivate, not only for their own use but for the benefit of the general public; and every facility was given for obtaining the water necessary for carrying on the cultivation of the staple food of the land. There were possibly many drawbacks in the method of government, but in Agricultural affairs the system adopted was one that was most desirable, in that it not only made the people dependent on their land, but made them independent of extraneous aid in the procuring of the necessaries of life. Even up to the present day we see somewhat of the same state of things existing in many of the country districts of the Island. Every man is a landowner and raises the few products required for his sustenance, and which are sufficient for his wants except perhaps during exceptional seasons when rain fails and as a consequence drought prevails. It will be found that in the majority of instances the criminals in our Island are largely derived from the landless population. The landowners are kept busy with their daily vocations and are in their own sphere a contented lot.

It may well be assumed that the more we deprive the peasant proprietors of their holdings the greater will be the increase in the number of vagrants and do-nothings who not only disturb the peace of the villages but resorting to populous centres in search of work and failing to find it turn their hands to unlawful occupations.

Since of late a large number of lands belonging to these peasant proprietors have changed hands.

The new owners who acquire the land as cheaply as possible, utilise it for raising products not for meeting the wants of the local population but for supplying foreign markets, while the original owners frequently become their employers.

It may be said, however, that the villagers who sell their lands, the greater part of which is left uncultivated and neglected for long periods, obtain the market value of property and hence in one sense, instead of being losers, they gain the money value of the land which was practically unproductive to them. Granted, they do so, how do they invest their newly acquired "wealth"? Being generally an illiterate and ignorant class, the only use they see for the money they have in hand is to spend it. They cannot possibly be expected to rise to the level

of the intelligent native or European capitalist and find better means of investment or embark in industrial schemes or trade. They have been accustomed from generation to generation to cultivate their lands the only occupation which they have any knowledge of; and giving up this occupation they find themselves possessed of money which is comparatively of little value to them and does them little good in the long run. It has been said that those villagers who own large tracts of partly cultivated land will benefit by selling a portion of their holdings and applying the proceeds towards the improvement of the remainder. But the question is, do they? Is it not rather the case that he who experiences the novel pleasure of possessing money and of spending it in the enjoyment of luxuries, does not cease to spend till there is nothing left of his money?

It often happens that a capitalist is able to buy only a small bit of land, say, twenty to fifty acres, but before such a purchase is effected the first inquiry the buyer makes is, whether there are any more native lands surrounding the block: if there are any he is quite satisfied, since he knows fully well that he will be able to extend his property by making further purchases from the villagers. Often it is the village headman, who with the object of pleasing a wealthy proprietor induces the villager to part with his lands to extend a newly purchased property. If the villager does not see his way to oblige his headman, it will happen in many instances, that the former will lose both the land as well as the money. It is well known that in many cases the villager is induced to part with his land, by bringing outside influence to bear on him and very often by harassing him in a hundred and one ways. He will be prosecuted for trespass on the capitalists' land, he will be charged for damages for the trespass of his cattle, his cattle will be shot down, a survey will be made and the villager probably charged with encroachment, and in the end he will be forced to see that if he parts with his land he will be rid of all this worry and will in addition get a little money for his expenses. How many properties are there not, in the Kurunegala and Kegalle Districts, which began with twenty to thirty acres or fifty acres and which have now extended to hundred and hundreds of acres. How many men who possessed land at one time and who led a life of peace and plenty in their villages have turned out to be penniless drunkards, vagrants and thieves? A census will show that they could be counted by hundreds, and yet the "Capitalists" complain of a little wholesome advice given to these villages by a well intentioned revenue officer. Mr. Davidson's circular has been published in the vernacular papers since the discussion in Council and the fact is that he has understated the case instead of overstating it. All the vernacular papers in the land, papers which are often in conflict with one another in their opinions, are unanimous in welcoming the circular in question as one that was not issued a day too soon. In fact most people who know anything about the villager and village life would like to see the intervention of Government to prevent the sale of native ancestral holdings, to the first capitalist who can pay down money or exercise his influence to acquire them.

W.A.D.S.

MILK AND MILK PRODUCTS.

By MR. JAMES MOLLISON
Supt. Govt. Farms, Bombay.

(Continued.)

The wash room with a built-in copper boiler should be a separate building.

The dairy for a herd of 20 to 40 milk cattle should be equipped as follows:—

	Rs. a. p.
One Laval Separator "Alpha Baby"; separates 30 gallons per hour; complete	360 0 0
Refrigerator with stand and fittings, complete, with two block tin drums or receivers	190 0 0
Six block tin pails	36 0 0
Two milk strainers, one fitted with wire gauze, the other with muslin	5 0 0
Two hair sieves	3 0 0
Sandringham Herd Recorder with pail and tripod for weighing milk	35 0 0
Iron scales with China pan for weighing butter	14 0 0
Temperature can	4 8 0
Thermometer	2 8 0
Half pint, 1 pint and 1 quart measures with hook handles	5 0 0
Victoria Churn (No. 3) to churn 40 lbs. of cream	85 0 0
Cunningham butter worker	45 0 0
One pair Scotch hands, one pair scoops and one pair beaters for handling butter	10 0 0
Moulds and prints for Making 2 oz., 4 oz., and 8 oz. pats of butter	3 0 0
Set of three cleaning brushes for chururs, cans and separator	4 8 0
One gallon refined oil for separator	4 0 0
Total...	806 8 0

Cream-separators as now manufactured are simple and effective, and although protected by patents, which necessarily enhance their value, are still moderately cheap. They vary in size and price. The hand power machines can effectively separate 30 to 40 gallons of milk per hour. The larger horse or steam power machines separate 200 gallons or more. The principle of all is the same. The milk is fed at a regular rate into a cylinder which revolves at high speed. The rate of revolution is so great that it exercises centrifugal force on the milk constituents. The lighter cream forms itself into a column which occupies the centre of the cylinder whilst the heavier separated milk is thrown against the inner wall of the cylinder; each product escapes separately from the cylinder and runs through separate tubes into different vessels. The De Laval "Windsor" hand-power machine is the one in most common use in India. It separates 35 gallons per hour and costs in England £ 24. For thorough separation the handle should be worked at a regular rate of 38 revolutions per minute; if worked at a higher rate, the cream comes thick; if at a lower rate, separation is not complete. The driving power is obtained partly by cog-wheels and partly by friction pulleys. The cylinder revolves on the latter. If the friction pulleys are coated with oil, the cylinder partly turns with and partly slips upon the friction pulleys, and therefore although the handle gets the correct number of revolutions, the cylinder

does not turn at the proper rate which is about 6,500 revolutions per minute. To safeguard against this error the friction pulleys should be rubbed free of oil immediately before starting the machine. The separator should be set accurately level and fixed, so that it cannot be dislodged from its position. All its parts must be kept scrupulously clean and the friction portions be regularly oiled with the purest lubricating oil obtainable. Milk should be warm when undergoing separation. The temperature at which it is drawn from the under is sufficiently high. If milk is colder than 90° F. before it is brought to the dairy, it must be raised to at least that temperature before it is separated. This is specially necessary with buffalo milk which ordinarily is extremely rich in butter fat. A temperature can *i.e.*, a tin vessel with a tight fitting lid, and containing hot water, if dipped into milk and gently moved through it, will soon raise the temperature to the desired standard. All milk before separation should be well strained first through a wire or hair sieve and then through muslin, a double-fold of which may be stretched on a strainer frame of ordinary form. If the quantity of milk to be strained is considerable, both the wire and muslin strainers should, from time to time, be rinsed in pure water as the straining proceeds. This should be done as often as there is any observable accumulation of foreign matter on the strainers.

Complete separation means that less than $\frac{1}{2}$ per cent. of butter fat remains in the separated milk. It may be stated that approximately whole buffalo milk yields $\frac{1}{2}$ cream and $\frac{2}{3}$ separated milk, and that 2 lbs. of the cream will yield from 1 lb. to $1\frac{1}{2}$ lbs. of butter. A pound of butter can be made from 9 lbs. of milk, if rich, but it will take 16 lbs. to make the same quantity if the milk is poor. Buffalo milk is so rich in butter fat that the ordinary lactometer as graduated for use in England is necessarily misleading in India—thus it will indicate that separated milk is of better quality than whole buffalo milk. To make this plain it may be stated that the lactometer will show pure milk when 8 per cent. of water has been added to separated milk.

Slightly salted pure butter should contain approximately:—

Water	7.5
Salt	1.1
Casein	0.6
Milk-sugar	0.3
Butter fat	90.5

Butter can be made to take up water to the extent of nearly 20 per cent. The presence of a high percentage of water indicates that the butter has not been properly washed; because the removal of butter-milk and other impurities from butter implies not only thorough washing, but thorough working or squeezing also. The process should not leave more than 10 or 12 per cent. water in the butter. Imperfectly washed butter contains butter-milk and curd. The nitrogenous substance, casein, is highly fermentative and the presence in the butter of even a small percentage causes the butter soon to turn rancid. Rancidity is believed to be due to a chemical change, *i.e.*, The splitting up of butyric into butyric acid and glycerine. Air and light are

necessary to initiate the change. The melting point of butter is of some importance. It is a means by which expert analysis can detect whether it has been adulterated by animal fat or vegetable oil. The food given to dairy cattle however, influences the melting point. Those foods which are least astringent produce the softest butter. Cotton seed, pulse meal, pea straw and other pulse fodders, also groundnut cake produce firm butter, whilst many oil cakes give soft greasy butter. A simple and homely method of detecting impurities in butter is to place a small piece in a test tube and plunge the tube into hot water. The butter melts and separates into layers which will indicate approximately the relative proportions of its constituents. The clarified butter (*ghi*) will form the upper layer, the curd a middle layer dividing the *ghi* from the water which will occupy the bottom of the test tube.

THE CLASSIFICATION OF COTTONS.

A late issue of the Agricultural Ledger Series deals with Indian Cultivated Cottons. The account is written by Mr. T. H. Middleton, B. Sc. Professor of Agriculture, Baroda College. In a concluding note, the Editor (Dr. George Watt) takes exception to some of Prof. Middleton's "botanical interpretations" in the latter's paper which Dr. Watt readily admits is "a most valuable contribution to our knowledge of the cotton plants of India." The Editor thus refers to the difficulties in classifying the various kinds of Cotton that are found under cultivation:—

The subject of the origin of the various races of cotton in the world is a subject which unfortunately has its parallel if not its origin in the obscurity that involves the determination of even the species of *Gossypium*. While a very large proportion of the cotton area of India still remains to be explored by me, I do not propose to publish my peculiar views of the botanical problems briefly touched on by Professor Middleton. I may say, however, that the errors that obscure the study have passed down from the very earliest times, so that certain species described by even Linnaeus himself in his *Species Plantarum* will have to be spoken of in future as not being the species of that name in his herbarium. If, therefore, uncertainly exists as to the exact plants meant by Linnaeus under such names, for example, as *Gossypium barbadense*, *G. hirsutum* and even *G. arboreum*, it is no wonder that numerous subsequent writers have got hopelessly confused and new names such as *G. obtusifolium*, *G. indicum*, *G. Wightianum*, *G. roseum*, and *G. neglectum* have been proposed and rejected or translated from one form to another. The writer had the pleasure recently to receive a large and valuable collection of botanical specimens of *Gossypium* from the United States of America. These proved of exceptional interest since they revealed the fact that *G. herbaceum* of American writers was for the most part neither the *G. herbaceum*, *Linn Sp. Pl.* nor *G. herbaceum*, *Linn Herb.* The interest in this matter turns mainly on the interpretation that must now be placed on the so-called American hybrids between that

species and *G. barbadense*. Indeed it is from an exactly similar reason that the whole problem of the solution of the species of *Gossypium* calls most urgently for solution. Until we are in a position to say so and so are definite forms, varieties, or species, we are not in a position to propose the steps that should be taken in the direction of improvement of stock.

NEW INDUSTRIES FOR CEYLON.

When the question of establishing a technical College in Ceylon was under discussion, much was said about the way that it would help the people of the country in acquiring a knowledge of what to them would be new arts, and in showing them how to work at new industries. Technical education is a very wide term, and no doubt the present position of the Ceylon Technical College as a training school for those who would qualify to enter the Railway, Survey, and Telegraph departments does not belie its name, but it is questionable whether the Institution would not have been better employed in helping to develop the latent resources of the Island and open new fields of work for the people. A careful consideration of the subject will show that there are many industries which can be established with benefit both to the governors and the governed. Take for example the extraction of catch. The Island is rich in tan producing trees of which there are so few in western countries. Some trade is no doubt being done in the exporting of tanning barks and myrobolans, but how much more remunerative will such a trade be to those engaged in it, if they know how to extract the material for which the bark or fruit of trees is valued, and export it in a concentrated form. While the people of the country remained in ignorance of the technical knowledge which would have stood them in such good stead, we find that a Scottish Cutch Company has stepped in and established itself in the Island. Apart from the question of a trade in Cutch, our local tanners would be able to turn out much better leather if they were in a position to treat their hides with tanning extracts of standard strength instead of by the more or less indiscriminate use of tanning barks in the raw state. Another way in which technical knowledge would have helped to develop local industries is in the treatment of indigenous and naturalised fibres.

Indeed there are many natural products which the natives of the country could be taught to make capital out of, such as gums, resins, oils &c.

We would go still further and say that chemical industries like inkmaking, pottery, the art of dying and cleaning by chemical means and other operations would form part of a technical school curriculum with much resulting advantage to the people. We note that an enterprising native is advertising ink of his own manufacture. All honour to him. The wonder is that it has taken so long for so simple an industry—particularly in a country where tan-yielding substances are so easily available—to be started. Cleaning and dying works are sadly wanted in Ceylon, where owing to tropical conditions woolen and silk

clothing soon becomes unfitted for wear. We have only referred to a few of the ways in which a technical education of a more varied character that is available at the Technical College (which has so far been a school of mechanical engineering) would help the people of the country, and we have no doubt that after a careful enquiry a curriculum for a very useful course of training could be arranged for.

BREEDER'S TABLE, giving period of gestation, and date of production from time of service of the MARE, COW, EWE, SOW, and SLUT.

PECULIARITIES OF COCONUT CULTIVATION IN INDIA.

[In concluding the account of coconut cultivation in Bombay, we should have stated that according to the various district Gazetteers there are from 30,000 to 40,000 acres under the palm, with about 100 trees to the acre. Kanara, Ratnagiri, and Kathiawar appear to be the districts where the largest number of trees occur. Of Ratnagiri, it is stated that where grown for the fruits only each tree gives a net yearly profit of R1.3 as.]

II.—MADRAS.

In the Madras presidency the palm is stated to frequent the banks of estuaries and back waters, abounding on the sandy tracts near the sea, especially along the Malabar and Coromandel coasts. In South Canara it is estimated that there are 80,000 acres under coconuts. "The Malabar coast and the Laccadive and Maldive Islands are pre-eminently the seats of the coconut industry. The enquirer after Indian coconuts, coir or oil, need practically concern himself with no other part of the country unless he add to these the Nicobar Islands." The Nicobars are said to produce a large number of nuts, but, apparently, the Islanders are ignorant of, or too indifferent to learn, the art of making coir and expressing oil, while the same is said of the Maldives. The imports from the Maldives in 1888 were 7,897,453 nuts to India, and from the Nicobar Islands 4,510,000 nuts. The imports from the Laccadives (which are mainly under the administration of the collector of Malabar) are treated as if they were produce of the mainland and are not given in the trade returns. The inhabitants of these groups of Islands are not reported to manufacture coir and apparently prepare a small quantity of copra, although they sell their nuts at a price below that which prevails on the Mainland of India. The following reference to the system of coconut cultivation in Madras occurs in Morris's Descriptive and Historical account of the Godavery district: young plants of a year's growth are planted out and watered for six years, after which they do not require much water. The trees generally bear fruit about the ninth year after transplantation. The expenses of cultivation are stated to be R668 for a *putti* of land namely R140 being the price of 600 young plants, R48 being the value of the labour required for planting them, and R480 being the wages of labourers employed to water and tend the trees until they come into bearing. When the trees begin to bear fruit the value of the produce of a tree, exclusive of the fibre is estimated at about 12 annas a year, making a total value of the produce in a *putti* of land R300.

III.—MYSORE.

In Mysore there are four varieties of the coconut, (1), red (2) red mixed with green, (3) light green, (4) dark green. These varieties are permanent, but although the red is reckoned somewhat better than the others, they are commonly sold promiscuously, and their produce is nearly the same. The soil does not answer in the Bangalore district unless water can be had on digging in to it to the depth of 3 or 4 cubits and in such situations a light sandy soil is best. The black clay (called *ere*) is the next best, and the worst is the red clay (called *kebbe*); though with proper cultivation all the three varieties of soil answer well.

The manner of forming a new coconut garden is as follows:—The nuts intended for seed must be allowed to ripen until they fall from the tree, and must be then dried in the open air for a month without having the husk removed. A plot for a nursery is then dug to the depth of 2 feet, the soil is allowed to dry 3 days. In March one foot of

earth removed from the nursery and the surface of the plot covered with 8 inches of sand. Upon this the nuts are placed close to each other, with the end containing the eye uppermost. They are then recovered with 3 in. of sand and 2 in. of earth. If the supply of water be from a well, the plot must be watered once a day; but if a more copious supply can be had from a reservoir one watering in 3 days is sufficient. In 3 months the seedlings are fit to be transplanted, and by this time the garden must have been hoed to the depth of 2 feet. Holes are then dug for the reception of the seedlings at 20 feet distance from each other in all directions, for when planted nearer they do not thrive. The holes are 2 ft. deep and a cubit wide. At the bottom is put sand 7 inches deep, and on this is placed the nut with the young tree adhering to it. Sand is now put until it rises 2 inches above nut, and then the hole is filled with earth and a little dung. Every day for 3 years, except when it rains, the young tree must have water. The palm begins to produce when 7 or 8 years old. Young trees produce more fruit which comes forward in every season of the year. A good tree gives annually 100 nuts.

Coconuts are planted in Chicknayakanhalli in rows round the arca-nut gardens, and also separately in spots that would not answer for the cultivation of the latter. The situation for these gardens must be taken rather low, but it is not necessary that it should be under a reservoir: any place will answer where water can be had by digging to the depth of two men's stature. The soil which is reckoned most favourable is a red clay mixed with mud. It must be free from lime and saline substances. Other soils are used but black would be reckoned very bad. The nuts intended for seed are picked in the second month after the winter solstice. A square pit is then dug which is sufficiently large to hold them, and is about a cubit in depth. In this fifteen days after being picked are placed the seed nuts, with the eyes uppermost, and contiguous to each other, and the earth is thrown in so as just to cover them, and on the top is spread a little dung.

In this bed, every second day for six months the seed must be watered with a pot, and then the young palms are fit for being transplanted. Whenever during the two months following the Vernal Equinox, an occasional shower gives an opportunity by softening the soil, the garden must be ploughed five times. During the next month it is allowed to rest. In the month following the summer solstice the ground must again be ploughed twice, and next month, at a distance of 48 cubits in every direction, there must be dug pits a cubit wide and as much deep. In the bottom of each in little dung is put and the young plants, having been previously well watered to loosen the soil, are taken up and placed one in each pit. The shell still adheres to the young palm, and the pit must be filled with earth so far as to cover the nut. Over this is put a little dung. For 3 months the young plants must be watered every other day; afterwards every fourth day, until they are 4 years old except when there is rain. Afterwards they require no water.

(To be continued.)

THE NUTRITIVE PROCESS IN PLANTS.

(Prof. J. REYNOLDS GREEN, D.S.C., F.R.S.)

Proteid stores are not however confined to seeds. If we examine a young potato we find in certain cells, a little way below the outer skin some regular cubical transparent crystals of apparently the same material as the crystalloid of the complex aleurone grain.

The fleshy roots we have noticed as containing stores of sugar, also contain large stores of proteid material, which is held in the meshes of the protoplasm of the cells in amorphous and not granular form. It can be dissolved out by appropriate solvents and its chemical nature ascertained. The way in which these bodies reach their ultimate reservoirs is not quite so well known as is the case with starch. The seat of construction we have seen to be, in the first case the cells of the leaves, the same cells most likely in which the carbohydrate matter is formed. But we have not yet found any enzyme there which will act upon them as diastase acts upon starch. We do not know what form of proteid the leaf constructs. But whatever it may be, and however it may be made soluble, there is no doubt that it leaves the leaf and travels down the vascular bundles much as the sugar does, the form in which it goes being partly that of some variety of proteid, and partly that of crystalline bodies called by the chemists *amides*, of which *asparagin* is the most common. Arrived at the seat of its deposition, the packing away of it in the form of aleurone grains seems to be carried out by the protoplasm of the cell, and not to be the work of a plastid of any kind. The mode of the formation has been traced out in the seed of the lupin, a leguminous seed a good deal like the bean. In this seed they begin to be formed at a very early period, just as the growth of the embryo is sufficiently advanced to swell out the seed coat. The cells of the embryo at that period show the protoplasm not sufficient in amount to fill each cell, so that a number of spaces or vacuoles occur filled with sap. Somewhere from the protoplasm small projections of spherical or ovoid shape may be noticed which gradually increase in size, growing inwards into the protoplasm as well as outwards into the vacuole, till they can be seen to be in the form of grains embedded in the protoplasm, which in consequence of their development, assumes the appearance of a coarse net work. As this process continues, the original grains growing in size and new ones being constantly formed, the original vacuole becomes obliterated and the cell swollen out by its own deposits.

While this mechanical process is going on, chemical changes also take place in the material deposited. The protoplasm forms the grains originally at the expense of the amide bodies brought down to the cell; these can be detected in it at the time the aleurone formation is beginning. As the grains begin to be formed they are not soluble in 10 per cent or saturated solutions of common salt. Later on they can be dissolved by both of these fluids.

The deposition of aleurone in the cells is thus, like that of starch, a process of secretion carried out by the protoplasm, a process, that is, of manufacture of the grain by the latter out of less

highly organized material brought to it. It is so constructed by the intervention of the protoplasm itself, the grain growing at the apparent expense of the substance of the latter. There is no doubt that the amorphous deposits of proteids in the cells of fleshy roots and stems are due to a similar process of secretion.

There is yet another form of reserve material which is of very common occurrence in many agricultural plants; this is oil which is prominent in the seeds of various families. Specially may be mentioned rape, hemp and linseed; in less amount we find it in many leguminous and cruciferous plants. The mode of deposition of oil or fat is not much known. It is generally found saturating the protoplasm of the cell in which it lies, and not occupying a definite space as do aleurone and starch grains. Whether it is secreted from the substance of the protoplasm, or whether the materials of which it is made are taken to the latter in a state near the state of finished fat, is uncertain. It is formed by the combination of a fatty acid with glycerine. Both these bodies can be formed in the plant, but how they are finally presented to us in the state of oil is still in need of elucidation. As the oil appears in the cell it seems to point to a process of breaking down of the protoplasm itself, and not to a direct combination of the antecedents. Thus if we stain cells which are forming fat with osmic acid, which colours fatty bodies brown or black, we see in the protoplasm small specks of fatty matter, which, while in the youngest cells are mere dots, are in the older ones larger, and can be recognised as droplets. In older ones still the blackness permeates the whole protoplasm, indicating that the latter is saturated with the oil, the droplets having run together in consequence of their number and dimensions.

Fat or oil is not only deposited in seeds but also occurs in similar quantity in the leaves of plants belonging to certain orders, particularly the Liliaceæ. Drops of oil may be seen in the cells of the epidermis of the leaves of vanilla, of the coloured floral leaves of *ornithogalum* &c. These cells also contain curious bodies of very irregular shape, lying near the nucleus, which have been thought by their discoverer to be plastids like the chloro plastids and leucoplastids already spoken of. They are like them composed of a spongy protoplasmic frame work, but contain no colouring matter. The oil is formed in the meshes of these plastids, much as it is formed in the protoplasm of the seeds already described. These bodies have been called *elaioplasts*.

Other forms of stored material may be met with in plants. Inulin in artichokes, cellulose in palms and other plants (to a small extent in cereal grasses); curious bodies known as glucosides in many plants, particularly seeds of crucifers such as mustard &c. These are less common than the forms described, and seems rather to be appropriate only to a few plants.

Whatever may be the character of the material, its meaning is the same; it shows us the provision of nature for the maintenance of the organism during times unfavourable for nutrition, and for the survival of the species under the peculiar conditions of cessation of active life which are characteristic of the seed.

(The End.)

RAPE.

Dr. Watt in his Dictionary of the economic products of India says that the Indian forms of *Brassica Campestris* may, with at least a certain degree of certainty, be referred to three primary sections:—

Section I. Colza, which corresponds to Roxburgh's *Sinapis Dichotoma*, and the abnormal forms of that plant which have come to be known as *B. trilocularis* and *B. quadrilocularis*.

Section II. Rape or *Sinapis glauca*.

Section III. Toria or another form, most probably of rape, which has received the name of *S. glauca*.

There is every reason to believe that II and III are commercially known as rape, although perhaps the last may be occasionally classed as mustard. These three forms individually represent agricultural products of the greatest importance to India.

The subdivisions of the Indian forms of *B. Campestris* as above helps for one thing to separate the oil which in Indian Commerce is called rape-oil from that which might with advantage, in order to remove confusion, receive the name of Colza, as well as both these from mustard oil and other oils obtained from members of the same genus. It is enough to suggest such a separation; subsequent research may reveal further connections and sub-divisions, for there are many points which it is difficult to settle definitely in the present state of information. Perhaps the best botanical character which can be cited in support of the proposed separation is the glabrous nature of the ground leaves of *S. Dichotoma*, corresponding with those of Colza. The seeds in the former are smooth and light, in the latter smooth or rough, but dark coloured. Rape oil (*S. Glauca*) is regarded as better in quality than the oil from *S. Dichotoma* (colza), the latter being chiefly used to anoint the body, while the former is largely used in cookery and is exported to Europe for illuminating purposes and to meet a demand in Indian rubber manufacture. In the trade returns of the export of rape oil and seed from India, apparently both the above are included as different qualities of rape, if not the oil expressed from *B. Juncea* (Indian Mustard, Sin Aja) and *Ernea Sativa* (a cruciferous plant closely allied to mustard and extensively cultivated in N. W. India.)

In European commerce rape and colza are names which unfortunately have come to be used almost synonymously. The separation recommended of the corresponding Indian forms has been deemed advisable chiefly with a view to more clearly identifying the Indian oils allied to mustard. The oils obtained from these are even more distinct than the oils from the European plants and their respective properties are well understood and appreciated in India. In India rape seed is very commonly sown mixed with mustard seed and almost always as an auxiliary with grain crops. It prefers loams and does not thrive on clay soils. The sowing takes place in October, and the harvest in the following February, the plants being cut somewhat prematurely to prevent the bursting of the pods and the shedding of the seed. The seed is ripened by exposure to the sun for 3 or 4 days on the threshing floor,

and is then easily separated. The Indian seed known as Guzerat rape, largely crushed in Dantzic, is found to yield $3\frac{1}{2}$ per cent more oil than European seed, and leaves a cake richer in fatty matter and albuminoids; it is shipped from Bombay and brings the highest price of any.

Guzerat rape, regarding the superiority of which much has been written, seems to be a superior quality of Toria (*S. Glauca*). The Bombay Gazettee has the following note of this form. "Rape seed holds the first place among oil seeds and the third place among crops in general. Land intended for it is left fallow for four months and ploughed twenty times before the seed is sown. The crop does not require any watering. The seed is sown in drills in November at the rate of 2 to 5 seers to the bigha, and reaped in March, and the average yield varies from 400 to 800 lbs." Besides yielding $3\frac{1}{2}$ per cent more oil than European seed, the cake contains 10 per cent of fatty matter and 34 per cent albuminoids—both in excess of the amounts yielded by ordinary rape.

GENERAL ITEMS.

The *Indian Agriculturist* in reviewing Dr. Ribbentrop's reports on Forest administration in India says: The benefit which the people themselves receive from forest operations cannot be represented in figures. If left to their own devices they would fell timber indiscriminately, burn clearings for cultivation, destroy young trees, and of course take no thought whatever for reproduction. The Government steps in and its Forest staff prevents the deforestation of large and valuable tracts. Their operations are often distasteful to the villagers, and occasionally the regulations do bear hardly upon the rural population. The latter however are not deprived absolutely of all their time-honoured privileges. In the year under review, the value of forest produce given free or at reduced rates to right-holders and free grantees amounted to 59 lakhs of rupees.

The experiments with various kinds of paddy on the Bardwan Farm in Bengal have led to the conclusion that the better prices obtained for the finer varieties more than compensate for the larger yield of the coarser crops.

The Science and Practice of Dairying is the title of a new translation from the German by Dr. Aikman and Prof. Wright. The author is Dr. Fleischmann, Prof. of Agriculture in Konigsberg University, Prussia. The publishers of the English version are Messrs. Blackie & Son, and the value of the book 10s 6d.

—Two well-known Dutch analysts have sent for signature to the cocoa-manufacturers in Holland a memorandum, which they are requested to subscribe and to forward to the Dutch Parliament. The memorandum states that serious injury is done to the reputation of genuine Dutch cocoa by the prevailing practice of offering for sale as cocoa powder a mixture of ground cocoa and flour. Parliament is asked to make it an offence to sell

anything, except pure cocoa under the name of cocoa, and to decree that all parcels containing mixture shall bear in plain figures an indication of the percentage of adulterants. It is said that the great majority of the Dutch cocoa-manufacturers have signed the memorandum, which is about to be laid before the States-General.

Dr. Somerville, Prof. of Agriculture, Newcastle, draws particular attention to the benefits of mixed manures even of the same class, in a paper on "some aspects of the practice of manuring." He says:

The reason why a complex dressing produces a larger crop than a more simple application is not far to seek. Where plants are fed on, let us say, one form of phosphate the probabilities are that their phosphatic food is either too soluble or not soluble enough, so that they either get too much in the early part of the

season and are starved later, or *vice-versa*. But, on the other hand, if one offers plants a mixture of phosphatic foods differing in their degree of solubility, the plants feed upon the most easily assimilable portion in the early part of the season, and as that is gradually exhausted the other forms come into use and supply the crop with sufficient nourishment later in the year. And similarly with regard to nitrogenous and potassic food. In this way, then, the crop is well supplied with nourishment right through the period of growth, and a maximum yield at the minimum cost is the result.

Among the subjects which are lectured on or taught practically in the Glasgow Technical College are Agriculture and Agricultural Chemistry, Agricultural Botany, Forestry, and Horticulture, Poultrykeeping, Beekeeping, and Butter making.

ALEXANDER CAMPBELL WHITE, Esq.

* The TROPICAL AGRICULTURIST *

◇ MONTHLY. ◇

Vol. XVI.]

COLOMBO, FEBRUARY 1ST, 1897.

[No. 8.

“PIONEERS OF THE PLANTING ENTERPRISE IN CEYLON.”

(*Second Series.*)

ALEX. CAMPBELL WHITE,

PLANTER AND MERCHANT.

E confined our first series of Pioneer Colonists, connected with Ceylon, to men who had passed “that bourne whence no traveller returns.” In beginning a second series, we are pleased to include

several who, though long ago retired from the Colony, are still in the flesh, and who continue to hold property in the island, to read their *Overland Observer* and to take an interest in all that concerns the welfare of old Lanka and its people. It was our privilege during a recent visit to England to meet several of these retired pioneers; but, unfortunately, we were not able to keep a promise to visit Cheltenham and meet once again the subject of our present notice, or we should have been able to fill up a great many blanks in our story. But as it is, we must make what we can of the rather scant material before us.

ALEXANDER CAMPBELL WHITE'S birth dates so far back as 1816, so that he must now be in his 81st year. Born a Scotchman he had the privilege of being fitted for his work in life with that useful practical education for which the Parish Schools of Scotland (long before the era of Board Schools) have been specially famous. In Glasgow, Mr. White acquired some experience of business before

SAILING FOR BOMBAY

as a youth of 18, with the mission of starting the Firm of “White, Barlow & Co.” What would be thought in the present day of a youngster in his teens coming out to the East to start anything! But

in the early part of the century men remembered that William Pitt was Prime Minister of England at 23 and that both Clive and Warren Hastings had landed in India when they were only 18 years of age. To return to A. C. White: on his way to Bombay, he visited Cairo and met, and made friends, with the enterprising, far-seeing Lieut. Waghorn, at the time engaged in his enterprise of opening and establishing the “Overland route” which shortly after became an accomplished fact. At Suez, Mr. White had to remain ten days before he got away in the East India Company's steamer “Hugh Lindsay” which had been sent from Bombay to ascertain whether the Red Sea and Gulf of Suez were really navigable and safe for steamers. The whole voyage from London to Bombay occupied nearly *three months*; while, now-a-days, letters (and passengers travelling with the mails) can get from St. Martin's-le-Grand to Bombay in *twelve days*!

Mr. White remained eight years in Bombay with varying fortunes but ever-increasing experience, until, in 1842, he decided to make a new departure and to venture his then comparatively limited capital (£2,000, we have heard mentioned as the total) in a coffee plantation

IN CEYLON.

The Colony was fast coming into notice. Five years earlier, Mr. Tytler—with the experience of Jamaica—had shown how the shrub could be properly cultivated and the cherry fruit properly prepared for market. A rush into the new product had commenced: the extensive and attractive hill country of the island was invaded from

all sides. Still there was no lack of forestland at the upset price of 5s per acre; and any competition was considered such "bad form," that as soon as a pioneer made his selection, he cut the boundaries and began forming a nursery as if the land had already been knocked down to him and the Crown transfer made out. And that there was a rapid fortune in

"COFFEE" IN THOSE EARLY DAYS,

let the following illustration testify:—

Here is an estimate we find in the *Ceylon Observer* of May 1842, referring to Oduwella estate, in Hantane probably, which will give an idea of the yield and profits of coffee from its growth on virgin forest-land in a favourite district in those early days:—

"The O—— Estate was commenced in July 1837
—Extent of Forest 1892 acres.

DR.

"Total Expenditure up to 31st December 1841, including purchase of forest, planting 305 acres, stores, machinery, &c. £6,938 7 3½

CR:

1839 Sale of seed and 42 bags of coffee ..	445 18 6½
„ Sale of 176 acres of forest ..	176 0 0
1840 Sale of seed and 796 cwt. of coffee ..	3017 10 5
1841 Estimated value of 2,000 cwt. shipped	8000 0 0
	<hr/>
	£11,639 8 11½

"The crop of last year, 2000 cwt., which is now going home, was gathered off 200 acres, and only about 50 acres of that in full bearing. The crop of the coming season is estimated at 3,000 cwt. and it will be gathered off about 250 acres. Judging from the experience of these two years, when the whole planted part (about 350 acres) is in full bearing, it will give fully 5,000 cwt."

The total export of coffee from Ceylon in 1841 was 80,000 cwt.; in 1842 it rose to 120,000 cwt., but it went to a splendid market protected at the time by a differential duty as may be judged from the prices indicated above.

On arriving in Colombo, Mr. White at once proceeded upcountry and on to the Knuckles District as well as he could—for there was neither bridge beyond Kandy nor road beyond Katugastota, in those early days.

IN THE KNUCKLES,

however, he had secured through the agency of the then well-known Mr. Donald Davidson, a compact block of 400 acres of forestland which he proceeded to open as the Kandekettia estate, which is in existence to this day, though it has long ago passed out of the hands of the original owner. At the same time, Mr. White—young (in his 24th year) and energetic—opened Allacolla estate for Mr. Davidson. He must have had for his neighbours at the time Mr. James Wright, still of Dimbula and his then Assistant, poor "Sandy Brown." Mr. White continued to reside for several years in the Knuckles district and he there experienced the financial crisis of 1845-6 and the dark period of depression which followed, when one-tenth of al

the coffee estates opened in Ceylon, were abandoned and many more were forced to sale for a fraction of their value.

MR. WHITE AS PROPRIETARY PLANTER AND
MERCHANT—HIS MARRIAGE.

Mr. White next moved

TO PUSSELLAWA

where he took up land and opened the well-known properties of Dawatagas and Doragalla. Early in the "fifties" we find Mr. White had his own Firm of "A. C. White & Co." in Kandy; but very soon after he became partner in the Colombo House of "Nicol, Cargill & Co." which included besides Mr. Andrew Nicol, C. B. Cargill and S. T. Richmond. Mr. White had by this time married and we, personally, recall his handsome, stalwart figure on Galle Face early in the "sixties," Mr. and Mrs. White being always on horseback of an afternoon. The adventurer "F. Hudson," at one time a large estate proprietor in Ceylon, got Nicol, Cargill & Co. into trouble by obtaining heavy advances, and eventually about 1868, there was a dissolution of partnership and the coffee estates of the Firm were divided between Messrs. White and Nicol. The former got for his share the now splendid property of Mount Vernon which then included Hudson or Fairfield, the whole aggregating 840 acres (with 538 acres in coffee), Mr. John Martin being Superintendent; while Mr. Nicol took Union and Niagara 740 acres (with 480 in coffee), Mr. John Stronach being Manager. The latter now form the Dimbula estate with nearly 600 acres of tea, while Mr. White has 750 acres of the same product on Mount Vernon.

HIS RETIREMENT AND SETTLING DOWN AT HOME.

Retiring from Ceylon soon after, Mr. A. C. White was long known as about the largest (individual) owner of estate property connected with Ceylon. For, besides his Dimbula and Pussellawa plantations, he owned Bukanda near Gampola, Delpottonoya in Medamahauwara and with interests in some other districts. Were there time and space, good stories could be told of how the once famous "Wm. F. Forsyth" of Waitawa managed for Mr. White as an absent proprietor, while opening Delpottonoya. Still Mr. White was one of the fortunate Colonists—everything he touched, for many years, "turned to gold" and he became one of the wealthiest proprietors connected with the island. After settling down at home, Mr. White paid occasional though rare, visits to the island in the "seventies" and "eighties," and he would have come out again and again since, were it not for an accident he met in the hunting-field, through falling and breaking his collar-bone some years ago. It shows what a splendid constitution he has had, that well on in the "seventies"—perhaps in his 75th year—Mr. White should be able to continue to fol-

low the hounds as he had done in Gloucestershire for many years after retiring from Ceylon, and still more that he should recover so well from the shock and breakage of bones caused by his fall.

IN CHELTENHAM.

For several years back Mr. White has resided in a very comfortable mansion surrounded by a fine garden in Cheltenham. He continues to be the most regular of men in all his arrangements. After breakfast, from 9 to 12 noon, nearly every day he gives to his correspondence and to anyone calling on business, and then he has his midday walk, seldom going out of an afternoon, though fond of visitors coming in to "tea" or dinner with him. Nothing delights Mr. White more than to encounter Ceylon men and talk over old times, and lately he enjoyed in this way at Mrs. Mackie's residence, meeting Messrs. Wm. Rollo, Humphreys and Tilly. Were it not for the heat of the Red Sea, Mr. White would even now visit Ceylon, so much would he like to see the dear island again, where he laboured so long and well. But of this, we fear, there is little hope. We were not aware till the other day that Mr. White had become a Roman Catholic—a fact that must shock his nephew, Lord Overtoun (John Campbell White), the well-known Liberal supporter of Evangelical Protestant Missions, and a great philanthropist. But our Mr. A. C. White is not wanting either in good works, according to his light: he is the most liberal supporter of his Church in Cheltenham; but he goes further and in deeds of kindness and charity which are confined to no Church, few men are so open-handed; and the Treasurers of the Hospital, Convalescent Home, and other deserving charities in Cheltenham have reason to bless the day that the wealthy Ceylon estates proprietor settled in their midst.

Our latest news through a friend is that Mr. White, though over 80, continues to look young for his age, with his erect figure, and steady walk, a favourite little dog being his companion. What tales he could unfold of his "days of old," fifty years ago, on the hills of Ceylon, when he laboured and watched

The coffee shrubs in springing up
The forest going down;

—and of all the vicissitudes of the Colony since, until now as proprietor of Mount Vernon in tea, he has a property far more valuable than ever it was in its days of virgin soil in coffee. Altogether no tale in romance can be half so strange as that of the coffee-cinchona-tea Colony; and no one has stuck by it more faithfully and continuously in good and evil report (for heavy losses had to be experienced from time to time, even in recent years) than the subject of our notice, **MR. ALEXANDER CAMPBELL WHITE.** May his shadow never grow less!

Agricultural Pests :

WITH METHODS OF PREVENTION.
BY MISS E. A. ORMEROD

(LATE CONSULTING ENTOMOLOGIST TO THE
ROYAL AGRICULTURAL SOCIETY OF
ENGLAND).

(Special for "Tropical Agriculturist.")

II.

PESTS AFFECTING FROM CROPS AND
ANIMALS.

GAD FLIES, WARBLE AND BOT FLIES, FOREST FLIES, &c.

The family of the *Tabanidae*, or Gad Flies, which are injurious as blood-suckers, include some of the largest flies which we have in this country, and cause injury by piercing into the skin (it may be of cattle, or it may be of ourselves) with the lancet-like apparatus which they carry in their proboscis. In shape they may be described as like common flies; but the great, dark brown fly, striped across with yellow, known as Ox Gad fly, is sometimes as much as an inch and three quarters in the spread of the wings.

From the circumstance of the Larva, or maggot, of the *Tobanus Bovinus* having a distinct horny head, and the pupa being naked and incomplete (that is to say in some degree resembling the perfect fly, it will be seen that, technically, this family is nearly allied to those of which the *Tipula* may be taken as a type. But the points under consideration being the animals or plants attacked, I deal with the Gad Flies here, together with the other cattle flies. As in this case it seems impossible to lessen attack by destroying the maggots, the next best way of saving the cattle from annoyance would appear to be moving them from pastures by streams, or such localities as the flies frequent, to more open and drier land, where the state of the ground would not suit the gad-fly maggots, and the flies would not find the trees which they love to lurk amongst. In case of dressings being desirable to ward off infestation, the same that are known to answer in the preventing attack of Warble Fly would be useful.

The large family of the *Æstridae*, popularly known as Bot Flies, differ from the Gad Flies, entirely, in their method of doing harm, inasmuch as, generally speaking, the mouth of the *Æstridae* is obsolete, only represented by a few minute fleshy tubercles; also the maggots of this family of flies live within some part of the animal that is attacked. Prof. Westwood notes three principal differences in their habits: some live in tumours beneath the skin; some attack the cavities of the head, which are reached through the nostrils; and some are gastric in their attack, by the maggots being introduced into the stomach.

The kind we are about to notice (the *Gastrophilus equi*, or Horse Bot Fly) are about the size of a house fly, or rather larger, and are somewhat gaily coloured with yellowish and dark markings, and very hairy.

In the case of this Horse Bot Fly, the female hardly touches the animal, but, whilst lightly flying to and fro, places the eggs on the hairs, until the very numerous supply are laid. These are fixed by a kind of sticky moisture on the shoulder, or on the mane, inside the knee, or on any other part selected. The maggot forms within the egg, and when it is ready to hatch (which may be in a period of from about five days to three weeks), the warmth and moisture of the horse's tongue in licking the infested hair, causes the kind of lid or cap to open or crack, and the maggot within sticks to the tongue, and is thus gradually transferred to the stomach. Here the maggots fix themselves to the mucous membrane by means of two dark brown hooks, one of which is placed on each side of the slit which serves for a mouth, and there they nourish them-

selves by suction, and are considered to pass from eight to ten months in maggot state, attached by their mouth hooks to the living membrane of portion of the stomach.

Sometimes there may be only a few of these maggots present; sometimes (as I have seen myself) they are present in such numbers as to lie close up against each other over a large patch of surface, so that it hardly seemed possible to find room for another amongst them. Here they live until, when full-fed, they lose their hold; and after being thrown to the ground, turn to a brown pupa, from which the fly comes out in a few weeks.

For prevention of this attack, such treatment as combing, brushing, or clipping hair, so as to get rid of the eggs, is sure to be of use. Also the application of soaps, or washes, with scents deterrent to insect attack; and, likewise, freedom to the horses to shelter in sheds in the heat of the day. Remedies fall within the province of the veterinary adviser, as special advice is needed for their safe application.

The Ox Warble Fly, or Bot Fly, is a two-winged fly, upwards of half-an-inch in length, so banded and marked with differently coloured hair as to be not unlike a humble bee. The face is yellowish, the body between the wings yellowish before and black behind, and the abdomen whitish at the base, black in the middle, and orange at the tip. The female is furnished with a somewhat telescopic-formed extension of the end of the abdomen, which acts as a long egg-laying tube, and the egg is white and oval, with a small brownish lump at one end.

On hatching from the egg, the maggot is not of the thick, oval shape to which it afterwards changes, but is almost worm like in shape, and is furnished with a pair of cutting forks at the mouth end. By careful examinations of sections of hide in the very earliest stage of attack, a fine channel or perforation will be found leading from the outside of the hide, right through it, down to the under side. Here the young maggot will be found, and by gentle pressure, the course of the maggot channel may be clearly traced by the little drop of blood which (in my own observation) I have found can readily be forced along it from the larvæ working below, till it stands as a minute drop on the outside of the hide. This channel I have found to be rough and jagged at the side, thus showing it was gnawed or torn (not cleanly pierced, as by an ovipositor), and the direction was very various, so as even to be much cured.

The maggot gradually increase in size, still lying with the tail end uppermost, or nearest the opening in the hide; and as it grows it presses back and opens the surrounding tissue, till it lies with the tail extremity in the opening of the boil-like swelling, commonly known as the "warble." Here it draws in air through what look like two small black spots in the tail, but which are really the spiracles, or masses of minute breathing openings, by which air is admitted into the breathing-tubes or *tracheæ* of the maggot. It feeds by sucking in the putrid matter flowing into the cavity its presence has caused, and there it remains until it is full grown, that is, about an inch long. This may be at any time from May to much later in the season, and then, with the help of the rows of prickles with which it is furnished outside, and the powerful net-work of muscles with which it is furnished within the skin, it drags itself through the opening of the warble, tail foremost, and falls to the ground, where it finds some shelter, either in the ground or under a stone or clod, where it changes to a chrysalis. The chrysalis is dark-brown or black, much like the maggot in shape, only flatter on one side; and from this brown husk the warble fly comes out in three or four weeks, but this length of time is increased by cold weather.

Where the attack is severe, the condition of the surface of the carcass beneath known as "licked beef," or "butcher's jelly," is to be found, which is a very serious drain on the health, condition,

and quality of the animal, thus well described by Mr. C. E. Pearson, wholesale butcher, Sheffield:—"I may say that the effect of warbles on the carcass is more serious than can possibly be imagined by the outside appearance of the beast. . . . The carcass of beef assumes a nasty yellow colour, and also a soft, flabby appearance on the outside rind of the beast (where the warble has been in operation), so much so that the carcass has, in some cases, to be paled down to the flesh to make the appearance of the animal at all presentable for the market, causing thereby a grievous amount of loss to the butcher. I am speaking from practical experience, killing on an average twenty beasts or more a week."

On applying to Mr. Henry Thompson, M.R.C.V.S., of Aspatria, Cumberland, who has long devoted much attention to warble attack, for an exact description of the damage, he replied:—"What causes the damaged meat or beef is the chronic inflammation set up by the warbles in the skin, which extends to the connective tissues, thence to the flesh, producing the straw coloured, jelly-like appearance of a newly slaughtered carcass of beef, which, in twelve or twenty-four hours, when exposed to the air, turns a dirty greenish yellow colour, and thus spoils the beef, having a frothy discharge oozing from the surface with a soapy-like look."

Its prejudicial nature in all points of view is thus shortly given, in the last words of some observations with which I was favoured by Mr. John Penberthy, Prof. of Pathology at the Royal Veterinary College, Camden Town, N.-W., regarding some specimens on which I had requested his opinion:—"The material is not fit for human consumption. I think it very deleterious to the health and comfort of the affected animal."

The yearly loss from this attack of is enormous. Firstly, there is the loss on milk, and on many other points of damage consequent on the wild gallop of the cattle when terrified by the fly. Secondly, there is the loss on the condition of the infested animal. Every warbled hide is a sign of so much out of the farmer's pocket, for the food he spent in feeding grubs in his cattle's backs which should have gone to form meat and milk, instead of being wasted in foul maggot-sores. Thirdly, there is the loss, falling mainly on the butchers, consequent on damage to surface of carcass known as "licked beef" or "butcher's jelly." Fourthly, there is a great loss on the injured hides. The two following returns, from Newcastle-on-Tyne and Aberdeen respectively, taken from a number of returns from hide or cattle companies, etc., with which I was favoured in 1888, give some slight idea of the loss going on, simply on this one item of perfectly needless waste. The following is from Newcastle-on-Tyne:—

"In a period of twelve months, 102,877 hides passed through the market; of these, 60,000 were warbled. Loss estimated at £15,000."—J. McG.

"In five months, from February 3rd to June 24th, 61,103 hides passed, of which 14,630 were warbled. Loss, £2,873."—W. M. & Son, Aberdeen.

The above loss, in all its details, is wholly unnecessary. By the use of the simple measures mentioned below, we have now found, from the experience of our leading farmers, cattle owners, and veterinary surgeons, during about twelve years (that is, since attention was first directed to the subject), that the attack may, to all practical purposes, be stamped out.

Squeezing out the maggots is a sure method of getting rid of them, but they may be destroyed easily and without risk by dressing the warble with a little of McDougall's smear or dip, or with a little eart-grease and sulphur, applied well on the opening of the warble. Mercurial ointment answers, if carefully used—that is, in very small quantity, and only applied once as a small touch on the warble; but where there is any risk of careless application it should not be used. Any thick, greasy matter, that will choke the breathing-pores of the maggot, or poison it by running down into the cell in which it

lies and foeds, will answers well; and lard or rancid butter, mixed with a little sulphur, has also been found to answer. Tar answers if carefully placed, so as to be absolutely on the hole, into the warble. Bought cattle are often badly infested, and need attention.

To prevent fly attack in summer, train-oil rubbed along the spine, and a little on the loin and ribs, has been found useful; so has the following mixture—4 oz. flowers of sulphur, 1 gill spirits of fat, 1 quart train oil; to be mixed well together, and applied once a week along each side of the spine of the animal. With both the above applications it has been observed that the cattle so dressed were allowed to graze in peace, without being started off at the tearing gallop so ruinous to flesh, milk, and, in the case of cows in calf, to produce.

Where cattle are suffering badly from warbles, so that the health is clearly affected, and the animal wasting, the use of the old well-known black oils has been found to do much good.

Mr. Henry Thompson, M.R.C.V.S., gives the following recipe used for a bad case:—"Turpentine, 1½ oz.; sulphuric acid 1 drachm (here a chemical action sets in and must be done with caution). To this I added 10 oz. raw linseed, and rubbed the cow's back once a day with the mixture. . . . In a fortnight the back was cleaned, and all the maggots destroyed.

There are many other points that bear on prevention, of which one is the noting that Warble Flies are most active in heat and sunshine, and appear not to pursue cattle over water; consequently, allowing the cattle the power of sheltering themselves, and access to shallow pools, is desirable. Likewise, with regard to pastures, or standing-ground of infested cattle, it is matter of course that where the maggots have fallen from their backs the flies will shortly appear to start new attacks.

The attack of the Sheep Bot Fly is a very serious matter, which causes much suffering to the animals, and loss to their owners. This fly is rather larger than the common house fly, and of an ashy colour, spotted with black between its wings and silvery or yellowish white. The female either lay her eggs, or deposits living maggots on the margins of the nostrils of the sheep by means of the mouthhooks with which they are furnished, and attach themselves to the membranes of the cavities. Here they feed on the mucus; and it is stated that they at times feed on the membrane itself. Their presence causes great irritation; and where the attack is severe leads to gradual loss of strength, and convulsions and the death of the animal. When full grown the maggots are about an inch in length, and in the common course of things they remain in the head of the sheep for ten months to a year before they are mature. They then leave the animal, by going down the nostrils, and fall to the ground, where they turn—either amongst roots of grass, or in any convenient place above or below the surface—to a black or brown pupa, from which the fly comes out in about six or eight weeks, or after a variable number of days, according to the climate.

The preventive in this case is to keep the fly from getting access to the nose of the sheep. The sheep protect themselves to the best of their power by holding their nostrils down to the ground, or in any other position which will keep off the fly, when they are aware of attack, and this principle is worked on, in the application of tar or other remedies to keep the fly from settling.

The attack of Sheep Nostril Maggot is of quite a different nature from that of the *Cenurus cerebralis*, or Hydatid, which in its young state causes the disease known as staggers or "gid" in sheep; but the two attacks are popularly confused. The difference is easily shown by an anatomical demonstration of the maggots in the nostrils in one case, and the hydatid-infested brain in the other.

The Forest Fly (*Hippoidea equina*), which infests horses and cattle, and is especially common in the New Forest in Hampshire, may be taken as a type of the division. This fly possesses an egg-like pupa,

and also a peculiar toothed claw. The main colours of the little fly are brown or black, varied with some shade of yellow. It causes irritation both by blood-sucking, and by creeping, which it can do backwards, forwards, or sideways with great nimbleness, on the parts of the animal especially preferred for infestation. The remedies used are local applications obnoxious to the fly, and careful attention to cleanliness.

In some cases the head of these flies (*pupipara*) is so withdrawn into the body, and the horns into the head, that in addition to their sometimes being without wings or poisers they have a spider-like appearance, and are known as Spider Flies. The *Maclophagus ovinus*, known, though incorrectly, as the "Sheep-tick," which lives in the wool and sucks the blood of the sheep, is one of this division.

BIBLIOGRAPHY OF CACAO.

PLANTING IN LAGOS, WEST AFRICA.

From the 31st Report for the Quarter ended 30th September, 1895, on the Botanic Station, Colony of Lagos, we quote the following passage:—

ECONOMIC PLANTS.

(Continued from page 448.)

Sir,—I have the honour to submit for the information of His Excellency the Deputy Governor the following report on my tour to and from Abeokuta.

Having been granted permission to accompany His Excellency the Acting Governor to Abeokuta I made every preparation for collecting, and departed from the Botanic Station on 12th September and returned on the 30th of that month.

I should mention that owing to work requiring my supervision since my return I was prevented in submitting this report at an earlier date.

The collection of plants made when travelling were principally confined to the forest roads or paths, and

also my observations on the vegetation, I had not sufficient time at my disposal to collect in the forests where accessible, or I should have been left behind.

The collection of herbarium numbered 408, this includes duplicate specimens, one of each specimen will be forwarded to Kew for determination. Many living plants were also collected.

Cultivated Plants:—Throughout the whole route taken the products grown are very similar, the principal articles of food being Corn, Zea Mays, Yams, Dioscorea sps., Cassava, Manihot utilisissima, Colocasia antiquorum, Phaseolus, several species of this plants are extensively grown around Abeokuta, Aractus hypogoea is not often seen, a large variety of this species is cultivated, Cajanus indicus is used also as an article of food.

Rubber producing plants:—The chief source of Lagos rubber is obtained from Ire, Kickxia africana, a tall growing tree in the forests. This tree is plentiful throughout the forests from Ottoto Papalayito also near the forests at Adawo, and from Ilaro to Ajilite.

Landolphia L. ovariensis:—This species is the most common. When I had time to go in the forests I met it, but it appeared not to be sought after, for it is more difficult to collect and requires more time. I found several other plants that furnish rubber probably of the Genus Vocanga but unfortunately these trees were not in flower. Several species of Ficus were frequently seen on the journey. I noticed that at Abeokuta ceura rubber Manihot Glazivio had been introduced.

Fruits:—These like most other plants receive but little attention in their culture, the Pine apple Ananas sativa is found growing everywhere in a wild condition, Papaws, Carica Papaya, Sour Sop, Anona muricata, Sweet Sop, Anona squamosa, also Bananas and Plantains grow near towns and villages and I noticed a very dwarf Banana at Abeokuta, similar to the Grand Canary Banana. Oranges and Limes are seen but not in any quantity, the Hog Plum was grown around the villages on the way Spondias lutea no doubt. Thaumatooccus Danielli is grown throughout the whole of the districts, it is not grown so much for its fruits as its leaves which are used in lieu of paper, also for thatching roofs of houses. Sideroxylon dulcificum, another fruit possessing very sweet properties and known as one of the Miraculous fruits of West Africa, was not seen to any extent. Another of the peculiar fruit I also found in large quantities, evidently an annual, for the plant had died down and I was only able to obtain the seed of it which had been sown.

Kola acuminata:—In some districts this is grown extensively at Otta, Igbessa, Ilaro, and Adu, this tree appears to thrive best in damp situations and under the shade of forest trees.

Palms:—The most common of all palms met with throughout the journey was the African Oil Palm, in some districts it is almost the only vegetation. After leaving Papalyto on the 15th September the vegetation somewhat changed, plains of tall growing grasses and large numbers of the Fan Palm Borassus aethiopus existed, a small Phoenix probably P. spinosa was also seen, Raffia Vinefera were found only in damp situations.

Timber trees:—Chlorophora excelsa or Iroko tree is very common in some of the forests, it is the indigenous wood used as it is very durable and resists the attack of white ants. Irvingia Barteri:—This I found only within two days journey of Ebute Metta. Spathodea Campanulata was the only large tree I could recognise by its large bright clusters of flowers; in the forests large lofty trees are seen, but to collect specimen from these is indeed a work that will take time to obtain and overcome.

Fibres:—Sansevieria guineensis: this plant under the shade of forests trees grows luxuriantly, but its fibre is not sought for much by the Natives. Adansonia digitata:—Before reaching Abeokuta this tree was not often seen, but when travelling on the Ibadan road it was one of the chief trees seen, its fibre is used by the Natives. I saw a few plants of a species of Pandanus, many other plants were seen

from which fibre could be obtained. 3 Hibiscus, sp. Crotalaria sp. Sida sp. Cereorus sp. abutilon etc.

The Vegetation by the forest roads is comparatively the same, up to the Ogun river, where the forests do not exist it is long grass, or scrubby bush; near villages the land is cultivated. The soil is much richer than that around here, and as one gets near to Abeokuta stones and rocks are frequently seen, and several streams are passed, which would prove very beneficial if planting should take place.

At Abeokuta and surrounding it for miles the land is under cultivation or has been; like all other places the natives have no idea of manuring the land, but this work is left for nature to fulfil, land is cleared and planted for a few years then abandoned for sometime; this means great destruction to the forest; consequently the forest for some distance around this large town have been destroyed.

The soil here is very rich and the food crops are very large.

The soil is of a volcanic nature; at one time cotton was grown extensively at Abeokuta, but as it is very short staple, it cannot compete with American cotton. I visited a small plantation in the town, it consisted of plants of Liberia Coffee, Cocoa and another species of Coffee which is evidently not Liberian; all the plants were in a most thriving condition, and large crops were being produced, this convinced one that the soil was everything that could be desired for the cultivation of these and other economical plants.

After spending sometime around Abeokuta I travelled a day's journey on the road towards Ibadan, here the country is hilly, and most of the growth is stunted, here for the first time I saw the shea butter tree Butyrospermum Parkii, but unfortunately it was not the season to obtain seed. Adansonia digitata was also very numerous, & Acacias. Among the many dye plants found around this district which include Indigofera, and Bixa etc. Lonchocarpus cyanescens, native dye, this latter plant is cultivated and is the one principally used, in some places it was very abundant, and I noticed to induce young leaves from which is prepared the dye old leaves are gathered off the plants.

Calabashes—Lagenaria vulgaris and species of the cucurbitaceaeous order are largely represented, and cultivated to a large extent, and used largely by the natives for utensils.

On returning by way of Ilaro His Excellency gave me permission to visit the plantations at Soto and Ajelete. I have already sent in this report (see appendix I. of the quarterly report for September quarter on this Station.) These plantations are in a very thriving condition, cultivation is carried on to a far greater extent inland, and I think that if a Botanical out-station was established near some of these large inland towns the people would soon become aware of the value of Coffee and other economic plants, and take up the cultivation of commercial plants.

I have the honour to be,
Sir,
Your obedient Servant,
H. MILLEN,
Curator.

(To be concluded.)

TEA PLANTING THIRTY-FIVE YEARS AGO IN INDIA.

(By an Old Planter.)

Having at length accomplished the raising of seed, the next process we took in hand was planting out the seedlings; for the expeditious method of sowing in the open did not answer; purchasers, who are always fastidious, asserting, when they came up in the Poojahs to report upon or examine the property, that they expected to see rows of plants instead of, as one impertinent person observed, a beggarly array of empty stakes. One gentleman of an economic turn of mind had utilised fresh eka stems for lining off, with the result that his stakes sprouted but the seed didn't follow suit, somehow. Once the plantation

was staked off, we had a little leisure, for our notions of the proper season for transplanting were rather crude, and as the bustee-wallahs waited for the rains, to plant out their rice, we came to the conclusion that, as they must be the best judges in all agricultural matters, we could not do better than follow their example; so, until the middle of June, we visited one another, talked shop or whiled away the time in studying the luxuriant growth of the under-wood, as it came on merrily with the advance of the season; we did not imagine such vegetation needed removal, as it would keep the ground moist and cool. The proceedings of the professional gentleman, we regarded as something akin to lunacy, for he put in his plants in the dry weather—a slow laborious process, over which there was much shaking of heads—moreover, he kept his place as clean as a roadway, waging constant warfare with the second growth. There had been a talk of importing labour, but it ended in talk, so that when the first burst of the monsoon came on us we had but a fortnight to get all in, or, as we phrased it, “slapping in,” for labor was only available for the above-mentioned period, when the people went off to attend to their own affairs. The slapping-in process was peculiar—though expeditious one operator was provided with a pointed stick, which he drove into the ground anywhere in the neighbourhood of the stakes, when such were found, keeping the lie as best he could, when those landmarks were missing, then came No 2 with a bundle of seedlings, torn bodily up from the nurseries; the downpour washing the root clear from all such contamination as soil, these were pushed down into the dibbled holes, the earth round the surface stamped well round the stem, leaving a vacuum for the rootlets to spread in, and so the plant was *in situ*, as one planter who had started in the Educational Department, was wont to observe. Weeding was put off to a more convenient season, for the best of all reasons—there was no labor to carry out such an operation, even had we deemed it necessary, which we didn't. In October, or thereabouts, the bustee folk again made their appearance and re-clearance began, but the first operation being to clear the underwood and the coolies not up to distinguishing tea from jangle, a goodly number of promising seedlings fell before the reclaiming dhao; porcupines, crickets, withes and creepers had also had full fling during the recess, so the early plantings were not so successful as we desired. It must not be supposed that we were left entirely unmolested during the summer, for our employers were hard at work in town preparing those prospectuses that burst upon the public in the autumn of 1862. Alluring epistles, admirably composed, shadowing forth such dreams of El Dorado that drove all India mad. Whatever may have been the laches or muddles of the average planter of the day on the plantations, the crash that eventuated was brought about mainly by the gentlemen in town, who pandered to the public rage of the times. As the *dak* reached us, day by day there were the same imperative instructions to slap in your plants. Fortunately, indeed for us, there was no telegraphic communication, or we should have gone demented; so we slapped in till there was nothing left to slap. A short respite, and then came peremptory instructions to have all cleared by the Poojahs, as a deputation of freshly caught shareholders would be up by then to inspect the gardens; the Secretaries' letters didn't call the new proprietors by that name, which was a local invention; there were dark hints as to possible losses of situations if the place was not presentable, which alarmed the more sensitive but merely elicited the remark, from those who took the ups and downs of this life with equanimity. “Well, we can't make coolies.” As a general rule, the inspecting deputation did not turn out such dreadful people as we had been led to expect, and seemed, on the whole, pretty well satisfied with matters—as they ought to have been considering that they travelled at the Companies' expense, diverging as a rule to Cherrapunjee, though why they went there did not

transpire in the published reports. However, out of evil came good, and one thing was impressed upon the Agents, that dependence on local labor was a myth: then arose the class known as coolie contractors; but ere describing their early efforts we must take a retrospect as to the formation of the various Companies that rose before the public with meteoric brilliancy. The prospectuses, after a discursive dissertation upon tea in general, plunged into figures, and, as is well-known, if you can manipulate them cunningly, you can do almost anything with them, especially when periodic frenzy seizes the public mind. One concoction, with a lordly disregard for details, dealt in nothing but round numbers, so people were informed that an acre of tea would produce 300lbs. and realise Re. 1 per lb., that the up-keep would absorb half this and the balance be divisible among those lucky enough to get the scrip. The morning that this announcement appeared caused a block in Church Lane, like that on Boxing Night at the doors of popular London theatres. Energetic brokers fought and scrambled on the stairs, the durwans were swept clean away; obese baboos, Marwaries, every one in fact who could collect a hundred rupees besieged the portals of the Agents. The benign vendor of this wonderful property, who “hung out” at the butt end of the thoroughfare, chuckling to himself as he viewed the scene from his terrace; and thus the great Sylhet and Cachar Tea Companies saw the light. Up went the shares, and then the wild gamble commenced. Prospectus after prospectus followed each other in quick succession: the preamble of one on the Assam side was remarkable, for the inditor somehow got mixed, devoting a whole paragraph of the preamble to dwelling upon the tea house being in a right line with some peak in the Khasia Hills; the connection between the site of a building for the manufacture of Pekoe Souchong and a dissertation upon plane trigonometry was somewhat hazy, though the public appreciated it, as the capital was subscribed for twice over. The rush for shares begat a similar demand for assistants, and all sorts and conditions of men, who could get an introduction, went up the office stairs as simple clerks, descending them again, after a short interview, full blown tea planters. We were thus reinforced; the station of Cachar presenting a butling aspect, between the arrival of coolies and budding planters almost daily. Ere going into the coolie business, I may as well glance at the community of which their masters was composed. An amusing, but perfectly correct, list was given in one of the dailies, about 1862, of the previous avocations of those sent up, which reminded one of the rather mixed society that dwelt in Canvastown, Melbourne, ten years previously. Clerks predominated: there were lawyers' clerks, bank clerks, merchants' clerks, and one who had been in holy orders, run-away apprentices from ships and one or two ship captains, leadsmen and pilots, raw schoolboys from home who addressed their Managers as “Sir,” a stray German whose career commenced as a flageolette player in the Calcutta town band, bar assistants and one from a job master's stable (the last named subsequently becoming our authority on all racing matters), gentlemen from the lower grades of the Uncovenanted Service; while home importations were drawn from equally heterogeneous sources—it was ere the days of trained gardeners of premium wallahs. Few remained very long, soon finding that they had mistaken their vocation, though many settled down and now form our best planters.—*Indian Planters' Gazette*.

THE SORGHUM PLANT makes an excellent forage crop, and is especially relished by cattle. It is cut and dried somewhat like hay. If syrup is to be made from the plant, the blades are removed and used for stock, and the stalks run through the mill. The refuse from the syrup-mill makes an excellent grade of paper.—*Southern Planter*.

THE FUTURE OF TEA IN CEYLON:
THE MISCHIEF ALREADY DONE BY MIS-
LEADING INDIAN PROPRIETORS AS TO
LOCAL CAPABILITIES;
A WORD OF WARNING TO INDIA FOR THE
FUTURE.

There can be no doubt that the chief factor in the lowering of the average prices in Ceylon tea for the past two years has been the great development of production in India as well as the increased attention given to preparation by our neighbours. And in respect of the future, there is no element so full of risk to our staple as the continued planting of more and yet more land out of the immense reserves fit for tea, both in Northern and Southern India. What may be done by producers or agents in Java, or in China and Japan to improve their teas, does not touch us so nearly as the prospect of our Indian neighbours continuing in the course which has marked their labours in the past few years. Now, one of their chief encouragements in this course has been the belief that Ceylon was fast reaching the limit of its production. We have done all in our power to dissipate this unwarranted belief—we have again and again shown that even though Crown land sales fell off, there were private reserves bound to be planted, to add to our crops and that a steady increase year by year from Ceylon as from India must be faced. With singular perversity, as well as pertinacity, has our position been locally assailed, and our motives questioned. We were denounced for prophesying the day of a hundred million lb. export from Ceylon. "Exaggerated estimates" have again and again been made the text of attacks; and "smooth things" for Indian planters' ears have been far too much the rule in some business and planting circles as well as in a contemporary's columns. What has been the consequence? Why, of course, that the utmost encouragement has been given to Indian Tea Companies, individual proprietors and pioneers, to clear and plant large areas with tea in both Northern and Southern India of recent years. Had the truth been known about Ceylon and its prospects, we feel certain the process of clearing new areas would have been a far slower and more judicious one. But no—"Ceylon has got to the end of its tether—has used up all its land—has almost reached its maximum export"—seem to be the substance of the consolation which some in our midst would still send to India! And surely we have a specimen before us in the following editorial deliverance in the local "Times":—

"Other things being equal, Dimbula has nearly reached the limit of its production. And the same remark holds good of several other districts, such as those we have named and many other besides. Extension now is nearly confined to the low country and Uva, and the total amount is not, we think, increasing, but decreasing, yearly."

Can anything be more mischievous in its effect on Indian proprietors and planters? What encouragement for them to pursue the course which already—as a merchant said today—has led to London at this time being full of Indian teas? Let it be granted that the available reserves in certain of our districts are nearly all planted,

what about *manuring*? Not one word of reference does our contemporary make to a departure which is now every year more followed in Ceylon and which, of itself, with the results before us, ought to render Indian Tea Company Directors and other planters of tea, more and more careful how they rush on large new clearings without any proper consideration of how the over-production already threatened, is to be cleared off. The response already made to our "Manuring" circular shows that the majority of planters clearly recognise the importance of making their Indian brethren acquainted with what is being, and can be done in Ceylon. Only one of our correspondents thinks it better not to stir this subject of manuring, lest it should become more general. As well may the ostrich hide its head in the sands in view of its pursuer! The Ceylon tea country is far too compact, too well opened by roads and railways, far too admirably served by Visiting Inspectors and shrewd business agents, to find any profitable departure neglected in any district or among an appreciable group of estates. Some planters may wisely decide that the time for *them* to manure has not yet come. But let Indian tea men understand that, taking our tea country as a whole, the time for careful judicious experiments with fertilisers has almost, if not fully, come—and let them moreover *beware of the result*. For, we aver, without fear of contradiction, that the capitalist who, at this time of day, whether in India or Ceylon, goes clearing and planting any *large area* with tea is imperilling his own as well as his neighbours' investments. If the market as well as planting statistics are carefully studied, we think it will be found that the time for large additions to the cultivated area is not the present year. We may except tea grown at such a high elevation as to compete with Darjiling's or our finest Ceylon's. For such the market may not be overdone; and the same argument leads to the counsel that Ceylon planters generally would do well to pluck and make finer teas in view of possibly approaching contingencies. But our chief object in writing today is to warn our neighbours over the way that Ceylon is by no means played out, that the maximum of our exports has not been reached, and that they will do wisely not only to pluck finely, but to restrict new clearings; and above all to unite as one man with their Ceylon brethren to *advertise their teas and win over new markets in America and Europe*.

A JAPANESE TEA VISITOR.

We have now in the island a Japanese gentleman, Dr. K. Obayashi, who has come chiefly on a "Tea Mission." He has letters of introduction to several influential residents, and notably one to H. E. the Governor from the British Legation in Japan. He is very interested in our Tea Industry, wants to know all about it, spends a few weeks in the island and left for Kandy today. He is acquainted with our *Tropical Agriculturist*; and is studying all the available literature bearing on our planting and agricultural products.

CEYLON TOBACCO.—According to the season reports for December in the *Gazette*, a large extent of tobacco land at Nilaveli in the Trincomalee district has been abandoned.

PORTMORE TEA COMPANY OF CEYLON, LIMITED.

Registered on December 7th by Murray, Hutchins and Company, 11, Birelin Lane, E.C., with a capital of £50,000 in £1 shares. Objects: To adopt an agreement with R. C. Bowie for the purchase of the Portmore Tea Estate, in the Agra Patana Division of the Dimbula District, Ceylon, and with Lionel M. Torin for the purchase of the "Aldourie" Tea Estate, in the Agra Patana Division, and to plant, grow, and produce tea, coffee, chinchona, cardomans, plants, etc. The subscribers are:—

	Shares.

The first directors (to number not less than three nor more than five) are: R. C. Bowie, L. M. Torin, and W. H. Anderson. Qualification £20. Registered office, 24, Rood Lane, E.C.—*Financial Truth*, Dec. 11.

THE CEYLON LAND AND PRODUCE COMPANY, LIMITED.

DIRECTORS:—James Wilson, Esq., Chairman, William Keiller, Esq., Sir N. A. Staples, Bart.

Report of the Directors, to be submitted to the Twelfth Annual General Meeting of Shareholders, on Tuesday, the 15th day of December, 1896, at 2 o'clock p.m.

Your Directors have the pleasure to submit the annexed profit and loss account and balance sheet for the crop year ending 30th June, 1896, duly audited.

The amount at credit of profit and loss account is £12,125. 15s 2d, which, with the sum of £437 0s 10d brought forward from last year, leaves £12,562 16s to be distributed.

On the 22nd July last, an interim dividend of 7½ per cent on the ordinary shares and 3 per cent on the preference shares was paid, and your Directors now propose to pay on the 24th day of December, 1896, the balance of the fixed cumulative dividend on the preference shares (3 per cent), making 6 per cent for the year, and 7½ per cent on the ordinary shares, making 15 per cent for the year, and in addition a bonus of 5 per cent on the ordinary shares—all free of income tax. It is also proposed to transfer £5,000 from profit and loss account to reserve fund, increasing that account to £7,000, and carry forward the balance of £1,675 16s, subject to the Directors' remuneration for the year under review, to be fixed at the general meeting, and to the payment of income tax, &c.

Your Directors are again pleased to chronicle the continued success of the Company, the Tea and Cocoa crops largely exceeding the estimates framed at the commencement of the financial year. The prices obtained for the Company's Cocoa mark an improvement upon those seen for the previous crop, but the net average for Tea was somewhat lower for the period under review.

TEA.—During the eleven months from January 1st to November 30th, the total number of packages from Ceylon Estates disposed of at Public Auction, amounted to 962,000, realising 8½d. per lb. average compared with 896,800 at 8½d. per lb. for the same period in 1895, so that the result should on the whole be favourable to the trade of the Island, owing to the larger out-turn, although the price realised shows a falling off. Deliveries, moreover, about kept pace with the fuller supply, and the London Bonded Stock on the 31st October only shewed a small in-

crease over that of 1895, standing at 18,033,000 lb., against 16,382,000 lb. This must be considered satisfactory, as evidencing that the Market has been able to deal with the extra quantity shipped without any decided reduction in values. The Crop has been about an average one in quality. Quotations on the whole ruled below those of last year, especially in the case of the Common to Medium grades, owing mainly to increased shipments from other producing countries; but Fine and Finest met a good demand throughout.

It is to be noted with pleasure that the shipments from London to Russia, the Continent generally, as well as to Canada and America, continue to expand, the total figures for the first ten months of this and the two previous years to 31st October being:—

	1896.	1895.	1894.
	6,684,000 lb.	6,073,000 lb.	4,400,000 lb.

Cocoa.—The more hopeful view taken by your Directors of the prospects for improved values of this article has been realized, and a gradual advance in the price of good to fine red Ceylon from 65s. up to 75s. per cwt. has taken place during the twelve months, although other growths have been much depressed. A further recovery in values is probable.

Coffee.—This article, as anticipated, has not maintained the values of last year, and the price of bold yellow Ceylon Liberian has fallen from 90s. to 75s. per cwt. The prospect of large supplies from other producing countries prevents hopes of a permanent recovery in values.

Acreages.—The following Statement shews the approximate acreage of the Company's Properties at date:—

Names of Estate.	Tea.	&		Total Acreage.
		Cocoa, Coffee Coconuts.	Forest, Grass Chena, aban- doned, &c.	
Alloowiharie Group	117	400	153	670
Andangodde Estate	135½	—	40½	176
Fettcresso Estate	405	—	33	438
New Peradeniya Estate . .	386½	17½	54½	458½
North Matale Group	296	822	459	1577
Owella Estate	26	75½	159½	261
Rickarton Estate	500	—	96	596
Strathisla Group	127	216	59	402
Forest Land	—	—	430	430
	1993½	1530½	1484½	5008½

Since the date of the last Report, the litigation therein referred to, which your Directors felt compelled to enter upon with the Company's late Ceylon Agents, has been brought to a successful issue, they having paid more than was claimed, and would have been accepted by the Company had an amicable settlement been come to at the beginning. Your Chairman, shortly after his arrival in Ceylon, discovered that the late Agents had debited the Company with unjustifiable items in account; he therefore instructed the solicitors who were conducting the legal proceedings for the Company to claim repayment of such amounts. The result of the proceedings was that after protracted negotiations, initiated by the defendants, and shortly before the date fixed for the trial, your Chairman decided to accept an offer that was made by them (the defendants) which settled the amount at their debit in the Company's books, covered estimated amount of costs and charges connected with the litigation, also the Chairman's expenses during his prolonged absence, and in addition left a balance to credit profit and loss account with.

The crop prospects for the season 1896-97 appear to be, so far, favourable, and according to last reports the estates were in excellent condition.

Your Directors are pleased to learn from reports brought home by your Managing Director that he considers the present staff of Superintendents &

Ceylon to be of a high standard of efficiency, and that they show much intelligence in all they undertake appertaining to the Company.

Mr. Henry Beveridge having placed his resignation in the hands of your Directors, they have, in pursuance of the power granted to them under the Articles of Association, elected Sir Nathaniel Alexander Staples, Bart., in his place. Sir N. A. Staples, Bart., by rotation, retires from the Directorate, but, being eligible, offers himself for re-election.

MARKET FOR TEA SHARES.

THURSDAY EVENING, Dec. 10.

Notwithstanding a general easier feeling in the Stock Markets, Tea share prices are, on the whole, maintained, although here and there, especially among the Preference issues, a little weakness is manifested. Considerable lines, however, of the better known shares, which stand at relatively lower prices than others, continue to be absorbed by investors.

INTERIM DIVIDENDS.

Brahmapootra announces 8 per cent., as last year. The following are the companies which, thus far, have announced interims on the Ordinary capital for the current year's working:—

Assam .. 5 per cent.	East India	
Balijan .. 5 "	and Ceylon	3 per cent.
Brahma .. 8 "	Jhanzie .. 4 "	
Chargola .. 3½ "	Jokai .. 5 "	
Chubwa .. 3½ "	Lebong .. 5 "	
Dooma .. 5 "		

Other announcements are expected shortly.

Mincing Lane again rather easier for common and undesirable Teas, but steady to firm for fine classes. Quality tending to improve, and consumption, as well as export demand, good and increasing. Recent lower values in Calcutta seem also to be stimulating the off take thence for the Colonies, America, and other out ports, as well as for Central Asia (via Bombay).—*H. & C. Mail.*

CEYLON AND CHINA TEA.

Judging by the tone of some remarks in the latest Ceylon papers, though affecting to pooh-pooh possible competition from China tea prepared by new methods, the island seems to be aware that China is waking up in the matter of her tea trade. It is said the tea-makers of China are not to be influenced or made to alter their ancient methods of manufacture, simply because a syndicate of British merchants, with characteristic energy, have started a factory with improved machinery on the sea coast. But this is not quite correct. No factory on the sea coast that we are aware of has yet been erected, though inquiries are now being made as to the most suitable machinery, &c. These teas have been prepared upcountry by the Chinese, though the suggestion has of course been made by the foreigner. The difference between the two classes of tea is not probably one of soil or climate, but one of preparation. The teas sold last week were prepared with the tannin largely retained, so that they liquor like Ceylons and Indians. To lovers of *real* China tea it would seem that the difficulty they now experience will be made even greater, and the soft, delicate flavour, hitherto its excellence, give place to rough, dark liquoring leaf.—*L. & C. Express*, Dec. 11.

PLANTING AND PRODUCE.

(From the *H. & C. Mail*, Dec. 11.)

CHATTY NOTES ABOUT TEA AND CINNAMON, COFFEE, B.C. AFRICA, &c.

THE PROSPECT OF TOO MUCH TEA.—Some of the Indian and Ceylon papers are sounding a note of alarm lest the cultivation of tea should be overdone, and are expressing the view that China and Japan will not remain content with the back seat they are forced to take as tea exporters. It is always

safe to preach caution, and a warning against the exuberance which leads to unlimited cultivation is useful. The *Globe*, in re-echoing the advice thus given, sounds a note of warning on its own account which is in some respects a little too shrill. It says: "Enormous as is the world's consumption of tea, and largely as it is increasing, it seems to be a question whether supply will not exceed demand before very long. It is now very clearly demonstrated that the shrub needs only certain conditions of soil and climate to thrive and produce first-class leaves. It is equally proved that the required conditions exist in many parts of the world which have never gone in for tea growing. In both South America and South Africa initial experiments are said to have been crowned with brilliant success, while Russia is making a determined effort to supply her own requirements. At the same time, the outturns of Assam and Ceylon steadily increase, in spite of the discouragement afforded by lower prices. The Dutch East Indies are also beginning to compete in earnest, and there are some who believe that the industry would flourish in Northern Queensland. It may be taken for granted, too, that China will, before long, make strenuous endeavours to regain her lost hold on external markets; when the empire is opened up by railways, the cost of transport to the coast is bound to be largely reduced. All present circumstances thus point to the likelihood of a continuous augmentation of production, and unless consumption increases proportionately, tea drinkers will have a better time than tea growers. Happily, our Indian and Cingalese gardens have achieved such high reputation that they will enter into this competition with great advantages in their favour. But they should spare no exertion to cheapen cost without loss of quality. We do not think that Indian and Ceylon tea planters have much to fear from the threatened competition in South America, Queensland, and Russia. It is highly probable that Chinese and Japanese tea growers will make a strenuous effort to regain lost ground and that they will try new methods. This is a greater source of danger than any other. Yet it is well to be wise in time. There is a widespread notion that tea planting is very profitable, and that there is no limit to the demand for tea. It is very necessary, therefore, to lay to heart advice as to the perils of over-production, and the uses of economy in the cost of cultivation and manufacture.

CHINA AND TEA MACHINERY.—We referred last week to the effort which is being made in a small way at present to manufacture tea in China in imitation of the Indian and Ceylon methods. We now learn that this movement is favoured by capitalists interested in the China tea trade, and that operations on a larger scale will be undertaken by a syndicate. Machinery has been imported for the purpose, and great expectations are formed as to the advantages that may accrue to the Chinese tea trade in consequence. We have mentioned that in the absence of patent laws the Chinese may endeavour to imitate the British tea machinery thus imported, although for the present and for some time to come the chances of their being able to do this successfully will be very small. So long as the experiment is controlled by British capitalists inventors of tea machinery will not run much risk in this direction. We should say that there is greater danger to inventors of tea machinery from the imitative skill of the Japanese. Should the Japanese tea-growers use machinery in their manufacture efforts will soon be made to turn out a complete native outfit. A "tip" for machinery engineers is given in a San Francisco telegram to the *New York Herald*. M. Oshina, technical director of the proposed steel works in Japan, and four Japanese engineers have arrived in that city on the steamer "Rio de Janeiro" from Yokohama. They are on a tour of inspection of the great steel works of America and Europe, having in contemplation an order to buy a plant costing approximately 2,000,000dols. They have informed the Americans that they will buy where

they can get the best and the cheapest. The plant when finished is to have a capacity of 100,000 tons. It will be built in the coalfields of Southern Japan. Both Martin and Bessmer steels are to be manufactured. "We want to put our country," said Mr. Oshina "where it properly belongs—in the van as a manufacturing nation."

PLANTING IN CENTRAL AFRICA.—The Right Hon. Lord Loch, G.C.B., formerly High Commissioner at the Cape, presided on Tuesday night over a large audience which assembled in the Whitehall Rooms to hear a lecture delivered under the auspices of the Royal Colonial Institute by Sir Harry H. Johnston, K.C.B., British Administrator in Central Africa, on England's work in Central Africa. In the course of his lecture Sir Harry Johnston said that at the present day, while the whole of British Central Africa, otherwise known as the British sphere of influence north of the Zambesi, was placed under a Commissioner and Consul-General, only that portion of it which was directly styled the British Central African Protectorate was administered by the Imperial Government through the said Commissioner, while the remainder lay under the charter of the British South Africa Company, and was administered by that body. The growth of that administration had merely kept pace with the increasing development and prosperity of the Protectorate. In 1891, when they commenced this direct administration, the total trade of Great Britain with British Central Africa scarcely reached the annual value of £30,000. At the present time the trade was over £100,000 in value per annum, the exports having risen from £3,000 in 1891 to nearly £20,000 in 1896, much of this being represented by the coffee grown in the country. In 1891 the Europeans in the British Central African Protectorate scarcely exceeded ninety in number. They now amounted to about 300, of whom about 100 were connected with the planting industry. In 1891 the total amount of coffee exported from British Central Africa was twelve tons, whereas in 1896 no fewer than 320 tons had been exported, and the prices touched by the recent samples had been almost the highest in the market, viz., 11s per cwt. Tea was grown to a slight extent and cinchona. Tobacco was extensively cultivated by one firm, who had started a cigar manufactory. Cotton was grown on one or two estates, and another company was developing the various fibres, some of which were of considerable value.

THE QUARTERLY SALE OF CINNAMON.—At the periodical auction of cinnamon, the last of the series, held last week, only 1,400 packages Ceylon, or barely one-half the quantity put forward in November, 1895, were included. A brisk demand prevailed from both the home trade and exporters, so that the bulk of the above supply was taken off at enhanced rates. The medium and lower sorts realised $\frac{1}{2}$ d to 1d, and the finer and superior qualities 2d to 3d, per lb. advance on the prices ruling on the August sales, thus establishing the following range of quotations: Ordinary to fair firsts at 11d to 1s 1d, fine garden cinnamon at 1s 4d, superior quill at 1s 6d to 1s 7d, and very low at 8d to 9d; seconds from 10 $\frac{1}{2}$ d to 1s 2d, finest plantation at 1s 5d, and coarse at 7 $\frac{1}{2}$ d to 8 $\frac{1}{2}$ d; thirds from 7d to 1s 1d, and best at 1s 2d to 1s 4d; with fourths at 7 $\frac{1}{2}$ d, and 9 $\frac{1}{2}$ d to 1s per lb. The "unworked" portion went at from 8d up to 1s 1d for the commonest to the better kinds, with a few lots broken (in boxes) at 8 $\frac{1}{2}$ d to 9 $\frac{1}{2}$ d.

THE BLACKWOOD COFFEE COMPANY, LIMITED.—Mr. Justice Chitty heard a petition last week asking the Court to confirm resolutions which had been passed for the reduction of the capital of this company. The company was formed in 1879 to cultivate coffee estates in Ceylon. The nominal capital was £100,000, divided into £5,000 shares of £20 each; 3,250 shares had been issued, of which 3,140 were fully paid up, the remainder (110) having been forfeited. Shortly after the incorporation of the company two estates

were purchased for £58,000, but owing to the almost entire failure of the coffee crop in Ceylon the cultivation had been discontinued, and the estates were sold for £5,200. The directors estimated the present value of the Blackwood estate at £15,000, and the entire loss amounted to £37,800. This deficit it was proposed to extinguish by writing off £12 per share, and as the company had capital in hand, far in excess of its wants, it was proposed to return £2 per share. Resolutions had been passed for reducing the capital of the company from £100,000, divided into 5,000 shares of £20 each, to £39,340, divided into 4,890 shares of £8 each, such reduction to be effected by (1) cancelling 110 shares which had been forfeited, (2) cancelling capital which had been lost or was unrepresented by available assets, to the extent of £12 per share on 3,140 shares, amounting to £37,680, and (3) by returning to the shareholders paid-up capital to the extent of £6,280, being at the rate of £2 per share, which was in excess of the requirements of the company. Mr. Carson, who appeared for the company, having stated the above facts, his lordship made an order sanctioning the reduction, and directed the company to use the words "and reduced" after its name for a period of one month.

THE INCREASE OF TEA GROWING.

Enormous as is the world's consumption of tea, and largely as it is increasing, it seems to be a question whether supply will not exceed demand before very long. It is now very clearly demonstrated that the shrub needs only certain conditions of soil and climate to thrive and produce first-class leaves. It is equally proved that the required conditions exist in many parts of the world which have never gone in for tea growing. In both South America and South Africa, initial experiments are said to have been crowned with brilliant success, while Russia is making a determined effort to supply her own requirements. At the same time, the out-turns of Assam and Ceylon steadily increase; in spite of the discouragement afforded by lower prices. The Dutch East Indies are also beginning to compete in earnest, and there are some who believe that the industry would flourish in Northern Queensland. It may be taken for granted too, that China will, before long, make strenuous endeavours to regain her lost hold on external markets; when the Empire is opened up by railways, the cost of transport to the coast is bound to be largely reduced. All present circumstances thus point to the likelihood of a continuous augmentation of production; and unless consumption increases proportionately, tea drinkers will have a better time than tea growers. Happily, our Indian and Cingalese gardens have achieved such high reputation that they will enter into this competition with great advantages in their favour. But they should spare no exertion to cheapen cost without loss of quality.—*Globe*, Dec. 8.

THE TEA TRADE IN RUSSIA.

Tea is the national drink *par excellence* in Russia; it is as indispensable in the food of the people as bread or meat, and is taken at all hours of the day. In every town tea-houses are found where a large glass of tea, with plenty of sugar in it, is provided at a cost of from three halfpence to twopence halfpenny, according to the town and the position of the customers frequenting these establishments. In these circumstances it is only natural that the consumption of tea in Russia attains enormous proportions, and is yearly on the increase. According to the *Journal de la Chambre de Commerce de Constantinople*, Russia imported in 1894, through the port of Odessa, 15,692,000 kilogrammes (kilogramme=2,204 lbs) of tea from China. Through the Custom-houses of the Baltic large quantities of tea are entered, chiefly consigned to Moscow, or for local consumption, and by the land customs of Eastern Siberia, about 20,000,000 kilogrammes of tea, representing a value of about 50,000,000 roubles, were imported. All the tea

imported by way of Odessa or other European frontiers is leaf tea, but that coming into the country *via* the Chinese frontier is chiefly tea in bricks of different dimensions. These teas are consumed by the nomads and the northern peasants, by reason of their cheapness and the facilities of transport. The customs duties on this kind of tea are much lower than those on leaf tea. In the various retail shops leaf tea is sold in packets weighing $\frac{1}{8}$, $\frac{1}{4}$, $\frac{1}{2}$, or 1 Russian pound at prices, varying according to quality, from 80. copecks to 5 paper roubles the pound, but as a rule sufficiently good tea may be purchased for 1 rouble 50 copecks to 2 roubles 50 copecks per pound. Russia exports annually a certain quantity of tea in packets, prepared by the large importing houses of Moscow, which are well-known throughout the whole of Europe. By way of Odessa, 30,000 kilogrammes were shipped in 1894 to the destination of Roumania, Bulgaria, Turkey, and Austria-Hungary. About two years ago tea from Ceylon began to be imported, but the quantity so far has been inconsiderable.—*Journal of the Society of Arts*, Nov. 27.

COFFEE AND TEA IN MLANJE.

(From the *Central African Planter*, Nov. 1.)

We lately had a visit from the genial manager of the African Lakes Co. who has been at Chinde and returned via Mlanje. The Nyasaland Coffee Co. has also had a visit from the Mandala Gardener.

Owing to the bush fires being early this year, we have experienced great heat—the thermometer rising to 90 deg. in the shade. This is also the driest year on record in Mlanje, nearly two months with only .27 in. of rain.

There is a splendid blossom in spike only wanting for sufficient rain to bring it out. I have seen a blossom stand in spike two months at both high and low elevations, and when the rain did come, the lower estates' blossom was burnt off at the collar and fell to the ground; the higher ones set well, resulting in a fine crop.

Tea is decidedly a promising product in Mlanje as we have tea bushes at three years old which would equal if not surpass any I ever saw at either a high or low elevation in Ceylon or India. The bushes were topped about eight months ago and regular flushes plucked about once a month or three weeks ever since. It is equal in flavour to high grown Indian and Ceylon and resembles very much in aroma the teas produced about Kandapola and Nuwara Eliya, Ceylon, which fetch very high prices in the London market. The Tea plant unlike our coffee seems so far to have no enemies and flushes freely all the year round, except during our winter months, May, June and July, during which time pruning should be done. It is satisfactory to know that we have another string to our bow should King Coffee (of course the better paying product of the two) fail, by the importation of leaf disease or otherwise.

Our coffee has been a good deal scorched by the late drought in fact many trees have suffered from sunstroke which I have not seen before in this country, so I am now convinced that suitable light lofty shade would not be out of place in some parts of Nyasaland. I shall give you my experience and opinion of shade in another paper.

TEA PLANTERS AND THEIR WORK.

Labore et Scientia.

The popular conception of a tea-planter's life is a very hazy one. Those unacquainted with the true facts of the case, and who judge from a mere cursory glance of things, seen from the outside, imagine the life to be one continual round of enjoyment. To them it seems that all a planter has to do, is to mount his horse or pony, ride round the garden, if necessary swear at some of his coolies, and then return to his bungalow; have his beer or his peg,

and spend the rest of his day, either in playing tennis or cards, or some other form of amusement.

The vocation of tea-planting is just as important a one as any other calling or profession in life, and should not be undertaken lightly. Directors and shareholders of tea companies at home are sometimes inclined to think that no educational outfit is required by those entering tea. That no qualifications are necessary, and that any booby will manage to get along, somehow or other, in the business. The result is that occasionally (thank goodness it is not often), dolts, utterly unfitted for any other calling in life, are pitch-forked into billets in tea. Influential personages at home, with sons or wards on their hands unable to pass the severe competitive tests for entrance into any of the professions or services, naturally turn with longing eyes to farming and planting industries abroad. The tea industry in India and Ceylon looms before them as a most desirable opening for their off-spring or proteges, so all the influence they can bring to bear on directors and shareholders is brought into play, and an appointment eventually secured. If the young men have received a sound general education, and been subject to discipline in some good school, they turn out well. But if they have been petted and spoilt in their homes, allowed always to have their own way, and work their own sweet wills, they cannot but help proving failures. Tea-planting is gradually but surely rising to the high level of a science. The call is now for young men with intellects trained to habits of thought and observation—the alumni of our colleges at home, who know by experience what study is, and who, when they join their appointments out here, will continue to study one, or more, of the branches of knowledge in which they have already received a thorough grounding. This is the class of men the tea industry wants from home. Men who have received their preliminary training, and who when they come out here, can at once catch on to some particular branch of knowledge connected with tea-planting and make of it a thorough study. To such men there is a vast field open for research and investigation. There is every opportunity for them to make a name for themselves. The harvest is great, but the scientific labourers are few at present. The industry for her ordinary wants, such as merely supervising the coolies, can obtain more than her requirements in this country.

The body of young men in this country, available for service on tea estates, are just as intelligent and well educated as the majority of those sent out from home, and equally good, if not better, in point of physique. They have the further advantage of being acclimatised, and knowing the people and the language can make themselves useful at once. Although they may possess no knowledge of tea at the first start, they very soon pick up their work, and are at home with their labourers. Not so the young men fresh from home. They are, and feel themselves to be strangers in a strange land. It takes them a long time to get accustomed to the manners and customs of the natives, and to settle down to their new life. The remarks do not apply to the men who come out as Mechanical Engineers. They are professional men and can make themselves useful from the day they first set foot upon a garden. As these men have been trained to manual (combined with intellectual) labour, so the planting industry requires men from home trained to mental (combined with scientific) study. Scientific men can, like their confreres the engineers or the doctors, start work at once on one or other of the special courses of studies they have elected and decided to make a speciality of, in connection with their general work on a tea estate. Possessing a thorough knowledge of the principles of the subjects they purpose making a special study of, they know exactly what to do and how to set to work to accomplish their purpose. The necessary materials being at hand, they can start experimenting without delay, and although their investigations will doubtless take time, being naturally a laborious process, still they are doing

olid good work for the advancement of the so much-needed knowledge. Whatever works they initiate are done with a purpose, and directly tend to fruit bearing in due course. No haphazard slovenly methods are adopted, but the latest systems in vogue, and the most recent discoveries of the scientists, the world over, are employed in the analysis and synthesis of the work in hand. For the outdoor *i.e.*, garden work, men who have graduated in some standard agricultural college, and have also made a study of entomology are the class most needed; for factory work, men who have gone through a course of study in the laboratories of well known chemists and scientists, in which scientific experiments have been systematically carried on. It may be urged that this class of men can always find ample congenial work at home and would not care to come out to tea gardens. They certainly would not on the meagre pittance at present apportioned to the young men sent out. But if sufficient inducements were held out doubtless advantage would be taken of them. Men who have received years of special training and education at a heavy outlay, will certainly not come out to this country on small salaries. But to engage the services of such men, at whatever cost, will repay the industry a hundred fold in the future. The old and experienced planters, whose services are being dispensed with, yearly to make room for the new importations of raw youths from home, would not have such just reason to complain if the recruits were specialists but when they have to give away to youngsters, whose only recommendations are rich or influential relatives at home, their cup of woe is not only filled to the brim, but runs over. The draught, bitter enough at the best, is made all the more poignant by the knowledge that their places are being filled by others, who are not as competent as themselves to fulfil even the most ordinary duties on an estate; others, who cannot "hold a candle" to them in respect to their abilities. The industry undoubtedly suffers from the dismissal of old and experienced hands. Introduce "fresh blood" by all means, but not at the sacrifice of old and faithful servants, who have devoted their whole lives to the cause, and who have been instrumental in bringing up the industry to its present pitch of prosperity. These men but require scientific men to help them, and as in the past they have done their duty and gradually worked up the industry to its present greatness, so in the future, they will, with the assistance of competent men, raise tea-planting to the status of a science. The progress will be from within, and developed by the men in the ranks themselves, and although help from exterior sources will be gladly welcomed, planters, as a body, will not need to look to outsiders to advance their interests. Their hands strengthened with the right stamp of men from home, they will be in a position to cope with all difficulties, surmount all obstacles, and build up the tea-industry on a broad and solid foundation.—*Indian Planters' Gazette*, Dec 19.

BOTANICAL STAFF, CEYLON.

The Royal Gardens, Kew, Bulletin of Miscellaneous Information. Appendix III. 1896, has for contents:—List of staffs in Botanical Departments at Home, and in India and the Colonies. For Ceylon we quote:—

CEYLON.—Department of Royal Botanic Gardens:—		
	Director	*John C. Willis, M.A.
Paradeniya	Curator	†Hugh McMillan
	Clerk	J. Ferdinandus
	Draughtsman	W. de Alwis
Hagala	Superintendent	†William Nock
	Clerk & Foreman	M. G. Perera
Henaratgoda	Conductor	S.de.Silva, Araehchi
	Anuradhapura	"
Badnlla	"	D. A. Gunoratne.

* Recommended by Kew. † Trained at Kew.

We are glad to see worthy Mr. Macmillan made "Curator,"

THE TEA MARKET.

In the Tea market, though business at this period of the year slackens down, prices rule at so moderate a range there seems no margin for a further drop; indeed, good liquoring Teas encourage competition. The inferior qualities from all sources are in excess. The machine-made China Teas promise to make headway, and, with a demand created, must interfere with the Ceylon industry; meanwhile, deliveries of the latter for the twelve months show a marked increase over 1895.—*L. and C. Express*, Dec. 18.

MARKET FOR TEA SHARES.

Thursday Evening, December 17, 1896.

A fair business continues in many of the Tea companies' shares, though the range of price is a little lower, and the lines sold are not quite so large. Many, however, of the best reputed shares still stand at high figures.

Mincing Lane has again gone a little easier for the lower grades, but sales are now beginning to be curtailed in quantity for the Christmas closing. Calcutta advices by mail, just in, show further increased absorption for Australia, Central Asia, and other ports.—*H. and C. Mail*, Dec. 18.

PLANTING PROSPECTS.

BRITISH CENTRAL AFRICA.

At a meeting of the Royal Colonial Institute on Tuesday, Sir Harry H. Johnston read a paper on England's work in Central Africa. The chair was taken by Lord Loch. Sir Harry Johnston said that the administration of British Central Africa was begun in 1891, when the total trade of Great Britain with that part of the world scarcely reached £30,000 annually. At the present time it was over £100,000. The local revenue had risen from £1,700 to £22,000. There was reasonable hope that before long there would be a continuous line of railway from the East Coast of Africa to the healthy districts, where the coffee planters were established. Besides coffee, tea was grown to a slight extent and cinchona. Tobacco was cultivated by one firm; cotton was grown on one or two estates; another firm was developing various fibres; and gold miners were already busy in the western districts, where gold was believed to be present in paying quantities. There were also several valuable deposits of coal; hematite iron was very abundant; and the forests afforded valuable timber, indiarubber, and gum. A young planter going out to the healthier portions of the protectorate ran no more risk than he would in going to Brazil, while he could start with infinitely less capital and would find abundant and cheap native labour. Sir H. Johnston said he did not believe in the eventual colonization of tropical Africa by the white man.—*London Times*, Dec. 11.

PLANTING IN; AND CLIMATE OF, NYASSALAND.

Mr. J. W. MOIR's paper on the climate of Nyassaland accepted for the British Association, is promised to us for the *Tropical Agriculturist*. In a letter dated Edinburgh, 28th November, Mr. Moir writes:—

"Your *Tropical Agriculturist* I have taken from its beginning, as Manager of the African Lakes Corporation, and have found it most useful and stimulating. It was a remark of one of your contributors that started me on Agricultural Chemistry. Now, I am spending my whole days analysing my own coffee soils."

THE NAHAVILLA ESTATES CO., LTD.

REPORT OF DIRECTORS.

The following is the report of the directors submitted at the annual meeting:—

The directors have the pleasure to submit their annual report together with a statement of accounts for the year ended 30th September 1896.

The coffee crop this last season has been a short one as compared with the harvest of 1894-5 and the year's profits have in a great measure been delivered from tea, the output of which was 221,976 lb. not reckoning some Mahapahagalla leaf sold in the green state.

With the amount carried forward from last year the profit and loss account shews a balance of R42,216.78 at credit after paying an interim dividend of 6 per cent and all expenses in connection with the conveyances of Mahapahagalla and Gallella estates besides other legal outlays. The directors now recommend that a final dividend of 7 per cent (making 13 per cent for the year) be paid which will absorb R27,330.00, and that the balance, subject to director's fees and an allowance for Secretariat, be carried forward to season 1896-97.

During the past season some small addition has been made to the area of Ury, and the acreage of tea on that estate, has been largely extended, there being now 478 acres under that product, against 311 acres this time last year.

Since the shareholders last met the purchase of Gallella estate in Maturata has been concluded by the directors. The price paid was £7,000 stg.: and particulars as to the acreage of the property are given below.

It is thought, that the coming coffee harvest will be better in the matter of quantity than that of 1895-96, and the output of tea will also, it is believed, be larger.

The following is a definition of the Company's property as at present constituted.

	Nahavilla.	Ury.	Mahapahagalla.	Gallella.	Total.
Tea in full bearing..	195	177	170	320	862
Do partial Bearing ..	78	32	25	..	135
Do not in bearing	61	269	22	3	355
Coffee ..	120	48	35	...	203
Forest ..	44	66	5	72	187
Cinchona, patana, scrub, chena, &c..	103	85	66	244	498
	601	677	323	639	2240

Mr. W. Anderson retires by rotation from the board of directors, but is eligible for re-election.—
By order, GEORGE STEUART & Co.,
Agents and Secretaries.

Colombo, 8th December 1896.

THE RATWATTA COCOA COMPANY, LIMITED.

An extraordinary general meeting of the shareholders of this Company was held at the Queen's Hotel, Kandy at 10-30 p.m. on Saturday. Present Messrs. Gordon Pyper (in the chair) and E. Jeffries, Directors. Messrs. M. Athorpe, J. A. Burmester, T. B. Campbell and J. A. McGillivray representing the Agents and Secretaries—By Attorney Capt. A. Burmester and Mr. F. M. Mackwood, and by proxy Messrs. J. R. Fairweather, A. G. Seton, S. P. Blackmore, A. Collingwood Smail and G. J. Jameson.

Proposed by Mr. Gordon Pyper, seconded by Mr. M. Athorpe and carried unanimously.

1. That the share capital of the Company be and the same is hereby increased from R150,000 to R200,000 by the creation of 100 new shares of R500 each.

2. That the remaining uncultivated area of the Estate (400 acres) be planted up with Tea—

The meeting closed with a vote of thanks to the chair.

CINCHONA CULTIVATION IN INDIA.

The report on the plantations in Bengal states that the capital cost of the plantations has long since been paid off, and that the sole object of the Government is now to secure for the people of India a cheap remedy for fever without loss. The whole of last year's crop, amounting to 467,190 lbs. of bark has been made over to the quinine factory, with the exception of small quantities supplied to medical depots or sold to Government institutions; and 170,000 lbs. has been bought from various tea Companies in Darjeeling. The factory has produced 9,004 lbs. of quinine sulphate, and 3,124 lbs. of cinchona, febrifuge. There has been an increase of 2,725 lbs. on the issue of quinine sulphate, partly owing to the demand for pice packets to be sold through the post office, and partly to the demand in connection with the Chitral expedition. The stock of quinine sulphate at the end of the year was 2357 lbs., and that of fabri-fuge 748 lbs. The scheme for the sale of quinine through the post office department makes steady progress, and the demand is increasing with such rapidity that it has been necessary to limit the sales in Bengal and Assam, and to discontinue the supply to other provinces. As a further satisfactory result of the operations, it appears from the Sanitary Commissioner's report that there is a general correspondence between fever mortality and the demand for quinine. The severe drought of last year has had a very damaging effect upon the young seedlings intended for extending the plantations, but, on the whole, the Lieutenant-Governor considers the results obtained to be entirely satisfactory.—*Planters' Gazette*, Dec. 1.

CEYLON AND INDIAN TEA IN AMERICA.

"A new Tea Company called the Marzapoura Tea Company, has lately started in New York, Brooklyn and surrounding towns. They have ladies canvassing from house to house, and are advertising extensively with papers, have large board signs in every elevated railway carriage (some 700 in number) large posters at railway stations, a tea room at one theatre, and have rented a room for \$1,800 in a principal street, which they are to open as a ladies' tea room, after the fashion of similar rooms in London. All this means expenditure of a deal of money on behalf of Ceylon and Indian tea, since it is these they sell."

De gustibus non est disputandum.

It is often difficult to decide which is the better of two articles which depend for their value to a great extent on habit, faith, and individual opinion.

A chemical test may determine which of the two has the most *wholesome* ingredients, as *wholesomeness* goes this year or this decade, but the fickleness of medical authority is proverbial.

Then, analysis may show that the component parts of one article are, at the present moment, standing at a higher price in the market than those of the other. But next year's harvest may reverse the position.

When we find, however, that an article which has had possession of the field for generations is being rapidly driven out of all civilized countries by a young and more expensive rival, we may

reasonably conclude, that some MERIT has been discovered in the new article, which was awaiting in the old.

A signal instance of *unanimity* of public judgment is the gradual disappearance of the old teas of China, before their young rivals from Ceylon and India. Inherently there is great similarity in the analysis of those teas. But *the methods of manufacture* make all the difference. The old teas of ancient nations are made by hand processes in the unclean hovels of Mongolians.

Mark the contrast. The modern teas of white Capitalists are made by *machinery* in AIRY, CLEAN and MODERN FACTORIES. W. MCK.

HARD LABOUR IN THE TROPICS.

The scene is a lovely tropical Isle, about which Poets and Travellers have raved through many volumes. The time is early morn, when the first rays of the sun are seen in the East, shooting far up athwart the gray sky, heralding the speedy approach of the God of Day, while towards the West, the stars are still shining. For in this latitude, Dawn and twilight are short—the change from darkness to brilliant sunshine in the morning, and the reversal of the order in the evening, being matters of only a few minutes. These rapid changes, too, occur at almost the same hours throughout the year, say from 5-45 to 6 a.m. and again between 6 and 6-15 p.m.—the length of the day being always 12 hours.

All nature awakes suddenly. In the jungle the birds are singing, in the marshes the toads are croaking. Round the huts of the natives, dogs are barking and roosters are crowing.

The rat-a-tat, rat-a-tat of a tom-tom drum is being beaten to summon native workmen to their muster ground and they can be seen tightening up the long ends of their many colored cotton garments, as they walk along by the devious roads, which starting from the lines or villages where they live, converge towards the factory. They are of both sexes and of all ages from 6 to 60. In truth, I might say from 3 months to 60 years, as many of the mothers carry babies in their arms; while beside fathers and mothers, trot several infants naked as when to earth they came.

When mustered and counted, they are sent in gangs to different parts of the plantation. The men, peradventure, go pruning; or armed with crowbars and shovels, go clearing fresh land, cutting roads or digging holes for plants, or a new field opened, for the further extension of the cultivated area.

The women and children are sent to light work, such as pulling weeds or gathering crop from one or the other of the many plants, cotton, coffee, cocoa, or tea, which grow luxuriantly in these happy Isles. Headmen or overseers accompany the laborers in the proportion of about one to twenty. Besides the cotton garments worn by all, these petty chieftains generally wear a coat of some thick woollen material—often an old one of masters—the owner of the plantation—and they invariably carry umbrellas. If an umbrella covered with a brilliantly red cover, to obtain which is the acme of his ambition, cannot be procured, then the headman or “kangany” as he calls himself must be content with a black or white one—but an umbrella there must be; and one often meets several kanganies walking with their umbrellas open long after the sun has gone

down, protecting their dusky countenances from the light of a misty fickle moon, or an unlucky star. Vanity, as expressed in parti-colored sun-shades, is not peculiar to women.

Arrived at the field of operations, one laborer is told off to each row of shrubs to prune, pluck or whatever the work may be. Among them are many good singers—as they judge singing. One of such is told by the Cangany to “strike up.” Then follows what we all have heard in more advanced gatherings. He or she pleads a cough, or inability to sing, or the lack of any incidents worthy of song. For your native, in this case, improvises as he goes along, and does it, too, very cleverly. After the usual badinage he does “strike up,” sometimes a chant which all know, with a chorus, which all join in; sometimes a verse which is responded to by another, when the song take the shape of a duet. Or the singer improvises, and touches in rhythm of measured length or cadence on such events as their simple life supplies—the goodness or otherwise of their curry—flirtations of Ramon with Letchemie—the glances which Sadion was seen to throw at Salachy, during the absence of the latter’s husband Coropin—or the doings of the Cangany or Master, for even the follies of their white employer are fearlessly shot at by these fun loving rogues.

A wise employer always encourages this singing, as while it goes on, all the laborers, even when joining in a chorus diligently attend to their work. On the other hand, when no one sings, chattering, chaffing, arguing and laughing are incessant, and work is less carefully done.

About mid-day, there is a halt, and the crop gathered by each laborer is weighed, counted or measured. In the illustration photo you sent me, Master has come, and is awaiting the arrival of carts which are to carry the produce from the basket to the factory. The pluckers have gathered around him, and are sitting examining their baskets lest any foreign substance, or portion of branch, or even too coarse a leaf, may have found its way into them.

Even these children of the sun feel the heat at noon on a sultry day, and are grateful for the rest this halt gives them. At this hour, too, many of them take “a snack”—the simple lunch they affect being brought to them by children or friends from the villages, or, as is often the case, having been brought out by themselves in the morning, carefully rolled up in a banana leaf or a handkerchief.

Then to work again till 4 p.m. when a horn is blown with a note as lugubrious as that of an Atlantic steamer during a fog, as a signal that work is over for the day. The gangs are again mustered and counted, and the day’s work checked. As soon as dismissed, away they all rush singing and shouting, chaffing and chasing each other. Old and young, they are all as happy, *because as thoughtless and improvident*, as kittens or puppies at play.

Bless them! they care nothing for politics or stocks; winter and want are unknown to them, they have free houses, fuel costs them nothing, and two cents worth of oil gives them all the light they want for a month. They can dress extravagantly on two dollars a year, the tax collector never visits them, Tammany never squeezes them, and when ill, doctors, medicine and food are supplied gratis.

These labourers are absolutely free, and can leave their employer without notice, if their wages are 24 hours overdue,

They work only three or four days a week, for though the employer is obliged by law to find them work, or at all events, pay them, should they desire to work six days, they never do desire it. Even when crop is ripe and all hands are needed, it is useless to appeal to them to "turn out" one extra day. No! their few wants can be supplied by four days' work, and their philosophy inculcates no work not actually necessary. As for "next year," or a "rainy day," "well, 'Sammie poorium,' or 'the Lord may provide!' but, we 'count not our troubles before they come."

This picture is one of a Ceylon tea plantation and from such leaf as is observable in the baskets above, is made by *machinery* the famous new and pure teas of Ceylon and India, which have supplanted the coloured and adulterated hand-made teas of China and Japan, in nearly all the tea markets of the world. W.MCK.

"Hard Labour in the Tropics" is an answer to assertions made in U.S.A. that coolies are slaves.

WHEAT:—INDIA'S SCARCITY—AMERICA'S OPPORTUNITY.

The rapid rise in the price of wheat has come as a surprise, as well as a blessing, to the thousands of western farmers, who have been struggling for years against dwindling prices, and who were told by Bryan and other silver blatherskites that no rise of any consequence was possible until silver was placed on a par with gold. Or in other words, until these honorable gentlemen were empowered by Law to pay their household bills of \$100.00 with \$60.00.

Short crops in Europe, locusts in the Argentine and drought in Australia, have all helped to stimulate the upward trend of prices of grain. But the chief factor has undoubtedly been the dry weather and water famine in the Northern, Middle and Western Provinces of India. From being an exporting country, India has suddenly and unexpectedly become an importer of wheat. True, the imports have not as yet been large, and it is to be devoutly hoped they will not become so:—as that would mean that famine, with all its dire consequences, had overtaken its peaceful and industrious populations of an ancient and interesting country.

To us, good Americans, who are in the habit of regarding the west as the most marvellous portion of the Earth, the word India is as Mesopotamia. We think of it only as a vast country which good old "John Bull" has exploited to his own advantage, rather than for the good of the teeming millions of many Races and Religions who inhabit it. "John's" bold and adventurous seadogs, who pursued the Spanish, French and Dutch explorers into all parts of the new Continents and Islands discovered in the 16th and 17th Centuries, and by dint of hard knocks, marauding and privateering, generally succeeded in reaping where others had sown, have left him a legacy of a bad name, which his many good deeds since, have failed to eradicate.

But let us think for a moment of what "John" has done in India. Unless it be the astonishing one of his own recent success in Egypt, *with administrators trained in India*, we doubt if the history of the world can furnish a similar instance of improvement in the internal Government of a nation.

A hundred and twenty years ago, India, far from being a homogeneous nation, as the one name for all of it would imply, contained as many different countries, rulers, races and religions, as our great republic has states. The nations were constantly at war with each other:—the robust and warlike tribes of the North-west and mountainous regions, annually devastated some portions of the great plains and fertile valleys of the Indus and Ganges, whose lazy, cowardly and eringing inhabitants seldom offered any resistance. Besides these, what might be called—invasions by neighbouring nations—bands of well armed robbers called Dacoits, roamed at will over the continent of India, burning, pillaging and ravaging without check or restraint.

At that time "John" or "John Company" as he was called, was a peaceful trader in Calcutta. To defend himself from a repetition of the awful tragedy of the Black Hole of Calcutta, he had to arm some defendants and to fortify some territory beyond the walls of that city. From this small beginning, "John" was literally forced in self-defence by the incessant attacks of barbarous neighbours on his everwidening frontiers, to annex and occupy province after province, until his strong but peaceful sway has made life and property safer in a vast region containing 300,000,000 of people, than they are now, in our United States.

This population too has doubled during the last 100 years, and there seems to be no limit to its extension. Before the reign of "John," internal wars, consequent famines, with their never failing attendants, Cholera and Pestilence, kept down the population. By roads, canals and railways, besides suppressing wars and dacoitry, "John" has to a great extent put an end to famines.

When rains fail and crops are short, relief works are started, wells are dug, and food is purchased and poured into the threatened province. Pestilence is combated by science, for doctors, dispensaries and hospitals abound. The consequence is that population increases with tropical rapidity.

Without the aid of immigration, the increase is actually, not comparatively greater than that of the United States. And when the last trumpet sounds, and "John" is asked, "What of thy brother?" he can point to the vast increase of a native race under his sway. But what answer have we to give as regards the Red man, the Spanish of the Mexicans, or the Australians of their dusky predecessors?

As already indicated, it is in the northern middle and north-western provinces of India that wheat is the staple food. Rice is the mainstay of the East, Central and Southern Provinces, known as Madras and Travancore. In the north-east provinces it has been many years since the government has been called upon to find food and work for the people because of famine.

The Indigo fields employ many; numerous factories are working with large gangs of natives; and the Tea Industry which has sprung up like a Gigantic Exhalation gives work to hundreds of thousands of laborers from the congested districts. To give some idea of the strides made by tea, it will be enough to say, that where India a few years ago imported tea from China, it now not only supplies its own wants but will export about 150,000,000 pounds this year.

In Southern India actual famine is rare, as is a very ancient, extensive and elaborate system of irrigation. The people of Southern

India called Tamils, are industrious and enterprising. When long drought brings the pinch of scarcity upon them, they swarm in hundreds of thousands across to the little Island of Ceylon, ancient Lanka. There, they find relief and plenty of work, on the flourishing Tea Gardens.

Perhaps no industry ever grew so rapidly as that of Tea in Ceylon. Fourteen years ago, the export was 1,000,000 pounds, this year it will reach 105,000,000 pounds. The Teas of India and Ceylon have only recently been brought to the notice of the American public, but their superior strength, purity and flavour are already making them household dainties.

Americans are great travellers, but only a few penetrate as far as India, yet that country would well repay a visit, and we would advise all who go there, first to read the glowing pages of Macanay's Essays on Clive and Warren Hastings, India's ancient civilization, its temples, its grand ruins at Delhi, Lucknow, Benares and a hundred other places and the Taj at Agra, the "glory of the world" would all teach us to be less boastful of our hideous twenty storied modern iron structures.

A RECENT SOJOURNER IN INDIA.

PLANTING AND PRODUCE.

(From the *H. & C. Mail*, Dec. 18.)

A TEA DEALER'S VIEW OF INDIAN TEA PROSPECTS.—It is not often that tea dealers are sympathetic with tea growers, or show any disposition to weep for tea with them. The following note on Indian tea prospects issued by Messrs. Brooke, Bond and Co. is interesting, not only on account of its review of the position generally and its fervent advocacy of British-grown teas, but also by reason of its appreciation of some of the difficulties which attend the planter. The following is the note referred to: "The Government figures show that the British people drank more tea in the last financial year than in any previous twelve months; and in these days of foreign competition it is gratifying to know that though thirty years ago all our tea came from China, very nearly all we consume nowadays is grown on the British soils of India and Ceylon. It is hardly possible to think of India just now without being depressed by the appalling famine which has so sorely smitten that densely populated Empire. Though our Government can and will save the lives of many millions who would otherwise perish, it will be impossible to prevent the awful misery of starvation, extending over many months, with resulting life-long weakness. Though the famine will not appreciably affect the quality or quantity of Indian tea, it is indirectly a disaster to the British planter, for the doubling of the price of rice means nearly doubling the cost of cultivating his crop. Under every contract between the tea garden coolie and his employer the latter is bound by the Government to provide for staple food—rice—which the coolie may require for his family at a price not exceeding a certain normal limit. If rice is cheaper, the cunning coolie can buy his rice elsewhere, but so soon as the market price touches the stipulated limit he and his family flock to their master's granary and demand all they want at a price which already in this famine is but half that which the planter has to pay. Fortunately the drought has come too late to lessen the new season's growth of leaf in the Indian gardens, so the tea-loving English public will get their tea at the same price as usual. As to the general quality of this year's output, it may be classed as 'average,' and whilst '96 will not be known as a 'vintage year' in tea, the leaf this season is very good. Unfortunately the excessive rainfall in England early in the autumn has not improved the tea-making properties of the water now being supplied to our northern towns, but if the British house-wife will only buy teas of universally good

repute, and will make her tea carefully, she will have every reason to be satisfied with this season's infusion of her favourite leaf."

THE WONDERFUL CAUCASUS.—The Caucasus seems the modern Land of Promise. Not only is tea cultivation the subject of great expectations, but M. Rotovsky, a well-known Russian botanist, has just published a report on the medicinal plants in the Caucasus. During last year he carried out experiments in the cultivation of these essential oil plants, and at the same time investigated the Caucasian flora. He discovered about 100 varieties of medicinal plants. The satisfactory results of his investigations have induced the Russian Government to cultivate the castor-oil plant in the Caucasus, with the view of providing Russian firms with large quantities of this drug. M. Rotovsky has been appointed to superintend this undertaking.

COFFEE PLANTING IN CENTRAL AFRICA.—In our reference last week to Sir Harry H. Johnston's paper on Central Africa and planting operations there we mentioned his reference to the development of the coffee planting industry. The British administrator, in the course of his paper, read an extract from the report of a well-known firm of colonial brokers to an industrial mission in Central Africa, which especially concerns itself with the spread of coffee-planting amongst the natives. This report says: "With reference to the shipment of thirty-four bags of Nyasaland coffee just arrived, we have carefully examined the samples, and the quality of the coffee reminds us of high-grown Ceylon coffee in its palmy days. It is a good, bold plantation bean of rather open character, well prepared and dried, and from its stylish appearance would always command a ready sale, being well liked by both home trade and export buyers. It is singular that although every effort is being made all over the world in coffee-growing districts to produce fine quality, it is quite the exception such a result as yours is obtained. The two bags of peaberry that realised today 107s per cwt. would fetch 115s in larger quantities of fifteen to twenty bags and upwards. The same remark applies to a certain extent to the other small lots. "A reference," said Sir Harry Johnston in his paper, "is made in this quoted opinion to Ceylon coffee. It has been a great satisfaction to me to note the interest taken in our Protectorate by the Ceylon planters, who very soon made inquiries about our country, and two years ago established a strong Ceylon company, the Nyasaland Coffee Company, which is now busily planting in the Mlanje district of our Protectorate."

THE PLANTING OUTLOOK IN JAVA.—The crop prospects do not appear to be bright in Java. Drought is complained of, and the outlook for produce generally is not encouraging.

THE PLANTING OPERATIONS OF THE BRITISH NORTH BORNEO COMPANY.—At the half-yearly meeting of the British North Borneo Company, held on Tuesday, the chairman (Mr. R. Biddulph Martin), referring to the planting operations of the company, said that arrangements were now being made to cultivate on a large scale ramie, for which it was believed there would be a practically unlimited market. The syndicate interested in that matter had already engaged a manager, who would shortly proceed to Borneo. The growth of indiarubber would, he hoped, also receive attention. This was a product which was in increasing demand, and could only be cultivated in certain parts of the world. The result of the tobacco-planting operations of 1895 had been, generally speaking, highly satisfactory, and the prospects were most encouraging. Then they had a syndicate engaged in the manufacture of catch, and they heard that it was doubling its plant in their territory. In reviewing the present position of the company as compared with former years, he could not help being struck with the marked improvement that had taken place. The constant de-

ficit shown in the earlier years between the revenue and expenditure, amounting to £62,000 in the first year, was gradually diminished until in 1895 the balance was for the first time on the right side. The amount of that credit balance was more than doubled in the first half of the current year, and if their surplus continued to increase from year to year as rapidly as the deficits were reduced they would not have much to complain of in another ten years. The volume of trade in the country was what they had to look to in order to find out their real position and prospects, and with this they had cause for satisfaction. In 1895 the imports were 1,663,000 dols and the exports 2,130,000 dols, while for the first six months of 1896 the imports were 898,000 dols and the exports 1,850,000 dols, which was a very large increase. He believed they had now not only turned the corner, but had made good progress in the right direction.

A SUGGESTION TO WEST INDIAN PLANTERS.—Mr. Thos. T. P. Bruce Warren, of the Indiarubber, Guttapercha, and Telegraph Company, Silvertown, suggests that the West Indian planters should cultivate Indiarubber. He says: "I have no hesitation in saying that the West India Islands are well situated, geographically, for the cultivation of indiarubber of good quality, and, looking at the fact that our supply is diminishing, I think that our Government may assist the West India planter with seeds or saplings of different varieties or species, to find out what plant will be best suited for the soil and climatic conditions, and, what is of equal importance, what plants can be depended on to yield a profitable product as soon after planting as possible. Arboresecent plants, as a rule, yield better qualities of rubber, but, of course, must stand a few years before being tapped; vines and creepers reach maturity sooner for yielding, and, although the quality is inferior, it is far more encouraging to a planter to obtain a commercial status for his product than to place the whole of his venture on more ambitious hopes. It is not unreasonable to try plantations of plants yielding indiarubber quite equal in quality to what we get from Central America, or even Brazil. An inspection of the map will show that they are in the same physical zone, and, being so near to the American coasts, there is a fair prospect of success; but, of course, a few years will be required before a tree can be freely tapped."

INDIARUBBER IN AFRICA.

THE LANDOLPHIA VINE AND THE LAGOS-RUBBER TREE.

SIR,—I have read, as I am sure many West-Coasters will have read, with great interest your article in the *Spectator* of November 14th on india-Rubber, and I should much like to ask the learned writer thereof if something might not be done to reinstate the rubber-vines in those West African districts where the wasteful way in which the natives have collected it has stamped the trade out, and whether this reinstating might not be effected by the judicious felling of timber at a slight expense, because, if done judiciously, the timber felled would be of value and help to pay expenses. From what I have seen of the rich rubber districts of Western Africa stamping-out of rubber in a district arises primarily from the native pulling down every rubber-vine he sees and cutting it up into small pieces with a view to putting those pieces round a fire and running the rubber into a calabash; or, when the vines are too strong for him to do this, making murderous wounds on them with his machete; secondarily, it arises from the very trying habits of the Landolphia in insisting on starting life from a seed—it will not send out side branches if its top is cut off, and it will not send up shoots from its roots. Now in dense African forests the chances of seeds are few and far between. They fall upon the ground 150 ft. or 200 ft. below the region whereon the sunshine and the rain plays. You may go for months through the great Forest Belt of Africa in a grim twilight gloom, seeing

nothing day out and day in but countless thousands of bare grey tree-stems festooned with great bush-ropes twined and twisted round each other and round the tree-columns, as bare of foliage as a ship's wire rigging, and looking like some Homeric battle of serpents arrested at its height by a magic spell. If your way takes you on to a mountain-top and you look down on the country you have traversed you can hardly recognise it in the wild, luxuriant mass of beauty, redolent in colour and perfume, that stretches before you, the top of the forest; but if you keep on the level ground you will come now and again to an oasis of new life where one of the forest giants having grown above his fellows and so given the tornado a grip on him, has been destroyed. He has been cast by the tornado wind a wreck to rot, or turned in a second from a glorious living thing into a seared skeleton by the tornado's lightnings. If you will carefully examine such an oasis of new life, caused by the sunlight and rain reaching the ground instead of the top of the forest, you will see thousands of young plants coming up, and among the medley you will, I think I may say, always see young rubber-vines. A very few of these vines will ultimately survive; only those, in fact, which by their wonderful hook-tackle arrangements have gripped on to the two or three saplings of great forest trees which are destined to win in the race for life with their neighbours, and take the place of the great fallen monarch tree and those round him which have been wrecked by his fall. Of course, to carry out clearings in West African forests means the institution of a Forestry Department like that of India, and this for trade purposes is not immediately required; for the quantity of rubber in West Africa is enormous. The *Kicksia*, the Lagos rubber-tree that has been brought so profitably forward by Sir Alfred Maloney and Sir Gilbert Carter of Lagos, is by no means confined to Lagos. It grows in great luxuriance all along the South-West Coast; but at present the African does not know it is a rubber-tree down there, and confines his attention to the vines, to *Landolphia Owariensis*, from which he gets the high quality rubber; to *Landolphia florida*, from which he gets flake rubber; and to five other bush-ropes, from which he gets a sap which is not true rubber at all, but which he uses, with many other things, to adulterate his rubber with, to the end of making it heavier, because it is bought of him by weight, and it is his nature to adulterate everything that passes through his hands. A Forestry Department is, however, a great need in those portions of the West African Coast that fringe the Western Soudan, like the Gold, Ivory, and Slave Coasts. The forests here are only fringing forests between the Sea of Sand, the Sahara, and the Salt Sea, or the Bight of Benu, and are in danger of being destroyed by the native, in his terribly destructive way of making his farm,—clearing a patch of bush, cultivating it for a season, then letting it go into a worthless jungle; and clearing another patch. Such disforested regions you will find round Accra and the Elmina Plain; and in those regions of this disforested land most remote from the Forest it is almost impossible now for the native to make a plantation whose yield is sufficient for his needs, because the destruction of the forests diminishes the rainfall,—for example, the rainfall at Accra is about 45 inches per annum, and this is not sufficient to support a luxuriant food-producing vegetation in a tropical district subjected to a long dry season and the intensely drying action of the wind from the Sahara, and if the destruction of the forests is allowed to go on at its present rate for a few more years, we shall find ourselves facing famine in West Africa. The South-West Coast, which commences at Cameroon, is under different climatic conditions. Cameroons, with its volcanic island series of Fernando Po, San Thomé, and Principe, has an infinitely richer soil and heavy and evenly-distributed rainfall; below Cameroons you are in the region of double seasons, two wet and two dry, until you reach Congo; and in this double-season region the growth of vegetation is so rapid that the native has to fight back the forest as a Dutchman fights the sea, and

moreover the mass of the South-West Coast natives are not so much dependent on plantations as those of the West Coast, for they are nomadic hunters. I see you notice the German efforts to improve the producing power of Cameroons, and I should like to add that the French Government in Congo Française are equally active, and among other things have encouraged the planting of the para-rubber tree, which flourishes exceedingly.—I am, Sir, &c.,

M. H. KINGSLEY.

100 Addison Road, Kensington, W.

THE WEST INDIA SUGAR INDUSTRY.

We are officially informed that General Sir Henry Wylie Norman, Sir Edward Grey, and Sir David Barbour have been appointed to be Commissioners "to inquire into the conditions and prospects of the West India sugar-growing Islands"—not, be it observed, solely into the conditions and prospects of the cane sugar industry. The wording of this communication is not quite clear. British Guiana, which is the seat of a larger sugar industry than any of our possessions in the Western Tropics, is not one of the West India Islands, though a Secretary of State at one time thought that it was, and thus described it in a Despatch. It is contrary to common sense to suppose that this Colony is to be excluded from the scope of the investigations of the Commission, for it is the best, if not the last, stronghold of the West Indian planter. Nor is it inquiry, we apprehend, to be limited to the "West India sugar-growing Islands," for, with the conspicuous exceptions of Trinidad, Barbados, Jamaica, and one or two others there are several islands where the cultivation of sugar for export has practically ceased. What we understand the Colonial Office to mean is that the Commission is to inquire into the economic conditions and prospects of all the West India Colonies, whether island or mainland, and whether sugar cultivators still fight for life or have given up the struggle. It is admirably constituted for its task. If we were asked to describe it negatively, we should say that it is decidedly not a planter's Commission. If its composition is analysed, it will be seen that there is little hope for the belief that was entertained in some quarters that the Commission would be more favourably disposed towards the planters than to any other class of West Indian producer. It is a thoroughly impartial body. General Sir Henry Norman was Governor of Jamaica from 1883 until he was sent to Queensland in 1889. In other words, he was at the head of an important West Indian Colony during years of crisis in the sugar industry, when Jamaica was compelled to seek other outlets for productive energy than in the cane fields. Thanks in some measure to him, though more to necessity—the fruitful mother of new enterprises. Jamaica has succeeded fairly well in keeping out of bankruptcy. Sir Edward Grey has no West Indian experience that we can recall, but he is an able man, with much business faculty, and will doubtless find the Islands a pleasant place for a Winter holiday. Sir Edward Barbour is a distinguished Indian Treasury official, who lately served on the Commission on the Financial Relations between Great Britain and Ireland. We shall be surprised if he does not discover that the West India Colonies are wastefully governed and that drastic economies can be effected and inequalities of taxation redressed. With the coolie question Sir David Barbour, of course, will be particularly fitted to deal. We note that the Commission is to have the expert help of Mr. Daniel Morris,

the Assistant Director of the Royal Gardens at Kew. Mr. Morris graduated as a botanist in the West Indies, and there is not, perhaps, another man available who possesses his wide knowledge of the commercial uses to which the vegetable wealth of these Colonies might be put, were capital and energy forthcoming. It is evident from the constitution of the Commission that what the Colonial Office has in mind is a general and all round development of these neglected Colonies, many of which are, for the most part, beautiful primeval wilds. If it can also incidentally assist the sugar planters to continue to hold their own, it will be a useful service.

—*Standard*, Dec. 19.

RUBBER PLANTS AND THE CYCLE TRADE.

At the meeting of the Royal Botanic Society at Regent's Park on Saturday three new Fellows were elected—Mr. H. S. Clutton, Mrs. W. Hern, and Mrs. Twiney. An interesting collection of indiarubber-producing plants grown in the gardens was shown by the secretary, Mr. Sowerby. There are about a dozen varieties of the plant from which rubber is produced for commercial purposes, and special importance is given to the subject by the large consumption of rubber for cycle tyres, which has caused the price to increase something like 2s. a pound within the last few years. The price would have gone still higher but for the discovery in Central Africa of several species of *landolphia* a climbing rubber plant which is likely to provide the great reserve supply for future use. Several specimens of *landolphia* were shown. Other kinds exhibited were the *castilloa elastica* (Central America), and the *manihot glaziovii* (Brazil). A large proportion of the supply of rubber at present comes from America, but American cultivators are said to be very reckless in their methods, destroying large numbers of plants for a greater immediate return. Although rubber was used by the natives of San Domingo for making balls and for waterproof shoes even in the time of Columbus, it was looked upon merely as a curiosity, and had no commercial use until 1792, when Dr. Priestley noticed its value in rubbing out pencil marks. It was brought at the time from the East and West Indies, and from the purpose to which it was applied became known as "indiarubber." In 1843 its usefulness was greatly increased by the discovery that it would absorb sulphur, and by this process, described as "vulcanising," became capable of withstanding high temperatures.—*Daily Chronicle*, Dec. 14.

TEA IN AMERICA.

NEW YORK, Nov. 25.

Demand is not as quick as in October, but prices are well sustained for all descriptions. There is no evidence that the lower grades are not holding their advance. Greens are firmly held. Japan steady. Fine Formosa strong.

Today at noon the Montgomery Auction and Commission Company will sell 4,010 packages, viz: 1,159 packages Moyune, including chops new season's; 1,679 boxes Pingsuoy, new season's; 98 half-chests Japan Nibs; 9 half-chests Dust; 551 half-chests and boxes Congou, including fancy new season's; 159 packages India, Java and Ceylon, an attractive assortment; 278 Foochow, the celebrated "Tong Shing" Third; 79 half-chests and boxes Formosa.—*American Grocer*.

MANURING BY CEYLON PLANTERS

AND OTHERS:

THE NEED OF A FERTILISERS' ACT.

The time has not yet come for summing up the valuable information contained in the several letters sent us in reply to the circular on the Manuring of Tea Plantations. Indeed only a fraction of the responses have, as yet, seen the light. In the last budget published—including two letters from Northern Districts, one from Dimbula and one from Maskeliya,—there was given not only practical information of the utmost importance to all engaged in tea cultivation; but a question was raised, not for the first time, to which attention should at once be drawn. From the Correspondence we refer to, it is becoming evident that planters are awaking to the necessity of Guaranteed Purity in Manures. More than one of our correspondents makes pointed reference to this, and the examples which both "Hantane" and "D" have adduced, show how buying in the dark is about as unsatisfactory as the proverbial purchase of "a pig in a poke." Things according to their showing have been improving in some directions, and falling away in others, but even where the improvement is most marked, the need for still further care is manifest enough. Fifteen to twenty per cent of sand in "fish-manure" is a very large proportion, and when it is remembered that this useless stuff may have to be conveyed to distant estates, and all the expense of applying it gone through, while the planter is wholly unaware of the value, it is about time that something were done to let in light. In the mother country, there is a "Fertilisers and Feeding Stuffs Act" which has done very much to protect buyers of artificial manures, and it would seem, as if now that the question of manuring is locally so much in evidence, and the need to avail ourselves of every advantage in connection with our principal product is so keenly realized, that some such Ordinance should find a place in the Statute-book of Ceylon. What is wanted is a warranty of sale. "Every person," says the English Act "who sells for use as fertiliser of the soil, any article manufactured in the United Kingdom, or imported from abroad, shall give to the purchaser an invoice stating the name of the article and whether it is an artificially compounded article or not, and what is at least the percentage of the nitrogen, soluble and insoluble phosphates, and potash, if any, contained in the article, and this invoice shall have effect as a warranty by the seller, of the statement contained therein." If the fertiliser is not up to the standard guaranteed, there are penalties, which, of course, are only intended for the fraudulent. Before the Act came in force the trade in artificial manures in the United Kingdom had become very degenerate; but now things are completely changed and the Act is a hardship to no one, as the seller knows what he sells, and the buyer what he buys. Merchants here can easily protect themselves, through local analytical talent, and a Fertilisers' Act would be a boon to all concerned—to the dealers and importers as saving all disputes and dissatisfaction on the part of their customers; and to the planters as showing them precisely, the value of the fertilising constituents, they were applying to their tea. We do not think His Excellency the Governor would have the slightest objection to the passing of such an Act.

THE TEA ESTIMATES.

A proprietor writes:—

"V. A. surely meant 15 millions over last year's estimate, not 15 millions over actual shipments. District estimates for 1897 are compared with 1896 estimates, not with the actual output.

"Something should be done to make the Customs and Chamber of Commerce returns correspond. At present it is very much a case of you don't know where you are."

That would mean 116, in place of 120-122 millions lb. for 1897; but surely, in the case of the districts, the comparison will be between actual results for 1896, and the estimate for 1897. Why should a Committee with the actual results available, go back to an estimate framed nearly a year ago? We agree that it would be an advantage and great convenience to have the Export figures of the Customs Department and Chamber of Commerce made upon the same basis, if that were possible, and so to agree.

COFFEE PLANTING IN NORTH BORNEO.

From the letter of a reliable correspondent this Dependency, we quote as follows:—

"Coffee is certainly looking up in B. N. Borneo. Large clearings are being opened in Maundu Bay, and felling has just begun. Labour is very plentiful just at present. Could you not induce a few more Ceylon planters to come over? There are only two planters here. I am sure either Mr. Henry Walker or myself would be most happy to give all information about the country and coffee."

Here is a chance for young gentlemen commanding a certain amount of capital and who, after learning all about "planting" in Ceylon, find the openings for moderate capital and experience, are locally few and far between.

MANURING TEA AND THE LABOUR SUPPLY.

An experienced planter in sending in his answer to our circular says:—"I cannot help thinking were all owners of tea estates on old coffee lands to go in for manuring systematically we should find we had not done half enough in pushing our teas into new markets. That the extra production, the result of manuring with the increasing area coming into bearing, would prove too great for the demand, provided we had the coolies to apply the manure and harvest the result."

THE CEYLON TEA OUTPUT:
A HARD CASE?

The editor of the "Times of Ceylon" thinks we have dealt hardly with him—indeed that our censure is for his not suppressing the truth!—and further that Mr. James Ryan put forward the "fact" on which his remarks were based and that we did not attempt to justify our own position. Well, let us compare the "Times" of the 6th Jan. with that of the 4th Jan.:—

"Ceylon Times," Jan. 6th.

We recently called attention to the fact, newly revealed by the figures published by Mr. James Ryan, the Hon. Secretary of the Dimbula Planters' Association, that some of the larger upcountry districts having all their large acreage already planted up, in tea, had nearly reached the limit of production.

"Ceylon Times," Jan. 4th.

Other things being equal, Dimbula has nearly reached the limit of its production. And the same remark holds good of several other districts, such as those we have named [Dikoya, Maskeliya] and

many others besides. Extension now is nearly confined to the low country and Uva, and the total amount is not, we think, increasing, but decreasing yearly."

There is a good deal more than Mr. Ryan's "fact" here, especially in the words we have italicized.

In justifying our censure we need only quote two sentences from our article:—

"Let it be granted that the available reserves in certain of our districts are nearly all planted, what about *manuring*? Not one word of reference does our contemporary make to a departure which is now every year more followed in Ceylon and which, of itself, with the results before us, ought to render Indian Tea Company Directors and other planters of tea, more and more careful how they rush on large new clearings without any proper consideration of how the over-production already threatened, is to be cleared off."

What our contemporary means by the "total amount decreasing" it is hard to say—surely not that Ceylon is to give a lower tea export in 1897-8 or 9 than in 1896 and yet where is the "truth"!

THE CEYLON TEA OUTPUT—AND MANURING.

With reference to our evening contemporary's statement that besides Dimbula, Dikoya and Maskeliya, "*many other districts*" had nearly reached the limit of their production, an experienced planter very pertinently asks:—"Is not manuring equal to opening up new land, thereby increasing the output of tea?"—and in illustration we are told of a case where castor-oil cake and bones doubled the yield nine months after application and this on land that had been in continuous cultivation for forty years with coffee, cinchona and tea. "If any bulky manure has been applied to this estate, it would only have been in small quantities, such as a little stable manure or from a few milch cows and scarcely worth alluding to."

We may well ask whether it was consistent with "telling the truth," to say nothing about what "manuring" is doing and is likely to do for the "many districts" that have no more land to plant.

We are, however, more and more struck with the agreement in opinion among planters, that unless the Labour Supply is reinforced, it will be impossible to keep up or extend manuring, to do justice in plucking leaf, or in cultivation, and even to ensure due care in preparation of the tea.

TOBACCO PRODUCTION AND CIGAR- MAKING IN CEYLON.

At a time when tea production, if not planting, is supposed to be overdone and when we are receiving such discouraging news of cacao (as comes today from one district "most distressing how old cacao is dying"),—it is almost refreshing to receive such a paper from a Tobacco Expert as we publish below. He alleges that tobacco, even in Ceylon, should be made to pay better than tea and that a fair trial has never been given to this product,—that there is a great market at our very doors and that Ceylon cigars should beat those of India and North Borneo; while never before was there such a chance for profitable investment with Cuba and the Philippines in trouble.

Now how is it that only an Indian Expert knows all this? And why does he reveal the secret to provoke competition, and not rather make hay in his own gardens while the sun shines? Ceylon planters are supposed to be pretty sharp and yet some of the shrewdest of them, of late years even, have tried tobacco and burnt their fingers. Let "Expert" raise the capital in India and come and show us "how to do it" with tobacco in Ceylon.

Our Expert friend sent us a previous paper on the same subject which can be referred to at page 378 (December's) *Tropical Agriculturist*.

THE CIGAR TRADE AND CEYLON TOBACCO.

No. II.

(Communicated by an Expert.)

When comparing the success that Borneo tobacco and Borneo cigars have obtained at home with the efforts of this Island in this direction, the comparison is indeed an unsatisfactory one, the reason is not far to seek. Every up-to-date Tobacconist at home stocks Borneo cigars while a Ceylon cigar is not in it and never has been.

The general excellence of Borneo leaf coupled with the enterprising manner in which this leaf has been forced upon the public notice, has done everything to make a Borneo cigar a popular one and the demand for the same a great one.

To flood the markets at home with any hope of permanent success requires a good thing to begin with. Borneo has this in its tobacco; the rest is mere push and enterprise. To be able to put a first-class cigar upon the markets to retail at 2d and 3d each, means an enormous demand. About nine-tenths of the cigars consumed at home are those that sell at 3d each and under, mostly under and this is the class of trade to cater for.

So far Ceylon has not had a chance to look in. The experiments that have been made have proved beyond question, that a very fine and high class leaf is produceable in the Island and the fact that these experiments were not continued or enlarged upon is certainly not due to any failure to produce a requisite leaf. There is nothing that pays like "Baccy"—not even "tea"—given a fair start and fair conditions.

The Havanna trade, owing to the Cuban insurrection is in a state of collapse and now is the time for Ceylon to make a fresh start. Dealers at home are being forced to look about for new fields to fill up the gap made by the failure of the Havanna trade. Anything in the shape of a good and pure cigar that is placed before the public, is bound to do well always provided that it is well and sufficiently forced upon the markets. The Havanna trade is not at all likely to recover itself for a year or two yet, even supposing that the Cuban troubles are now coming to an end and this is by no means the case.

Borneo Cigars are now being pushed at an opportune moment and Indian manufacturers have also awakened to the situation and are doing all they know to take advantage of it.

India would have no chance against Ceylon, were Ceylon to properly contest the trade. Indian tobacco is not and never can be any thing equal to that produced by Ceylon; the climate and soil are against this.

What Ceylon should do, is not only to produce leaf, but also to manufacture it and export only

after selection, such leaf that it does not itself require for manufacturing purposes. India would prove a good market for any excess of leaf, manufacturers are constantly looking out for new stuff for blending purposes.

In this way Ceylon would secure for itself only the choicest leaf and therefore Ceylon should be of the very best, while the profit upon the same would be uncommonly satisfactory. The cost of production would be infinitely less than that of Borneo leaf, while the cost of manufacture infinitely less than that of the home-made cigar.

Ceylon imports from India something like 20 lacs of cigars annually upon which import duty is paid.

A good cigar made in the island would as a natural consequence divert the most, if not the whole, of this trade, if only the question of duty were taken into consideration.

All that is necessary to ensure success is a thorough knowledge of growing and of manufacturing, coupled with businesslike management and the requisite capital.

An opportunity such as at present offers itself to develop this trade is never likely to occur again and should not be lost sight of.

I am firmly convinced that tobacco in Ceylon could be made to develop into a great success with the necessary enterprise.

OUR STAPLE EXPORTS FOR 1896. THE CREAM OF THE FIGURES.

The principal totals of the Chamber of Commerce tables with the export results for 1896 are as follows:—

	1896	1895	Increase or decrease.
TEA lb.	108,141,412	97,939,871	10,201,541 inc.
COFFEE cwt.	22,747	63,920	41,173 dec.
COCOA cwt.	31,366	27,420	3,946 inc.
CINCHONA lb.	1,309,560	921,085	388,475 inc.
CARDAMOMS lb.	452,595	374,635	77,960 inc.
COCONUT OIL cwt.	343,497	384,140	40,343 dec.
PLUMBAGO cwt.	340,491	334,921	5,571 inc.

As to the distribution of our great staple, *tea*, we have the following main facts:—

	In 1896.	1895.	Increase.
	lb.	lb.	lb.
United Kingdom ...	93,936,361	85,753,339	8,183,022
Australasia ...	11,062,832	9,379,561	1,683,271
America ...	718,600	393,527	325,073
Rest of World...	2,423,619	2,413,444	10,175

The great increase has been to the United Kingdom; but nearly 1½ million lb. additional to the Australasian Colonies is very good, and also the 325,000 lb. of increase to America, although, of course, a good deal re-exported from London should be added to these figures.

THE TRADE OF CEYLON IN 1896.

Having noticed, above, a very few of the principal figures and comparisons afforded by the staple exports of the island during 1896, we are now enabled through the courtesy of a mercantile authority to give our readers the benefit of a Review of the Import and Export Trade in its main features for the past year. The increase in the import of coal and in the export of "desiccated coconut" are among noteworthy experiences:—

IMPORTS.

RICE.—During the first six months of the year, prices were moderate and steady but about September they advanced and, continued to do so, as the prospects of the monsoon rains in Northern India became less favourable. Soolye rice is now about R2 per bag dearer than it was in January last; but as the much needed rains have fallen in many parts of India, the famine, which otherwise must have supervened, has been to some extent averted. Imports of all kinds in 1896 have been 5,917,096 bushels against 8,722,822 in 1895.

COTTON GOODS.—Business was overdone in 1895 but in 1896, the imports were on a smaller scale, being about 2,000 packages less than were imported in 1895. During the past few months the purchasing powers of dealers have been much curtailed owing to the limiting by the banks of the facilities hitherto afforded, for the discount of promissory notes.

METALS AND HARDWARE.—A good and extensive business has been done in tea requisites, and metals and hardware generally, but there is still a large proportion imported from continental countries. It is hoped that English manufacturers when they see the samples of continental made goods that are being exhibited by the London Chamber of Commerce will awake to the necessity of meeting more fully, the wants of their customers by trying to provide what a consumer wants, and not only what a manufacturer prefers to make.

The high rates of exchange that have been ruling for some time have stimulated import business generally, owing to the lower rupee cost for which goods could be laid down.

From 1st January 1897 the old method of entering goods at the Customhouse for duty is being discontinued, and in future, sterling invoices will be taken at the exchange ruling, which will be fixed from time to time. A Select-Committee of the Legislative Council has been appointed to consider and report upon the question of *ad valorem* and rated articles for duty and also the kerosine oil duty, which is considered to be far too high.

COAL.—The imports of coal in 1896 were 340,750 tons against in 1895 326,297 tons.

Indian coal is now being more largely used than formerly, the quality having considerably improved.

EXPORTS.

TEA.—The total quantities exported in the last two years have been:—

	1896.	1895.
	lb.	lb.
To United Kingdom	93,936,361	85,753,339
Continent	617,345	786,741
Australia	11,062,832	9,379,561
America	718,600	393,527
India	924,272	831,070
Other Countries	882,002	795,633

108,141,412 97,939,871 lb

During the first half of the year, the weather was favourable and the yield on most estates was good, but during the latter half there was a super-abundance of rain which, in most districts, has kept back flush.

Shipments to Australia show a marked increase, whilst those to the United States and Canada are growing steadily. The Russian markets should now be more vigorously exploited and every encouragement should be given to those who are striving to introduce Ceylon Tea into these markets. The area under cultivation in

the island is being slowly increased, and production in 1897 will show up larger than in 1896, but there is no large expansion of planting, nor can there be, especially in the higher districts. [Although the effect of extended manuring must not be overlooked.—Ed. T.A.]

The higher exchange now prevailing is curtailing producer's profits by about 1d. per lb. and if it continues, either the sterling price of tea must go up, or, the value of tea estates must come down.

COFFEE.—The past year has been an unfavourable one, only 22,747 cwts. having been exported as compared with 63,920 cwts. in 1895. With the good prices obtainable, it is surprising that more Liberian is not planted.

COCOA.—The crop of last year has been on the whole a good one, 31,366 cwts. having been sent away, and prices have lately shown signs of recovery.

CINNAMON.—Shipments have been on more than average scale, and as the value has continued to rule high in Europe, the stocks there being light, rupee prices here have been maintained at a high level.

The heavy rains of the past few months ought to have stimulated growth, and the cuttings the first half of 1897 ought to be large.

COCONUT OIL.—This article has been very depressed in the markets of Europe and America during the past year owing to the abundance and cheapness of other greases, chiefly tallow, which has been in large supply from South America and Australia.

A strong demand, however, has prevailed for Indian, and ports farther East, partly owing to scarcity of Cochin oil. The total quantity exported in 1896 was 339,870 cwt., against 384,150 cwt. in 1895.

COPRA.—A lively demand for this has been experienced, and, besides the usual export to Indian ports, a considerable quantity has been sent this year to Antwerp and Hamburg, where copra oil is made.

PLUMBAGO.—The exports have been on an average scale, and the quantities taken for Continental ports and for America have been about the same as in 1895. The total quantity sent away was 340,470 cwt., against 334,921 in 1895. Fine qualities have been scarce and in demand and low qualities plentiful and neglected as usual.

In the latter half of the year, the enquiry for America has been slack owing to the Presidential election interfering with trade.

FIBRES.—There has been a poor business in these during 1896 and a considerable falling-off in the quantities exported, chiefly owing to first cost having been forced so high. These remarks apply to coir, kitul and palmyra.

DESICCATED COCONUT.—The trade in this article has increased by 2,052,525 lb. as compared with 1895, the figures being:—

1896.	1895.
10,603,598 lb.	8,551,073 lb.

the great bulk going to the United Kingdom.

TEA IN JAPAN: OUR JAPANESE VISITOR.

DR. OBAYASHI has returned from his trip to the Central Province, charmed with Kandy, astonished at the extent and variety of the Royal Botanic Gardens, very much impressed by the tea districts he saw, and by the machinery in the New Peradeniya and Scrubs factories, and with the feeling that Nuwara Eliya is "too cold." He now returns to Japan and will probably recommend some machinery being imported, although he says it is not so suitable in the preparation of Japanese green teas. The "facing" of Japan teas, our visitor says, is done in the godowns at the shipping port, and this "facing," as we have often mentioned, is of Prussian blue and other deleterious matter. Latterly, however, American dealers—according to Dr. Obayashi—have been objecting to the facing. Our visitor is greatly impressed with the fertility and resources of Ceylon and thinks (despite our depreciation and attempted correction) that our future crops of tea must very largely increase—indeed to a figure which we pointed out to be impossible; but in vain! How far this impression may affect the extension of tea growing in Japan or still more in Formosa, we cannot say. But our visitor is certainly anxious to introduce improved tea factory buildings and machinery into his native land.

VARIOUS PLANTING NOTES.

"CHOCHO."—It is wonderful how the merits of the West Indian vegetable introduced to the East for the first time, we believe, by Mr. Nock, of our Hakgalla gardens, get spread after a round-about fashion. A London daily newspaper has the following editorial note upon it:—

It is of interest to note that as a result of the work done at the Nundy Coog Nursery, the Chocho, Christophine, or vegetable pear introduced from the West Indies is now being cultivated by the natives in several villages in Mysore, and is becoming quite a popular vegetable both in the vilages and in some of the towns. It is largely used in the gaol at Bangalore, where it is carefully grown, and it is considered one of the most useful and wholesome of foods for the prisoners. The large fleshy part of the root sometimes weighs nearly twenty pounds, and is very good when cooked and eaten like a yam, a fact which is not generally known. It is, we believe, now being grown under glass in this country, and does well under similar conditions to tomatoes and grapes or cucumbers, and the large flat single seeds, carefully cooked, are considered a great delicacy.

COFFEE IN THE FAR WEST.—There is no end to the coffee investments of Ceylon planters in America: we call attention to the cheering report given on page 541 of the Dumont-Brazil Company; and now we learn from Mr. Maitland-Kirwan that he is interested in no less than 10,000 acres of land in Independent Honduras, taken up mainly for coffee, of which 200 acres are planted and in bearing. The estate is within 20 miles of the sea with a river for boat transport; but the supply of labour is uncertain. We shall have more to say on the subject. Meantime Mr. W. J. Forsyth, formerly of Matnrata, sends us a Mexican paper with correspondence and reports showing that a fungoid disease (*Stelbum Flavidum*, Cooke) already known in Jamaica and elsewhere, has appeared in one division in Mexico. We shall give the whole Correspondence as also extracts from the pamphlet on Coffee in Honduras.

MARIAWATTE TEA PLANTATION.

We learn through the courtesy of the Chief Manager of the Ceylon Tea Plantations Co. that the whole estate of 467 acres has given 410,436 lb. tea, or 878 lb. per acre in 1896, against 870 lb. per acre in 1895. We are promised an exact return for the old 100-acre field, which cannot fail to be interesting.

MARIAWATTE OLD 100-ACRE TEA FIELD
STILL GIVING NEARLY 1,100 LB.
PER ACRE.

We are indebted to Mr. Salmund, the Manager of Mariawatte, for the following extremely satisfactory return:—

“Mariawatte Estate Tea Crop return for 1896.--Total acreage 467 acres; total yield 410,436 lb., being 878 lb. per acre all round; of which the original 100 acre field has contributed 1,090 lb. per acre.”

This 100-acre field is now 18 years old and that it should still give nearly 13 maunds of made tea per acre is, we fancy, unique in the history of tea cultivation. From our “Handbook and Directory” we quote the past record of Mariawatte:—

“Mariawatte Estate original 104 acres planted 1879. —Yields: 1884, 1,050 lb. per acre; 1885, over 1,133 lb. per acre; 1886, 1,018 lb. per acre; 1887, 1,115 lb. per acre. The acreage of young and old tea plucked over in 1887 was 307 acres and the total yield was 184,695 lb. or 600 lb. per acre, and when it is considered 147 acres of this was only 3-year old tea, the yield may certainly be called magnificent—Mariawatte yield for 1889 over 424 acres was 625 lb. per acre; the original hundred acres gave in 1889 1,094 lb per acre; in 1888 the yield from this field was 1,023 lb. per acre; in 1890 the crop was 321,167 lb. or 757 lb. per acre in bearing, the old 104 acres giving 140,144 lb. or 1347 lb. acre—no manure for two years. In 1891, the yield was over 120,362 lb. or 1,114 lb. per acre; For 1892, it was 417,801 lb. for the estate--the old 100-acre field giving 1,114 lb. This was planted in 1879 and from 1884 has given over 1,000 lb. an acre, the highest return being 1,347 lb. in 1890. The average for nine years is 1,130 lb. For 1893, 1894 and 1895 we may say that the yield of the old Tea is still keeping up to over 1,100 lb. per acre and has every appearance of continuing its large yield, owing to the systematic application of bulky manure, say over 20 tons per acre one-third of estate being so manured every year.”

THE “FORESTS” AND THE “NINETIES.”

IS HISTORY REPEATING ITSELF IN CEYLON
PLANTING ?

The gentleman who wrote the first Essay on Coffee Planting in Ceylon early in the “forties”—a planter and afterwards a merchant (member of a firm still in existence), writes to us from England, under date Dec 23rd:—

“Tea Companies are starting weekly and as each Company comprises three or four properties, very soon 75 per cent. of your tea gardens will be in the hands of Companies, a rather prominent indication of the drift of proprietary public opinion, though in any case the enormous sums paid are inducements which few can allow to pass by. We have had all this in Ceylon before, except that individuals not Companies were the buyers and for tea we had coffee.”

THE RAGALLA TEA ESTATE, LIMITED.

DIRECTORS' REPORT.

Report of the Directors to be submitted to the shareholders at the ordinary general meeting, to be held at 39, Lime Street, E.C., on Tuesday, 29th December 1896, at 1 p.m.

The directors beg to submit their report, and also statement of accounts duly audited for the year ending 31st July last, on which date the balance at credit of profit and loss account, including £840 15s 5d brought forward, stood at £2,035 5s 2d. Against this an interim dividend of 8s per share was paid on 1st July last, and it is proposed to pay, on 1st January next, to shareholders on the Register at this date a further dividend of 4s per share, free

of income tax, in respect of the 3,100 shares fully paid as at 31st July last, making altogether six per cent for the year.

During the year the crops realized in London were:—

Tea, 188,535 lb., at a gross average of 10.42 per lb.
Coffee, 373.020 cwt. do 92s 9d per cwt.

The following are the acreages now in tea on Ragalla and Halgran Oya estates:—

In bearing.		Partial bearing.		Young Tea.		Total.	
ing.							
Acres.	Acres.	Acres.	Acres.	Acres.	Acres.	Acres.	Acres.
623	193	117				933	
The total acreages being as follow:—							
		Ragalla.	Halgran	Oya.		Total.	
		Acres.	Acres.	Acres.		Acres.	
Tea	..	722	94	}		933	
Tea and Coffee	..	—	117	}		73	
Timber	..	73	—	}		385	
Patna, &c.	..	204	181	}		999	
Totals	..	999	392	}		1391	

During the season under review, the directors authorised further expenditure on capital account to the extent of £2,070 5s 4d, as shewn in the accounts, this sum being spent on machinery, buildings, roads and drains, nurseries, and general improvements. A new down draft sirocco drying machine was purchased, together with the necessary appliances. Considerable additions were made to the coolie lines, thirty-six new rooms having been built; new caddies were also built and the old ones and approaches put in order. The item of roads and drains includes the cost of draining 482 acres, this important work being practically finished on the estates, only about 30 acres remaining to be done. The purchase of tea seed amounted to 50 maunds, the cost of this being charged to nurseries account.

As already advised to shareholders, a further issue of 800 ordinary shares of £10 each has been made for the purpose of erecting a new factory on Ragalla estate at a cost of about £7,000, and to provide for other improvements which it is estimated will involve an outlay of about £1,000 to £1,500.

The estimate for Ragalla and Halgran Oya estates for the year are as follows:—

Tea Crop.—275,000 lb. at 9d per lb. nett	10,312
Coffee Crop.—200 cwt. at 90s per cwt. nett	900
	£11,212
Profits on Leaf Purchase, Caddies and Manufacture	500
	£11,712
Less Expenditure in Ceylon for upkeep; rupees, 96,768 at exchange 1s 3d	6,048
Gross Profit	£5,664

The directors having obtained the sanction of the shareholders, also completed the purchase of the Kelburne estate, at a cost of £35,000, as from 1st July last, from which date profit on the working will accrue to the Company, and have every reason to believe that the addition of this estate to the Company's properties will prove of great value. The provision for the purchase was arranged by the issue of 7,000 cumulative 6 per cent. Preference Shares of £5 each, all of which have been taken up.

Under clause 97 of the articles Mr. M. P. Evans retires from the Board, but being eligible offers himself for re-election.

The appointment of Auditors also rests with the shareholders under the articles of Association, and Messrs. Fuller & Wise, the present Auditors, offer themselves for re-election.

C. E. STRACHAN, Chairman.

17th December 1896.

BANANA CULTIVATION IN MADEIRA.

Two varieties of banana are generally grown in Madeira, viz., the dwarf banana and the silver banana. The dwarf banana, the *banana ana*, or Chinese banana, the botanical classification of which is *Musa Cavendishii*, of the order of *Scitamineæ*. Consul Crawford, of Funchal, says that this is the banana most preferred for the export trade, the fruit being much larger and the bunches much heavier than the silver variety of the fruit. The silver is much the more delicate in flavour, and only about one-half the size of the dwarf variety, but it is seldom exported, as the total quantity grown in the island is scarcely sufficient to supply the home consumption, but Consul Crawford says that in all probability if this variety of fruit were better known it would be in greater demand, and, although smaller in size, it has a much better appearance, being of a beautiful bright golden-yellow colour without any of the dark brown spots or patches which usually disfigure the dwarf banana when ripe, whilst, as regards the flavour, it is so much more delicate that those who have once eaten the silver banana seldom use the dwarf or ordinary variety, except for cooking purposes. The dwarf banana forms by far the largest proportion of the total quantity of fruit that is exported from Madeira. The greater part of bananas are grown on the south side of the island in plantations varying from a few plants to many thousands; they thrive best on fresh land sheltered from heavy gales of wind, which are liable to uproot the plants and to damage the bunches of fruit. The artificial manure has been used with great success in their cultivation, but large quantities of effal from the slaughter-houses and the fish markets are also freely used, and this treatment is found to be most beneficial in increasing the weight of the bunches, and also of the individual size of the fruit. The season for bananas virtually lasts the whole year round, the largest export taking place during the winter months when fresh fruit is scarce in England, but the fruit is at its greatest perfection from July to December, being much more abundant, the bunches larger, and the fruit better flavoured. The banana is one of the very best fruits grown in Madeira for exportation, as the bunches can be cut whilst the fruit is green and firm, it sustains comparatively little damage in transit, and the fruit ripens by degrees according to the temperature in which it is kept. The usual method of packing is in large rough wooden crates, holding a dozen or more bunches, between each of which straw is placed to keep them firm and to prevent them rubbing one against another; another method of packing is in baskets made of a coarse native broom, one bunch only being placed in each basket, straw or bracken leaves being likewise placed round them to ensure their safety in transit.—*Journal of the Society of Arts*, Dec. 18.

PRODUCE AND PLANTING.

(From the *H. & C. Mail*, Dec. 25.)

CHINA TEA AND INDIAN METHODS.—The fact that China tea growers and manufacturers are very anxious to acquire Indian methods of manufacture, and that one enterprising Foochow manufacturer has imported machinery, is cheering to the spirits of China tea importers, who believe that with the use of machinery the tea trade of China may be set on its legs again. But the men in possession of the market are not likely to be scared because one or two Chinese growers intend to use machinery. Even if the use of machinery should become general in China, the re-capture of the tea markets would be well-nigh impossible task for the Chinese. Indian and Ceylon teas are so popular, and the planters who grow them are determined to hold the markets against all comers. The use of machinery by the Chinese and the adoption of Indian methods will only lead to further efforts on the part of their British competitors to increase the strong hold they now have on the tea trade of the world. Competition in the production of tea, however, must be expected and provided for. Indian and Ceylon planters who are prudent have recognised the possibility of this competition becoming very keen in the future.

BRAZIL AND TEA CULTIVATION.—The success of Indian and Ceylon tea in the markets of the world has naturally occasioned a little excitement amongst those planting communities whose operations have not hitherto extended to tea. In Brazil they believe they can grow nearly everything. Tempted by the wonderful accounts received of the tea industry of India and Ceylon, and the comparative ease with which tea companies can be floated in London, capitalists and planters are turning their attention, as we stated some weeks ago, to Brazil. It is said that the soil and labour conditions are very favourable to tea cultivation, and that the three provinces of Rio de Janeiro, Minas Geraes, and Sao Paula possess first-rate tea-producing qualities.

COFFEE PLANTING IN MEXICO.—Coffee planting in Mexico is making rapid strides, and, if we except silver mining, coffee growing is the most important industry in the Republic. The sudden development of this industry is ascribable to the coincidence of the increase in the price of coffee in the United States with the decrease in the cost of labour in Mexico, consequent on the depreciation of the silver dollar, which called the attention of investors to the large profits to be made by its cultivation. There is little doubt, however, that, even without these more or less ephemeral advantages, the conditions of climate and soil in Mexico, added to the cheapness of land and labour, are sufficiently favourable to its production to enable Mexican coffee to compete profitably in foreign markets with that of almost any other country. The exports in the year 1895 amounted to 334,059 cwt. valued in the returns at £4 3s 9d per cwt. Nine-tenths of this total was exported to the United States, and the remainder was divided between Germany, France, and England.

SUGAR PLANTING AND THE ROYAL COMMISSION.—It is to be hoped that the Royal Commission to enquire into the state of the sugar industry in the West Indies will not be merely a pleasure excursion. The Special Commission will meet on December 31 at the Colonial Office, and will receive evidence from traders and others interested in the West Indian colonies between that date and January 13, when the Commissioners sail in the "Don" for British Guiana. Their itinerary subsequently will be as follows:—From Demerara to Trinidad, where cocoa as well as sugar will be dealt with; from Trinidad to Grenada and St. Vincent, probably to Barbados. The Commissioners then go north to St. Lucia, Antigua and St. Kitts, possibly visiting Dominica and Montserrat. In Jamaica an extended inquiry will be made. New York is the last place on the list, and the inquiry there will be as to how West Indian trade is affected by the United States tariff and other arrangements. The tour is to last over four months. The constitution of the Commission is as follows:—General Sir Henry Wylie Norman (Chairman), Sir Edward Grey, M.P., and Sir David Barbour to be Commissioners to inquire into the condition and prospects of the West India sugar-growing islands; and Mr. Sydney Olivier, B.A., to be their secretary. Mr. Daniel Morris, D. Sc., Assistant Director of the Royal Gardens, Kew, will accompany the Commission as expert adviser in botanical and agricultural questions. Sir Henry Norman, the chairman, has been Governor of Jamaica and of Queensland, and is therefore well acquainted with both the sugar-growing industry and with the labour problems which have to be considered in connection with it. His Indian experience also is invaluable on questions of administration where native races are concerned. Sir David Barbour shares with him the great advantage of this Indian experience. Sir David is besides, by this time, thoroughly well up in Commissioner's work, having served on the Royal Commission on the Financial Relations between Great Britain and Ireland and the Currency Commission. Sir Edward Grey is an ex-Under-Secretary for Foreign Affairs, and one of the best-informed and most statesmanlike men on the Radical side of the House. In sending Mr.

Olivier as secretary to the Commission Mr. Chamberlain gives up his own private secretary—one who before receiving that post had been engaged at the Colonial Office in the West Indies Department. Finally, for an expert adviser on cultivation questions the Commission will have the services of Mr. Morris, from Kew Gardens.

A VERY TRYING POSITION.—Even the ardent lovers of Free Trade will admit that the condition of most of our sugar growing colonies calls for sympathy. Although British Guiana is developing its mining industry as rapidly as circumstances admit, sugar and its by-products are understood to account for 92 per cent. of the total exports, in Barbados for 94 per cent., and in St. Kitts, St. Lucia, St. Vincent, and other smaller islands for about the same proportion. In Jamaica the sugar exports are still 60 per cent. of the whole, and even in Trinidad, where a pitch lake is a valuable asset, sugar is the largest product. The colonies do not suffer from a lessened power of production or from a falling off in demand. During the last fifteen years the annual production of cane sugar, most of it West Indian, has increased from 2,200,000 to 2,904,000 tons, and the annual consumption by the whole world has increased from 3,830,000 to 7,879,000 tons. The immediate cause of the depression of the trade in the West Indies is, of course, the increased production and the artificially sustained cheapness of beet sugar in non-British countries. The output of beet sugar has risen in the fifteen years from 1,630,000 to 4,975,000 tons. According to the evidence given before a colonial Commission in 1894, the cost of producing both the cane and the beet sugar was greater than the current price. A ton of cane sugar, it was stated, cost £14 15s 10d to produce, and fetched £13 19s 2d, while a ton of beet sugar cost £9 and fetched £8 15s. For the beet sugar producers the loss was turned into profit by bounties from their Governments, amounting in 1894 to £4,290,000. The loss to the West Indian growers might have been saved, nevertheless, if consumption had been given free play. But the bounty-giving Government are also Protectionist in the commoner sense of the term. By protective duties on foreign sugar France helps to keep down the average annual consumption of sugar by each of her inhabitants to 28lb a head. Germany to 26lb a head, and Austria to 17lb a head. Were all the inhabitants of Europe consuming sugar, like Englishmen, at the annual rate of 73lb apiece, our West Indian growers might still make shift to live, but they are very hard hit by a policy which checks the demand for their sugar while it bribes others to sell theirs for less than it costs.

A NEW MANURE.—Mr. F. J. Lloyd, a well-known analytical chemist, has called attention to a result of the use of basic slag as a manure which has not previously received attention in this country. It appears that basic slag, in addition to its phosphate of lime, contains a good deal of free or caustic lime, which acts as a solvent to any nitrogen stored up in the soil in humus or otherwise. Thus, unlike superphosphate, which depends for its fertilising utility upon the phosphoric acid which it contains, basic slag has its greatest effect in rendering inert nitrogen suitable for assimilation by plants. This difference may account for variations in comparative trials of superphosphate and basic slag, which have often puzzled observers by their apparent contradictions. Where there is plenty of nitrogen in a soil in a form fit for plants, superphosphate is usually more efficacious than basic slag; but if there be a deficiency of available nitrogen the converse result is likely to be shown. If this theory be proved beyond dispute it will follow that slag must be regarded as a nitrogen-exhausting manure when used freely without any nitrogenous accompaniment. A French chemist, whose remarks on the subject, received by Mr. Lloyd since he broached it recently at a meeting of the London Farmers' Club, has made some experiments to determine the question, and he states that he found that slag converted

the inter nitrogen in humus (organic matter in the soil) first into ammonia and next into nitrates, in which forms it is readily assimilable by plants.

THE CEYLON LAND AND PRODUCE COMPANY, LIMITED.

The twelfth annual general meeting of the shareholders of the Ceylon Land and Produce Company, Limited, was held at the registered office of the company, 353 and 354, Leadenhall House, 101, Leadenhall Street, London, E.C., on Tuesday December 15. The chair was occupied by James Wilson, Esq.

The Secretary having read the notice convening the meeting,

The Chairman rose and said: Gentlemen, the report of the directors, with statement of accounts for the year ending June 30 last, are presumably in your hands, and with your permission I will take them as read. With your leave I will first take you with me through the figures. One of the main features of the debtor side of the balance-sheet is the total amount of our liabilities, which you will notice works out at £52,000, constituting a reduction of £4,675 as compared with the previous year. It is worthy of notice that during the past two years we have been enabled to reduce our liabilities by £14,000. These figures speak for themselves. On the other side of the account, the capital value of our estates, &c., has been increased during the past twelve months by £3,270—being the capital expenditure incurred in the purchasing and opening of land plus the up-keep of planted area not yet in bearing. Perhaps I may here point out that the company has in bearing 1,555½ acres of tea and 1,137 acres of cocoa and other products, or a total of 2,693 acres. This area divided into the total capital works out under £37 per acre. If, however, we take the planted area, 1,993½ acres under tea with 1,530½ under cocoa, &c., it will be found that the capital value will be £28 per acre, without taking into account either our unopened lands or our reserve fund. There is no doubt that at the prices presently ruling for Ceylon estates, our properties are worth considerably more than what they stand at in the company's books. At the moment the estimated produce account has been reduced to £1,350, and I have every reason to believe that this account will soon be closed at a profit of, say, £100. The other items do not call for any special comment at this time. Turning to profit and loss account the expenditure on crop is much the same as last year. Charges in London and Ceylon mark a reduction, owing principally, to a much lesser debit of exchange. Our gross revenue for the year amounts to £38,913, against £35,838 in the previous period, whilst the net profit figures at £12,125. The past year has been a record year in this respect, the previous best being 1890-91, when, before allowing for the £9,052 written off, the profit amounted to £12,121. The report of the board is so full that it leaves very little for me to add, but you will be glad to hear that our clearings are coming on very well, having regard to the bad weather encountered when a portion of them were planted, but I think, in spite of this, they are to be a success, and our last reports from the island corroborate my view. With Strathisla I am specially pleased, and I look forward to the time when this estate will be very remunerative. At last meeting the chairman explained the then position of the litigation entered upon by the company against their late Ceylon agents. You will now see by the report that this very troublesome matter is at an end. There is no doubt but that we ought to congratulate ourselves upon the successful issue of this litigation, which has caused me an immensity of trouble and anxiety.

TEA.—The Secretary then reported that the intake of the company's own tea created a record, the figures for the crop being 694,000 lb. against an estimate of 655,000 lb. The total crop for 1894-95 was 597,000 lb. against 1893-94, 698,000 lb. The net prices realised

are as under:—1895-96, 6'80d; exchange, 1s 2d; rupee cents, 48½; 1894-95, 7'34d; exchange, 1s 1¼d; rupee cents, 55½; 1893-94, 6'77d; exchange, 1s 2½d; rupee cents, 46½. The total outturn of all tea, including tea made for others and that made from purchased leaf, being—1895-96, 1,286,000 lb; 1894-95, 1,033,000 lb; 1893-94, 950,000 lb. The yield per acre—1895-96, 446 lb; 1894-95, 384 lb. To indicate the progress made during the current year, I may say that to November 15, 1896, the crop totalled 256,000 lb. against 229,000 lb. to same date last year.

COCOA.—The crop for 1895-96 was 2,335 cwt. comparing with an estimate of 1,905 cwt. The crop for 1894-95 was 2,840 cwt; 1893-94, 1,211 cwt. The net price realised for 1895-96 was 66s 6d (estimated); 1894-95, 52s 9d; 1893-94, 58s 4d.

COFFEE.—The crop for 1895-96 was 865 bushels, against an estimate of 875 bushels; 1894-95, 618 bushels; 1893-94, 986 bushels. Net price: 1895-96, 75s per cwt. (estimated); 1894-95, 82s 9d per cwt.; 1893-94, 86s 10d per cwt. I conclude by placing before you the estimates for the current year. The company's own tea, 686,000lb.; total tea, 1,096,000lb.; cocoa, 2,316 cwt.; coffee, 415 bushels.

Mr. T. J. LAWRENCE congratulated the directors upon the favourable state of things as disclosed in the report, and remarked that there was certainly no need of writing the properties down, but rather that they might be written up considerably. He was very glad to see the litigation in Ceylon brought to such a successful issue, and thought that the directors deserved the thanks of the shareholders. He criticised the action of the board in making a call of 10s upon the ordinary shares; but the CHAIRMAN explained that for years many of the shareholders have given opinions that it would be better if the whole of the uncalled capital could be gradually paid up, thus making, in time, all the shares fully paid. This view had commended itself to the Board, and it was hoped that the dividend of 15 per cent. would still be continued, with a bonus added in prosperous time.

The Report and Accounts having been adopted, dividend and bonus declared, Sir Nathaniel A. Staples, Bart., re-elected a director, and Mr. James B. Laurie as auditor, the Chairman moved a cordial vote of thanks to the company's superintendents in Ceylon, of whom he spoke in the highest terms.

Mr. T. J. LAWRENCE seconded the motion, which was carried unanimously.

Mr. L. A. LEWIS proposed a hearty vote of thanks to the chairman and directors for their careful, prudent, and economical management of the company's affairs, which was seconded by Mr. W. E. Thompson Shaipe, M.P., and carried *nem con.* *H. & C. Mail*, Dec. 25.

THE PUBLIC SALES OF TEA.

The monotony of life with those who frequent Indian tea sales has been somewhat relieved lately by a few gentlemen lighting their cigarettes whilst the sale was proceeding. The non-smokers, of course, resenting this invasion of their old customs, and a considerable discussion has been the outcome of it. The following circular from one of the leading buying brokers has been extensively circulated in "the Lane":—

PUBLIC SALE OF TEA
IN THE
LONDON COMMERCIAL SALE ROOMS,
MINCING LANE.

December 1896.

The sale of tea in public sale does not constitute a right for the public in general to bid for tea in that public sale. For public sale is simply "publicity" in contradistinction to sale of tea by private contract.

The assembly of members of the tea trade in public sale is due to the fact that those members find it convenient to meet in a given centre to compete and bid for each successive lot, and facilitate the sale of the enormous mass of tea to be sold in a

quick and expeditious, and, at the same time, fair and public bid for each lot, by which the merchant may know that the best has been done for his interests.

Under the old system of private contract, still in use for re-sale of tea and also for some class of merchant's tea, it would be impossible to deal with the daily sale of 500 to 800 breaks of different teas except in public sale.

In the course of twenty years' attendance in public sales in Mincing Lane Commercial Sale Rooms, I have never known an instance of one of the general public bidding for any lots offered in public sale, and, in fact, the conditions of sale and customs of the trade render this proceeding on the part of the general public impossible.

Before anyone outside of the trade can sample any lots of tea advertised for sale in public sale, it is necessary that two brokers shall certify that that person is a fit and proper person to draw the sale, and with this certificate ceases to be of the general public and becomes a member of the tea trade, the secretary of the Tea Brokers' Association issuing on that certificate a sampling card, without which card as permit no one can draw the tea lying in the wharves and warehouses.

Supposing that one of the general public obtains a sample of tea on show at the broker's office on the morning of the sale, the stipulation of the selling broker's catalogue that he does not hold himself responsible for the correctness for any such sample on show, together with the fact that dry tea requires an admirably trained mind and a delicate palate to distinguish the value of such tea, and, if this stranger did bid, so many questions would be asked as tantamount to refusal to accept his bids, so long as unguaranteed by some well-accepted warranty from a broker of the Lane present in sale.

The contention, therefore, that the public sale of tea in a public room to which the general public is admitted to bid is untenable for, except strangers who are curious only the members of the tea trade ever come to public sale, where each seat in the public sale room is appointed in name to the several firms in the tea trade who compete daily for the lots sold in public sale. Such apportionment of seats, so as to be without dispute or disturbance of the sale (a result solely due after great contention to your humble servant) a contention that we are members of a trade, and have a business right to be undisturbed in the "peaceful carrying out of our business," and free from disturbance or annoyance, which contention was eventually admitted, and fixed seats granted and appointed.

The warrant and weight notes issued against tea sold in public sale and private sale stipulate as sold in public sale, or when sold privately as sold by private sale, and deliverable to the several parties concerned, with the stipulation of public sale or private sale respectively—that the tea was sold in market overt, either with publicity or privately, and according to the conditions of public sale, not in any case that the general public were concerned, but solely that it concerned the members of the tea trade, that the tea in question on the face of the warrant was sold with publicity in contradistinction to sale privately, and always under the conditions of market overt.

Up to the present time the possibility of any question of public sale of tea being disturbed, and annoyance sprung upon the members of the tea trade assembled in the public sale rooms by individuals of this trade who wish to contend that the public sale room is a public room and that therefore the persons coming into the public sale rooms, other members of the tea trade or otherwise, were not bound to observe the accepted customs of the public sale, room for sale of tea by public auction is absolutely futile, for the public sale room is a sale of tea to members of the tea trade only, assembled in public to buy tea in market overt by public auction in contradistinction to private sale in market overt.

It is therefore an impossible contention that a member of the tea trade, who is bound by the conditions and customs of the tea trade, that that member is also one of the general public who is not bound by the rules and customs of the tea trade when assembled together in the public saleroom, and for any member of the tea trade to smoke in the public saleroom to the annoyance and discomfort and causing disturbance to be sprung upon business men assembled to peacefully carry on their business, is contravening the accepted customs that have bound such members into a trade, and up to the present never been attempted.

Such smoking in public sale room causes injury to a delicate palate, and to breathe the nauseating nicotine atmosphere injury to health of other members of the trade present in the sale room.

I therefore humbly crave redress of this great grievance, and that I may be permitted to carry on my business, as heretofore, in a peaceful manner, free from annoyance or injury to palate or health, and therefore my business.

Your humble servant's contention for non-smoking is supported by all the principal firms in the tea trade, both by firms of dealers and brokers.

And I beg that redress for this great grievance may be that a clause shall be inserted in all public sale catalogues absolutely forbidding smoking in the public sale room, and the selling broker in possession of the room must order the removal of such smoker, and any catalogue without a non-smoking clause, the sale of the tea in that catalogue to be invalid.

And failing to obtain fit and proper redress I have no other option but (with great regret) to seek for such legal redress as the law may provide.—I beg to believe me, yours faithfully,

C. FRED HUNT.
(Tea Broker, 55, Eastcheap, E. C.)

—*H. and C. Mail*, Dec. 25,

DUMONT COFFEE COMPANY.

(From the *H. & C. Mail*, Dec. 25.)

The statutory meeting of the Dumont Coffee Company, Limited, was held at Winchester House, E.C., on Tuesday morning. The chair was occupied by Mr. P. R. Buchanan.

Addressing the large number of shareholders present, the Chairman said:—As you are aware, this is a meeting called in compliance with the Companies Act, so that there is really nothing on which we have to ask your decision today. But if I may be allowed to say so, it always seems to me one of the wisest provisions of the Companies Act that the shareholders joined together in any particular undertaking should meet together as soon as possible, so as to understand one another and to know what progress is being made in the new undertaking. Therefore, I need scarcely say that we are very glad to see you here today. In the first place I have to report to you that we have a body of 570 shareholders, and, if I may be allowed to say so, we have a very strong body of shareholders indeed, which is very gratifying to us to feel. We have had our calls most readily responded to; in fact, I may say that although the last call was only due a week ago, practically the whole of the capital has been paid up and is in our bank. (Applause.) We have managed to carry through, under considerable difficult circumstances, the transfer of the property. I say difficult circumstances, because, as you are aware, we have had to deal with Brazil, which is a considerable way off. But we have met with every assistance on the part of the vendors, and I am very happy to be able to acknowledge here the very straightforward way in which they have dealt with this company. (Hear, hear.) I am glad to be able to acknowledge it, and I am sorry there is no representative of those gentlemen present to hear what I have to say. The profits for 1896 you may remember were guaranteed by the vendors. The accounts for 1896 have not yet been made up, so we do not know exactly what the

profits are, nor have we any claim upon the vendors for that money until the accounts are complete, but I am glad to be able to tell you that the vendors have handed us the sum of £120,000 which is at our bank at the present moment, so that these 1896 profits are absolutely secured to the company. (Applause.) We shall have the accounts and expenditures of 1896 at least in March or April. Meanwhile, it is satisfactory to know we have the principal thing—the profit—in our hands. We have applied for a Stock Exchange quotation, and all the papers have been sent in in connection with the shares. They were sent in at least a fortnight ago, and the only thing remaining in connection with the Stock Exchange settlement is the reception of a document relating to the debentures, which is necessary before we can get that settlement. We heard that the document was dispatched two weeks ago from Brazil, and we are awaiting its arrival, so that we expect to get our quotation in a very short time. With regard to the prospects of the company for the future and the 1897 crop, it is not my business to prophesy, and in all my dealings with this company I have not the slightest intention to ever assume the role of prophet. But I think it is better to deal with facts. Well, with regard to the 1897 crop, we have good reports upon it so far. The blossoming has been good, and there is every reason to suppose that it will be a favourable crop. But the directors have turned their attention as much as possible to trying to improve the prospects of the company. At the first moment we took over the direction of affairs we started to see what could be done, and as Brazil is a long way off and only two or three members of the board were acquainted with the work, it was thought it would be very much better that one of our members should go out and arrange with our representatives out there for the working of the estates in the future, and who, when he came home, could advise us to what was the best thing to do for the interests of the company.

As you are aware, Mr. Talbot, our colleague, a considerable personal sacrifice, agreed to go out and to confer with our colleagues in Brazil as to what were the best steps to be taken for the future working of the property. Mr. Talbot, I am glad to say, is here today, and he will tell you himself his experience out there, so it is not necessary for me to dwell on that. So far as we have been able, we have carried out the recommendations made by him. We entirely agree with them, and we have every reason to believe that these recommendations will tend greatly to the benefit and prosperity of the company. You are all aware that the Brazilian methods of curing coffee have been of a somewhat crude description. There is great variation of prices between the Brazilian coffee and Eastern coffee, and even Costa Rica coffee. We are of opinion, and the opinion is shared by those in Brazil, that great improvement could be made in the curing and preparation of the coffee for the markets, and we are taking steps to have these methods, which have proved so successful in other parts of the world, introduced into the works of this company with regard to the curing of coffee. We believe that there is a very large margin of profit between the method hitherto carried on in the Dumont and what we shall be able to bring about gradually. We hope to do a good deal this year, but it is a very large thing, and we cannot do everything at once. However, we have made a good beginning, and are going energetically to work to improve the crop as much as we can. As you are aware, the Dumont Company have to deal with an unusually large crop. I have been assured that the crop we have to handle is about one-tenth of the whole coffee crop which Ceylon produced in its palmiest days; so that gives one an idea of what a big thing it is to handle. There is no doubt in my mind, and in the minds of those who have seen the property and have seen the coffee, that there is a great deal to be done to improve it; and, of course, the more we improve it the better the price and the better it is for the shareholders. Of course, gentlemen must remember that we have to deal with

a crop which, like all agricultural products, we cannot depend upon being always good. We have our good seasons and our bad seasons, and our good prices and our bad prices; there is no question about that, and, consequently, it is pleasant to think that we are in a stronger position, so far as we can judge, than any other undertaking of the kind. We have undoubtedly a magnificent property; there is no doubt of that. In the next place, only 60 per cent of our crop area has yielded a crop at present; therefore we have 40 per cent at least to come, and that places us in a very strong position. Again, we have the great possibilities in the improvement that I have mentioned, which we hope to be able to bring about in the curing of the crop. If we take these things into consideration, we shall see that we are in as strong a position as a company of this kind can possibly be. At the same time, it will be our endeavour still further to strengthen the position of the company by endeavouring to build up as strong a reserve as we can. (Applause.) That will be our policy, and I think you will admit that it is a right and proper one. We have a reserve, as I say, in our plant, we have a reserve in possible improvements, and we shall try to get a good cash reserve, which is the best of all. (Applause.)

The only other point I have to deal with is just to say what we propose to do with the Profits we have now in hand. The directors, after consideration, have agreed that, besides paying the interest on the debentures, which is due on the 31st inst., they will also pay at the same time a dividend at the rate of 7½ per cent. per annum on the preference shares; and they will also pay at the same time a dividend of 10 per cent. upon the ordinary shares. These moneys will be sent out on December 31 next, and will, I hope, be a pleasing commencement of the new year—a year which I sincerely hope will be a prosperous and satisfactory one to us all. That is all I have to report. Perhaps it would be as well for me to say one or two words more; in fact, I have been asked to do so, although it does not come exactly under the head reporting progress. It is on account of this fact, that our company is an exceptional one in this way—that it is the first of the kind that has ever been introduced to the British public, and, consequently, everyone is more or less interested in it. We are all specially interested in it because of the circumstance—I wish to emphasise that fact, although it was stated pretty clearly in our prospectus—that the most thorough investigation that could be given was given to this undertaking before we ventured to bring it before the public. We are satisfied that it is really a good property, and that the statements given were, so far as we can gather, absolutely correct, and we had no hesitation in bringing this company before the public as a good, and sound, and safe one for an investment of this sort. That was our opinion then, and it is our opinion now. We were aware then, as now, that there were a certain number of people who distrusted South American affairs and concerns altogether. Well, I do not know what to say to that. South America is rather a big place, and there are good things and bad things in it, I have no doubt; but as for making any general remark that all South American things must be bad, that does not seem me to a very wise thing. We believe, at all events, that there are good and bad things there as in London. Of this particular undertaking we believe it to be a thoroughly good and sound investment, and that it will be a most satisfactory one to the shareholders. But it can't help being situated in Brazil; for if it had not been there we should not have been here today. Certain people would prefer that it should be on Primrose-hill or in Hyde-park, and think if it would be safer. And so, perhaps, it would; but, so far as I can judge, I have very little reason to doubt that our position in Brazil is as strong and secure as if this property were situated in the United States, on the continent of Europe, or, as a matter of fact, in British India. We can only deal with history in trying to form our judgment, and the

Brazilian Government have never evaded their engagements, but have acted up to them. They hold out to foreigners that freedom of interest which England holds out. They make no difference between foreigners and their own people in the holding of lands and the titles of land and so on. They have behaved in a most liberal manner to British enterprises in the past, and we can only judge people by their record. Their record is good, and I have no hesitation in saying I have the most absolute confidence in the way we shall be treated by the Brazilian Government. It is well to know, when speaking of the Brazilian Government, that really we are under the San Paulo Government. I do not wish to draw distinctions, but as we are in San Paulo we can congratulate ourselves that it is well known to be one of the richest, if not the richest, and the most business like of all the United States of Brazil, and, as I say, it is a matter of congratulation that our properties are situated in this State, and I feel perfectly sure that the good citizens of San Paulo will be too much alive to the advantages to be gained by a closer connection and honorable relationship between the City of London and San Paulo, to endeavour to do us anything but good. So I think, really, the talk about the misfortune of our property being in Brazil is beyond the mark altogether. At all events, I have every confidence in telling you that I believe we shall find we have no reason to regret that it is so situated, and that it will prove itself in the future what it has been in the past—the most profitable coffee-growing concern, not only in Brazil, but in the world. (Applause.)

Mr. Talbot said that, as the chairman had stated, he had visited the estate. With regard to the estate itself, the points they would look to would be its accessibility, the climate, the soil, and the lay of the land. With regard to its accessibility, there was a railway to within 13 miles of it, and then there was a railway belonging to the company, which ran over it, so that the transport of goods was uninterrupted. As to climate, he was only there a short time; but it was very healthy, and it must be good climate, because the coffee, after bearing one very large crop, was in good blossom. The soil was a chocolate loam, and was very free, which was very necessary for coffee. It was a rather sandy loam, and the rain sank in, and yet it was rich, which was easy to see. The lay of the land was very easy. It was gently undulating, and could easily carry off the water. It was about the same kind of lay as Hyde-park. Coming to the coffee itself, it would be asked what the yield was, the vigour of the trees, and the cost of production. The yield of Dumont coffee was about 10 cwt. to the acre, which was a very good yield in the East. With regard to the vigour of the trees, they were grown there in a perfectly natural way. In the East, generally, the top of the tree was 3 ft. or 4 ft., and in some parts of Java they planted shade near the trees. At Dumont the trees grew naturally to a height of about 12 ft., and had no shade and yet with that more exposed system they were very strong and vigorous. With regard to the strength and lasting property of coffee in Brazil, he passed an estate which was pointed out to him as being seventy years old. If the Dumont trees lasted that time, and bore like they did last year, that would be good enough for them. With regard to the cost of the work, that was certainly very cheap compared with anything they had been used to, but he thought the picking had been done too cheaply, and would have to be done rather more expensively in the future. As to the security of tenure he had made a good many inquiries. He had consulted the manager of the English bank at San Paulo and many merchants there, and the conclusion that they came to was that their property was absolutely secure.

Answering a question, Mr. Talbot said he thought they need have no fear of not getting sufficient labour. In reply to another shareholder, the Chairman said he had no means of knowing whether the £120,000

was earned last year. His own private opinion was that £100,000 had been earned this year. They would do all they could to improve the interests of the company.

This concluded the business of the meeting.

THE DEVELOPMENT OF CEYLON : LAND FOR TEA AND OTHER PRODUCTS.

An old planting resident—one who has travelled about the country as much as anybody we know—thus treats of the reserve resources in land suitable for tea and, we suppose, other products :—

"I do not think anyone in Colombo even quite realizes the extent of land in Ceylon suitable for tea. When last in Surveyor-General's Office he showed me plans of such land already surveyed in blocks amounting to 200,000 acres, and this only forms a *small* portion of the available, and does not include the splendid plateau from Horton Plains onward, which had we known was to be locked up, the railway to Uva would never have been suggested. I do not say it would be wise to extend, but it is less wise to drive away capital and capitalists to Wynaad and elsewhere. Overproduction is, of course, possible in anything. We have it even in wheat, corn, meat, and silver, &c. Meanwhile it affords work for the many. It is our duty to cultivate and trust Providence that mouths will increase. Adam did as he was told and didn't worry about markets!"

Between Maskeliya, Balangoda and Bambarabotnwa there are large forest reserves; on the Western slopes of Adam's Peak, there is an immense extent of Crown land suited to tea, and lower down to cacao, Liberian coffee, and even coconuts. Our "Handbook and Directory" gives much information on the subject. But first we should like to see the Crown reserves between Dimbula and Uva unlocked, as we mention elsewhere; because these are specially suited for the growth of the finest teas, and the railway wants traffic.

CEYLON TEA IN AMERICA.

Under the heading of "Club Echoes and Tea Leaves" by "an ex-Upcountry Resident" on page 545, a report is given of an interview with our American Tea Delegate, in which reference is made to a circular sent out by a Boston firm. The following, we believe, is the circular :—

GENERAL LETTER TO CUSTOMERS.

The tea growers of the British Colonies, India and Ceylon, finding the markets for their productions of tea limited to consumers of the Congou or English Breakfast variety, and wishing to open up new markets have formed themselves into an Association, and for some time past have had a duty imposed on their export, the amount so collected being passed to a fund to be expended in advertising and such other means as will increase the consumption of these growths.

For such a purpose, naturally the largest tea consuming market using the smallest quantity of their tea would be sought as the best field for their labour. The United States offered this, the consumption being only about 10 per cent. of the breakfast sort, while more than two-thirds of the 90 per cent is green tea, the balance being Colong which, while black in dry leaf, is only slightly fermented, and resembles more in drink the green tea, thus showing the United States to be consumers of light liquoring, bright aromatic tea, rather than the black, thick liquoring type acceptable to the tea consumers of the British Isles,

Hence, the United States has been selected, a Commissioner appointed by each association, and the funds placed in their hands for disbursement. The advertisements extolling the virtues possessed by only India and Ceylon teas show these agents are at work.

While we are not advocates of this variety of tea, having no desire to change the popular taste (preferring to cater to that, rather than adopt any educational methods) we feel that the time is ripe for us to be represented by a package of this type of tea, that we may secure part of the ten per cent of consumers using the variety, and benefit by such demand as is influenced by the funds of the two associations.

We now offer such a tea under name * * * as we believe will prove more acceptable to consumers of the variety than any tea of its kind yet placed on sale, being of higher quality, than any other India and Ceylon tea on the market. Wholesale price for this tea is 40c. per pound f. o. b. Chicago—41c. per pound freight prepaid.

The "Orange Pekoe" will be packed only in half-pound lead packages, and in boxes of 18 and 36 lb. net—we think attractive sizes. The label we consider strikingly handsome. We recommend 60c. per pound for retail selling price, believing the margin shown is enough, while such quality should induce business at the price as against the inferior teas of English packing now being pushed for sale.

TEA-PLANTING AND CROPS (BY A CONTEMPORARY).

NOT A WORD AGAIN ABOUT MANURING !

Discussing the prospect for tea exports in the future, our evening contemporary writes as follows :—

"Extension is taking place chiefly in Uva, the Kelani Valley, Kalutara, and Sabaragamuwa, and the number of new clearings in Dimbula, Dikoya, Maskeliya, Ambagamua, Kotmalie, Hewahetta, Hantana, Pussellawa and in all the northern districts is comparatively trifling and insignificant. It may suit some people to ignore these facts or to minimize them; but we do not believe in half-truths or the self-satisfied morality which encourages them. We are not sorry that there is no prospect of a further large increase in the output of tea from Ceylon. If there were any prospect of such it would be disastrous for us. There is quite enough tea opened and being opened, as it is; and it will require all the efforts which we can command to maintain prices at a paying level. Let us, therefore, be thankful that further expansion will be on a moderate scale, such as the markets of the world will be able to take off without very great difficulty."

Not a word, it will be observed—not even the shadow of a reference to such an insignificant subject as Manuring ! But a curious commentary on "further expansion will be moderate," is the statement in the same paper that in Balangoda district, one firm is about to open 2,500 acres with tea !

We trust Indian tea proprietors will take note of the latter fact and also of our "Manuring" correspondence before they feel encouraged by our contemporary's wilful minimizing of the future of tea in Ceylon, to put in additional large clearings in North and South India.

COFFEE PLANTING IN BRAZIL.—Mr. Talbot's exposition of the way in which coffee is worked in Brazil, is very interesting; while his figures are distinctly encouraging to all interested in the Dumont Company (page 541).

COFFEE PLANTING IN SUMATRA.

Mr. W. Turing Mackenzie who has come to Ceylon on a visit from the Straits gave an *Observer* representative an interesting account of coffee planting in Sumatra. Lately Mr. Mackenzie has been travelling in Perak and Selangor. The coffee that he saw there he described as doing very well and he has a great opinion of the country remarking, "I would chuck up my Sumatra land tomorrow to take up land on the Government terms there, but the climate of Sumatra is very much better, at all events than that of Perak—witness the churchyard at Taping which speaks for itself. It is excellently well furnished mostly with men under 35 years of age, malaria being the great scourge. But to return to Sumatra, I have 4,300 acres of land there part of which I am about to open. For the most part the land consists of jungle, but a small portion has been planted with tobacco and another small portion with coconuts. As regards labour I consider the supply to be the best I have seen out of Ceylon."

"Which, according to some people," interpolated the pressman, "is not very good."

"Well," replied Mr. Mackenzie, "I was a good many years in the island and I never had any difficulty, though I heard a good many complaints. Our labour in Sumatra is indentured labour from Java. It is easy to manage, the coolies being under the direction of a Mandor, which is the same thing as a Kanganu. We pay 6 dollars a month for men and 3 dollars a month for women, which, roughly speaking, is about R12, and R6 respectively. You have to give 60 guilders (a guilder is about 1/8d) advance per head. Thirty guilders are recoverable from each cooly, and thirty guilders has to be written off capital account. Of this latter, 20 guilders goes to the cooly broker in Samarang and 10 guilders go for the cooly's passage and expenses in reaching the estate. Every cooly is registered before a magistrate, he is measured, and his name, age, village and special marks taken. Each cooly has his own paper, describing himself and when he is employed that paper is locked up in the estate safe by his employer. Do they ever bolt? you ask? Not very often. On each estate there are private police, who are also employed as *tapal* runners, &c., and they generally know when a cooly is going to bolt. If they find out he is handcuffed and sent to the Controller who gives him 12 days for the first offence and one month for the second offence. It is in the Sardang district of the Island that the coffee is planted. There is an Italian planter whose four years old coffee last year gave 10 piculs an acre equal to 1,335 lb., an acre. On another estate well-known to me owned by a German, and on which the coffee will be 4 years old next year the crop for the current year was 8½ piculs an acre. On this German's estate I know of coffee that was picked, dried, cured and despatched to Hamburg before the trees were 20 months in the ground. It is the wonderful richness of the soil, and it is hardly to be believed.

"Does this not injure the trees?"

I have heard people say it does; but I don't believe in that argument. We were told not to take the bark from our cinchona trees until they were so many years old and so on but the men who waited for the market found that the market went away from them. When nature offers you a thing, take it, don't wait for the "to-morrow." She may then give

you a slap on the face. What about life in Sumatra? It is not rougher than life was in Ceylon twenty years ago. There are three Englishmen and Scotsmen planting in the Sardang district.

VARIOUS PLANTING NOTES.

CEYLON LAND AND PRODUCE CO.—The Chairman's statement to the shareholders of the Ceylon Land and Produce Co. at the twelfth annual meeting shows a very satisfactory state of affairs. The liabilities of the Company in pursuance of the policy hitherto pursued, have been materially reduced and in the matter of gross revenue the past year has been a record one. We think the policy of the Directors in gradually calling in the capital so that the shares may be fully paid up, is a sound and wise one, inasmuch as it removes all element of dubiety about the position of the holders. We hope, with the Chairman, that the dividend of 15 per cent. will still be continued (page 539).

CEYLON TEA IN AMERICA.—On another page Our London Lady Correspondent under the heading "Club Echoes and Tea Leaves" reports an interview with Mr. William Mackenzie on his return to London from America in the end of last month. It contains much that is gratifying and we are proud of the success that has so far attended the energetic labours of our Tea Delegate, who, we are glad to know, is "well and hearty." It is extremely pleasing for instance to know that "in Philadelphia the firm which ranks second or third highest among tea houses in America is working in conjunction with us;" that "another firm in Boston which claims to stand equal with the one just mentioned" has intimated to its customers "that they had never hitherto pushed Ceylon or Indian teas, but now having discovered others were doing so they intended an alteration of their previous policy;" that "Ceylon tea is largely in most of the blends offered to the public;" and that excellent work was done on behalf of our staple product at the annual food show by a lady who was formerly resident in Ceylon. All this, we repeat, is very gratifying indeed and we rejoice at it; but does not the fact that firms such as the one mentioned are being obliged to handle our teas because others are doing so, go to support our contention that the time is approaching when we must treat all traders alike either by advertising or subsidising direct so that all may have an equal chance of participating in the benefit accruing from the local fund? We have only warm approval for expenditure in connection with exhibitions and Demonstrations. What we contend is that there must be a limit to special subsidies and grants, and that that point will ere long be reached both in America and Russia when private enterprise and trade competition must be allowed to take its ordinary course. If advertising in the press, as Mr. Mackenzie says, must be followed up by other means of bringing our teas before the public, surely the dealers might fairly be expected to do that seeing that we save them the expense of the former. The depreciation of newspaper advertising by our Commissioner at this time is rather inconsistent with his report a little while ago of a Canadian Firm who had been got to advertise Ceylon tea in over 300 newspapers. We plead for similar inducement to be given to all firms willing to follow this good example,

HOW TO PUSH CEYLON TEA IN AMERICA.

MR. WM. MACKENZIE OF THE CEYLON TEA ASSOCIATION

has but just arrived back in this country, having only landed last Saturday (Dec. 18), and looks well and hearty after his recent American visit. I found him conning over the editorial in the *Overland Observer* of the 25th November last, and not, as I presently discovered, at all agreeing with many of the sentiments therein expressed.

"It's an entire mistake in my opinion," he observed, "to suppose as this article has it, that advertisement by ordinary methods will be sufficient by itself to push our teas in America. Assisting agencies already on the spot *must* be united with newspaper advertisement. In America every kind of industry is put on the market by some such means as I have indicated. Agents having Ceylon and Indian teas to push, go to the large grocery shops, or stores as they are called over there, and they get the permission of the heads of such firms to establish demonstration stalls on the premises, the expenses being paid by the agents themselves. Girls are put in charge, whose business it is to offer customers coming to buy other goods a cup of tea. Such an offer you will easily see is welcome to most people; they accept the invitation, and listen to what the teamaker has to tell them as to the good qualities of the tea, how best to make it for themselves and so on. Then they probably buy a pound to take home with them, and on that pound there is a profit to the store proprietor. The people come back for more and by and bye in that store Ceylon and Indian tea are kept, and given a good place on the counter—not stuffed into any odd corner where no one will ever see it or think of buying it, but put in a prominent position so that the public get to know that tea is certainly to be had in the particular store in that particular street.

"In the 100 millions lb. of tea drunk in America," continued Mr. Mackenzie, "not more than one-fifth is black tea—all the rest is green, etc., imported from Japan and other places. It is to secure for ourselves that one-fifth we have to aim. At church fêtes which are extremely popular over in America, large firms put up stalls for the sale of tea, where demonstrations are given, and the same sort of thing is done in theatres and many other public places, even when they only pay half or a quarter of the expense it pays us to do this. As for jealousy, if any such exists among the Colombo merchants, it must be remembered that they do no missionary work themselves. After all we do not, as an association, exist for the tea merchants, but for the tea growers; and in a case of this kind, though it might be very pleasant to indulge in sentiment, we have to consider the question on the main issue. The method of advertising which gains most customers for Ceylon and Indian teas, will be the one which will eventually benefit all most. Paper advertising alone is perfectly useless. You may talk to people as long as you like about the merits of your tea, but as long as they do not see it, don't know where it is to be got, or how

to use it when they do get it, you will do practically no business with them in America. What competition we meet with there is healthy? Let people push their own blends, and they will push Ceylon tea along with them. Ceylon tea is largely in most of the blends offered to the public, and the more blends the better."

"Yes," said I, "one of the great tea blend people told me the other day *they* did not care for Lipton." "If there were *twenty* Liptons in the market," said he, "the better for us."

"Exactly," said Mr. Mackenzie, "that's precisely the idea, and only agents already actively engaged in pushing tea on the spot will do for us. The more trade the better for all. We must use the methods most expedient, and that shortsighted policy of keeping one another out lest one gets a slight advantage over his neighbour is injurious altogether."

"In Philadelphia now," resumed Mr. Mackenzie, "the firm which ranks second or third highest among tea houses in America, are working in conjunction with us. At the Annual Food Show there, for example, a fortnight ago, there was a lady—an old Ceylon resident by the way who, consequently, has some practical knowledge of tea growing—who was working away busily all day long with fourteen girl assistants, at the making and giving away of cups of Ceylon tea. That's what I call a good advertisement. Another firm in Boston, which claims to stand equal with the one just mentioned, has recently sent out a circular of an apologetic character to its 16,000 grocer customers to the effect that they had never hitherto pushed Ceylon or Indian teas, but now having discovered others were doing so, they intended an alteration of their previous policy. Again Siegel Cooper had six of these demonstrations of Ceylon and Indian teas going on at one time in New York and four others in their Chicago branches while an English firm gave no less than eighty of these object lessons lately. In short," summed up the Ceylon Commissioner, as I bade him good-bye, "if the *Observer* wants my opinion you have now got it on this question. Advertising by the press alone is perfectly useless. The main point to be arrived at is the selling of Ceylon tea. On that, I suppose we are all agreed. Then that can only be done on the lines I have mentioned. At present the American market is well, perhaps, overstocked with tea, and probably less this year will be taken into the country than has been the case for a short time previous to the Chinese and Japanese war. We can make little impression on the market as regards green tea, but we may secure the trade in black teas if we go the right way to work."

BROWN-PATERSON.

THE TEA SITUATION IN AMERICA.

The *American Grocer* of Dec. 9th, considers the tea situation a strong one, for the following reasons:—

The season at most of the China and Japan tea ports is over, and we now are enabled, through a compilation made by a prominent firm of tea brokers, Messrs. James and John R. Montgomery, to present the statistical position of tea on December 1. At that date there were afloat eight vessels carrying 9,146,333 pounds of tea, due here from now forward until March 15, 1897. The shipments include 3,462,385 pounds of green tea, 2,678,723 pounds of Japan, 2,115,825 pounds of Formosa, 275,280 pounds of Foo-chow, and 614,400 pounds of Congou. The situation

may be summarized as follows: [We only give the totals.]

Statistical position of Tea for United States and Canada on December 1, 1896)

	Total lb.
Total afloat to December 1, 1896	.. 9,146,333
Receipts to December 1, 1896	.. 51,057,858
<hr/>	
Total shipments advised by mail	.. 63,204,191
<hr/>	
Leaving to be shipped	.. 19,145,809
Estimated supply, Season 1896-97	.. 82,350,000
Supply, Season 1895-96	.. 105,300,581
<hr/>	
Afloat, December 1, 1895	.. 8,362,658
Receipts to December 1, 1895	.. 75,308,959

Tot. shipm'ts adv'd by mail, Dec. 1, '95 .. 83,671,617

The above shows a deficiency for 1896-97 of about 23,000,000 pounds, a loss in supply quite sufficient to account for the recent advance in cost.

From now on, the consumption should be much better than prior to the election, besides which dealers, both wholesale and retail, will carry a more liberal stock, as they have confidence that the future will be reasonably free from the factors which have so disturbed business since 1892. Then there is a prospect for the imposition of a tax on tea and coffee, as well as an additional tax on beer, and this ought to stimulate demand. There is a growing sentiment that taxes in the direction named are the easiest way to give the Government more revenue. The tea position is a strong one.

There ought to be encouragement in the above figures to ship Ceylon tea to America?

ORIENTAL ESTATES COMPANY.

The adjourned ordinary general meeting of the Oriental Estates Company, Limited, was held on the 17th Dec., at Winchester House, Old Broad-street, Mr. Quintin Hogg (the chairman of the company) presiding.

The Secretary (Mr. H. GREY) read the notice convening the meeting.

The CHAIRMAN said the first business they had to transact was to adopt the accounts and report. They were formally received at the last meeting, but not adopted. He then proposed their adoption.

Mr. A. W. CREIGHTON seconded the motion, which was put to the meeting and carried.

An extraordinary general meeting was then held for the purpose of receiving and adopting the committee's report with regard to reducing the capital of the company.

Mr. MACASKIE, in moving the reception of the committee's report, said it would be within the recollection of the meeting that in July last the committee were appointed when a scheme had been put forward which did not, at all events, satisfy the preference shareholders. They were invited to confer with two representatives, Mr. Slaughter and Mr. Touch, who represented the ordinary shareholders with the object that they were aware of. He could not help recalling, believing as he did, in the scheme which they had arrived at, the position of affairs today. The preference shares were at that time about £3 10s., or perhaps less in the market, but the difficulty that confronted the preference shareholders was perhaps chiefly that they had no control over the operations of the company by reason of the state of the capital account. The control rested with the ordinary shareholders, which was very unfair to the preference shareholders, because, according to their information, the bulk of the ordinary shares was held by comparatively few persons. Under those circumstances it was perfectly clear that the power of withholding dividends for a time, or indefinitely, rested with the directors and the majority of the ordinary shareholders. For that there was, at that time, no cure. Whatever a court of law might have said if the directors had chosen to declare dividends, he was quite certain that no court of law in the world would have ordered the directors, against their own judgment, to declare them, and therefore

they were face to face with the probability that the preference shareholders would have to go without dividends for five, ten, fifteen, or twenty years. That was a very uncomfortable position, and although he was very far indeed from saying that the ordinary shareholders would have used the power they had for their own interest against the company at large, it was, at all events, an uncomfortable position for the preference shareholders to be in. Accordingly, the committee set themselves to find some way of reconciling those conflicting interests by means of mutual concessions. He did not propose to discuss the details of the report, but there was one consideration he would like to bring before the meeting, which he did not think ought to be absent from the minds of the shareholders. He said little or nothing about the way in which they had treated the arrears of the preference dividends, because, after all, that was a comparatively small matter. He said nothing about the provision by which the preference shareholders acquired the controlling power over the operations of the company. That, of course, was obvious and patent upon the face of the report; but there was this consideration, which certainly never entered the head of anyone of the three gentlemen who represented the preference shareholders, but he was bound to say operated very powerfully upon the minds of Mr. Bishop, Mr. Lawrence, and himself, and that was that they gave up 18 per cent. of the capital, and, of course, 18 per cent. of the profits, to be earned by the ordinary shareholders. What did that mean? Before assuming the scheme did not go through, they were entitled to a preferential dividend of 7 per cent. To pay that they required, roughly, £14,000. The effect, therefore, of the scheme was that as long as the trading profits of the year were £14,000, or under, the preference shareholders were giving up to the ordinary shareholders about 18 per cent. of their £14,000, which the articles would have given to the preference shareholders. That was to the advantage, of course, of the ordinary shareholders. But, supposing the profits upon the year's trading exceeded £14,000, then 82 per cent. of that excess over £14,000 went to the present holders of preference shares, and in estimating whether or not the right to 80 per cent. of the excess over £14,000 was or was not equal to, or, as he thought, much more valuable than the concession that the preference shareholders were called upon to make, they must look at the results of the last six or seven years' trading. He had taken the trouble to go through the balance-sheets during the last six or seven years, and the results from the preference shareholder's point of view were very remarkable. He did not know whether they should assume that the results would in future be worse than they had been in the past, because in 1892-93 they suffered a good deal from the effects of a disastrous hurricane, which would not occur again, perhaps, for ten or eleven years. If they looked back at the balance-sheets, they would find that in 1890 the profit upon the year's trading was over £26,600—that was to say, £12,000 in excess of the £14,000, of which the preference shareholders would take about 80 per cent. In 1891 the trading profits were £27,000, in 1892 they were £28,000, and then came the year of the hurricane, from which they suffered a loss, and when there was a profit of only £14,000; but still, they would see that the advantage would have been in favour of the preference shareholders. He ventured to think that those figures, if they at all represented what they were likely to meet with in future, were in favour of the preference shareholders.

Mr. CLAUD BISHOP seconded the motion, which was supported by Mr. LAWRENCE, and carried unanimously.

The CHAIRMAN said the next business was to discuss the report of the committee, and before putting the clause seriatim he wished to say that he very cordially recommended the adoption of the report. He did not at all admit an entire difference in the two reports, but he contended that the second scheme was infinitely preferable to the first. If they took the average profits in the past two years and dealt with them on the basis of £20,000, the scheme, with the two modifications which he recommended, it would be seen was not very different

from the scheme of the committee. Roughly speaking, the preference shareholders got four-fifths, while the ordinary shareholders got one-fifth of the unified stock. They also got the advantage which they would not have got under the first scheme, namely, scrip not bearing interest for the unpaid portion of their interest. With regard to the question of strengthening the board, the directors had no objection to welcome anybody who was put forward by the shareholders; but it appeared to him that, as it was suggested that the committee should be kept alive for the purpose of carrying out the recommendations in the report, it would be a very good plan to refer the matter to the committee, and the board to recommend one or two names as members of the board.

Mr. Wood contended that the scheme was unfair to the ordinary shareholders, while other shareholders maintained that it was unfair to the preference shareholders.

After some discussion the following resolutions were carried:—(1) "That all the issued shares of the company, being fully paid, they be and are hereby converted into stock." (2) "That the capital of the company be reduced from £566,700, consisting of—stock resulting from the conversion of 40,992 preferred shares of £5 each, £204,960; stock resulting from the conversion of 223,092 ordinary shares of £1 each, £223,092; 19,028 preferred shares of £5 each, unissued, £95,140; 33,608 ordinary shares of £1 each, unissued, £33,608—£566,700; the stock of the nominal amount of £250,000 and that such reduction be effected by cancelling all unissued shares, and by writing off and cancelling, as being unrepresented by available assets, £182,602 of the stock resulting from the conversion of ordinary shares, in such a manner that the reduction of £182,602 shall be borne as between the several holders of the last mentioned stock, rateably in proportion to the amount of such stock held by them respectively." (3) "That the name of the Company be changed to 'The Anglo-Ceylon and General Estates Company, Limited.'" And a further resolution was agreed to altering the articles accordingly.

Mr. RADFORD proposed that the meeting recommend the election of Mr. Macaskie and Mr. Bishop, to whom they were all greatly indebted for formulating so excellent a scheme.

The CHAIRMAN stated that the directors had not the slightest objection to the appointment of the two gentlemen nominated, but he suggested that it would be better to leave the matter in the hands of the committee and the directors.

Mr. RADFORD assented to this suggestion.

Meetings of the preference and ordinary shareholders then took place, at which the agreement modifying their rights and privileges to give effect to the resolution was agreed to.

The proceedings terminated with a vote of thanks to the Chairman.—*H. & C. Mail*, Dec. 25th.

THE COMING CEYLON TEA CROP.

A correspondent reports that he hears the Planters' Sub-Committee give the Estimate for 1897 at a little over

117,200,000 LB.

We notice on the other hand that Messrs. Forbes & Walker, who are generally very accurate—and whose praise as compilers of tea statistics our contemporary has just been singing—estimate the present year's tea crop or rather export at

120,000,000 LB.

And this is just the figure we considered likely when a planter said we were to be 122 million lb. Messrs. Forbes & Walker give the total export for 1896 at 108,141,412 lb. Their Estimate for 1897 120,000,000 "

Estimated increase 11,858,588 lb. The "Customs" total for the Export of 1896 is 110,095,358 lb.

TEA PLANTING IN CEYLON AND CROPS IN THE FUTURE.

We direct the attention not only of readers of our journal in Ceylon, but of the not a few planters who get our daily or weekly issues (and the still larger number who read our monthly) in India, to the letter signed "Festina" further on. It comes to us authenticated by a responsible proprietor of estates, who has had prolonged experience both as coffee and tea planter in Ceylon; and he shows very clearly that those who would minimize the future tea crop resources of Ceylon or speak of our getting near the maximum export are greatly mistaken. The difference between the cultivated and total extent of the tea plantations in private hands in Ceylon, must amount to over 300,000 acres; and if we strike off even *two-thirds* of these reserves as unfit for profitable cultivation, we must still have fit for cultivation, an aggregate of 100,000 acres spread over all the tea districts already taken up. Of course the planting up of such reserves will depend on the encouragement offered. What our correspondent says about manuring is also worthy of very serious consideration.

BOTANICAL AND AGRICULTURAL PICKINGS.

The death of

BARON FERDINAND VON MUELLER

leaves a wide gap in the botanical world. His biography, it has been said, will be a history of Australian botany during the last four decades. The number of publications of the Baron is stated to be something enormous, though many individual works was sufficient to make the reputation of any man. Referring to his last hours his co-worker (T. O. MacLennan) writes:—"The Baron had at least his one great wish fulfilled, namely that he should die in harness. His illness only lasted a fortnight, and for the first week he would insist on getting up and going to his office though only for a short time. His death was, no doubt, due to an affection of the brain due to constant study, worry and insomnia, to which might be added, almost total want of bodily exercise. He passed away (Oct. 10th) quite peacefully without any apparent pain." This passion for work, strong even on the eve of death, reminds us of the last days of our late Director of the Peradeniya Gardens, who like the great Australian botanist, died in harness.

There has been some plainspeaking with reference to the alleged purchase by the Secretary of State of £10,000 worth of

CARROT SEED

for famine relief purposes in India—to sell to the ryots at cost price. A native Indian paper pronounces this an "atrocious piece of jobbery." The *Indian Agriculturist* referring to the transaction says that "even if the statement made in the *Pioneer* that the local Government is responsible for the purchase, is correct it is clearly unjust to charge the India Office authorities with an atrocious piece of jobbery. Tomfoolery, we fear, it is; tomfoolery in a somewhat unexpected place."

The "Agriculture Ledger" series of pamphlets and leaflets issued by the Government of Bengal is a most valuable publication as each fresh issue only tends to prove more conclusively. In a late pamphlet on cattle disease reference is made to local native remedies. They are not to be despised, says the writer, and though not scientifically explained, these remedial measures tried by the experience of ages, may not in some cases be without scientific foundation, and at any rate deserve to be investigated before being discarded. Speaking of native medicinal herbs and plants, the writer goes on to say that a systematic and patient investigation will not fail to yield results of some value,

There is without doubt much in native treatment of cattle disease even in Ceylon worthy of investigation and a qualified Veterinary Surgeon should be able to do some useful work in this connection.

ORYCTES RHINOCEROS

has of late being doing great damage among the coconut trees in Cochin. The Superintendent of the Calcutta Museum recommends the following treatment. Searching for larvae and pupæ and destroying; capturing the adults by attracting them to fires; cutting down the affected trees and burning to ashes. The Agricultural Department, Madras, suggests injecting the holes made by the pest with kerosene oil, or a strong soap solution.

Under the head

"HORTICULTURAL NOTES"

in an Australian paper occurs the following memo. "Mr. Chamberlain's collection of orchids is worth from £15,000 to £20,000. The collection of the Dowager Empress of Germany is worth nearly double that of Mr. Chamberlain. Miss Alice Rothschild's collection of roses is valued at £10,000, while Mr. Astor (the liberal donor of £2,000 to the Indian Famine Relief Fund) paid £1,500 to an English grower for the stock of a single variety of rose, which is said to have been introduced into Europe from Damascus by the crusaders, appearing first in England in 1306.

RHEA*

Mr. W. Gollan, Superintendent of the Government Gardens of Saharanpore, writes:—"I suppose like myself, you are often bothered over rhea. Mr. Ribbentrop, Inspector-General of Forests, published a note upon it in the *Pioneer* a few weeks ago, and since its appearance I have had no end of letters about it. In his article he mentions £7 per ton as a paying price for the dried ribbons landed at Bombay. I dare say the Rhea Fibre Syndicate would like to purchase them at that figure: considering it takes R75.4.0 (£ 4-7-9½ at 1s. 2d per rupee) to carry a ton of rhea from Saharanpore to Bombay, I do not see where the grower's profit comes in. Rhea is one of those erratic plants that will grow or exist anywhere in India, but to make it produce even one good crop of wands in Upper India districts, it requires the richest of soils, further enriched with expensive dressings of manure. Our highest outturn is a ton of wands per acre weighed, after stripping off the leaves, which yield from 3 to 7 per cent. of ribbons, according as they are well cleaned and scraped or not; so it takes from three-and-a-half to seven acres of land to produce a ton of ribbons, which will, according to Mr. Ribbentrop, fetch £2.12.2½ to the grower in Bombay after meeting freight. After the grower has paid land rent, irrigation charges, cultivation, cost of stripping the ribbons from the wands, drying, packing, delivery to railway station, etc., I greatly fear his £2-12-½ will be *non est*; in fact, at Mr. Ribbentrop's price, he will have to draw upon his banker pretty considerably after spending the above to even produce his ton for which he is to receive £7 at Bombay."

It will be seen from the above letter that there is no profit to be made in the cultivation of rhea in the North-West, unless prices go up considerably, and it is probable that, at the present rates, rhea cultivation in Assam will not pay. So far the Rhea Fibre Syndicate do not appear to have quoted f. o. b. rates for Calcutta.

It would be as well for members cultivating rhea to note that though plantations are made on rich soil, further enrichment is necessary to raise a remunerative crop.—*Indian and Eastern Engineer*, Jan. 16.

COFFEE STENOPHYLLA.

There are now three specimens of this variety of coffee growing on the Nilgiris, one of which is at Burtiari and the other two in private gardens. They

are apparently the only specimens of this variety left in Southern India, and were kindly sent us by Mr. Cameron of the Bangalore Lal Bagh, as they were not found to thrive there at all. The U. P. A. would do well to obtain a consignment of the seed through the Kew Gardens. The following details regarding this variety of coffee is taken from the Kew Bulletin, p. 167, of 1893:—

The narrow-leaved "wild," "bush," or native coffee, is sometimes found wild on the hills, and is more often cultivated by the natives than the Liberian. It grows very freely, and appears to yield quiet as much as the Liberian but it is somewhat longer in coming into bearing. Both the natives and French traders at Freetown say that it has a superior flavour, and prefer it to the Liberian. In fact, latterly, a certain amount has been exported to a wholesale French dealer, who is said to sell it at 4 francs 50 centimes a lb. as "best mocho." Considering that it is worth in Freetown about 6d. a lb., this should be a fairly profitable trade, and a trial shipment should be made by the English merchants to find out exactly what the market value in Liverpool would be. The plant appears to thrive best on the higher hills about Sierra Leone, on gneissose or granitic soil, and can be grown from 500 to 2,000 feet. Probably it may be grown both above and below these limits. — *Planting Opinion*, Jan. 9.

THE FAMINE AND THE TEA INDUSTRY is the subject of editorial remark in the *Indian Planters' Gazette* to hand. Our Indian contemporary characterises the *laissez faire* policy of the Supreme Government as suicidal in the extreme and fraught with the most dire consequences. Dealing with the famine as affecting the tea industry, the *J.P.G.* says:—

To tea-planters, specially those in the Brahmaputra and Surma Valleys, the matter is one of very grave moment. How are they to feed the enormously large labour force dependent on them? Leaving aside monetary considerations, where are the vast quantities of *dhán* the rice which will be required to feed some 700,000 souls to come from? Further, considering the deficient means of communication, how are regular supplies of food, in quantities, to be implicitly relied on? If the Railway, Steamer and Carrying agencies fail in their transit arrangements, and Planters hold no guarantees that their food stocks shall arrive punctually to time, how can Managers of Gardens rest satisfied that they will always have a sufficient stock of rice in hand to meet all demands? In the event of a deficiency, they will not be able to fall back on local supplies for, practically, they would, in such case, have to be reckoned upon as *nil*. At the best, local supplies are wholly inadequate to meet a severe strain. The mercantile tea agency houses, as well as the planters dependent on them for their rice supplies, are having a most anxious time of it. The capital to purchase stocks of paddy and rice is not wanting but the question is how are continuous and sufficient supplies to be kept flowing into the tea districts of Assam, Cachar, and Sylhet to meet the enormous demands. The scarcity will in all probability extend over a period of six or seven months yet to come, so that the trouble is now only commencing. Whether the Indian Tea Association are taking their cue from the Indian Government and waiting and watching events, we cannot say; but as yet it has taken no action in the matter, so far as the outside public are aware. If the advice of planters is taken and faithfully followed, the responsibility will be taken off the shoulders of the agency houses in Calcutta, but if ignored the firms will only have themselves to blame for the dire results which are sure to accrue in the future, if adequate action is not taken and promptly carried out. We trust that the Indian Tea Association and the agency houses in this city will soon make known the measures they have adopted to meet the great strain there will undoubtedly be on their resources.

THE KANDYAN HILLS CO., LTD.

A General Meeting of the Shareholders of the Kandyan Hills Company, Limited was held at the Registered Office of the Company, (Messrs. Carson and Co.'s) No. 21, Baillie Street, this afternoon.

Mr. F. Macindoe presided and present were Messrs A. Forsyth, E. R. Waldoek, A. Anandappa, G. J. Jamieson (by his Attorney Mr. F. Macindoe) and Messrs. Carson and Co. (represented by Mr. F. Macindoe). On the motion of MR. FORSYTH seconded by MR. ANANDAPPA the *provisional* Directors:—Messrs. J. N. Campbell, F. Macindoe, and E. R. Waldoek, retiring in terms of the Articles of Association, were reelected.

Following the Ordinary General Meeting an extraordinary General Meeting was held—present as before. The following resolution on the motion of MR. FORSYTH seconded by MR. ANANDAPPA was passed.

That the Directors be and they are here'y authorised to borrow a sum not exceeding five thousand pounds (£5,000) Sterling carrying interest at the rate of five per centum per annum upon such terms and conditions as to re-payment and otherwise as to the Directors shall seem proper and to mortgage the Pansalatenne Estate and premises as security for the sum to be so borrowed and the interest thereon.

It was explained by the CHAIRMAN that the money was to be raised for the purpose of paying off an existing mortgage of £4500 on Pansalatenne estate bearing interest at 7 per cent in favour of Messrs. G. H. Trail, R. A. Bosanquet and J. D. Balfour, and to replace it with a mortgage bearing interest at 5 per cent in favour of the Standard Life Office up to £5,000. The Standard Life Office had consented to lend £4,500, but the Directors hoped to arrange a loan of £5,000, the additional £500 being required to pay for extensions.

This was all the business,

KING COFFEE.

A NEW COFFEE LEAF DISEASE DEVELOPED IN SOCONUSCO CHIAPAS, MEXICO.

Coffee is king, because there is no shrub in the world so extensively cultivated as the coffee tree. America and Mexico, which latter countries have developed to large proportions during the last decade of years, and are taking their places among the higher rank of large coffee producing countries of the world. I have said that Ceylon was the third biggest producing country in the world. But a disease sprang into existence in that same year and checked its further progress. The effect of this coffee "small pox" in the industry was terrible. Devastation, disaster, ruin, are words that ill describe the awful working of the plague.

From 1,000,000, in 1869, the export gradually declined until the output reached the insignificant figure of 50,000 quintals, which is the very late figures quoted from the London press. This statement leaves nothing to be added. Had the cultivation been completely obliterated, the final end could not have been much worse.

There is another disease *Steilbum-Flavidum*. It might be truly called a twin sister to *Hemileia Vastatrix*. It is so very alike in appearance and the effect which it produces on the coffee tree, that I have mistaken it for that disease, which the letter copied below clearly shows. I observed a great change in the luxuriant growth of coffee in Soconusco, Chiapas, Mexico, from 1889, and its late appearance during the few years last past. I examined it closely and carefully, especially in the section of the district called Chicharras, and thought I had unearthed the terrible demon *Hemileia Vastatrix*; I accordingly collected some leaves, gathered from the San Juan coffee estate; prepared them carefully, and sent them to the director of the Smithsonian Institution of Sciences, Washington, for examination and report when completed.

The following is a copy of his reply:—

Smithsonian Institute,
United States National Museum,
Washington, May 22nd, 1894.

Mr. W. J. Forsyth, Chiapas, Mexico:

Dear Sir,—The coffee tree leaves recently transmitted by you for examination, have been referred to the curator of botany in the National Museum. He has submitted them to Mr. Ellis, of Newfield, New Jersey, who states that the disease, which has affected the trees is not caused by the fungus *Hemileia Vastatrix*, but by the growth to which the name of *Steilbum Flavidum* (Cooke) has been given. This, I am told, is quite widespread. Mr. Ellis has, in his collection, specimens of the same fungoid growth from Costa Rica, Jamaica and Venezuela. In as much as no experiments have been made in this direction, no remedies can be suggested.—Yours faithfully,

G. BROWN GOODE, Assistant Secretary.

(2683) True copy W.J.F.

This disease is entirely and altogether confined to the district I have mentioned. In no other place in the coffee zone of Mexico have I observed it. I have travelled over a wide field of the belt, particularly in the State of Oaxaca, and looked carefully everywhere for indications of the pest, but failed to see the slightest indications. It therefore behoves the governments of those States, which are exempt from the visitation of either of these coffee plagues, to take every preventive measure possible, to prohibit the bringing into the disaffected States, live plants from the affected district of Chicharras, Soconusco Chiapas. This can be easily done, as they are entirely isolated, with little or no traffic between the States.

Of late there has been a considerable exodus of capital from the United States to different parts of Mexico. It is therefore with the kindest feelings that I warn them to be guarded of an enemy subtle, to them, invisible, unknown, and which is only recognized by the scientific experts in the calling. Established estates are at all times the most engaging objects for investments of capital. There are

exceptions, however, to this rule, and the present is one. There are many estates in the District of Chicharras fairly well established, and are likely fields to attract capital; but a timely warning is herewith offered and it will be well for intending investors to investigate thoroughly what I say before committing themselves.

I shall before long have the pleasures of sending to my friends in New Iberia, a tale of life in Mexico.—
Yours truly,
J. W. FORSYTH.

—*New Iberia Enterprise*, Nov. 21.

COFFEE PLANTING IN BRAZIL.

MR. TALBOT'S VISIT TO THE DUMONT CO.'S PROPERTY.

Mr. G. A. Talbot, who returned to the Island on 18th Jan. last was good enough to give an *Observer* representative some interesting particulars, regarding the Dumont Coffee Company's estates which he has been visiting. In reply to questions, Mr. Talbot said:—"The property of the Company consists of about 14,000 acres in bearing. It is situated about 1,500 feet above the sea level; but you must remember that that it is not the same as 1,500 feet in Ceylon, for here coffee land is only about 7 degrees north of the equator, and in Brazil, the Company's property is about 25 degrees to the south of the line. Consequently, the Brazilian climate is much more temperate, resembling that of Arabia. Yes, the estate is planted with *Arabica*. As regards the location of the estate, it is situated in San Paulo state, about 300 miles distant from the town of that name. A railway runs from San Paulo to within 13 miles of the Company's property; and between the terminus and the estate, we have a railway of our own. This railway is of 2 feet gauge."

Can you give me any figures as to "the cost of haulage, working expenses, etc.?"

I cannot give you any precise figures, but it certainly answers very well and works economically. We also run passengers over the railway; the carriages are entered from the ends, and are fairly comfortable. The goods waggon are of the ordinary bogie type. I cannot work out the cost of transport per cwt but I know that in the aggregate the cost is low as compared with the cost of similar transport in Ceylon. Santos is our market, from which the coffee is shipped."

"What about the yield per acre?"

I think I am safe in saying that the average yield per acre is about 11 cwt. People in the district think that the labour supply is sufficient; but, according to Ceylon ideas, there are not enough of labourers. The labourers are principally Italians. They are not indentured. I believe you have to requisition the Brazilian Government for labourers and they assist in some way in bringing them over. I went to see some of the agents in Genoa on my way out, and they told me, if I went through this form, they could send me as many as I wanted. The bulk of the Italian labourers are peasants from the plains of Lombardy, with blue eyes and fair hair and many of them fine looking men and women. They do not pick so well as we did with Tamils in Ceylon.

"Can Europeans perform manual labour in the open without injury to health?"

"Oh yes! the property is just outside the tropics and the climate is very healthy, the daily pay is something over three shillings per head?"

Does not this high rate of pay largely increase the cost of production?"

No, because there is so little cultivation. The cost is about thirteen shillings per cwt. All the cultivation we have to do is hoeing and picking and the yield per acre being large, it makes the cost per cwt. much cheaper than it was in Ceylon; In Brazil we do none of the pinning, draining, handling and other odds and ends which were done by Ceylon planters.

"Does the absence of pruning not cause the bushes to deteriorate?"

Pruning appears to be unnecessary seeing the large yields we are getting. Draining can be dispensed with as the rainfall is not heavy. There was no rain gauge available but I should say the rainfall was about 70 inches a year."

"What about the temperature?"

"I fancy it would average about 70 degrees. Picking begins in April and goes on till about the end of August. There is a good deal of machinery on the estate but the curing is not nearly so well done as it is here. However, we hope that by introducing Ceylon methods, we will be able to improve the quality very much, and to get a very much better price. In Ceylon, as most people know, we pull the coffee when it is ripe, pulp it, dry it, and then what they call, peel it whereas in Brazil they pulp only a very small proportion they let it dry in the cherry and then hull it with a huller. The result is that the husk being on the coffee so long takes off what is called the "colour" or quality and it gives an inferior flavour as a sort of fermentation goes on. What we propose to do is first to get the picking carefully done, and by introducing Ceylon methods and Ceylon machinery we hope to get a better sort of coffee. That cannot be done at once, but it can be done by degrees. There will be a little difficulty in getting the men to adopt the new methods; and, probably, they will want higher wages for more careful plucking, and in that way it will increase the cost of production, no doubt, but we hope it will give us something like Ceylon coffee. As I have said, people on the estate say we have all the labour we want and that we can get as many as we like, which is very satisfactory as the introduction of new methods will necessitate a larger labour force. In saying that much less cultivation was necessary in Brazil than in Ceylon I forgot to mention that all the weeding is done with the hoe and not by hand picking, the work being done about five times a year. In Ceylon owing to the heavy rainfall, hoeing is impossible as the soil would be washed away. In Brazil no such difficulty presents itself and consequently the expense of weeding is very much less. The coffee bushes grow about 12 feet high, but they are not so lanky as those in Ceylon because of the more temperate climate of Brazil. The Italians have a comparatively easy time. When they are not required by the estate they cultivate maize in the coffee fields for themselves. The maize they use for fattening pigs, and they contrive to make a good deal of money out of it. In some of the young coffee fields you can scarcely see the coffee for maize."

"Does it not smother the coffee and exhaust the soil?"

"It is said not to injure it and the soil seems so rich as to be able to grow both. I, however, do not like it, and I hope we shall be able to stop, to some extent at least, maize being planted among the coffee."

"What about the cost of weeding?"

Weeding is done by contract, 80 milreis being paid for 1,000 trees, that is about £1 per acre."

"Have you ordered any machinery from Ceylon?"

"At present there is no Ceylon machinery on the estate. The machinery is by Ledgerwood, a Glasgow firm, which competes with Messrs. Walker. Now that we are going to adopt Ceylon methods, we shall certainly use Walker's peelers and pulpers."

"What about power?"

"Steam is used, but at two or three points on the estate water power is available."

"Have you any black labour?"

"Not much. There are a few negroes about. A most extraordinary thing about that part of Brazil is that the slaves who were only emancipated some eight years ago are hardly to be seen anywhere. Where they have gone to I don't know. Most of them I fancy have drifted into the large towns and others have squatted on waste land."

"What about the future of the Company?"

"I am very hopeful of the future of the Company and the best test of its continued prosperity is found in the fact that in the London market the shares are readily saleable."

"Does not the prosperity of the Company depend on the stability of the Government? What are your views on this subject?"

"I do not think the present Republic is a very stable Government; as a matter of fact, they were talking about a revolution when I was there. But a revolution in Brazil makes very little difference to property, especially if it is landed property, though it might be somewhat serious if the currency was disturbed. I consulted a man of some position—the manager of a large English Bank—on the subject telling him that one of the things urged against subscribing to the Company was the unsettled state of the country, and he said—'Nonsense, landed property, house property, real property is perfectly sound and one need not fear anything.' I also asked a leading lawyer—a man of standing in his profession—and he said since the Brazilians had to pay the large indemnities to Italians they had been very careful to guard the rights of foreigners. Personally the Brazilians, are a pleasant people to have dealings with."

Mr. T. L. Villiers of Yoxford, Dimbula, will take charge of the estates and he sails for England in the "Malta" on 11th Feb.. No doubt Ceylon methods under his direction will have beneficial results. Mr. Villiers is to be congratulated on this important appointment.

PRODUCE AND PLANTING.

(From the *H. & C. Mail*, Jan. 1.)

TEA SHARES AND THEIR VALUE.—A study of the review of the tea share market for the past year, which appears in another column, will afford gratifying proof that the interest taken in tea shares by the investing public has not been in vain. Rise upon rise is to be noted in the price of the shares in the leading companies, while the debenture stock rivals the position held by gilt-edged securities of the first class. This is an enviable position financially, and it is due alike to the confidence shown in the management at home and on the spot, and to the belief that tea planting is a sound and well conducted industry, subject to fewer fluctuations than some forms of enterprise about which there is more flourish and less performance. Thanks to the efforts of Mr. Geo. Seton, of the Indian Tea Share Exchange, and Messrs. Gow, Wilson, and Stanton, the well-known tea brokers, and others, whose efforts to popularise the shares of Indian and Ceylon teas have been persistent, the public no longer regard these shares as

something in the nature of a "dark horse." They can procure all the information they need, and when they have purchased shares they have been gratified in nearly every case, with the receipt of dividends and the prospects of others to come. The tea industry is in a healthy state, and although it will probably have to face increasing competition there is no reason why it should not show further and gratifying developments. We need not say that in eulogising the tea industry as a whole we are not necessarily endorsing the statements and prospectus of every venture launched as a tea company. The public must protect themselves, and thanks to the publicity given to the reports of the various companies and the information procurable from the brokers we have named, there is no difficulty in the way of information. As a whole, we repeat, the tea industry is on a sound footing. Investors who own well-selected tea shares are to be congratulated on their choice of investments, which certainly promise well, and are, so far as ordinary insight can judge, likely to give far less cause for anxiety than many other shares of the industrial order.

THE TAX ON CHINESE TEA.—In the able letter appearing in the *Times* on Chinese affairs from its correspondent at Shanghai reference is made to the taxation of tea and its effect on the tea trade of China. The *Times* correspondent says:—"The export duty on tea, fixed under the Tient-sin Treaty at 2½ taels per picul, represented no doubt in 1858 an *ad valorem* rate of 5 per cent., but at the prices which obtain to-day it represents much more nearly 10 per cent.; and, as if that were not a sufficiently crushing burden to place upon Chinese tea, the exactions levied upon it in the shape of *likin* amount to another 20 per cent. In many cases, indeed, the total taxation on tea before it leaves the Chinese port of export is estimated at no less than 80 per cent. *ad valorem*. Can anyone seriously contend that such extravagant taxation has had nothing to do with the disastrous condition into which the Chinese tea trade has fallen, and has not materially assisted the competition of Indian and Ceylon teas on the British market, or is not materially assisting that of Japanese green teas on the American market? Against 169 million pounds of tea exported to Great Britain in 1880-81, China exported only 37½ million pounds during the last tea season. With the change that has gradually come over the taste of tea-drinking public at home, it may be too late to recover all the ground already lost on the British market, but something may be done to save at any rate what is left of it and to avert the threatened loss of such other markets as China has still retained."

JAPAN AND ITS TEA TRADE.—According to advices from Yokohama the Japanese are striving to develop their tea trade in every possible direction. A committee of Japanese tea merchants has applied to the Government for a subsidy of 1,750,000 yen to promote the tea trade. It is proposed to spread the expenditure of this sum over ten years in maintaining two representatives both in India and in China to study the processes there adopted in growing and preparing tea and in advertising Japan teas in the United States and elsewhere. According to another account, it is proposed that the expenditure of the total sum shall be spread over five years only. It is very flattering to Indian and Ceylon growers that the Chinese and Japanese should wish to imitate their methods, but it is not at all desirable that Indian and Ceylon planters should teach the Chinese how to compete with them.

HUMOUR IN TEA.—In a chatty article about tea a writer in the January number of the *Cornhill Magazine*, E. V. Lucas, takes note of the paradox that a man who sells tea and nothing else occupies a rung in the Grundyan ladder far above him who sells tea and also sugar. Tea, in fact, confers a social rank of its own. "Mincing Lane and Park Lane," he continues, "are often on visiting terms,

and the scions of noble houses may be 'in tea' without shame. Similarly it is no disgrace to the daughters of Mayfair to serve tea in a West-end shop. Some of them perform this action with an air of condescension that reduces the timid man to pulp. A shy friend once told me of the tortures he had suffered in these resorts. 'But I was revenged at last,' he said, 'for an old countryfellow and his daughter who had been to the Academy, or Maskelyne and Cook's, or somewhere, came in. When he paid the bill he left an extra sixpence in the patrician's hand. She fixed him with her refrigerating eye, and told him cuttingly that he had paid sixpence too much. 'That's all right,' he said heartily, in a stage whisper; 'that's for you, my dear. Buy yourself a ribbon with it.' I like this story, because tea has not done too much for the humourist. Compared with alcohol it has done nothing." The writer recalls, too, the story told with great glee by the late Arthur Cecil, the comedian, of the cannibal tea to be obtained down at Kew—thus: "Tea, plain, 6d"; "Tea, with shrimps, 9d"; "Tea, with children, 1s."

COFFEE ADULTERATION.—The question of coffee adulteration is one which presents itself to the public mind occasionally, but it never awakens strong feeling. The consumer thinks, apparently, that a kind providence having ordained that coffee planters should grow coffee and experts manipulate it afterwards, it is the consumer's duty to accept the situation without complaint. A writer in the *Grocer* is good enough to tell us how some of the coffee adulteration frauds are carried out. One frequent kind of fraud has been the colouring of inferior berries to make them resemble those of better quality. For this purpose yellow ochre, chrome yellow, burnt amber, arsenite of copper, and coal-tar dyes are a few of the pigments which have been pressed into the service of those 'cute persons who devote themselves to exemplifying the dictum that "things are not what they seem." Take as an example the salvage coffee which is occasionally fished out of the sea after a wreck. Salted and sodden when recovered, it certainly does not look as though it would furnish a very saleable article. It is, however, by no means to be despised; after being purchased for a mere trifle it is washed with lime-water, dried, and then either browned by roasting slightly, or else coloured with an aniline dye. In the result berries are obtained which, in appearance at least, may even be superior to the original ones. Essentially the same kind of manipulation is said to be resorted to for the purpose of making green South American berries resemble the brown Java coffee, thus considerably enhancing their market value. A variant of this procedure is to take berries which have been already used to prepare "coffee extract" from, roast them up again with a small quantity of sugar, and then send them into consumption as genuine coffee. Another brilliant idea is to soak genuine berries in syrup before roasting; this causes the beans to retain more water than they otherwise would hold, and so increases their weight. A still more effective plan is to steam the berries after roasting, and then coat them with a film of glycerine or vaseline to prevent drying. The weight of the beans can in this way be increased as much as 20 per cent.

SPURIOUS COFFEE BERRIES.—Coffee adulteration offers a fine field for the man of genius. The writer in the *Grocer* gives particulars of another kind of deception practised on the Continent, and especially in America, where the manufacture of spurious coffee berries has developed into quite a flourishing industry. Only a few weeks ago the writer had brought under his notice a sample of coffee "made in Germany," in which the "berries" were composed of ordinary whicaten dough mixed with sugar; the mixture had been cast in moulds so as to closely resemble genuine berries, and then roasted till brown. By themselves the pellets were easily seen to be factitious, but when mixed with genuine coffee an appreciable proportion would readily escape notice

if not subjected to sharp scrutiny. As a rule, artificial beans of this character are made of flour, chicory, and sugar, with other additions such as bran, acorns, peas, and coffee-grounds. Some much more gross impositions have, however, been practised; for example, "berries" have been moulded from fire-clay, and then utilised for roasting with genuine coffee. During the heating process the factitious clay beans absorb some of the oil and colouring-matter from the genuine ones, thus simulating the appearance of the latter sufficiently closely to pass muster on a cursory examination. Clumsy frauds of this nature are, however, rather matters of ancient history now; at all events in the United Kingdom they are practically never met with at the present day.

ADULTERATED TOBACCO.—Planters grow produce and manipulators adulterate it. Tobacco, like coffee, is treated very badly at the hands of the adulterator. According to official reports it is adulterated with sugar, alum, lime, flour or meal, rhubarb leaves, saltpetre, fuller's earth, starch, malt comings, chromate of lead, peat moss, molasses, burdock leaves, common salt, endive leaves, lamp black, gum, red dye, scraps of newspapers, cinnamon stick, cabbage leaves, and straw brown paper. The grower would have some difficulty in recognising the original product.—*H. and C. Mail*, Jan. 1.

YATIYANTOTA CEYLON TEA COMPANY LIMITED.

Registered December 15, by Davidson and Morriss 40 and 42, Queen Victoria-street, E.C., with a capital of £250,000 in £10 shares (7,500 of which are preference shares). Object, to adopt and make binding on the company, and to carry into effect, with or without modification or alteration, an agreement, made December 7, 1896, between the Yatiyantota Tea Company, Limited, Colombo (a company incorporated under the laws of Ceylon), and George Hay Alston, the liquidator thereof, of the one part and C. S. Lott, for and on behalf of this company, of the other part; another agreement, made December 7, between the We Oya Tea Company, Limited, Colombo, and G. H. Alston, the liquidator, of the one part and C. S. Lott, for this company, of the other part; and a third agreement, made same date as above, between W. J. Smith, S. L. Harries, A. C. Roper, and Jn. G. Smith of the one part and C. S. Lott, for the present company, of the other part, and, generally, to carry on in all or any of their respective branches the businesses of tea, &c., planters, and growers, manufacturers, merchants, exporters, importers, traders, estate or commission agents, shipowners, engineers, shipping, insurance or advertising agents, bankers, bill discounters, &c.; to acquire and turn to account any tea estates or other landed property in Ceylon or elsewhere; as miners, smelters, and metallurgists; to construct and maintain rail and tram roads, reservoirs, warehouses, workshops, &c. The signatories are:—

R. S. Corbett, Highmore, Streatham-common.....	1	Shares.
W. H. Figg, Casewick-road, West Norwood.....	1	
J. Stevens, Loch Goil, Romford.....	1	
S. Gray, 9, Tregathnan-road, Clapham.....	1	
G. S. Lott, 97, Stormont-road, Clapham.....	1	
W. H. Bartlett, 24, Sudbourne-road, Brixton-hill..	1	
F. R. Carr, 9, Fenchurch-avenue, E.C.....	1	

The number of directors is to be not more than seven nor less than three. The first are C. Young, W. J. Smith, and W. H. Figg. Qualification, 50 shares. Remuneration, £100 each per annum and £150 for the chairman.—*H. & C. Mail*, Jan. 1.

TOBACCO CULTIVATION AND CIGAR MANUFACTURE IN CEYLON.—In answer to the papers of the South India Expert, we have got some interesting, practical information from a few Ceylon planters with tobacco experience, which we shall collate and give in an early issue. One paper has still to reach us.

SCIENCE AND TEA PLANTING.

The appointment of a scientific officer for the investigation of blights and other enemies of the tea plant has been under the consideration of the Indian Tea Association (London) for some time past. At the request of the Secretary of the Association a well-known authority on all matters connected with the cultivation of the plant and kindred subjects has given his views at some length. The opinions expressed are based on practical experience, and we have pleasure in placing them before our readers.

The correspondent referred to writes as follows:—

I shall endeavour to state as briefly as I can my opinions (based upon experience, observation, and study) upon the various points to which attention is directed in your letter. Of course, my remarks shall be entirely from a practical standpoint.

OVER-CROPPING.

Under the methods in vogue for the last eighteen years or so, I cannot conceive any general danger to the tea plant from over-cropping. On the contrary, without resort to manuring as generally understood, I am confident that, given labour and ample judicious cultivation, the produce from the present bearing areas in India, as a rule, falls very far short of their safe cropping potentialities, or what were in all cases originally the natural continuous productive capabilities of the soil. I do not venture to say over-cropping is impossible, but with careful, judicious pruning, under the present ideas of plucking for quality as I take them, it would not be easy, and must, I should say, be extremely rare. The tea crop is neither a heavy nor an exhaustive one; and more nitrogen is undoubtedly restored to the soil in the shape of vegetation turned in (or that ought to be turned in) in cultivation, also as derived from the atmosphere, and from the rainfall, than in more temperate climates. The average crop of green leaves taken annually is extremely light compared with the weight of agricultural crops (exclusive of the proportion returned to the soil) in this country. Recent methods are supposed by some to be more of a strain upon the tea plant than the old. But I am of opinion it is otherwise. In cropping for quality, the cutting in pruning is, perhaps, heavier over a majority of the years, but on the other hand, excessive cutting should be less frequent, and never to the same extent necessary. The pruning, therefore, should not be more exhausting. Plucking for quality necessitates going round the gardens very frequently, leaving the bushes with a constant layer of young shoots and leaves on (as well as the mature leaves) to perform all the functions of the foliage, and is not so trying as the old method of plucking at intervals twice or three times as great, commonly shaving off the flush to the very buds, so to speak. The shock to and strain upon the bushes was greater under the old method, and the temptation to overtax them more where, within an equal labour force, quantity could be more aimed at, the market not being so fastidious to anything but appearance.

There is no doubt that in too many instances the yield of old concerns, notwithstanding considerable extensions, has not increased proportionately, but in some cases may have even fallen off; but this, I believe, is due (1), and I trust mainly, to the altered mode of plucking, which has been more and more for quality, (2) to blights, (3) on hill lands, to injudicious, reckless cultivation, and loss of soil from "wash," (4) injudiciously heavy pruning, and, perhaps, (5) not infrequently to greater scarcity of labour than formerly; or to some or all these causes combined.

BLIGHTS.

The remedy for blights, of "selection of seed," as I understand to be recommended by Dr. Watt, is worthy of attention. Disease-resisting stock has accomplished something, at least temporarily, in regard to the vine and potato diseases for instance, after long periods of years, but it is problematical not only to what extent, but how long, this may take to benefit tea. At the best the remedy is not a very encouraging one for most proprietors in so far as it can now be of no benefit to the 450,000

acres or so of existing tea throughout India! I am able, however, to testify to having accomplished something by selecting the most vigorous and most likely to be disease-resisting seedlings, in the planting out of my Company's modern extensions.

RED SPIDER.

In regard to red spider I have had at least fifteen years of sad experience in battling against it. The soil of the gardens I managed seemed predisposed to this blight and favourable to its propagation, and I could not imagine any gardens to be worse with it than they were for years. From 1830 to 1835 this pest was in fact a dreadful scourge; but it has been practically overcome by sulphur. I learn that Dr. Watt has no belief in the cure of blight by any application in that way, but after having applied sulphur in quantities of from three to twenty tons annually since 1830, the effectual cure of red spider, at a moderate cost per acre, is with me no longer a matter of opinion, but something that has in my own experience been successfully achieved. It has also to be taken into account that the sulphur not only proved a remedy for the red spider, but for many soils, a valuable manure.

The accompanying printed article will be found to explain the simple mode of application of the sulphur, and give further information in some detail. (The article referred to, entitled "Sulphur as a Cure for Red Spider in Tea," appeared in our issue of August 30, 1895.)

OTHER BLIGHTS.

I am not, however, so hopeful of the eradication of mosquito blight by any similar application, because (1) the insect is winged and migratory, and (2) the blight is at its worst, and the remedy would have to be applied, at the season of the year when quality should be at its best. The study of the life history of this insect by several scientists does not seem to have afforded any clue as to a remedy. Some hold the opinion that the prevention of jungle fires by the Forest Department led to the increase of the pest on the gardens in the Terai. Be this as it may, it is not impossible that, like some other crop pests, it might be effectually treated in some intermediary stage in its habits away from the tea plant.

I have no experience of the white ant, beyond what little I have seen of its ravages when on visits to Assam and Cachar.

There are many other parasites and blights, but those I am familiar with do little harm, are amenable to treatment and easily kept in subjection, or do not spread. One of these more frequently alluded to of late, a white-thread fungus, I have seen a little of, and noticed making its appearance in different parts of the Dooars during my last trip to that district in 1893. I am inclined to attribute this pest to defective preparation of the ground prior to planting, dampness of soil, or excess of trade.

Undoubtedly a great safeguard against the ravages of parasites and blights is to maintain the plants in a healthy and vigorous condition. Still I believe that, wherever there is a large area under any crop, irrespective of the exhaustion of the plants, blights in some measure are sure to follow in time. But it stands to reason that with ill-conditioned plants—from whatever cause—blights must prove the more disastrous.

MANURING.

The subject of manuring is a wide one, and an essay, if not a volume, would be required to do any justice to it. Material is of an not available; and the fertilising properties of manures are difficult to preserve and apply in India. The transit of local supplies is in most cases too costly to be thought of. Besides, frequent labour is not available to any extent for manuring. In most instances all that is practicable over wide areas is "green manuring," and, as material and labour admit, top-dressing with leaf mould, such soil as is available, or leaves and twigs. Upon soil of fair quality, yielding crops of the average present day amount, I am not of opinion that for the permanent rude growth and health of the plants more is necessary. But beyond this the great desideratum would be to be enabled to manure for quality. This can never be accom-

plished successfully or profitably until it be ascertained what elements are lacking for quality in different soils. In this direction, as far as I am aware, no progress whatever has yet been made. It is the province of the agricultural chemist to investigate this, and place practical planters in a position to supply the elements wanting for quality in each case. Nothing can be of more vital importance to the tea industry generally than such discoveries. Nitrogen may mainly be supplied by "green manuring," but the mineral elements (which I believe will be found essential for quality) must I fear be provided or replenished, principally by means of artificial manures. Nitrogen supplied by "green manuring" will doubtless also render some of the dormant mineral constituents in the soil available for plant food. I am not, however, hopeful of artificial manures ever being profitably applied to the tea plant unless for the production of quality.

"GREEN MANURING."

"Green manuring" has very much to recommend it. I have practised this to great advantage, without the aid of leguminous plants specially cultivated for the purpose, and most extensively (prior to 1877) before the extensive introduction of machinery, when a large force of strong coolies were freed from manufacture, and otherwise available in the Darjeeling district, during October and November. As in much else, I need hardly say, results mainly depend upon the time and manner in which the operations are performed.

LEGUMINOUS PLANTS.

The fertilising properties of the leguminous plants have long (even from the time of the Romans) been well known in agriculture. From what source this class of plants derived these properties has also long been the subject of much scientific investigation and controversy. But some seven or eight years ago it was demonstrated beyond doubt (what was long disputed) that the *leguminosæ* have, under certain conditions, the power of assimilating the nitrogen of the atmosphere. It must doubtless be wise therefore to have the attention of planters generally directed to the benefits to be derived from this class of plants. But so far as the application of the *leguminosæ* by "green manuring" to tea is concerned, I look upon it as a purely practical and economic question. The tea industry, apart entirely from any export of its own, may have the full benefit of the results of those scientific investigations, as well as others still being carried out in Germany and elsewhere, in the inoculation of soil to secure the conditions favourable to the fullest development of the fertilising properties of the *leguminosæ* being always present.

The leguminous plants commonly cultivated in this country, such as lucerne, vetches, lupin, sainfoin, peas, and beans, grow too high to be used to the desired advantage with tea, unless the proposal be to go in for a regular "rotation of crops" in the proper sense of the term, by allowing a portion of the garden to remain "fallow" and uncropped in rotation every three, five, seven, or other interval of years. But this would seem to me an extreme measure (to be contemplated with satisfaction by few), which is to be avoided, and I believe, can be avoided by the judicious, skilful treatment of a garden. No doubt, ill-conditioned plots would lend themselves with great advantage to fallowing and special treatment. The clovers, however, are a low-growing plant, and on that account more suitable for a tea field being cropped, but land under them (at least red clover for a length of time is found subject to "clover sickness," and as fertilisers the clovers, as a rule, I do not esteem so highly as some of other leguminous plants. There is this to be said, however, that leguminous trees, shrubs, plants, and even weeds are much more abundant in the East than in this country, and some of the indigenous varieties may form a low sward and be most advantageously used for "green manuring," without having recourse to putting the tea under fallow. It of course remains a question to be determined only by trial and experience, how far the cultivation of the *leguminosæ*—certainly any that are

exotic—for tea will pay, unaccompanied by anything like the profitable feeding of cattle for the market, which in most cases is out of the question. I believe the low growing indigenous kind will be found the most suitable and effective.

Land impoverished by native cultivation, and doubtless much other land, would benefit immensely by being put under leguminous plant and allowed to lie fallow some years before being planted with tea. I can again testify as to the wonderfully good results from fallowing for three years under such vegetation as chance to grow. But how many will have the patience or incur the expense of such a delay, however urgent under certain conditions?

Exhaustion, or a poor condition of plants, may in some instances render desirable or even force the following of bearing gardens, by section in rotation on a seven, five, or three years "shift"; and over-production may soon render such a course the less unpalatable; when the best fertilisers among the *leguminosæ* may be used with less restriction and to full advantage.

CULTIVATION.

To most it will indeed be something novel to hear of tea gardens actually suffering from being kept over clear of weeds! We have heard of gardens in Ceylon being kept perfectly clear at all times by hand-weeding, but I am confident that in India such supererogation must be extremely rare. The extreme of cultivation with us may be taken to amount to eight or nine forkings or hoeings during the year—that is once in winter, and once a month during spring, summer, and autumn. In this way, I should say, there will be more vegetation turned into the soil than by only turning it in once, twice, or thrice a year. In the former case the harm is more likely to be done by turning over and "poaching" the soil in very wet weather. Wet cultivation is sure to aggravate and may even induce blight. When high cultivation is aimed at, a great drawback is, the hoeing must be done not always in the weather most favourable for it, but when labour is available. It would be safer and preferable as a rule, therefore, to cultivate a sward of the low-growing leguminous plants to fertilise the soil, and at all times eschew hoeing or forking in really wet weather.

SCIENTIFIC OFFICER.

As I have for thirty-five years followed the progress of agricultural scientific research to the best of my opportunities, and, since it has been mooted, taken a keen interest in the proposed appointment of a scientific officer for the tea industry, I may be permitted to make a few remarks on so important a subject.

From all I have learned previously, the proposed expert was to be appointed mainly to make a scientific investigation into the processes of manufacture and ascertain the deficiencies or otherwise of various soils and their needs in the form of manure. This has always been held out as the pressing necessity, and I believe wisely so. For such investigations a thorough knowledge of analytical chemistry, and as far as possible also of bacteriology, is indispensable and some experience of practical agriculture and plant life would, of course, likewise be advantageous. The great tea industry ought undoubtedly to employ such a scientific officer, and *permanently*. These qualifications (or almost similar), and also "a knowledge of the chemistry of plant life," have been recommended by Dr. Watt formerly. If a second expert be really in contemplation for blights specially, then one with "a thorough training in agriculture" (but better a horticulturist, I should say) "who has examined into the diseases of plants" might be suitable, no doubt. Such a man as the late Mr. Thomson, viticulturist, of Clovenforks, or of the Scottish head-gardener type (such as I had the privilege of consulting about red spider blight in 1877-78), men of valuable practical experience and great intelligence and sagacity would be of vast benefit for blights if the industry could secure their services for a few years. Or from such in conjunction with a competent agricultural chemist the best results might be expected.

I am not of opinion that there is much need of an expert specially for blights. All that is required are observant, thoughtful, practical men, methodical, with a scientific cast of mind, and withal, and above all, enthusiastic. It must be admitted that most gardeners and agriculturists sent out to tea commerce perhaps with too little home experience for this task; still I doubt not there are several men connected with tea in India, if set aside to devote their entire time and thought to the matter, would be able in time to accomplish much. In addition to the agricultural chemist one such might even be deputed to each group of blighted districts.

There is, I learn, no hope held out of pecuniary aid from Government. Upon the whole, this may not really be a disadvantage, because Government support would reasonably be accompanied by Government control. If there can be absolute certainty about anything regarding this appointment it is this: The Tea Association should engage the most competent and suitable scientific officer procurable, and if such be secured, there is no one in India I have heard of competent to "supervise his work." He should only be under the direction of sound business men financially, and must be allowed a free hand in regard to his scientific investigations, being at the same time led clearly and fully to understand that the success of his efforts to benefit the tea industry shall be to his own advantage and *vice versa*. But the Association must not be too impatient of results. No one can doubt that the scientific officer will always be very glad to receive suggestions and information from anyone Government may depute, for the good of the industry, to interest himself in and furnish information bearing upon the investigations. But, depend upon it, the control or supervision of the scientific researches of a competent officer, as suggested, could hardly fail to mar the efficiency of, if not wreck the undertaking.

Neither can I agree that the use of the Government laboratories would be advantageous as a rule. The scientific officer must have his own laboratories, though only a small bungalow or part of one. It would be impossible, for instance, to obtain any reliable results in the chemical investigation of the processes of manufacture unless the laboratories be close at hand. Government would no doubt place their laboratories and apparatus at the disposal of the scientific officer if necessary for any special investigation.

In regard to a suitable "scientific officer," laboratory accommodation, apparatus, and instructions to be framed to insure continuity of research in the event of inevitable changes, I believe the Association could not do better than consult Dr. John Augustus Voelcker (Ph. D., B.S., &c.), consulting chemist to the Royal Agricultural Society of England, who devoted thirteen months throughout India to an inquiry into its agriculture (mainly in its scientific bearings), and the qualifications, equipment, and appointment of agricultural chemists for the country.—*H. and C. Mail*, Jan. 1.

COFFEE:—THE ONLY WAY TO IMPROVE OUR COFFEE STRAINS.

ADVICE FROM DR MORRIS, DIRECTOR OF THE ROYAL KEW GARDENS.

The following is a letter in answer to some queries of ours, forwarded through a friend, regarding the advisability of replacing the disease-stricken coffee seed of South India with new and preferably wild strains. Our readers will note that, barring the valuable suggestion of beginning the experiment with first rate Blue Mountain seed (which has already been acted upon in a careless, haphazard manner), the gist of the sound advice Dr. Morris gives us is identical with that which appeared in our issue of December 5th from the pen of Mr. J. Cameron, of Bangalore.

There is one thing we would strongly impress upon our readers, and that is, the improvement

of our strains is *surely a planter's matter*. It is a work in which everyone of us can take our part, though the first steps, *i.e.*, the introduction of first rate Blue Mountain coffee, might fitly be undertaken by the United Planters' Association.

Writing under date of 14th December 1896, Kew, Dr Morris says:—

The suggestion [*i.e.* about going back to the wild stock.—Ed.] is similar to many that reach me from various parts of the world. It is based really on a misapprehension of the means adopted by highly skilled horticulturists in working up improved stocks of cultivated plants. Instead of going back to the original wild stocks these people start from the best of those now existing and by careful selection and cultivation produce strains of the highest merit.

Although plants affected by disease may have deteriorated individually, yet in a large area there would be found numerous individuals of healthy constitution and quite capable of responding to the influences of improved cultivation and a wise and skilful selection. If you go back to the wild stock you have to traverse a fresh all the gradations of improvement already obtained, with possibly no better result than at present.

The only way to really improve the present coffee plant is, as you [our friend, who forwarded the letter.—Ed.] suggest, to carry on systematic experiments extending over several generations and seizing upon every indication of improvement to fix it at each stage until the desired result is obtained. To some extent, but not in a very scientific way, improvement had taken place in the character of the coffee cultivated in the Blue Mountains of Jamaica. The plants are prolific, bear large beans of good colour, and the produce is possibly the best of any appearing in European markets. It often fetches 142/ per cwt. The quantity is small owing to the difficulty of obtaining forest land suitable for extending the cultivation.

If the planters of Southern India were to import selected seed from the Blue Mountains of Jamaica the results would be much more satisfactory than starting with really wild plants. They would then start where the Jamaica people have left off.

We always take up any new species or varieties of coffee that we meet with, and we distribute plants for purposes of experiment—in fact to furnish the raw material for planters to work upon if they like. *Coffea stenophylla* is a case in point. This is very near *C. arabica* and may indeed be a wild form of it. I do not suppose, however, that planters will take the trouble to work at the wild plant for, say, twenty years in order to get an improved variety. Experiments on a small scale are worthless. *It is purely a planter's matter, to be solved only on the estates where coffee is largely grown.* [The italics are ours.—Ed.] Only one plant in ten thousand may show any characteristics of a desirable character, the same as in the sugar cane. Although some hundreds of thousands of seedling canes have been grown, only two have shown any special characters of a valuable kind.

If it is proposed to import Blue Mountain coffee seed from Jamaica, correspondence might be opened with Beresford S. Gosset, Farm Hill Coffee Plantation, Hagley Gap P. O. Jamaica. He is a reliable man who has excellent coffee fields.—*Planting Opinion*, Jan. 9.

JAMAICA FRUIT IN LONDON.

Considerable interest was exhibited yesterday in Covent Garden in connection with the sale by auction of the first consignment of Jamaica fruit received direct from the island in this country by the steamer Port Victor. The market was unusually crowded, the leading wholesale dealers in Manchester, Liverpool, and Glasgow being represented. An inspection of the fruit, which was packed in cases of two sizes, showed that

in the majority of instances the fruit had arrived in the London Docks in a ripe and sound condition. It is considered certain, that with a regular fleet of steamers between London and Jamaica, the new method of direct importation will result in material benefit both to English growers in the island and to purchasers at home.

The Central News says the whole of the cargo of the steamer *Elderslie*, consisting of about 9,000 cases of oranges, &c., was seized yesterday in the South-West India Dock by the medical officer of the Port of London as being unfit for food. The steamer is about to proceed to Newcastle, and by arrangement with the London port authorities she will throw her tainted cargo overboard at sea on her way to the Tyne. The failure is doubtless due to the fact that instead of picking the fruit in a green state it was allowed to attain a certain stage of ripeness before being packed; but no doubt is felt by experts that the experience will prevent the recurrence of such a fatal mistake.—*Daily Chronicle*, Dec. 31.

TEA MARKET REPORTS FOR 1896.

Messrs. Gow, Wilson & Stanton furnish us with two very interesting Reports by this mail—one with reference to their business in Tea Company shares and the other their usual annual Report on Indian, Ceylon and Java teas. Both are sanguine in tone. Counting our Ceylon export for 1896 at 106 million lb. (it was in reality over 108 million) and that for India as likely to reach 146 million, they show that the tea consumption for the United Kingdom last year had increased on that of 1895 by 11 million or to a total of 201 million lb.; while Foreign and Colonial markets took 42, or 5 million more than in 1895. This grand total of 243 million lb. for Indian and Ceylon teas taken off in 1896, does not leave much of a surplus out of the exports and as cheap tea directly tends to increase consumption, there is every reason to anticipate a steadily improving demand both from the American and European continental markets, while Australasia is not likely to disappoint us. The total consumption of tea in the mother country is now 226,000,000 lb. equal to 5.73 lb. per head; but between this and the Australasian ratio of over 7 lb. per head, there is a handsome margin still for expansion. All this expansion both in Europe and America (not to speak of minor countries,) will be required to overtake an increased crop in India and our own 120, or even 117½ million lb. in 1897, leaving out of view what Java and China may do. The percentages of the tea used in the United Kingdom in 1896 were as follows:—Indian 54; Ceylon 35; China down to 9, and other kinds 2 per cent.

PLANTING NOTES.

NILGIRIS.—*Crop* ripened up in torrents of rain in November and December up to Xmas day. The rush in such inclement weather could not be kept in hand. A good deal is in. A good deal is on the ground on low lying estates and not much more to come in. *Outturn* very disappointing and estimates not to be realised. Leaf showing up. Pruning begun on stripped fields. Health good, but cholera at the foot of the hills keeps out influx of coolies. Grain rates unjustifiably high.

SHOLUN.—The year closed with 55.66 inches rain, 3.55 of which fell in December. The weather has been unusually warm since last report, the day temperature in shade between 6 a.m. varying from 50°

and 64°. Tea still continues to flush slightly—and as I write prospects of more rain—which will be good for pruned tea and an early start next year if happily it is not nipped by frost. Labour plentiful and prices of grain steady.

COONOR, Jan. 8.—Weather has now set in clear and cold, and there is more than a suspicion of frost in the air. The rainfall for December totalled 18 inches, against an average of past four years of not quite 6½ inches. Total for year 70.69 in., which is just about an inch above average. Fears of a wet spring may thus be put aside. Lower elevation estates have got in quite half their crops, which, on revised estimates, is coming about up to the mark. Leaf-disease showing up in a nasty way. Generally speaking crops are poor and much under the average, as it seems is general all over South India. Tea has stopped flushing or very nearly so. On the whole the crops of tea in the district have been good and above the average, though the first half of the year was so bad. Labour plentiful, health indifferent. Grain rates about the same but still high, *i.e.*, ragi 18 measures instead of the old 26 measures per rupee.—*Planting Opinion*, Jan. 9.

THE RAGALLA TEA ESTATES, CO. LIMITED.

Proceedings at the second annual General meeting of shareholders, held at the offices of the company, 39, Lime Street, London, on Tuesday, 29th December, 1896, Mr. C. E. Strachan presiding.

After the notice convening the meeting had been read, the Chairman, rising to move the adoption of the report and accounts, said:—

Gentlemen,—The report and accounts have been in your hands for some days, and have no doubt had your careful consideration. I now beg to move their adoption, and, in doing so, I feel that you will expect to hear something from me regarding the progress that has been made, and our prospects.

You will see by the Report that a considerable expenditure has been incurred in what we call permanent improvements: these are of great extent, specified in the Report and need not be repeated. Our aim has been to bring the Estates into a perfect state of cultivation as soon as possible, and to do so it has been necessary to expend a good deal of money. I may say that we have broken the back of the work; we have now completed the planting of all the Coffee land in Tea, have drained the whole of the Estates, repaired buildings and erected new ones, planted timber clearings for future fuel purposes, and carried out a host of other necessary works, and we shall, without doubt, benefit by this expenditure later on. Dealing with the Report itself there has been nothing of moment in the conduct or result of our business for me to comment upon. Our Tea has sold for 9½d. per lb. nett against 8½d. per lb. last year. The quality of the Tea has improved, owing to the greater age of the bushes, and also to better machinery, and we hope, when our new Factory is finished, to see a further improvement in quality. Our Coffee Crop has turned out very short of estimate, owing to a bad attack of bug. I am glad to say we are less dependent on this uncertain crop now as our Tea is coming on so satisfactorily and taking its place. We were unfortunate in losing a gang of coolies, and this reduced our yield of Tea. I am glad to say they have been replaced, and we are advised that the Estate is full-handed again.

During the year we issued a further £8,000 of our authorised Capital for the purpose of building a new Factory and providing for Capital expenditure—the amount was all subscribed by our Shareholders.

I am glad to say the Factory is making good progress, and we hope to have it in working order early in April.

We also purchased the Kelburne Estate for £35,000—raising the money by an issue of 7,000 Preference Shares of £5 each, all of which were taken up. We consider this a very good purchase, and likely, later on, to add largely to our income.

As to the future of our products, without wishing to prophesy, I can only say that the prospects of

British-grown Tea look as well as ever, and, although clouds appear on the horizon from time to time, and we are threatened with competition from other countries, I fully believe we shall be able to hold our own.

As to the accounts they have been audited by your excellent Auditors, and I need say nothing further about them except to ask you to be content with the modest dividend of six per cent. for the year, and, gentlemen, I hope I have your approval, as I have that of my colleagues on the Board, when I ask you to be satisfied with dividends not exceeding six per cent. until such time as we have built up a substantial Reserve Fund, which, with the progress we are now making, should not be long, and we shall then be in a position to treat you more liberally.

Mr. HANNEN seconded the adoption of the Report, which was carried unanimously.

The CHAIRMAN also proposed that a final dividend of Four shillings per Share, free of Income Tax, be paid on 1st January in respect of the 3,100 Ordinary Shares fully paid as at 31st July, and this, being seconded by Mr. Harwood, was also agreed to. This, with the previous dividend paid in July, will make a return of Six per cent. for the year.

Mr. M. P. Evans, who retired by rotation from the Board, was re-elected as a Director.

The Auditors, Messrs. Fuller and Wise, were also re-elected.

The proceedings closed with a vote of thanks to the Chairman and Officers of the Company.

C. E. STRACHAN, Chairman.

MARKET FOR INDIAN TEA SHARES,
THE YEAR 1896.

(From *H. and C. Mail*, Jan. 1.)

The early part of the year which is just drawing to a close was, so far as Indian tea companies' shares are concerned, much on a par with that of 1895. During the latter half of 1896, value of shares have kept fully steady, any declines which have taken place in the less marketable shares having been more than compensated for by the rises in the most favorite among the more marketable ones, especially in those of some of the older established companies. Among some of the more recent (especially the preference) issues, however, which were, at first, rather "boomed," there has laterly been a little setback.

The increasing interest of the public in tea planting investments, which was the feature of 1895, has been more than ever noticeable in 1896, and, as already suggested, this has been further stimulated by the difficulty now experienced by investors in obtaining a reasonable rate of interest on their money. Even now, despite the rise in values, a careful investor in tea shares can obtain, with reasonable security, a yield of six and half per cent on Ordinary and four and half per cent on Secured Preference shares of these concerns.

The Rupee exchange, though latterly a little higher, has not, on the whole, advanced sufficiently to affect materially the results of working, though cost of production will undoubtedly be slightly enhanced for 1896.

The high prices of food stuffs in Bengal and elsewhere will, in those districts where rice has to be imported, tell against the planter, but it must not be overlooked *per contra* that famine in the labour-recruiting districts will render the task of obtaining fresh coolies for tea districts much less onerous and less costly.

Although the creation of entirely new gardens has not been very marked, amalgamations of one estate with another and the absorption of smaller estates by large corporations has gone on apace, so that the demand by investors for a larger selection of readily-negotiable and officially-quoted tea securities has been amply supplied. We have to chronicle the formation of the following reconstructions in, dated order, during 1896:—

The British Darjeeling Tea Company (the late Mr. Lloyd's Darjeeling estates.)

The Consolidated Tea and Lands Company (Glasgow), combining the estates of the old private North Sylhet and South Sylhet companies.

The Darjeeling Consolidated Company combining four old and well-known Calcutta companies.

The Empire of India and Ceylon Company, composed of the Borjuli and Dapoota properties in Assam, and some Dooars and Ceylon properties.

The Amalgamated Tea Estates Company (Glasgow)—Formed of the estates of the old Land Mortgage Bank of India, of the well-known Darjeeling estates of the late Dr. Brougham, the Hathibari property in Assam, etc.

Besides several smaller reconstructions, which space does not admit of our recapitulating.

In addition to these the Makum Company has issued £25,000 of Five per Cent. Debentures, the Borelli Company issues £10,000 Five per Cent. Preference capital to provide for improvements, and the Moabund Company reconstructs as from next year, with a total capital of £300,000, divided equally into Five per Cent. Preference and Ordinary Shares, of which one half is now issued.

We append our usual abstract statement, showing in the case of the best-known shares the range of values during the year. This again shows a very remarkable rise in values:—

The larger number of Companies, it will be found, have their stocks at a lower quotation now than were current twelve months ago. Out of 50 local companies 32 are now lower than then, 17 are higher, and 5 are unaltered. And those which are higher are only very little higher. The greatest improvement in rates is shown by Wanarajah, the shares in which were R1,150 in January 1896, and are now R1,500 and R1,575. Next to that fine Company come Kirklees, Agraovah, and Glasgow, and in the order named, all improving properties at a high premium, but said to be likely to go higher still. For the sake of comparison we append a tabular statement, showing the prices current for them at the beginning of January, 1897, and at the beginning of January, 1896, separating those which are now higher from those which are lower, and giving those which are unchanged also separately, as follows:—

Ceylon Companies.	Amount paid per share.	Prices.	
		Jan. 1st, 1896.	Jan. 1st, 1897.
	R.	R.	R.

CONCERNING TEA.

AN AMUSING PAPER.

(From "Cornhill" for January, 1897.)

Men's tea, I think, excels women's. Taking them as a whole one may say that no class of men make such good tea as undergraduates. Time is theirs; conveniences are to hand; and though they are young and ardent, haste and enthusiasm are bad form. Hence the brow has a dignity, a gravity, a composure worthy of it. There is something Asiatic about the reserved undergraduate—and today the conscious ones are all reserved—that stimulates tea to do its best for him. Later in life, when he has left the university and met a woman, the undergraduate becomes again an Occidental. These undergraduate tea connoisseurs are a development of the last few years. The invitation, 'Look in this afternoon and try my new Orange Pekoe,' to which grey walls, stained by the stress of centuries, now re-echo, would strike dismay to the heart of Cuthbert Bede. The average undergraduate as soon misses his tobacco as his tea.

He presides over the teapot with the air of Roger Bacon in his laboratory. Men always bring to a culinary feat this interested manner a little touched by mystery. To the woman it is natural; to the man it is exorbitant, and, partially, a lark.

Just as men are more intimately interested than women in

THE MAKING OF TEA,

so are they more subtly conscious of its merits. Women do not discriminate so intelligently. Tea to them is tea; tea to a man is China, or Indian, or Ceylon, or a blend. This is because men buy tea, as a rule, only when they are single, and women buy it with the house-keeping money. It is not for men but for families that polysyllabic brands are put upon the market. Individual men remain faithful to the costly varieties—'golden-tipped,' 'overland borne,' and the like. For women, for women, does Arabi Pasha beguile the tedium of exile by overlooking plantations in Ceylon; for women, for women, are artists employed to delineate aged grandmothers in the act of being reminded of the delicious teas of thirty years ago. That is why men who understand offer you better tea than women. They also send round the sugar and milk (connoisseurs care nothing for cream) for individual use. Women are only just learning that this is a more excellent way than to ask, 'Do you take sugar?'—'And milk?' Moreover, men—bless them for it—hate sugar tongs. There was a time when to refuse sugar was to write oneself High Church, but today the fashion is all against it; and yet, as a learned professor wistfully remarked, as guest after guest rejected the proffered bowl, 'Sugar is an excellent creature.' Milk is treated more leniently, but there is a lamentable tendency abroad to call it cream. The poet Wordsworth, by the way (speaking vicariously through Mr. Barry Pain), notes this point in the following simple ballad:

'Come, little cottage girl, you seem
To want my cup of tea;
And will you take a little cream?
Now tell the truth to me.'
She had a rustic, woodland grin,
Her cheek was soft as silk,
And she replied, 'Sir, please put in
A little drop of milk.'
'Why, what put milk into your head?
'Tis cream my cows supply;
And five times to the child I said,
'Why, pig-head, tell me, why.'
'You call me pig-head,' she replied;
'My proper name is Ruth.
'I called that milk'—she blushed with pride—
'You bade me speak the truth.'

Plenty of milk and three lumps suggest nonconformity and blue-ribbonism. A slice of lemon implies that the drinker has been to Russia, or has read something of Tolstoi's. A man who likes tea neat is on the road to become a tea drunkard.

It must not be supposed that the art of appreciating tea is unknown to women. Nothing could be farther from the truth. I knew a venerable lady with whom tea making almost a religious rite. To her high-backed chair was first brought to the caddy—an inlaid casket—and deposited on a table beside her. Then from the depths of a china vase the key was extracted. My hostess assumed her spectacles, and, taking the key, turned it gravely, scooped out spoonfuls heaped high of the fragrant leaves—and they were very fragrant—and tipped them into the silver teapot proffered to her as by a royal cupbearer. Then she closed the lid, locked it, and handed the key to the attendant maid, who first bore it to its abode, and then, returning, carried the caddy reverently before her to its accustomed niche; while her mistress removed her spectacles, and relaxed the tension of her features until they once more shone with their natural benignancy. Women as a rule take tea more for its efficacy as a restorative than for sheer joy of drinking it. The charge has been brought against them that if left alone they would subsist entirely on tea and cake; and almost one believes it. Now and again we hear of attempts to dethrone

tea. At Girton and Newnham, for example, cocoa has entered the lists as a rival. 'Cocoas' are said to be as well attended as 'wines' were in Verdant Green's day. Cocoas!

The wise tea maker is suspicious of elaborate paraphernalia.

THE BEST TEA IS MADE

with a black kettle on the fire, and an earthenware or china teapot. Copper kettles on tripods (heated by tins spirit stoves that hold too little spirit), silver teapots and kindred refinements, do not help the leaf. Nor should strainers be desired. Tea requires no 'patents,' least of all a spoon resembling a perforated walnut, alleged to be unrivalled for the preparation of a single cup. A single cup! Who, if the tea were worth drinking, ever wanted but a single cup? Tea should be brewed of the right strength at the first instance, poured out at once into cups and reserved cups (or decanted into another teapot), and then remade. To burden the water with more leaves than it can attend to is thoughtless, and every drop that is afterwards added impairs the flavour of the liquor; notwithstanding the old Scotch lady who recommended a certain brand of leaf, because it 'had such a grip of the thir-r-d water.' Using too little tea is a fault never committed by the unwise and imprudent. The ordinary rule is one spoonful for each guest and one for the pot; but some brands go farther than others. A large pot is imperative. Few things in life are more saddening than the smallness of some people's teapots. The teapots should be wards for the reception of the leaves. Wetting the tea, as it is called, is a horrid habit; all the water that is required for each brew should be poured in at once on the instant that it boils. Water that has long been boiling is unprofitable and stale, and incapable of extracting from the opening leaf its richest essences. When there has been delay and it is impracticable to boil a full kettle again, it is well to pour into it from a high altitude a little fresh cold water. The more forcible the impact of this new water, the more is the old supply invigorated and fitted to cope worthily with the leaf. During the operation of emptying the kettle into the teapot the two vessels combine to produce a harmony, compared with which much of Beethoven is trivial, most of Mendelssohn beside the mark. The kettle should then be refilled and placed again on the fire, and after an impressive interval of some three or four minutes, spent by the boiling water within the teapot in the practice of supreme alchemy, the cups may be filled. 'At your ease,' sang the Emperor Kien Long in the poem that is painted on every teapot in China, 'at your ease drink this precious liquor, which chases away the five causes of trouble.'

TEA SELLING.

Tea confers a social rank of its own. A man who sells tea and nothing else occupies a rung in the Grundyan ladder far above him who sells tea and also sugar. Mincing Lane and Park Lane are often on visiting terms, and the scions of noble houses may be 'in tea' without shame. Similarly it is no disgrace to the daughters of Mayfair to serve tea in a West End shop. Some of them perform this action with an air of condescension that reduces the timid man to pulp. He begins with a feeling that he ought to carry the tray for them: he ends in an agony of anxiety as to the propriety of bestowing a tip. A shy friend once told me of the tortures he had suffered in these resorts. 'But I was revenged at last,' he said, 'for an old country fellow and his daughter who had been to the Academy,' or Maskelyne and Cook's, or somewhere, came in. When he paid the bill he left an extra sixpence in the patrician's hand. She fixed him with her refrigerating eye, and told him cuttingly that he had paid sixpence too much. 'That's all right,' he said heartily, in a stage whisper; 'that's for you, my dear. Buy yourself a ribbon with it.' I like this story, because tea has not done too much for the humourist. Compared with alcohol it has done nothing; although high-spirited people who adventure upon the golf links are grateful for

the opportunity of collocating the tea with the caddy. Fate is ever on the side of the punster; none knows better than the deviser of impromptu witticisms that all things come to him who waits. Lamb's remark to a schoolmaster, who was excessively given to the cup that cheered but never inebriated the poet Cowper, is among the neatest ever made. 'Tu doces,' said he ('Thou tea-chest').

TEA AND PICTURE GALLERIES.

For the full appreciation of afternoon tea there is no preparation to compare with a picture gallery. Certain social critics profess to have discovered that many art galleries exist solely in the interests of neighbouring tea resorts, and the memory of pictures sometimes found on their walls almost inclines one to accept the theory as a fact. It is a compliment to this divine fluid when the drinker is a little fatigued. But perhaps a cup of tea 'the first thing in the morning' is best of all. Then, pre-eminently, as Browning says, is it the time and the place and the loved one altogether. Tea in one's bedroom is a luxury which brings the humble person into line with the monarch and millionaire. It is akin to the luxury of staying away from church.

CHINA TEAS.

The happiest tea drinkers are they who have generous friends in China. No tea is like theirs. That inscrutable humourist, Li Hung Chang, left presents of priceless tea in his wake as he passed smiling through the West—tea of integrity hitherto unsuspected by the few persons whose glory it was to taste it. Among these was Mr. Gladstone, who is great among tea drinkers, and whose pleasant humour it is to speak of a cup as a dish. Dean Stanley was among the tea giants, and Dr. Johnson's prowess is a by-word. Hartley Coleridge was another colossus of the caddy. One who knew him tells that asking him on a certain occasion how many cups he was in the habit of drinking, the poet replied with scorn, 'Cups! I don't count by cups. I count by pots.' Once a man looks upon tea when it is green, his fate is sealed. Hyson and 'Gunpowder' between them have shattered many a nerve. Green tea numbers amongst its opponents Miss Matty. It will be remembered that when she set up her tea shop in Cranford, the whole country-side seemed to be out of tea at the same moment. 'The only alteration,' says the chronicler, 'I could have desired in Miss Matty's way of doing business was that she should not have so plaintively entreated some of her customers not to buy green tea—running it down as a slow poison, sure to destroy the nerves, and produce all manner of evil.' According to a story by Sheridan Le Fanu, one of the effects of green tea is to be visited o' nights by an impalpable monkey with red eyes. 'Punch,' with that happy, witty way it has, calls this state 'delirium teameus.' A cupful of green tea in a bowl of punch is a discreet addition.

BLENDS.

The commonest tea is black, and it is almost always a blend, even when the terms Congou and Souchong are employed. China, India and Ceylon—all three—are levied upon for these mixtures. Their description in the catalogues is worth study; indeed, all merchants' adjectives are worth study. A table of ten graduated qualities of black teas lies before me. The lowest priced variety is 'pure and useful;' then 'strong and liquoring;' then 'strong and rich flavoured.' While the same kind, but two-pence dearer, is 'finer grade and very economical;' then 'splendid liquor;' then 'extra choice and strongly recommended;' then 'beautiful quality;' then 'soft and rich;' then 'small young leaf, magnificent liquor;' and, finally, at three shillings and fourpence, 'very choico, small leaf, a connoisseur's tea.' In another list I find 'very pungent and flavoury.' 'Syrupy' is also a hard-worked epithet. It would puzzle a conscientious merchant to fit any of these terms, even the humblest, to some of the tea that one now and then is forced to drink. But the British tourist is attracted not by tea as tea, but by tea with accessories. The late Mr. Arthur Cecil, the

comedian, used to tell with great glee of the cannibal tea at Kew: thus—'Tea, plain, 6d.;' 'Tea, with shrimps, 9d.;' 'Tea, with children, 1s.' But tea that has such accompaniments is not to be run after by the epicure. Of all the public varieties the tea obtained at a railway station is perhaps the worst. The liquor served at those carnivals which are known to schoolboys as tea fights or bun struggles, is a close competitor, but being free, or inexpensive, it has an advantage over the station tea, which is costly. A question in an examination paper circulated among the students at a London hospital, asked the reader to 'give some idea of the grief felt by the refreshment room tea at never having seen Asia.' This sorrow might be shared by the station blend. Its only merit is its heat, but that usually is nullified by the brevity of the time limit allowed by the company for its consumption. Ship's tea, that is to say, tea in the cabin of the ocean tramp, would be worse only that at sea one is too hungry to care for refinements of flavour. The officers are said to discriminate between tea and coffee by taking the temperature of the milk jug. If hot, the beverage is coffee; if cold, tea.

COLD TEA.

Cold tea has its adherents no less than hot. One of the merits of cold tea is that, as the Bishop of Bedford would say, it 'looks like beer.' This to the ordinary member of society is a peculiarity which will cause no excitement, but the resemblance is of some value to publicans who do not wish to offend customers by not drinking with them, and yet do not care to be continually sipping alcoholic liquor. A glass of cold tea, on the other side of the counter, is to all intents and purposes a glass of beer. And, indeed, when one is really thirsty on a hot day, there is nothing more delightful. But care must be taken that the liquor cools apart from the leaves. The most welcome drink that ever came to me was tea. We found it in a charcoal burner's hut in the New Forest. The charcoal burner was absent, and we left a sixpence blinking at the bottom of the empty basin. I hope he was satisfied, but if on his return he was half as thirsty as we, he would, rather than have lost his tea, have forfeited the savings of his life. For the time being our need was greater than his.

HISTORICAL.

The English history of the plant is comparatively brief. According to the popular statement tea was introduced into this country from Holland in 1666. D'Israeli, however, thinks the date earlier, because he once heard of a collector whose treasure included Oliver Cromwell's teapot. Concerning the beginnings of tea in this country there is a story told by Southey of the great-grandfather of a friend of his, who made one of the party that sat down to the first pound of tea that ever came to Penrith. They boiled it in a kettle, and ate the leaves with butter and salt, wondering wherein the attraction lay.

Tea, generally, met with opposition which nowadays is reserved for motor cars and new comic papers. In D'Israeli's account of its introduction, he says that Patin, a French savant, called the leaf 'l'impertinente nouveauté du siècle'—the seventeenth—and that Hahnemann (with the upper part of whose body we are so familiar by reason of its place in the shop windows of homœopathic chemists) described tea dealers as 'immoral members of society, lying in wait for men's purses and lives.' Colley Cibber wrote that tea was 'the universal pretence of bringing the wicked of both sexes together in a morning.' The indictment was indeed persistent and grave. Commenting upon an attack made in tea's early days by Duncan Forbes, an 'Edinburgh' reviewer wrote, in 1816, the following summarising passage: 'The progress of this famous plant has been something like the progress of truth; suspected at first, though very palatable to those who had the courage to taste it; resisted as it encroached; abused as its popularity seemed to spread; and establishing its triumph at last, in cheering the whole land from the palace to the cottage, only by the slow and resistless efforts of time and its own virtues.'

E. V. Lucas.

THE MANURING OF TEA ESTATES.

This subject is of so much importance and we were so pressed by Mr. John Hughes of Mark Lane, Consulting Analytical Chemist to the Planters' Association, to look into the matter, that we decided to issue a circular to representative planters asking information on the following points:—

1. Has the manuring of tea estates become general in all, or only in old, districts? or, if your experience is local, in your own district?
2. Is bulky manure chiefly used?
3. Is the manure sent up by railway used alone or mixed, and is there much of bone-dust and nitrates as well as of castor-cake and fish manure now used?
4. Do you think harm is being done to any extent by the use of artificial manures in the case of tea?
5. How does the oldest manured tea compare with unmanured tea of the same age?

Here are the replies already come to hand:—
No. I.

Dec. 29.

DEAR SIR,—1. In both old and new districts manuring has been resorted to. But it cannot quite be said that manuring has become very general in either.

2. I should say that there never was less bulky manure used than at the present time. Tavalam bullocks are almost things of the past, and few cattle except for carts and dairy purposes are kept on estates, and many old grassfields have been planted with tea. Places like Mariawatte get a lot of bulk from adjacent towns. In the case of estates near the Sanitarium, and where people do mostly congregate, the application of what is euphemistically described as "bazaar manure" should not be encouraged.

3. Castor-cake chiefly, sometimes mixed with fish and a small quantity of bones. But bone-dust is supposed by some people to induce growth of seed.

4. I should say not, although I have heard it so stated in the case of some lowcountry estates. My own experience is that although cattle or farmyard manure was the best for coffee, it does not fetch tea so much as artificial.

5. Favorably. W.

No. II.

Dikoya, Dec. 29.

DEAR SIR,—In reply to your circular letter of 26th inst., manuring with castor-cake and bones is pretty general in this district; on some estates, however, to a small extent only. I cannot speak for Bogawantalawa division.

My opinion is *decidedly* in favor of manuring, and that much benefit has resulted to tea, both as to general appearance and yield, I have not a doubt.

The oldest manured tea here is giving 200 to 250 lb. more per acre than unmanured tea of same age.

I have seen no harm done anywhere by manure. E. S. A.

No. III.

Talawakele, Dec. 29.

DEAR SIR,—In response to your circular of Dec. 26th, I am a great advocate of manuring tea and am of opinion that prices are improved by its adoption, and the increase in yield is undoubted.

As a means of providing work for coolies when flush is short, manuring is invaluable, and if the results merely repaid actual expenditure, I should manure on this account alone.

Although keeping a large herd of stall-fed cattle and pigs I am doubtful if bulky manure pays as against artificial. I have not observed any superiority to attach to the use of farmyard manure. That is to say that fields manured solely with artificial have done quite as well as any manured with bulk, and naturally the work is quicker and cheaper in the case of artificial.

I am of opinion that the use of manure, and especially of artificial manure is on the increase. Persons who object to manuring "on principle" are usually hand-to-mouth men who have no money to pay for it, or who wish to pump their properties.

As a rule the manure used seems to be a mixture of ground bones and castor cake in the proportion of the 1 to 4 or 5 parts respectively. A few persons use nitrates and superphosphates as well. I think a slight addition of these substances distinctly advantageous.

I have seen no harm done by excessive manuring—and a glance at the tea round any set of lines would show the folly of imagining that the growth of tea can be injured by the most potent of fertilisers even in excess.

I think it is a mistake to imagine that manure need be applied frequently or that tea suffers from the discontinuance of manuring. I have known tea of very poor quality manured and then left for 5 or 6 years without the yield dropping below what it was before manuring was adopted.

As a rule manure of any kind tells rapidly—but I have known upwards of a year elapse before any improvement was apparent.

The moral of manure, as Capt. Cuttle would say,—lies in the application.

A rotation of manures is in my opinion advisable where possible; say in the following order:—

1. Bulk
2. Castor and Bones
(Nitrates and Superphosphates)
3. Fish

—Yours truly

KILLALOE.

NO. IV.

Hantane District, Dec. 29.

DEAR SIR,—We have not yet gone in for manuring regularly with artificial here but intend beginning next year with castor cake and bones which many seem using now with good effect. —Yours truly, W.

No. V.

Ratnatenna, Dec. 30.

DEAR SIR,—1. Manuring of tea planted on old coffee lands or on patana lands has, I think, become general in certain districts.

2. Artificial manures chiefly used as being less expensive, more easily applied, and giving results more rapidly.

3. Artificial manures are generally used mixed. Castor cake and bones as well as nitrates. Fish manure is generally mixed with soil, refuse, grass, etc.

4. I consider that the use of artificial manure is doing harm to the tea enterprise. Such manures as castor and bones give a fictitious value or should I say a fictitious energy to the plants, which sooner or later must produce the worst results. These manures are only fit

for annual root crops. It is surely needless to refer to the case of coffee. The most highly manured estates, *i.e.*, estates constantly worked up with artificial manures, were the first to succumb to disease.

I should be glad to see the practice of using distinctly artificial manures,—those which act as strong tonics,—abandoned. It is all very well to force root crops; but it is surely an error to force perennials.

I give the above as the humble opinion of one who has studied botany and farming in a small way, and I hope I may be absolved from any idea of pretence to speak with authority.

For my own part I purpose to use *no* artificial by itself; and only when mixed with bulk (compost of cattle muck, line refuse, ravine soil, jungle stuff, etc.) sparingly. E. G. R.

No. VI.

Kelburne Estate, Dec. 29.

DEAR SIR,—In reply to your circular *re* manuring tea, I beg to inform you our district is so very much in its infancy with this product, that but very little manuring has been attempted. I have myself made a small experiment of manuring 25 acres with crushed bones, castoreake and muriate of potash and I am awaiting to see the result.—Yours faithfully, C.

No. VII.

Maskeliya, Dec. 31.

DEAR SIR,—In answer to your printed letter, I would answer as follows:—

1. It has not become general anywhere, but is becoming more common.
2. Bulky manure is best, but very little is available anywhere. For this reason artificial has to be used.
3. The mixture is usually castoreake with a little bonedust added, and it is usually mixed in Colombo. Some fish manure is also used, and probably a very little nitrates.
4. I don't think any harm is being done.
5. The oldest manured tea yields much better than unmanured tea unless the latter is in very fine soil. PLANTER.

No. VIII.

Ramboda, Dec. 31.

DEAR SIR,—Yours duly received *re* manuring tea. There is not the least use in my writing on the subject, as I may say I have no experience. No manuring has been done here and of what I did on the other side I have not seen the effects. There are two fields opposite me on the other side the river, which have been manured twice: they look very well in the distance, and I am told have doubled their crop. B.

No. IX.

Hantane District, Jan. 1.

DEAR SIR,—In reference to your circular on the important question of manuring, tea estates in this district are using manure more or less.

Bulky manures are put out on estates where they can easily be got; others apply artificial. Of artificial fertilizers bonedust is not much used as it tends to increase seed: the favorites are a mixture of castoreake, fish manure, and a little bonedust, while some add nitrates or sulphate of ammonia. Manuring has in no case that I know done harm to tea—all the other way, by increasing the size of bushes, and the returns of crop.
